If we were able to obtain the result of every day's work, we should be surprised to find how large a proportion of that work is accomplished by men whose hours of study are in the midst of apparently uncongenial occupations, and who can only make use of a few precious half hours, and those, perhaps, taken from their periods of rest. Nay, more, I believe the man who is occupied the most with daily labour, is the one who does the most towards the completion of his own education and the good of his fellow-men. Faraday, William Allen, Miller, and Stephenson were bright examples of those who never could be accused of wasting a single spare moment.

One great, if not the greatest reason why so few shine out from the general mass, is the want of *observing power*. One of the first things a pharmaceutical student has to learn, is to make proper use of his eyes. This elementary lesson, I am sadly afraid, is too frequently omitted from the curriculum of many an eminent professor. A teacher cannot be too simple or too practical. When once the eye is trained, the slightest deviation from the ordinary course instantly arrests the pharmacist, and calls forth the "why and wherefore" inquiry into every-day occurrences, which are passed by unheeded, simply because they are so familiar. I will give you an illustration or two of what I mean. Most of you, and many thousands more, who have studied chemistry, have made hydrogen gas by dissolving a piece of zinc in diluted sulphuric acid, and have seen the sediment that remains in the solution of zinc. How invariably has this bit of dirt been thrown away as not worth a moment's consideration, or without the slightest idea of inquiring what it was? Nevertheless, nine years ago, Drs. Reich and Richter found this insignificant-looking sediment contained the new element, Indium, especially when the zinc came from the Freiberg mines.

Another still more remarkable instance occurred in the case of Thallium. For many years past, the waste dust had been collecting in the flues of vitriol factories without attracting attention, till Mr. Crookes chanced to examine it, when, to his utter astonishment, he found it to contain no less than the twelfth part of its weight of this curious metal; another new element unique in its properties, both optically and chemically. As you know, its spectrum differs from that of every other body, by a magnificent green band when ignited, and exhibiting the most perfect example of monochromatic light yet discovered.

Nor is there any occasion for you to go to the sulphuric acid manufactory for your material. If you will examine the bismuth, the chloride of zinc, or the hydrochloric acid on your shelves, you will most likely find this extraordinary body to be present in sufficient quantity to develope its spectral phenomena.

How many hundreds of mixtures have been dispensed with quinine, but how few of you have, perhaps, asked for the explanation of that grand fluorescence that always makes its appearance, or supposed you were looking at one of the most marvellous displays of force that chemical physics has ever striven to elucidate? When, however, the eye has been trained to notice the many reactions that occur daily in our pharmacies, the aptitude for education is wonderfully increased.

Is it not to be feared that the tuition in most of our schools and colleges is too exclusively based on the reasoning and not on the perceptive powers of the mind? If so, the inference must be, that the knowledge acquired will be theoretical instead of practical, the library being too much employed and the laboratory too little. I would, therefore, my friends, sincerely urge you to experimentalize, to examine for yourselves, and not to take everything for granted that you hear. You will quickly find that what you once thought a distasteful task, becomes a delightful pleasure.

A good criterion that you are becoming acquainted with your studies, is the conviction that you yet know but little in the broad field before you, and become cautious of the many pitfalls that await those who in their foolish pride think they know all.

"A little learning is a dangerous thing;
Drink deep or taste not the Pierian spring:
For scanty draughts intoxicate the brain,
But drinking largely sobers us again."

You will all have many difficulties and trials to surmount, but then they will be counterbalanced by many commensurate privileges. You are like a traveller in a strange country, and surrounded by innumerable objects of beauty and interest. Now stopped by some deep crevasse or rapid stream, now by some steep ascent or slippery rock. Sometimes the flora of some exquisite glade or the fauna of an extensive forest will arrest the attention. Would an enthusiastic naturalist, do you think, be daunted by such difficulties, or turned back by such obstacles? Decidedly not. On the contrary, he would be only stimulated to make more strenuous efforts to fill his vasculum, or complete his collection.

So is it with you, who are in the midst of equally fascinating objects, though you do not notice them from the before-mentioned familiarity. The exquisite tracery of a slice of sarsaparilla, liquorice, or calumba, the wonderful optical powers of morphia and quinine, or the extraordinary structure of a mustard seed, a lupulinic gland, or the under side of a matico leaf, are only a few of the many examples that with the assistance of a common lens must astonish the most careless. Many of the most charming experiments that were ever exhibited by Faraday or Tyndall may be shown any day in a druggist's shop. Not many months ago I showed to a London optician the spectra of lobelia, digitalis, hyoscyamus, and cannabis, when he was struck with admiration, and declared he had never before seen anything half so beautiful, and asked if I would tell him how they were prepared. My young friends, need I remind you that the answer to his inquiry was a reference to your old acquaintance, the British Pharmacopœia?

May I stop here to remark to my brother pharmacists how much good a master may do his pupil, if he would point out some of these wayside objects, and encourage an *esprit de corps*, instead of exacting the veritable pound of flesh, as is too commonly the rule? By so doing the pupil would often ransack the materia medica with an eager zest, instead of a dogged resignation to what is thought an irksome duty. As Mr. Kingsley says, "A walk without an object, unless in the most novel and lovely scenery, is a poor exercise, and as a recreation utterly *nil*. If we wish to do our children any good, we must give them an object in every walk. We can teach them to find wonders in every insect, sublimity in every hedgerow, and by teaching them to make full use of the limited sphere in which they now are, to make them faithful in a few things, that they may be fit hereafter to be rulers over many."

But I think I hear some of you ask me if there can be much sublimity or many wonders in the rows of bottles with which you are so well acquainted. Stop a moment and consider. Use your observing powers, and invest a little money in that good educational assistant, a moderate microscope, and by its aid look again at these absurdly common things. What do you see? Why many, if not all of these common drugs and chemicals, would fill a large cabinet with exquisite slides. Look, for instance, at the remains of former ages in the prepared chalk or the pretty button-like crystals in the carbonate of magnesia, the beautiful seeds of hyoscyamus, colchicum, linseed or poppy, the raphidian rosettes snugly placed in their little cells in the rhubarb, podophyllum or squill, the restless little nematoids on the vinegar tap, or the elegant fungus that grows and fructifies in the solution of emetic tartar. Time would fail me in anything like an attempt to describe the wonders contained in our bottles and drawers.

There is one warning that I am desirous to impress upon you with great earnestness, namely, the incalculable advantage of a systematic arrangement of your studies. I speak from experience when I say that a loose, indiscriminate manner of study is so much time lost. If you have ever so extensive a library, and dip at random into your Attfield, Bentley, Lindley, Fownes, and Royle, you will make a terrible mistake, and totally put a stop to profitable study. Should any of you attempt to pursue so erroneous a course, however industrious you may be, you will feel extremely uncomfortable when you have to face the Board of Examiners. You will resemble the poor fellows in the tower of Babel, so quaintly described by an old poet:—

"'Bring me,' quoth one, 'a trowel quickly, quick!'
One brings him up a hammer. 'Hew this brick'
Another bids: and then they cleave a tree.
'Make fast this rope,' and then they let it flee.
One calls for planks, another mortar lacks:
They bear the first a stone, the last an axe.
Thus crossly cross'd they prate and point in vain—
What one had made, another mars again.
These masons then, seeing the storm arrived,
Forsake their purpose, and, like frantic fools,
Scatter their stuff, and tumble down their tools."

A method I have always found to work extremely well is to draw up a tabular arrangement according to circumstances. Botany for one day, chemistry for another, materia medica for the third, and stick to it. If you are prevented from enjoying the half-hour allotted to Bentley, pass it over and work with Attfield on the appointed day, but never upset the arrangement. Use every spare five minutes. You will never know till you try what a large amount of work can be performed in a few odd moments. Do not think because you cannot have a couple of hours at a time that you are, therefore, debarred from study. Where there is a will there is also a way. Not one of your predecessors ever had the advantages you possess, the books you have, or the class instruction now offered.

A great outcry is now being made for provincial education; but is there so much need for that extra machinery that many would have you believe? My own experience leads me to doubt it. Every master ought at any rate to be able to direct his pupil *how* to study, and then generally it must be the pupil's own fault if he do not succeed. One man may take a horse to a pond, but not all the energies of fifty can compel him to drink. But work with a firm determination to win, and then you will have no apprehension when you have to meet those gentlemen who form the Board of Examiners. I believe that all the knowledge required to pass the Minor may be acquired by yourselves alone. Lectures and classes are, of course, great helps, and I would be the last to say anything that would tend to lessen the idea of their value. But do not think that genius or more than ordinary ability is required. It is the persevering, resolute, hard-working student that gains the Pereira medal. One who is really determined to reach the goal, and who, by accustoming himself to work, finds his studies become proportionally easier.

I hope all of you have embraced the study of pharmacy in its highest sense, and intend setting to work with brave, earnest and honest hearts. The knowledge you will thus have acquired will last you all your lives, and never evaporate like the temporary makeshift of the crammer. Our esteemed professors will welcome you, and take a delight and pride in guiding you forward with their lectures and their counsel; but I am sure they will tell you that their efforts must be supported by your own individual exertions. Indeed, the whole value of their lectures depends on the use you make of them. Chemistry must be learnt in the laboratory, botany in the field, and dispensing at the counter. A month of practice is worth a year of theory.

Do not think that when you have passed your examination you must put aside all your books, and have nothing else to do but to get a business. It is to you that we older ones look for the future prosperity of the Pharmaceutical Society. You, and not we, will be the gainers by its rise in the social and scientific scale. You will, I trust, see the day that we desire to see, when the examination fees will be cheerfully and gladly paid without thinking them too high, and will some day pass the bye-law enacting that the Major must be reached before being allowed to enter into what I hope will truly be entitled the profession.

We are often met by the old-fashioned assertion, that such an amount of scientific education will unfit you for the proper attention to business, and that you will become too proud for the ordinary duties of the retail counter. It is a very absurd idea; quite as much so as for you to think of commencing business without the necessary experience. I would be the last man in this room to slight business habits. On the contrary, I set the highest value on the young man, who, by punctuality and discriminating care, can show that he has an eye for business, but, on the other hand, I should think very little of an assistant who, however regular in his habits and correct in his accounts, was not able to give a sensible answer to the many unexpected questions that are daily asked by our customers. Would your dispensing powers be lessened by a foreknowledge of the results of a mixture, and therefore of incompatibilities? Would you make any of the preparations the worse, because you knew the chemical laws that control the elements? Or would you be a worse judge of drugs, because your botanical knowledge taught you the characteristics of the medicinal herbs? It would be monstrously absurd to say so. An increase of knowledge will give you a most valuable power, applicable to every circumstance of civilized life. You will be a better tradesman, a better fellow-citizen, and a better pharmacist.

I cannot understand how any one having an acquaintance with the scientific explanation of what is going on around him at home, in the shop, or in the garden, can be content to eke out his existence with only studying the wholesale price list.

I must think better things of you, for it would seem incredible that you could have proved the friendship of such men as Professors Redwood, Attfield, Bentley, or Tilden, and the gentlemen I see around me, in vain. It is not possible that you could enjoy their acquaintance without having a more elevated idea of things than you had before you knew them.

In conclusion, I would again urge you to make full use of the coming session. You will find that when you leave Bloomsbury Square, it will have been no time or expense lost. Never condescend to lower your profession in the eyes of the public, but let them find out, as they very soon will, that you may be depended on for truth, integrity and upright honesty; and, above all, a fixed determination to walk strictly in the path of duty.

The end will be that you will earn the greatest of all earthly rewards, a good name.

> "A spotless name
> By virtuous deeds acquired, is sweeter far
> Than fragrant balsams, whose odours round diffused,
> Regale the guests. Well may such men
> Rejoice at death's approach, and bless the hours
> That end the toilsome pilgrimage; assured
> That till the race of life is finished, none
> Can be completely blest."

May such a lot be yours.

At the close of this address, the PRESIDENT proposed a cordial vote of thanks to Mr. Stoddart, which was carried by acclamation.

It was announced that the next evening meeting will be held on Wednesday, the 6th of November.

Obituary.

PROFESSOR EDWARD PARRISH.

A letter but just received tells the sad tidings of the decease of one of the most prominent and most widely known representatives of pharmacy in the United States, Professor Parrish, of Philadelphia. Sad tidings, indeed, to all who knew him, for it is given to few men to win their way to the hearts of their associates as he did. Bright and cheerful in manner, and full of thoughtful kindness, the secret of his good fellowship was not far to seek. He held the office of Professor of Pharmacy in the Philadelphia College of Pharmacy, an institution in which he had for many years taken an active interest, and his contributions to pharmaceutical literature had earned for him the honorary membership of many kindred bodies at home and abroad. He had until quite recently nursed a hope of attending the Pharmaceutical Conference at Brighton, and during the meeting the writer received a message from him expressing his interest in the gathering, and regret that he had been compelled to abandon his proposed visit to this country. He was, in fact, just leaving home, on the mission referred to in the letter from which an extract is given below. The loss of his wife a few months ago was a fearful blow to one of his affectionate disposition, but he sought strength in work and hope, and had devoted his time and energies during the spring and summer to the details and practical working of a new State Pharmacy Act. He was a member of the Society of Friends, and, as is well known, to that religious body is now committed the task of distributing the money grants of the United States Government to the native tribes of Indians, and the general charge of negotiations with aboriginal races. The mission in which he was engaged at the time of his death was a labour of love in connection with "Grant's Quaker-Indian policy" by which so much good has already been effected.

The rest may best be told in the words of a letter from his son, Thos. C. Parrish, of Philadelphia:—

"He was sent by our Government at Washington, as a special commissioner, to adjust certain difficulties between the white inhabitants, on our borders, and a very warlike tribe, the Kiowas, and was further instructed to bring to Washington certain of the more refractory chiefs, to bring about a better understanding.

"He fully appreciated the great importance of this mission of peace and goodwill, and left us thoroughly imbued with the spirit of it. He arrived at Lawrence, Kansas, in good health and spirits, and then undertook the task of penetrating into the wilds of the Indian territory to Fort Sill, a Government post. This journey of 300 miles was accomplished by means of a stage ride without intermission or halt, except to change horses. It lasted three days and three nights, and left him thoroughly exhausted with diarrhœa and fever, subsequently running into malarial typhoid fever. After an illness of about two weeks he yielded up his spirit,—pure, noble and true.

"He was buried at Fort Sill by the officer commanding, and his funeral was attended by the entire military and civil population of the post."

Had time permitted, this notice might have been extended and some details added of the life and works of Professor Parrish, but his name is too well known amongst us to need an exposition of his merits as a scientific man and a teacher; and with those who knew him, and there are many even here of the number, memory rather than measured eulogium brings fittest testimony to his goodness.

Henry B. Brady.

Pharmaceutical Education.

The following further letters have been received by Professor Attfield in reference to the paper on Pharmaceutical Education, which he read before the British Pharmaceutical Conference at Liverpool:—

Glasgow, August 12th, 1872.

My Dear Sir,—Though quite unable to find leisure time to do your paper on Pharmaceutical Education that justice that its merits and your own well-established character as a teacher in our Central Institute so amply merits, I am unwilling, through maintaining an absolute silence, to give any one ground to suppose that I could feel uninterested in such a paper, or in the discussion to which it is proposed to form an introduction.

I trust, therefore that you will excuse the hurried character of this note, and I know that you won't quarrel with any angularity that may be noticed in the few remarks my limited time allows me to make.

I at once confess I cannot agree with your scheme any more than you do with Mr. Schacht's, or than Mr. Schacht does with Mr. Reynolds', or Mr. Mackay with either.

Whether we think it "desirable to make pharmaceutical education compulsory," is not, it seems to me, the question to ask; it is so, to all intents and purposes, even now.

You have a wholesome fear of "cram," and think that the best mode of overcoming this is to increase the stringency of the examinations, or to insist upon a prolonged attendance on certain recognized teachers, or at certain recognized schools.

Now, as a practical man, though quite as anxious as any one to see all our future pharmacists as well educated as the most highly qualified men in our business, I do not think that the time has come for increasing the stringency of our examinations, nor do I think that our doing so would lessen the amount of cramming of which you so justly, I have no doubt, complain. The numbers rejected on coming up for their examinations, and the very considerable number of our young men who are hasting out of our business, on account of the character of these and of their money lost, amply proves this position. Then, as to a prolonged attendance at our educational institutes, and the production of certain tickets in proof of this, being held as sufficient to pass our young men without the necessity of their examination by ourselves as a society, I will only point out how futile such a test has hitherto proved in the learned professions.

Then as to my own remedy, I confess at once that I don't know one! Hence the scheme I ventured to bring under the notice of the Council so far back as March last, and repeated, in Committee, in June.

We find everywhere a cry for aid in educating our young men so that they may pass the various examinations required. Well, we have the money. The money in our coffers is not ours or the Council's. The guinea of the humblest pharmacist in the most remote district of the land, is as heavy and as bright as is that of the very prince, be he who he may, of pharmacists, in our great metropolis itself.

Let us, after, as all are willing that we should, amply providing for all our requirements in London, see what our balance-sheet shows we can spare for this purpose; put it aside, let it be £1000 or £2000, and invite applications for it. The security, which I hold to be ample, that the money be well spent, is that before it be obtainable, the applicants, who must be well attested members of our Society, must have dipped their hands into their own pockets for a sum equal to or double that asked from the central fund.

I object to Mr. Reynolds' scheme, because he insists on a certain number of educational centres, as I do to London, as the "school for all the country," and which others hold to be the right state of things. The evils of one school apply to a dozen, or any fixed number of schools, though in a less degree. My proposal leaves the whole onus on each individual member of our Society. If they, on such a scheme being adopted, fail to establish schools suited to meet their special case, their own money will be undisturbed, and the blame will rest on the proper shoulders.

I fear Mr. Schacht's scheme of paying for results will fail, for two reasons:—First, because it asks me to put my hands in my pocket for the *whole* sum to be expended during the entire educational period, and to trust for repayment of a portion of this outlay to the passing of the proposed new test examinations with honours; second, and largely, because of its putting one more hedge in the way of of our future druggists attaining to the position now enjoyed by so many, without having had to pass through any such test. At present there are three examinations to be gone through, and paid for, before any new entrants can attain to the position of pharmaceutical chemist. If Mr. Schacht's proposals be adopted, as he wishes they should, all new entrants will have four examinations to pass. Now, I believe that the fear of these examinations having to be faced, even where there is ample qualifications, deters and hinders many from entering into our ranks.

In closing these most hasty notes, I must be candid, and say that in principle I agree with Mr. Mackay, that there is no inherent obligation resting on our Society to provide education for our apprentices or assistants. No other body does; and the time will by-and-by come when, I hope, we shall be able to cease doing so also. But still I advocate the most liberal use of our funds for this end now, because the position of our assistants at this time is altogether anomalous. We have suddenly and greatly raised the standard of qualifications required in our young men, and have made it a costly process. Our young men have not the means, financially or otherwise, of qualifying themselves without some extraneous help, and hitherto we, the masters, have not afforded them these means. It is high time that we should at least put it in their power to acquire the education necessary to get them out of their present position of comparative helplessness.—I am, yours very truly,

Daniel Frazer.

Professor Attfield.

Dresden, Staffordshire, August 12th, 1872.

Sir,—Having formerly had some experience in the subject, as Secretary of the Liverpool Chemists' Association, and still feeling a warm interest in anything which tends to the elevation of pharmacy, by the extension of sound pharmaceutical education, I venture to express my appreciation of the views you have so ably enounced. I cannot find words to express my utter detestation of the wide-spread system of cramming, which I believe is doing more than anything else to counteract the good effect of compulsory examination. All over the country advertisements are found in the newspapers of crammers for the Preliminary, and your remarks on the same system in the further stages are not at all too strong. From what I see and hear in this neighbourhood, and no doubt it is the same elsewhere, the examinations are looked upon as "a great bore," "a nuisance," etc., both by the young men and their employers. No idea of acquiring scientific knowledge for its own sake, or for the purpose of enabling the young man to discharge his duties with credit to himself and advantage to the public, ever seems to enter the head of either employer or employed. The great concern is how to "do" the Minor, and a very simple plan is offered. I cannot help thinking that the success of the plan must be largely owing to some defect in the examinations, or to some default of the examiners; but let that be as it may, the question is, how to check or stop it. I am free to admit that I do not like the idea of compulsory attendance at lectures being required before being admitted to examination. I should prefer a system of free-trade in this as in other things. No question asked as to where, how, or when the candidate acquired his knowledge, provided it can be ascertained beyond reasonable doubt that he really possesses it. Further, there are many young men who are willing to learn, and employers willing and able to teach all that is required, without compulsory attendance at lectures. It is rather unjust to deprive these parties of the credit due to them.

Still it is better that this comparatively small number should be compelled to make use of other means (which they would in most cases, be the first to do voluntarily) than that things should remain as they are; it is quite notorious that numbers of young men utterly unqualified, are sent out from the examination room, with the stamp of qualification upon them, to the injury of their employers, the public, and themselves (for having "done" the Minor, they fancy they must be very clever fellows, and "a little learning is a dangerous thing"). All attempts at voluntary education in which I have taken part, heard, or read of, have been failures. Young men will not attend lectures, or avail themselves of other means of education. They are, as a body, utterly apathetic and indifferent, the certainty of "getting through" is all they care about. "Bother qualification, if somebody gets me through," a young man said to me a short time since. On the whole, then, I see no other way out of the difficulty than by the plan you propose: requiring certificates of having undergone a defined course of pharmaceutical training under properly qualified teachers as a *sine quâ non* to being admitted to examination, will effectually crush cram, stir up a generous feeling of rivalry amongst the centres of education, and shut out from the circle of pharmacy all who are unable or unwilling to qualify themselves for a place there.

My great fear is that the Council does not possess, and could not, in the face of such an opposition as would be raised, obtain powers to carry out your proposal, but I hope and trust it will be done.

Yours very truly,

J. Attfield, Esq., Ph.D. Thos. D. Walker.

Examination Fees.

Sir,—The statements which I made in a letter addressed to you, August 27, and published on page 180, upon the desirableness of making such alterations in the present Examination Fees as might tend to the strengthening of our Society, which at present threatens to decrease rather than to increase in numerical and therefore political power, have called forth a counter statement from my friend Mr. Carteighe, to which I would ask your permission at once to reply. I exceedingly regret that Mr. Carteighe's explanations are not of so convincing a character as to allow me to retract what I have stated; had they been so, I would most gladly have admitted my error in judgment, and rejoiced in the prosperity of the Society; but facts are stubborn things, and the facts I desire now to lay before your readers, culled from "official documents," are such as will, I think, prove to demonstration that my statements were not "founded on fallacies," nor were my arguments based upon "a series of mistakes."

Figures speak volumes, and at once convey facts and ideas to the mind with a clearness which the most talented writer fails to accomplish by mere verbal explanation. I have, therefore, extracted from the published annual statements those items referring to the question in hand for the past eleven years, thus obviating the erroneous conclusions which are unintentionally conveyed in Mr. Carteighe's letter, by having based all his arguments upon the statistics of the last two years alone, omitting altogether the peculiar circumstances which surrounded those and the previous year, by which a harvest was unquestionably reaped, but the very relation of which, when viewed as a whole, proves the fallacy of relying upon the continuance of such harvest days.

	Members, Pharmaceutical Chemists.	Associates.	Apprentices.	Members, Chemists and Druggists.	Associates in Business.	Major Examinations.	Minor Examinations.
1861	1843	120	51			45	57
1862	1809	89	44			30	34
1863	1781	93	66			36	44
1864	1770	104	113			65	58
1865	1779	104	161			50	67
1866	1786	124	198			66	86
1867	1755	158	229			53	82
1868	1739	280	177			82	112
1869	1782	310	499	403	22	105	187
1870	1802	458	564	582	82	63	199
1871	1797	566	613	669	161	50	234

In the first place, exception is taken to my statement, that "*but a small proportion of those who pass the Major examination, think it desirable to join the Society as members.*" Do facts support Mr. Carteighe's objection upon this point? By the above table we see the statistics proving, beyond dispute, that on December 31st, 1871, the number of pharmaceutical chemists who were members of the Society was 46 less than on December 31st, 1861; so that, notwithstanding all the nominal increase, by "166 pharmaceutical chemists elected to membership," the supply entirely failed to keep up even the aggregate number. If again we turn with hope towards the large number of associates in 1871 (apprentices we cannot possibly take into account) they also will be found to fail us in supplying any large number of pharmaceutical chemists, for on inquiry I have received the following analysis of that number:—

Associates of 1842, and before the Pharmacy Act				25
„ Major	„	„	„	67
„ Minor	„	„	„	262
„ Modified	„	„	„	212
				566

Showing that at present only 92 are eligible for election from that source as members; and when we bear in mind the fact that the greater number of those who pass the Major do so within a few months of the Minor, I fear we cannot depend upon a very large proportion of the 262 qualifying themselves for membership.

Again, it is questioned whether "*our numerical strength as a Society is yearly decreasing, whilst that of outsiders is increasing.*" I sincerely wish Mr. Carteighe were right and I in error, but unfortunately it is not so, he having allowed himself to be drawn into reliance upon a source of strength on which not the slightest dependence can be placed for recruiting our number, so long as the present rule regarding the admission of chemists and druggists is retained. Here again statistics confront us, and but too plainly tell that the supply from that source, which for a moment seemed to meet our need, was purely accidental, and is now rapidly failing; the admissions falling from 403 the first year, to 87 the third; to rely upon such a source of strength is, I fear, to trust to a broken reed.

On the other hand, as regards the *numerical increase of outsiders;* we have no authentic records on which to base our calculation upon this point beyond that afforded by the number passing the Minor examination as given above, but if we refer to the data given by Professor Attfield in the paper read before the British Pharmaceutical Conference last month (page 155), given by him on the authority of the Secretary of the Pharmaceutical Society (no mean authority), we find him stating as his opinion "that in the course of a few years 1000 youths will pass the Preliminary examination annually; that 750 apprentices will annually present themselves as candidates for the title of chemist and druggist, and 600 gentlemen will annually start in business" (aside—a lamentable contemplation!). If this calculation be anything near an approach to the reality as regards the future, under the existing ordeal of examinations, at what rate may we fairly calculate the body of chemists and druggists to have been increasing during the past eleven years? I leave it to the judgment of your readers to decide which body is most rapidly increasing in numerical strength.

One word upon the probable *increase in the number of pharmaceutical chemists apart from membership.* A glance at the above table again tells a sad tale, by no means favourable to any probable large increase in this higher class of chemists. In 1861, out of 57 who passed the Minor, 45 passed the Major, continuing about the same average up to 1866, in which year the Pharmacy Bill began to assume shape; from that time to the present the distance has been widening each succeeding year until last year, when out of 234 who passed the Minor, only 50 passed the Major, becoming thereby pharmaceutical chemists.

Upon the amount of Fees, and the probable appreciation by students of the alteration I have proposed, it is unnecessary for me again to enter, further than that I still hold to the principle, although not wedded to the exact sums. I believe such a change would be fair to the student, and advantageous to the Society; giving to the former his legitimate position as a qualified man; and at once securing to the latter the direct support and influence of every gentleman passing the Major examination.

The free issue of the Journal I by no means desire to abolish; the suggestion was made to meet a difficulty which I believed to exist, but which Mr. Carteighe assures us is far otherwise.

Such, then, are the exact facts of the case so far as I can judge. I put them forth in no cavilling spirit, or with any desire to depreciate the position of the Society, and I would emphatically add, with no other feeling than that of high personal esteem for your correspondent, my only motive being to substantiate the statements of my former letter, with the hope that when thus brought face to face with stern realities, it may be thought advisable to consider whether something cannot be done to render the higher examination more attractive, and membership with the Society to flow directly from such qualification.

EDWIN B. VIZER.

63, *Lupus Street, Belgravia, South,*
September 24*th*, 1872.

Mrs. Stockman and Family.—The following further contributions have been received:—A 2*s.* 6*d.* subscription by F. M. M'Cullock, Esq., per J. Wavell, Local Secretary, Ryde, £12. 12*s.* 6*d.*; Mr. J. W. Euston, 5*s.*; Mr. T. Hughes, Llandilo, 10*s.* 6*d.*; Amicus, 1*s.*; Pharmacist, 10*s.*; Nemo, £2. 2*s.* Collected by Mr. J. Robins: Lieut. Skipton, 19th Regt., 6*s.* 6*d.*; Dr. Haire, £2. 2*s.*; Mr. Frazer, 10*s.* 6*d.*; Mr. J. Robins, 5*s.*; smaller sums, 13*s.*; in all, £3. 17*s*; "Conatum," £1. 1*s.*; A. F. C., £1. 1*s.* Contributions will be gratefully acknowledged by G. Perfect, Havelock Park, Southsea, or Charles Mumby, Pharmaceutical Chemist, Gosport, Trustees.

A. P. S. (St. Austell.)—Dr. Smith's 'Smaller Latin-English Dictionary' (Murray) would perhaps answer your purpose.

S. K. B.—Apply to the Secretary for a copy of a pamphlet entitled 'Hints to Students.'

S. W. W.—We believe you could not claim more than about ten shillings per day and some allowance for travelling expenses, unless there was a special agreement.

G. J. Cutcliff.—We agree with you, but do not think that giving publicity to such cases would be of any benefit.

W. H. Cotterell.—See an answer upon the subject in the PHARM. JOURN. of December 30th last, p. 540.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. G. Mee, Mr. F. M. Rimmington, Mr. Ellwood, Mr. Brewis, Mr. G. H. Proctor, Mr. Rich, Mr. W. Wilkinson, Mr. Jeffrey, Mr. A. P. Baker, "Jacobus," "One of the Laity," "Ranunculus," "Minor."

In consequence of the unusual length of the official proceedings, several answers to correspondents and communications are unavoidably postponed.

QUINOA.

(*Chenopodium Quinoa.*)

BY M. C. COOKE, M.A.

It is not long since that the seeds of this plant were procured from Peru, and sent to India in order to secure its introduction as a food plant into the Himalayan region. It is in Peru and Chili that the plant is chiefly cultivated, although Humboldt remarks that in Mexico it ranks in utility with the potato, maize and wheat. Meyen says that for those countries in which it is grown, it is, next to the potato, the best gift which nature has bestowed on man. Over all the plateau of Southern Peru, above the height at which rye and barley still ripen, the quinoa is the principal object of agriculture, and on the plateau of Chuguito are vast fields quite covered with this plant, which, however, do not give the landscape the charm of our own beautiful cornfields. On good soil this plant attains the height of three or four feet, and bears an immense quantity of seeds, which, unfortunately, for a long time feed an innumerable flock of birds, like sparrows, for this plant has the disadvantage that all its seeds do not ripen at the same time. The quinoa is still cultivated in Southern Chili, but before the introduction of cereals it was doubtless a more general food. The variety which according to Molina is called Daline by the Indians of Chili, and which has ash-grey leaves and white seeds, is the one commonly cultivated around the lake of Titicaca.

In 1834 it was first known in this country, and in 1838 was described and figured in Curtis's 'Botanical Magazine.'

The *Chenopodium Quinoa*, Willd., is a herbaceous annual, with a stout erect angular stem of from three to four, or even five feet in height in a good soil; it branches considerably, with short erect branches. The lower leaves are as large as the human hand, and of somewhat triangular shape on long foot-stalks, and of a pale rather glaucous hue. Small green inconspicuous flowers, and afterwards the fruit, are produced on numerous panicles, both axillary and terminal. The whole habit of the plant closely resembles the goosefoot and spinach. The peculiar hue is caused by the myriads of glandular hairs, with subglobose iridescent heads, with which the plant is studded, and which are exceedingly beautiful under the microscope.

It is said that any light argillaceous soil is suitable for its cultivation. The ground appropriated to it is ploughed or well broken up, and the seeds sown in furrows a yard apart. Or the seeds may be sown in beds and afterwards transplanted. The seed time is in the spring, and the harvest about seven months after.

When quite ripe, the seeds, which are about the size of white mustard seed, but flatter, are easily reduced to a whitish meal. It is not tenacious when mixed with water, as is the case with wheaten flour, but more resembles oatmeal, and is therefore scarcely fit for making bread.

The starch granules are exceedingly minute, and constitute nearly 40 per. cent. of the grain in its natural state. According to analysis it contains upwards of five per cent. of sugar, seven and a half per cent. of casein, and upwards of eleven per cent. of albumen, and other protein compounds. This large amount of protein is unusual in farinaceous seeds, and indicates considerable nutritive value.

The varieties cultivated in Arequipa are called "Colorada," "Amarilla," "Blanca," "Real," "Ccosccossa," "Uchacachi," "Ccancolla," Ccoyto," and the bitter seeded variety "Amarga."

In Lima two methods are employed in the preparation of quinoa. In one case it is boiled in water like oatmeal, and a kind of gruel is the result, in which the seeds float, or at least the remains of them; this is seasoned with pimento. The other method is a favourite with the ladies of Lima. The grains are slightly toasted like coffee, and boiled in water, yielding a brown coloured soup, which is seasoned with spices, and is of a taste so peculiar that few strangers like it.

The red quinoa "amarga" is chiefly cultivated in small quantities in gardens. The seeds bruised and boiled in water are said to form a bitter decoction, which, mixed with sugar, is employed as a vulnerary for sores and bruises. Cataplasms are also made of it. The bitter quality is said to be removed by soaking in water. From other sources we learn that this variety is employed internally as an emetic, and also as a substitute for quinine in cases of ague, and externally as a poultice for cancer, gangrene, contusions, etc.

The leaves of the quinoa are commonly eaten as a vegetable, and much resemble those of other species of *Chenopodium*, as, for instance, the *Chenopodium bonus-Henricus*, and its ally the spinach.

It still seems to be uncertain what is the medicinal value of the red quinoa, and to what its bitterness is to be attributed. Whatever it may be, the bitterness seems to be confined to the husk or testa of the seed, and may be removed by digesting the seed in a dilute solution of carbonate of soda, and afterwards washing. It was this seed which was analysed by Dr. Voelcker with the following results:—

	Natural state.	Calculated dry.
Water	16·01	——
Starch	38·72	46.10
Sugar and Extractive	5·12	6·10
Gum	3·94	4·60
Oil	4·81	5·74
Casein and a little soluble albumen.	7·47	8·91
Insoluble albumen and other protein compounds	11·71	13·96
Vegetable fibre	7·99	9·53
Inorganic matters	4·23	5·06
	100·00	100·00

A somewhat similar plant, or perhaps two or three species, has long been cultivated in India for its farinaceous seeds, which are very much smaller than those of the Quinoa. Under the names of *Amarantus gangeticus*, *Amarantus frumentaceus* and *Amarantus anardana*, plants are referred to by different authorities as yielding seeds resembling small millet, which are employed in a similar manner and for a like purpose.

THE MICROSCOPE IN PHARMACY.

BY HENRY POCKLINGTON.

(*Continued from p.* 181.)

SCILLA.—The "sliced and dried bulb of *Urginea Scilla*" does not present features of special interest. Its structure is that of most bulbs, and consists of parenchyma, with vascular bundles, enclosed within two external layers of semi-compressed cells, or false cuticles. The cells of the parenchyma are of irregular shape, thin walled, and not pitted or porous. The vascular vessels are composed of pitted and spiral vessels, neither the bundles nor vessels being of large size or otherwise remarkable. The only interesting point is the presence of great numbers of raphides and prisms, probably of phosphate of lime. Gum and uncrystallizable sugar form the other cell contents. The powder should contain 6 to 10 per cent. of the raphides and prisms. The other structures are of course easily recognizable. The only probable adulterants are flour and starches, the presence of which will easily be detected.

Serpentariæ Radix.—This is very much more difficult to deal with than most of the roots of the Pharmacopœia, on account of its aberrant character. As is probably well known to most of my readers, the following natural orders present very remarkable instances of departure from the usual type of stem and root structure. Specimens of many of them may be found on the quays and lying about the warehouses of Manchester, Liverpool and other places where Brazilian cotton is stored. The bales in which this cotton arrives are commonly secured with "natural ropes," formed of the Llanos, or climbing plants of the region where the cotton is exported. Amongst these aberrant stems, those of Sapindaceæ, Malpighiaceæ, Bignoniaceæ, Bauhiniaceæ and Aristolochiaceæ are perhaps the most interesting. In the first two, part of the vascular bundles remain separate, and become secondary cylinders of wood, the whole being surrounded generally by a common bark. Frequently in Sapindaceæ the compound stem is triangular, and the wood cylinders thoroughly individualized, giving the cursory observer the impression that it is a natural graft of three stems. But this, as Schleiden has shown, would be an erroneous conclusion. In Bignoniaceæ the wood in certain portions of the stem ceases to grow, and its place is occupied by cortical substance which is easily removed, and leaves the wood cylinder with four to seven deep indentations. This is a common kind amongst the cotton bale Llanos. In Bauhinia the whole structure is often very confused, the medullary rays run in radiating curves, and with the exception of a medulla and vascular central cylinder, the "wood" is chiefly parenchymatous. But the Aristolochiaceæ carry off the palm for their departures from the normal type, and for their variations amongst themselves. Some one or other member of the family is to be found in the collection of most microscopists, they being favourite objects when viewed either by polarized light or dark ground illumination. The Serpentaria of the B. P. is not so pretty, nor perhaps so interesting an object as most of the Aristolochiæ, but I think it "sports" more. This renders it difficult to draw up a description that shall be generally applicable. The rhizome and rootlets will require separate notice.

The structure of the rootlet is generally this. A central cylinder is surrounded by a largely developed cortical substance. The central cylinder in the smaller rootlets consists of little else than large, well pitted vessels and wood cells. The cells of the outer substance are large, thick-walled, polygonal in cross section, and contain great quantities of starch. The larger rootlets agree pretty much with the rhizome, where we find the aberrant structures common to the order. The central cylinder is surrounded by cells containing a dark fluid.

Medulla.—Present, well developed, and composed of large cells with thick walls, circular or hexagonal in cross-section, sometimes thin-walled and irregularly shaped; their contents are great quantities of starch. The medullary rays are remarkably large, but not invariably so, and vary in number (in the same sized root or rhizome), from 6 to 40 or 50. They are usually wedge-shaped, the broad end of the wedge being towards the circumference of the stem, and composed of oblong, oval, or cubical cells, excepting where given off from the medulla, with which their connection is very evident, where they are, of course, approximated to the medulla cells. The wood wedges consist of large-sized vascular vessels, very much pitted. The wood cells vary widely. Near the medulla they are much thickened, and their central cavity is barely visible in cross-section. In the centre and near the cortical substance they are but little thickened, and are of irregular size and shape.

The cortical layers are chiefly remarkable for their liber bundles and laticiferous canals containing a yellowish-brown matter.

The starch granules are either aggregate and consisting of three or four granules, or separate granules, with an indistinct punctate hilum, and give the usual black cross with polarized light.

In examining the rhizome, sections should be cut between the points where the rootlets are given off and also at those points, the structure being subject to important modification in all cases where a rootlet or other bud is given off. In older rhizomes the cortical and medulla cells have much thickened walls, and are frequently stained brown, apparently by transfusion from the vessels.

Zingiber.—The rhizome of *Zingiber officinale* consists of four classes of structure. The outer, cortical, structure (removed from the finer kinds) consists of angular cells of a more or less yellowish-brown colour; thin-walled and containing a substance which becomes semi-mucilaginous on immersion in water.

The structures below this are large, thin-walled, variously shaped parenchyma cells, dotted vessels, and very minutely pitted long wood cells with square or fusiform ends; and specialised cells containing a rich yellow coloured substance. The parenchyma cells contain great quantities of starch in the form of flat oval discs composed of somewhat distinct separate layers, and not very energetically doubly refractive. In shape they resemble the granules of East India arrowroot somewhat closely, but have not so distinct a hilum and are somewhat smaller.

The vessels are barred, thin-walled, and enclosed, in ones or twos, in bundles of long woody fibres, which are slightly pitted and are probably to be regarded as *vasa propria.* In ground ginger of good quality there should be but few of the angular, cubic, or compressed cells of the epidermis. The cells of the parenchyma will be found much broken, and the starch will have escaped from them. The wood fibres of ginger form a small proportion to the other structures, are considerably longer than other fibres likely to be used as adulterants, and the starch granules are very distinct from those of wheat, rice, potato, or maize, the common adulterants. The yellow cells resemble those of turmeric rather closely, but form only a small proportion of the total cells. Cayenne pepper and mustard husks are said to be used as adulterants, but I have not myself found them. The only common adulterant is farina of various kinds added to the powder of a low-priced unbleached ginger. Detection of any adulterant (except turmeric) very easy; the latter not difficult to one familiar with its structure.

(*To be continued.*)

LIEBIG'S EXTRACT OF MEAT.

The following letter upon the subject of Extract of Meat has been addressed to the editor of the 'Times' by Baron Liebig:—

Sir,—In a paper read by Dr. Edward Smith, in Brighton, before Section F of the British Association, respecting the alimentation of the population of Great Britain, on "Preserved Food and Extract of Meat," of which an abstract appeared in the 'Times' of the 20th of August, Dr. Smith expresses opinions which are incompatible with the present state of science.

Having directed my special attention to this subject, and the leading ideas upon nutrition and food being the same which have been made known by me 25 years ago, I trust I may be considered entitled to elucidate and correct in your widely circulating paper the injurious and erroneous inference of Dr. Edward Smith.

Dr. Edward Smith attaches great importance to the preparation of food; the economy of nutrition, however, depends essentially on the right proportion in the nourishment consumed of the nitrogenous substances (meat, fish, eggs, etc.), and those free from nitrogen (starch, butter, sugar, etc.).

An excess of meat in the diet is waste, and the exclusive consumption of potatoes is likewise waste. The chemical composition of meat and of potatoes (as well as of all other articles of food) is perfectly well known, and it is therefore easy to calculate the proportion in which they must be mixed in order to obtain the *maximum* of nutritive value for every individual at every stage of life.

The alimentation of a population can only be judged by means of a knowledge of their wants, and of the above-mentioned proportions. The great economical successes in the production of meat and milk by agriculturists who are acquainted with the relative nutritive value of the various sorts of food are well known, and as long as Dr. Edward Smith does not specify what weight per head "the small morsel of meat" and the potatoes or rice should have in order "to form a highly nutritious diet," and as long as he does not explain why the small morsel of meat should be fat meat and not lean, which "the poor, in their fastidiousness, prefer," so long Dr. Edward Smith must allow us to consider his assertions that the English were worse fed than the Irish or Scotch as a mere fancy.

In the selection of food, which is influenced by necessity or want, the instinct and the experience of the million are infallible, and a far better guide than the theoretic speculations of men who have remained ignorant of the composition of food, as well as of even the simplest laws of nutrition.

"Fish," says Dr. Edward Smith, "is sometimes suggested as a substitute for meat; but fish is rather a relish than food, and contains little more nutriment than water."

From Payen's investigations it is well known, however, that the flesh of fish on the average does not contain more water than fresh beef, and as much solid substance as the latter. For instance, the flesh of salmon contains 75·70 per cent. water and 24·296 per cent. solid substances, while beef (muscle) contains 75·88 per cent. water and 24·12 per cent. solid substances. The flesh of herring contains still less water than salmon, and even flat fish, such as soles, are as rich in nitrogenous substances as the best wheaten flour weight for weight.

The assertion of Dr. Edward Smith that the flesh of fish contains little more nutriment than water is, as may easily be perceived, in direct opposition to well ascertained facts.

Truly comical are Dr. Edward Smith's views respecting tea and extract of meat. "He laments the amount of money which is, as he holds, wasted, and worse than wasted upon tea, the amount of nutriment contained in an ounce of tea being infinitesimal."

Dr. Edward Smith cannot seriously imagine that tea is taken by certain ignorant and stupid people because they believe it to be a nutriment, which tea indeed is not. The capability of swallowing not one single camel, but an entire troop is, however, required in order to believe that if an individual a short time after having retired from a well-supplied table, satisfies the longing for a cup of tea, he does so for no other reason than to add to the food and wine consumed in abundance an infinitesimal fraction of carbon and nitrogen, the two chief elements of nutrition.

Tea is no nutriment in the ordinary sense. The individual who takes tea after his meal feels, without being able to define it, that tea has a favourable effect upon certain highly important functions in his body, that digestion is accelerated and facilitated, and that his brain-work is benefited thereby; and if a poor factory workman imposes on himself privations in his food and other necessaries of life in order to spare a few pence for tea, there must be a deeper cause for this than mere custom.

Neither tea nor extract of meat is nutriment in the ordinary sense; they possess a far higher importance by certain medical properties of a peculiar kind. The physician does not employ them as specific remedies. They serve the healthy man for the preservation of his health. Taken in proper proportion, they strengthen the internal resistance of the body to the most various external injurious influences which combine to disturb the general vital processes, and they adjust these latter.

Health is nothing but resistance to injurious influences, and its degree in different individuals depends upon the force of this resistance. The object of every intelligent physician will be directed in the cure of an illness towards strengthening the internal resistance to local disturbances, and to restore the normal functions by his remedies, which in this case are called medicines; and he knows therefore to assign the proper place to the beef tea or meat juice which he prescribes to his patients and convalescents.

It is surely a grave offence against all laws of physiology to compare tea, coffee, and extract of meat to the more common articles of food, and because they are not that, to draw the inference, as Dr. Edward Smith has done, that they are nothing at all. This is certainly not scientific reasoning.

As regards coffee, Julius Froebel, in his work 'Seven Years in Central America,' says:—

"For the men accompanying the great mercantile caravans in Central America coffee is an indispensable necessity. Brandy is taken as medicine, but coffee is quite a necessary article, and is drunk twice a day. The refreshing effects of this beverage in heat and cold, in rain and dry weather, are extraordinary."

Of the composition and the value of extract of meat Dr. Edward Smith holds the most singular opinions. He says, "This is sold as a very thick liquid, in jars, and 1 lb. is said to represent 32 lb. of flesh."

It has, however, never been asserted that 1 lb. of extract of meat represents 32 lb. of flesh; this is simply an invention of Dr. Edward Smith. The truth is that 1 lb. of extract contains the substances soluble in hot water of 32 lb. flesh.

Dr. Edward Smith proceeds to say:—

"The composition is water (if you will completely dry a pot of the extract you will see how large is the proportion of water), the salts of meat and the phosphates, extractive matters of a soluble kind, the peculiar flavour of roasted meat and common salt, which are added to it."

It is utterly impossible to suppose that Dr. Edward Smith intends to make us believe by this sentence that extract of meat is water, to which are added common salt, the phosphates of meat, the flavour of roasted meat and soluble extractive matters. It is rather to be assumed that Dr. Edward Smith would have expressed himself quite differently and more correctly respecting the composition of extract of meat if he were possessed of even a faint notion of the science of chemistry.

As regards the proportion of water contained in extract of meat, it is well known, through innumerable analysis, that it amounts on the average to 19 per cent. (*maximum* 22 per cent., *minimum* 16 per cent.) Extract of meat is beef tea made from fresh beef—not roasted—in the purest state, condensed to the consistency of a thick honey, to which nothing whatever is added by the manufacturer. The assertion that common salt is added to the extract is an unjustifiable invention. The juice of the muscles contains, as a never absent component part, a small quantity of chloride of potassium, but no chloride of sodium (common salt).

The eminent African traveller, Dr. Schweinfurth, dwells on the extract of meat as follows:—

"Those only are probably fully able to appreciate the value of extract of meat who, like myself, were compelled for weeks together to live upon purely vegetable food. Such a diet engenders a peculiar state of weakness, and lowers the mental and bodily energy, which is raised again through the use of meat. I can state from my own experience that in the absence of meat, the addition of extract of meat to vegetable food produces the same good effect on the body as fresh meat, and that under such circumstances it is the only means of supplying the lack of meat. When my American extract of meat was consumed I prepared some myself from the flesh of antelopes which did excellent service."

With regard to the considerable saving effected by the use of extract of meat we are indebted to Dr. von Schneider (Chief of the Chemical Department of the Imperial Mint in St. Petersburg) for the following highly interesting communications ('Norddeutsche Allgemeine Zeitung, No. 12, 1872, Sonntagsblatt):—

"In order to ascertain the economical value of extract of meat, all soups consumed during the months of November and December, 1871, and January, 1872, in my small household, consisting of three persons, were prepared from remnants of bone, fat, and vegetables, with addition of extract of meat, and all the meat (mutton, pork, beef, veal, poultry, and game) was roasted.

"In the month of October, 1871, on the other hand, the beef was used for the preparation of the *pot au feu* (with the addition of rice, semolina, maccaroni, potatoes, etc., exactly as in the other three months), consequently without any extract of meat, and all the meat was consumed as boiled meat.

"It was proved at the end of these experiments that in the month of October 40 per cent. more money was spent for meat than on the average in any of the other three months—viz., the consumption in the month of October of boiled meat amounted to 120 lb., in any of the other three months on the average, 80 lb.; of roast meat, therefore, 40 lb. less. We used daily 6 grammes extract of meat, in 83 days 1 lb."

These facts prove incontrovertibly, in my opinion, the physiological effect of extract of meat. The necessity for the consumption of meat is considerably lessened when extract of meat is added to the vegetable food; in addition to the nutritive value which vegetables possess in themselves, they acquire in the soluble component parts of meat those substances which give to a meat diet its peculiar effect. In view of the present high price of meat Dr. von Schneider's observations are deserving the most careful attention. The trial is easily made, and it is in everybody's power to make it.

ARTIFICIAL BUTTER.

In an extract from the 'Revue Hebdomadaire de Chimie,' given in the 'Chemical News,' it appears that Monsieur Mége-Mouriez, some years ago, was requested by the Victualling Department of the French Navy to try to find a wholesome substitute for butter, which would not become rancid by keeping. Experiments made with cows submitted to a very severe and scanty diet, led to the discovery that these animals continued to give milk, although in very much smaller quantity, and that this milk always contained butter; the author surmised that this butter was due to the absorption of the fat contained in the animal tissues, which was converted into butter under the influence of the milk-secreting glands. This led to experiments on the splitting up of animal fats, and, further, to the following process for making butter artificially. Best fresh beef-suet is first mechanically cut up, by means of circular saws fitted to a cylinder, and is next placed in a vessel containing water, carbonate of potassa, and fresh sheep's stomachs previously cut up into small fragments; the temperature of this mixture having been raised to 45°, the joint influence of the pepsine of the stomachs and heat causes the fat to be separated from the cellular tissue; the fatty matter floating on the top is decanted, and after cooling submitted to very powerful hydraulic pressure; the stearine is used in candle-making, and the semi-fluid oleomargarine is used for making the artificial butter in the following manner:—Fifty kilos. of the fat are poured along with 25 litres of milk and 20 litres of water into a churn, while there is added 100 grms. of the soluble matter obtained, by soaking for some hours in milk, from cows' udders and milk glands; a small quantity of annatto is also added, and the operation of churning then proceeded with. The butter thus obtained is well washed with cold water, and, if required to be kept for a long time, melted by a gentle heat, to eliminate all the water. According to reports of sanitary committees, as well as of the authorities of the Victualling Department of the French Navy, this artificial butter is really an excellent substitute for genuine butter, and can be exposed for sale if the vessels are marked to distinguished the artificial from the genuine butter.—*Journ. Soc. Arts.*

RECENT PROGRESS OF THERAPEUTICAL SCIENCE.*

The properties of cicutine and atropine (from hemlock and belladonna respectively) have of late been carefully investigated. MM. Martin Damourette and Pelvet, in their study of the former, have been able to verify, through experiment, some of the historical details in the death of Socrates. Atropine has opened a new way of treatment for diseases of the eye, from its curious property of causing that organ to dilate when applied to it; and its effects on the whole nervous system, now better known, also throw light on accounts, in ancient authors, of poisoning by belladonna.

The properties of the alkaloid contained in the Calabar bean (first separated by M. Vée in 1865) are the opposite of those of atropine; it causes rapid contraction of the pupil of the eye. The pupillary constriction reaches its maximum about an hour after ingestion of the substance, and continues at this for about three hours; thereafter gradually disappearing. This antagonistic quality is being utilized by ophthalmologists.

It is found that each alkaloid, independently of its general action on the system, has a special action on

* Abstract of part of a paper by M. Papillon in the 'Revue des Deux Mondes.'

a particular organ or part of the system. Thus digitalis is a poison or a remedy for the heart. It was at one time hardly used except as a diuretic. But recently M. Traube of Berlin, and M. Hirtz of Strasburg, have shown the importance of its action on the circulation and animal heat. From its retarding effect on the movements of the heart, it is found valuable especially in diseases of a febrile character. It is only quite recently that the active principle of digitalis has been properly isolated, by M. Nativelle. The digitaline prepared by the new process is so active, that a dose of even a quarter of a milligramme will affect the heart's movements, while five milligrammes will cause death. Its effect is also so characteristic and sure, that when it exists in a mixture in so small a quantity as to escape being detected by chemical reaction, an infallible method of recognizing it is to examine the action of the mixture on the heart of a frog. Another substance which acts energetically on the muscular fibres, especially those of the heart, is *veratrine*, which has been found of great service in cases of internal inflammation.

The *eucalyptus*, imported some years ago from Australia to the South of Europe, where it has been easily acclimatized, is a large tree of the family of Myrtaceæ. Its leaves and bark contain a volatile oil which promises to be most useful in therapeutics. It deadens the reflex sensibility of the spinal cord, and relieves the oppression and tendency to cough, in pulmonary diseases. It is a valuable anti-catarrhal agent. The tree, further, contains a bitter principle very efficacious against intermittent diseases, especially marsh fevers. In South America, Spain, Corsica, Algeria, and other countries, the infusion of eucalyptus is becoming largely used as a febrifuge, and it has been found effective in cases in which quinine failed. The balsamic emanations from the tree perfume and purify the air. In marshy districts, it acts against fever, not only thus, but by drying the soil, and preventing the growth of miasma-forming vegetation.

One substance of mineral nature, viz., *bromide of potassium*, has of late years taken an important place in treatment of nervous diseases, especially epilepsy. Administered in a dose of several grammes daily, it has a remarkable sedative action; if not completely curing the disease, at least prolonging the interval between the attacks, and abating the violence of these. *Arsenious acid*, another mineral medicine is shown by M. Magitot to be of value to the dentist, as it has the property of causing the renewal of ivory.

Is there a relation discernible between the chemical nature of substances, and the degree of their toxical and therapeutical value? Attention had for some time been given to this point, and it was known that the salts of heavy metals are more active than those of light metals; that the salts of lead and mercury had poisonous properties, while those of soda and magnesia were relatively harmless. The comparison, however, was not rigorous; and M. Rabuteau has been able to formulate the general relation between physiological energy of mineral compounds and their chemical nature. The energy of soluble metallic salts is in direct ratio of the atomic weight of the metal contained in the salt. The atomic weights of metals being in inverse ratio of their specific heats, M. Rabuteau's law may be given in this form:—The metals are more active in proportion as their specific heat is smaller. The law is the same for the metalloids of the oxygen group; but it is reversed in the case of those which are congeners of chlorine, and for those of the class of arsenic. The practical value of these results is obvious; as a medical man can tell the respective activities of various salts, and thus determine the dose proper to be given, from consulting a table of atomic weights. A physiologist, wishing to ascertain the action of a metallic compound, could predict its relative intensity, and regulate his experiments accordingly. Some years ago, when salts of the new metal thallium were being examined in their influence on animals, surprise was excited by their strong toxical qualities, seeing they otherwise resembled so closely the salts of sodium or potassium; but the atomic weight of thallium is very high, and its poisonous properties are quite in accord with M. Rabuteau's law.

The perfecting of the medical art is thus connected most intimately with the progress of knowledge as to the real action of toxical and medicinal substances. The study of such effects is one of much delicacy, and it is necessary that those who engage in it should acquire a practical acquaintance with the principles and instruments of physics, of chemistry, and of physiology.

LENTIL-MEAL.

At a time when cheap and efficient substitutes for animal food and for bread are being much sought, we shall render a service in directing attention once more to the highly valuable qualities of lentil-meal, properly prepared and ground to a fine powder, and mixed with some other impalpable nitrogenous meal, such as rye-meal. The value of this combination has been recently tested anew by Dr. F. W. Beneke, of Marburg, who is led very earnestly to recommend its use as a substitute for animal food for poor people, in convalescence from sickness, for invalids generally, and for many forms of indigestion. For the latter purposes, sold at a most scandalous price as "revalenta," and accompanied by flaming testimonials, it has long enjoyed a considerable reputation amongst wealthy dyspeptics, and Dr. Beneke records his gratitude for the saving of the life of one of his children by its use.

His observations as to the best mode of preparing it for general use are very interesting. He points out that the Leguminosæ contain nitrogenous and non-nitrogenous substances in the proportion of nearly 1: 2·0—2·2; they contain a sufficient amount of phosphates, and a small quantity of fatty matter, part of which resembles the fat contained in yolk of egg, and part is cholesterine. Such a meal is quite capable of replacing animal food, apart from its kreatinin; and with this view he experimented upon these meals, but found that, as ordinarily prepared, they were much too coarse to be easily digested. At last, however, he found a lentil-meal and also a rye-meal both equally carefully prepared, which, when mixed together in equal proportions, produced a most admirable nutriment for convalescents from acute disorders, for those labouring under certain gastric ailments, and as a substitute for animal food for poor people. A healthy adult uses nitrogenous and non-nitrogenous elements, the latter reckoned as starch, in the proportion of 1 : 5. Human milk contains the same ingredients in the proportion of 1: 3·8–4. Lentil-meal contains them as 1 : 2, and rye-meal as 1 : 5·7, while a mixture of the two in equal quantities contains those components in the proportion of 1 : 4, a proportion which may, of course, be varied according to desire, or the needs of the case. These impalpable meals Dr. Beneke has been in the habit of procuring from W. J. von Coppenaal, 556, Reguliers-Breeskaat, Amsterdam, at 40 cents. per kilogramme for the rye-meal, and 60 cents. per kilogramme for the lentil-meal (about 8*d.* for the one and 1*s.* for the other $2\frac{1}{4}$ lbs., the price of the same quantity of revalenta being 6*s.*). These meals, from containing little water, have four times the nutrient power of beef, weight for weight, so that their relative values as articles of diet may be readily calculated. The digestibility of these meals, and the consequent absence of flatulence during the process, depends primarily upon the impalpability of the powder to which they are reduced; and, secondly, on the mode of preparation. The meal should have a little salt added, then be mixed with cold water, and boiled for half an hour or an hour. The addition of a little extract of beef makes the preparation tasty, without adding greatly to its expense.—*Brit. Med. Journ.*

PHARMACY ACT, 1868.

RECTIFICATION OF THE REGISTERS OF PHARMACEUTICAL CHEMISTS AND CHEMISTS AND DRUGGISTS.

We are requested by the Registrar to publish the following List of persons whose names will be erased from the Register unless they communicate with him on or before 30th December next.

*Those marked * are Pharmaceutical Chemists.*

Abel, William	Brownhills, Staffordshire.
Acton, Aubrey	122, Stobcross Street, Anderston, Glasgow, N.B.
Acton, Samuel Frederick	Compton Road, Wolverhampton.
Adams, William John	Cheltenham.
Aldridge, William	Sewardstone, Essex.
Alexander William	Glasgow, N.B.
Allard, George	Liverpool.
Allen, Benjamin	Birmingham.
Allen, Frederick	High Street, Hereford.
Allen, William	68, Spring St, Landport, Hants.
Allingham, George Samuel	London.
Allman, John Dowling	London.
Allwork, Frederick	Redhill, Surrey.
Anderson, Charles William	Southampton.
*Anderson, David Kennedy	Rothesay, N.B.
Anderson, James	7, New Road, Newcastle-on-Tyne.
Andrewes, Henry Manning	3, Acre Lane, West Brixton, Surrey.
Angus, Henry	Gateshead-on-Tyne.
Annette, Alfred George	Cheltenham.
Appleby, Thomas	88, Meanwood Road, Leeds.
Ariell, William Whittaker	38, King Street, Snow Hill, London, E.C.
Aris, Augustus	3, Mount Street, New Road, London, E.
Armstrong, Benjamin	Plymouth Iron Works, near Merthyr, Glamorgan.
Ashby, William	Nottingham.
Ashton, Thomas Gray	London.
Aspinall, George James	Brunswick Square, Westminster Road, Kirkdale, Lancs.
Aston, Thomas	Newcastle-on-Tyne.
Attwell, Arthur	London.
Aymer, David	Fore Street, Hexham, Northumberland.
Ayre, Henry Mills	Coventry.
Bailey, Henry	Bexley Heath.
Baker, Frederick	London.
Baker, Henry Rutler	34, Hambrook Street, Southsea, Hants.
Baker, John Thomas	London.
Baker, Oswald	London.
Baker, Thomas	Blandford, Dorset.
Baker, William Ritchie	Hounslow, Middlesex.
Ballard, Phillis	39, St. Paul's Road, London, N.
Bamber, Henry Kelway	Exeter.
Bamford, James	218, Mill Street, Liverpool.

Bourne, William Kemsey	Coventry.
Bowe, Oswald Routh	25, Cleveland Street, Middlesborough-on-Tees, Yorks.
Bowen, James	Deptford.
Bower, Albert Hunter	41, Warrior Road, Camberwell, Surrey.
Bower, William	Broadstones, Bradford, Yorks.
Bowles, Edward Henry	Fisherton Anger, Salisbury.
Bowles, William James	London.
Boyle, Alfred	14, Cardigan Rd., Bow, Middlesex.
Bracegirdle, John	24, Half Street, Manchester.
Braddock, James	Manchester.
Bradley, John	Leeds.
Brandreth, Elizabeth	96, Moor Lane, Preston, Lancs.
Brereton, Matthew Bayfield	Putney, Surrey.
Brereton, Thomas Arthur	New Swindon, Wilts.
*Brewer, John Wm. Northway T.	Okehampton, Devon.
Briggs, George	21, High Street, Bath.
Brigstocke, James	London.
Brinsmead, Thomas James	London.
Briscoe, John	16, Grafton Street, Leeds.
Britten, John	Bromley, Kent.
*Brocklesby, David Hyde	London.
Bromley, Edward	London.
Brooker, John Bedford	89, Lake Road, Landport, Hants.
Brookes, James	105, West Graham Street, Glasgow, N.B.
*Brown, Allen McLaren	Brighton.
*Brown, Archibald	Glasgow, N.B.
Brown, John	London.
Brown, John	Newcastle-on-Tyne.
Brown, Thomas Scrafton	134, Beaufort Street, Toxteth Park, Liverpool.
Browne, James	Rugby, Warwickshire.
Browne, Thomas Llewellyn	Chester.
Broxholm, Charles	4, Heath Street, Barking, Essex.
Bryan, John Nicholas	552, Kingsland Road, London, E.
Bryant, John	33, Horsferry Road, Westminster, Middlesex.
Bryars, William Hudson	Goole, Yorks.
Brydon, Thomas T.	Edinburgh, N.B.
Bullock, Alfred Hugh	Manchester.
*Bulmer, Thomas Fitzgerald	Preston, Lancs.
Burks, Benjamin	95, Mare Street, Hackney, Middlesex.
Burleigh, William	1, Tredegar Road, Bow, Middlesex.
Burman, William R.	London.
Burnett, Joseph	4, Moreton Street, Strangeways, Manchester.
Burrows, Robert	94, Gibson Street, Hyde Road, Manchester.
Burt, Frederick George	Clifton Place, Plymouth.
Butler, Alfred Bulteel	Maidstone.
*Butler, John Symes	Frome, Somerset.
Byerlee, John	92, Opie Street, Liverpool.
Callaway, James	London.
*Calvert, John	Durham.
Cameron, Alexander Forbes	27, Clyde Street, Edinburgh, N.B
Cameron, William Alexander	Egremont, Cheshire.
Campbell, Alfred	Hounslow, Middlesex.
Campbell, William	Glasgow, N.B.
Cannell, George Arthur	127, Hinde Street, Scotswood Rd., Newcastle-on-Tyne.
Canning, Philip Stoneham	Coventry.
Canning, William	101, Borough Road, Southwark, Surrey.
Carr, Henry	Tunbridge Wells.
Carroll, Denis	London.
Carter, Thomas Wright	St. Alban's.
Cartwright, John Horncastle	Leeds.
Castell, Thomas Barford	4, Theresa Terace,, Wood Green, Middlesex.
Cave, Alfred	London.

Challener, Theophilus	Harbury, near Leamington, Warwickshire.
Challice, Swann	London.
Chalmers, David	Manchester.
Chambers, George	22, Great Garden Street, Leeds.
Chapman, James	4, Lower Bland Street, Great Dover St., Southwark, Surrey.
Charlesworth, Wm. George	Miles Platting, Manchester.
Cherrington, Barchell	Taunton.
Chirm, John	2, Providence Place, George Street, Lozells, Birmingham.
Christmas, Samuel George	78, Borough Road, Southwark, Surrey.
Clapham, Edward	Leeds.
Clark, Andrew	Edinburgh, N.B.
Clark, Shadrach	3, Crofton Terrace. Hammersmith, Middlesex.
Clarke, William	Newcastle-on-Tyne.
Clarke, Joseph James	Keswick, Cumberland.
*Clarke, Thomas	Oxford.
Clarke, Thomas Watson	London.
Clarke, William	3, Duke Street, Bury, Lancs.
Clarke, William Lang	London.
*Clarkson, James	Hull.
Clayton, William	London.
Cliffe, William	Mushroom St., New Town, Leeds.
*Clifford, John Richard Shepherd	London.
Coates, Joseph	Newcastle-on-Tyne.
Cochran, Robert	Forfar, N.B.
Cole, George William	High Street, Chepstow, Mon.
Collins, William Alfred	63, Collier Street, Pentonville Road, London, N.
Compton, Samuel	24, Hatcham Park Road, New Cross, Surrey.
Constable, Edwin	Hunter's Vale, Birmingham.
*Cook, Thomas	Glasgow, N.B.
*Cook, William	Grantham.
Cooke, William Marcus	Kidderminster.
Cookson, George	Hall Street, Dudley.
Cooper, William	Neville Street, Ulverstone, Lancs.
*Copeland, John	Woolwich, Kent.
*Copney, William	London.
Corbett, William	Edinburgh, N.B.
Corbett, William	Worcester.
Corner, Thomas Brodrick	London.
Corps, Charles	London.
Corrin, William	London.
Cort, John	Portland Place, Doddington St., Regent Road, Salford, Lancs.
*Cotton, Charles N.	Plymouth.
Coulding, John James	19, King Street, Salford, Lancs.
Cox, Henry James Wilson	Brighton.
Cox, Oliver	London.
*Cracknell, Benjamin	Halesworth.
Craigie, James	57, High Street, Tillicoultry, Clackmannanshire.
Crawford, George	Edinburgh, N.B.
Crisp, Owen William	1, Ormond Row, Smith Street, Chelsea, Middlesex.
Crocker, George	Weston-super-Mare.
Croskell, James	London.
Cross, Thomas	Batley, Yorks.
*Cuddeford, John	Edinburgh, N.B.
Curry, George John Symons	St. Leonard's-on-Sea.
Dain, Leopold	40, Dane Street, Nottingham.
Dakin, John	Chester.
Dale, Alfred	20, Bittern Street, Liverpool.
Dale, George	York.
Dalton, Charles	88, Lee Bank Road, Birmingham.
Dalziel, Hugh	New Ferry, Cheshire.
*Davidson, James	Newcastle-on-Tyne.
Davies, Hopkin Jones	Ferry Side, Carmarthenshire.
Davies, John Richards	Worcester.
Davies, Rees	Colchester, Essex.
Davies, Richard	99, Morton Street, Manchester.
Davies, Richard Goodman	72, Great Howard Street, Liverpool.
Davies, Samuel	Rowley Hill, Staffordshire.
Davis, John Poole	20, Fore Street, Taunton.
Davis, Richard	184, Old Kent Road, Surrey.
Davis, Thomas	7, Bruce Road, West Bromley, Middlesex.
Dawson, Cautley	Stockport, Cheshire.
Dawson, Robert	Manchester.
*Day, Charles Wm. Henry	London.
Day, John	24, Shumac Street, Scotswood Road, Newcastle-on-Tyne.
Deane, Alfred	Brighton.
Denby, Walter Phillipson	Highworth, Wilts.
Dewhurst, William	135, Attercliffe Road, Sheffield.
Dibble, John William	Bristol.
Dickins, Benjamin	Stratford-on-Avon.
Dickins, Joseph	Leeds.
Dixon, Joseph	37, Orient Street, Everton, Liverpool.
Dixon, Robert	51, Bold Street, Northwood, near Hanley, Staffordshire.

Dods, John Thomas	Portobello, N.B.
Donald, John Hardy	Edinburgh, N.B.
Dooks, Richard Boulby	33, Castle Gate, Huddersfield.
Doughty, Richard	Bushey Heath, Herts.
Douglas, James Palliser	Charles Street, Goswell Road, London, E.C.
Douglas, Joseph Stringer	69, Tower Street, Westminster Bridge Road, Surrey.
*D'Oyle, John	Chelsea, Middlesex.
Draper, James Henry	Trowbridge, Wilts.
Draper, Richard	Newark-on-Trent.
Draper, Thomas	48, McAslam Street, Glasgow, N.B.
Drury, Morris Hayward	26, Oxford Street, London, W.
Dry, William Henry, jun	36, High Street, Poplar, Middlesex.
*Duchesne, Richard	Cambridge.
Duck, William Masterman	Stokesley, Yorks.
Duncalfe, William Picken	Kinver, Staffordshire.
Duncanson, Andrew	Edinburgh, N.B.
Dutton, John	Eastbourne.
Dyer, Alfred Knyaston	London.
Dyer, William George	3, Union Road, Clapham, Surrey.
Dymond, John	5, South Square, Gray's Inn, London, W.C.
Easson, Robert	Glasgow, N.B.
Eastes, Charles	Gravesend, Kent.
Edward, William Wales	Aberdeen, N.B.
Edwards, John Morgan	67, Union Street, Southwark, Surrey.
Edwards, William James	107, Hampstead Rd., London, N.W.
Edwardson, Joseph	Liverpool.
Elkington, Jacob	21, Broadway, Deptford, Kent.
Ellidge, John Wesley	Southampton.
Ellis, Charles Samuel	Fordham, Cambs.
Embleton, Bradley	235, Strand, London, W.C.
Emerson, Edward Gerard Wetherall	6, Holland Road, Notting Hill, Middlesex.
Evans, Henry	Lloyd Street, Whitmoreans, Staffordshire.
Evans, Henry William	156, Walton Road, Kirkdale, Liverpool.
Evans, John	156, Walton Road, Kirkdale, Liverpool.
Evans, Roger Jones	30, Priory St., Everton, Liverpool.
Evans, William	3, Lodge Lane, Liverpool.
Eveleigh, Francis William	24, Suffolk Road, Dalston, London, E.
Eyre, Henry Reynolds	Ipswich.
*Fairbarn, George	15, Windermere Street, Everton Liverpool.
*Farrer, John Downing	Great Yarmouth.
Faulconbridge, Alfred	155, Dale Street, Liverpool.
Fawcett, Christopher	Linthorpe, Middlesborough-on-Tees.
*Featherston, John Peter	London.
Feltwell, John	London.
Fenner, Edwin	Brighton.
*Fidell, Albert James	Oxford.
Fields, Cotnam	Birmingham.
Filmer, George Alfred	1, Bromley Road, Notting Hill, Middlesex.
Fish, Lawrence	Fielden Street, Blackburn, Lancs.
*Fisher, Glengarry	Edinburgh, N.B.
*Fisher, William Henry	Liverpool.
Fisher, William Raymond	Leytonstone Road, Stratford, Essex.
Fitzgerald, Henry	Bath.
Flanagan, William James	7, Rugg Street, Limehouse, Middlesex.
Flann, Joseph	Rotherhithe, Surrey.
Fletcher, George	Sneinton, Notts.
Floyd, John	Liverpool.
Forbes, Alexander	Lochee, Forfarshire.
Ford, William Henry	53, Kensington Park Road, London, W.
Foster, Henry	Manchester.
*Foster, Henry James	London.
Foster, James	61, Scotch Street, Carlisle.
Fowke, Robert Main	Worcester.
Fowler, Charles Henry	London.
Fox, Robert George	15, Cirencester Place, Portland Road, Middlesex.
Foy, Edwin	1, Lion Street, Norwich.
*Francis, Robert Dolbey	Bishop's Castle, Salop.
Francis, Thomas Brook Turnor	1, St. George's Square, Worcester
Franklyn, Thomas	London.
Fraser, Donald Halliday	Easton Street, High Wycombe, Bucks.
Frayne, William Richard	46, Hospital Street, Birmingham.
*Freeman, William	Devizes.
Frith, John Bruff	Ipswich.
Fryar, Robert	Edinburgh, N.B.
Fuller, Ira Thomas	Beccles.
Furley, John	13, Boston Terrace, Bradmor Park, Hammersmith, Middlesex

Furze, Leader	47, Hughes Street, West Derby Road, Liverpool.
*Fyfe, John Lawrence	Brighton.
Gambier, Gerald Garth Colliton	Bowmont Lodge, Queen's Road Richmond, Surrey.
Garlick, George Pope	174, Sherlock St., Birmingham.
Garry, George	34, Shamrock Street, Glasgow, N.B.
Gavin, John	Leith, N.B.
Gee, Isaac	4, Robert Street, Hampstead Road, London, N.W.
Gerard, Gaston	27, Paradise Street, Liverpool.
Germain, Thomas	6, Lower Bridge Street, Chester.
Gibb, Adam	18, Rosebank Cottages, Edinburgh, N.B.
Gibbings, Henry William	15, Garlick Hill, London, E.C.
*Gibbs, Nathaniel B.	London.
Gibbs, Paul Taylor	London.
Gibson, Charles Alfred	14, Penny Street, Leeds Road, Bradford, Yorks.
Gibson, John	Strickland Place, Kendal, Westmoreland.
Gibson, Robert Hart	42, St. Andrew Square, Edinburgh, N.B.
Gill, Thomas	5, Nile Street, Leeds.
Gilliatt, William	96, Albany Street, London, N.W.
Gillman, Rufus	Sherston Magna, Wilts.
Glaister, Chambers	King Street, Wigton, Cumberland.
Glover, John	Queen Street, Earlstown, Lancs.
Goadsby, Francis	53, Park Hill Road, Liverpool.
Gollop, Robert	Tetbury, Gloucestershire.
Goodale, John Wallett	Leicester.
Goodison, Thomas	Chesterfield.
Goodlad, John Jonathan	Birmingham.
*Goodwin, Felix	Yeovil, Somerset.
Gordon, Richard	44, Adelaide Street, Liverpool.
*Gover, Robert Mundy	Spalding.
*Gowing, James John W.	Great Yarmouth.
*Gowland, William	48, High Street, Sheffield.
Goy, Robert	Hull.
Grant, John	34, Eglinton St., Glasgow, N.B.
Grant, John Smith	Edinburgh, N.B.
Gray, Alfred	172, White Horse Street, Stepney, Middlesex.
*Gray, Frederick	London.
Gray, John Frederick	Shrewsbury.
*Gray, Thomas Scott	Melton Mowbray.
*Green, Conrad Samuel	Stratford-on-Avon.
*Green, Joseph	York.
*Green, Thomas	Leamington, Warwickshire.
Green, William Gunthorpe	Northgate Street, Ipswich.
Greeves, John Williams	13, Mabledon Place, Burton Crescent, London, W.C.
Greeves, Robert Taylor	13, Mabledon Place, Burton Crescent, London, W.C.
Gregory, John Thomas	London.
Grey, Daniel	154, Sauchiehall Street, Glasgow, N.B.
Gribble, George William	41, Park Street, Upper Street, Islington, London, N.
Griffiths, Griffith	Merthyr Tydvil.
Griffiths, Henry William	Pen-y-Graig, Carnarvonshire.
*Grimsdale, James	Chelsea, Middlesex.
*Grosvenor, Frederick	Hanley, Staffordshire.
*Guesdon, Victor	London.
*Guy, George Henry	Bristol.
Hall, Henry	Holme Cottage, Kirkstall, Leeds.
Hall, John	Mitchell Dean.
*Hall, John William	Birmingham.
Hamilton, Archibald	7, India Place, Stockbridge, Edinburgh, N.B.
Hammond, Benjamin	2, Liongate Rd., Landport, Hants.
Hands, George William	Smethwick, Staffordshire.
Harden, Charles	Bristol.
Hardwich, James	Exeter.
Harker, James	68, Corporation St. Halifax, Yorks.
*Harnett, Alfred	Kingston.
Harrington, Philip John	Clifton.
Harris, Edmund	78, Borough Road, Southwark, Surrey.
Harris, Robert	Northampton.
Harris, William Edmund	261, Kingsland Road, London, E.
Harrison, Frederick	Vaughton St. South, Birmingham.
Harrison, John	100, Duke Street, Liverpool.
Harrison, John Cope	90, Bristol Street, Birmingham.
Harrison, John Mather	33, Mount Pleasant, Liverpool.
Harrison, William	168, Hinde Street, Newcastle-on-Tyne.
Hart, George Francis	2, Tarvit St., Edinburgh, N.B.
Hartley, Charles Henry	23, Burley Road, Leeds.
Hawkes, James	Birmingham.
Hawksworth, John Lewis	Nafferton, Yorks.
Hayles, William Wheeler	109, Commercial Road, Southampton.
Haylock, Frederick	177, Green Street, Bethnal Green Road, London, E.
Hayward, Henry Thomas	215, Vauxhall Road, Liverpool.
Heath, Thomas	3, Victoria Terrace, Addiscombe Road, Croydon, Surrey.
Heathcoat, Thomas	79, St. James' Road, Holloway, Middlesex.
Heathorn, Alfred	Reading.
*Heathorn, William	Maidstone.
Hebb, Thomas	Craven Terrace, Sale, Cheshire.
Henderson, Mary Jane	51, Bridge Street, Glasgow, N.B.
Hendry, Alexander Massie	Bridge House, Woodside, Aberdeenshire.
*Hepple, Henry	Bideford.
*Herring, George	Doncaster.
Herron, William Kilburn	2, Garden Street, Wakefield.
Hick, Henry	7, Frederick Place, Caledonian Road, London, N.
Higman, Richard	89, Union Road, Southwark, Surrey.
Hill, Alexander Scott	103, Hospital St, Glasgow, N.B.

THE TESTIMONIAL TO DR. TILDEN.

We have been requested by the Secretary of the "Tilden Testimonial Fund" to give insertion to the following letter received by him from Dr. Tilden:—

"*College Gate, Clifton College, Bristol,*
"*7th October*, 1872.

"My dear Shenstone,

"I have just received your letter and the magnificent balance, for which I hope you and your fellow-students will accept my warmest thanks. My first feeling with regard to this is naturally one of pleasure at receiving so handsome a present, and gratification that I should have been successful in gaining the esteem of those under my charge. But I am obliged, in the midst of my gratification, to remind myself that in so far as I have succeeded in doing my duty, I have done no more than my predecessor did, or than those who come after me will do. And I feel that it must be placed to the credit of the students as much as of myself, that so good an understanding has always been maintained between us.

"I accept your gift, therefore, in nowise in the sense of a reward, but as a memorial of old times, and of the good fellows with whom it was my privilege to work at Bloomsbury Square. It will also remind me that I am not to forget "pharmacy," though I believe there is little chance of my doing that.

"I hope you will not think it inopportune if I take this occasion to remind you of the claims which the School of Pharmacy, in which we all received instruction, has upon our interest and support. A College of this kind should not be regarded as made up of so many individuals, but as one whole, with work to do and a reputation to be maintained, and to sustain which every student past or present should strive to the utmost of his ability.

"I hope in the course of time to hear great things of its increasing importance and usefulness. This, however, can only be brought about by the co-operation of every one interested in the advancement of pharmaceutical education. When you have an opportunity, therefore, do not forget to say a good word for the old place, and when you all become full-fledged members of the Society, give it all the encouragement you can, by showing an interest in the work that goes on, and sympathy with the efforts of those engaged in it.

"I have now only to add, with my reiterated thanks for your kindly feeling towards me, my best wishes for the prosperity and happiness of all of you.

"Believe me to be, my dear Shenstone,
"Yours very sincerely,
"WILLIAM A. TILDEN.

"W. A. Shenstone, Esq."

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION.

On Friday, October 4th, at the close of the annual meeting thirty members and friends of this association sat down to supper at the Blackfriar's Hotel; Mr. W. S. Brown occupied the chair, and Mr. W. Wilkinson was vice. The usual loyal toasts having been drunk with musical honours, Mr. Hermann Woolley proposed "The Pharmaceutical Society of Great Britain," alluding in his remarks to the pleasant recollections he had of time spent in the school at Bloomsbury Square.

Mr. W. S. Brown, Vice-President, responded. Mr. W. Wilkinson, Local Secretary, also replied to the toast.

Mr. Bostock then proposed "The British Pharmaceutical Conference," and Mr. Benger responded.

"The Medical Profession," proposed by Mr. J. T. Slugg, was ably responded to by Dr. Downs, of Stockport, who expressed the great pleasure it gave him to be present and witness the cordiality and good feeling which existed amongst the Manchester chemists. "The Manchester Chemists and Druggists' Association" by Mr. Linay. "The Chemists' Assistants' Association," and other toasts followed.

The Pharmaceutical Journal.

SATURDAY, OCTOBER 12, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE NEW ADULTERATION ACT.

WE are glad to inform our readers that the question raised by our correspondent "Pharmaceutist," in the Journal for September 28, has now been decisively answered. The question was essentially a legal one; and though there might at first sight appear to be some reason for supposing that the word "medical" in the Act would render the Pharmaceutical Chemist or the Chemist and Druggist ineligible for the appointment of analyst, it is satisfactory to find that the interpretation of this term, not only by the Society's solicitor, but also by the highest legal authorities, has, as a matter of law, resulted in sustaining that view of the case which we have already enunciated as regards the qualifications necessary for the office of Public Analyst, and the fitness of pharmacists to perform its duties.

In accordance with the advice of Messrs. FLUX a case was submitted to the ATTORNEY-GENERAL, the SOLICITOR-GENERAL, and Mr. LANGLEY, with a most satisfactory result, as will appear from the following:—

"3, *East India Avenue, Leadenhall Street, London, E.C.*
October 8th, 1872.

"To the President of the Pharmaceutical Society of Great Britain.

"Dear Sir,

"*As to the Appointment of Analysts under the* 35 *and* 36 *Vict. cap.* 74.

"An opinion of the Attorney-General, the Solicitor-General and Mr. Langley has been obtained by us upon a case framed to raise the points lately suggested regarding the eligibility of Pharmaceutical Chemists and Chemists and Druggists for the office of Analyst.

"The case referred to the Statutes of the present reign, 15 and 16 cap. 56; 21 and 22 cap. 90; 23 and 24 cap. 84; 31 and 32 cap. 121; and 35 and 36 cap. 74.

"Of the question submitted and of the opinion a copy is annexed.

"The authority of the opinion must set at rest all doubts,—it must be considered clear that Medical Practitioners are not in any favoured position with regard to the appointment, and that any Pharmaceutical Chemist or Chemist and Druggist, or other person who in the opinion of the appointors possesses 'competent medical, chemical and microscopical knowledge,' may lawfully be appointed to the office of Analyst.

"We are, Dear Sir,
"Yours truly,
"FLUX and Co."

Question.

"Whether the words medical, chemical and microscopical knowledge in the Act 35 and 36 Vict. cap. 74 must be read and construed to limit the choice of analysts so that only duly qualified Medical Practitioners can be appointed, or whether the question whether the elected person does possess competent medical, chemical and microscopical knowledge is not one of fact to be considered by the appointors (subject to the approval of the Secretary of State) without reference to any register of Medical Practitioners or Pharmaceutical Chemists or Chemists and Druggists or the roll of membership of any body of Microscopists.

Opinion.

"We have considered this case and the Acts of Parliament referred to in it, and we are of opinion that the words "medical, chemical and microscopical knowledge" in the 5th section of the 35 and 36 Vict. cap. 74 are not to be construed so as to limit the choice of Analysts within that section to duly qualified Medical Practitioners only. We are further of opinion that the second branch of the question submitted to us must be answered in the affirmative.

"J. D. COLERIDGE,
"G. JESSEL,
"A. G. LANGLEY.

"*7th October*, 1872."

We think the thanks of the pharmaceutical body are due to our correspondent for having distinctly stated the doubt that had suggested itself to him, inasmuch as it might, if passed unnoticed, have practically resulted in the prevention of the appointment of pharmacists to the office of analyst under the new Adulteration Act.

We may mention, as a fact within our knowledge, that the possibility of the term "medical" being interpreted as restricting the appointment to medical practitioners had been recognized in other quarters, and for that reason gave rise to remonstrances while the Bill was before the House.

THE RECTIFICATION OF THE REGISTER.

THE important notice given by the Registrar in this week's Journal, is one to which we would call our reader's special attention, for it offers points of interest not only to those persons who are warned that their names will in a short time be struck off the Register of Chemists and Druggists unless they communicate with the Registrar, but also to every person who has a claim to be upon that Register. As this is the first time that it has been thought desirable to publish a List of those names which would require to be struck off the Register in compliance with the provisions of the Pharmacy Act, 1868, it may be well to recapitulate the steps that have led up to the present result. About two years ago, the Registrar was instructed by the Council of the Pharmaceutical Society to issue a circular in reference to certain details in the working of the Pharmacy Act, 1868, to every person whose name appeared on the Register. A large number of these circulars, although addressed correctly according to the Register as it then stood, were returned through the Dead Letter Office. Shortly afterwards, and on more than one occasion, attention was called in these columns to this imperfect state of the Register with some slight effect, as the Registrar received information respecting a few persons, but the proportion of these to the whole number was so small that he determined to put in force the provision of the Act of Parliament for enabling him to keep the Register correct. As a preliminary proceeding, a circular was sent to every Chemist and Druggist whose name appeared on the Register, except only those connected with the Pharmaceutical Society, and with whom he is therefore in communication weekly in the transmission of this Journal. Of these circulars, about 1200 were returned through the Post-Office. The "first registered letter" referred to in the tenth section of the Pharmacy Act, 1868, was then (in March last) addressed to the persons whom these circulars had failed to reach; and in September,—after the specified interval of six months,—the "second registered letter" was sent. About 150 of these letters reached the persons for whom they were intended, and their addresses have been corrected. There still remain, however, as will be seen by the List published at page 286, 1040 persons whose whereabouts are not known.

One of the principal causes from which this state of affairs arises is the fact that many young men who pass the Society's examinations are registered at a time when not being in business they have no fixed address, and they never afterwards communicate with the proper authorities. Another cause, which we have repeatedly pointed out, is the number of unreported deaths. It does not appear to be generally known by Registrars of Deaths throughout the country that it is their duty to report the death of any Chemist and Druggist occurring in their districts to the Registrar of the Pharmaceutical Society, inasmuch as that duty is seldom performed, although it entitles them to a fee. All of our readers, and more especially the Local Secretaries of the Society, might assist in obviating this by ensuring, as opportunity may occur, that the Registrar of Deaths in the district in which they reside is acquainted with this "Instruction."

The Registrar has now performed all the duties prescribed by the Act of Parliament in endeavouring to find the persons named in the List. It now only remains to wait until three months shall have elapsed since the issue of the second registered letter, dated 30th September last, and on the 30th December next he will be authorized to erase the names of all those in this List who have not up to that time communicated with him. The names of all such persons will, therefore, be omitted from the Register of 1873.

LADY PHARMACISTS.

It may interest some of our readers to know that, as the result of the decision of the Council at their last meeting to allow the attendance of ladies at the professors' lectures, there has already been one entry for the present course. In alluding to this subject, we may mention that we have received a letter from a correspondent who is of opinion that "the new dodge" of allowing ladies to pass the examinations and become chemists and druggists is "one of the most disgusting acts the Board of Examiners has allowed since he joined the Society in 1844." Probably this fresh decision of the Council will be still more obnoxious to this gentleman; and doubtless there are those who, without endorsing his rather coarse language, may agree with him in opinion as to its policy.

With respect to the first point, however, we apprehend that the Examiners had no legal power to refuse a person who is not excluded by the terms of the Act. As to the second, there is little doubt that, considering the present state of public opinion on the general question, the Council acted wisely in judging that they had no moral right to object to ladies availing themselves of the School of Pharmacy to a certain extent, in order to fit themselves for a position allowed them by law.

As illustrating the general tendency of public opinion on this subject, we may point to the address of the Rev. Canon Kingsley, delivered at the Birmingham and Midland Institute on Monday last. In it he said that he had for twenty years past, and should as long as he lived, advocated the training of ladies to the medical profession. And now he was seeing the common sense of England, and indeed of every civilized nation, coming round to that which seemed to him when he first conceived of it a dream too chimerical to be cherished save in secret; and he trusted soon to see a supply of lady doctors sufficient to establish in every town health classes for young women.

The question has been carried to a further stage in the profession of medicine, in which an attendance at a recognized source of instruction is compulsory; but it must be remembered that in pharmacy there is no limitation as to where or how the education has been obtained, so long as the candidate is able to pass the examination. Therefore, should intending lady pharmacists be nearly so numerous as fear suggests in some quarters, according to the known law of supply and demand, there would not be much difficulty in their obtaining the education they require. But these fears, like those that suggest the time when the strictness of the Examiners shall have rendered the supply of pharmacists insufficient, are probably very wide of this mark.

UNIVERSAL EXHIBITION AT VIENNA.

Vienna, which in 1869 was the seat of the third and latest meeting of the International Pharmaceutical Congress, is next year to become the head quarters of an International Exhibition that will probably, revive the interest in such gatherings which frequent occurrence and consequent familiarity have allowed somewhat to flag. For besides being the capital of an empire with immense resources comparatively undeveloped, Vienna will form the nearest point of contact with International Exhibitions yet furnished to Eastern Europe and Western Asia, and especially to the millions of semi-civilized people living in European Turkey, including the Danubian Principalities.

For the purpose of representing this country and in pursuance of an invitation received from the Austrian Government, Her MAJESTY has been pleased to nominate a Commission, at the head of which is H. R. H. the PRINCE OF WALES, and this Commission has established its offices at 41, Parliament Street, S.W., where Mr. PHILIP CUNLIFFE OWEN, the secretary, will receive applications for space and give every information as to the forwarding, exhibiting, and returning of the objects of exhibition.

The Exhibition will be opened on the 1st of May, 1873, and closed on the 31st October the same year. British exhibitors can communicate with the Austrian authorities solely through the above-mentioned Royal Commission by whom detailed plans showing the space allotted and the objects to be exhibited must be sent to the Director-General, Baron SCHWARZ, before the 31st of January, 1873.

In the official classification of objects, "Plants for Food and Physic" forms section (*a*) of Group 2 (Agriculture, Horticulture and Forestry). Group 3, relating to chemical industry, is divided as follows:—

(*a*.) Chemical products for technical and pharmaceutical purposes (acids, salts, chemical preparations of all sorts).
(*b*.) Raw substances and products of pharmacy, mineral waters, etc.
(*c*.) Fats and their products (stearine, oil acids, glycerine, soaps, candles, and tapers, etc.).
(*d*.) Products of dry distillation (as refined petroleum, slate oil, paraffin, phenylic acid, benzoïne, anilin, etc.).
(*e*.) Ethereal oils and perfumeries.
(*f*.) Matches, etc.
(*g*.) Dye-stuffs, mineral and organic.
(*h*.) Resins (washed, dyed, or bleached), sealing-wax, varnish, albumen, isinglass, glue, starches, dextrin, etc.
(*i*.) Contrivances and processes used in chemical production.
(*k*.) Statistics of production.

We are authorized to state the greatest possible facilities will be given to the exhibition of objects in Section (*b*), but immediate application for the required space should be made at the office in Parliament Street.

We may also mention in connection with this subject that Mr. P. L. SIMMONDS, who has already devoted considerable attention to the utilization of waste and residues from manufactures, and has published a popular work on the subject, has been requested by the Austrian Commission to form for the Exhibition as complete a collection as possible, to illustrate what has been done in this direction since 1851. To assist him in attaining this object, Mr. SIMMONDS would be glad to receive specimens of waste and their resulting products at 29, Cheapside, E.C.

Provincial Transactions.

TYNESIDE CHEMISTS' ASSISTANTS' ASSOCIATION.

A Meeting of the above Society was held on Thursday evening, the 26th ult.; the President (Mr. Alfred Brady) in the chair.

The minutes of the last meeting having been read and adopted, the President announced that the Committee had arranged with one of the masters at the Royal Grammar School to conduct a Latin class in connection with the Society on two evenings in each week; the fee is to be regulated by the number of pupils who join the class, which will commence on Tuesday, the 1st of October.

A Sub-Committee, which had been appointed to draw up a plan for the fitting and ultimate working of a laboratory in connection with the society, had presented a report to the Committee, which had been passed with a few alterations, and now stands as follows:—

"The Sub-Committee are of opinion that the present smoke-room shall be made into a laboratory, as it possesses ample space for eight good working benches, viz.:—

"*Four* on the window side of the room "*Three* opposite the fire-place "*One* opposite side to the windows	*Eight.*

"In order to commence on a small scale and with as little expense as possible, simple benches $2\frac{1}{2}$ feet wide will be affixed to the wall, each with a drawer on the under side. Shelves in front of the student may be afterwards added as funds allow.

"Each separate bench should have the following apparatus:—1 spirit lamp; 1 tripod and sheet of metal for sand bath; 1 retort stand; 1 test-tube stand; 6 glass rods; distilled water. Each student to supply his own towels, duster, and reagents. The water may be brought into the room in carboys or stone jars with taps as most convenient; the waste water to be run into a similar vessel, kept for the purpose, and emptied at intervals by the person cleaning the rooms. Suggestions for any apparatus to be made to the General Committee for approval.

"Rules for the regulation and systematic working of the laboratory students to be drawn up by the General Committee.

ESTIMATE.

	£.	s.	d.
"For benches and drawers about	2	16	0
Apparatus, as specified . . .	2	4	0
Sundries	1	0	0
	£6	0	0

"Each student entering for a bench in the laboratory to pay five shillings per half-year. Should this not prove sufficient, means will be taken to add to the amount in the treasurer's hands."

The President said thanks were due to the Sub-Committee for the pains they had taken in drawing up their report, which contained all that was required for a commencement, but he hoped that as the funds increased all the apparatus required for a systematic course of chemistry would be supplied to the students free of expense.

Mr. R. D. Spence, in acknowledging on behalf of the Sub-Committee a vote of thanks that was passed, said he hoped that now the question of their having a laboratory was settled, all the members would take an interest in it and keep it afloat.

Mr. B. S. Proctor then addressed the meeting on pharmaceutical education. He said he thought that a small amount of chemistry and botany should be introduced into the Preliminary examination, as well as some knowledge of at least one of the following subjects, viz., Greek, German or French. As to book-keeping, which had been proposed by some who had written on the subject, he did not think it needful, as every day the pupil is in business he is to a certain extent using the books, and the keeping of them in order is a mere matter of practice. Mr. Proctor then spoke of the "Minor" and "Major" examinations, which he considered answered their purpose very well, and need not be much altered; he said that any student who wished to prepare to pass them could do so by a systematic course of study in from three to nine months, there being nothing difficult in either of them to those who work for the sake of learning. He concluded by saying that those who, looking upon the examinations as a hardship to be got over as soon as possible, and go through a course of cramming to enable them to do so, deserve to be "plucked."

Mr. Welch advised all who had not passed their Preliminary examination to do so at once, as there was no doubt but that it would be a great deal more difficult this time twelvemonths than it is at present. He also proposed a vote of thanks to Mr. B. S. Proctor for his very able address.

Mr. R. D. Spence seconded the motion, which was carried unanimously.

The President then presented the association with a framed photograph of the members of the Pharmaceutical Conference.

The President announced that Mr. Shaw had presented his resignation to the Committee at their last meeting, he being about to leave this country for India. Mr. Shaw was one of the founders of the society, and one of its hardest workers.

Mr. Shaw returned thanks for the kind way that he had been spoken of, and said he should always remember with pleasure the association which had gained him so many friends.

BRADFORD CHEMISTS' ASSOCIATION.

At a Meeting of this Society on the 27th ult., a discussion arose on the merits of the scheme for aiding provincial education suggested to the Council of the Pharmaceutical Society in the 'Chemist and Druggist.' The general opinion of the meeting was favourable to it as containing in it more that is practical and better suited to the present exigency than any scheme yet proposed. The meeting was not insensible to the difficulty of making even so simple a plan as this, and it was proposed that the following resolution should be forwarded to the Council:—

"That the suggestion made in the 'Chemist and Druggist' (August 15th) to the Council of the Pharmaceutical Society deserves the attention of the Council, and that it be respectfully requested to give it full consideration."

NORWICH CHEMISTS' ASSISTANTS' ASSOCIATION.

The Annual Meeting of the above Association was held at the rooms, September 30th; the President, Mr. Alfred Hill, in the chair.

After briefly alluding to the past session, the President called upon the Treasurer, Mr. W. J. G. Butler, to read the financial report, which showed an income of £36. 10*s.* 0*d.*, and an expenditure of £35. 9*s.* 3*d.*, leaving a balance in hand of £4. 10*s.* 11*d.* against one of £3. 10*s.* 2*d.* last year.

The Secretary, Mr. G. C. Fox, read the reports of class teachers. The Materia Medica Class had met seven times; average attendance, ten. The Chemistry Class met twenty-three times; average attendance, ten. The Botany Class met eight times; average attendance, nine. On one occasion the class was not held, owing to the fact that five members only were present. The progress of the pupils in the above classes was reported to be on the whole good. The class preparing for Preliminary examination was attended by six pupils. On the whole the attendance was regular. Finding the work at first done very unsatisfactory, owing perhaps to the long interval of time between the lessons, the teacher gave an additional lesson per fortnight, which had the effect of increasing the amount done. Of the number, only two were able to go over the whole work prescribed for examination, for which they presented themselves in July, one of whom passed.

Mr. Fox then continued—The council is desirous of drawing attention to the small attendance at these classes, which has been even less than that of the preceding year, but at the same time it is gratifying that the small number who did attend acquitted themselves with great diligence and success, as was shown by the reports of the various examiners. They had also to consider a new feature in regard to the Latin Class, viz., all the fees of the tutor had been paid by the association, without any pecuniary demand upon the students; but it was a matter of considerable regret that the members generally failed to avail themselves of the great advantage of having a tutor gratis in a subject of so vast importance, and allowed him to attend at the rooms with only the few members of the Preliminary Class present. The prizes during the present year, the council believed had, to a limited extent, accomplished thedesired result, of a closer attendance to study on the part of those who really endeavoured to improve themselves; but they regretted exceedingly that all the students at the class did not compete. The council were disposed to recommend that the experiment be repeated in the approaching session.

The lectures during the present year had been a decided failure, as owing to the sparse attendance on such occasions, it had been found difficult to induce any gentlemen to undertake the task, and the council recommended that lectures in the summer should be discontinued, and a practical chemistry class substituted.

Lectures had been delivered on Nitrogen by Mr. F. Sutton, on Botany by Mr. O. Corder, on Coal Gas and on Water Analysis by Mr. Mason, and on Volumetric Analysis by Mr. E. Nuthall. The Library Report was highly satisfactory, both on account of the additions made during the present year, and a decided increase in circulation. During the year large additions had been made to the museum by the liberality of various London firms. The council greatly regretted that so few have attempted the Pharmaceutical examinations of the present year (two only having passed the Minor and three the Preliminary), the more so as they felt assured that several other gentlemen could have easily overcome the Minor examination, and until they did so, it would be impracticable to extend the teaching to the higher branches required for the Major. Two members had succeeded in passing the Science and Art Examination in Chemistry in a most satisfactory manner.

The officers and council for the ensuing year were elected as follows:—President, Mr. Alfred Hill; Vice-President, Mr. E. Nuthall; Financial Secretary and Treasurer, Mr. W. J. Gooch Butler; Secretary, Mr. George C. Fox; Council, Messrs. Boultbee, C. E. Canham, N. Lincoln, P. H. Mason, and G. S. Tooke; Librarian, Mr. N. Lincoln; Assistant Librarians, Messrs. Woolnough and King.

Mr. Nuthall proposed that a note should be appended to one of their laws for the purpose of reversing the definition of the word "pharmacy," which had been given at the outset of the association. Then it had been defined as embracing all subjects connected with the trade, either Preliminary or otherwise, but he now thought the time had come when they should discontinue subsidizing the class of teaching required for the Preliminary, on the ground that all that knowledge should be acquired before entering the trade. He did not wish it to be thought that heretofore he had been assisting in a scheme to which he objected; on the contrary, he thought that up to the present they had been justified in assisting the Preliminary students, but now a sufficient time had elapsed since the passing of the Pharmacy Act, he thought they should discontinue to do so. Just now, pharmaceutical education was an all-absorbing topic, and its discussion had brought forward many different schemes, but in nearly all of these there was one point upon which unanimity seemed to prevail, viz., that to advance the best interests of the trade it was necessary to insist upon passing the Preliminary examination before a youth should be apprenticed, and he now asked them to endorse this principle. Mr. Nuthall then proceeded to say that with this association the Preliminary Class had always proved a dead weight. In their first year not only had it been an expense to them, but an unfortunate misunderstanding led to great unpleasantness, and in the present year the results of the teaching had been almost nothing. This was not the fault of the teacher, for he was most suited for the task and had had great experience, but it was that of the students who, he was sorry to say, had been represented to him as most negligent.

Mr. Tooke, in seconding this resolution, said he felt very strongly on this subject, and was glad that it had been brought so prominently before the meeting. He thoroughly agreed with what Mr. Nuthall had said.

Mr. Lincoln, although admitting the force of Mr. Nuthall's remarks, hoped the society would not act rashly upon so important a subject. He would remind them that those of their members who had not yet passed, as well as some who might be about to join, were entitled to some consideration.

Mr. Fox thought by passing the resolution before them, they would do great injustice to some of their members, and would also deter others from joining. He thought it would be better to continue the Preliminary Class during the ensuing session, and discontinue it in the year following. Meanwhile, the discussion that night would show the apprentices what to expect, and act as a warning to them not to look for further help. He would propose as an amendment that the Preliminary Class be continued during the ensuing session.

Mr. Butler seconded the amendment for although he agreed in many respects with what Mr. Nuthall had advanced, he thought they would be thinning their ranks were they to adopt his proposition, and further they would lose the support of some of the honorary members, as he thought several employers regarded the Preliminary Class as an important part of the business of the association.

Mr. Mason said, while agreeing thoroughly with the theories enunciated by Mr. Nuthall, he thought it would be better to wait a year, and then enforce the principle by declining to admit to membership any who had not passed the Preliminary examination.

After some further remarks, Mr. Nuthall stated in reply that he quite expected that some apprentices would not join when they saw that Preliminary subjects were omitted from their curriculum; but he thought that would be better than carrying out what they omitted to be wrong in principle, and he much questioned whether the association would be a loser by this, for more than these subscriptions would be absorbed by the tutor's fee. With regard to those who were already members, and had not yet passed, he thought no injustice would be done, as they all had the benefit of one session's classes, and some had actually attended them for two years. Further, it was open to them to withdraw from the association, if they thought it failed to give them the help they required. Allowing another year to pass before adopting the course he proposed he thought would be useless, as at the end of that year they would in all probability have members who had failed to pass, and again the cry of injustice would be raised. In reply to Mr. Mason's remarks, he thought it would not be advisable to refuse to admit those who had not passed the Preliminary.

A division resulted in the amendment being carried by a majority of 3, several not voting.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION AND SCHOOL OF PHARMACY.

The fourth Annual Meeting of the above association was held in their new rooms, 37, Blackfriars Street, on Friday evening, October 4th; Mr. W. S. Brown, President, in the chair.

The following report was read by the Secretary, Mr. F. B. Benger, and the statement of accounts by the Treasurer, Mr. G. S. Woolley:—

FOURTH ANNUAL REPORT.

In again laying before you an annual report, your council are compelled to express some disappointment. Great hopes had been entertained that the association would receive the hearty support of the whole trade of the district; but the number of enrolled members and associates is slightly less than last year. It was felt that the objects aimed at by this association were such as should arouse the interest, and claim the sympathy and cordial assistance of every chemist and druggist; and, inasmuch as every effort has been made to bring these objects under the notice of all, it has been somewhat disheartening to those who do the work of the association, that no more ready response has been made; at the same time, the council have been cheered by the fact, that so large a number of old members continue warmly interested in the work which the association has set itself to accomplish; and that so many assistants and apprentices, who have come to Manchester during the year, have availed themselves of the privileges offered, and obtained great benefit from the use of the library and museum. It is encouraging to note, that the list of associates almost equals that of the members.

Five ordinary monthly meetings were held during the session, and the following lectures and papers given:—

1st.—"On some of the difficulties of Dispensing." By Mr. W. Wilkinson.

2nd.—"On the Natural History of the Mineral Substances used in Medicine." By Professor W. C. Williamson, F.R.S.

3rd.—"On Pharmaceutical Education in its relation to Pharmaceutical Examinations." By Mr. Louis Siebold.

4th.—"On Dispensing." By Mr. W. Lane.

5th.—"On the Pharmacy and Materia Medica of the Bible." By Mr. J. T. Slugg, F.R.S.

These meetings were all held at eight o'clock in the evening, and tea was provided; but some members having complained that they are unable to attend at this hour, it is proposed to return to the original plan of holding the monthly meetings, alternately, in the afternoon and evening.

The reading-room has been opened three evenings a week during the winter months; and on a fourth, it has been placed at the service of the "Chemists' Assistants' Association,"—a society consisting of your own associates,—who met weekly for mutual improvement. Students have been admitted at any other time by applying to the secretary.

It was a subject of deep regret to your council that the lecture courses, established in connection with Owens College were suspended last session, because the minimum number of students required by the college authorities failed to present themselves. Nevertheless, as you have all been made aware by a recent circular, a very complete course of pharmaceutical instruction has been again organized.

Two large and convenient rooms at 37, Blackfriars Street, within a few minutes' walk of either of the railway stations, have been taken and furnished. One to contain the library and materia medica specimens belonging to the association; the other as a lecture and class room, and the lectures on chemistry, materia medica, botany, and Latin, about to be commenced by Mr. Louis Siebold and Mr. J. J. Smith, B.A., will be delivered there.

As will be seen from the treasurer's statement of accounts, the funds of the association have been heavily drawn on to provide this accommodation, and the annual cost of maintaining it can only be met by the subscriptions of an increased list of members.

The lecture fees have been fixed so low as to call forth some adverse criticism from the pharmaceutical press; but in making these arrangements your council have been influenced by a desire to place the lectures within reach of every apprentice in Manchester and district; and by the hope that the united fees of large classes would render them self-supporting. Moreover, the example of the very successful evening class department at Owens College has been followed.

In response to an appeal from the pharmacists of Chicago for aid in replacing their library and museum destroyed by fire, your president and secretary, assisted by a committee of members of the association, canvassed the district, and the sum of £52. 2*s.* 6*d.* was collected from 163 subscribers, and forwarded through Professor Attfield.

The following donations to the library have been received:—'The PHARMACEUTICAL JOURNAL,' weekly from the Society; 'The Year Book of Pharmacy for 1871,' from the British Pharmaceutical Conference; and occasional copies of the 'Chicago Pharmacist,' from the editors. 'The Lancet,' 'Chemical News,' and 'The Chemist and Druggist' have been subscribed for and placed in the reading-room as published.

Members and associates are reminded that subscriptions become due on the 1st of October. The association may be saved considerable expense, and the secretary some labour by these being forwarded at the earliest opportunity.

The balance-sheet showed an income of £56. 1*s.* 5*d.*, and an expenditure of £88. 2*s.* 10½*d.*, leaving a balance in hand of £41. 5*s.* 5*d.*, against one of £73. 6*s.* 10½*d.* from last year.

The Chairman, on moving the adoption of the report and treasurer's statement, said he could not help expressing a feeling of regret that a much larger number of students had not presented themselves to partake of the advantages which the institution afforded. The object of the association was mainly educational, and it was formed almost exclusively with a view to interest young men, who by the passing of the Pharmacy Act of 1868 were called upon to pass an examination before they were permitted to commence business as chemists. It was to be regretted that the society had failed to connect itself with Owens College, but he looked forward to the time when that end would be accomplished. The association numbered at present 92 members and 71 associates, and he believed it still retained its position as the largest association of the kind in the kingdom; but taking into consideration the number of chemists in Manchester and the surrounding district, from whom they should draw a large number of members, he did not think the strength of the association was quite satisfactory, and they might fairly look forward to an increase to double that number. The society had never sought extraneous aid, and he hoped it would always be self-supporting.

Votes of thanks were then passed to the officers and members of council, and these gentlemen were all re-elected for the ensuing year:—viz., Mr. W. S. Brown, President; Mr. J. T. Slugg, F.R.A.S., and Mr. W. Wilkinson, Vice-Presidents; Mr. G. S. Woolley, Treasurer; Mr. F. Baden Benger, Hon. Secretary; and Messrs. Barnaby, Blain, Bostock, Halliday, Hughes, Kay, Robinson, Mumbray, Hermann Woolley, J. Waterhouse and Hall, members of council; and Messrs. Johnstone and Paine, auditors.

Mr. W. Lane, President of the Manchester Chemists' Assistants' Association, thanked the council for the use of the room for the meetings of that association.

The names of one member and sixteen associates were then read, and these having been elected, the Chairman announced that the next meeting would be held on the first Friday in November, due notice of which would be forwarded to every one connected with the association. The classes would be commenced, and the rooms opened every evening but Saturday, according to the prospectus, and that the Chemists' Assistants' Association would have the full use of the new rooms, as of the old, free from charge. The meeting then terminated.

LIVERPOOL CHEMISTS' ASSOCIATION.

The Annual Meeting of the Liverpool Chemists' Association was held, October 4, at the Royal Institution, Colquitt Street; the President, Mr. E. Davies, F.C.S., in the chair.

Messrs. Thomas Johnson, John Fidler and D. T. Toppin were elected members, and Mr. James Loadanam was elected associate of the association.

The council of the association, in their twenty-third annual report, which was read by Mr. J. Hallawell, the secretary, stated that nine members and an equal number of associates had been elected during the present session, while twelve members and associates had resigned, leaving the number of members at present enrolled at 133, an increase of six on the list as compared with last year. The President reported that seven students had attended the course of lectures on chemistry, and three more the course of practical chemistry in the laboratory. The botany class, conducted by Dr. Carter, had been attended by twelve pupils, eight of whom were pharmaceutical students, and the attendance was regular and well kept up to the end of the series. A series of papers had been read during the session, some of a very useful and scientific character, attracting considerable attention by their importance, and all the papers had been of an instructive and interesting nature. The library had been enriched by several additions, and the librarian reported that there had been more than an average number of applications for books by the members, the number of books lent being 350. The treasurer, Mr. Shaw, read the balance-sheet, which showed that at the beginning of the year there was a credit balance of £9. 4*s.* 10*d.*; and the expenditure left a balance in hand at the close of the year of £11. 4*s.* 7*d.* Mr. Summer, in moving, and Mr. Armstrong, in seconding the adoption of the printing of the report and transactions, lamented the fact that though there were such a large number of chemists in Liverpool, the society numbered so few members and associates. Mr. Taylor suggested, as a reason for that state of things, the late hours at which shops were closed. The President hoped something would be done to introduce a system of early closing among chemists and druggists. The Secretary remarked that several complaints had been made by students that the session had not been of a character to interest or instruct them, the proceedings being either too advanced or of no practical use to them. Whether anything would be done during the coming session to meet those complaints, he did not yet know.

BRISTOL PHARMACEUTICAL ASSOCIATION.

The council have the pleasure to announce that they have made arrangements by which they are enabled to offer to their fellow members and associates the following complete course of instruction in chemistry, botany and materia medica:—

Chemistry.—A course of thirty lectures by Mr. Coomber, F.C.S., on "Inorganic Chemistry," every Tuesday, at 8 P.M., commencing October 15th. A course of thirty lectures by Mr. Coomber, F.C.S., on "Organic Chemistry," every Thursday, at 8 P.M., commencing October 17th.

Botany.—A course of six lectures by Mr. Leipner, on "Botany, Physiological, Economic and Systematic," every Monday, at 7.30 P.M., commencing October 14th.

At the conclusion of this series, that is in May next, an examination will be held in each subject, at which every student is required to present himself.

Tickets for either of the two subjects, that is, for Chemistry or for Botany, will be five shillings for members and associates, provided the holder complies with the condition of presenting himself for examination, and shall have attended not less than 25 lectures in each course, in accordance with the regulations of the classes; if not, the fee will be ten shillings. Students are earnestly advised to abstain from entering for more courses than they can reasonably expect to follow up.

By the renewed consent of Mr. Stoddart, the Council is also able to announce a series of lessons on materia medica, adapted to the requirements of those associates of the society who are preparing for the examinations at Bloomsbury Square. Mr. Stoddart declines to accept any payment for his labours, but agrees with the rest of the council in the propriety of charging a fee of £1. 1*s.* for attendance at these lessons, the proceeds being arranged to go to the augmentation of the fund to meet the expenses of a pharmaceutical museum.

The lessons will be on Friday evenings at 9 o'clock, commencing October 18th.

Tickets for this course to be obtained only at Mr. Stoddart's, North Street.

Mr. Coomber is also prepared to offer a course of practical laboratory instruction on Friday evenings at the laboratory in Nelson Street.

The fee for this instruction is £1. 1*s.* per quarter, and the tickets are to be obtained of Mr. Coomber only.

Arrangements are also in the course of completion for the renewal of the monthly evening meetings that appeared to give general satisfaction in previous sessions.

The first of the series is announced for Friday, the 11th, when the President, Mr. Townsend, will deliver an address and introduce for discussion the subject of Pharmaceutical Education.

Proceedings of Scientific Societies.

ALUMNI ASSOCIATION OF THE PHILADELPHIA COLLEGE OF PHARMACY.

Edward Parrish.

An adjourned meeting of the Alumni Association and graduates generally of the Philadelphia College of Pharmacy was held in the hall of the college; Mr. C. L. Eberle occupied the chair.

The committee appointed on the 17th September to draft resolutions reported as follows:—

"At a meeting of the Alumni Association and graduates of the Philadelphia College of Pharmacy, held September 17th, 1872, the following memorial, expressive of our sad bereavement in the death of Professor Edward Parrish, was directed to be presented to the family of our beloved friend and teacher, towards whom our hearts are drawn in tender sympathy, who have been so suddenly bereft of their life-long companion and friend, and are stricken with a grief too full for utterance and almost overwhelming. We feel that there is not one here in this meeting, of those who have been privileged to sit under his instruction, who can but bear testimony to the great and almost irreparable loss which the profession and general community have sustained, and to the personal sense of a vacancy in the circle of our truest and dearest friends.

"To this community in which he has so long laboured, and maintained an untarnished reputation, where indelibly are written the marks of his earnestness, integrity, philanthropy and public spirit, his memory will long be green.

"The graduates and students of the College will sorely miss their genial, warm-hearted and fatherly teacher, who was so approachable, and so readily entered into sympathy with them in the difficulties that beset their paths.

"The profession over this broad land will acknowledge and deplore his loss, and wherever his professional merit has been recognized, or his name introduced, all must unite in regretting the dispensation that has removed him thus early from the field of his usefulness.

"But while we thus express our feeling of a common sorrow, we have the great consolation of all Christian hearts to know that he was calmly prepared for and anticipated the sad event, that he was surrounded by those who, while strangers, ministered tenderly to the necessities of his last illness, and, that soothed and sustained by an unfaltering trust, he approached his God "like one that draws the drapery of his couch about him, and lies down to pleasant dreams."

The above paper was unanimously adopted.

Parliamentary and Law Proceedings.

The New Licensing Act.

At the Royton Petty Sessions, Edward Whittaker, druggist, Shaw Lane, near Oldham, obtained a licence to sell liquors and sweet made wines. Subsequently Mr. Whittaker asked if he could keep his shop open for the sale of drugs during hours in which the sale of liquors was prohibited, as his was the only druggist's shop in the neighbourhood. The Bench refused to give him permission to do so.—*Manchester Guardian.*

Death from an Overdose of "Infants' Cordial."

An inquest has been held at the St. Stephen's Tavern, St. Stephen's Street, Salford, by Mr. F. Price, on the body of Samuel Riley, a child six weeks old, the son of Mary and Richard Riley, living at 26, King Street, Salford. On Wednesday afternoon the mother of deceased sent another daughter, about six years of age, to the shop of Mr. O'Brien, chemist, 1, Gravel Lane, to purchase a pennyworth of "infants' cordial." With the mixture printed directions were given, but, in consequence of the mother being unable to read, she did not know what was the proper quantity to give the child. About half-past three o'clock she gave the deceased, who had been a "cross" child from its birth, a teaspoonful of the cordial. At half-past seven o'clock the mother and child went to bed, and the mother soon afterward fell asleep. She awoke at one o'clock the next morning, and the child was lying dead by her side in bed.

The coroner asked Mr. O'Brien whether there was any recommendation by the Pharmaceutical Society with reference to medicine being supplied to children.

Mr. O'Brien said that he was not aware that there had been such a recommendation.

In summing up the evidence, the Coroner said that the mother of the deceased was evidently an ignorant woman. It was for the jury to say whether they believed that the child had died from an overdose of cordial. The deceased had had a teaspoonful of the cordial, while the directions said that a child of its age should only have from five to ten drops. If the jury were not satisfied that that had been the cause of death, he would adjourn the inquest in order that a *post-mortem* examination might be made. He might, however, say it was very difficult for traces of laudanum to be found in the body, so that the jury would perhaps not be in any better position were that to be done.

Several of the jury condemned the practice of chemists and druggists supplying medicine of a dangerous character to children without giving them verbal instructions, and were of opinion that such practice ought to be discontinued.

The jury, in returing a verdict that the deceased died from the effects of taking an overdose of "infants' cordial," recommended that chemists and druggists generally ought not to sell medicines of a dangerous character to children who are not old enough to carry a proper message to their parents.—*Manchester Courier.*

Obituary.

RICHARD STURTON.

The death of Mr. Richard Sturton, of Peterborough, Local Secretary of the Pharmaceutical Society, took place, after a short illness, on Sunday, September 29th, in his 39th year. The sudden and premature close of his life was a source of the most poignant grief to a large circle of relatives, by whom he was dearly beloved, while the high regard in which he was held by all who had the pleasure of his acquaintance caused a very deep feeling of regret when it was known that his career of usefulness had been ended.

He was in every respect a Christian gentleman, a thorough man of business, and an excellent pharmaceutist. He became a member of the Pharmaceutical Society in 1855, having previously studied in the laboratory at Bloomsbury Square, and passed the Major examination with honours. During the funeral, most of the houses of business in Peterborough were partially closed.

THOMAS ELLIS HOOKER.

It is with deep regret that we have to announce the decease of Mr. Thomas Ellis Hooker, for twenty years a member of the Pharmaceutical Society. He died at his residence at Sidcup, on the 28th ult., at the early age of 48. His knowledge of business was acquired in the establishment of Messrs. Randall and Son, of Southampton, and Messrs. Lea and Perrins, of Worcester.

Whilst living in the country he studied for the Minor and Major examinations, and passed them successfully without the assistance of teachers or classes.

From 1851 to 1867 he was in business at Wellington, Somerset. From his earliest years, however, science presented great attractions to him. To electricity especially he devoted much time and thought, and in the West of England he was well known as a lecturer on voltaic and frictional electricity, the induction coil, thunder and lightning, etc. His lectures were always highly appreciated, owing mainly to the large number of interesting facts he brought forward, and the illustration of almost every fact by an experiment, in the preparation of which he spared no cost or trouble. He invariably performed his experiments at home first, and thus ensured their success on the lecture-table. Where there was the slightest probability of a failure in any of them, he would repeat them before the lecture commenced, so anxious was he that not a single illustration should be wanting. Some few years since he relinquished the business for pursuits more directly connected with his scientific attainments, but subsequently returned to it, and for the last three and half years he held the position of manager in the dispensing department at Messrs. Allen and Hanbury's. In this responsible position he gained the sincere esteem and respect of all who were brought in contact with him.

Correspondence.

PHARMACEUTICAL EXAMINATIONS.

Sir,—In reading the letter of Mr. Frederick Andrews, upon the subject of Pharmaceutical Examination, printed in the Journal of the 14th ult., my attention was arrested by the statements that "it is sufficiently notorious that many incompetent men do manage to pass the Minor examination," and that the vigilance of our examiners is "being constantly and systematically evaded. I wish to ask Mr. Andrews whether he has well considered the meaning of these words and all which they imply. If so, I hope he will think with me that it is high time we had something more than such mere general statements to do duty as evidence. Since speaking with you on this subject the other day, I find another correspondent in your last number repeating, at p. 279, the statement of Mr. Andrews, and with the same vague generality. As strangely inconsistent with these statements, I may point to another which I remember to have been made less than twelve months since by Mr. Louis Siebold, of Manchester, to the effect that "nobody can bring himself to believe in the real unfitness of so great a number of men as are annually turned back;" and I for one, in the absence of some statement of facts to assist me, am unable to judge with which of these conflicting statements the truth lies, or whether both are wrong. Until such evidence is produced, perhaps it will be fairest to the examiners to give them credit for knowing their business.

QUÆRENS.

Errata.—In last number, p. 266, at foot of col. 2, Messrs. Flux's address should be, "3, East India Avenue, E.C.," instead of "3, East India Avenue Road." Page 278, col. 2, l. 1 from bottom, *for* "money lost" *read* "money cost; page 279, col. 1, l. 34, *for* "their own money" *read* "our own money."

"*Spofforth.*"—Want of care in preparing diluted hydrocyanic acid, will cause it to become coloured as you mention. Pereira states, "I have seen prussian blue formed and deposited after the hydrocyanic acid has been carefully distilled three times." We think that this is rarely the case with that found in the market at the present time. Aqueous hydrocyanic acid undergoes decomposition spontaneously by being converted into formiate of ammonia,

$$CNH + 2H^2O = CH(NH_4)O_2.$$

A little diluted hydrochloric or sulphuric acid is generally added to the medicinal acid by the manufacturers to prevent this.

J. A.—Iodide of potassium decomposes on exposure to the air, especially if the latter contain any mixture of nitrous acid or chlorine gases, as is frequently the case in dispensing establishments. The colorization is due to a little iodine being set free. Ozone produces a like effect. It is much more liable to decomposition if the iodide contain more than traces of iodate of potash as an impurity, which it often does.

G. L. (*Brixton Hill*).—Dissolve the bromide in half the water; having slightly powdered the quinine, add the remaining water to it, and mix with the bromide solution and add the spirit. If the bromide contain much free ammonia, some pure quinine will be precipitated and adhere like a resinous substance to the sides of the bottle.

"*One of the Unfortunates*" who, having been born too late to be registered for the "Modified," writes lamenting the grievance of having to pass the ordeal of the Preliminary examination before being admissible to the Minor, fails to excite our sympathy, or to convince us that the "peculiar hardship" under which he supposes himself and "numbers of others" to suffer, is one worthy of discussion in the Journal.

H. (Trowbridge).—The drug you allude to is probably *Guarana*, a sort of paste made of the seeds of *Paullinia sorbilis*, and remarkable for containing thëine. See a paper by Stenhouse in PHARM. JOURN., vol. XVI. (1857) p. 212.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. W. F. Barrett, Mr. G. H. Snell, Mr. H. E. Godfrey, Mr. P. Vincent, Professor Tuson, Mr. Rimmington, Mr. Abbott, G. C., T. H., A. P. S., J. R. C., "Elector," "A Chemist," "An Associate."

THE BOTANICAL ORIGIN AND CHARACTERS OF THE OFFICINAL RHUBARBS.

By the courtesy of Dr. J. Léon Soubeiran we have been favoured with the following extracts from a communication made by Professor Baillon, in the recent session of the French Society for the Advancement of Science, held at Bordeaux.

The fine officinal rhubarbs which are known by the names of Russian and Chinese rhubarbs, appear to be the product of a single botanical species, growing in Thibet, about the 40th degree of latitude, in deserts, which have usually been looked upon as vast plateaux of sand, but which are really inaccessible citadels, formed of superposed stages of perpendicular rocks, the craggy buttresses of which have been but seldom, and then with difficulty, scaled by Europeans. It was thence that about the year 1868 M. Dabry procured some stalks of the true officinal rhubarb. How he procured these plants is not known, but probably they were carried off by a Chinese workman from land devoted to the lamaseries, from which the common people are scared by terrible imprecations.

Boerhaave and Pallas, like the explorers of the Meikong in our own time, appear not to have known the true rhubarb except from the accounts of the dealers who transported it from Thibet, either to Kiatcha, the principal mart for it in Russia, or to China. Linnæus, however, was pretty near the mark when he wrote that the Asiatic rhubarb grew "*ad murum Chinæ*," although the real locality is doubtless further east. But it has long been known that the plant is furnished with palminerved or digitinerved leaves, which are deeply incised on the margin. This has induced authors to think that the finest quality of the Asiatic drug is produced by a species in the same group as *Rheum hybridum*, probably by *R. palmatum*. Guibourt also arrived at this opinion after having cultivated and studied in Paris all the species of *Rheum* which he could obtain. But M. G. Planchon has shown that the roots of *R. palmatum*, as they are found in Guibourt's collection, do not present the histological characters of the Chinese or Russian rhubarbs of commerce.

Hitherto but little attention has been paid to what is said respecting the rhubarb plant by the authors of the Chinese "Pun-tsaou," namely, that the leaves are "green during the first month, and that when well developed they are as large as a fan, and resemble those of the *Ricinus communis*;" also, that the stem is very large, one to two feet long, covered with a black bark, soft, humid, and containing a yellow sap-wood. These characters are very perceptible in a plant sent by M. Dabry to M. Soubeiran, in the putrified mass of which some shoots were found still intact by M. L. Neumann. These shoots carefully cultivated have produced some plants, one of which has flowered with M. Giraudeau, in the valley of Montmorency, and another is cultivated in the Garden of the Faculty of Medicine at Paris. It has there produced leaves of about a metre and a half in length, and of which the limb, a little broader than long, is orbicular, deeply five-lobed, and incised, cordate at the base, pale green, glabrous above, densely covered underneath by a fine white down, which does not alter the green tint. In the inflorescence, the bracts of about two metres in length, ramified, foliate, and bare at the summit, are surmounted by numerous cymes of whitish flowers, remarkable for the depth of their concave receptacles and the green colour of their disks. The aerial portion of the axis of this plant, for which the name of *Rheum officinale* is proposed, is a thick, short, ramified stem, whilst the subterranean portions are cylindrical, of small size,—therefore of little practical use,—and easily destroyed, from which cause it is rarely, and in but small quantity, imported into Europe. This is the reverse of what is found in the European rhubarbs, of which the fuller developed root is the part usually employed, together with a small portion of the stem. But in the Thibet rhubarb the part principally employed is the aerial stem or branches. Hence the peculiar characters of this drug as it is generally met with in commerce. It is characterized by its colour, smell and taste—found in the living plant from Thibet—and by the numerous starred spots which are observed in sections of certain portions. The pretended black bark which is removed in cleaning this rhubarb is nothing but a mass of leaf bases and of ochreas which cling to the surface of the stem. As the stems of *Rheum* which have been planted in France comport themselves as true sympods, on the surface of which there are not only leaves, but also axillary buds, it is not astonishing that these buds, separated from the mother-plant, readily develope adventitious roots, allowing of their easy reproduction. Thus the future is assured of a large number of stalks of this plant, handsome in an ornamental point of view, and susceptible of being successfully cultivated in France in the open air, where it has already supported a winter of 20°.

The radiated spots in rhubarb are really transverse sections, more or less oblique, of adventitious roots, which penetrate from the base of the root into the parenchymatous mass of the stem, where they appear as a pith of medullary rays, with triangular portions of parenchyma and wood interposed. This makes it practically possible always to distinguish the rhubarbs met with in commerce consisting of the cauline portions of the plant from those consisting of the root.

THE MICROSCOPE IN PHARMACY.

BY HENRY POCKLINGTON.

(*Continued from p.* 283.)

Turmeric.—This is a convenient place in which to notice the structure of turmeric so far as is sufficient to enable us to detect its presence in the form of powder in such articles as mustard, where it is a tolerably common adulterant. The general structure of the turmeric tuber is reticulate in cross section, with a few isolated vascular bundles of one to three barred vessels and enveloping wood fibres. The walls of the parenchymatous cells are thinner than those of ginger, the wood fibres are not so long, and apparently unpitted. The chief characteristic is the great quantity of the colouring matter contained within the cells of the parenchyma. This colouring matter appears to be dissolved in the nitrogenous cell contents from which it can readily be removed by maceration in water and glycerine, leaving the other cell contents pretty nearly uncoloured and withdrawn from the bounding walls of the cell. A more intensely yellow colouring matter is contained within special receptacula, large parenchymatous cells, and unpitted vessels. The starch granules can only be seen when the colouring matter has been wholly, or partially removed, and they resemble those of curcuma arrowroot rather closely.

Hassall says ('Adulterations Detected') that "on the application of iodine, the cells of turmeric become of a deep blue, and with potash, of a reddish colour." With iodine the *cell contents* become blue, this being in no way peculiar to turmeric, but the cells themselves certainly do not without the help of sulphuric acid. Potash also affects the colouring matter only. The action of sulphuric and sulphochromic acids is perhaps more interesting than that of iodine and potash. Immediately on the application of these reagents, the colouring matter changes to a rose pink of a rather unusual shade; a reaction which is not without its use in the examination of mustard.

Arnicæ Radix.—I shall describe the structure of the rhizome only.

Medulla.—Largely developed, and consists of parenchyma of the loose spongy type, its cells being either globose or hexagonal (in cross section) and very thin-walled. Starch in small quantities in minute ovate or globular granules is contained in a few of such of the medulla cells as are not filled with a dark brown, when dry almost black, colouring matter which rapidly dissolves in potash, and is of deep turmeric yellow in solution. The medulla is encircled by vascular bundles, oval in cross section, and consisting of liber tubes enclosed within pitted or barred vessels. Immediately outside this incomplete medullary sheath are well devoloped canaliculi, or secretory ducts of unusual size, and frequently in twos. The structure of these ducts is similar to that of the oil receptacula in the rind of an orange, figured in Balfour's 'Outlines' and many other books on botany. They are cavities bounded by a layer of somewhat compressed cells, and then by the ordinary cellular tissue of the cortical substance. The direction of the canals is not directly perpendicular to the cross section of the rhizome, but somewhat oblique. These vessels contain a dark yellow colouring matter, and are best seen in a thick section mounted as an opaque object. Their structure must of course be studied in the ordinary way. The structure of the cortical layers is not distinguished by any special features.

The minute structure of the barred vessels of the vascular system is rather interesting on account of their varied cohesion, and the distinctly present annuloid thickening of the vessels where the septa have been absorbed.

Valerianæ Radix.—The structure of the rootlets of valerian is simple. A largely developed cortical structure, consisting of large-sized angular cells, encloses a cylinder composed of barred vessels and wood fibres, none of which present any characteristic features. The cortical cells contain great quantities of starch granules, separate or in twos, rarely more, doubly refractive and with a distinct radiate hilum. The structure of the rhizome is much modified by the rootlets. Its cells are smaller than those of the rootlets, and are deeply stained by a dark yellow (or brown) fluid which is contained in the long liber tubes surrounding the abortive vascular sheath of the medulla. The plant is so easily obtained in a fresh state and readily examined that a further description here is unnecessary.

Iris Florentinum.—Orris root is occasionally used as an adulterant; a brief notice of it may, therefore, be useful here. The readiest way of preparing specimens for examination is to cut thin slices, and allow them to macerate in water for a few hours, when the starch-containing cells may be readily isolated. The root may also be reduced to fine powder, and thus examined in glycerine and in balsam. Examination of cross section of the entire root will be of little use for detective purposes, as it consists of little else than a very largely developed central parenchyma encircled with a single ring of vascular vessels, around which are the cortical layers. The cells of the parenchyma are large, irregularly shaped, and contain great quantities of starch granules. The vascular vessels are entirely of the common type and few in number. The same remark will apply to the wood fibres. Very large prismatic crystals are found in connection with the vessels, and are brilliantly doubly refractive.

The starch granules are the only components of the root with which it is necessary to become familiar. They are large, of tolerably uniform size, but rather varied in shape. The hilum is usually a longitudinal furrow, rarely radiate, and very rarely punctate. The general shape of the granules is oval, sometimes they are mussel-shaped, triangular and, when small, circular. The largest granules are flattened and somewhat concave. All of them give a cross, varied in character with the shape of the granule, when viewed by polarized light. A slide prepared by the rough and ready method of scraping a piece of root, and mounting the powder so obtained in Canada balsam forms a lovely polariscope object, from the presence of portions of the crystals just mentioned and wood fibre, all of which are doubly refractive, but differently. The crystals give good "rings." Amongst the illicit uses of orris root, Hassall mentions the adulteration of marmalade and snuff. I have not myself detected its presence in either.

CINCHONA PLANTATIONS IN BRITISH SIKKIM.

Tenth Annual Report by George King, Esq., M.B., *Superintendent, Botanical Garden, and in charge of Cinchona Cultivation in Bengal.*

I received charge of the cinchona cultivation in Sikkim from my predecessor, Mr. C. B. Clarke, on the 10th July, 1871. Since doing so I have had an opportunity of visiting the Government cinchona plantations both on the Nilgiris and in Ceylon, and, by the courtesy of the proprietors, many of the private plantations as well.

2. *Natural features of the Rungbee Valley.*—As none of the reports of my predecessors contain a description of the natural features of the Rungbee Valley, where the cinchona cultivation is conducted, it may be of advantage to the better understanding of what is to follow if I begin this report by giving a short sketch of these.

3. The Rungbee Valley* runs almost due west and east. At its western end it is shut in by a ridge of mountain more than 6000 feet high, in which the Rungjo stream has its origin. By its eastern extremity, which opens into the valley of the Teesta, the Rungjo stream escapes to join its waters with those of that river. Compared to its length, which is only about sixteen miles, it

---

* The valley ought properly to have been named after the Rungjo, which is its chief stream; the Rungbee is but a small tributary of the Rungjo. The smaller stream has, however, been allowed to give its name to the valley, and it is too late now to alter the arrangement.

is a wide valley, measuring from crest to crest probably little less than four miles, but contracting towards its mouth. The southern side of the valley is formed in its upper (western) half by a high range continuous with Sinchul and not much inferior to it in height,* the slopes of which above the zone of cultivation are covered with a dense virgin forest of most luxuriant growth. About halfway down the valley, at a point called Mungoot, this high range curves away to the south-east, throwing out a low ridge called the Mungpoo spur, which running in an easterly direction forms the southern side of the Rungbee Valley along its lower (eastern) half. In the valley intervening between this Mungpoo spur and the main ridge, runs the Ryang stream. The ridge along the north of the Rungbee Valley is, on the other hand, low and pretty nearly clear of forest. Its western part is indeed occupied by the plantation of the Pomong Cinchona Association, which is separated from that of Government by the Rungjo stream. The Government plantation forms an irregular belt at the bottom of the valley and along its southern side, and has therefore a northern exposure. This belt extends from the margin of the Rungjo stream upwards along the slopes to a height above the sea of about 3500 feet. Cinchona cultivation was first begun by Government at the western end of the valley, on the piece of ground known as Rungbee Proper, and has gradually been extended eastward or down the valley. The eastern portion covers the ground locally known as Rishap, and, as will be subsequently explained, the extensions now being made are still eastward of Rishap.

4. The climate of the Rungbee Valley is peculiar. Being so completely shut in upon all sides, it is protected in a striking degree from wind, and up to the higher limits of the cinchona belt the air is rarely stirred by even the gentlest breeze—a state of things in striking contrast to that obtaining in the Nilgiris, where in exposed places great and permanent injury is done to the cinchona plants by the high winds. At the lower levels frost is completely unknown, and the climate is indeed subtropical; while on the higher southern and western slopes frost, and even snow, are the order of the day during the cold season. Occasionally heavy hail-storms pass over the valley, tearing to pieces the thin broad leaves of the red-bark trees. The mischief thus done is, however, rapidly recovered from. The rainfall is heavy, but not equally so in all parts of the valley. The warm, vapour-laden air passing up from the plains has its moisture condensed into clouds by the cool, high, forest-clad ridges that form the northern and western boundary of the valley, and for a great port of the year the higher parts of these are enveloped in a drizzling fog. Even at the driest season one is struck by the amount of mist which, condensed at the higher elevations, almost every evening creeps well down their slopes, while the whole of the opposite side and of the lower part of the valley continue quite clear. During the monsoon the rainfall on these high southern ridges must be very great. Some idea of its extent may be formed from the fact that at a bungalow standing in the south-western corner of the valley, at an elevation of only 5000 feet, and thus far below the crest, the rainfall for the year averages about 200 inches. At lower levels in the valley the rainfall is very much less, and no part of the Government cinchona cultivation is exposed to such a downpour. For example, at the Rishap plantation hut (2000 feet above the sea), where a rain-gauge has been kept for some years, the average is shown to be about 120 inches, and as the mouth of the valley and the Teesta are approached, the climate becomes very much drier. The northern side of the valley being itself comparatively low and cleared of forest, and being, besides, beyond the influence of the high ranges, shares in the drier climate.

* The highest peak of Sinchul rises to 8600 f. above the sea.

5. Now the greater part of the Government plantation lies under the high southern ridge just described, the drainage water of which consequently passes through it on its way to join the Rungjo. This drainage is carried off by numberless streams, most of which originate a good way up the slopes, but much of it also passes underground for a great part of its course, and comes to the surface only a short way above the Rungjo. Moreover, on becoming superficial a great deal of this water, scorning to be confined in channels, spreads itself over a considerable extent of ground and forms swamps. It is needless to say that in such places cinchona will not grow. The most disagreeable peculiarity about these swamps, however, is that they are sometimes unexpectedly formed at places which previously appeared quite dry. This is probably due to the extreme irregularity of the surface, to the inequality of the soil and sub-soil, and to the frequency of the enormous boulders, both superficial and underground, which have been rolled down the mountain-side by the action of the weather. But whatever the cause may be, the effect is that wherever one of these swamps is formed, any cinchona that may have been planted there dies out rapidly. Further down the valley, and below the point where the higher range bends away to the south-east and throws out the low Mungpoo spur as its eastern continuation and as the southern side of the Rungbee Valley, these conditions do not occur. The lower slopes there have not only a much lighter rainfall, but they have only their own drainings to get rid of, and are not required to transmit also that of a high forest-clad mountain extending several thousand feet above them. It is in these drier parts that the extension of the plantation made during the past year has been carried on.

6. *Condition of the plantation.*—The trees of red-bark cinchona (*C. succirubra*), of which the plantation mainly consists, are in my opinion in a state of health which on the whole may be considered as satisfactory. Many of the older trees are indeed extremely healthy and vigorous. Originally placed six feet apart, alternate lines of these have in some places been thinned out, and yet, standing at a distance, one is unable to detect where the thinning has taken place, so completely do the leafy heads of the trees hide the soil. Experience has shown that for the first year or two the plants grow slowly, but that as soon as their heads are large enough to meet and to give shade to the soil, they start away with great vigour. The reason of this lies in the tendency the plant has to throw out fine superficial rootlets, which ramify close to the surface of the ground, and for the very life of which protection from the sun's rays is necessary.

7. *Cinchona officinalis.*—The species yielding the crown bark of commerce has not answered well in any part of Sikkim; and so sickly were the plants at Rungbee during their visit in February 1871, that the Commission appointed to report on the plantation recommended the abandonment of Crown bark cultivation. A large proportion of the plants of this species have died out, and over almost the whole area of permanent *officinalis* plantation *succirubra* has been substituted. I am not without hope, however, that on drier spots than have hitherto been tried the species may yet be got to grow. Only 100,000 plants of *officinalis* are now returned as in permanent plantation.

8. *Cinchona calisaya.*—The plant yielding the yellow bark of commerce, and a sort second to none in value, promises to do well in Sikkim. From the difficulty of propagating this species artificially, the progress made has hitherto been slow. A few trees have, however, now begun to yield seed. This is scrupulously saved for sowing, and every effort is being made to extend the cultivation of this most valuable species, which with *succirubra* must be our stand-by in Sikkim. There are now about fifty acres of *calisaya* planted out, but I

hope before next year greatly to enlarge the area. It is interesting to note that whereas *officinalis* has done well in the Nilgiris, *calisaya* has hitherto thriven badly there, and is indeed now little cultivated.

9. Grey bark, although rich in the other alkaloids, is found to be poor in quinine. The cultivation of the species yielding it (*C. micrantha*, *nitida*, and *peruviana*), has therefore been practically abandoned for some years. The 29,000 old trees in permanent plantation look well, and are growing rapidly.

10. *Disease.*—In his evidence given before the Cinchona Commission in February last year, Mr. McIvor, Superintendent of the Nilgiri Plantations, gave rather an alarming account of a disease prevalent at Rungbee, and expressed it as his opinion that there were on the plantation at the time his evidence was taken (28th February, 1871), 100,000 plants at the age of from four to six years which would die before the end of the year, and that this disease would make the formation of a permanent cinchona plantation at Rungbee or Rishap impossible. The same gentleman has since entered into greater detail on this subject in a report addressed to the Madras Government, and which, having been noticed in an English scientific periodical, has apparently got into circulation in England.

11. Opinions of this sort, so strongly expressed by such an eminent cinchona cultivator, naturally led me to examine the whole plantation carefully and with some anxiety. Since doing so I have had the advantage of going over all the Government and most of the private cinchona gardens on the Nilgiris in company with Mr. McIvor, and I must candidly say I cannot agree with him in his gloomy views regarding either the present condition or probable future of the cinchona enterprise in Sikkim. The four to six-year old plants particularly referred to by Mr. McIvor have been most carefully watched. They form some of the best pieces of the plantation, and I am glad to say that at the end of March, 1872,—that is, thirteen months after Mr. McIvor's prophecy was made,—they were not only in life, but growing vigorously, and that the dreadful mortality predicted by Mr. McIvor does not seem even now to be impending. In his report Mr. McIvor enters on some calculations illustrative of his anticipations as to the small outturn of bark which will be yielded at Rungbee owing to this disease and to other causes; and concerning one of the finest plots of trees on the plantation he writes as follows:—

"On the thirty acres of red bark near the Rishap bungalow, already mentioned as being the finest and most uniform on the Sikkim plantations, each alternate row of plants was cut down when three and half years old. The produce obtained from these plants was 40 maunds (equal to 3200 lb.) of dry stem and branch bark. The quantity of bark on the trees left standing on the ground would thus be 40 maunds also. Previous to the alternate line of trees being removed, about 20 maunds (equal to 1600 lb.) of bark from thinnings had been obtained from the same piece of ground. I thus estimate that if these 30 acres had been entirely cut down, they would have yielded a total produce of 100 maunds or 8000 lb. of dried stem and branch bark, or 273 lb. per acre." Now these thirty acres were a few months ago carefully pruned and slightly thinned, and the bark obtained from the prunings and thinnings was daily weighed. It amounted to no less than 26,459 lb. when wet, which is equal to more than 8000 lb. when dry. In other words, the bark actually obtained in the course of an ordinary cultural operation, undertaken without reference to bark, and by which the trees are supposed to have benefited, is equal to more than twice the amount, which, according to Mr. McIvor's estimate, would have been got by cutting them all down for the sake of their bark. Nor has the pruning knife been used severely, for the ground on which the trees stand is still in deep shade from their spreading heads. Mr. McIvor prefaces his report to the Madras Government by saying, "I would respectfully call attention to the fact that I visited the Himalayan plantations at a season of the year when the plants are in the worst condition. My observations were made during a short stay and at an unfavourable time, and my impressions as to the condition of cinchona cultivation in the north of India might have been somewhat modified had my visit been made at a more favourable season." He advances his opinion, that "permanent plantations of these species (*C. succirubra* and *C. calisaya*) cannot be formed in British Sikkim," "with the deepest regret," and I have no doubt whatever will be very glad to learn that the two predictions concerning these plantations in which he enters on special details have not been fulfilled.

(*To be continued.*)

HEAT AND THIRST, AND SOME OF THEIR POPULAR ANTIDOTES.

(*By the Author of a "Report on Cheap Wines."*)

(*Continued from p.* 88.)

There are some personages of a dogmatical and categorical frame of mind, who are always perplexing their neighbours with classifications and distinctions, and who are pleased to draw a line between food and physic, or between food and stimulants. The difference, however, really lies in the application rather than in the absolute nature of things. A dietary should embrace all that is needful, not only for life but for health and comfort, and (above all things) for the exhilaration and enjoyment of soul and body; and this whether the circumstances be ordinary or extraordinary—in rest and idleness, or in great fatigue and exhaustion. Hence it is not enough for the quenching of thirst to have water merely. We want that which shall make water pleasant to the palate, and we may make it the means of introducing those supplementary and occasional forms of food which we vulgarly call physic.

In the shape of mineral waters, we have such things ready to our hands, whether they come from some "Deus," or "Melior natura," as Ovid says, or whether due to the fortuitous concourse of atoms. If medicine be a supplement to food, then it ought to be taken with food, if sufficiently palatable and congenial to the stomach not to interfere with the enjoyments of the table.

Of table waters in common use, it is unnecessary to reckon up the common soda-water and the real soda-water, such as is made by Ellis or Hooper, the common Brighton seltzer of the pastrycook and that which is made by scientific chemists, at Brighton and elsewhere. The German (real Nassau) seltzer-water is also well enough known, but not so much prescribed as it deserves to be, from its mild, soothing, milky, nourishing taste, and sedative effects on the throat and lungs. The objection commonly raised against these waters is, that they are debilitating, that they tend to wash people out. But it must be borne in mind that the most debilitated persons may be thirsty, that dryness at the mouth may be caused by tonics, and that the skin may be dry and unrefreshing and the kidneys overloaded, and that some such remedy as the seltzer-water, which unites the gently piquant with the sedative in an admirable manner, may make the patient very grateful to the practitioner who recommends it. Seltzer-water and milk, equal parts, suit well in cases of irritable throat-cough, acute bronchitis, etc. But it is not everybody that likes seltzer-water, and they who do may like a change, and no practitioner is ever the worse for two strings to his bow.

Amongst table waters of the decided alkaline sort, I need not mention the *Vichy*, which is a whit too powerful for general use. The *Vals* (*Précieuse*) is a delicious water—cool, sparkling, and light. The *Apollinaris* is remarkable for the tenacity of its aeration, so that, however exposed, it does not get flat. The *St. Galmier* is simply delicious. The *Condillac*, described on the label as "*la reine des eaux de table*," seems to be in great favour at Smyrna, Alexandria, and Gibraltar, and is a palatable, refreshing water. The *Schwalheim* water is highly diuretic; more so, it appears to me, than those of *Ems* and *Faehingen*, as imported. If I may venture to advise my medical brethren, it would be to study these waters as they would so many kinds of wine, and the only available way is to have a few bottles and drink them. They would then know instinctively what patients each was likely to suit.

The above waters are alkaline and aerated, containing chiefly bicarbonates of soda and lime, with minute quantities of common salt, iron, etc. But iron itself, in my judgment (if it is, according to the prevalent hypothesis, to act on the blood, and not merely as an astringent on the digestive mucous membrane, which is the truer explanation of its *modus operandi*), is best given at meals. A few drops of tincture of steel in a glass of cold water is not to be despised, but it has not the subtlety and virtue of a really good aerated iron water. The Spa water is hard, heavy, and headachy. As for the cold, flat English waters, as those of Tunbridge Wells, etc., practitioners on the spot generally prefer to give steel as a medicine. But of steel waters fit for table use at mealtimes there are three chief ones. The *Orezza* I have recommended to several patients labouring under diseases of chronic debility, who have described it as very exhilarating and tonic; the *Schwalbach*, less alkaline, highly invigorating; and the *Bussang* (which is said also to contain arsenic) may be recommended to any patient who likes to take his food and his physic at one operation.—*Medical Times and Gazette.*

THE ADULTERATION OF PALM OIL.*

BY CHARLES A. CAMERON, PH.D., M.D.
Analyst to the City of Dublin.

The fatty substance known by the name of palm oil is obtain from the pulp of the fruit of the *Elais guineensis*. Its colour is bright orange, and its odour somewhat resembles that of violets. It consists of a mixture of liquid and solid fats, and its consistency is, at 60 degrees Fahrenheit, about that of butter. The solid fat—the most abundant ingredient—is termed palmitin, and is a compound of palmitic acid with the hydrocarbon of glycerine. Palm oil is easily saponified, and enormous quantities of it are imported into the United Kingdom (chiefly from the west coast of Africa), to be employed in the manufacture of soap. This fat is also largely used in the manufacture of candles, and of compounds used for lubricating machinery. When fresh, palm oil melts at 80·6 degrees Fahr.; but after some time its fusing point rises to about 100 degs. Fahr.

Palm oil, hardened by the addition of tallow, is the material chiefly employed for the purpose of lubricating the wheels of railway carriages. Some railway companies pay several thousand pounds per annum for palm oil. The purity of this article is, therefore, a matter of considerable commercial importance. I presume that soap boilers, who are the chief consumers of this fat, are well able to judge of its purity, and are not likely to have an adulterated article palmed off upon them; but the managers of railways, whose attention is occupied by so many different matters, often, if not invariably, purchase, as pure palm oil, an article containing from 25 to 90 per cent. of foreign matter.

Some time ago the manager of the Midland Great Western Railway Company of Ireland sent me some specimens of palm oil and other greases for examination, and I was surprised to find in each of them a large amount of water. The following table contains the results of the analyses of these samples, and of a few others which I procured from different sources:—

Composition of Palm Oil and Waggon Grease.
100 parts of each contained—

No.	Name under which the grease was sold.	Fats.	Tar and matters insoluble in Ether.	Mineral matter.	Water.	Total.
1	Palm oil	96·60	0·78	0·22	2·40	100·00
2	Do.	97·00	1·40	0·44	1.16	100·00
3	Do.	33·40	6·30	0·08	60·22	100·00
4	Do.	25·13	5·99	0·08	68·80	100·00
5	Do.	39.00	3,40	0·12	57·48	100·00
6	Best do.	50·31	6·99	0·10	42·60	100·00
7	Best Waggon grease ...	74·64	20·12	3·12	4·12	100·00
8	Sir Wm. Rose's Infusible Waggon grease	69·43	11·23	1·40	17·94	100·00
9	Palm oil	10·11	15·80	0·66	73·42	100·00
10	Do.	19·21	6·89	0·32	73·58	100·00

No. 1 and No. 2 were obtained from the establishments of Messrs. M'Master, Hodgson and Co., Capel Street, and Leslie and Co., Bride Street, Dublin, wholesale druggists. The other specimens were sold or offered for sale to railway companies and other large consumers of lubricating grease. No. 7 and No. 8 contained a large proportion of tarry matter; and neither melted at a temperature of 160 degs. Fahr., showing that tallow entered largely into their composition. Two of the samples of palm oil appeared to contain horse grease coloured with annatto.

It is surprising how large a quantity of water could have been incorporated into Nos. 3, 4, 5, 9, and 10. The latter two contained very nearly three-fourths of their weight of water, whilst in pure palm oil there is only from one to three per cent. of moisture. Of really effective matter for lubricating purposes, No. 9 contained only ten per cent.

The following are the prices at which some of the more commonly used fats are at present sold per ton:—

Palm oil, from	£37 to £40.
Cocoanut oil	£32 to £36.
Cotton Seed oil	£26.
Horse grease	£32.
Australian tallow	£38 to £43.
Best tallow	£52.

The adulterated palm oil above referred to was sold at a much lower price than the genuine article commands, but still at prices considerably above their actual value. I believe the lowest price asked for any of the specimens of grease, the composition of which is given in the table, was £26 per ton. The actual money value of No. 10 could not have been more than £12 per ton at the very highest estimate.

Considerable injury must be occasioned to the "wearing parts" of the wheels of locomotive engines, and railway waggons, and carriages by the use of such spurious stuff as Nos. 3, 4, 5, 9, and 10 in the above table. If lubricated with such a poor material, the steel or hard parts of the wheels and axles would soon become highly heated, and after a time permanently soft. In extreme cases the metallic parts might become red hot by the continuous friction of dry surfaces. Under such circumstances, an accident might probably occur. Fortunately, the railway people generally prepare themselves a lubricating compound, by mixing palm oil with tallow; but even this mixture may prove to a great extent inoperative, if palm oil containing 70 or 75 per cent. of water forms the greater part of the mixture.

* Read at a Meeting of the Anti-Adulteration Society of Irealnd.

MEETING AT MANCHESTER.

A meeting of the pharmacists of Broughton and Cheetham was held at the Knowsley Hotel on Wednesday night. There was a good attendance. With the exception of a few who were unavoidably absent, all the pharmacists of the district were present. A resolution was passed recommending the entire closing of shops on Sunday, and, where practicable, at eight o'clock on other days. Reference was made to the Post-Office arrangements for the late collection of letters from receiving-houses, which often prevents early closing. An advance upon the retail prices in the Manchester list was also approved. It was suggested that at the next meeting the subject of Pharmaceutical Education should be discussed.

NORWICH CHEMISTS' ASSISTANTS' ASSOCIATION.

The annual supper of the above association was held at the Rooms, on October 10th; the President, Mr. A. Hill, occupying the chair.

There was a fair attendance of members. After the usual loyal toasts, the Chairman rose to propose the health of the Vice-President, Mr. E. Nuthall, and at the same time stated that he had the pleasure of asking his acceptance of a despatch-box, subscribed for by the members of the association, in token of their esteem; and also of gratitude for the kindness and untiring energy which he had displayed in conducting the affairs of the society. Mr. Hill said further that Mr. Nuthall had founded the association, and it was mainly due to his great exertions that it had prospered.

Mr. Nuthall made a brief reply in acknowledgment, and the remainder of the evening was spent in proposing various toasts, which were pleasantly interspersed with songs by a few of the members.

LEEDS SCHOOLS OF ART AND SCIENCE.

On Monday, October 7th, there was a large gathering in the picture gallery of the Mechanics' Institute, Leeds, the occasion being the distribution of prizes to the successful pupils connected with the Leeds Schools of Art and Science. Sir John Pakington, M.P., presided, and in opening the proceedings said that there was no use mincing matters, but, no doubt, partly from their insular position, and partly from the habit Englishmen had of entertaining rather a good opinion of themselves, they in their pride were formerly unconscious of the ignorance which was a disgrace to the people, and which was not only a disgrace, but was interfering with and marring the material welfare and prospects of the country. He alluded to the spread of mechanics' institutes throughout the country; and said that where, as in Leeds, the commerce consisted of a great variety of manufactures, he was convinced that nothing could be more likely to promote those manufactures and make them creditable to the locality and beneficial to the people engaged in them than the cultivation of art and science.

CANON KINGSLEY ON LECTURE TEACHING.

As President for the year of the Birmingham and Midland Institute, the Rev. Canon Kingsley delivered the inaugural address on Monday, October 7, before a numerous audience. The address was a very important and suggestive one, and contained the following remarks upon the extent to which attendance at lectures is of service to the student:—

"The student, if he wished to diverge from the narrow ruts of an old-fashioned grammar-school curriculum, had to find his way for himself; to search for himself for facts, for books which might contain the facts he needed scattered up and down in them. Probably he never found the books he needed; too probably, also, the books did not exist—certainly not the school books; and if he found them he had to arrange and to infer for himself, with what mother wit he might possess, while they now had all, and more, done ready to their hand than he in his youth could do for himself, or even get done for him. Other men had laboured, and his dear young hearers were entering into their labours. If they asked his friend Professor Henry Morley how he got the materials for those lectures on English literature, in which he, above any man in England, had the right to be heard —lectures at which he would gladly sit at his feet as a disciple, and which moved in him as much energy as he was capable of; if they asked him, he said, how he came to know all that, he might be too modest to answer them, but he (Canon Kingsley) would answer for him—not by other men's speech, but from his own work; not by attending lectures, though he might have done that and profited by them, but by that which alone could make lectures profitable to him—by honest private toil, by long and careful study of the documents themselves, by deliberate and original thought about them, spread, he doubted not, over many years. The once famous Sir Nicholas Grimcrack, who tried to teach himself to swim by lying on his dinner table, and striking out in imitation of the frog in his basin, taught himself at least the attitude of swimming; but by merely attending lectures they would not teach themselves even the attitude necessary for their subject—the attitude of mind by which the facts were discovered, by which they must be understood, by which they must be turned to use—they would not acquire the inductive habit of mind which arranged and judged of facts. Still less, therefore, would they acquire the deductive habit of mind which made use of facts after they had been arranged and judged, and the lecturer would be to them but a sort of singer, a player upon a fiddle, who made for them pleasant and interesting noises for a while, producing mere impressions, which never sank into the intellect, but merely touched the emotions, to run off them, at the first distraction, like water off a duck's back. He would therefore advise his younger friends to remember this for themselves in this age of periodical literature and learning made easy,—that we were all too apt to forget that we must work for ourselves; that good lectures, like good reviews, were not meant to see for us, but to teach us to use our own eyes; and those they must use at home, in hard study, personal study, continuous study—and study, too, rather of one subject than of many subjects, in order that, by learning how to learn one thing thoroughly, they might learn how to learn anything and everything else in its turn. If the students would bear in mind this homely saying of his, they would find, he doubted not, their admirable programme of lectures and classes as useful as it was comprehensive."

EARLY CLOSING IN BALLARAT.

A meeting of chemists and druggists, and their assistants, was held at Lester's hotel, Ballarat, on the 10th June, at 10 o'clock P.M., to consider the feasibility of shortening the hours of business. The strongest argument that could be advanced in favour of the reform was, that their time of meeting, and the close of their deliberations, extended beyond our usual time of going to press. At the latest moment we learn that extracts from a leading article of the PHARMACEUTICAL JOURNAL, by Mr. Giles, of Bristol, were read, and reports of the movement in the different towns in England; and it was resolved that, on and after the 1st August, the chemists and druggists of Ballarat should be respectfully requested to close their shops at nine o'clock, the public to be duly notified by advertisements in the daily papers of the change, so that no vexation or disappointment should be caused. Cases of emergency to be attended to as usual. The hon. secretary, Mr. Chamberlain, was instructed to obtain the signatures of all who were prevented from attending the meeting, and to notify them of the unanimity and necessity which existed in the movement. He was also instructed to notify the change to the public.—*Ballarat Courier.*

The Pharmaceutical Journal.

SATURDAY, OCTOBER 19, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the Editor, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to Elias Bremridge, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. Churchill, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

PATENT MEDICINE LICENCES.

A correspondent has directed our attention to the "great injustice" he and others similarly situated labour under from the present state of the law with respect to the rates of licence for the sale of patent medicines. It may be of service, therefore, to indicate what the law on the subject actually is, and what are the regulations under which these licences are granted.

There are no less than three rates of licence for makers or vendors of patent medicines—

	£	s.	d.
The cities of London, Edinburgh, and Westminster	£2	0	0
Within the limits of the twopenny post	2	0	0
In any other city or borough, or in any town corporate	0	10	0
In any other part of Great Britain	0	5	0

These rates of licence have been in existence for many years, but it is questionable whether there is any good ground for continuing the special rate of licence for places within the range of the twopenny post. This range is not very well defined; and it is not very evident what equivalent advantages it presents to a dealer in patent medicines that he should be compelled to pay for a licence four times as much as is paid by a chemist in any town in England. There is perhaps no great hardship in compelling a chemist in a corporate town, city, or borough, to pay ten shillings for a licence, whilst a person in a smaller place pays only five shillings, because it may be supposed that the business of the latter will, as a rule, be much more insignificant than that of the former. For the sake of simplicity, however, it would be much better to have one uniform rate of licence, and we think this change would be an advantage both to the Revenue authorities and to the vendor of patent medicines.

As long as these rates of duty are legal, such anomalies as those mentioned by our correspondent must exist; on the borders of cities, boroughs, and corporate towns, there will be cases where chemists within the boundary will pay the ten shilling licence, and others just outside will only pay five shillings; similarly, those immediately within the limits of the twopenny post will pay £2, whilst those just outside will also pay ten or five shillings, as the case may be.

It matters not how many shops may belong to one person, one licence will authorize the sale in them all, if notice be given to the Revenue authorities when the licence is taken out; but it must at the same time be distinctly borne in mind, that if one shop is so situated as to be liable to a higher rate than the others, such higher rate must be paid for the general licence. Under this regulation, our correspondent has to pay a licence of £2 for two shops, because one is within the limits of the twopenny post, and, therefore, he must pay the higher rate of duty.

The publicity given to the subject in the Journal may possibly direct the attention of the Revenue authorities to the present anomalous state of the laws regulating the granting of licences for the sale of patent medicines; and we hope it will not be necessary for further action to be taken to induce the Legislature to deal with the subject. A suggestion has been made by our correspondent to abandon the present rates of licence duty, and to substitute in lieu thereof a uniform rate of duty just sufficient to raise the same amount of revenue as is obtained under the present laws, which average rate would be about eleven shillings. For our own part we should be inclined to agree with that suggestion, so far as the equalization of the rate for licences is concerned, but we would at the same time suggest that it would be advisable to adopt the present higher rate of £2 for all licences, or at least some approximation to that sum, rather than the lower rate mentioned by our correspondent. We believe such a course would be conducive to the interests of the chemist and druggists, inasmuch as it would tend to prevent the now very general sale of patent medicines by booksellers, grocers, and hucksters, and transfer it to the hands of those who are legitimately entitled to deal in the potent drugs frequently contained in the preparations sold under stamp.

In connection with this question we may mention that the 'Medical Times and Gazette' has recently urged that in view of the prosperous state of the revenue, an attempt should be made to induce the Chancellor of the Exchequer to repeal both the stamp duty on proprietary medicines and the excise duty on medicine vendors. It is of opinion that no tax inflicts so much injury on public health and morality, since for less than £100,000 per annum the nostrum purveyors are enabled to vaunt that they carry on their trade "under Government patronage," or "protected by a Government stamp." We cannot agree with our contemporary in the opinion that the abolition of the duty would at all restrict quackery.

THE EARLIER CLOSING MOVEMENT.

In referring again to the Earlier Closing Movement among pharmacists, we are glad to be able to report that it is still making considerable progress. We learn that several pharmacists at the West End have commenced closing their shops at eight o'clock on week days, and keep them entirely closed on Sundays. The chemists and druggists of Lewisham, Blackheath, and Lee, also, having unanimously agreed to close their shops at eight o'clock (Saturdays excepted) after October 21, have issued a joint notice to their customers to that effect, bearing their signatures. A similar resolution has been arrived at by the chemists and druggists of Camden Town and Kentish Town. In Manchester, the pharmacists of Broughton and Cheetham have decided not to open on Sundays, and, where practicable, to close at eight on other days.

But perhaps the most remarkable instance of the spread of the movement is to be found in the fact that the chemists and druggists of Ballarat, induced by the example of their brethren in this country, and especially by an article which appeared in this Journal, are also attempting to arrange for a shortening of the hours of business.

We hope that in order to obviate any possible desire to recede from this attempt to educate the public into sending earlier for their medicines, etc., this movement on the part of the principals to curtail the hours of business will be fittingly responded to by the assistants and apprentices, by their making good use of spare time to prosecute their studies, and thus disproving fears that have been expressed upon the matter. We cannot do better than recommend them, and all connected with pharmacy, to read attentively Mr. Stoddart's most excellent Inaugural Address, delivered on the Opening Meeting of the Session, and endeavour to carry out his admirable suggestions.

THE NEW ADULTERATION ACT.

The carrying out of the provisions of this Act as to the appointment of analysts has been as yet but very partial. Probably it will be necessary to wait some little time to allow local authorities to move in the matter; but if the Act is eventually to become anything more than a dead letter, it is probable that the superior powers vested in the Secretary of State and others will have to be exercised; and those who wish to make the Act operative by the appointment of public analysts will meanwhile have to use their influence to secure that end.

At Liverpool the Local Government Board have appointed James Campbell Brown, D.Sc., as public analyst, and a prosecution for adulteration has already resulted. In Bolton, where Mr. John Collins has been appointed public analyst, the Act is being put into force, as we are enabled through the courtesy of Mr. Dutton, to report at p. 317. It is also stated that a public analyst is to be appointed at Glasgow. On the other hand, an application to the Bermondsey Vestry from the local Master Bakers' Association to carry out the provisions of the Act has been received with laughter, and the Clerkenwell Vestry has decided not to appoint an analyst. This, as far as we are aware, is all that has yet been done in the matter, but we shall be glad to receive information from any of our readers concerning further appointments or prosecutions under this Act.

EXAMINATION IN LONDON.

October 11th, 1872.

Present—Messrs. Allchin, Barnes, Carteighe, Cracknell, Davenport, Edwards, Gale, Garle, Haselden, Ince and Linford.

Dr. Greenhow was also present on behalf of the Privy Council.

Modified Examination.

Forty-five candidates were examined; of these, *fifteen* failed. The following *thirty* passed, and were declared qualified to be registered as Chemists and Druggists.

Appleby, William .... Scarborough.
Atkinson, Robert John .... Sheffield.
Betts, William .... Newtown, Gosport.
Boorman, Charles John ...... Manchester.
Bowen, John Thomas .... High Wycombe.
Bratley, William .... Gainsborough.
Calvert, Edwin Archer .... Brighton.
Clutterbuck, Samuel Richard .. Birmingham.
Coke, Richard Sweet .... Swindon.
Davies, Charles Edward ...... London.
Daymond, Samuel .... Tavistock.
Donston, William .... Woodhouse.
Furniss, Thomas .... Halifax.
Houseman, Alfred Hodgson .... Tunbridge Wells.
Hughes, John Henry .... Holywell.
Johnson, Edward .... Southport.
Jones, Owen .... Litherland.
Kay, John .... Crewe.
Lambert, George Pitt .... Brompton Road.
Leithead, John Henry .... Chester.
Markham, John, jun. .... Reigate.
Miller, William Edwin .... Liverpool.
Moate, Benjamin .... Lincoln.
Penrose, Thomas Samuel ...... Launceston.
Prentice, Charles William .... Shrewsbury.
Sharpley, Samuel .... Sheffield.
Smith, Henry, jun. .... Wellington.
Spinney, Frank .... Bournemouth.
Strachan, James .... Aberdeen.
Taylor, Isaac .... Doncaster.

Preliminary Examination.

Certificates, as under, were received in lieu of this examination:—

Certificates of the University of Cambridge.

Need, John .... Great Malvern.
Standen, Peter .... Ironville.

Certificates of the University of Durham.

Nicholson, Walter Joseph ...... York.
Umpleby, Samuel Sayer ...... Harrogate.

Certificates of the University of London.

Greenish, Henry George ...... London.
Pumphrey, John Henry .... Evesham.

Certificate of the University of Oxford.

Morris, John Quarles .... Bristol.

Certificates of the Society of Apothecaries.

Dent, Francis A. .... Holloway.
Vickery, Alice .... Camberwell.

Certificate of the College of Preceptors.

Bray, Ernest Edward .... London.

N.B.—The list of successful candidates at the Preliminary examination held on the 7th instant, will be published in the next number of the Journal.

Provincial Transactions.

SHEFFIELD PHARMACEUTICAL STUDENTS' ASSOCIATION.

On Thursday, October 10th, a meeting of assistants and apprentices of chemists and druggists in Sheffield was held in the Music Hall, Surrey Street, for the purpose of inaugurating a society to be called "The Pharmaceutical Students' Association." There has been a great want of a society of this kind, and it is to be hoped that the efforts of the founders may be successful in benefiting educationally the young men, and also prove conducive to the welfare of the trade generally. Upon the proposition of Mr. Hollinrake, seconded by Mr. Thompson, Mr. E. R. Learoyd was unanimously appointed president, Mr. James Appleton being elected secretary and treasurer. A general committee was also formed. Mr. Bradwall has kindly consented to give the opening paper of the session.

BRISTOL PHARMACEUTICAL ASSOCIATION.

The first general meeting of the present session was held at the Philosophical Institution, Queen's Road, on Friday, October 11th, under the presidency of Mr. C. Townsend. There was an average attendance. It had been announced that the president would introduce the subject of pharmaceutical education, with the view of eliciting from the members of the association an expression of opinion thereon.

The President, in introducing the business, said he was glad to meet the members and students at the commencement of another session, which he hoped would be even more prosperous and harmonious than the one before.

The minutes of the last meeting having been read and confirmed,

The President delivered the inaugural address as follows:—

The council of your society having in a moment of weakness re-elected me as president, it becomes my duty to open our fourth session. But, in place of the usual address, it has been thought well that this evening should be devoted to the consideration and discussion of the one question which is of the most vital importance in the future of pharmacy; which lies at the root of all success, and will become, accordingly as it is dealt with, either a source of strength and vigour, gathering fresh life and energy for us every year, or a rock of danger and ruin upon which we may, if we are not wise and cautious, find ourselves in a wreck of almost hopeless and helpless confusion.

It is not too much to assert that, upon the treatment of the question of Pharmaceutical Education in the present crisis will depend the entire character of pharmacy for the next half century; a mistake may prove fatal to all our brightest hopes; a wise decision, carried out with breadth and firmness, will win for us the respect of the whole trade, by degrees remove the prejudices of those who now would willingly stand aloof, and will lay the foundation, strong and firm, for a future of gradual and wholesome progress.

In introducing the subject for discussion this evening, I propose very briefly to recall to your attention some of the most important and prominent opinions which have already been expressed, notably at, and subsequent to, the meeting of the British Pharmaceutical Association at Brighton in August last. These may be fairly taken as representative of the various phases of thought in the matter throughout the kingdom, and will clear the way for a better understanding as to the position in which matters now stand. And the first point which comes out is, that it was the idea and intention of the founders and early supporters of the Pharmaceutical Society that it should be and should continue to be an educating body; and that as time progressed, local and provincial schools of pharmacy should be established. Then, according to Dr. Attfield (and I see no reason to doubt his conclusions), there has been, since 1868, a large and most unhealthy increase of cramming for the Minor examination,—the result doubtless of the desire upon the part of large numbers of applicants whose early education has been defective to qualify themselves to enter into business. This is to be deplored, but might reasonably have been expected under the circumstances; and the remedy for this appears to be a more severe Preliminary examination in the future, and the compulsory requirement that the applicant shall have attended a course of lectures upon chemistry and botany, with some recognized teacher or school (not necessarily in any way connected with our Society); and last, but by no means least, that he shall have spent two, three, or four years with a chemist and druggist, or pharmaceutical chemist. All the laboratory instruction, course of lectures, and other aids to scientific knowledge, absolutely necessary as they are, will never enable young men to dispense with that practical knowledge which can only be gained at the counter and in the dispensary at home.

If it were possible to prevent any chemist taking an apprentice who had not passed the Preliminary examination, I would go as far as this in the future. The fountain must be kept bright and clear if we are to have a pure and healthy stream.

Passing on, you will find several schemes proposed for the establishment of either technical schools in the provinces or local schools of pharmacy to be aided more or less by the parent Society; and Dr. Attfield himself suggests the establishment of residential halls in connection with such schools. My friend Mr. Schacht has, as you are aware, himself proposed a scheme which has met with more approval than any other, and since he is, I am happy to say, present here to speak for himself, he will enlighten you on this part of the subject far more than I can do. A late President of the Society, Mr. Sandford, dissents from Dr. Attfield's conclusions that the Society was originally intended to be permanently an educating body, and protests against the conclusions that it was to become "a vast charity for the education, not of the children of chemists, but of all those lads whose parents might in future claim to make them chemists." Doubtless the founders had no intention to form any such permanent charity; and as Mr. Sandford points out, the London schools having established the fact that they can be made self-supporting, all other schools must, if they are to last, be ultimately made self-supporting also.

Mr. Sandford proposes to grant aid to such provincial schools as prove themselves to be working in the right direction, and this unfettered either by special details or by payment for results, until they are able to stand alone.

The most important contribution to the discussion of the whole question is the paper by Professor Redwood, published in the Journal of September 28th.

I will endeavour to indicate its chief points. Strongly urging the need of an early passing of the Preliminary, the Professor thinks that young men of average ability, having the acquirements necessary for this examination, ought in a three or four years' pupilage under a competent master, either with the aid of systematic instruction by classes and lectures, or without that aid if the pupil be properly guided in his studies, successfully to prepare for the Minor. Considering that there may be some gradations in the needed qualifications for a chemist and druggist, suitable to different circumstances, Professor Redwood yet believes the present minimum qualification to be sufficiently low, and our present arrangements defective and insufficient even for the accomplishment of what the law demands; advocating the establishment of schools where in every case provision should be made for complete and thorough instruction in all knowledge required for the highest qualification in pharmacy, and urging that these schools should be all self-supporting, and not mere sucklings of the parent society.

Remembering also that the contemplated education in the future is for all, whether connected with the Society or not; that scientific knowledge is now absolutely requisite; that in the past and as an experiment, education has been supplied by the Pharmaceutical Society at a merely nominal charge, as the only means to give it a fair trial; but having now been tried, approved, and sanctioned by law, Professor Redwood considers it ought in the future to be paid for by those to whom Parliament now exclusively entrusts the practice of pharmacy.

He also thinks that to subsidize schools is unwise, and that their present weakness is in the insufficiency of fees charged to students, and that all occasion for thus cheapening education has ceased.

In place of this he proposes to endow such schools as are required, and argues that this is strength, when a subsidy is weakness. He would not alter the constitution of the Board of Examiners, believing it to be the fittest for its purpose, and also that it would be a mistake to endeavour to suppress superficial training by giving the examination a higher and more scientific character.

In view of more work, Professor Redwood proposes the addition of assessors to the Board; considers that examination is now the all important work to be accomplished by the Pharmaceutical Society, and that it should apply its available means principally in this direction rather than in that of education.

Very hastily and imperfectly, gentlemen, I have endeavoured to sketch an outline of opinion on this vexed question. I must say that for myself I do not see that any sufficient reasons have been given to prove that it is the duty of the Pharmaceutical Society, permanently to grant pecuniary help for educational purposes, either in the Metropolis or in the provinces, but I am nevertheless of opinion that for a time, and in the present stage of matters, aid to establish schools should be given when it can be proved that there is a reasonable prospect of their being efficiently maintained; and that our future safety and stability lies in a strict and compulsory preliminary entrance examination, and in ultimately raising the standard of examination to that of the Major. Any permanent system for granting pecuniary help to schools or pupils in town and country, either in the way of payment for results, or by cheapening education, will, I believe, only weaken our strength, and lower the level both of men and their attainments; and I look forward to the time when every school, both in London and the provinces, shall be independent and self-supporting, and the Pharmaceutical Society of Great Britain shall become chiefly, if not wholly, an examining body.

Before I close I feel that I ought to make some reference to our Bristol Society. The report published in July proves that we have not been idle; every one of our students who went in for examination passed, and for the second time a Bristol student has been honoured by a Queen's Medal. With more than three-fourths of the whole of the trade in our city members of our society, and with a large number of earnest and industrious students, we may claim to have evinced a practical interest in the educational movement second to no provincial city or town; and it is a source of great gratification to feel that Bristol is represented at the Council Board by two gentlemen who are not its least distinguished members.

Let me say one word in conclusion to our friends, the students present. You have many of you done well, but do not, I pray you, depend upon mere book knowledge; do not think that an attendance upon so many lectures is all that you need. Learn to distinguish between *knowledge* and *wisdom*,—between a mere collection of facts, or of principles which you do not know how to use or to apply. Remember that all you can gain now is only a stepping-stone to new and unexplored fields of information.

Charles Kingsley wisely said the other day that "lectures were but intellectual dissipation unless supplemented by work and thought at home;" and you will find all you now know pass from you like a dream unless you are willing to educate yourselves, and to turn to profitable account the active principles which are given you to manipulate.

> "Knowledge and wisdom, far from being one,
> Have oftimes no connection. Knowledge dwells
> In heads replete with thoughts of other men;
> Wisdom in minds attentive to their own.
> Knowledge, a rude, unprofitable mass,
> The mere materials with which wisdom builds,
> Till smoothed and squared and fitted into place,
> Does but encumber what it seems to enrich.
> Knowledge is proud that he has learned so much;
> Wisdom is humble that he knows no more."

I now beg to call upon Mr. Schacht to move a resolution of which he has given notice.

Mr. G. F. Schacht said that though he had prepared a resolution he had endeavoured to frame it so as to limit as little as possible discussion on the matter. In common with the President he hoped most sincerely that this evening's discussion would be such as to elicit every gentleman's ideas on the subject. But although he hoped that the expression of opinion would be ample, he wished to be allowed to say that his special attention having been given to the subject since he had the honour of being a representative, he had been brought to the conclusion he was not quite prepared for a few months ago, that, as public opinion upon the matter appeared to be so indefinite, it would be unwise in the executive of the Pharmaceutical Society to adopt at the present moment any scheme whatever. He was in hopes that their discussions would gradually lead to something like a crystallization of ideas around a few central doctrines, and then action might be taken with more hope of useful result. It was in that hope he had preluded his own scheme with three "principles," and in the same hope he now introduced his resolution—

"That in the opinion of this association it is desirable that scientific pharmaceutical education throughout the country be promoted by the Pharmaceutical Society of Great Britain, and be assisted by its funds; and it declares its hope that the attention of the entire pharmaceutical body will continue to be directed to the subject until a generally satisfactory scheme for the distribution of that assistance can be devised."

That resolution he thought was sufficiently vague not to tread on the corns of any one who had a pet project; but it asked a distinct verdict upon the principle their President had already alluded to, and which lay at the bottom of the whole concern, whether or not, it is desirable that the Pharmaceutical Society of Great Britain should take on itself any responsibility in this matter. A good many opinions had been offered, more or less bordering on the position that the Pharmaceutical Society had better leave the whole question alone; and an endeavour had been made to get quit of the question by contending that the Society should confine its attention to the examinations and the distribution of the Benevolent Fund. Now, he thought they should look this position straight in the face and see what it involved. The Pharmaceutical Society had been established something like thirty-one years, and through all its course up to the present time, whatever had been the theory of its founders, one thing was quite clear, that the managers of the institution had decidedly adopted the course of educating or promoting education. That they had done so in a very unmistakable manner was proved not only by the large number of students who had received the benefits of the institution, but also by their having spent an enormous sum of money on education—a sum amounting to over £100,000.

The President: Is that the gross sum expended?

Mr. Schacht: Yes.

The President: The receipts from students were not equal to that.

Mr. Giles: That is not the balance of expenditure over returns.

Mr. Schacht said he quoted it as the gross expenditure of the Society in this direction, and his contention was that—so large an expenditure could not have occurred unless the principle of which he was speaking had been adopted. If the Society's duties were now declared no longer to include an educational department, a large portion of their invested funds would become unproductive capital; it would involve the necessity of dismissing their professors; handing over the institution in Bloomsbury Square to the highest bidder; discontinuing all connection with the Pharmaceutical Journal—another great means of instruction—and then, perhaps, they might reduce the subscriptions of members to, say 2*s.* 6*d.*, which indeed would be quite sufficient. He thought that would be a somewhat revolutionary proceeding, though it need not frighten them; it was a perfectly logical position, and one for which a great deal might be said. There was another idea which he was sorry to say had received a considerable amount of support. Many who seemed to go with them so far as to think it would be a mistake, certainly at present, to close the connection of the Pharmaceutical Society with education in the abstract, dissented from them when they ventured to move it out of the establishment in London. The position thus assumed appeared to him to be much like this,—they admit the right and duty of the Pharmaceutical Society to educate, but endeavour to concentrate all their power in strengthening and fostering education at the central establishment only. In his opinion this was open to greater objections than the other doctrine. For himself he declared distinctly that it was the duty of the Pharmaceutical Society to do the best it could to assist education. It was right and proper for the Society to do so if on no other ground than that they had gone to Parliament announcing a certain standard of qualification, and obtaining a legal power to refuse the right to practise in the trade to all that failed to reach this standard. Therefore, they should be prepared to show that they had made corresponding efforts to supply the opportunities for the acquisition of those qualifications. Another set of arguments was what might be called the confederacy line of argument, and ran somewhat in this direction: It was said, let the pharmacists teach their apprentices themselves and cease to look to the Pharmaceutical Society for aid in so doing. No doubt a very large number of masters were qualified to teach their apprentices the sciences as well as the practical management of the shop. But it might not be convenient nor advantageous for them to do so, and it struck him that the best qualified men in the business would find it more to their own and their pupils' interest not to undertake to teach them the two sciences of chemistry and botany, but to provide this teaching for them away from home. Again, the entire income and power of the Association were gathered from the length and breadth of the land, and by the abstract rule of right and justice, its benefits should be dispersed on an equally broad principle. To gather from the many and lavish on the few,—to develope high scientific culture in a few, and to leave the many uncared for,—must be wrong under any circumstances, and especially wrong in the case of an organization that had itself set the standard of legal qualification. They could all rejoice in the fact that men like Professor Redwood, Professor Bentley, Professor Attfield and Dr. Tilden had sprung from their body, but they ought rather to rejoice could they succeed in elevating the average chemist and druggist by such an education as would enable him to pass the required examinations creditably. Whether they agreed with him remained to be seen by the vote he asked them to give; and allowing him for one moment to suppose that they did, he would pass on for a few minutes to the question they were necessarily thinking of, viz., the next step in the process. Supposing it granted that the Pharmaceutical Society ought to promote scientific education amongst the trade generally throughout the country various methods suggested themselves. Their President had briefly but with very good judgment summarised the general opinions on the subject. Briefly, there was the process advocated by Professor Redwood, which, seeking for a word to characterize it, he should call the process of endowment. Then he thought there were only two alternative schemes, consisting of that generally recognized as proceeding from Mr. Reynolds, and that which bore his own name, and which he would call, for distinction sake, payment for results. It seemed to him that the notion of endowment was, with all respect to its origin, a professor's idea completely, and one which he did not think would be generally acceptable to the other side of the community, for in the first place they had no stock from which the endowments could come. The funded property of the Pharmaceutical Society amounted to a few thousands—£14,000. £100 per annum represented £3000 so that £14,000 would not go far in endowments. In the next place having endowed, they parted with all management of the fund. Possibly this difficulty might be in part met by a carefully devised project, but the chances were that having parted with their money they would lose all control over it; and in what respect, supposing the scheme to be well conducted, it excelled that of subsidizing, which the Professor regarded in such an unfavourable light, he could not imagine. Subsidizing left untouched the capital—its resources were the current income of the Association, and as long as the Association lived it came in, and when it died its duties died with it. Subsidizing too presents this argument, that it need not be given unless it be supposed to be earned; you give on the year's experience, while if you endow you give for fifty years hence, of which time you know nothing and can form no opinion. As regards Mr. Reynolds' scheme, it was a kind of multiplication of Bloomsbury Squares throughout the country; and though there were not many objections in his mind to this in principle, there were many in respect of the details. It was an extremely difficult matter to arrange and work, for every scheme and application would have to be judged by a different set of individuals from year to year, and no recognized principle could be carried out excepting by the imposition of a very rigid set of regulations, the first attempt to impose which had disgusted the authors of the scheme. With regard to his own scheme, he considered it open to none of the objections he had named; because, as he had ventured to say at Brighton, not a single sixpence would be expended unless earned. The process leaves the individual organization to manage its own affairs exactly as it may think best adapted to the circumstances of the locality. It merely helped those who worked to recover part of the money cost without imposing any more than the simplest regulations on local institutions. They had seen it working most satisfactorily under Government management at the School of Mines in their own city, and no doubt elsewhere. Consequently he was still of opinion that it was the duty of the Pharmaceutical Society to aid in scientific pharmaceutical education as broadly as possible, and he knew of no better scheme of distribution than that founded upon the principle of payment for results.

The President remarked that perhaps he might be allowed to say that it appeared to him the question of the entire giving up any control over education on the part of the Pharmaceutical Society was not quite what would seem to be indicated by those to whom Mr. Schacht had alluded, but rather that education must be made self-supporting; that while the London school existed under the control of the Society, the school as a school should be made to pay. His own feeling was that all schools should be made to pay in future, and that those who intended to enter into the business of chemist and druggist should be prepared to pay for their education just in the same way as they paid for their schooling and apprentice fees. He thought a necessity had been shown for assistance up to a certain point, from the fact that the whole thing wanted further development, and that for some years they would not have the standard of preliminary education so high as it would be ultimately.

Mr. Giles suggested that the words "assisted by its funds" be omitted from the resolution, and then they could all assent to it.

Mr. W. Stoddart seconded the resolution, as he thought it must be self-evident that it was the duty of the Pharmaceutical Society to help education in every way possible. The time however had not come for the adoption of any particular scheme; but one of two things must take place,—either the adoption of some such scheme as Mr. Schacht's, which embraced every locality and circumstance, or one dependent on the requirements and circumstances of those requesting aid. If every place was like Bristol, with large classes and plenty of students, there would be no difficulty. But if they took the outlying districts where there were only two or three young men, it would be as difficult for them to come to Bristol as to go to London. Then, again, there was more value attached to going to London than to Bristol. Most young men would prefer going to London, because there was more value attached to an education there. Where they had a class of fifty students, and all passed well, the payment for results would be something worth having; but if only a few passed, the results would be so small as not to be worth troubling about. In any scheme each application should stand on its own footing, as in one case very little help might be required in money, while in another they would find the entire help of the Society was required. He did not see his way to the adoption of any scheme, though Mr. Schacht's was the best of which he had heard. In some towns the classes did not answer, and, therefore, the results would be very small. At the present time all they could do was to entertain each application on its own merits. Mr. Schacht's resolution held good for that, and no doubt the Pharmaceutical Society would tacitly admit the principle and help them. He knew as a fact that if they applied for a subsidy they would get it, because they were helping themselves; but the Society would do a wrong thing to say "yes" to applications from places where they never tried to help themselves. But to help those who helped themselves was just what the Pharmaceutical Society did, and they could not be expected to go further at present. There was a danger of making the way too easy, against which acting in the light of trustees they should guard. They should improve as much as they could, and not go back to the state from which they were endeavouring to raise pharmacy. If they made the way easy by lowering the fees, they would be doing an injustice to those coming after them. They should raise the status of the profession, if they wished to leave behind them a better state of things than they had in their own time. He did not understand Mr. Schacht's allusion to Mr. Reynolds' scheme as a multiplication of Bloomsbury Squares, as both schemes proposed to better the status, though he did not think it would be politic to say positively that any scheme should be adopted for future guidance. That did not debar him from seconding, with great pleasure, the proposition of Mr. Schacht, because he believed that the Pharmaceutical Society would help any scheme for the development of pharmaceutical education in the provinces.

Mr. Taplin said he had drawn up a statement which he intended sending to the Pharmaceutical Journal, and which he would read to the meeting. It would be difficult to disagree with Mr. Schacht's resolution, although his friend Mr. Giles had been clever enough to find some objection in it, and he (Mr. Taplin) intended to move a resolution that would put things in a more practical shape. The Pharmaceutical Society had been in existence for nearly the third of a century, and it was pretty well time that they had ready something like a scheme for the development of compulsory education. He would first of all read the statement, and then move a resolution:—

"Pharmaceutical education is a question of absorbing interest to those engaged in the honourable, responsible and laborious occupation of a chemist and druggist, and of no small consequence whether realized or not to the public generally. For more than 30 years efforts have been made as is well known, to improve the qualifications and thereby the status of this important section of the commercial community, which resulted some three or four years ago in an Act of Parliament, rendering that compulsory which had hitherto been voluntary. By this means the Pharmaceutical Society obtained an engine of mighty power, but which, after five- or six-and-twenty years' preparation, and three or four years' possession, the Council appear unequal to set in motion; and whilst there has been a great deal said by authorities, reputed great and small, it appears very little indeed has been done, inasmuch as Bloomsbury Square remains as before education was rendered compulsory by Act of Parliament. Notwithstanding the time that has elapsed since obtaining compulsory powers, and the large increase of funds from annual subscriptions, the Council of the Pharmaceutical Society seem to be making a football of the question, kicking it from Dan to Beersheba. It is time we have had one or two definite proposals: one which has met with no little favour has been propounded by an earnest worker in our midst, viz., Mr. Schacht, but which I humbly think is altogether insufficient for the object to be attained, from its want of comprehensiveness; as well expect to capture a beleaguered city by flying a kite into it, or obtain a crop of grain without tillage and sowing, as to meet the requirements of pharmaceutical education by the proposed process of payment by results. Another able and earnest worker amongst us, is Mr. Stoddart, who gave last season (without fee or reward) to the students of Bristol fifty lessons, and proposes to give another course this session on the same generous terms. I rather think the time has not arrived to take action by the Council of the Pharmaceutical Society, notwithstanding that young men cannot qualify as associates or members or go into business on their own account without passing the necessary examinations; and Bloomsbury Square cannot, according to the evidence of Professor Attfield, accommodate more than a fifth of the number who should annually present themselves for examination. The latter gentleman's enigmatical statement that pharmaceutical education is not compulsory, is beyond my comprehension, and he is very loud in his condemnation of 'cram.' Why, cram is the natural outcome of compulsory education, without suitable provision, as much as smuggling is the natural outcome of extravagant duties on imported goods. Do the Council propose to accumulate the subscriptions until Three per Cent. Consols will pay the cost of establishing and maintaining an efficient pharmaceutical college or colleges, which may be somewhere in the end of the next generation? or will they take the matter resolutely in hand and provide suitable and sufficient educational establishments for the whole kingdom, either in London altogether, or in London, Birmingham, Bristol, Manchester, Glasgow, or Edinburgh? and with, I would suggest, two annual sessions of four or five months' duration, at fixed moderate charges—say £20 or £25, including board, lodging, and education;—then I think we may obtain an Act of Parliament requiring that every apprentice should spend one or more sessions at these establishments, and thereby do away with the necessity or temptation to that bugbear and sham, 'cram,' and show to the public and our brethren that we have not only obtained what we had long sought, but know how to appreciate the boon, both to our own and the public weal." Mr. Taplin moved the following resolution :—

"That in the opinion of this meeting the time has arrived for the establishment of one or more pharmaceutical halls or colleges, and that action should be taken by the Council of the Pharmaceutical Society for this purpose."

He wished to say, with regard to Mr. Schacht's scheme, that it was not sufficiently comprehensive. It might do very well, as Mr. Stoddart said, in a place like Bristol, but how would it act in small towns such as Clevedon, Taunton, or Bridgewater, where young men had very few opportunities for qualifying themselves beyond the ordinary routine of the shop? He submitted that young men in such towns ought to have the opportunity given them of going to some public institution where they could obtain scientific instruction of the highest character. The payment for results would answer pretty well in Bristol, where they had such men as Mr. Stoddart, Mr. Leipner, Mr. Coomber, and Mr. Schacht, but they would not find their equals in a place where there were only three or four chemists. A great injustice would be done to young men in small towns if they were placed on the same level with students in towns of larger size and possessing convenient educational appliances. With respect to the proposed halls, he would have three or four only—at Bristol, Birmingham, Manchester, and Glasgow or Edinburgh. Residence in one of these halls should be compulsory before proceeding to the examinations in London, by which means they would do away with the system of "cramming." The sessions need not be too long, costing about £25 each, including board, lodging, and education, and if necessary the members of the Pharmaceutical Society should increase their subscriptions to two guineas rather than lower them to 2*s.* 6*d.*, as suggested by Mr. Schacht. He did not care whether any one seconded his resolution or not. It embodied his own convictions on the matter, and he wished to place it on record.

Mr. Schacht, as a matter of order, said they could not discuss Mr. Taplin's resolution now, unless it was to be moved as an amendment.

Mr. Taplin declined to move his proposition as an amendment.

The President invited the opinions of the students present.

Mr. Sampson (a student) inquired whether payment for results worked well in connection with South Kensington. If the system worked well there, they might have every hope that it would do the same in pharmacy; if not, it would be a great pity to follow it.

Mr. Giles asked the President whether he understood him to say that he gathered that the universal expression of opinion was that it was the duty of the Pharmaceutical Society to provide education?

The President: Not quite that; but that the idea and intention of the founders and early supporters of the Pharmaceutical Society was that it should be and continue to be an educating body.

Mr. Giles said he was quite content with that. There was no doubt the Pharmaceutical Society was established as an educating body. They had, however, arrived at a new epoch, and the less they looked back and the more they looked forward the better. They had heard that the Society had expended some £100,000 in education, and it would be utterly beyond its powers to provide education over the whole country. It never undertook to do so, and could not be accused of failure if it declined what it had never undertaken. Let them see what were the circumstances of the trade. The law required a candidate to pass a certain examination as laid down by the Pharmaceutical Society. The Society had laid down a Preliminary, Minor and a Major examination, but the Legislature had cut out the Major and reduced the standard. He thought the Legislature did wisely in coming to the conclusion that the standard was too high. It was advantageous and honourable to have among them their Bradleys and Stoddarts; but it would have been a most lamentable thing if the standard had been placed so high that the large majority of those desirous of being chemists and druggists must have failed. Looking at the various schemes of education, Mr. Giles said they would all help to form their views into shape and prevent their rushing blindly at this important stage into any definite course. He did not think it required much assistance to attain to the qualification as fixed by the Legislature for a chemist and druggist. Certainly they did not want any assistance in Bristol, nor did he see that assistance was wanted in smaller places, because any man capable of ordinary application, with ordinary assistance, could pass the Minor examination. He did not want to see the system of pharmaceutical education made too easy. In law and medicine there were no means of obtaining collective instruction. Pupils knew the conditions of entering those trades, and they fulfilled them. So in their own trade, especially as they had not come to a very high standard, it should bring men prepared mentally and financially to meet the requirements of the trade. Mr. Giles therefore expressed an opinion that the Pharmaceutical Society should confine its assistance to those who desired to go further than the Minor examination. That was the kind of education the Society was established to promote, and not that kind that every young man could get for himself behind the counter, or by reading; and it was a question whether it was proper to limit to such the school of pharmacy in Bloomsbury Square, or whether they should have a kind of matriculation examination in the Minor and extend the school to high pharmacy. He was pleased to hear Mr. Taplin enunciate the opinions he had expressed at Brighton, that they should establish a few schools in various parts of the country. He had said that the time had arrived for that to be done in Edinburgh, but it was not at all fair to come on the Pharmaceutical Society to pave the way for people to slip into the trade in an easy manner. They should tax themselves to advance the higher pharmaceutical education, such as exists at Bloomsbury Square, by utilizing the opportunities of scientific instruction existing in the country and also by encouraging local organizations. By so doing they would effect a great national good to other classes besides their own. He did not think they wanted anything more than the organizations throughout the country already provided for. Science schools should only be kept up in certain centres. There would be outside places in everything; and they could not suppose that young men would have the same opportunities at Stoke Pogis as in Bristol. Things always equalized themselves, and there were few young men who would not get to London or some other big town. The question resolved itself into this—that, having made the Minor examination compulsory, they should associate with that the Major examination for which some special training was required. Now all that was requisite had dwindled down to the Minor; every young man with fair opportunities as an apprentice ought to pass, as the difficulties were not of that nature to require any heroic exertion. The Pharmaceutical Society should keep the higher standard of pharmacy up to a satisfactory point.

Mr. Schacht said he was obliged to Mr. Sampson for his inquiry. Possibly his faith in the scheme had been somewhat shaken by a correspondent asserting from time to time in the PHARMACEUTICAL JOURNAL that the South Kensington scheme had been an utter failure. But he was happy to say, on the authority of the 'Blue Book,' that the total number of students in January, 1871, was 5760 more than the number two years before, and that in the subject of chemistry alone the number of students was 5000 odd in 1871, as compared with 2000 odd in 1869. That looked so little like a collapse that he was astonished at the audacity of the writer who made the assertion. He was obliged to Mr. Giles for his remarks; and he could not help, without any violent twist, perverting them as an argument in favour of his own scheme. He gathered that whilst approving and estimating highly the good which the school in Bloomsbury Square accomplishes for high pharmacy, he also sees that for the requirements of the Minor examination a not very high class of qualification is necessary. And yet the Minor required something like the study of two important sciences, and the skeleton scheme of his aimed at little more than imparting these two sciences as part of the qualifications of the many students who may be brought into the smaller centres. He failed to see that Mr. Taplin's plan would prevent "cram"; on the contrary, he feared it might encourage it, by inducing men to substitute a three months' course of chemistry and botany for the more legitimate and effectual study of these sciences.

Mr. Giles said he was not speaking against Mr. Schacht's or any scheme.

The resolution was then put to the vote and carried unanimously.

Mr. Taplin then proposed his resolution, and said their students had not the same facilities as medical or law students. Medical students went to some hospital, while law students went to their employers' agents in London to get that knowledge they could not procure in provincial towns or villages. Mr. Giles was favourable to keeping up Bloomsbury Square as a high school of pharmacy, but that was not so legitimate as the establishment of halls in various parts of the country.

Mr. Giles seconded the motion.

Mr. Boorne said he preferred the resolution passing without the rider of Mr. Taplin. The Pharmaceutical Society from the first had sought to make examination compulsory, and had recently obtained the sanction of the Legislature to the Minor examination; but if they committed themselves to the obligation to educate, they must ask Government to make compulsory the Major examination. The difficulty was not as to the desirability of promoting education, but as to the mode. Mr. Schacht's scheme in theory was a really practical one, but it was like putting the cart before the horse. It asked the Society to give payment for results when they wanted payment in order to obtain results. He thought it was desirable that the Society should make grants to any provincial association that would use them usefully, and from which results were likely to flow. As to the establishment of colleges, he hardly imagined that the day was come for that, but it might shortly. At present hardly sufficient support would be given to maintain such colleges in the provinces. The tendency of all technical education was towards London. It was desirable that young men should learn all they could in the provinces, and so prepare themselves for a very short time in London to complete their education.

Dr. Tilden, in response to an invitation from the President, next addressed the meeting. He thanked them for the honour they had done him in admitting him as an honorary member of the association, and was glad of that opportunity of meeting his old pharmaceutical friends. With regard to the question of the establishment of colleges and the question of pharmaceutical education, he had very little sympathy with any scheme for the distribution of the funds of the Society merely to enable students to pass the examination. He thought Mr. Schacht's scheme would supply the demand for local education, but would only go so far as to bring a considerable number of students up to the Minor. That was a very low standard, and one of which he was not particularly proud. They should look for something beyond that. Another difficulty had been alluded to by Mr. Giles, and that was the position of the institution in Bloomsbury Square. Pharmacy had cut a very poor figure in times past, and its present position was owing to the existence of the school in Bloomsbury Square in a flourishing condition. That school showed the outside public that they were doing a good work, and not merely following the occupation of an ordinary chemist and druggist. He had supported Mr. Schacht's motion, because he took it as an expression of opinion in favour of scientific pharmaceutical education—that education that leads on to pharmaceutical research, leaving the money-grubbing behind, and leading on to better results than in the past. He had a notion that local branches associated with Bloomsbury Square could not fail to be an advantage in enabling young men to get a thorough grasp of the subject, and there was an advantage in working with fellow-students which could only be obtained in large establishments.

The President said he was glad the subject had excited discussion, but as it was late he must ask them not to prolong it much longer.

Mr. Schacht said this resolution was offered to the Council of the Pharmaceutical Society, and urged on them a certain course. He was not sure if he was correct, but did Mr. Taplin wish them to assume the duties of housekeeping in which they had had no experience?

Mr. Giles: That was in the speech, not in the resolution.

Mr. Schacht: The resolution goes for a home for students from all parts of the country.

Mr. Taplin: That is perfectly right.

Mr. Schacht: Rather a new field for the Council of the Pharmaceutical Society to enter upon. But in his capacity he must be silent, and receive the request from the association if they chose to adopt it.

The President said he did not see any great advantage in residential houses or colleges. He would rather support the idea that all young men take lodgings and provide for themselves.

Mr. Taplin pointed to the facilities for board and lodging afforded at Cambridge and Oxford, and said he hoped the resolution would pass, as he should be glad to see it brought under the notice of the Society.

The resolution on being put to the vote was negatived by two to one, and the proceedings terminated.

MANCHESTER CHEMISTS' ASSISTANTS' ASSOCIATION.

The second annual meeting of the above association took place in the new lecture-room of the Chemist's and Druggists' Association, 37, Blackfriars Street, on Monday evening, October 7th; the President, Mr. W. Lane, was in the chair, and, after delivering a few introductory remarks, called upon the Secretary, Mr. J. T. Clarke, to read the report on the past session.

The committee reported that during the second session ten papers had been read, followed by animated discussion, which, it was believed, must have afforded matter of interest and instruction to all present. Reference was made to the want of good attendance of members; and it was pointed out that the larger the attendance, the greater the encouragement for the production of papers. Another point in which there is room for improvement was said to be the small number of members on the roll. It was suggested that each one should do his utmost to make known to his friends the existence, object and result of the meetings, and induce them to attend, so that while increasing their knowledge they might promote generally that feeling of friendship and union so necessary to their existence as an educated and influential body.

The President, in moving the adoption of the report, wished to thank those gentlemen who had contributed so largely towards the success of the past session. In doing so he had to regret the loss of a most energetic member in Mr. Arkle, whose excellent paper, entitled "Notes," was one calculated to do much good.

A vote of thanks was then passed to the retiring officers and committee, and the following gentlemen were elected for the present session:—

President, Mr. W. Lane (re-elected); Vice-President, Mr. J. Tyson; Secretary and Treasurer, Mr. J. T. Clarke (re-elected); Committee, Messrs. Blayney, Booth, Burton, Dodge, Hedley and Sanders.

The President, after thanking the meeting, called attention to the increased accommodation and means provided for the benefit of students preparing for examination, and others connected with the business. He said that with the source of instruction now thrown open, Manchester would be second to no other provincial town in England; and urged students to appreciate the untiring efforts of those gentlemen who had laboured hard to procure for them these facilities. This was to be done by regular attendance at the lectures; and not only by actual attendance, but also by that careful attention to every fact brought before their notice, which would undoubtedly gain for them the respect and admiration of their fellows as being a class of hardworking students. This he felt sure would be the highest reward and thanks they could possibly tender the founders of the Manchester School of Pharmacy.

The next ordinary meeting will be held at 35, Blackfriars' Street, on Monday evening, October 21st. A paper on Elementary Chemistry will be read by Mr. J. T. Clarke.

Proceedings of Scientific Societies.

AMERICAN PHARMACEUTICAL ASSOCIATION.

The twentieth meeting of the American Pharmaceutical Association was commenced in the city of Cleveland, Ohio, on Tuesday, September 3, at 3 o'clock.p.m., under the presidency of Professor Enno Sander. The permanent secretary, Professor J. M. Maisch, called the roll of the members present; about eighty registered their names before the close of the meeting. Credentials of delegates from twenty colleges of pharmacy and pharmaceutical associations were accepted. The names of seventy-five candidates for membership were read, and they were, after a ballot, declared to be elected.

Various reports were then read. One from the Business Committee, upon a proposition to take the management of the business matters from the general body of members and vest it in a council, was considered the next morning, and after discussion, in which the bulk of opinion was adverse to such a course, the subject was indefinitely postponed.

The President then read his annual address, in which he said that the financial affairs of the Association were in a much more prosperous condition than they had ever been before, and advised that the fees for initiation should be funded for future use.

The second session was held on Wednesday morning at 9 o'clock. The committee on nomination presented their report, recommending the appointment of Albert E. Ebert, of Chicago as President for the ensuing year, and, as Vice-presidents, S. S. Garrigues, Ph.D., Saginaw, Mich.; E. P. Nichols, M.D., Newark, N.J.; and H. C. Gaylord, Cleveland, Ohio. It also nominated the members of the Executive Committee, the Committee on the Progress of Pharmacy, the Committee on the Drug Market, the Committee on Papers and Queries, and the Business Committee. The report was accepted, and on a ballot, all the persons nominated were elected.

Professor Ebert, the President elect, having, at the request of the President, been conducted to his seat by Mr. Wm. Procter, jun., and Professor J. F. Moore, briefly returned his thanks for the honour conferred upon him.

The Report on the Drug Market, by John M'Kessor, jun., was then brought forward, accepted, and referred to the Publishing Committee. The following are a few extracts from this report:—

"The drug trade of the past two years has been more generally prosperous than in any previous one succeeding the war. Drugs are mostly imported commodities; and as the premium on gold advanced during the year from 13 per cent. to 15½ per cent., the general tendency of prices was upward.

"The prospect for business for another year has been improved by Congress further increasing the free list, adding to it almost all of the crude drugs, including a number of the essential oils, which will reduce considerably the value of goods. The few crude articles still subject to duty were probably overlooked, and the error will no doubt be rectified at the next session of Congress. Among these are opium, which pays a specific duty of 1 dollar per lb.; assafœtida, 20 per cent. *ad valorem*; Barbadoes tar, 20 per cent.; lime-juice, 10 per cent.; quicksilver, 15 per cent., etc.

"We have to deplore the growing tendency among merchants to give longer credits as an inducement to obtain orders, rather than as an aid to retailers to meet their engagements. That manufacturers should require extended credit until their productions can find a market is not unreasonable; but for dealers who sell their merchandise for cash, prompt payment is the only correct principle, as the extension of time to this class of buyers often leads to over-trading, followed by those periodical disturbances of business relations.

"The great facilities for intercommunication that have arisen in the extension and the opening of new lines of railways, has had a wonderful effect in benefiting business, and the enormous increase in the consumption of all articles of luxury indicates a continued advancement of wealth in the interior.

"*Chemicals* have excited considerable attention, and those for which we are in a great measure depending upon England, and that are so largely used by our manufacturers, have been in extensive demand. The enhanced price of labour and of fuel in Europe have added so much to the cost of production that an advance in nearly the entire list has taken place.

"*Morphine* has, as usual, followed the variation in value of opium, and the market has been well supplied with quinine. This has not been the case during September, when there was a very deficient supply of this important remedy, and the rather extraordinary figure of 3 dollars 75 cents was paid for some small parcels to meet urgent demands which had suddenly sprung up in the west owing to the prevalence of fever; telegraphic orders were sent to Europe, but by the time the quinine arrived the excitement had subsided, and importers had to accept the then ruling figure, 2 dollars 50 cents, or hold their stock in bond for re-shipment. The English makers have advanced their rates, and now ask equal to 18 cents more than the opening price; and our manufacturers are obtaining an advance of 15 cents. This price is likely to be maintained, as the foreign article will cost, to import under the new tariff of 20 per cent. *ad valorem*, about 2 dollars 60 cents. Probably the quantity contracted for has been lighter than usual, so that if any unexpected demand arises next fall, as was the case last September, the manufacturers may make their price as low as they please, but those who may have a stock will be able to get any price they may ask. The finer grades of calisaya and red cinchonas have been scarce, but the higher prices offered in Europe have induced shippers to seek that market; and for the best red bark we have been compelled to get our supply through London.

"*Cundurango Bark.*—The extraordinary properties ascribed to this article, and the enormous prices, 50 dollars to 100 dollars per lb., paid for the first few pounds brought to this country, were an inducement for parties in South America to send here all that could be gathered, and between October and February 1367 ceroons were entered at our Custom-house. Whether it is going to rank in our materia medica among important alteratives is as yet an unsettled question; opinions as to the value of its medicinal properties are greatly at variance. The medical fraternity have not been disposed to look upon it favourably, owing perhaps to the effort which was made to introduce it to the public in the form of a proprietary remedy. Much of the stock in market is considered worthless; the best bark can be bought in small lots at 75 cents per lb.

"*Vanilla Beans* of really fine quality have been scarce, and the new crop which but recently came into market is not much better than last year's, and high prices are asked; although the duty of 3 dollars per lb. is to be taken off on the 1st August next, consumers will not be able to purchase lower than heretofore, and some holders even ask higher prices."

William Procter, jun., then read a letter from Mr. H. B. Brady, President of the British Pharmaceutical Conference, accompanied by an album containing the photographs of the past and present officers of the British Pharmaceutical Conference, the Pharmaceutical Society of Great Britain, and some of the prominent members of each of the organizations.

A resolution was passed accepting the present, and the secretary was requested to return the hearty thanks of the association for this token of friendship.

At the third session, which was held on Wednesday afternoon, the report of the Committee on Legislation was read by its chairman, Professor Maisch. The paper gave a *résumé* of the subject of pharmacy as affected by the laws that had been passed in several of the States, and of what had been accomplished in improving the status of the profession. The attempt of certain persons in Pennsylvania to secure the passage of a law which would require all in the State now engaged in the business to pass before a *single* "Board of Pharmacy," who were authorized to charge a high fee for examination, and to receive the fees in lieu of other compensation, was alluded to, and its defeat noted. As the subject of legislation on pharmaceutical matters will probably be brought before several of the State Legislatures at the coming sessions, members were recommended to be on the alert, and see that no swindling laws were passed.

In reference to the value of cantharidate of potash as a vesicant, Dr. E. R. Squibb stated that having made large quantities of the preparation, and distributed it in various directions, he expected to hear at a future time some conclusive proof of the therapeutic value of this article. In some cases, when of recent make, it had been effectual, prompt, and cleanly in use; but recent trials of some which had been made for nearly a year failed to act promptly or satisfactorily. He expected by next year to report further on the subject. Messrs. Eberle and Ebert stated that ointment and plaster made by a method in which cantharidate of potash would be present had proved ineffectual in their experience.

Mr. Procter read a paper from R. Rother, of Chicago, in reference to the best method of separating the pectinous principle from senega root in making the preparations of the drug. After the reading of the paper Mr. Eberle stated that he had attained the most satisfactory results by exhausting senega root with water, evaporating to a syrupy consistence, treat the result with alcohol, filter, distil off the alcohol, dissolve the residue in water, and, with the proper proportions of sugar, form a syrup.

Mr. Bedford stated that he had no difficulty with the officinal formulæ, modifying the treatment of the tincture (obtained by exhausting the root as directed in the U. S. P.) by heating it for a few moments to the boiling-point, allow it then to stand until *cold*, filter, evaporate or distil off the alcohol, and then, with the proper quantity of sugar, form the syrup.

A paper by Mr. E. J. Weeks, of Jackson, Mich., on tests of purity for Oleum Erigerontis Canadensis, was read, suggesting that liq. potassæ with an equal bulk of the oil, if pure, will separate in two strata and remain clear, while any fixed oils, if used as an adulterant, would cause an emulsion, and, at times, a black colour. The use of sulphuric acid as a test was also mentioned.

Mr. J. F. Hancock, of Baltimore, read a paper on the best arrangement for the dispensing counter. The paper was illustrated by drawings, which helped greatly to appreciate the description. The front store, or dispensing department, was 16 × 24 feet, and the prescription department 15 feet square. The drawing represented a door with windows on either side at the front of the building, counters on three sides of the store, with a space of two feet between the front of the rear counter and the ends of the other counters, and the same space between the back of the counters and the face of the drawers behind, except behind the prescription counter, which should have three feet or more behind it. The partition dividing the store from the back room should have an arch door opening in either direction, kept closed by springs; on the top of prescription counter a frame 30 inches high containing a French plate glass, protects the counter from unnecessary interruptions, and yet permits the persons employed at the counter to observe what may occur in the store. Within sight are balances, weights, desks, and all the operations of dispensing prescriptions. We briefly note a few items suggested. Balsams, oils, honey, and similar substances should be kept in an appropriate closet in the counter, and the counter should be specially arranged to give ample facilities for labels, cut paper, spatulas, and all the various "tools of our art." Poisons used for dispensing should be kept in a separate closet. The main point insisted upon was plenty of small drawers, slides, and shelves arranged to meet the constant wants of the dispenser.

Dr. E. R. Squibb read a volunteer paper on aconite root. In alluding to the fact that much of the aconite root is destitute of the activity of the drug, he states that he relies mainly on *taste* as a means of determining quality. In taking a small handful of roots from a bale as a sample, at least eight of ten should give the peculiar feeling of *numbness* to the tip of the tongue and lips which is characteristic of this drug. In testing this root but a very small fragment should be tasted, and immediately spat out; if no numbness is experienced within five minutes, another piece of the sample may be tasted; but whenever numbness is produced, no other piece should be tried until the sensation disappears. If this method be adopted he thinks no one need be troubled with an unsatisfactory lot of aconite root.

A volunteer paper on rhubarb was also presented and read by Dr. Squibb, in which he reviewed the character and quality of supply during the past year, and alluded to the disposition to prepare the root in a form convenient for use, but which destroyed the appearance, so that the characteristic appearance of the original was lost in manipulation, and thus afforded opportunities for unprincipled persons to foist a worthless article on the public.

A paper on the quality of phosphoric acid in the market, by Professor A. B. Prescott, of Ann Arbor, Mich., was in his absence read by Wm. Procter, jun. The paper stated that in six samples examined all contained a small proportion of soda, and traces of silicic acid, and in one sample a trace of arsenic. Dr. Squibb stated that he had been troubled with minute quantities of manganese which gave it a pinkish colour, and of late always passed sulphuretted hydrogen through the solution, and filtered before completing the process for dilute phosphoric acid.

Mr. Enno Sander read a paper on the existence of wood creasote in the market. On trying several samples, only one of them, according to the test proposed by Morson, indicated that it was wood creasote. Mr. Remington stated that his experiments indicate that glycerine would make a clear solution with all creasotes he had tested except Morson's; and Professor Maisch remarked that Flückiger had asserted that glycerine was not a reliable test for German wood creasote.

(To be continued.)

PARIS SOCIÉTÉ DE PHARMACIE.

At the sitting of this Society on the 7th of August, under the presidency of M. Stanislaus Martin, M. Adrian shortly described some researches by M. Mondet upon squill. The author had operated upon some squill collected in Algiers from which he had obtained two products—one diuretic and non-poisonous, scillitine; the other having an acrid taste and very poisonous, which he described under the name of skulleine.

M. Marais remarked that M. Mondet had really reverted to antiquated ideas upon this subject; it was now admitted that, contrary to the opinion of Vogel and Tilloy, only one active principle existed in squill.

MM. Delpech, Méhu, Vigier ainé, Duquesnel and Mayet, were appointed as members of the Commission of Prizes for 1872.

M. Bussy described M. Vial's process of printing by means of nitrate of silver. He presented to the Society an album containing various designs printed upon cloth by this process.

M. Limousin recalled the fact that paper impregnated with nitrate of silver is reduced by free hydrogen. He illustrated this by directing a current of hydrogen upon white paper which he had marked in several places with solution of nitrate of silver. The previously invisible writing immediately became visible, assuming a black colour.

M. Baudrimont wished to draw the attention of the Society afresh to the question, how best to avoid errors from the substitution of one substance for another. He read a memoir which he believed to contain a solution of the problem, and at its conclusion requested that a committee should be appointed to consider the subject, and that a copy of his paper should be sent to every member of the Society, in order that a thorough discussion of it might be taken at a future meeting.

M. Buignet said that a committee appointed in November, 1867, had made an analogous report, which had received great publicity, and some of the measures which it had proposed had been adopted in practice. Nevertheless, he thought the proposition of M. Baudrimont of sufficient importance to justify the Society in submitting the subject to a fresh investigation.

M. Limousin, in conjunction with M. Lebaigue, had made some experiments which induced them to think that it would be useful to introduce into certain poisonous medicaments an inert colouring matter; for instance, a few drops of a dilute solution of fuchsine in poisonous salts before crystallization.

M. Roucher thought that all these modifications were good, but they would have no real efficacy unless they received a legal sanction; they ought to be submitted to the commission appointed to consider the changes to be made in the law regulating the practice of pharmacy.

It was finally decided to remit the subject to the consideration of a new commission, consisting of MM. Baudrimont, Mayet, Lebaigue, Limousin, Schaeuffele, Vigier ainé, and Grassi, and that a copy of M. Baudrimont's paper should be sent to each member of the Society.

M. Bourgoin detailed the result of the analytical researches upon the leaves of Boldo, undertaken in conjunction with M. C. Verne. The other papers read were one on "Curare," by M. Mayet fils; and one on the "Preparation of Tar Water," by M. Teillet.

Parliamentary and Law Proceedings.

PROSECUTIONS UNDER THE NEW ADULTERATION ACT.

Several prosecutions under the Food Adulteration Act came before the Bolton magistrates on Monday, Oct. 14. A grocer named Hurst was summoned for selling ½ lb. of coffee adulterated with chicory, and without either verbally or by other means informing the purchaser that it was sold as a mixture of chicory and coffee. The magistrates imposed a fine of only 2*s*. 6*d*. and costs, as this was the first offence of the kind. The same defendant was fined 2*s*. 6*d*. for having sold butter which contained 20·31 per cent. of water and 7·63 per cent. of salt, the same being highly-coloured and rancid.—A woman named M'Moran was fined 10*s*. and costs for selling a pint of milk which contained an admixture of 20 per cent. of water and only 2 per cent. of cream, whereas there ought to have been from 6 to 9 per cent. of cream.

SELLING PETROLEUM WITHOUT A LICENSE.

At Tunbridge Petty Sessions, Mr. Arnold, chemist and grocer, of Edenbridge, was summoned for having a quantity of petroleum on his premises without a licence. Mr. Palmer, who defended, explained that on his application the oil had been sent to Mr. Howard, of Tunbridge Wells (Mr. Wibmer refusing) for an independent test. Mr. Alleyne (the magistrates' clerk) read Mr. Howard's certificate, which was that the oil flashed at 98°. Mr. Palmer said Mr. Francis, the inspector, made the oil flash at 94°. Some of the oil was sent to a person in London, who said that the oil flashed at 104°. The certificate with the oil when sold guaranteed that it would not flash under 106°. He only mentioned this to show that Mr. Arnold had exercised every diligence and care. He had advised Mr. Arnold to take out a licence. The bench fined the defendant 10*s*., and costs, £1. 2*s*. 8*d*.—*Grocery News*.

ROBBERY OF SURGICAL INSTRUMENTS.

At the Middlesex Sessions, Edward Marsh, 43, described as a "chemist," and well educated, pleaded "Guilty" to stealing, on the 28th of February last, a case of surgical instruments, the property of Mr. George Stevens, surgeon, of Stoke Newington; and on or about the same day, a second case of instruments belonging to Mr. Wadsworth, surgeon, of Dalston. In both cases the prisoner had called at the prosecutors' houses in their absence, and, under pretence of waiting for their return, gained access to a room where the instruments were kept.

Reeves, a prison warder, stated that in 1869 the prisoner was convicted at the Middlesex sessions of a similar offence, and was sentenced to two years' imprisonment, on which occasion there were four charges of the same kind against him.

The prisoner, in mitigation, urged that he was suffering from a painful malady necessitating the use of opiates and stole the instruments when under the influence of that drug.

Sir W. Bodkin sentenced him to be kept in penal servitude for five years.

SUICIDE OF A CHEMIST BY STRYCHNINE.

On Monday, October 14, an adjourned inquiry was held at Bethnal Green by Mr. Humphreys, touching the death of Mr. Ebenezer Aquilla Toye, aged 27, a chemist, who was alleged to have committed suicide by taking poison. It appeared from the evidence at the previous inquiries, that on Sunday fortnight Mrs. Toye, widow of the deceased, upon returning from church found the house had been on fire, and her husband was much excited. The deceased said he believed the fire occurred through an escape of gas. She thought he was insured for £150, but there was not much damage done. About one o'clock on Monday morning she found her husband trembling violently in bed. He asked for some mustard and water several times, which was given him. He said that he had taken something, which he must bring off his stomach, or he would be a dead man very soon. A doctor was at once sent for, but Toye never rallied. She believed he died from the shock from the fire. William Withers, superintendent of the Salvage Corps, said he attended the fire, which broke out under the showboard in the shop window. There were gas-fittings above it, but the meter was turned off. The deceased was insured for £300. Witness thought the stock and furniture worth about £200, and that the fire was not accidental. John Blyth, Salvage Corps Auxiliary, was left in charge of the house on the night in question. The last he saw of the deceased was at twelve o'clock, when he retired to rest. Mr. Toye said he would be ruined by the fire, as he was not insured sufficiently, and he had some bills coming due. He was but little excited. He came downstairs again a few minutes after twelve, and went into the back parlour, took a bottle from off the sideboard, and said, "There is no sherry in it." He took another bottle, containing essence of lavender, smelt it, and put it down again. A bottle was missing from next the one he had replaced. Mr. Shepherd, landlord of the house, living opposite, saw deceased standing at his door within ten minutes of the fire breaking out. Mr. Llewellyn, surgeon, found no marks of violence on deceased. He had forwarded the contents of the stomach to Dr. Tidy, of the London Hospital, for analysis, as directed. Mr. Bass, gas inspector, examined the meter, which had not exploded, but was melted by the fire. The fire could not have originated through the fault of the meter. Dr. Tidy, lecturer on chemistry, etc., at the London Hospital, said he analysed the contents of the stomach of the deceased man, and found minute but distinct traces of strychnine, which he believed was the cause of death. The Coroner then summed up, and the jury returned a verdict that "Deceased took a quantity of strychnine while of unsound mind."—*Standard.*

Suicides by Prussic Acid.

On Tuesday, October 1st, an inquest was held by Mr. William Carter, the coroner for East Surrey, respecting the death of Mr. Edmond Edmonds, aged 76 years, who committed suicide by poisoning himself with prussic acid. Mr. George Edmonds stated that the deceased was his father, and carried on the business of a surgeon and physician at Hercules Buildings, Lambeth. On the previous Tuesday morning, at about a quarter past one o'clock, while witness was engaged in the surgery, the deceased came in, having on his boots, but being otherwise undressed, with the exception of his nightdress. After speaking to witness deceased walked into the consulting-room at the side of the surgery. The gas was burning at the time, and witness observed him walk towards a desk between the counter and the surgery door. Witness asked him what he wanted there, and he replied, "Nothing, nothing." He then opened one of the small drawers, and upon witness walking into the room he observed the prussic-acid drawer partially open. Witness closed it and said to him "What do you want; you don't want anything out of this room?" He replied, "No, nothing." He then opened two or three other small drawers, but witness did not see him take anything out of either. He then walked back into the surgery, and thence upstairs, as witness believed for the purpose of retiring to rest. About five minutes afterwards witness heard a groaning and gasping noise proceeding from the drawing-room upstairs. He ran up to that room immediately, and found the deceased lying upon the couch upon his back, gasping for breath. On the table in the room he saw a blue vial, which was partially filled with prussic acid. The room smelt very strongly of that drug, and upon going to the deceased witness found him in a state of insensibility, and foaming from the mouth. Medical assistance was sent for, but deceased died in about half an hour. The jury returned a verdict "That the deceased destroyed his life whilst in a state of mental derangement."

A determined suicide by prussic acid is also reported from Derby. Mr. Joseph Pickering, a well-known conveyancing solicitor in Derby, on Saturday evening, October 12th, retired to rest at his usual hour. Deceased and his wife slept in separate rooms. Nothing was noticed in his manner to excite the least suspicion, but early next morning, as he had not made his appearance downstairs, his room was entered, and he was found lying undressed by the bedside quite cold. Beside him lay a small bottle, three parts full of prussic acid. Medical assistance was called in and pronounced life to have been extinct for several hours. The bed clothes were merely turned down, and it is supposed that deceased took the poison, and died before he could get into bed. No motive can be assigned for the rash act beyond a complaint he had uttered of loss of memory.—*Standard.*

Obituary.

GEORGE CONDER.

We regret to have to record the death, after only a week's illness, of Mr. George Conder, Pharmaceutical Chemist, of Hastings, at the age of 29. In 1869, Mr. Conder obtained the Pereira medal. Since then he had resided for nearly two years at Hastings, where he had been very much respected.

Notice has also been received of the following deaths:—

On the 30th of August, Mr. Philip Marrack, Pharmaceutical Chemist, of West Cowes, Isle of Wight, aged 29. Mr. Marrack had been a member of the Pharmaceutical Society since 1867.

On the 16th September, Mr. Walter Tracey Walker, Pharmaceutical Chemist, of Croydon. Mr. Walker had been a member of the Pharmaceutical Society since 1867.

On the 1st of October, Mr. William Collier, Pharmaceutical Chemist, formerly of Sheffield Moor, Sheffield. Mr. Collier had been a member of the Pharmaceutical Society since 1853.

On the 6th September, Mr. Edward Russell Warrington, chemist and druggist, of Castleford.

On the 10th September, Mr. Alexander Wylie, chemist and druggist, of Port Glasgow.

On the 16th September, Mr. Richard Twitchell, chemist and druggist, of Plymouth.

On the 16th September, Mr. William Whittle Brown, chemist and druggist, of Ormskirk, Lancs.

Pharmaceutical Examinations.

Sir,—In common with many of my pharmaceutical brethren I have been deeply interested in the discussion started by Professor Attfield, and just concluded by Professor Redwood.

I feel it is a subject not only of deep interest to us all, but, moreover, affecting our very characters individually. My opinion is, that the question, whether desultory laboratory instruction, or precise cram are to be the order of the day, is of very little consequence indeed, The problem we have yet to solve is, how to make the Minor examination a real test of a man's capacity to carry on to the satisfaction of the public and medical profession the business of a chemist and druggist.

Smatterings of chemistry and botany are about as useful to a chemist as they are to the medical man; and the Minor examination will never be a real test until the candidates are examined more on their five years' apprenticeship or practical instruction, than on that knowledge which can avowedly be picked up in Bloomsbury in five months, or at a cram shop in one.

How many men spread a plaster at their examination table?

How many candidates run out of a chemical and prepare it, if practicable, on the spot?

How many blisters are prepared by the candidates in the course of a year?

How many candidates are asked to test for albumen, sugar, or bile, etc., in urine in the course of a year?

How many kinds of pills are prepared by each candidate, and how many coated or silvered?

To what extent are they tested as to their capacity for incorporating essential oils in pills?

How many students are tested in making pills with creasote or carbolic acid?

How many men are asked to clean a dirty bottle expeditiously?

How many prescriptions are dispensed by a candidate to test his accuracy, and is not this the last accomplishment a chemist learns, and a vital one, too?

I ask these questions, a few only; it is wondrously easy to add to them; and are they not the questions a man has practically to solve daily behind his dispensing counter?

I say, if you make your examination a crammer, cram is the best answer for it, and the public will be more perplexed with licensed chemists than they ever were with licensed doctors; and it will be almost a science to sift the wheat from the chaff.

Two really good practical assessors would be well worth £800 a year* to the Society, and that I consider is the direction our surplus funds should take, and not be frittered away in dilute chemistry and botany through the provinces.

Five years is supposed to be devoted to practical instruction. Ten months is the top run for the theoretical. And yet I understand the practical in value, compared to the theoretical, is about 1 as to 7. Five years will scarcely teach the former; the latter can be picked up at Bloomsbury in five months, or, still better, at a cram shop in one. Of course, cram succeeds with men of average memories, for the practical knowledge and handicraft count a mere nothing against the ornaments.

Let me be thoroughly understood. I value science and scientific thought very much; but if I wanted a carpenter to work for me, what would it avail me that he knew the grain of every wood, the composition of cellulose, the laws of cell multiplication and division, the difference in structure between exogens and endogens, if he sawed in a crooked manner or planed awry? And so with the Bloomsbury brand. Unless it marks the neat plaster-spreader, the apt chemical-maker, the careful tester, the deft pill-maker, and the tidy silverer, in addition to the ornaments of a pharmaceutical curriculum, we shall fall into greater error than did our medical friends before they insisted on at least three sessions attendance at a medical school as a *sine quâ non* for candidates for medical diplomas; for we do not work in the cloud land of mystery—patients must die some day; but flat pills are terrible accusers; we cannot hide our misfits underground.

George Mee.

79, *Grosvenor Road, Highbury New Park,*
September 30th, 1872.

* I say £800 a year, because three days' practical examination would be little enough for a batch of candidates, and for £400 a year each we could always secure the best men.

Sir,—I would very willingly have left the revision of the examinations in the hands of the Board of Examiners without any public comment on my part, had it not been for the report of the Tyneside Chemists' Assistants' Association's meeting, giving a notice of my remarks upon this question, which is calculated to give a false impression of my views. At the meeting alluded to, I described the kind of Preliminary education I thought desirable, and hoped that the revision of the regulations of the Board would do something towards ensuring it. I thought that the Preliminary examination should not only show that the youth had had an ordinary liberal schooling, including a sufficient knowledge of Latin, but should show that he had an aptitude in the kind of subjects which would afterwards become his special studies, and for that reason I would include elementary botany and chemistry, I thought that the Preliminary examination should not only show that the mind was stored with certain facts, but had acquired certain powers; that the observing and thinking faculties had been so far developed as to put the youth in a position to take advantage of the circumstances with which he would be surrounded during his apprenticeship; and that while I would not object to French, German, and Greek questions being included in the examination paper, the student being at liberty to choose for himself which he would answer, I was much more desirous to see physical subjects added, which, however elementary in character they might be, would give some guarantee that the apprentice was in a condition to observe and understand something of the materials and processes coming under his daily notice. I would like to see the examination paper include questions upon heat, light, electricity, and the general properties of common objects; the candidate again being left at liberty to choose which of these subjects he would select for treatment. And the subjects given for English composition might also be changed with advantage; instead of being as now a request for twenty lines upon "strikes," or "Westminster Abbey"—subjects as far as possible removed from his pharmaceutical requirements,—they might with advantage require a short essay on "glass," "iron," "paper," "water," "grass," "a plant," "chalk," "coal," "heat," "light," "magnetism," etc., which would not only afford opportunity of showing his power of expressing himself correctly, but also giving some clue to his general information and intellectual condition.

I thought it most important that the regulations for the Preliminary examination should be such as to keep from entering the business all such as were not sufficiently informed and sufficiently educated to prosecute pharmacy with advantage. I thought comparatively few of those who might enter the business under such circumstances would be found deficient after their term of pupilage, but at the same time the Minor and Major examinations might be made broader and more practical, being spread over a longer time, and including practical operations in testing, etc. And I will now add a point which I did not then advocate, but which I think of some importance, viz., that the two latter examinations might be divided into two portions, a written examination to be conducted as the Preliminary now is, and which might advantageously include, as Professor Redwood suggests, an inquiry into the particulars of the candidate's education. The time of the Board, and both the time and money of the student, would be saved by calling to the metropolis for the practical part of the examination only those candidates who might give satisfactory evidence in their written replies of having at least a fair prospect of passing the remainder.

Barnard S. Proctor.

11, *Grey Street, Newcastle, Oct. 14th,* 1872.

Patent Medicine Licences.

Sir,—I wish to point out a circumstance which in the present state of the law, is "a great injustice" to a certain portion of the chemists and druggists, viz., "The Patent Medicine Licence." I have two shops, the one in Thames Street, Kingston-on-Thames, Surrey, the other in High Street, Hampton Wick, Middlesex. They are within ten minutes' walk of each other, by just crossing Kingston bridge. For the shop in Kingston the licence is 10*s.*, while for the other in Hampton Wick I am made to pay £2, the latter sum allowing me to sell at both shops, but were they occupied not by the same party, the licence would be £2. 10*s.* for the two shops.

Now at Moulsey (Hampton Court Palace) the licence is but 5*s.*, and distant from hence, about a couple of miles. Upon mentioning the difference of charge to the Inland Revenue officer, he concurred with me that it was an unfair charge, and said a similar grievance existed until this year with the pawnbrokers, those within the limit of the twopenny post paid just double the amount of licence to those without it; they represented their grievance to the proper authority, and obtained an equal adjustment of their licence. And I have no doubt if the Pharmaceutical Society were to place the matter before the same authority and point out its injustice, they too would obtain redress.

As a sufferer with others, I would respectfully request the Council of the Pharmaceutical Society to use their efforts to obtain an equal adjustment of this licence.

J. Barker, Pharmaceutical Chemist.

Thames Street, Kingston-on-Thames,
and High Street, Hampton Wick,
Sept. 4th, 1872.

Early Closing.

Sir,—I have been much gratified by receipt of a kindly communication from a previously unknown correspondent at Ballarat, which, I think, will also interest many of your readers who have taken part in the recent endeavour to effect some amendment of the unreasonable hours of chemists' business.

Mr. Brind and his pharmaceutical friends in Ballarat have been stimulated, and are kind enough to say, assisted by the efforts in the mother-country, to make a first attempt to obtain similar advantages for the similarly suffering pharmacies at the antipodes, adopting, though with a difference and for this occasion only, the homœopathic maxim, "similia similibus curantur."

It seems by reports of meetings and newspaper articles, which Mr. Brind has obligingly forwarded, that the hours of business observed by pharmaceutists in Ballarat have hitherto been extremely onerous, viz., from early morning till ten and eleven P.M., with but little relief on Sundays: such hours in fact as we knew in England before the Pharmaceutical Society had taught us to estimate our own value a little more worthily and to be a little less jealous of our neighbours. We learn by these reports that the moderate appeal of our Australian brethren for an abridgment of their hours of business has been cordially supported by the medical profession and the public press, and that it has been adopted with much unanimity by those more immediately concerned.

It is impossible not to feel an emotion of pleasure at this evidence of the good influence exerted by home proceedings in lands so distant, yet so closely associated with the old country; and we see in it an illustration of the wisdom of seemingly improvident admonition, "Cast thy bread upon the waters and thou shalt find it after many days." We heartily wish our upside-down brethren "God speed," and that their present action may contribute to their personal and scientific advancement.

Richard W. Giles.

Clifton, September, 11th, 1872.

The Reports of the Meetings of Council.

Sir,—May I be allowed, through the medium of your Journal, to ask the reason that of late the names of gentlemen voting in divisions of the Council are not given as heretofore? it seems such an omission is most undesirable, depriving the members of all knowledge as to the votes of their representatives. I would ask you to draw attention in your next issue to this omission, and urge the return to the open voting.

Elector.

The Jacob Bell Scholarships.

Sir,—The perusal of the amendment concerning the Jacob Bell Scholarships gave me great pleasure; certainly a better step could not have been taken, for it is not when they have finished, but when they are commencing, their studies after apprenticeship that pharmaceutical students want assistance.

We have no business to expect too much, but there is one thing that I think might be given without spoiling us. Of course the scholarships are in a great measure intended to aid brains that are not backed by too comfortable pecuniary circumstances. Now supposing a young man, at the expiration of his apprenticeship, competes for the scholarship, and is successful, he would not have great difficulty in getting through a year. At the end of this time he should be fit for the Minor; but after that, to study for the Major, he is left wholly dependent upon his own resources, even for the continuation of his education. Now if a Scholarship could possibly be offered for competition among holders of the Minor diploma, it would give the man of limited means another chance, and, if he were successful, enable him to study for the Major. This plan has its objections, but with a few modifications I think it might be carried out, and prove a very effectual stimulation.

I could say more, but will not trespass further on your patience, but conclude with a hope that those who have influence will give this point consideration.

Syrupus.

October 13th, 1872.

Chloride of Calcium as a Disinfectant.

Sir,—Among the advantages claimed for Chloride of Calcium as a disinfectant, it has been said to be "harmless," and the statement has passed unchallenged, so far as I am aware, by the medical journals; I believe this to be a dangerous error, and that a wineglassful of concentrated solution of Chloride of Calcium would, if swallowed, be as certainly fatal as a like quantity of Chloride of Zinc; nor would the irritant properties of the former salt be diminished by the proposed admixture of a considerable percentage of Hydrochloric Acid.

W. Bland.

57, *Penton Street,*
Sept. 28th, 1872.

Erratum.—A course of sixty lectures on Botany will be delivered by Mr. Leipner in connection with the Bristol Pharmaceutical Society, and not six, as was, through a printer's error, announced last week on p. 299.

Mr. F. Andrews.—We have received your letter in reply to "Quærens," but we are unable to find room for it in this week's Journal.

"*Ranunculus.*"—There is no limitation as to age at pesent.

G. W. Stephens.—Dorvault's 'L'Officine' may be obtained from Messrs. Dulau, Soho Square.

"*Darenth.*"—The plant is *Lycium barbarum.*

"*A Student*" (Alresford).—Hardwich's 'Photographic Chemistry.'

"*Inopis.*"—' Journal de Pharmacie et de Chimie:' Paris; Masson, Place de l'Ecole de Médecine.

James Copley.—The subscription is 18 fr. per annum, and it may be obtained through Messrs. Williams and Norgate, or direct from M. Masson, the Paris publisher, Place de l'Ecole de Médecine, for an additional ten centimes per number.

"*Jacobus*" will find the formula in Redwood's 'Supplement to the Pharmacopœia,' Beasley's 'Pocket Formulary,' and other works of a similar nature.

"*Minor.*"—We do not think there is any method for doing it effectually.

R. C. Moore.—You will find the full formula for Parrish's Chemical Food in vol. I of the present series of this Journal, p. 857.

"*Weston-super-Mare.*"—The question is of a legal character, concerning which we should recommend you to consult a solicitor.

J. C. S.—The article referred to is a proprietary one. Consequently we cannot give you any information as to its preparation.

F. J. M.—You will find formulæ for Brilliantine on p. 437 of the first volume of the present series of the Pharm. Journ. Your question should be addressed to the Apothecaries' Company.

M. P. S.—We cannot undertake to recommend makers of apparatus. You should consult some acquainted with the practical working of the instrument.

Mr. T. H. Hills.—The newspaper received with thanks.

Communications, Letters, etc., have been received from Mr. C. Umney, Mr. Jackson, Mr. G. Harrison, Mr. A. Courtenay, Mr. E. Clift, Mr. Valentin, Mr. W. Wilkinson, A. D., "A Local Secretary."

THE MEDICINAL PROPERTIES OF THE COW TREES OF SOUTH AMERICA.

BY JOHN R. JACKSON, A.L.S.
Curator of the Museums, Kew.

The presence of milky juices in plants is not uncommon; indeed, it is a character of many natural orders. In the numerous plants which yield caoutchouc, or india-rubber, the juice, as it flows from the tree, is milky white, becoming coloured on exposure to the air, or in process of solidifying. The juices of some of the milk-yielding trees, however, do not solidify, and they are used as an article of food. Several of these trees, from the fact of their yielding wholesome milks are known as Cow-trees. In South America, which is the head-quarters of these Cow-trees, they are called Palo de vaca, or Arbol de leche. Perhaps the best known of these trees is that referred to *Brosimum galactodendron*, Don. It grows in large forests on the mountains about Cariaco, and in other parts of the sea-coast of Venezuela. It forms a tree frequently over 100 feet high, and often running to a height of 60 or 70 feet before branching. The milk, which is obtained by making incisions in the trunk, is said to have a very agreeable taste, somewhat resembling that of sweet cream, and a slightly balsamic odour; the only unpleasant feature about it is that it is somewhat glutinous, but it is very nourishing and perfectly wholesome. Humboldt says, "We drank considerable quantities of it in the evening before we went to bed, and very early in the morning without feeling the least injurious effect. The negroes and the free people who work in the plantations drink it, dipping into it their bread of maize, or cassava, The majordomo of the farm told us that the negroes grow sensibly fatter during the season when the Palo de vaca furnishes them with most milk. This juice, exposed to the air, presents at its surface—perhaps in consequence of the absorption of the atmospheric oxygen—membranes of a strongly-animalized substance, yellowish, stringy, and resembling a cheesy substance. For several months of the year not a single shower moistens its foliage. Its branches appear dead and dried; but when the trunk is pierced there flows from it a sweet and nourishing milk. It is at the rising of the sun that this vegetable fountain is most abundant. The blacks and natives are then seen hastening from all quarters furnished with large bowls to receive the milk, which grows yellow, and thickens on its surface. Some empty their bowls under the tree itself; others carry the juice home to their children. Like animal milk, it turns sour and putrefies after a few days' exposure to the atmosphere. It has been found to contain more than 30 per cent. of galactin."

Tabernæmontana utilis, Arn., known as the Hya-Hya, or Cow-tree of British Guiana, likewise yields a milky juice, which is perfectly bland and wholesome, though the general characters of the order are poisonous and acrid. The tree is tapped to obtain the milk. The milk, or Cow-tree of Para, known as the Massaranduba, has been referred to *Mimusops elata*, Allem; but its determination is doubtful, though there is no question of its belonging to the natural order Sapotaceæ. The milk, which flows slowly from the wounded bark, resembles good cream in consistence, but it is said to be too viscid to be a safe article of food.

Certainly, the most important in a pharmaceutical point of view of all the Cow-trees is the *Clusia galactodendron* of Desvaux. The tree has a thick bark covered with rough tubercles, and bears leaves of an obovate form and about three inches long. It is a native of Venezuela, but is also found in the Cauca Valley, north of the State of Antioquia, on the banks of the Abraeto river and on the Pacific coast as far as Tumaco.

Many interesting accounts have been given of this tree, but the following notes from a letter on the subject, written by Mr. R. B. White, of Medellin, are the most comprehensive. The tree, it appears, has a decided partiality for certain localities, and there can be no doubt that while it needs the warm damp climate of the Choco, it likes good drainage, as it is always found on the low ridges just rising off the plains; mean temperature 27° to 30° Cent., and never exceeds 200 metres above the level of the sea. The general utility of the milk of this tree is well known, but its most valuable property has been quite overlooked, that of curing dysentery. It contains a resinous and an astringent principle, and an aromatic and tonic substance. The action of this combination is mechanical so far as relates to the resin, which no doubt coats the intestines with a film and allays irritation; and, secondly, it is astringent, tonic and antispasmodic. So far a knowledge of the constituents of this milk would lead one thus to judge theoretically of its action. With regard to practice, no other medicine is used in the Choco and on the Pacific coast of New Granada for dysentery; and this disease is thought little or nothing of as it is so easily cured. The milk is to be procured everywhere, and is generally sold at from one to two dollars per bottle. Mr. White says, "For upwards of two years I saw it constantly used amongst the workmen employed on the Buena Ventura Road, Pacific Coast, and in the most unhealthy climate. We had at times from 500 to 700 men employed, and out of numberless cases of severe dysentery I never knew of a fatal case, and I have seen cures effected when the cases had gone so far as to seem hopeless. As a general illustration of its action, and method adopted of using it, I will refer to my own case. I was attacked with diarrhœa, which in two days passed into dysentery, very severe. In the short space of twelve hours I was reduced to a state of utter prostration, suffering the most excruciating pains imaginable. The bloody discharge was so terrible that it seemed easy to predict death within a few hours; not a shadow of a medicine was to be had, as I was in a hut in the woods, and the violent phase of the disease was only developed at night-fall, and thus I passed the night in a helpless state. At daybreak the wife of one of our inspectors was called in as a nurse, and by 9 o'clock "leche de vaca" was procured. Up to this time I had been getting rapidly worse, and was then hardly conscious. The milk was given to me (a table-spoonful in a glass of water with a little sugar) every half-hour till 12 o'clock midday, and at this hour I was perfectly free from dysentery or the slightest symptom of it. Broths and light food were then given to me for a few days, and I was restored to perfect health without taking any more milk or other medicine, and without having the least recurrence of symptoms of dysentery. I have seen many severe cases successfuly treated in this way, but none more severe than my own, and am sure that no medicine or known system of treatment can be so efficacious as the leche de vaca treatment.

"Admitting the fact of its power to cure dysentery, a little reflection will convince one that the composition of this milk is wonderfully calculated to produce the results I have stated. The only question is, can it be used otherwise than in a fresh state. Up to a certain period I can answer this question in the affirmative. The milk, even when corked in a bottle, soon turns sour and coagulates, but this for many months at least does not impair its efficacy. It is possible that if putrefaction ultimately ensues, the milk will lose its properties. It is also possible that in certain cases the sourness of the milk would be prejudicial, but I do not see why this should not be remedied by the addition of some inoffensive alkali."

Mr. White says he has some milk which he brought himself from the Choco, which has been contained in a bottle for more than a year and a half, and is apparently as good as ever. One of the great advantages of the use of this milk in dysentery is the radical cure it effects. Its tonic and astringent properties appear to be brought into play as they are required, and as the resinous principle first serves as a palliative, the antispasmodic tonic and astringent properties work out the cure.

Mr. White's opinion of the medicinal properties of this milk is so favourable that he concludes his notes by saying that he cannot but think that, in combination with other medicines, it might serve as a base for successful treatment of cholera.

It has been said that a single tree will yield as much as a quart in an hour. These notes will, no doubt, prove interesting to the readers of this Journal. An examination and trial of the milk in this country would also prove of much interest.

PEPSIN, BISMUTH AND STRYCHNIA.

BY R. ROTHER.*

The most direct and satisfactory quantitative test for pepsin is unquestionably its power to dissolve coagulated albumen. This method of assay should invariably hold a conspicuous rank in all processes for the liquid preparations of pepsin, and none should be deemed complete before their strength has been adjusted by this standard. But to obtain accurate and strictly reliable results in every instance by this method, a most perfect familiarity with every phase of the operation is indispensable. The delusive simplicity misleads all beginners, and no one should consider himself qualified to pronounce on the questions of pepsin until he has thoroughly digested this rudiment.

Eberle, in his researches on artificial digestion, first pointed out the existence of the principle now known as pepsin. But Schwann was the first who isolated the body by precipitating it from its solution with mercuric chloride, and who further ascertained that its acidified solution acted as a powerful solvent upon coagulated protein substances.

Wasmann instituted the most elaborate investigations. He prepared pepsin by digesting the mucous membrane of a hog's stomach with distilled water at slightly elevated temperatures for several hours; then rinsed it well with cold distilled water, and again macerated it with successive portions of distilled water until putrefaction set in. The viscid neutral liquid resulting from these macerations he precipitated with plumbic acetate. By separating the metallic oxide from this precipitate, he obtained the pepsin in solution. This liquid, after careful concentration, he treated with alcohol, which completely separates the pepsin as a flocculent precipitate. According to Wasmann, this pepsin, when dissolved in 60,000 parts of water acidulated with hydrochloric acid, dissolves coagulated albumen in six to eight hours, and also acts powerfully as a similar solvent upon bone cartilage and gelatinous tissue. He also ascertained that an aqueous solution became turbid in the presence of a small quantity of mineral acid, but again became clear by adding an excess of acid. He likewise made the important observation that alkalies destroy the digestive property of pepsin by abstracting the free acid, and that higher temperatures also had a destructive effect.

Pappenheim found that ferrous and cupric sulphates and other salts precipitated pepsin, and that the precipitate is again soluble in an excess of some of these reagents.

Bidder and Schmidt isolated pepsin by neutralizing the peptic fluid with lime water, filtering, evaporating to a syrupy consistence, and precipitating with alcohol. This was dissolved in water, reprecipitated with a large excess of mercuric chloride; the mercury removed with hydric sulphide, and the solution evaporated to dryness. The residue could endure a heat of 170° Centigrade without suffering decomposition. C. Schmidt promulgated the theory that the true digestive principle was a combination of Wasmann's pepsin and hydrochloric acid. This coupled acid he denominates pepsin chlorhydric, or chloropeptic acid—a compound of a definite character, for whose formation the hydrochloric acid must never be below a certain fixed proportion. The effect of this agent upon the protein bodies results in the production of peptones and parapeptones.

The methods for the preparation of effective pepsin have heretofore been tedious and circumstantial. But Mr. Scheffer, taking advantage of the well-known property of concentrated saline solutions to precipitate the protein bodies, has succeeded in producing pure pepsin easily and expeditiously by precipitating it from the peptic fluid by adding sodium chloride to saturation. The pepsin thus obtained is dried after mixing it with lactin, and further attenuated with this substance until the dry pepsin amounts to one-tenth of the whole weight. Scheffer calls this mixture saccharated pepsin. Pepsin carefully prepared in this manner is always definite in its action, and forms the most convenient and reliable base for the preparation of liquid pepsins. But to obtain the whole of this again in solution requires a prolonged maceration with acidulated water before filtering, and even then a small quantity of insoluble residue always remains. This liquid filters with great difficulty, and after part of it has passed through, the sediment obstructs the filter, and a new one must be supplied to procure additional quantities of filtrate. To obviate this annoying difficulty, the writer filters the solution through cream of tartar. A beautifully clear filtrate and a rapid process are thereby ensured.

The numerous liquid forms of pepsin, called pepsin wine, rennet wine, liquid rennet, liquid pepsin, and elixir of pepsin, being always in demand, the writer constructed a formula for a liquid preparation to supplant them all, as follows:—256 grains of saccharated pepsin is macerated for several days in eight fluid ounces of water acidulated with hydro-

* Reprinted from the 'Pharmacist.'

chloric acid or cream of tartar; two drops of oil of orange peel or oil of lemon, three fluid ounces of syrup, three fluid ounces of orange-flower water, and two fluid ounces of strong alcohol are then mixed, united with the first solution, filtered through cream of tartar, and sufficient caramel added to give the filtrate the colour of sherry wine. Moderately acid mixtures containing fruit oils of the aurantaceæ rapidly generate the disagreeable odour which characterizes a mixture of oil of turpentine and strong sulphuric acid. But a saturated solution of cream of tartar, which even then contains mere traces of this substance, especially in the presence of alcohol, does not affect the grateful flavour of orange peel, moreover the presence of oil of orange flower seems to exercise a protective influence.

The simple solution of pepsin in water acidulated with cream of tartar, and filtered through this substance, was mixed with water acidified with hydrochloric acid, and fifty grains (a slight excess) of freshly coagulated albumen added. An unfiltered solution of saccharated pepsin in six fluid drachms of water acidulated with hydrochloric acid was also treated with fifty grains of albumen. Both mixtures were then placed in a water-bath, at a temperature ranging from 100° to 105° Fahrenheit. After about four hours the albumen in both mixtures was almost completely dissolved. Double the quantity of albumen, with twice as much of the pepsin solution, was then diluted with water to six fluid ounces, and set aside. At the ordinary temperature, after a little over three days, only a trifle of the albumen remained undissolved. To the mixture of the unfiltered pepsin solution an additional 50 grains of albumen was added, and diluted with an equal volume of water. After four hours, at a temperature of about 105°, no very appreciable diminution of the albumen was visible. More of the acidulated pepsin solution was then added, and after about four hours only six grains of albumen remained.

Popular opposition to the use of alcohol in solutions of pepsin, and the writer's aversion to glycerine, induced him to make a syrup of pepsin, by dissolving without heat about 12 or 13 ounces of sugar in 8 fluid ounces of aqueous pepsin solution filtered through cream of tartar. In making syrup without heat, the operation is much facilitated by reserving a small portion of the liquid, pouring the rest over the sugar, stirring frequently during a proper period, and decanting the syrup through a strainer; then, by adding the reserved liquid to the residuary portion of undissolved sugar, this will quickly dissolve, and may be added to the rest through the strainer.

To try the effect of a concentrated syrupy solution of pepsin upon albumen, a quantity of unfiltered acid pepsin solution, representing six grains of saccharated pepsin, was added to half a fluid ounce of simple syrup containing 45 grains of albumen, and diluted with water containing hydrochloric acid to the volume of a fluid ounce. After a digestion of six hours at the required temperature, no apparent change in the albumen had occurred. This, on removal from the liquid, and thorough drying between folds of bibulous paper, seemed larger and firmer than before its treatment, and had actually gained 10 grains over its original weight of 45 grains; showing that an assimilation of water had probably taken place without materially affecting the physical appearance.

(To be continued.)

THE PRESENCE OF AN ORGANIC ALKALI IN BOLDO.

BY E. BOURGOIN AND C. VERNE.

The boldo is a tree indigenous to Chili, which sometimes attains the height of from five to six metres, and belongs to the order *Monimiaceæ*. It was first attributed to a laurel, the *Laurus dioica* of Dombey. It is the *Boldoa fragrans* of Jussieu, the *Ruizia fragrans* of Ruiz and Pavon, and the *Peumus fragrans* of Persoz. Baillon has recently described it under the name of *Peumus boldus*. The leaves have a strong piquant camphorate savour. They contain an essential oil and an organic alkali, to which the authors propose to give the name of boldine. The following method was adopted by them in their researches.

The powdered leaves were exhausted with washed ether in a displacement apparatus, by which method a well-saturated aromatic tincture was obtained. When this was submitted to distillation, the thermometer after the ether had passed over remained stationary at 185°, and a certain quantity of an essential oil, recalling the odour of the plant, was collected. The thermometer then rose gradually to about 230°, when it again remained stationary for some time, and afterwards mounted to about 300°. These facts showed that the ether had taken up some complex volatile products; in other words, that the essential oil of boldo is a mixture of several bodies, agreeing with what has been observed in regard to most aromatic plants.

When the powder would yield nothing more to ether, it was exhausted with 90° alcohol, containing tartaric acid in solution. Upon evaporation, a syrupy acid residue was obtained, which was agitated with washed ether, in order to remove a brown odorous matter, soluble in ether, alcohol and acids. After saturation with bicarbonate of potash it was agitated afresh with ether, which then took up a matter presenting all the characteristic reactions of an alkaloid; this was impure boldine.

In order to purify this product, it was dissolved in water slightly acidulated with acetic acid, and then precipitated by ammonia added in slight excess. This alkaloid existed in small quantity in the leaves operated upon—about one part in one thousand,—and moreover it was difficult to obtain it pure, since the aromatic matter previously mentioned, which was soluble in acids, clung to it with great persistence.

The above process being one rather of research than of extraction, after various experiments the following was adopted:—The leaves, coarsely powdered, were exhausted by infusion in water acidulated by thirty grains of acetic per kilogram of product. The liquor was filtered and evaporated in a water-bath to the consistence of thick honey. It was then acid, and contained, beside the alkaloid, a little aromatic matter and a large quantity of acetate of lime. When the acetic acid was replaced by citric acid, alcohol caused a voluminous precipitate of citrate of lime; with sulphuric acid it formed an abundant deposit of sulphate of lime. These facts indicate the presence in the leaves in large proportion of a lime salt. The operation was terminated by washing with ether, saturating with the alkaline bicarbonate, and taking up the alkaloid with ether. Upon evaporation a residue was left which was dissolved in diluted acetic acid and then precipitated by ammonia. It was usually necessary to repeat this process to rid the alkaloid of a small quantity of yellow matter.

Boldine is very slightly soluble in water, to which, however, it communicates an alkaline reaction and a perceptibly bitter taste. It is soluble in alcohol, ether, chloroform, caustic alkalies, and in crystallizable benzine. From solution in acids it is precipitated by ammonia and the double iodide of mercury and potassium, and gives with solution of iodine a chestnut-brown precipitate. Concentrated nitric acid immediately colours it red, and it assumes the same coloration in the cold with sulphuric acid.—*Journal de Pharmacie et de Chimie* [4] xvi. 191.

CINCHONA PLANTATIONS IN BRITISH SIKKIM.

Tenth Annual Report by GEORGE KING Esq., M.B., *Superintendent, Botanical Gardens, and in charge of Cinchona Cultivation in Bengal.*

(*Concluded from p.* 304.)

12. Mr. McIvor, in the body of his report and in his evidence, refers to only one disease, and that he calls "canker." After a very careful examination it appears plain to me that two distinct forms of disease occur in the Sikkim plantations,—the one, a constitutional malady affecting the whole plant and usually fatal; the other, local and by no means fatal. The former disease is confined entirely to trees which have been originally planted in damp situations, or in situations which have become damp subsequently by the oozing of drainage water in the way already explained. Disease first attacks the roots of such trees. Its existence becomes apparent by the discolorization of their leaves, which ultimately all fall off. Gradual shrivelling of the cortical and woody tissues then takes place from the root upwards, and before this process has gone far the death of the plant has begun. This disease is in fact apparently nearly identical with that known to gardeners in England as "canker;" it is not in any way infectious or contagious, as some appear to think. It depends entirely on a local cause, namely, excess of moisture in the soil; and where that does not exist it cannot occur. In the cinchona planted on the western end of the Rungbee Valley (the peculiarities of which will be borne in mind) patches of trees killed by this disease are not uncommon. Such patches are invariably co-extensive with damp, watery soil, and should never have been planted. At the time they were planted, there was absolutely no experience whatever on the subject of cinchona cultivation to appeal to; the peculiar physical conditions of the Rungbee Valley, as above explained, were unknown; and the idea prevailed that cinchona in its natural habitats delights above all things in shade, moisture of soil, and a misty atmosphere. The mode of planting adopted was to form a continuous belt, and where these damper places fell in the line of extension, they were not passed over. I am assured that for some years many of the patches that have now died out from this form of disease were for the first two or three years extremely healthy, and I do not think that those who planted them can be charged with any want of judgment. But with the experience now accumulated, showing as it does that cinchona suffers more from an excess of shade and moisture than from the opposite conditions, it would be folly to plant in similar places. I have accordingly decided to do so only on such selected spots as possess good and equal soil with free drainage, and all the plants recently put out are in such situations. The recurrence of this first and fatal form of disease need not therefore, I hope, be anticipated.

13. The second form of disease does not affect the entire constitution of the plant, but manifests itself in patches on the stem and branches. The appearance of one of these patches is as if some escharotic had been dropped on the bark, which is of a dark, unnatural colour, shrivelled, dry, and brittle; occasionally these appearances extend to the wood, but as a rule they do not. In size the patches vary; many are about the size of a shilling, others are much larger. They are not numerous on one tree, and are often confined to a single branch. When small, no apparent affection of the general health of the plant occurs, and growth goes on unchecked. Where, however, a large patch occurs on a small tree, involving the bark pretty nearly all round the stem, death results. Death from this disease is, however, as far as my observations go, not common; and it is a well-established fact that a tree which has been extensively affected will, when cut down, throw up from its stump perfectly healthy shoots; while in hundreds of trees at Rungbee I have seen illustrations of recovery, the little patches of diseased bark being thrown off and replaced by perfectly healthy tissue, and the plant apparently as robust as if it never had been attacked. I had not sufficient leisure last year during the season at which this affection is most prevalent, namely, the rains, to make successive observations on the state of the diseased tissues, and I am prepared with no theories about its cause; I hope, however, to find out something during the approaching rains. This disease is not confined like the last to certain spots, but is found on plants in all parts of the plantation. I do not think it is to be feared much, and I certainly do not concur in Mr. McIvor's views concerning its dangerous nature. In my opinion it must be accepted as one of the drawbacks attending the cinchona experiment in Sikkim, in the same way as high winds and dear labour have to be accepted in the Nilgiri cultivation. Orchard-planting is not given up in the south of England because apple trees are especially subject to canker, nor are plantations abandoned in Scotland because a deadly disease (compared to which this form of cinchona disease is a trifle) attacks the larch.

14. *Summary of the year's work.*—During the past year 166,285 plants of *Cinchona succirubra* and 44,500 of *Cinchona calisaya* have been added to the permanent plantation. Propagation has been carried on vigorously, and the seed and nursery beds at present contain 600,000 young plants of the former and 147,500 of the latter species. The whole of the plantation has been carefully gone over, and every sickly plant has been rigorously cut down, while the healthy ones have been pruned and thinned. This has taken a great deal of time and labour, but I am convinced they have not been ill bestowed. A considerable extent of new land has been cleared and prepared for planting, and will be covered with cinchona as soon as the weather is favourable. Some new plantation roads have been made, and the old ones have also been kept in repair.

15. *Yield of bark.*—Nearly a hundred and sixteen thousand pounds of green bark (equal to about thirty-nine thousand pounds of dry bark) have been collected from the prunings and thinnings above mentioned, not a single tree having been cut merely for the sake of its bark. In accordance with the recommendation of the Cinchona Commission, a quantity of the best of this bark has been packed for transmission to England. The smaller bark, which it is considered more profitable to utilize in the manufacture of alkaloid, has, conformably to the instruction of Government, been stored up, pending the appointment of a quinologist. The bark will not deteriorate by being kept, and its storage costs nothing.

16. *Expenditure and Revenue.*—The budget allotment for the past year for all purpose, was Rs. 63,621, and the expenditure Rs. 50,463-13-5, showing a saving of Rs. 13,157-2-7s. The present is the first year in which revenue has been received from the sale of bark. During the year 7016 lb. were sold by auction in the London market. The bark was very varied in quality, a large proportion of it consisting of small quills of little value. The average price realized per pound was about one shilling and five pence, and the total amount received was equivalent to Rs. 5,068-1-2. When the mixed quality of the bark is considered, I think the result of this the first sale may be looked upon as favourable. The sum of Rs. 783-14 was received as rent for small patches of land within the cinchona reserve which are unsuited to our cultivation and which have been let to natives. This amount was paid into the civil treasury at Darjeeling.

17. *General considerations.*—The production in India

of cinchona bark as a crop cannot, I think, fairly be considered as yet beyond the condition of an experiment. It has indeed been demonstrated that cinchona trees can be grown successfully up to the age of about ten years, and that their bark is quite as rich in alkaloids as that obtained from the South American forests; but whether they will reach maturity remains to be seen. It has still to be settled how the bark crop can most advantageously be taken, and the respective merits of the systems of mossing as invented and practised by Mr. McIvor, of systematic coppicing, and of working forest-fashion by selection and thinning, cannot be determined without much additional experience. Connected with the commercial aspect of the matter, there are as unsettled problems, the probable extent to which the price of the drug will be affected by the introduction into the European market of the large quantities of bark which must soon begin to be turned out by the various Indian and colonial plantations that have been established, the amount by which the demand for preparations of cinchona will be increased by the fall in their price, which is almost certain to take place, and finally, the advantages or disadvantages of the manufacture of an amorphous preparation at the plantation as opposed to the complete separation of each alkaloid in a pure form, or to the more primitive plan of exporting all the bark to England, and of taking prepared alkaloids in exchange as part payment.

18. It is, however, a matter of satisfaction, that substantial progress has been made towards the realization of the great object which Government had in view in undertaking this experiment, namely, "to secure for the fever-stricken millions of India the inestimable blessing of an abundant and cheap supply of the only specific for the most deadly of all Indian diseases." That object will not be thoroughly secured until a febrifuge in some efficient form is procurable in every village in India. The amount of fever prevalent in the rural districts is, I believe, much greater than is usually supposed, and for its alleviation the sufferers have at present, as a rule, nothing more effectual than some selections from the wonderful farrago of substances known as "native medicines," few of which have much therapeutic influence in malarious fever. Any preparation of cinchona is to many a villager a thing unknown, unseen, unheard of. The amount of labour lost annually to the State by reason of the prevalence of fever is simply incalculable, while the loss of life is enormous; and I have no hesitation in saying this state of matters is to a great extent preventible by the dissemination of a cheap febrifuge.

19. As to the probable quantity of quinine that could be used in the Bengal Presidency, I calculate as follows:—There are in the provinces of Bengal, Orissa, Assam, Burmah, Behar, Oude, the North-Western Provinces, Central Provinces, and Punjab, probably a hundred millions of inhabitants, all more or less subject to fever, and it is, I think, no extravagant estimate to allow five grains of quinine *per annum* to each, which is equal to a total of 65,000 lb. or about 29 tons. In these circumstances it is probably premature to fear that too many cinchona trees are being planted.

20. In conclusion, my acknowledgments are due to Mr. Gammie, the resident manager of the plantation, and to Messrs. Biermann and Jaffrey, for the efficient and hearty way in which they have performed their duties.

21. The usual returns are appended.

Table showing the Number and Distribution of Cinchona Plants in the Government Plantations at Darjeeling on the 1st April, 1872.

Names of species of Cinchonia.	Number in permanent plantation.	Number of Stock Plants for Propagation.	Number of Seedlings or Rooted Cuttings in Nursery Beds for Permanent Plantations.	Number of Rooted Plants in Cutting Beds.	Number of Cuttings made during the Month.	Total Number of Plants, Cuttings, and Seedlings.
C. succirubra	1,400,000	....	480,000	120,000	....	2,000,000
C. Calisaya	77,500	10,000	70,000	77,500	....	235,000
C. micrantha	29,667	....	....	....	....	29,667
C. officinalis and varieties	100,000	....	....	....	25,000	125,000
C. Pahudiana	5,092	....	....	....	....	5,092
C. Pitayensis	....	16	....	....	24	40
Total......	1,612,259	10,016	550,000	197,500	25,024	2,394,799

THE LAVENDER COUNTRY.

In a ride by rail from West Croydon to Sutton, and on both sides, commencing at Waddon, as far as the eye can reach, are long narrow strips and occasionally broad expanses of lavender. After a thunderstorm, refreshed by the rain, the colour is deep and intensified, and the perfume crosses the pathway of the train. When the sun is shining with unusual brightness, any one standing in the midst of those fields may see the sky reflecting back the colours from the earth, the blue tints exchanged to lavender. Alighting at Sutton—the limit for the present of this cultivation—the road turns sharply to the right, and passes the well-known sign of the Cock, an hostelry of sporting notoriety, and brings us back on foot in the direction of Carshalton. Had we chosen the left-hand side of the railway, we should have been upon a plain stretching far away from Banstead Downs to Epsom Downs. There seemed something so unusual, peculiar and attractive in the appearance of the landscape; to ride through miles of vineyards in the Côte d'Or, the "golden hillsides" of France, or watch the terraced heights on the Rhine banks, where the sun casts back it rays from the broad waters like a mirror, and great and influential people discuss the merits of this or that year's vintage of Burgundy or hock in all parts of the world—compared with such scenes and thoughts lavender seemed to possess far humbler pretensions. But then we are told that it had unfailing medicinal qualities most valuble to workers in the fields; moreover it formed a component part or entered more or less into the composition of every description of scent; and the toilette and boudoir are not trifling questions in our days of supposed luxury and refinement unprecedented. We well remembered those little muslin bags—possibly there might be one or two stowed away forgotten in drawers at home. Hereafter they would be better appreciated for their modest appearance by the side of the gorgeously-decked perfumes of a Rimmel. The road lies high, and commands an extended view, and the patches of lavender seemed to thicken and multiply, some near at hand, others in the hollow, to our unaccustomed eye having a strange effect, when placed in contrast with light greens of standing waving corn, the graver greens of the fences, and the still darker green of the trees, with the fairy-like structure of crystal glistening in sunlight on the horizon. The crop, we were told, was looking remarkably well, with every chance in favour of an average. The subject appeared to possess considerable interest to wayfarers like ourselves. It was not difficult to get information from the humbler sort of folks, and we followed the route prescribed through Carshalton, frequented by trout fishers and brothers of the angle, and described by a great art critic as the most picturesque of all the villages of England. A stream that emerged into the roadside seemed to race with our footsteps, then disappeared, when turning sharply about on the right we were at Wallington, in the centre of our search. The district of Beddington, associated with the palatial residence of the Archbishop of Canterbury, of which Wallington is a hamlet, contains about 200 acres devoted to the growth of lavender. According to our informant, throughout the whole locality, including Sutton on the extreme verge, Carshalton and Mitcham, there may be counted about 300 acres of lavender fields. Mitcham is the parent source of the herbal or "physic gardening," in the native *parlance*, and from that place, about twelve or fifteen years ago, some transplants were made to Beddington. From thence the growth has extended to the neighbouring parishes, until, as at present, the eye is attracted on all sides by the broad sheets of colour, and the air is scented with the perfumes. In no other part of England has the same success attended this kind of gardening, except in Cambridgeshire, where the production is said to be inferior, although this opinion might even be reversed by inquiries in that quarter. However, it is evident in the case of the hop gardens in Kent and Sussex, something peculiar existing in the soil or climate, or both, makes these plants to thrive. Those who have crossed the plains of Spanish Estremadura could have seen miles of waste land covered with the *Lavendula* species, and florists conclude that the same skill brought to the assistance of nature might equally result in the successful crop that finds its way first to the distillery, and then by many transmutations to the scent-bottle or the medicine chest. The only peculiarity observable is a loamy upper surface for several feet upon a substratum of chalk, rather of a "holding nature," although dry. The ploughing at present is not so deep as in former years, and to this circumstance has been assigned the reason why in place of bearing for eight or nine years as formerly, the plants are now exhausted in three or at the utmost in four years. Upon an open space at Wallington of thirty acres, the largest lavender field in the locality, we were able to observe the different growths of the one, two or three years. Nearly adjoining was another four-acre enclosure spread out as level as a billiard-board, which we can readily believe to be the finest example of the one year's crop that could be seen anywhere. Only a moderate application of manure is necessary at the outset in the autumn, when the planting takes place; and after the first year's harvesting, the plants have grown to such dimensions that every other row has to be taken out, and every other plant in the row that remains. The three years' growth are the first to come to maturity, and then the second, and then the third. The harvest takes place in August. The cutting, which is done by the sickle, appears an art of itself, which affects the crop in the future year. The labourers are followed by women and girls, who immediately pack and tie the lavender up in mats, to protect it from the rays of the sun, or otherwise the quantity of oil to be extracted would be reduced before it could be taken in hand at the distillery. Small quantities have been previously cut before they are fully ripe, for Covent Garden Market, or for sale about the towns and villages in the neighbourhood. The distillery process is carried on upon the spot; as the volumes of smoke from several chimneys and the strong odour of herbs around the buildings sufficiently testified to some very odoriferous process within; for it must be remembered that peppermint, rosemary, dill, chamomile, as well as lavender, have to find their way to same crucial test. Beneath a brick-built shed stands a row of stills, with what are called worm-tubs attached to each still. Upon the ground-floor the furnaces are being attended, and the percolator watched, as a trickling noise indicates that the oil is being extracted by the process going on. Above the furnaces are the stills, of dimensions sufficient either to contain half a ton or a ton weight of herb, and the building is spacious enough to admit of carts being driven in for the purpose of unloading. The still is filled thrice in four-and-twenty hours, namely, eight hours to a run. The men get upon the upper floor, remove the still-head by a lever, then take the lavender from the mats and tread the stalks down with their feet until the copper is tightly filled to the brim. Liquor at boiling heat is then taken from the top surface of the worm-tub, although at the bottom and lower surface the water is quite cold, and the furnaces are set to work. The *worm* consist of piping attached to the head of the still, and passes round and round the tub which contains the cold water. The men watch the bringing over of the still—that is, the moment when the liquor begins to flow over the head into the worm. Directly it does so, they know that the oil is running, and immediately damp down the furnaces. The boiling liquor from the herbs, by passing through the tubing immersed in cold water, becomes condensed, and the oil separates from the water and runs into the percolator at the foot of the worm-tub. This bringing over is the most critical point in the whole operation; then great attention and experience are needed, otherwise the herbs, both stalk and flower, might be taken into the worm, and the oil be spoiled. So well practised, however, are the men employed that what is called a "run foul" is scarcely known during the whole of the distilling season. From thence it is taken and placed in dark glass bottles with short necks, containing 4 lb. to 7 lb. each, ready for merchandising. When one lot has been distilled the still top is removed by the lever, and the charge taken out with long forks. The steam and vapour that arise are very great—for the uninitiated quite overpowering; and what is termed the "walk" being very heavy, the men themselves have to labour hard to get out the refuse, which is thrown just at the back of the building for manure. The coppers are filled up again with herbs, fresh water is pumped into the worm-tub to supply what has been taken off the surface for the still, and to replace what has passed off in the evaporation that has been always going on, and the process again proceeds. The quantity of oil extracted from a ton of lavender varies according to the influence of the season; from 15 lb. to 16 lb. is considered a fair average, very seldom it reaches 21 lb., sometimes not more than 10 lb. The distilling lasts about two months, from the first week in August to the second week in October, according to the abundance or otherwise of the surrounding crop. The business itself is separate from the growing; the small growers as well as the large take their crops to the distillery, and pay a certain agreed upon rate per ton. The results during the present season have been favourable, although the continuance of wet whether somewhat interfered with the out-door work. These operations may be seen and inquired into by following out the route we had taken from Sutton, through Carshalton to Wallington, thence by the footpaths across the lavender fields to Beddington, and on to Waddon station upon the railway of the London and Brighton Company.—*Journal of Applied Science.*

The Pharmaceutical Journal.

PHARMACEUTICAL REMUNERATION.

THE labourer is worthy of his hire, and despite all the inequalities and injustice which exist, he generally gets the value of his abilities and attainments in an open market. The employer who engages a servant at wages below those current in the labour market, as a rule discovers defects in the service performed. If not, the servant quickly discovers the value of his labour, and either takes it to another market, or demands increased pay. In public appointments, to which the salaries affixed are limited, in order to obtain the right men for the right places, the vacancies are announced, with the emoluments attached to them, in the most suitable channels for attracting the eye of would-be candidates. If a church living becomes vacant, the *Times* announces the death of the vicar, and that the living, which is in the gift of so-and-so, is worth so much. To replenish the ranks of the army the recruiting sergeant, with his ribbons and jests, haunts taverns and frequents fairs and markets, where loiterers and idlers are to be met with. But a more frequent way of making these announcements is by an advertisement in a public journal. Whether it be an errand boy, a secretary, or a professor that is wanted, he is advertised for. The plan has many advantages; it generally draws a choice of candidates to select from, and evades the possibility of round men being placed to fill square holes.

A Birmingham correspondent, at page 340, has directed our attention to one of these advertisements. The hospital for women in that city, being in want of a dispenser, advertised the vacancy, offering the modest salary of "£20 a year. Hours from 3 to 6 or 7 P.M." His letter tells its own tale. The poor we have always with us, and Birmingham, we know, nobly supports its charities. The governors of these have a duty to perform in seeing that the funds entrusted to them are judiciously and economically disbursed. Nevertheless, justice comes before generosity, and to offer a candidate competent to fill the post such a salary is defrauding him of his due. The hours are short, but they are the golden hours of a pharmacist's day; and one in whose hands is entrusted the balance of life and death of thousands annually, ought to receive a higher remuneration than threepence per hour for his services.

When such tempting offers as the above are held before the poor disciple of ÆSCULAPIUS and GALEN, need we wonder that the faint-hearted ones amongst us, deterred by examinations, as well as by poverty, should leave our ranks to join those of MARS, whose humblest worshipper, the raw recruit, is better remunerated than the Birmingham dispenser. Should his lot be cast in with FALSTAFF'S followers, and he likes them not so well as his first love, he may still adhere to this with advantage both to pocket and to pride, if we may judge from the following extract from a contemporary,* which another correspondent has kindly sent us:—

"Sergeant Wade, now serving as hospital-sergeant of the Dublin City Militia, has been appointed dispenser of medicines at the Royal Hibernian Military School. This is an appointment of great responsibility, and is worthy the ambition of many a young fellow who has passed some of his time with a chemist and druggist before enlisting in the army. There are several such appointments in the army, and they are all well paid, and the holders of them comfortably lodged."

They manage things differently in Ireland, but we think the elected candidate would have better certified his fitness for the appointment if he could have shown a qualification superior to that which at one time accepted the recruiting sergeant's offer. In all these appointments we hope the day is not far distant when the candidates for them must show that they possess a pharmaceutical qualification. The old-fashioned apothecary is, in hospitals and dispensaries, either a *non est*, or he is above performing the duties the pharmacist is proud to do. Hence, the dispensing is frequently left to be done by porters, errand boys, and "compounders," who are frequently unaware that ether and spirit of ether are not synonymous, and do not know the difference chemically between a perchloride and a subchloride.

THE SALE OF QUININE WINE.

IF we may judge from the numerous inquiries received respecting the sale of Quinine Wine, considerable doubt and anxiety exist amongst chemists and druggists as to the regulations of the Board of Inland Revenue in reference to it. We therefore readily give insertion to the following letter, which has been kindly placed at our disposal by a correspondent who applied to the Board of Inland Revenue upon the subject:—

"*Inland Revenue, Somerset House, London, W.C.,*
"*9th October*, 1872.

"Sir,—In reply to your inquiry of the 5th instant, I am desired by the Commissioners of Inland Revenue to acquaint you that no licence is required for the sale of quinine wine, if made according to the recipe in the British Pharmacopœia, and not sold as a proprietary or patent medicine.

"I am, sir,
"Your obedient servant,
"Mr. J. Ingall." "C. W. PLOWMAN.

* *Weekly Dispatch*, Oct. 6th, 1872.

PHARMACEUTICAL UTILITY OF BOTANICAL GARDENS.

Botanic gardens and their uses is a subject that has been taken up and treated of very fully in a lecture by Dr. Von Mueller, of Melbourne. The great utility of a well-managed botanic garden in its various phases is pointed out, and he advocates that, in a pharmaceutical point of view, a botanic garden is not only an indispensable element in the education of the student, but is a constant and ready help through life. Dr. Mueller says:—"For toxicological experiments in a botanic garden the various poison plants become of importance, irrespective of the guardianship, which the display of these plants in a living state so instructively exercises. Investigations of this kind require lengthened attention, the separation, analyses, and identification of organic poisons being surrounded with far more difficulty than the examination of metallic or other inorganic substances. Besides, the development or intensity of the deleterious principle depends often on local causes, which are not always within ready range of observation, or perhaps even involved in mystery, such as physiology and chemistry have hitherto striven in vain to clear away. The so-called Cape weed (*Cryptostemma calendulacea*), for the presence of which I am not responsible, as it had already irrepressively invaded some parts of Australia as early as 1833, was recently subjected in my laboratory to examination, with a view of ascertaining whether any chemically separable active principle might produce the violent purging, terminating in acute, and often fatal dysentery, to which flocks occasionally become subject; but the investigation gave negative results. The deleterious effect arises, therefore, either merely from mechanical irritation and distension when sheep have gorged themselves with this weed, or it may be traceable to a locally developed poison, which in ordinary circumstances does not exist. The latter was ascertained to be the case by my own experiments as far as *Swainsona Greyana*, *S. lessertiæfolia*, *Lotus australis*, *Gastrolobium bilobum*, and, perhaps, *Stypandra glauca*, are concerned. The two former cause in some localities cerebral affections in horses and other pastural animals, terminating in death; but the cultivated plants were found harmless. *Gastrolobium*, with some species of *Oxylobium* and *Isotropis*, the bane of the heath pastures of West Australia, has hitherto baffled all efforts to detect an antidote, but one of the most dreaded species, *Gastrolobium bilobum*, proved here in cultivation inert. Desert specimens of *Lotus australis* produced in my local trials deadly effects on sheep, while our garden plant, or the fresh herb from the sand shores of Port Phillip, showed themselves innocuous. *Stypandra glauca* is reported to produce complete blindness of sheep in some districts of West Australia, the eyes, it is said, assuming a blue tinge throughout. Unless this grass lily has been confused with an alien and externally similar weed—namely, *Agrostocrinum stypandroides*—we have again a plant, which, with capriciousness, has hitherto baffled our toxicologic experiments. *Anguillaria* and *Burchardia*, which early in the spring sprinkle their pretty blossoms so universally over the pastures of the whole of extra-tropic Australia, produce, so I have ascertained, innocuous bulbs, although belonging to a tribe of plants which includes the dreadfully deleterious veratrums and sabadilla."

IPECACUANHA CULTIVATION IN INDIA.

In the report of the Royal Botanical Garden at Calcutta for the year ending March 31st, 1872, the superintendent, Dr. George King, refers to the progress of the experiment which is now being made to propagate the ipecacuanha plant in India. At the beginning of the year five plants in Sikkim and seven in the Calcutta garden represented the whole surviving offspring of a single plant received from Dr. Hooker in 1866. From the five Sikkim plants about four hundred cuttings were obtained, the greater proportion of which have formed good roots, and were at the date of the report fine healthy little plants. During the year, the plants—about one hundred—which last September* we informed our readers Professor Balfour had ready for transmission from the Edinburgh Botanical Gardens, have arrived at Calcutta in five Wardian cases, as well as about one hundred and fifty, in three cases, from Messrs. Lawson, the eminent nurserymen. The climate of Calcutta having, however, proved totally unsuitable to ipecacuanha, all attempts to propagate it in the garden there have been abandoned, and the plants were, by an order of the Government, based on the experience of the late Dr. Anderson, forwarded as soon as practicable to Sikkim, where the experiment of cultivation will be made under similar conditions to that of cinchona. The propagation is being carried on under the immediate care of the European gardeners of the cinchona plantation, chiefly in one of the hot deep valleys of the Rungbee reserve. Ipecacuanha appears to thrive best under deep shade, and in a hot, steamy, equable climate, conditions which are fully supplied in the valleys of the outer slopes of the Sikkim Himmalaya. A small valley near Sookna has accordingly been taken up as an ipecacuanha reserve; and soon as plants can be spared, experimental patches will be planted out at various places so as to discover the conditions of successful cultivation as soon as possible.

Last week, at Sidney Sussex College, Cambridge, a Scholarship in Natural Science was awarded to Mr. William Foster, F.C.S. Mr. Foster was Senior Bell Scholar in the Laboratory at Bloomsbury Square, during the Session 1869–70, and since that time has acted as one of the Gas Examiners under the Metropolitan Board of Works.

EXAMINATIONS IN EDINBURGH.

October 15*th*, 1872.

Present—Messrs. Aitken, Gilmour, Kemp, Kinninmont, Noble and Young.

Professor Maclagan was also present on behalf of the Privy Council.

Major Examination.

The undermentioned was examined, and declared qualified to be registered as a Pharmaceutical Chemist:—

*Moss, Albert .... Ilkeston.

Minor Examination.

Nine candidates were examined, of whom *three* failed. The following *six* passed, and were declared qualified to be registered as Chemists and Druggists:—

*Mathie, William .... Edinburgh.
Carroll, George .... Bath.
Davidson, William .... Edinburgh.
Shepherd, Alexander Moir.... Aberdeen.
Platt, Jakeh Wright.... New Delph, Saddleworth.
Lindsay, George William .... Sunderland.

The above names are arranged in order of merit.

Modified Examination.

Four candidates were examined, and were declared qualified to be registered as Chemists and Druggists:—

Barton, Septimus William .... Manchester.
Kendle, John Cuthbert ...... Newcastle-on-Tyne.
Oakley, Robert .... Bridgnorth.
Proctor, Alexander Duff ...... Glasgow.

EXAMINATIONS IN LONDON.

October 15*th and* 16*th*, 1872.

Major Examination.

Seven candidates were examined, of whom *four* failed. The following *three* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Davies, Peter Hughes .... Peterborough.
Thomas, John Darby Dermott Clifton.
Brown, James .... Bideford.

October 16*th*, 17*th*, *and* 18*th*, 1872.

Minor Examination.

Seventy-one candidates were examined, of whom *thirty-six* failed. The following *thirty-five* passed, and were declared qualified to be registered as Chemists and Druggists:—

*Tully, John .... Brighton.
Equal. { *Hugo, Richard .... Bideford.
{ *Robertson, John............ Plymouth.
*Culverwell, John Sayer ...... Windsor.
*Aldersladc, William.......... Southwark.
*Hefford, Charles .... Sydenham.
*Russel, Thomas Gregory...... Cambridge.
Equal. { Lester, Henry .... Northampton.
{ Smith, Thomas Henry........ York.
Equal. { Capstick, John William ...... Lancaster.
{ Taylor, Stephen John .... Westbury.
Davis, William Richard ...... Douglas.
King, Horatio Alfred .... Norwich.
Parrott, John................ Norwood.
Rees, John Henry Williams .. Clutton.
Jefferson, John Mitchell ...... Southport.
Shirley, Stephen Shillito ...... London.
Equal. { Marjason, John Morriss........ Dublin.
{ Smithies, William Edward .... Elland.
Maitland, Pelham Christopher.. Launceston.
Rivett, Arthur James .... Yarmouth.
Pearson, Daniel .... Dudley.
Farr, Joseph .... Peterborough.
Hiscocks, Edwin Hilliar ...... Fairfield.
Bennett, Charles.............. Bristol.
Equal. { Flinders, Matthew Tom........ London.
{ Pickup, William.............. Blackburn.
Jenkins, Thomas Morgan...... Merthyr Tydvil.
Smith, Richard Fox .... Barton-on-Humber.
Cunnington, Richard Elliott .. Bristol.
Norweb, Arthur .... Nottingham.
Kershaw, Joseph Henry ...... Manchester.
Stamps, Fredcrick .... West Bromwich.
Dymott, Frank .... Southampton.
Litten, Henry................ Sittingbourne.

The above names are arranged in order of merit.

Preliminary Examination.

The Certificate of Examination of the undermentioned, by the Incorporated Law Society, was accepted in lieu of this Examination:—

Pryer, Henry .... Chipping Norton.

* Passed with honours.

The following is the result of the Preliminary Examination held on the 7th instant:—

England and Wales.

Two hundred and fifty-eight candidates presented themselves for this examination, of whom *eighty-five* failed. The following *one hundred and seventy-three* passed, and have been duly registered as Apprentices or Students.

Hall, John Marsden.......... Huddersfield.
Campbell, Neil Stewart ...... Newcastle-on-Tyne.
Smith, George .... Sunderland.
Hobson, Thomas Coultas...... Doncaster.
Holl, Edmund .... Scarborough.
Phillips, Thomas Powell...... Carmarthen.
Vaughan, John.............. Newtown.
Equal. { Bullock, John Alfred .... South Shields.
{ Evans, David .... London.
{ Hartley, Thomas .... Haslingden.
Ashweek, John Sydney ...... Torquay.
Equal. { Gilling, John Thomas .... Ripon.
{ Jones, James................ Southport.
{ Maggs, Frederick William.... St. Leonard's-on-Sea
Equal. { Edwards, James John .... Coventry.
{ James, Thomas Cragg........ Dalton-in-Furness.
Equal. { Bell, Henry .... Newcastle-on-Tyne.
{ Futcher, Alfred James........ Sandown.
{ Maish, Walter Machado ...... Bristol.
Chadwick, George Nicholas .. Dewsbury.
Equal. { Ponçon, Alfred Augustus .... Wallington.
{ Spencer, Robert .... Stourbridge.
Equal. { McGuiness, Joseph .... York.
{ Rushforth, George Frederick.. Louth.
Equal. { Allison, Joseph William ...... Sunderland.
{ Evans, David .... Porth.
{ King, William .... Southend.
Equal. { Littlefield, James Clarence.... Ventnor.
{ Jacobs, Henry Garrard ...... Portsmouth.
{ Carter, William Gibbon ...... York.
{ Wylde, James .... Reading.
Dalzell, Edward .... Burwell.
Equal. { Bessell, James Walter........ Ludlow.
{ Higgs, Alfred Henry .... Bristol.
{ Reade, Leonard James........ Wolverhampton.
Equal. { Davis, Richard Frederic ...... Ventnor.
{ Marshall, Charles William.... Devonport.
{ Williams, William Richard .. Carmarthen.
North, John Slingsby .... York.
Equal. { Marlow, Frederick William .. Coventry.
{ Stiling, John Edward .... Exeter.
Lewin, Arthur Clayton ...... Plymouth.
Equal. { Pattinson, William .... Hexham.
{ Sainsbury, Allan Fox .... Clapham.

Equal.	Fisher, John Little	Workington.
	Hodgson, Thomas Samuel	Hulme, Manchester.
	Taylor, Edward Lyon	Rochdale.
	Williams, John Frederick	Southsea.
	Griffiths, Benjamin Lloyd	Cardiff.
	Green, Edwin	Billinghay.
	Bletsoe, Francis Ferriman	St. Neots, Hants.
	Atkinson, John Thomas	Boston.
Equal.	Crooke, Charles Gibbins	Walsall.
	Kidd, William Champley	Malton.
	Kerr, William Henry	Honiton.
	Leslie, George	York.
	Dobson, Fred	Great Driffield.
Equal.	Oldershaw, William	Nottingham.
	Wells, Albert Charles	Leamington.
Equal.	Burrell, John Benjamin	Norwich.
	Satterthwaite, James	Ulverston.
	Lawton, John Dyson	Louth.
	Sketton, Tom	Maryport.
Equal.	Beach, Joseph	Colchester.
	Bevan, William	Ipswich.
	Jackson, George	Heywood.
Equal.	Davis, James Bailey	Chester.
	James, Joseph	Hanley.
	Knowles, James	Burslem.
Equal.	Case, William	Norwich.
	Wingrave, Thomas	St. Albans.
Equal.	Bright, Thomas	Shrewsbury.
	Daniel, John	Ceibach.
Equal.	Ellis, James	Dewsbury.
	Parkes, George James Robert	Tipton.
	Sewell, Jonathan Joseph	Workington.
	Swift, Phillip Dickerson	Spalding.
	Hopkinson, Stephen	London.

Equal.	Payne, Edward Marten	Wolverhampton.
	Williams, James Edward	Louth.
Equal.	Blencowe, Frank	King's Lynn.
	Clegg, James	Heywood.
Equal.	Collins, Thomas Robert	Leicester.
	Johnson, Edward	Stockport.
	Lakin, James	Derby.
	Sands, Thomas	Tunbridge.
	Thomas, David	Haverfordwest.
	Thomas, Thomas Gratton	Bagillt.
Equal.	Thornber, William	Preston.
	Yates, Charles William	Kegworth.
	Symington, William	Sheffield.
Equal.	Dunn, Albert Charles	Hereford.
	Morgan, Thomas Phillip	Tredegar.
Equal.	Griffith, Charles	Weston-super-Mare.
	Jeanes, George	Alverthorpe.
	Longmore, Henry Edward	London.
	Mills, William Hamer	Heywood.
	Wardle, James	Liverpool.
	Weatherley, Richard John	Teignmouth.
	Sharp, Everard Parkinson	Pinchbeck.

Scotland.

Twenty-four candidates presented themselves for this examination; of these, *seven* failed, and the following *seventeen* passed, and have been duly registered:—

	Dick, John Johnston	Dunfermline.
	Wallace, Andrew	Dunfermline.
	Aymer, James	Aberdeen.
	Thom, Robert	Glasgow.
	Davidson, Alexander	Insch.
	Clark, William Coltart	Dalbeattie.
	Cowie, John	Glasgow.
	Drysdale, Joseph	Edinburgh.
	Beveridge, William	Edinburgh.
	Irving, Peter	Dumfries.
	Buchanan, David	Stirling.
	Robertson, John	Inverness.
	Murray, Matthew David	Annan.
	Steele, John Cockburn	Greenock.
	Cairns, John	Kelso.
Equal.	Ogston, William	Aberdeen.
	Gibson, Robert James	Glasgow.

The following is a list of the Towns at which the Examinations were held, with the numbers of Candidates annexed:—

The questions for the Examination were as follows:—

LATIN.

Translate into English two at least of the following sentences:—

1. In castris Helvetiorum tabulæ repertæ sunt, literis Græcis confectæ, et ad Cæsarem relatæ, quibus in tabulis ratio confecta erat, qui numerus domo exisset eorum, qui arma ferre possent, et item separatim pueri, senes, mulieresque.
2. Hac oratione ab Divitiaco habitâ, omnes qui aderant, magno fletu auxilium a Cæsare petere cœperunt. Animadvertit Cæsar, unos ex omnibus Sequanos nihil earum rerum facere quas ceteri facerent; sed tristes, capite demisso, terram intueri.
3. Fiat mistura, de quâ cochleare largum unum secundis vel tertiis horis exhibeatur, sæpius rariusve prout febris vehementior vel mitior fuerit.
4. Macera per horas viginti quatuor; tum decoque ad congium, et liquorem adhuc calentem cola; denique ad idoneam crassitudinem consume.
5. Give the Nominative Case Singular of each of the following nouns: *domo*, *pueri*, *fletu*, *capite*, *horis*, *pacem*, *crassitudinem*.
6. If the persons differ in a sentence, with which does the verb agree? Give two examples.
7. Mention four *Impersonal* verbs. How are they conjugated?
8. Give the meaning of the following terms and sentences: Jusjurandum—ratibusque compluribus factis—obsides—gladiis destrictis—circiter mille passuum.
9. What parts of the verb are contigisse, tribui, consecuti, reservaretur, pervenerint, intellexit?

ARITHMETIC.

10. Write down in figures the following numbers: Two hundred and three millions four hundred and six thousand five hundred and eight.
11. Divide £7086. 8*s*. 0½*d*. by 785.
12. If 15 men build 37 roods of wall in 27 days, how many roods will 74 men build in 63 days?
13. What is the value of $\frac{7}{8}$ of a pound sterling?
14. Multiply ·786 by 100.

ENGLISH.

15. What is an Interjection? Name some.
16. Explain the difference between Copulative Conjunctions and Disjunctive Conjunctions.
17. What are *a* or *an* and *the* called in some modern systems of Grammar, and why are they so called?
18. Which is the Subject and which the Predicate in the following sentence?—"Good wine exhilarates the spirits."
19. Parse the following: They went to Switzerland for the annual trip.
20. Write from fifteen to twenty-five lines upon *one* only of the following subjects:—
    A. The Autumn Manœuvres.
    B. Westminster Abbey.
    C. The Game of Cricket.

Provincial Transactions.

ROCHDALE CHEMISTS' ASSOCIATION.

On Wednesday evening, the 9th instant, the first ordinary meeting of the Rochdale Chemists' Association was held in the refreshment room of the Town Hall. There was a good attendance of members. After the election of new members, and a special vote of thanks to Messrs. Evans, Sons and Co., of Liverpool, for their gift of a valuable cabinet of specimens, illustrating pharmacy and materia medica, Mr. Councillor

Booth (the President of the Association) delivered the following address:—

I congratulate the association on the position which they now occupy. Some years ago, before the establishment of the Pharmaceutical Society, the chemists and druggists of England were a disorganized body. They had no centre of life, no trade organization or association, and were consequently largely and sometimes perilously exposed to attacks from without, calculated to endanger the trade, and inconveniently to confine its operations. At the time to which we refer, the labour and anxiety, for instance, of getting up an opposition to an obnoxious measure was very great, and even at such times it required no small degree of eloquence and demonstration to arouse the generally dormant spirit of the trade, who appeared to think the world was bounded by their own horizon and themselves the centre thereof. On such occasions, the interests of the trade were greatly jeopardized, and but for the philanthropic and praiseworthy labours of such men as the late Jacob Bell especially, with Messrs. Allen, Farmar, Ince, Gifford, Herring and Barron, and the indefatigable secretary of the Pharmaceutical Society, the late Mr. George W. Smith, the business of pharmaceutical chemists and druggists would have been so crippled, "cabin'd and confined," that it would have ultimately died out, and the verdict would have been, "Died under the visitation and oppression of the Apothecaries' Acts."

It was in the year 1841 that a large and influential public meeting of the chemists and druggists of London was called at the Crown and Anchor, to take into consideration "a Bill to amend the laws relating to the Medical Profession in Great Britain and Ireland," introduced by Mr. Hawes, M.P. The object of this Bill was to curtail the freedom hitherto enjoyed by chemists and druggists prescribing and recommending medicines; in fact, to deprive them of the right to do so. The audacity of this proposal had alarmed the leading members of the trade in London, and forming themselves into a committee to resist the passing of the Bill, they entered into correspondence with members of the drug trade in the country. We believe the anxiety thus expressed by the London members was heartily responded to by the country, and Mr. Hawes soon intimated his intention to withdraw the obnoxious clauses affecting the drug trade, upon which his friend Mr. Wakley entreated Mr. Hawes to withdraw the remaining portions of the Bill. He did so, asking leave to bring in a new one, thus showing that the prime object of this Bill was so to break down and check the rising importance of the drug trade, that the interests, etc., of apothecaries might be enhanced. I am happy to say Rochdale took its part in this successful opposition, and continued to do so, for in the following month, an amended Bill was introduced by Mr. Hawes, "more insidious and injurious to the trade than the intelligible, clear provisions of the former Bill."

This Bill, had it become law, would have had the effect of suppressing the trade altogether, and establishing a monopoly of the sale and dispensing of drugs in the Society of Apothecaries; would have left the public, and the poor of England especially, to the tender mercies of those who were ready to say with Dr. Letsom,

"When patients sick apply to me,
I purges, bleeds, and sweats 'em;
If after that they choose to *dee*,
What's that to me, J. Letsom?"

On this occasion a petition was presented from Rochdale by Mr. Fenton and Mr. Brotherton. The House was "counted out" before the determination of the debate.

The committee who had thus so actively and successfully opposed the Bill, in reporting to their constituents, expressed their opinion that it had become necessary to watch with attention any future attempts at legislation with respect to the trade, as they had ascertained clearly that it was the intention of the College of Physicians, the College of Surgeons, and Apothecaries' Company, in their scheme for medical reform, to bring chemists and druggists by some legislative enactment under their joint control, but *especially that of the Society of Apothecaries.*

This meeting held on the 15th April, 1841, unanimously adopted the Report, and resolved, "That with a view to the protection of permanent interests of the trade, an association under the title of the Pharmaceutical Society of Great Britain should then be formed, and that a committee should be appointed to frame laws and regulations for its future government." Thereupon deputations visited various large towns, and everywhere met with hearty reception. Manchester and vicinity, represented at a special meeting in the Mechanics' Institute, was visited by the late Mr. Bell on the 15th November, 1841, and after an interesting discussion resolved on the formation of a branch association which was vigorously carried on for several years. Courses of lectures on Botany and Pharmaceutical Chemistry, etc., were delivered and fairly attended. But in five years, I am sorry to say, the library and reading-room were closed for want of sufficient interest.

As a proof of the necessity of some organization to watch over the interests of the trade, and that the establishment of the Pharmaceutical Society was most opportune and judicious, it may be stated that many attempts were made in Parliament to carry clauses in various Bills which would have been prejudical to their interests.

The Pharmaceutical Society was incorporated in 1843; and awake to the duty of guarding our trade interests, as well as providing means for the better education of chemists and druggists, set themselves with spirit to arouse their brethren to a sense of their responsibility to the public, and to the prime necessity of that better education for the right performance of the duty chemists and druggists professed to discharge, so they presented a bill for the regulation of the qualification of chemists and druggists in England and Wales—pronouncing it to be essential to the security of the public that those engaged in the preparation and sale of drugs and medicines, should possess competent knowledge of their characters and properties, and such other information required to enable the dispenser to prepare correctly the prescriptions of medical men. It is very remarkable, and is an exhibit of the general indifference to the subject in England, that almost every other European nation regulated by law the education of those engaged in pharmaceutical pursuits.

I will draw a veil over the state of pharmacy fifty years ago in this country. I will not particularize lamentable cases of presumption and ignorance, nor will we mention the fraud and imposition practised on the public by the sale of articles, mere adulterations and substitutions, which were palmed off as "the thing."

The attention drawn to the subject of pharmaceutical education has been beneficial; on all hands we perceive improvement. There is springing, up we might say, a new race of pharmacists who bid fair to be an honour to their country, and who will shortly far out distance their predecessors, as their opportunities and advantages are so much greater than theirs were. It is greatly to be desired that this progress (general as it is) were more rapid. The daily signs of it, however, give ground for cheering and bright hope.

The sale and preparation of medicines was in early times in the hands of comparatively few. They must have been observant and careful men, for they could only have arrived by such means at the knowledge of the particular effects of medicines. How many accidental deaths there must have been! How many cases in which experiments in medicines must have had terrific results! Reference to their works prove how they believed medicines to have been under the direction of the planets and zodiacal signs; and we may easily imagine how they would excuse some *disastrous effect* by the supposition of a malevolent influence intruding to mar the expected effect. And doubtless, under such circumstances, the practice of physic was doubtful and hazardous. Fearful must have been the suspense of individuals, when brought low by sickness, when some panacea said to have the effect of *kill or cure* was presented. No wonder then that physic should be suspected of being an ally of *Mors* himself. Heathen mythology relates that Æsculapius, the son of Apollo, made great progress in the medical art and gained the reputation of ability to raise the dead. But it is recorded that his success was so great that Pluto, who saw the number of his ghosts daily increase, complained to Jupiter, who killed Æsculapius with his thunderbolts. Doubtless it would be said by some medico-astrologer that there was an unfortunate conjunction of stellar influences.

After referring to the progress of knowledge, invention and discovery which has happily delivered us from the superstitions that formerly held the human spirit in bondage and retarded liberation from its wide-spread thraldom for ages, and paying a tribute to those who by their labours have prepared the way for the student of the present day, the speaker continued,—

Some here present have passed through difficulties to which I have only alluded, and have made good use of the advantages which they had to seek as they could, and for which, under stress of business, they had to deny themselves of needful rest and recreation; and some are now about entering the gate through which we passed. What will they find? They will find a path rendered easy by the labours of their predecessors; the difficulties which had well-nigh excusably deterred them smoothed down; and everywhere the hand of intelligent instruction eagerly inviting to progress.

Shall the opportunities now so freely offered be carelessly passed by? Shall all the wise provision of the Pharmaceutical Society, and the associations everywhere rising up in the country, be negatived by indifference and neglect? I trust not. The chemists and druggists of Rochdale, actuated by laudable feelings, now band themselves together, and appear at this their first ordinary meeting, to take the oath of allegiance to pharmaceutical science, and swear fealty to her rule and sway. And they desire in thus associating themselves together to render to each other assistance in the prosecution of their interests, whether commercial or scientific. Feeling each a brother's care, they desire to strengthen each other's hands, and diffuse around them thorough wise educational schemes,—the advantageous opportunities of instruction they have devised. Let no youth entering on the study of pharmaceutical chemistry be discouraged. Pluck up heart and hope on. How did Faraday obtain knowledge? By diligence, attention; by labour and work. And so with a thousand others. And so must it be with the young aspirants for pharmaceutical knowledge and fame. Let them remember the prize before them,—a status and a position to which we have not yet attained. But it can only be reached through labour. I remember in the frontispiece to an old school-book the Temple of Fame represented as being placed on an eminence, and in the valley below Science pointing ardent youths to the path which led to it, apparently cheering them on to the path leading to the temple. The path could not be seen; it might be dark, difficult, rocky and steep, but the light of the temple shone over the path if not upon it. So it is with you. It is a true saying there is no royal road to learning. Nor is there a railroad either. The way is too steep, even with all that can be done to ease it. But there is a real way, and you do not need to miss it. While I would commend you to enter with determination, I would have you enter with caution. Inquire for the right path. Do not take any side path however promising. There are real pleasures in store for you, and every turn of the true path will bring you to some halting-place for your encouragement; but you cannot make progress by merely looking out and staying in these groves of delights. Nerve yourselves again for the upward path.

I have been distressed to find so many incapables turned back at the Preliminary examinations. More strict examinations into progress must be the rule in educational establishments, for young persons ought not to fail at such an examination, to pass which may be said to be only the test of ordinary attention to study. The observations of Dr. Temple, Bishop of Exeter, go to confirm all that is said as to the necessity of application to study.

Offering advice to students, he warns them not to give way through weariness, for if there was not weariness in the work, they might be sure it was not so thorough going as it ought to be. Of all work that produces results, nine-tenths must be drudgery. There is no work, from the highest to the lowest, which can be done well by any man who is unwilling to make that sacrifice. Part of the very nobility of the devotion of the true workman to his work consists that a man is not daunted by finding that drudgery must be done, and no man can really succeed in any walk of life without a good deal of what in ordinary English is called pluck. This is the condition of all work whatever, and it is the condition of success. And there is nothing which so truly repays itself as this very perseverance against weariness. This is the Bishop's experience, and it is that of every successful man. On that which costs us labour we set most value in proportion to that labour. And we shall love and prize the learning we attain because it has cost us labour and anxiety. I counsel you to perseverance even under most adverse difficulties, assured that you will find solid pleasure and enjoyment in the study you pursue; and, finally, you will come to love the work most ardently. Read, mark and learn then with that persevering attention to which I have pointed. Wordsworth says of learning that it is—

> "A substantial world both pure and good,
> Round which, with tendrils strong as flesh and blood,
> Our pastime and our happiness will grow."

Mr. Alderman Taylor then moved a vote of thanks to the President for his valuable address, with a request that it should be printed. In the course of his observations he reminded the young men present of the superiority of their privileges over those enjoyed by young men in the days of his apprenticeship. Then, no time was left at liberty during the day for either study or recreation. Mental improvement could only be sought in hours that ought to have been devoted to sleep. Now, not only is time allowed, but teachers are provided, and the young man is without excuse if he fails to improve himself.

Mr. Councillor Scott seconded the resolution. He corroborated the statements of Mr. Alderman Taylor with regard to difficulties in the way of young men forty or fifty years ago. He also referred to the obstacles to the trade that had risen from the action of the Legislature, commencing with that promoted by the Apothecaries' Society, and having its last illustration in the action of the Medical Department of the Privy Council in reference to the question of poison regulations.

On the motion being submitted to the meeting it was carried very heartily.

Mr. J. W. Bramford then read a short paper on "Old Books," calling attention to some preparations in use a century ago, but now no longer used—illustrating one phase of the advance that pharmacy has made in the interval.

After this Mr. Robinson gave a brief description of a few of the fine specimens of drugs contributed by Messrs. Barron, Harvey, and Co, of London, viz., kousso, cassia fistula, areca nut, Indian hemp, St. Ignatius's bean, Chinese cantharides, guarana, and English otto of roses—a very rare specimen. He also described some of the valuable contributions by Messrs. Mottershead and Co., of Manchester. One of the most important of these was a drying closet, fitted with an apparatus for maintaining a constant temperature—a most important aid in the preparation of pharmaceutical products and analytical operations. It is so constructed that when the required temperature is secured, by the simple turning of a tap, any variation in temperature is prevented, and if left to itself will remain at that temperature for days if required.

A simple compact and useful pharmaceutical stove and drying closet, with a contrivance for heating the plaster spatula, and a kettle in which a pint of water may be boiled in less than four minutes, was also exhibited and described. The luminous butterfly was the most wonderful object exhibited. On exposure to the magnesium light, it became luminous when viewed in a dark room, and continued for several minutes to display the natural colours painted by the artist. Hydrometers, electric telegraphs, and other articles were also exhibited. The contents of the case given by Messrs. Evans were also displayed, as well as a similar one contributed by Mr. Alderman Taylor. Several microscopes were on the table, accompanied by a large number of interesting mounted objects. Mr. Lord brought for exhibition a number of vacuum tubes, to illustrate the phenomena of luminosity produced by a current of magnetic electricity being passed through them. Books, microscopes, manuscripts, photographs, skeleton plants, metric measures, etc., were contributed by the Chairman, Messrs. Alderman Taylor, R. Robinson, E. Lord, J. Hadfield, and J. W. Bamford.

The thanks of the meeting were presented to Messrs. Barron, Harvey, and Co., and to Messrs. Mottershead and Co., and also a very cordial vote of thanks to, and of sympathy with, Mr. Hudson, brought the proceedings to a close.

The next ordinary meeting will take place on the third Wednesday in November.

LIVERPOOL CHEMISTS' ASSOCIATION.

The first General Meeting, twenty-fourth session, was held at the Royal Institution on Thursday evening, the 10th inst.; the President, Mr. E. Davies, F.C.S., in the chair.

Messrs. Kennerley, J. T. Pratt and E. S. Sumner were elected members, and Mr. J. L. Warburton was elected an associate of the Association.

Mr. T. J. Abraham, on behalf of Dr. Cameron, presented to the museum a specimen of Guaraná.

The President then delivered the following opening address:—

President's Address, 1872.

Gentlemen,—The old proverb that "union is strength," and the saying of the wise king, "in the multitude of counsellors there is safety," receive in this age a very full application. From shoeblacks to philosophers associations for common purposes are everywhere met with, and co-operation is the panacea for mental and spiritual wants, as well as for material ones. Banded ourselves in such an association, I think that we shall derive benefit from a careful consideration of the objects of our union together, and how we can best increase its efficiency. Twenty-three years ago the founders of the Liverpool Chemists' Association first met; their objects being then strictly pharmaceutical, and the government of the society confined to chemists and druggists. That I am honoured by re-election to the post of your president is proof that those exclusive views have ceased to prevail, and now our constitution is as comprehensive as is the science by whose name we are called.

This is a matter of rejoicing; a merely class association might have degenerated into a trades-union, but with wide basis we can build a noble edifice, and being chemists in the widest sense, all things chemical have an interest for us.

The idea at the root of all such associations is a noble one. It is the helping of the weak by the strong; the abandonment of the position which exclusive knowledge gives by raising our fellows to the same level by imparting that knowledge, and the abnegation of self for the common weal. That, human nature being what we know it to be, this high standard is not perfectly attained does not astonish us, but it is a legitimate cause for joy that this thought is not forgotten, and that, to a great extent, it is carried out. There is a cynicism abroad, and rather fashionable, which disbelieves all this, or professes to do so, but I scarcely think that one amongst us is so bad as never to have felt that it is "more blessed to give than to receive." I shall take it for granted that you do think so, and that you wish the success, and, not content with wishing, will work for the prosperity of the association. Our object, as stated in the rules, is the advancement of chemical and pharmaceutical knowledge. Do we take the best means for the attainment of this end? if not, how shall we proceed in a more promising direction?

The almost universal plan in our own and other like societies is to have a paper read by some member, followed by a discussion upon it. This has the advantage of ensuring a thorough examination of a subject, by its being made a matter of careful thought in the quiet of the study, where authorities can be consulted and arguments maturely weighed. The disadvantages are the desirability of the paper embodying the results of original research, for which comparatively few have time in these busy days, when the ties of business and the feverheat of competition leave few opportunities for retiring from the noise and bustle of the world to work for other than material advantages. Then the modesty of some whose aid should be given, lead them to dread the ordeal of facing an audience, whose business is to be critical, for half an hour. The courage to do this is not always found in those who would really have nothing to fear, whilst it is sometimes present where there is little else to praise. The papers thus fall into the hands of the same individuals, and, in the dearth of anything new, subjects are chosen on which controversy has ceased, and the discussion resolves itself into a vote of thanks. I am not disparaging this feature of our proceedings, and should be sorry indeed if the reading of papers should cease to be the main attraction of our meetings, but I would like a variety in the bill of fare, and I believe that we should gain by it.

It is always easier to point out a difficulty than to show how to surmount it; to pine for improvement than to attain it. One suggestion, which I am happy to say will be tried when we meet again, is to have a subject expressly for discussion. It may be laid before us briefly by some member who has made it a subject of thought, and then opinions for and against, fairly and freely expressed, will give life and interest to the meeting. Each can speak on the particular aspect which is best known to him, and I trust that we shall all bear cheerfully to hear our cherished opinions somewhat roughly handled, and to meet opposition without anger or loss of temper. This is the *sine quâ non*, without which we shall either lose all profit in a strife of tongues or fall into listless acquiescence.

Meetings for miscellaneous contributions have been tried, and in some cases without great success. I have been sorry to find that this announcement on the circular has had the effect of reducing the attendance to a minimum. This might be remedied if notice were given to the secretary of the nature of such communications so that they could be announced on the circular. The fact is that so many of our members are content to be merely receptive, without troubling themselves to impart, that it never occurs to them that they ought, as a duty owed to the society, to help in ever so small a way. This feeling has doubtless been fostered by formal papers being the only means which they have recognized as proper; and as they perhaps could not aid in this way they never think to aid at all. Yet how much might be done if a new preparation were made known, or a new drug described, some quaint passage read from an old book, or prescription read presenting points of difficulty or interest, or some discovery in scientific or practical chemistry explained? It is deserving of thought whether it might not be desirable to have at least one evening in the session occupied by a lecture by some eminent stranger; but as this would involve an application to our treasurer, I forbear.

I would make one other suggestion, namely, to have an informal conversazione and microscopical meeting, not a dress affair, or, at the risk of being thought ungallant, open to ladies. The illustrations at this should be purely technical, and the object distinctly understood to be mutual intercourse of opinion on our noble science.

Our regular work at the ordinary meetings should not, in my opinion, be rudimentarily educational. Knowledge which can be derived from ordinary text-books is, I think, best got from them or from a competent teacher. This brings me to the consideration of the association's relation to its young members and associates.

Primarily, the idea in opening the association to these was to afford the aid which a valuable and well-selected library and museum could give to form a well-instructed mind; and that by listening to men of experience, they might learn in time to take their father's place as members. As examination has become compulsory, and young men must in some way qualify themselves for passing this, it becomes a matter for consideration what the association should do under these new conditions. Direct aid to education your association does not give; it does not pay teachers or provide apparatus or lecture-room. The advancement of chemical and pharmaceutical knowledge, not raising scholars to the present standard, is its end and aim. Yet, as a subsidiary object, I do not know how the energies of the association could be more usefully applied than in this direction. What line of action will be adopted I cannot say; and, as your President, I feel loth to say anything which might seem to commit your Council to any steps which they had not well weighed and deliberated. A suggestion that a box should be provided for the reception of queries to be answered by myself or any member most thoroughly acquainted with the special subject, met with the hearty approval of your Council, and has been carried out. Henceforth the receptacle will stand on the table, and any one may before the meeting insert the question, or on sending them to the secretary he will do so.

Another plan suggested, is to provide a place where students may meet and study, availing themselves of the aid which those more advanced can give. As this has not been discussed by your Council, I do not at present express any opinion upon it. One thing only I would say to any young fellow-student (for I am myself still a student) as one who has not yet forgotten his younger days and early struggles with the difficulties of knowledge, depend mainly on yourselves; do not believe that mental work can ever be replaced by anything in the world besides. What you find out you will remember, what you are told you may. You may get faster over the ground by the aid of a coach, but to know the country, its beauties and its riches, you must walk on your own legs, see with your own eyes, and know with your own head.

Perhaps the subject which will now occur to you as my next, is the general use of pharmaceutical education. I shall refrain, however, as it will be the subject of our next meeting, and my views have been expressed to the association in a former address. On one branch—namely, chemistry—I would offer a few remarks. We all claim the name of chemists, either pure, simple, or combined with "druggist." In the former case there is no need to speak of the necessity of the study of chemistry, scientific and practical; it is the business of our workday lives. But how far, in the other case, are the members of our association willing or desirous to abandon the title altogether, and as "pharmacists," or by any other name, drop the standing proof that at one time their predecessors were *the* chemists of the day? This should be done, if the knowledge of chemistry is to be thought a slight matter, or, indeed, anything but a primary requisite. You may fancy that I am guilty of the "nothing-like-leather" fallacy; that because it is important to me I think it must be good for everybody, but I don't think that I do.

I know that many who wish to become chemists wish to get the minimum of information which will just pass them, and avow their intention of then letting it drop. I fear the modern monomania among the heads of the scientific part of the profession for speculating on the hidden mysteries of a molecule, and the fearful pictures recalling the Chinese puzzles of our youth, are answerable for some of the distaste which seems growing. It is good to study these, as all theories with a sufficient basis give some help to an advanced student; but I confess to a sympathy with Professor Bunsen, who would not let his pupils use symbols for three or four months, and Gay-Lussac, who pursued the same course. Truly one may debate on the manner of expressing a fact until the fact itself sinks into comparative insignificance; and if students would remember that an intelligent knowledge of the facts of chemistry may be made a possession which will lead to the explanation of the theories if they wish, but which in itself is practically most valuable, they would cease to despise it. I strive when teaching to express the facts in the simplest possible form—H_2SO_4 for sulphuric acid involves no theory, and not until a student has mastered a fair portion of the field of chemical knowledge would I willingly put $SO_2 \left\{ \begin{matrix} Ho. \\ Ho. \end{matrix} \right.$ in his way. If there be any disposition to demand this abstract knowledge from pharmaceutical students, I would most strenuously oppose it, whilst any fair quantity of knowledge of chemical reaction or operations may be demanded as an absolute requirement. To turn from the subject to one to which I alluded last year, that of adulteration of food and drugs, I have no change to make in my faith. Another pottering with the question has occupied the attention of Parliament; and now, if a dealer says that an adulterated article is pure, and you can prove that he knew it was not, you can punish him. I do not know if you are in the habit of asking when you buy anything whether it is pure. I must own that I do not, and in getting a week's grocery, for example, it would be a pleasant operation to put the question in each instance. As far as regards the adulteration of drugs, our public analyst, I see, is left to his own discretion; and if he should think with one of our daily papers that he is bound to show a reason for his official existence, you may expect a descent upon you. My own experience would lead me to believe that he will not find much prey amongst pharmacists. Still

> "If there's a hole in a' your coats
> I rede you tent it;
> A chiel's amang you taking notes,
> And faith he'll prent it."

The past year, taking the period in its official sense, has not been marked with great pharmaceutical novelties. In scientific chemistry another great discovery has been made. By a scientific investigation, which for difficulty and complexity is almost unequalled, the colouring matter of indigo, indigotine has been added to the list of natural products now made artificially. Nitro-acetophenon, obtained by the action of nitric acid of acetophenon, itself a product from the dry distillation of benzoates and acetates mixed, only differs from indigotine by H_2O and O. By heating with soda-lime and zinc, small quantities of indigotine are produced. The process is in no sense commercial; but neither was that by which alizarine was first produced. The way being pointed out, probably improvements will be introduced, and indigo become a product of our own country. Benzoic acid is now made in quantity from naphthaline, a product of coal tar, so the new colouring matter is related to that exhaustless store of valuable chemical treasure.

On the other hand, conine, which was supposed to have been formed artificially, has eluded the chemist's grasp. The new product, though closely resembling the natural alkaloid, and having the same atomic constitution, is only isomeric with it and not identical.

A new process for estimating morphine in opium deserves attention. It depends on the well-known reaction of morphine on iodic acid, by which I is set free; the I is taken up by chloroform or CS_2, and the liquid compared as to colour with a solution of a known quantity of iodine or morphine treated in like manner. In conclusion, I would urge on the members more earnest interest in the association. Its success is in their hands, and they will reap the benefit. I hope to see the day when it will include on the roll the chemists of Liverpool as a body. There is no ground for jealousy; we make no exclusive claims or interfere with any man's private arrangements. No purely trade questions are discussed, but on the points common to all chemists we invite the fullest inquiry. In these days private claims are often overlooked; a large body alone is listened to, and its influence felt. In the past your association has done good work in upholding the interests of chemists, and in the future it will not fold its hands.

I ask your aid in fulfilling the arduous duties of your president. I promise my best exertions, and trust that this year will be one of unusual success.

Mr. J. Abraham, in moving a vote of thanks to the President, remarked that, concurring with all that he said, he felt there was rather a want of pupils than means of instruction; he hoped, however, that this state of things would soon be changed.

Mr. A. H. Mason seconded the motion, and said that the Council of this Association had provided, and would continue to provide, ample accommodation for pharmaceutical students, and for the instruction and interest of members at the general meeting. The motion was then carried.

Proceedings of Scientific Societies.

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.

RECENT SANITARY LEGISLATION.

On Saturday evening, October 19th, the Association of Medical Officers opened its session at the Hall of the Scottish Corporation, Crane Court, Fleet Street.

Dr. Letheby took for the subject of his Inaugural Address, "The Sanitary Legislation of 1872." He observed that foremost among the labours of the session was the Public Health Bill. He recapitulated the provisions of the Act, and pointed out that the appointment of sanitary officers was made compulsory, instead of permissive, and not the least important of these was the medical officer of health. The trust thus reposed in the profession demanded the most anxious consideration as to the manner in which it ought to be fulfilled; for although the Act merely directed that the medical officer of health should be a legally qualified medical practitioner, yet it was obvious that the duties of the office required something more than the mere knowledge of routine medical practice. He was very strongly of opinion that the medical officer of health should be entirely free from the conflicting interests of private medical practice, for it might well happen that the worst places in the worst districts would be the property of men who were the best patients of the sanitary officer. Too often, also, the owners of unwholesome tenements, or the managers of offensive trades, or the dealers in adulterated food, force themselves into Local Boards for no other purpose than to protect their own interests, and to check, as far as they could, the application of sanitary measures; and if the medical officer of health was dependent to any large extent on the income of private practice, he could not venture to be meddlesome. That difficulty was in some degree provided for by the 10th section of the Act, which gave the Local Government Board control over the appointment and dismissal of an officer of health, when any portion of his salary was paid out of money voted by Parliament. That kind of protection might, perhaps, be advantageously extended, although he was far from thinking that a central sanitary authority was as capable of managing the sanitary affairs of the country as the local authorities of the districts, and he should be sorry to see an excessive centralization in this respect. Another effort at legislation during the year was "the Act to amend the Law for the Prevention of Adulteration of Food and Drink and of Drugs." Its object was to amend the Act of 1860, which was found to be a dead letter, for the adoption of it by local authorities was entirely permissive and optional, and, even where it had been adopted, as in the City, it was wholly inoperative from the circumstance that the public, and not the local authority, were to put its provisions in force. Looking back at his own experience in the City, where for the last twelve years he had been the food analyst under the Act of 1860, he perceived that although every inducement was offered to the public by the Commissioners of Sewers for the effective working of the Act, as by distributing circulars among the citizens inviting them to put it into force, showing them how it was to be done, and even giving them discretionary power to make analyses for the poor without charge, yet in the whole of that time only 57 analyses of food and drink had been made, and he seriously believed that not one of them was called for for the purposes of the Act. That was rather disheartening, considering how sensationally loud had been the cry about adulterations during the whole of that time. In some respects the new Act was an amendment of the old, for it made the appointment of analysts almost compulsory, and it threw upon the legal authority the duty of conducting all proceedings under the Act. The 5th section provided that the City Commissioners of Sewers, the Vestries and district Boards of the metropolis, and certain local authorities in the United Kingdom might, and when required so to do by the Local Government Board, should, appoint for their respective districts one or more persons possessing competent medical, chemical and microscopical knowledge, as analysts of all articles of food, drink, and drugs purchased within their respective districts, paying them such salary and allowances as they might think fit. It no longer rested with the public to initiate an inquiry, for the inspectors of the district could procure articles of food and drink, or drugs, suspected to be adulterated, and deliver them to the analyst, who, if he found them adulterated, would instruct the inspectors to summon the offender before a justice of the peace. Any purchaser of such articles might apply to the analyst for an analysis and obtain it on the payment of a fee not exceeding half-a-guinea and not less than half-a-crown, and in cases of adulteration might institute proceedings against the dealers. But the question was—What is an adulteration? That was left in very nearly the same condition of doubt as it remained in the old Act. The third section, however, of the new Act made it illegal for "any person to sell any article of food or drink, or any drug, knowing the same to have been mixed with any other substance, with intent fraudulently to increase its weight or bulk, unless he declares such admixture thereof before delivering the same and no other." But who should decide, and how many analysts were there throughout the country who would agree as to what was and what was not injurious to health? Again, what was the exact meaning of the words "such admixture" in the clause he had just quoted? Already he had been made acquainted with the opinions of high legal authorities differing very considerably from each other in the interpretation of these words; for while some held that it meant a simple declaration of the fact that the article sold was a mixture, others were of opinion that it would be necessary to specify the substances of which the mixture was composed, and others again held that the exact proportions of those substances must also be stated. But it would be for the magistrates to decide this difficult question. Again, with respect to drugs, how was the case to be met when there was no adulteration whatever of the article sold, notwithstanding that it was absolutely worthless and inert, either from its having undergone decay, as in the case of roots and leaves, or from its having been grown in a country where its active principles were not developed, as with rhubarb, senna, etc., or from a fraudulent abstraction of those active principles, as in the case of cinchona bark, opium, etc.? It was evident that to meet those cases they ought to have a clear and comprehensive definition of the word "adulteration," and until that was given, as in the Seeds Adulteration Act, 1869, and the Licensing Act, they would not have a workable Adulteration of Food Act, which should protect the public from injury and fraud without interfering with the legitimate objects of trade. He thought it would be far better to refer the matter to some central authority whenever a dealer considered himself aggrieved by the report or certificate of a local analyst, and to let that authority decide definitely for the information of the magistrate. The penalties for adulteration were greatly enlarged, and they applied to persons engaged in the preparation of adulterated articles as well as to those who sold them. Imprisonment also might be given in second and subsequent offences, and the names and addresses and offences of the persons convicted might be published and advertised. There was a power of appeal to Quarter Sessions, and, in certain cases, to a higher court. The adulteration of intoxicating liquors was provided for by the Licensing Act of 1872. The schedule of deleterious ingredients which it was unlawful to mix with the liquors sold or exposed for sale mentioned cocculus indicus, common salt, copperas, opium, Indian hemp, strychnine, tobacco, darnel seed, extract of logwood, salts of zinc, or lead and alum, and the list might be enlarged at any time. Looking at the multitude of Acts of Parliament which dealt with questions of adulteration, and to the divided authority and jurisdiction of the matter, it was evident that what were required were a consolidation of the law and a very clear and explicit declaration of the thing to be dealt with as well as of the authority and its duties, powers, rights, and obligations. Dr. Letheby concluded by briefly referring to the Government inquiry recently made at Whitehall by Lord Methuen and other Commissioners into the regulations issued by the water companies under the Metropolis Water Act, 1871, remarking that it was to be hoped that when the constant service was in full operation in the metropolis, they would be able, under the provisions of the Act, to do away with the filthy butts of the poor and substitute for them a constant supply of water by means of a waste-water preventer external to their houses.

Dr. Tripe expressed an opinion that the medical officers of health should not undertake the additional duties of analysts under the various new Acts unless properly qualified assistants were supplied to them; and Dr. Stevenson, of Guy's Hospital, said his only fear as to the Adulteration Act was that it might fail for want of proper definitions. The Act, the latter gentleman observed, had already caused some excitement and apprehension among tradesmen, for he had been often solicited of late to testify as to the purity of articles sold, but he had, of course, declined to do any such thing. The discussion was principally as to whether the medical officers should accept, if they were offered them, the analytical work under the Acts, and this matter in the end was referred to a committee.

Lord Eustace Cecil, M.P., said the Adulteration of Food Act was carried through at the fag end of the session, and he had not previously expected for a moment that it would become law. But when he observed that the food question was not touched by the Public Health Bill, he determined to do what he could in his individual capacity to carry the Bill, which then stood in the name of Mr. Muntz. He only co-operated with that hon member on the understanding that the Bill should be compulsory and not permissive, and he at once changed the word "may," whenever it occurred, into "shall." Had that been allowed to stand the 5th clause would have made the appointment of analysts positively compulsory, and the local authorities would have been obliged to select the officers forthwith. He passed his amendment to that effect through the House at two o'clock in the morning, but next day he was informed by a member of the Government that the clause as it then stood would trench upon the question of local taxation, and that he must proceed more cautiously if he wished their support. He therefore put in the words "may, and when required so to do by the Local Government Board shall," appoint an analyst, and that alteration was assented to by the Government. On the question of the third reading, however, he was told that, unless he withdrew all his amendments, the Bill would not pass, and he did accordingly withdraw them. But he admitted that he used a little piece of stratagem to effect his object. He obtained the support of his brother, Lord Salisbury, who consented to introduce all his amendments in the House of Lords, where they were carried. The Bill came down to the Commons and passed, without alteration, in a House of about a dozen members. All the amendments, however, had previously been carefully considered by the Government, and if there had been anything wrong in legal phraseology, they had every opportunity to alter them. A definition of articles injurious to health was thought to have been sufficiently provided by the incorporation into the Act of the Pharmacy Act, which contained a schedule of poisonous ingredients; and as for adulteration, he believed the intention of Parliament was that anything done in the way of fraud in the adulteration of food should be considered as a breach of the Act. It appeared to him to be a small consideration what were the proportions of the ingredients, provided that something had been mixed with the article, and anything done to increase its weight or bulk was a sufficient adulteration. If there was any difficulty as to the interpretation of the statute, the best plan would be, at the first opportunity, to state a case for the decision of one of the superior courts. He must say that the words were submitted to lawyers at the time they were put in the Bill, and were said to include a fair and workable definition of adulteration, and he should be most disappointed if it proved otherwise. If any amendment of the measure was, after a trial had been given to it, found necessary, he would use his best efforts to secure it.

Parliamentary and Law Proceedings.

Suicide by Prussic Acid.

At the inquest to inquire into the death of Mr. Pickering, of Derby, reported last week* Mr. Burnham, druggist, Osmaston Road, spoke as to the deceased coming to

* *Ante*, p. 318.

his shop last Saturday evening, and asking for one ounce of prussic acid. He represented that he had a pig in an unsound condition, and wished to poison it and bury it in the garden without the neighbours knowing. Witness explained to him that half an ounce would be more than ample, and supplied him with that quantity. Deceased seemed quite calm and collected, and knew what he was doing. He signed a book as required by Act of Parliament. On the 9th of September witness supplied him with the same quantity of prussic acid. Mr. Iliffe, surgeon, having given evidence as to the cause of death, the jury returned a verdict "That deceased destroyed himself while of unsound mind."

Serious Charge against a Chemist and Druggist.

On Monday, October 21st, Edwin Eastwood, chemist and druggist, of Dukinfield, was brought up on remand before the county magistrates at Stockport, charged with causing the death of Ann Jones, at Marple, by administering to her a noxious drug for an unlawful purpose. The deceased, a domestic servant, in the early part of the year formed the acquaintance of the prisoner. In March she left her situation to live with a married sister, at Marple. It being discovered that she was *enceinte*, the prisoner was communicated with on the subject. Deceased complained of intense suffering up to the beginning of October, when Mr. Hibbert, surgeon, who was called in sent for Mr. Moore, another surgeon. The young woman had been in labour four days, and her life being in danger, a magistrate was sent for and her dying deposition was taken. She died a few hours afterwards. The prisoner made no reply to the charge. The effect of the deceased's testimony was that the prisoner had given her medicine several times. He gave her two bottles of stuff in his own shop; a bottle produced was one of them.

Evidence was given that sealed packets containing the medicine and the stomach had been handed to Professor Crace Calvert, of Manchester, for analysis.

The prisoner was remanded.—*Manchester Guardian.*

Double Suicide by Strychnia.

On Wednesday, October 23rd, Mr. Bedford, the coroner for Westminster, held an inquest upon the bodies of a man and woman, names unknown, who on Saturday last were found dead in their apartments in Golden Square, Soho.

Mr. Slight, surgeon, deposed that when he saw the bodies they had both been dead some hours. Upon the hearthrug was a small bottle with a label upon which the words "Strychnine—Poison" were written in pencil. The bottle contained several crystals. There was also a mug upon the mantelpiece containing several grains of crystals. The bottom of the mug was blackened as if it had been held over a candle to heat it. The analysis of the stomach had not been completed, but strychnine had been found.

Evidence was also given as to the finding of a paper in which the deceased stated that they had taken strychnine and that nobody was to blame. The inquest was adjourned to allow of the completion of the analysis, and also if possible the identification of the deceased.

Obituary.

FRIEDRICH WELWITSCH, M.D., F.L.S., etc.

Dr. Welwitsch, the well-known African botanist, died on Sunday last, aged 65 years. He was born in the Austrian Duchy of Carinthia, and in early life showed his great love for the study of nature. He dated his first lessons in botany from an apothecary, who seeing him pass his door with a bunch of flowers, engaged him in conversation, told him the names of the plants and instructed him in preserving them. This gave an incentive to his exertions, and every week found him in the good apothecary's company. When old enough, Welwitsch was sent to Vienna to study law, but this very soon became distasteful, and he entered himself for the study of medicine as likely to give him the best groundwork for the study of natural history. For this step his father for some time suspended his allowance, and young Welwitsch had to support himself by writing dramatic, musical and other critiques for the papers. His progress was rapid, and before he had obtained his diploma, he was appointed on a cholera commission to visit Savoy, etc. This high mark of distinction brought about a pleasing family reconciliation. It would be impossible in a notice like this to give a full account of such a varied and useful life, and we must content ourselves with a mere outline. While still young he was sent by a Society of Friends of Natural History (Unio Itineraria of Würtemberg) to collect plants in Portugal, etc., and afterwards he was appointed to the directorship of the Botanical Gardens of Lisbon. An offer being made to him to take charge of a nobleman's garden, he relinquished the royal gardens, as the new appointment would give him more time for examining the flora. He was also engaged in getting up collections for the 1851 Exhibition as well as those of 1862 and 1867. In 1853 he started to Africa in order to explore for the Portuguese Government their possessions on the west coast. There he remained till 1861 collecting and examining the flora and fauna of Angola, Benguela, etc., and on the magnificent results his fame will rest. His collections of critically studied plants are unique, and are undoubtedly the finest ever brought from West Tropical Africa; and the 'Flora of Tropical Africa' (two volumes of which have already been published) will owe much to his labours. In other departments of natural history his collections are no less valuable. In Entomology his collections are unrivalled, and in Zoology he enriched our knowledge amongst other things with a new species of *Hyrax* near to *H. Capensis*, and which has been called *Hyrax Welwitschii*. Amongst plants one can hardly particularize individuals. One he discovered, and named *Corinanthe paniculata*, has a very Cinchonaceous habit, and its bark is used by the natives for the same purposes as that of *Cinchona* is used. His name is preserved in a very curious and interesting Gnetaceous plant, which Dr. Hooker has fully monographed under the name of *Welwitschia mirabilis*. Since his return from Africa he has occupied himself in working up his collections, and during the whole time has suffered in his health from fevers, etc., enough to daunt an ordinary man from any work whatever. During the last few months, however, his friends clearly saw he could not last much longer, but he kept to his work as long as he had strength to hold his pen.

His explorations have been recognized by two or three decorations of knighthood and by many scientific societies.

His funeral took place on Thursday, the 24th inst., at Kensal Green, a number of botanists being present.

Notice has also been received of the following deaths—

On the 15th October, Mr. Mark Ward Cooper, pharmaceutical chemist, of Bridlington. Mr. Cooper had been a member of the Pharmaceutical Society since 1845.

On the 15th of August, Mr. John Newton, chemist and druggist, of Kennilworth.

On the 19th of October, Mr. Edward Hart, chemist and druggist, of Kegworth.

BOOKS RECEIVED.

Sanitary Science as applied to the Healthy Construction of Houses in Town and Country. By R. Scott Burn. Glasgow: Collins and Co. 1872.

First Principles of Human Physiology, and a few Applications of them, with Suggestions for Practical Work. By W. T. Pilter. London: Kempster and Co. 1872.

Correspondence.

Patent Medicine Licence.

Sir,—Under this head I observe in your leader of last week that you entirely coincide with the suggestion of a correspondent as to the desirability of fixing some uniform rate throughout the country for the above licence. I agree with you, and think the higher rate of £2 would be "conducive to the interests of the chemists and druggists throughout the country," for, as you truly observe, "it would tend to prevent the now very general sale of patent medicines by booksellers, grocers and hucksters, and transfer it to the hands of those who are legitimately entitled to deal in the potent drugs frequently contained in the preparations sold under stamp." In a small place like this we have no fewer than *five* dealers in patent medicines, there being but *one* chemist's shop. The last addition to the patent medicine vendor's stock is the harmless preparation Laudanum, which is now raised to the dignity of a patent medicine, and retailed throughout the country by grocers and hucksters, thanks to the Patent Medicine Licence and the Pharmacy Act. Whether the makers of this strange patent medicine intend running entirely through the Pharmacopœia I cannot say, but I shall not be at all surprised if before very long we are presented with such innocent preparations as prussic acid and strychnine in the form of patent medicines, and retailed by all patent medicine vendors, be they druggists, grocers, or hucksters.

As a country chemist, I would willingly pay the higher rate of £2; and I believe this is the opinion of most in the trade. I think this is more a matter for the whole trade to take up than one within the province of the Pharmaceutical Society; and I have no doubt if proper representations were made to the revenue authorities a remedy for this grievance would soon be found.

Alexander Ellis.

Skelton-in-Cleveland, Oct. 21st, 1872.

Examination Fees.*

Sir,—The exceptions which I ventured to take to some of the statements made by Mr. Vizer in his communication inserted in your number for August 31st,† are not in any way disposed of by the statistics and counter-statements contained in his rejoinder.‡

In the first place, statistics referring to a period prior to the passing of the Pharmacy Act, 1868, are of no value in the discussion between us. By the passing of that measure, the Society was so materially changed in character and constitution, that it has become to all intents and purposes a *new* Society; and therefore the only figures available are those of 1869, 1870, and 1871. Being comprised within a narrow period I do not, and did not, attach an exaggerated importance to them; but taking them as they exist, they do not bear out my friend's assertions.

I repeat then, that—disregarding 1869 as peculiarly exceptional—the proportion of pharmaceutical chemists who joined the Society in the two last-named years compared with the number who passed the Major examination was not *small*, as stated by Mr. Vizer, but *large*. It is not the fault of the present generation of Majors that the total numerical strength of Pharmaceutical Chemist members was less in 1871 than in previous years.

Again, as regards the numerical strength of the Society. On this point the table published by Mr. Vizer shows that the total number of members was, in

1869	2185.
1870	2384.
1871	2466.

And of associates in business the total number was, in

1869	22.
1870	82.
1871	161.

These figures do *not* prove his statement that our numerical strength as a "Society is decreasing, while that of outsiders is increasing;" but the contrary. Mr. Vizer, in his first letter, either ignored, forgot, or did not know of this rapidly increasing class of associates enjoying all the political privileges of members.

I am aware that the *unexamined chemist and druggist* class of members is annually falling off (notwithstanding that there are some thousands who have not yet applied for admission); but this difference, if not already balanced by the increasing number of *associates in business*—the corresponding class of examined men—will be so in another year.

I have not hitherto expressed an opinion one way or the other upon the scheme of fees proposed by Mr. Vizer. Some time ago, one very like it was discussed informally, either at the Council table or in committee, so that the subject has not come upon me altogether *de novo*. Allow me, therefore, to trespass further on your space by stating that I am in favour of making one change at the present time, and *one* only, viz., to increase the fee for the Minor examination to eight guineas, which, with two guineas for the Preliminary as heretofore, would increase the fee for obtaining the certificate of a chemist and druggist to ten guineas in all. I consider that this qualification, being the passport to a business of tangible value, is well worth that sum from a purely mercenary point of view, and that the chemist and druggist of the future ought to contribute in this way, as well as by payment of a yearly subscription, towards the maintenance and extension of the Society, which has literally created him, and from whose efforts and money expenditure he and he *mainly* will reap a decided pecuniary advantage.

It is premature to alter the fees for the Major examination or for the annual subscription. An experience of at least ten years from the passing of the Pharmacy Act, 1868, ought to be gained before dealing with this part of our fiscal arrangements. In my judgment it is *not* the fee which deters larger numbers from presenting themselves for the Major, nor the subscription which prevents *all* our Majors from joining the Society. I am sanguine enough to think that when a sufficient period has elapsed, those youths who have passed a good Preliminary examination before being apprenticed, will, in much greater numbers than now, present themselves for the higher examination, and afterwards enrol themselves in the Society as members.

Michael Carteighe.

* See Pharm. Journ., No. 117, p. 240.
† *Ibid*, No. 114, p. 179.
‡ *Ibid*, No. 119, p. 279.

Sir,—As the question of examination fees is likely to come before the Council at their next meeting, may I, through your Journal, ask for a slight concession to that numerous class of persons who have passed the "Modified."

Doubtless there are many of these men who regard this as merely a temporary qualification, and, when time and opportunity occur, will endeavour to obtain a higher standing in the trade. Now, in order to do this, they are at present compelled to go through the same course and pay the same fees as a beginner, no notice being taken of their connection with the trade.

The concession I ask for is, that when any such person wishes to compete for the Minor, the fee for him shall be one guinea less than that usually charged, being the amount he has already paid to the Society. As our aim ought to be to improve, I ask not any mitigation of the educational test.

Modified.

Too Much Light.

Sir,—The well-known action of light upon tinct. ferri perchlor., and, as all observant chemists know, upon most other preparations, suggests the adoption of some means to prevent so serious an alteration in the constitution of such drugs and preparations as are daily exposed on our shelves to the sun's rays. Bottles made of non-actinic glass might prevent such decomposition; but the objection would be the difficulty of observing the colour and appearance of the contents. No doubt the real cure would be an alteration in our present mode of building pharmacies. Windows should be constructed so as to admit a minimum quantity of light, and the shelves arranged to hold the bottles away from the direct rays of the sun. Modern fashion dictates enormous plate-glass windows, glaring open shops, and a show of as many preparations as possible in large clear glass bottles, so placed as to attract the eyes of passers-by. It is time such fashion changed. Light open shops are the inevitable consequences of combining a profession with trade; and as pharmacy is at present constituted, I fail to see a road out of the dilemma. Allow me to suggest to the secretaries of the Pharmaceutical Conference to include in next year's list of papers one on "The Proper Storage of Drugs and their Preparations."

M. J. Ellwood.

Leominster, September 30th, 1872.

Payment of Fees to Local Secretaries.

Sir,—As a local secretary, allow me, through the medium of your Journal, to thank Mr. Sutton for the motion he brought forward at the meeting of the Pharmaceutical Council, viz., payment of fees to local secretaries who have to superintend the examination of candidates for the Preliminary examination. Personally, I should consider it *infra dig.* to receive any such fees, but if the Society is in that prosperous state as to be able to pay our expenses to London to attend the Anniversary Meeting, I, for one, would hail with pleasure Mr. Hills' proposal.

A Local Secretary.

Pharmaceutical Education.

Sir,—I shall feel obliged if you will allow me to summarize the views which I expressed lately upon the educational question at a meeting of the Bristol Pharmaceutical Association, as they appear somewhat obscured in the report of my observations upon that occasion.

1st. The Legislature having adopted (wisely, as I consider) a lower standard of qualification for pharmaceutists than was proposed by the Society, the educational difficulty is greatly reduced.

2nd. Existing organizations (especially the Science and Art Schools directed from South Kensington under Government auspices) may be made sufficient to meet the educational demands called into existence by recent pharmaceutical legislation.

3rd. The Pharmaceutical Society should continue to promote that higher pharmaceutical education which is essential for the advancement of the science of pharmacy. (Its school might be ultimately restricted to this object by the adoption of a matriculation test representedby the Minor examination).

4th. The time appears to have arrived when some extension of this higher education should be accomplished, say by the establishment of a second Society's College in Edinburgh.

It will be seen that this system would have the effect of terminating the anomaly of the Society educating for the statutory examination which it is appointed to conduct.

Richard W. Giles.

Clifton, Oct. 21st, 1872.

A Dispensing Difficulty.

Sir,—As I cannot dispense the accompanying prescription to my satisfaction, perhaps some of your readers may be willing and able to help me.

T. A. Jeffrey.

Pittville, Cheltenham, Oct. 1st, 1872.

℞. Creasote . . . . . . ♏xx.
Pot. Chlor. . . . . . ℨss.
Rhei Pu. . . . . . . ℨss.
Ft. pil. xx in fol. arg. involv.

They are required to be small, hard, and round, and the full quantity of Creasote must be used.

[*** The addition of one grain of oil of theobroma will have the desired effect, and form a hard, compact mass. In all cases where creasote is ordered in pills along with dry powders, it will be found useful, as creasote and it are miscible. The above will require careful manipulation; on trituration, the oil of theobroma will soon become plastic, but the mass should not come in contact with the warm hand, or the pills be kept in a warm place. The silvering should be done by means of a little thin mucilage, in which the pills should be rolled in a gallipot, so as to get them well moistened and partially dried before placing them upon the silver leaf.—Ed. Pharm. Journ.]

Payment of Dispensers.

Sir,—The following advertisement recently appeared in one of the Birmingham papers:—

"Dispenser wanted, for the Hospital for Women. Salary £20 a year. Hours from 3 till 6 or 7 p.m.—Apply personally from 12 till 3 to Mr. Lawson Tait, 7, Great Charles Street."

I should like to know what sort of qualifications a man would be expected to possess who was to be remunerated with the handsome sum of 1*s*. for four hours' dispensing, exactly 3*d*. an hour!

Are not such things insults to pharmacists at large?

Indeed it seems to me a positive insult to offer an educated man such a salary as any little lad of 15 years old could easily obtain as a porter!

A. P. S.

Birmingham, October 9th, 1872.

T. H.—No.

J. R. C.—The only exception in the Pharmacy Act in favour of veterinary surgeons is that they shall not be prevented from dispensing medicines for animals under their care.

F. Abbott.—The office of the Society is at 9, Conduit Street, W., and the Secretary is Mr. W. R. Cooper.

A. D.—An article on the subject was published in the Pharm. Journ. 2nd series, vol. I. p. 471.

S. P. S.—The reply to your letter had been crowded out with others. Pereira's 'Materia Medica' would answer your purpose.

J. A.—The berry of *Physalis Alkekengi* (Winter Cherry) are said to be diuretic in their action, but are seldom prescribed. They enter into the composition of the Sirop de Rhubarbe Composé of the French Codex, and reduced to powder have been prescribed by Dr. Gendrin in 10 to 30 gram doses as a febrifuge. A bitter principle to which the name physalin has been given, obtained by treating an infusion of the plant with chloroform is described in the 'Journ. Pharm. et de Chimie' [3] xxi. 24. Dr. Wood ('Dispensatory,' p. 1584) says that six to twelve berries or an ounce of the expressed juice may be taken for a dose.

"*A Registered Assistant.*"—'Fair Play' has addressed a letter to the Secretary in which he appears to complain that that gentleman has not noticed in this Journal some previous assertions of the writer's. As complete ignorance exists respecting these assertions, and since '*Registered Assistant*' writes, "I cannot give my address has I am continually traveling," advantage is taken of his statement that he shall see the Journal to ask him what they were and what notice he requires, or whether the present notice will answer his purpose, but no further communications will be noticed unless they are accompanied by the writer's name and address.

A. P. S. (Birmingham)—Your communication was acknowledged at p. 300. You are too hasty in forming your opinions. We are always indebted to correspondents for any communications they may send to us, although in taking them into consideration we are obliged to adopt the ordinary rule, "first come, first served," at the same time having regard to the urgency of the question.

"*Forgetfulness.*"—Recipes for making colours for carboys will be found in vol. I. p. 516 of the present series.

B. P. and "Apprentice."—Apply to the Secretary for a copy of the pamphlet entitled 'Hints to Students.'

E. W. B.—We think not, for, taking the British Pharmacopœia as the law for pharmacists, you will find that rectified spirit is directed to be used for both preparations.

X. Y. Z.—As alum when present in bread is considered to be an adulterant, a baking-powder containing it would probably come under the penalties laid down in the Adulteration Act.

Alpha.—Cooley gives the following recipe for Red Ink:—Brazil wood (ground) 1 oz.; white wine vinegar (hot) 1¼ pint; digest for several hours in glass or well-tinned copper or enamel saucepan, then gently simmer for half an hour, adding towards the end gum arabic and alum of each ½ oz.

J. Leay.—Your letter has been handed to the Secretary.

R. Rees.—See Cooley's 'Cyclopædia of Practical Receipts' under the head "Infusions," and an article by Mr. Grundy in Pharm. Journ., 2nd ser. vol. VI. p. 259.

Communications, Letters, etc., have been received from Mr. Dymond, Mr, C. B. Bell, Mr. C. Umney, Mr. W. A. Powell, Mr. Claypole, Mr. Hodges, Mr. Harrison, Mr. R. W. Fowler, Mr. A. Ellis, Mr. Crampton, Mr. F. Andrews, Mr. R. Brierly, Mr. Lathbury, Mr. Parkin, Mr. G. P. Druce, V. P., W. F. C., A. P., "In Embryo."

THE MICROSCOPE IN PHARMACY.

BY HENRY POCKLINGTON.

(Continued from p. 302.)

SARSÆ RADIX.—The structure of sarsaparilla root differs widely from that of the roots I have hitherto discussed in these papers, where I have dealt chiefly either with roots of true exogens, where the characteristic concentric rings are found disposed round a central medulla (sometimes suppressed), and medullary rays proceeding therefrom; or with tubers, corms and the like, of herbaceous endogens, not possessing any true stem structure at all. But we now have to do with a class of structure which is essentially different from those other structures, and also with a structure which is on the face of it transitional, and unites the features of the other two. The structure of the aërial stem of Smilax is very different from that of the roots and rootlets, and is that (with slight modifications) common to all arborescent endogens. The structure of the root on the other hand, is approximated to that of the aberrant exogens lately mentioned. The chump or rhizoma unites the two classes of structure. In the aërial stem there is no medulla, there are no regular wood-wedges, or concentric rings, and no medullary rays. There is no true bark or separable rind. Whence it follows that the course I laid down early in the present series for the examination of roots and stems, must be supplemented.

In investigating the structure of fully developed endogenous stems (such as those of palms, bamboos, etc.) we shall find it of primary importance to dissect them longitudinally for some considerable distance, that the course of the vascular bundles may be followed as far as possible throughout. In palms, if a "vascular bundle be traced from the point of the insertion of the leaf backward, it is found that it runs in a curve, the convexity upward, to the centre of the stem; then in the neighbourhood of the centre runs down a certain extent deep in the stem, but soon again loses the direction parallel to the axis of the stem, gradually again approaching the surface till it lies beneath the rind, and there passes down the stem beneath it."*

All monocotyledons do not possess identically this same structure. Aloes is a notable instance of variation therefrom, as also the several members of the sub-class Dictyogenæ (Lind), of which Smilax and the easily procured *Tamus communis* are members. In Smilax, according to Henfrey, the bundles do not pass wholly into the leaves, as in palms, but run continuously through the structure. Henfrey also states, erroneously as regards some species at least, that the bundles stand in circles. In other respects, the stem structure of Smilax is endogenous, and examinations of its root and stem must severally partake of the plan recommended in the examination of exogenous stems, and that more applicable to endogenous.

I will take the stems first, as they will not occupy us long, inasmuch as they are not officinal, and it has unfortunately happened that I have not had opportunities of examining any large number of species, and none in a fresh state. It may be as well to remark here that slides of sarsaparilla, as sold by English dealers, are very commonly prepared from the aërial stem, and not from the root.

* Mohl, 'On the Structure of the Palm Stem.'—*Ray Society's Publications.*

My attention was first called to the structure of pharmaceutical botanicals by a "mounter's slide" of *S. syphilitica* given me years since by a west country friend, and found on examination to differ so widely from the usual diagnosis given in botanical books that I commenced an examination of the species. I then prepared one of our British Tamus, and presently concluded that the slide should go with my illustrations of stem, and not of root structure. I mention this lest beginners should be similarly troubled.

I select the stem of Mexican Sarsaparilla for description. The general appearance in cross section is that of a cane or bamboo. The vascular bundles are large and evenly distributed through the stem. In longitudinal section some are seen to proceed from leaf scars, but they run straight and are continuous down the stem as soon as they have assumed a direct course. Three classes of structure enter into the composition of the vascular bundles. First, large pitted vessels with oblong pits. Second, long, thin, walled cells. Third, liber or wood cells. The wood cells are of uniform size, but vary in shape, as seen in cross section, and are very porous. Their length is variable, and often considerable; their diameter about the 1-1000th of an inch. The vascular bundles are more or less circular in cross section, and stain intensely with magenta. A cross section judiciously stained and mounted in balsam forms a pretty object but is not equal to a similar section from the root. The vessels are septate, the septa (sometimes absorbed) are porous. The pitting is various, usually oblong as above stated; it is sometimes in the smaller vessels punctate. Some of the vessels have scalariform markings. The cellular tissue consists of subcylindrical cells containing great quantities of starch in compound granules (two to six) and with an indistinct punctate or radiate hilum. Special cells, apparently not porous, contain bundles of acicular raphides, such as are commonly found in this and some other natural orders.

The structure of the rind need not occupy us now. The connection of the vascular vessels of the stem with the root is not easily made out. In fact, it is a matter of very great difficulty when we have to deal with dried specimens only, and it is further complicated in sarsaparilla by the confused structure of the "chump." We shall better understand it if we dissect the root upward towards the chump, where we shall find that the vessels which surround the central cellular portion gradually spread out and apparently lose themselves amongst the vessels of the rhizoma, but may be traced with care into the stem. The central cellular portion of the root is lost sight of immediately we enter upon the rhizoma, but probably, as Mohl has shown is the case in the palm stem, it "penetrates the fibrous layers of the stem and spreads out on the outer layers of wood bundles."*

The structure of the stems of such other Smilaceæ as I have been able to examine, do not differ from the foregoing so greatly as to render their description desirable in this place, and I will in my next paper proceed to discuss the structure of the roots of the more common commercial varieties, and to describe as well as possible without woodcuts their distinguishing structural peculiarities.

* Mohl adds, "in the form of a disk" but I have not been able to satisfy myself of this in the case of sarsaparilla. One tuberous chump appears to point in this direction.

PEPSIN, BISMUTH AND STRYCHNIA.*

BY R. ROTHER.

(*Concluded from page* 323.)

The writer, adopting the syrup of pepsin acidified with the potassic tartrate as the basis, extended the series by adding the syrup of pepsin and bismuth, and the syrup of pepsin, bismuth and strychnia. Ammonio-bismuthous citrate, dissolved in four times its weight of water, will completely dissolve one-fourth its own weight of acid potassium tartrate. This concentrated solution slowly deposits a fine white powder, which remains suspended a long time after shaking the liquid, and is again readily and completely soluble in ammonia. If, however, only about one-third as much cream of tartar is added as before to a more dilute solution, no separation will occur. The bismuth solution then has an acid reaction similar to the solution of pepsin. A mixture of the two solutions retains its transparency, and acid reaction indefinitely and undisturbed, dissolving strychnia with facility. The syrup of pepsin and bismuth is prepared by macerating 256 grains of saccharated pepsin in 6 or 7 fluid ounces of water in the same manner as for syrup of pepsin, and filtering through cream of tartar. 256 grains of ammonio-bismuthous citrate is dissolved in one or two fluid ounces of water, with the addition of a few grains of cream of tartar, to ensure an acid reaction. This is united with the filtered pepsin solution, the measure, if necessary, made up to 8 fluid ounces, and 12 to 13 troy ounces of sugar dissolved in it, as above directed, without heat. The syrup of pepsin, bismuth and strychnia is prepared in all respects similar to the preceding, with the addition of 4 grains of strychnia to the above quantity. These syrups are permanent, and even when diluted with an equal volume of water containing a little alcohol, and exposed, no degeneration seems to take place in a moderate length of time. Therefore the writer believes that the above proportion of sugar can be advantageously reduced, and the syrup protected by a small proportion of alcohol. When treated with hydrochloric acid, a copious precipitate soon appears. This is again perfectly and permanently soluble in an excess of hydrochloric acid; but when separated from the solution it is insoluble in ammonia; whereas the precipitate, with nitric acid, under the same circumstances, is redissolved by ammonia. 20 grains of citric acid added to 1 fluid ounce of these syrups has no observable effect.

The ammonio-bismuthous citrate, employed in some of these processes, was prepared by a modification of the recent process of Mr. Wood. But the writer considers the proportion of citric acid unnecessarily large. It is also found that the basic nitrate does not yield an oxide of good appearance. This is always of a greyish or light brown colour and sandy character. However, the bismuthous oxychloride is much more easily prepared. Itself a very definite and permanent compound, it yields in every respect a physically superior oxide of a rich lemon-yellow colour. The writer believes that the bismuthous oxychloride and the anhydrous oxide, as well as the simple citrate, should be made officinal. By this change the two indefinite and unstable, difficult and circumstantial, preparations—the basic nitrate and carbonate—would be most completely superseded.

* Reprinted from the 'Pharmacist.'

Herapath has shown that fixed caustic alkali decomposes the insoluble bismuthous arsenate, with separation of pure bismuthous oxide and soluble alkaline arsenate. But the writer has found that bismuthous arsenate (resulting from the presence of arsenic in commercial metallic bismuth) is readily, completely, and abundantly soluble in a neutral or acid solution of ammonium chloride, and that the solution can be diluted to an enormous extent (1 to 7000) before the arsenate is reprecipitated. Therefore, to purify bismuthous oxychloride from contaminating arsenate, wash away the excess of hydrochloric acid resulting from the decomposition of the bismuthous chloride, decant as much water as possible, and to the residuary oxychloride add a moderate quantity of ammonium chloride and a sufficiency of water. After a short time remove the solution and supply a fresh portion. Remove this also, and separate the ammonium chloride complelely by washing. This procedure ensures an oxychloride absolutely free from arsenate, without any difficulty. A dilute alkaline solution readily decomposes the basic nitrate even in the cold, but a concentrated alkali is necessary to decompose the oxychloride. This may be effected by maceration in the cold, but much more rapidly with heat. The writer obtains ammonio-citrate by dissolving powdered metallic bismuth in chlorhydric acid with the application of heat and addition of sufficient nitric acid to oxidize the hydrogen of the hydrochloric acid, as seen in the subjoined equation:—

$$2(Bi)+6(HCl)+2(NO_3H)=2(BiCl_3)+4(OH_2)+N_2O_2$$

The resulting solution of bismuthous chloride is diluted by pouring into it a moderately large volume of water (about 30 of water to 1 of metal), whereby all the bismuth in solution is precipitated as dazzling white oxychloride in a very finely-divided state. The powder is very heavy, and subsides quickly and compactly, and can, therefore, be readily washed by decantation.

The change is explained in the following equation:

$$BiCl_3 + OH_2 = BiClO + 2HCl.$$

After several washings with large volumes of water, the powder is allowed to settle firmly; as much of the water poured off as possible, and to the residue an excess of potassium hydrate is added. The mixture is then boiled a short time, and the resulting yellow oxide washed by decantation.

This oxide is now boiled with acid ammonium citrate, resulting in the formation of normal ammonium salt and insoluble bismuthous citrate; which is then dissolved by a sufficiency of ammonia.

The British solution of ammonio-bismuthous citrate is treble the strength of that used in this country. It contains 3 grains of oxide in the fluid drachm, equal to 6 grains of the double salt. This solution is sufficiently concentrated to keep without the addition of alcohol, and therefore greatly preferable to the weaker solution.

The writer, however, prefers to prepare this salt and its solution directly from the simple citrate. But the methods for its production have heretofore been too troublesome, on account of the bulky magma, in the condition of which these processes always produced it. By the writer's method this is now obtained in a compact, heavy, crystallized form, can be expeditiously washed, and most rapidly and easily dried.

The production of crystallized bismuthous citrate is based upon the fact that it is but sparingly soluble in citric acid, or acid ammonium citrate. If, therefore, citric acid is added to a moderately dilute solution (about thirty of water to one of the oxide) of ammonio-bismuthous citrate, the ammonia is converted into acid salt, and the bismuthous citrate slowly separates in crystals. Rather more than two ounces of citrate are thus produced from one ounce of the oxide. The writer deems this process superior to all others at present known, as by it the metallic citrate can be easily and cheaply made in large quantities, for the preparation of all compounds into which this citrate enters, and, moreover, as it could be more extensively used in medicine directly by supplanting some of the less desirable bismuth salts. This process is rendered practicable by dissolving metallic bismuth in nitric acid, diluting the solution to about thirty times the weight of the metal by adding water, then introducing only the necessary quantity of citric acid to form metallic citrate, and then adding ammonia until a small portion of the precipitate which each addition causes remains undissolved, then set the liquid aside for twenty-four hours, to allow the salt to crystallize. Another small crop of crystals can be obtained by cautiously mixing more ammonia with the mother-liquor; or the ammonia can be first added to the concentrated solution, and then be diluted.

The citrate is readily and completely soluble in ammonia, in nitric and in hydrochloric acid, but separates in granular crystals when the nitric solution is diluted with water. A precipitation results when the hydrochloric solution is diluted, but this precipitate is not the citrate, as it is insoluble in ammonia. In this connection the writer finds it convenient to state that the officinal process for basic bismuthous nitrate does not by any means yield a preparation of the supposed composition. Becker shows that the curdy precipitate produced by adding water to a solution of the normal nitrate is the body which answers to that composition, and that if this be treated with water a much more basic salt is formed. If this be further treated with hot water, a dingy white residue remains, containing only one or two per cent. of nitric acid. The writer finds the best method for producing the medicinal nitrate in the form of a loose crystalline powder is to dilute the solution to about thirty times the weight of the metal, and then adding ammonia so as to leave the liquid slightly acid. After subsiding, the precipitate is transferred to a filter and washed with a moderate amount of water.

Mr. Scheffer considers it impossible to combine bismuth with pepsin in permanent solution. The writer finds that the syrup above prepared is permanent, but cannot vouch for the activity of the pepsin contained in it. That the pepsin originally introduced is still in solution is unquestionably certain, as no precipitation of any character whatever had taken place after the mixture of the two solutions was effected; and that these were of a decided acid reaction before and after the mixing is also a positive certainty; yet with all this, the writer has made the observation that the presence of bismuth utterly vitiates the method of assay by which the power of the simple pepsin solution is ascertained, and in this respect Mr. King is most grievously mistaken.

Mr. King attempts to show that in an alcoholic preparation, in the production of which a certain amount of a questionable quality of pepsin had been used, tbe pepsin could be determined by the amount of coagulated albumen it was capable of dissolving. But Mr. King did not exercise the necessary discretion to judge rightly between albumen actually dissolved and difference of weight caused by shrinkage. To exemplify this, the following experiments will suffice:—Firstly, let it be premised that dissolving albumen never shrinks, but, on the contrary, expands and becomes soft and pulpy as the solution progresses, and that solution results much more rapidly towards the last than in the beginning, because at the outset the albumen is more compact, and presents less surface. To facilitate the solution, and give the pepsin full scope, the writer introduces the albumen not in cubes, but in very thin slices or ribbons.

The writer, in the experiment with syrup of pepsin with little water, found that no apparent action of the pepsin could be observed, but, on the contrary, the albumen had considerably gained in weight, whilst preserving its compactness. But now 6 fluid drachms of syrup of pepsin and bismuth were acidulated with hydrochloric acid in sufficient excess to prevent precipitation, diluted with water to a little over a fluid ounce and 45 grains of coagulated albumen added, and a proper temperature maintained. During a digestion of twelve hours no impression appeared on the albumen. It was then removed, and found to have a hard and compact exterior. It had lost 15 grains of its original weight in opposition to the large presence of syrup. The writer does not hesitate to say that no albumen whatever was dissolved, but the loss was simply caused by the abstraction of water.

$1\frac{1}{2}$ fluid ounces of syrup of pepsin and bismuth was diluted with water to 5 fluid ounces, and acidulated with enough hydrochloric acid to prevent precipitation. 95 grains of albumen in cubes was digested with this for eight hours. A very considerable contraction occurred, but the firm exterior remained unyielding for a long time. The cubes were then crushed with a glass rod. The peculiar tenacity, differing from that of freshly coagulated albumen, was remarkable. The crushed albumen, after at least four hours' digestion, was carefully collected on a strainer, and dried between folds of bibulous paper, weighed 45 grains, showing that the original weight had sustained a loss of 50 grains.

Simultaneously with the preceding experiment, $1\frac{1}{2}$ fluid ounces of syrup of pepsin and bismuth was diluted with water to 4 fluid ounces, and acidulated with hydrochloric acid beyond the limit of precipitation, and 95 grains of coagulated albumen in cubes was digested in it for eight hours without rupturing the cubes. These had the identical appearance of those in the parallel experiment, and weighed exactly the same.

The residue of the first of these two experiments was washed with water, then thoroughly triturated in a mortar, and digested with 6 fluid drachms of acidulated water for four hours; as no change of appearance took place, an unfiltered hydrochloric solution of pepsin, representing 6 grains of saccharated pepsin, was added, and the digestion continued four hours longer. The insoluble residue was then carefully collected on a strainer, the superabundant moisture absorbed with bibulous paper, then scraped up cautiously and weighed. 15 grains out of the 45 was still left. This, however, was a purely white flocculent sediment. When boiled with diluted nitric acid it turned intensely yellow from the formation of xanthoproteic acid; and ammonium sulphide added to the nitric solution produced a voluminous brownish black precipitate of bismuthous sulphide. The moist mass applied to a bright surface of iron or zinc gave a copious black deposit of metallic bismuth. From this it is evident that the residue consisted mainly of bismuth albuminate, probably associated with hydrochloric acid. This result explains that the shrinkage in volume and weight is due to an exterior layer of bismuth albuminate, which, contracting, eliminates the absorbed water of the coagulated albumen, and that the non-action of the pepsin is owing to the immediate seizure of any exposed albuminous surface by the bismuthous chloride, as long as there is any of this salt in the solution. The writer finds that if the syrup of pepsin and bismuth is diluted with water, and the resulting liquid saturated with sodium chloride, the pepsin is completely precipitated. Hence, to assay this preparation by means of coagulated albumen, the bismuth must first be removed as sulphide.

From this accumulation of evidence the writer is convinced that the usual pepsin assay, when applied to solutions containing bismuth, is utterly unreliable.

THE CHEMICAL EFFICIENCY OF SUNLIGHT.*

BY JAMES DEWAR.

Of all the processes proposed to measure varying luminous intensity by means of chemical effects, not one has yet been expressed in strictly dynamical measure. This is owing to the very small amount of energy to be measured necessitating very peculiar processes for its recognition. The chemical actions generally induced by light are of the "trigger" or "relay" description; that is, bear no necessary relation to the power evolved by the transformation. There is one natural action of light, however, of a very different kind, continuously at work in the decomposition of carbonic acid by plants, necessitating a large absorption of energy, and thus enabling us to ascertain the proportion of the radiant power retained, through the chemical syntheses effected.

So far as I am aware, the following passage, extracted from Helmholtz's Lectures "On the Conservation of Energy," delivered at the Royal Institution in 1864, and published in the 'Medical Times and Gazette,' contains the first estimate of the chemical efficiency of sunlight. "Now, we have seen already, that by the life of plants great stores of enegy are collected in the form of combustible matter, and that they are collected under the influence of solar light. I have shown you in the last lecture that some parts of solar light—the so-called chemical rays, the blue and the violet which produce chemical action—are completely absorbed and taken away by the green leaves of plants; and we must suppose that these chemical rays afford that amount of energy which is necessary to decompose again the carbonic acid and water into their elements, to separate the oxygen, to give it back to the atmosphere, and to collect the carbon and hydrogen of the water and carbonic acid in the body of the plant itself. It is not yet possible to show that there exists an accurate equivalent proportion between the power or energy of the solar rays which are absorbed by the green leaves of plants, and the energy which is stored up in the form of chemical force in the interior of the plants. We are not yet able to make so accurate a measurement of both these stores of energy as to be able to show that there is an equivalent proportion. We can only show that the amount of energy which the rays of the sun bring to the earth is completely sufficient to produce such an effect as this chemical effect going on in the plant. I will give you some figures in reference to this. It is found in a piece of cultivated land producing corn or trees; one may reckon per year and per square foot of land 0·036 lb. of carbon to be produced by vegetation. This is the amount of carbon which during one year, on the surface of a square foot in our latitude, can be produced under the influence of solar rays. This quantity, when used as fuel and burnt to produce carbonic acid, gives so much heat that 291 lb. of water could be heated 1° C. Now we know the whole quantity of solar light which comes down to one square foot of terrestrial surface during one second, or one minute, or one year. The whole amount which comes down during a year to one square foot is sufficient to raise the temperature of 430,000 lb. of water 1° C. The amount of heat which can be produced by fuel growing upon one square foot during one year is, as you see from these figures, a very small fraction of the whole amount of solar heat which can be produced by the solar rays. It is only the 1477th part of the whole energy of solar light. It is impossible to determine the quantity of solar heat so accurately that we could detect the loss of so small a fraction as is absorbed by plants and converted into other forms of energy. Therefore, at present, we can only show that the amount of solar heat is sufficient to produce the effects of vegetable life, but we cannot yet prove that this is a complete equivalent ratio." This estimate is, strictly speaking, the mean agricultural efficiency of a given area of land, cultivated as forest; and, considering that active growth only takes place during five months in the year, we may safely adopt $\frac{1}{600}$ of the total energy of sunlight as a fair value of the conserved power, on a given area of the earth's surface in this latitude during the course of the summer. As chlorophyl in one or other of its forms is the substance through which light becomes absorbed and chemical decomposition ensues, it would be interesting to acquire some idea of the storage of power effected by a given area of leaf-surface during the course of a day, and to compare this with the total available energy. Here we are dealing with strictly measurable quantities, provided we could determine the equation of chemical transformation.

Boussingault's recent observations on the amount of carbonic acid decomposed by a given area of green leaf seem to me to afford interesting data for a new determination of the efficiency of sunlight. By experiments made between the month of January and October under the most favourable circumstances in atmospheres rich in CO_2, one square decimetre of leaf was found to decompose in one hour, as a mean, 5·28 cub. centims. of CO_2, and in darkness to evolve during the same period of time 0·33 cub. centims. of CO_2. In other words, one square metre of green surface will decompose in twelve hours of the day 63·36 cub. centims. of CO_2, and produce in twelve hours of the night 3·96 cub. centims. of CO_2.*

This quantity of carbonic acid decomposed does not represent the whole work of sunlight for the time, as water is simultaneously attacked in order to supply the hydrogen of the carbonhydrates. Boussingault, in

* Read before the Royal Society of Edinburgh, May 6, 1872, and printed in the 'Philosophical Magazine.'

* The rate at which the leaf functions is dependent on the luminous intensity. The relative amounts, therefore, of carbonic acid decomposed through the action of the different coloured rays are proportional to their luminous power; and the curve of assimilation is found to follow the curve of Fraunhofer. This proves that the judgment we form of equal luminous impressions is in reality due to equal mechanical effects associated with the different coloured rays. Professor Draper, of New York, in his recent paper "On the Distribution of Heat in the Spectrum," by dividing the spectrum into two portions of equal luminous intensity, obtained identical thermal effects by absorption. This does not prove that each ray has the same total energy, but only that in all probability those at equal distances on either side of the mean wave-length in the normal light-spectrum of the sun are identical.

summing up the general results of his laborious researches on vegetable physiology, says, "Si l'on envisage la vie végétale dans son ensemble, on est convaincu que la feuille est la première étape des glucoses que, plus ou moins modifiés, on trouve répartis dans les diverses parties de l'organisme; que c'est la feuille qui les élabore aux dépens de l'acide carbonique et de l'eau.—*Ann. de Chimie*, tom. xiii. p. 415. The fundamental chemical reaction taking place in the leaf may therefore be represented as follows:—

$$(1)\ CO,O + H_2O = CO,H_2 + O,O$$
$$(2)\ 6(CO.H_2) = C_6H_{12}O_6.$$

In the first equation carbonic acid and water are simultaneously attacked, with the liberation of a volume of oxygen equal to that of the original carbonic acid, together with the formation of a substance having the composition of methylic aldehyde. The second equation represents the condensation of this aldehyde into grape-sugar. The transformation induced in (1) necessitates the absorption of a large amount of energy; and if we neglect the heat evolved in the combination of nascent CO and H_2, which can be shown to be very little, the calculated result is made a maximum; whereas the condensation of (2), being attended with an evolution of heat, diminishes considerably the amount of power required. Happily, Franklin's direct determination of the thermal value of grape-sugar leaves no doubt as to the true equivalent of work done in its formation. Taking the following thermal values, $CO,O = 68,000$, $H_2,O = 68,000$, $C_3H_{12}O_6 = 642,000$, 1 cub. centim. of CO_2 decomposed as in (1) would require 6·06 gramme-units of heat, or its light-equivalent, whereas the complete change into grape sugar of the same amount of carbonic acid requires only 4·78 gramme-units. But, we have seen before, 1 square decimetre of green leaf functions at the rate of 5·28 cub. centims. of carbonic acid assimilated per hour; therefore, $5·28 \times 4·78 = 25·23$ represents the number of gramme-heat units conserved through the absorption of light in the above period of time. Pouillet estimates the mean total solar radiation per square decimetre exposed normally to the sun's rays in or near Paris per hour as 6000 gramme-units, so that $6000 \div 25·23 = \frac{1}{238}$ represents the fraction of the entire energy conserved. The estimate is by no means too great, as Boussingault has shown the leaf may function at twice the above rate for a limited time; and as both sides of the leaf are included in the measurement of the green surface in his memoir, we ought to double the fraction for a leaf exposed perpendicularly to the sun's rays, increasing the above number to the 120th part.

In connection with equation (1), above given, as representing the action of sunlight on the leaf, it is worthy of remark that, supposing the carbonic acid and water equally efficient as absorbing agents of the vibratory energy (although each has a specific absorption for certain qualities of rays), the decomposition of the two compound molecules may take place continuously side by side, owing to the equality of the thermal equivalents of carbonic oxide and hydrogen. We already know, from the laborious researches of Tyndall, how thoroughly aqueous vapour retains thermal radiations; and Janssen has further shown the same substance has a strong absorptive action on the rays of light of low refrangibility (just those rays that are in part selected by chlorophyl), producing the well-known atmospheric lines of the solar spectrum. The presence, therefore, of varying quantities of aqueous vapour in the atmosphere in all probability produces a considerable difference of rate in the decomposition effected by the leaf, and may in fact end in carbonic acid and water being attacked in another ratio than that given as the fundamental equation of decomposition. Thus the same plant in different atmospheric conditions may elaborate different substances.

ODOURS.*

BY M. FERNAND PAPILLON.

The subject of odours, considered in the light of recent discoveries in chemistry and physiology, has been recently discussed in an interesting memoir by M. Fernand Papillon. The paper is too long to be reproduced entire in these pages; we must, therefore, be content with extracting some of its more salient points. In doing so, we shall merely indicate the arguments in the physiological portion, giving to the physical and chemical portion the greater prominence that is in keeping with the object of this Journal.

The seat of the sense of smell is the pituitary membrane which covers the inside of the nostrils. It is a mucous surface in which a certain number of nerves terminate in delicate ramifications, and is kept constantly moist by a liquid which it secretes. The mechanism of smelling appears to consist in the contact of air-borne odoriferous particles with the olfactory nerve; if the passage of air be interrupted, the sensation is not experienced. The sense of smell varies very much in different individuals, being sometimes without any apparent cause absent altogether; in other cases there is insensibility to certain odours, analagous to Daltonism in the sense of sight. A close connection exists between smelling and tasting, and it has been shown that many tastes are the result of a combination of olfactory and gustatory sensations. In reality there are but four primary and radical savours, viz. sour, sweet, salt and bitter; and if a variety of sapid substances be tasted while the nostrils are closed, or while the pituitary membrane is out of order, it will be found that the tongue only perceives these four sensations.

In 1799 Prevost first pointed out that certain odorous substances, both solid and fluid, when placed upon a piece of wet glass or in a saucerful of water, act immediately upon the molecules of the liquid with which they come in contact, and in dispersing them give rise to more or less of a vacuum. In later years, these movements of odorous substances on the surface of liquids, have been studied by M. Liégeois. He found that the majority of these bodies execute various gyratory and other movements analogous to those of camphor upon the surface of water; but that while some, such as benzoic acid, succinic acid, and bitter orange peel comport themselves in an exactly similar manner, the movements of others cease more quickly, since they rapidly become surrounded by an oily medium in which they are imprisoned. It was found necessary to reduce them to powder to produce the same phenomenon. When experimenting upon liquid substances, M. Liégeois saturated very light, spongy and odourless seeds with them, and these when thrown upon water underwent the same movements. From a series of observations, methodically conducted, he came to the conclusion that these movements are not due to a disengagement of gas causing a recoil, but to the separation and rapid diffusion of odorous particles into the body of the water. The phenomenon depends exclusively upon the affinity of fluids for these particles, and also for those of fatty matter. For instance, M. Liégeois found that a drop of oil placed on the surface of water parts with an enormous number of microscopic particles without sensibly diminishing in volume, and that aromatic essences give the same result. However insoluble in water they have an energetic tendency to become diffused through it, and it suffices for water to receive the odorous principle in an extremely delicate proportion to acquire all its perfume. Thus it is that while the flowers are covered with the glistening drops of dew, or after a slight shower, they exhale the sweetest and freshest perfumes. So also in the phenomenon of smelling; the air carries the odorous particles into contact

* Abstracted from a memoir, entitled 'Les Odeurs d'après les Découvertes Récentes de la Chimie et de la Physiologie' (Moniteur Scientifique-Quesneville, xiv. 296 et seq.).

with the moisture of the pituitary membrane, which seizes them, and in the presence of the delicate nerve fibres gives rise to the most varied sensations.

The great diffusibility and divisibility manifested by certain odorous substances is worthy of notice. Ambergris freshly deposited upon a bank spreads a perfume which assists the collector in his search, and the sources of petroleum are to be smelt at a long distance. A single grain of musk will perfume an apartment during a year without sensible loss of weight. Haller records that he preserved for forty years some papers which had been perfumed by one grain of ambergris, and at the end of that time they still retained their odour. He calculated that each inch of surface had been impregnated by $\frac{1}{2691064000}$ of grain of ambergris, which had sufficed to perfume during all that time a layer of air at least a foot in thickness. It is impossible to conceive how small was the actual quantity of the odorous principle present in a given quantity of this air, and such examples are cited by physicists to illustrate the divisibility of matter. The presence of oxygen, as well as of the odorous principle, appear to be the express conditions of the phenomenon of smelling; but whether the oxygen exercises any chemical influence upon the particles, or even whether the sensation is due to a mechanical action or to a decomposition that takes place is not known. In a recent work, Mr. Piesse has shown considerable ingenuity in tracing a harmony of perfumes analogous to that existing between colours and between sounds.

(*To be continued.*)

PRESENTATION TO MR. HAMPSON.

The purpose for which the Chemists' Defence Association was instituted having been fully accomplished, and its labours brought to a successful termination, it was felt by the committee that before the association was finally dissolved, some acknowledgment ought to be made to Mr. Robert Hampson the late honorary secretary, whose unwearied exertions and untiring devotion contributed so materially to its success.

Subscriptions were accordingly solicited from the members, in order that a suitable testimonial might be procured; and sufficient funds having been collected, the committee decided to purchase a silver inkstand, with a gold pen and holder, as being the most appropriate articles for presentation to one whose pen is ever ready in the service of pharmacy, either to advance its interests or defend its cause.

It was originally intended that the presentation should be made to Mr. Hampson at a public meeting of the subscribers, but that being found impracticable, the testimonial was exhibted at the October meeting of the Manchester Chemists' Association, and afterwards forwarded to him, with an address on vellum, as follows:—

"To Robert Hampson, Esq., Pharmaceutical Chemist.

"Dear Sir,—The desire of a Government Department to apply to chemists and druggists vexatious and impracticable regulations upon the storage of poisons, shaped itself into the so-called Pharmacy Bill of 1871.

"Circumstances which need not further be recalled gave a dangerous probability to the passing of the measure, in spite of the indignant protests of those who were most nearly concerned. The largest of the various Defence Associations was fortunate in having you as its honorary secretary. To your earnest, incessant and self-sacrificing labours at this time, the success achieved by our cause was due to a very large extent. We desire to record our sense of the deep obligation thus incurred.

"We know that your action was founded upon a conscientious sense of the responsibilities of our profession, and was supported by an unflinching faith in your principles. Like ourselves, you endorsed the opinion of John Stuart Mill, who says, 'Speaking generally, there is no one so fit to conduct any business, or to determine how or by whom it shall be conducted, as those who are personally interested in it. This principle condemns the interferences, once so common, of the Legislature, or the officers of Government with the ordinary processes of industry.' Like you, we recognize a high sense of individual responsibility as being a better safeguard to the public interest than the addition of penalties to the Statute-book.

"We look back upon our late struggle as being accompanied by much that is for the good of pharmacy, besides the reward of success. The self-reliance of our body was never so fully developed, and many friendships have been established amongst those who worked together for a common cause.

"Will you do us the favour of accepting the accompanying silver inkstand, subscribed for by members of the late Chemists' Defence Association, as a small memento of their friendship and esteem, and as an expression of their gratitude for your great services to their cause.

"Signed on behalf of the late
"Chemists' Defence Association,
"W. S. Brown, *Chairman*,
"W. Wilkinson, *Hon. Secretary*.

"*Manchester, October* 21*st*, 1872."

To which Mr. Hampson sent the following reply:—

"205, *St. John Street Road, E.C.*

"My Dear Sirs,—I feel it very difficult to acknowledge as I wish the expressions of friendship and commendation, much beyond my due, which your very kind address conveys to me, and which I see reflected in the elegant gift accompanying it.

"There was no need for the committee or members of the late Chemists' Defence Association to single me out that they might thus mark the little work I did, when so many laboured for the good cause with an ardour equal to, if not greater, than that which I gave to it.

"But I must confess that I feel deeply your kindness, that I value your esteem, and the tangible memento I receive from you I shall treasure with genuine gratification. The friendships gained during our contention for principle will be to me a life-long pleasure, and have fully repaid any labour expended in the work. I only wish that I had had greater strength to devote to the cause.

"The battle of the 'Poison Regulations' is happily over, and we may fairly congratulate ourselves that we do not wear the trammels of unnecessary legislation. The words of John Stuart Mill, which you so aptly quote, give the pith and significance of the opposition carried on by the Chemists' Defence Associations.

"Now that the needful educational test is required, I believe that pharmacists will be so united as to be able successfully to oppose any interference which detracts from the sense of personal responsibility in the conduct of their business.

"Will you convey to the members of the late Chemists' Defence Association my sincere thanks for their useful gift, and for their many expressions of kindness.

"I am, my dear Sirs,
"Yours faithfully,
"Robert Hampson.

"*October* 24*th*, 1872.

"W. S. Brown, Esq., Chairman,
"W. Wilkinson, Esq., Hon. Secretary of the late Chemists' Defence Association."

On the inkstand the following inscription was engraved:—

"Presented to Mr. Robert Hampson by a few members of the Chemists' Defence Association, in recognition of his services as Hon. Secretary, and their successful result.

"*Manchester, October*, 1872."

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 2, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

IMPORTS OF DRUGS, ETC., IN 1871.

THE much earlier publication of the annual statement of the trade of the United Kingdom with foreign countries and British Possessions for the year 1871, enables us to furnish an abstract of those articles most interesting to the chemist and druggist. But this earlier official publication is attended with some disadvantages, seeing that the return is shorn of many details and figures which were given in former years under the section of "other articles," in which were formerly enumerated the minor drugs and varieties of imports that are now omitted altogether. Thus, in previous years we were able to ascertain the official imports of aloes, annatto, arrowroot, balsams, unenumerated barks, berries, cardamoms, cantharides, cassia fistula, cocculus indicus, cubebs, various extracts, gentian, grains of paradise, miscellaneous medicinal gums, honey, ipecacuanha, jalap, leeches, manna, musk, myrrh, nux vomica, pomatum, quassia, quinine, sarsaparilla, seneka root, senna, mineral waters, and other articles, about which we are now left in the dark. And we consider this omission to enumerate the miscellaneous articles is but a false economy, which deteriorates from the value of the returns for statistical and commercial reference.

However, in the absence of the minor articles, we must be content with the return of the major ones. Glancing at them in the alphabetical order in which they appear, of alkali of various kinds the imports last year were close upon 100,000 cwt., valued at £143,741; bark for tanners' or dyers' use 415,528 lb., value, £166,529; extract of bark, or other vegetable substances, for the same purpose, £29,616 in value; Peruvian bark, 21,043 cwt., valued at £285,976; other sorts of bark, 29,525 cwt., valued at £76,483; sulphur, 935,131 cwt., valued at £303,663; chemical manufactures and products of the value of £851,757, of which Italy sent £353,724, France £203,246, and Germany £149,756; 55,429 cwt. of cochineal was received, valued at £719,624; cutch, 5339 cwt., valued at £111,140; drugs, unenumerated, of the value of £405,096; dyestuff of various kinds, 234,548 cwt., valued at £502,738; and dye-woods, 62,734 cwt., valued at £183,518; extracts, unenumerated, £27,490; farinaceous substances, such as arrowroot, tapioca, etc., to the value of £274,281; gambier, 25,207 tons, valued at £399,955; gums—Arabic, 76,136 cwt., valued at £250,088; lac, of all kinds, 60,665 cwt., value, £348,689; unenumerated gums, 95,426 cwt., value, £324,229; indigo, 106,307 cwt., value, £2,937,224; isinglass, 4266 cwt., value, £72,189; madder, munjeet, and garancine, 277,093 cwt., value, £865,592; myrobalans, 145,450 cwt., value, £100,695; naphtha, crude, 1,985,845 gallons, value, £72,030; Cubic nitre, 1,451,520 cwt., value, £1,131,700; oil nut 31,126 tons, value, £417,067; cocoa-nut oil, 190,492 cwt., value, £357,260; olive oil, 38,281 tons, value, £1,858,779; palm oil, 1,047,882 cwt., value, £1,820,698; seed oil of all kinds, 10,354 tons, value, £404,386; oil and spirit of turpentine, 178,615 cwt., value, £317,877; chemical and essential oils, 530,401 lb., value, £174,916; other oils to the value of £195,093; opium, 591,466 lb., of the value of £596,158, of which 514,860 lb. came from Turkey and Egypt; perfumery unenumerated to the value of £66,710; petroleum, refined and unrefined, value, £614,017; rosin, 736,942 cwt., value, £330,994; safflower, 15,333 cwt., value, £138,808; saltpetre, 329,561 cwt., value, £419,099; sumach, for tanning and dyeing, 16,481 tons, value, £206,617; ginger, raw, 32,723 cwt., value, £70,884; turpentine, rough, 6650 cwt., value, £2,698; valonia, for tanning, 27,999 tons, value, £448,458; wax, 16,736 cwt., value, £99,529.

Glancing from the above aggregate quantities to the imports from special countries, and taking those of the East first, we find that from India there is an increase in the value of unenumerated drugs. The quantity imported last year was of the declared value of £53,309, an increase of more than cent. per cent. in the last five years; for only £16,000 worth was received in 1867, and £29,000 in 1868. The value of the chemical products imported from India in 1871 was a little over £23,000, which is a decline upon the previous two years,—£52,953 having been received in 1869, and £33,620 in 1870, Of cutch, 90,210 tons were received from British India last year against 108,453 tons in 1870. In dye-stuffs there is a large increase, for although indigo keeps steady at about two million cwt. per annum (a little more or less), the unenumerated dye-stuffs imported in 1871, were 75,535 cwt., against 45,690 cwt., in 1870. There is a large decline in the quantity of galls received from India, which amounted to but 1457 cwt. in 1871, whilst in 1869, nearly 29,000 cwt. were received from there. The supply of East India ginger does not fluctuate much, the average import being about 28,000 cwt. Of gums, Arabic is decreasing, only 8548 cwt. were imported in 1871 against 19,178 cwt. in the previous year; but of lac of all kinds, and lac-dye, there is a very large increase shown: the imports in 1871 were 343,224 cwt. against 240,041 in 1870, and in 1867 only 160,239 cwt. were received. In unenumerated gums, there is no great progress shown, 45,000 to 50,000 cwt. being the average imports. The supply of myrobalans, for tanning, varies considerably; last year 98,604 cwt. was received, in 1870 but 29,000 cwt., in 1869, 124,243 cwt. The supply of cocoa-nut oil from India is decreasing rapidly, although that from Ceylon is steadily on the increase. Only 53,228 cwt. of cocoa-nut oil came from British India last year, against 108,403 cwt. in 1870. In seed oil there was shown an enormous increase, 55,737 tons being received in 1871. The demand for safflower appears to be extensive, judging by the import of 130,387 cwt. Saltpetre from India is also on the increase; the receipts last year were 373,198 cwt.

From the Straits settlements, chiefly through Singapore, we received last year 417,012 tons of cutch and gambier; 2612 cwt. of lac of various kinds; 45,214 cwt. of other sorts of gums and resins; 26,897 cwt. of isinglass, and 7475 lb. of essential oils. From Ceylon there came 76,913 lb. of essential oils, valued at £14,398, and 138,141 cwt. of cocoa-nut oil, valued at £257,641. From New South Wales 5565 cwt. of kowri resin was received, the produce of New Zealand, and 31,723 cwt. of cocoa-nut oil from the islands of the Pacific. From New Zealand 82,240 cwt. of kowri gum, valued at £149,287, chiefly used for varnish making, a very large increase on any previous year's export; 1237 cwt. of other gums were also received from that colony. 13,350 cwt. of extract of bark for tanning was received from Canada. From the West India Islands 8542 cwt. of ginger, and 1149 cwt. of wax were received.

This survey shows an aggregate import of articles of the value of £22,500,000, in which the chemist and druggist is more or less interested, and which add largely to the progress and prosperity of our chemical manufactures and other great industries. By a comparison with former years the imports are for the most part progressive; in the supply of very few raw materials is there any decline, the exceptions are perhaps galls, gums, isinglass, liquorice and a few others.

If we glance at the exports of the produce of the United Kingdom we find articles of the following value were sent away last year:—Alkali, £1,747,269; chemical products and preparations, £1,588,763; drugs and medicinal preparations, £720,830; painters' colours and materials, £1,019,243, being a sum of over £5,000,000 in these four enumerated items, independent of the various minor articles, the soap and candle trade, and the enormous home consumption.

SUNDAY CLOSING.

That the rapidly spreading movement in favour of shortening the hours of business in pharmaceutical establishments should originate some doubts and difficulties is only what might be expected. And on page 358, Mr. Slugg, of Manchester, gives utterance to one in his question, "What is meant by Sunday closing"? We believe that it is intended by the advocates of the movement to keep the shop entirely closed, but at the same time to have some one in attendance capable of dispensing or selling medicines when required. Some houses, with a large connection, are obliged always to have an assistant on duty in case of emergency; others have a notice stating at what hours medicine can be obtained, or, as in Edinburgh, where neither proprietor nor assistant resides on the premises, a notice is placed on the door informing the public where the manager or assistant can be found, and medicine obtained. It would be impossible to refuse to dispense or sell medicine on a Sunday, or at any other time, but the great object chemists and druggists should have in view, is to curtail the hours of business by closing their shops altogether on Sundays, and on other days at eight o'clock P.M. By so doing the public would be induced to send for their medicines earlier, as well as to anticipate (where possible) their requirements on a Sunday, and thus shorten the too lengthened hours of work.

THE GOVERNMENT SCIENCE CLASS SCHEME.

A statement made by a "Country Major Associate," in a letter printed on p. 100 of the present volume, that the Science Class Scheme of the Government had only just escaped a collapse, and reiterated in another letter on p. 257, where he also speaks of the Directory as a Blue Book got up to appease "My Lords," has caused Mr. G. F. Schacht and other correspondents to ask upon what authority these assertions are based. We have failed to obtain from "A Country Major Associate" any reply more definite than that he has drawn his inferences from facts that have come under his notice, therefore we think it but fair to give insertion to the following statistics, taken from the official returns in connection with the Science and Art classes, published under sanction of the Privy Council. According to the last Report, the total number of students under instruction in all subjects was 34,435, an increase of 7640 over the number in 1869. In the classes in Chemistry alone, there were, in January, 1871, 5942 students under instruction, whilst in 1869 they numbered 2,261.

The next Evening Meeting of the Pharmaceutical Society will be held on Wednesday next, when a paper on Tincture of Orange Peel will be read by Mr. A. F. Haselden, F.L.S. The chair will be taken at half-past eight.

Provincial Transactions.

NORTHAMPTON CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The first meeting of the winter session of this association was held on October 7th, 1872.

Mr. H. Masters, the President, announced that it had been thought best to alter the name of the association, so that in future it would be called "The Northampton Pharmaceutical Association."

The first business was to arrange the different class nights (the class teachers had been previously elected by ballot), and after some discussion it was agreed that the chemistry class conducted by Mr. F. Branson should meet on Monday; materia medica, Mr. H. Lester, on Thursday; pharmacy, Mr. O. Wallis, on Monday; botany and prescriptions, Mr. G. C. Druce, on Thursday.

The President then requested the Secretary, Mr. Druce, to read the report of the Council for the year just completed:—

"The Council have much pleasure in placing this their first year's report before the members. The satisfactory manner in which the association has been conducted, the estimation in which it is held, and the position it has attained, tend to make it imperative upon all assistants and apprentices in Northampton to become connected with what must necessarily be to them a most useful association.

"Classes have been held twice weekly during the winter, and once in the summer session, with, the Council are pleased to say, a much higher rate of attendance than many similar associations. The classes conducted have been chemistry, botany, materia medica, pharmacy, and during the summer, by the kind aid of the Pharmaceutical Society, they have been enabled to add one on practical chemistry. The Council take this opportunity of thanking the class takers for the efficient manner in which they have carried out their onerous duties; and give notice that they have under consideration a plan, which will be carried out if the funds permit, of giving prizes to the most successful candidates at the Christmas examinations.

"During the year two members have passed the Preliminary and one the Minor examination. The latter passed second in honours, and subsequently obtained the prize of books.

"The Council trust the members will make good use of the circulating library which has been recently formed.

"The Council offer their hearty thanks to the principals for the very liberal aid which they have rendered the association since its commencement, and hope that the general conduct of the association has met with their approval; also for the numerous presents they have received from pharmacists in other towns.

"Finally, the Council, in closing what cannot but be considered a very satisfactory report, have great pleasure in announcing that the association will in future be *self-supporting*. The Council thank most warmly the members for the support and confidence reposed in them."

The balance sheet for the year showed an income of £31. 7*s*. 6*d*. (including a grant of £10 from the Pharmaceutical Society), and an expenditure of £27. 17*s*. 10½*d*., leaving a balance in hand of £3. 9*s*. 7½*d*.

The following gentlemen form the Council for the ensuing year:—President, Mr. H. J. Masters; Vice-President, Mr. C. Hester; Secretary and Treasurer, Mr. G. C. Druce; Messrs. J. Tutton, A. J. Lance and A. Thomas; Librarian, Mr. J. Cross; Assistant Secretary, Mr. E. H. Cooke; Curator, Mr. Chibnall.

The President then delivered an address, in which, after thanking the members for the honour they had conferred upon him by again electing him as their President, he described the progress the association had made in less than twelve months as most gratifying to all who were connected with it, especially to those who had been the chief workers in bringing it to the satisfactory position it had attained. He said that arrangements would be made for nearly every member to fill some office, whereby each would feel that he was of use to the association as well as receiving benefit from it. He trusted the ensuing session would prove even a greater success than the past. He was happy to find that so long as their own resources were sufficient to supply the instruction required, so long would the association be self-supporting. But when it became necessary for them to have higher instruction, then of course they must look elsewhere for aid, and that he hoped they would find in the arrangements made by the Parent Society, when it had settled the now important question of pharmaceutical education. With regard to that question, he thought if the suggestions recently made by Mr. T. B. Groves, of Weymouth, and 'A Local Secretary' in the PHARMACEUTICAL JOURNAL, "that every youth should pass the Preliminary before being bound an apprentice; that he should be compelled to pass the Minor before being allowed to dispense, and the Major before entering business on his own account," were carried out, they would go far to raise the "status" of the trade, and he would be very glad to see them become law, although he himself would be affected by them. Another suggestion made by Mr. Groves he thought would be well for all parties if adopted; and that was, "let every assistant at present employed in dispensing be compelled to pass either the Preliminary, Modified, or Minor examination." The only objection to it that he could see was that Mr. Groves would give too long after the passing of the Act (two or three years), his own opinion being that any assistant, who is at present engaged in dispensing poisons, and could not pass either the Preliminary or Modified, or even the Minor by six months' application, had better for his own sake and the public safety, give up pharmacy and take to some trade where physical abilities are at a greater premium than mental. He then commented upon Professor Attfield's recently expressed views concerning pharmaceutical education, in terms of general approval, and said that it appeared to him that, as the "Minor" is now, only those who pass it in honours are worthy the title of chemists and druggists. He thought persons who could show that they had attended a recognized school for a certain period should be subjected to an entirely different examination to the one for those who could not do so, and, therefore, might be suspected of having been crammed. In reference to Professor Attfield's remark, "that the Bell Scholarships do good to all other professions except our own," the speaker asked would it not then be making a great stride in the right direction, if the Pharmaceutical Society engaged some of the Bell scholars to lecture in the provinces at schools like their own, where they would be only too happy to receive them, and pay for the instruction as far as they could afford? One lecture a month only would greatly assist provincial schools, would not be putting the Society to a very great expense, and pharmacy would retain some of her best talent which would otherwise be lost; besides the schools paying part of the expenses that would by that plan be incurred. He believed every chemist employing an assistant would also help, so that the expense to the Pharmaceutical Society would be scarcely anything appreciable except in small towns. He could not agree with Professor Redwood that the interest of the public seems to demand that there should be to some extent a gradation of qualifications amongst chemists and druggists. Surely the interests of the public would be better considered if the law compelled every one who had a shop for the dispensing of medicines to possess abilities of a certain standard, and that should not, in his opinion, be less than the "Major" qualification; there would be then quite sufficient gradation in men's natural abilities to suit the different conditions under which businesses are conducted. Besides, it seemed only fair to those who had gone to the expense and trouble of passing the Major examination that none but "Major" men should be able to open a *dispensing* establishment.

After the address a long and animated discussion took place. The points to which opposition was principally raised were a compulsory Major examination, and that part relating to the enforced passing of the Preliminary, Modified, or Minor examination by assistants at present in business before being qualified to dispense. The suggestion made that a candidate should be admitted to a shorter and different examination upon proving he had attended the classes of a school of pharmacy for a certain time, also met with disapproval.

The officers of the association having returned thanks for their election, the meeting terminated.

It is very gratifying to find that, with the exception of three, all the assistants and apprentices in Northampton have joined the association.

HULL CHEMISTS' ASSOCIATION.

The fourth winter course of lectures, under the auspices of the above association, was inaugurated on Wednesday evening, the 16th ultimo, at the Society's room at the Church Institute, Albion Street, by the Vice-President, Mr. Anthony Smith, who delivered the following address:—

In the absence of the President of the Hull Chemists' Association, the duty devolves upon me to open the fourth course of lectures on chemistry, materia medica, etc., which we have provided for you. It is a source of great gratification to myself and fellow-committeemen to be able to congratulate you on the very bright prospects the coming session presents. We have been fortunate, as you are aware, in securing the services of a gentleman as lecturer, who not only is possessed of great ability—as his position on the list of the successful candidates at a recent Major examination of the Pharmaceutical Society will show—but is enabled to impart to you a class of teaching which has the strong recommendation of being modern; and as fashion, even in education, is varying, the more recently the lecturer has been before the Board of Examiners, before which ere long you are destined to appear, the better chance he has of successfully instructing you. Far be it from me to infer for a moment that the gentleman who has been kind enough to place his services at our disposal for the three past sessions lacked either the qualification or disposition to impart the class of instruction which it is our great anxiety you should receive; his urgent professional duties alone have induced us to look elsewhere for assistance, and my estimate of human nature is very inaccurate if you do not find in your teacher Mr. Parson an earnest tutor and a friend. The prospects of those who are serving their apprenticeship, never since the business of chemist and druggist was established could present a more encouraging future; the number entering the trade will be reduced at such a ratio that the great competition of the present day that we are now contending against will gradually decline, and you will reap the benefit of the little extra compulsory studying to which you must necessarily give your attention. With the Pharmacy Act of 1868, in its entirety I do not agree, but of the educational part I am an enthusiastic admirer; it will not only raise your social status, but will prevent a class of men elbowing their way into the trade and styling themselves chemists and druggists, who know nothing of chemistry and little of pharmacy, and who sometimes have amassed large fortunes, whilst their more legitimate opponent has probably died comparatively poor. Though the result I have referred to may not become very apparent during the next fifteen or twenty years, I doubt not, when most of us now in business have passed from the commercial arena and you are in your business prime, it will have developed itself. If you require something to stimulate you to devote attention to these lectures, which it is our earnest hope you will give to them, let the success in life which I have referred to as being in store for you be the great incentive. With the exception of a few other large towns in the kingdom, apprentices have not the opportunity offered them of receiving the instruction we are enabled to provide for you, consequently I hope that you will not only be punctual in attendance, but most assiduous in your studies; and though there may be some amongst you to whom it is less easy to learn than to others, I will add, by way of encouragement to them, "the race is not always to the swift, or the battle to the strong," and in the friendly rivalry that will naturally be generated amongst you, I ask you all to take for your motto "Labor omnia vincit," or, like Julius Cæsar, rise to the summit of your ambition by being actuated by the spirit he termed "Incredibilia industria." Should any neglect to take advantage of the facilities offered by us, and then fail before a Board of Examiners, it will be useless their looking for sympathy, as their own negligence will have brought about their discomfiture, and they will occupy a situation similar to the man who, having murdered both his father and his mother, appealed to the court for mercy on the ground that he was an orphan. It is our intention as usual to offer Senior and Junior prizes in both chemistry and materia medica, and the earnest wish of the committee will be that the most deserving man may win, and that the unsuccessful will take courage from the thought that our hand has aided them in every struggle, and our heart sympathized in every care.

Mr. Parson then addressed the students, intimating his desire to be of use to them, and for them to look upon him more as a friend than a teacher, and trusted that at the close of the session there would be but one feeling, that he had done his utmost to teach them and they to learn.

Mr. C. B. Bell addressed to them a few words of encouragement, and pointed out the necessity of regularity of attendance and attention to their teacher, and concluded by proposing a most cordial vote of thanks to Mr. Smith for delivering the inaugural address, which was seconded by Mr. Parson, and carried amidst applause.

The Committee of the Hull Chemists' Association have announced that a winter course of twenty-six lectures, comprising elementary chemistry, materia medica, pharmacy, etc., will be delivered by Mr. H. J. Parson, in the Society's Room, at the Church Institute, Albion Street, on Wednesday evening, October 16th, at 8.15 precisely, and continued weekly at the same place and hour. Fee for the course, £1. 1*s*., due in advance. Intending students are requested to send in their names as early as convenient to the honorary secretary, Mr. C. B. Bell, who will furnish further information if required. The course of instruction will have special reference to the requirements of the Minor examination of the Pharmaceutical Society, which it is now incumbent on all chemists and druggists to pass before commencing or taking charge of a business.

At the close of the session it is intended to offer four prizes for competition, viz., senior and junior materia medica and pharmacy, and senior and junior chemistry.

LEEDS CHEMISTS' ASSOCIATION.

The tenth annual meeting of the Leeds Chemists' Association was held on October 22nd, when a company of 120 persons, composed chiefly of members, associates and other chemists and druggists partook of a substantial tea at the Trevelyan Hotel. After the tables had been cleared, the President, Mr. Edward Brown, took the chair, and called upon the Hon. Secretary, Mr. E. Yewdall, to read the Report of the Committee. The

Report expressed regret that the number of members had decreased during the past year, whilst a still larger decrease had occurred in the list of associates. At the meetings of the association, the following subjects had been introduced, viz., an Inaugural Address, by the President; Early Closing and Retail Prices, by Mr. W. Smeeton; A Retrospective Glance at Our Trade, by Mr. T. B. Stead; Dr. Black, and the Chemistry of His Time, by Mr. E. Thompson; The Germ Theory, by Mr. James Abbott; Oxidation, by Mr. S. Jefferson, F.C.S.; Provincial Education, and the Duties of the Pharmaceutical Society thereto. The attendance had varied, being sometimes numerous, and at others it had been but scanty. In the early part of the session, the committee were enabled to offer a series of prizes for the best essay upon each of the following subjects: Cinchona Barks, their history, preparations and derivatives; Iron, its officinal and non-officinal preparations; Rhubarb, its history and preparations; Magnesia, and its officinal preparations. There was a fair amount of competition excited amongst the associates, and Mr. Schacht, of Clifton, was so kind as to adjudicate upon the merits of the respective essays. The valuable additions of books to the society's library during the year were named, being chiefly due to a grant from the Council of the Pharmaceutical Society, and to a valuable donation of Gmelin's 'Handbook of Chemistry,' from Mr. T. Harvey. The financial statement of the Treasurer was read, showing a balance of £15. 14*s.* 4*d.* in favour of the association.

Mr. Smeeton moved the adoption of the Report, and urged upon young men to avail themselves fully of the advantages offered to them by the society.

Mr. S. Taylor seconded the motion, which was carried.

Mr. E. Thompson moved, and Mr. Horsfield seconded, a vote of thanks to those gentlemen who had contributed papers or donations of any kind during the past year.

Mr. R. Reynold proposed the thanks of the meeting to the retiring officers, which was seconded by Mr. Duckenfield.

The election of officers for the ensuing year having been conducted by ballot, it was announced that the following was the result:—

President, Mr. E. Brown; Vice President, Mr. S. Taylor; Curator, Mr. S. E. Payne; Librarian, Mr. G. S. Highmore; Honorary Secretary, Mr. E. Yewdall; Committee, Messrs. T. Day, Mr. W. Smeeton, R. Reynolds, F.C.S., Geo. Ward, F.C.S., T. B. Stead, and E. Thompson.

The President alluded in suitable terms to the pleasure which it gave him to welcome two gentlemen representing the Chemists' Association of a neighbouring town, viz., Messrs. F. M. Rimmington and R. Parkinson, Ph.D., from Bradford. He congratulated the association upon the very large attendance at that meeting, and urged all who had not yet joined their ranks to do so without delay. He also gave some excellent advice to the younger portion of the meeting.

Mr. Rimmington expressed his pleasure in being present upon that occasion. He could cordially endorse the advice of the President upon self-help. Even when the advantages of a chemist's apprentice were much inferior to what they now were, he could state from personal experience that the determination to use those means thoroughly, would lay up a store of information that was afterwards of great value. He had found this valuable information by making the best of his opportunities of studying Paris's 'Pharmacologia' and Brande's 'Chemistry.' This self-help, fortified, and directed by the opportunities for class-instruction afforded by most large towns, would give a foundation for the higher training offered by the School of Pharmacy at Bloomsbury Square. Mr. Rimmington referred to the present position of state medicine as a reason for pharmacists asserting their fitness and claims for the functions of analysts.

Dr. Parkinson spoke chiefly upon the subject of the forthcoming meeting of the British Pharmaceutical Conference at Bradford in 1873. The chemists of that town were taking such steps for organization as they hoped would ensure for the Conference a true Yorkshire welcome. One feature of this ought to be a very large addition of names to the roll of its members from all parts of the county, and especially from the West Riding. Now that its members received so ample a *quid pro quo* in the Year Book of Pharmacy, self-interest alone would dictate immediate membership of the Conference, in order to receive the new volume of the Year Book, which might be expected in the course of a few weeks.

The following were duly proposed and elected members: Messrs. E. Hollings and J. W. Longley; Associates: Messrs. Barraclough. E. O. Brown, Clough, Downing, Drake, Fisher, Forfitt, Greaves, Harrison, Kilner, Knowles, Laycock, Leete, Linscott, McTannet, Pearson, Scott, and Sunderland.

A cordial vote of thanks to the President terminated this pleasant and successful gathering.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL ASSOCIATION.

The first general monthly meeting for the winter session was held in the Rooms on Wednesday evening, October 23rd; Mr. H. Horncastle, vice-president, in the chair.

The opening address was delivered by the President, Mr. W. V. Radley, as follows:—

Gentlemen,—Since the formation of this association it has been the custom for its president, at the commencement of the winter session, to make a few introductory remarks, and in conformity with this regulation I appear before you on the present occasion.

If my observations should seem too discursive or commonplace, I trust you will give me credit for sincerity of purpose, and peradventure in some mind, at least, a stimulus to thought and action may be given, which hereafter may result in personal advantage.

Allow me, in the first place to remark that no business presents so many reasons for union of effort and interchange of thought and opinion, as that of a chemist and druggist. There are great and varied interests to promote, uphold, and defend; there is further the most watchful vigilance required in reference to propositions yearly coming before Parliament, as well as to the Acts of our Legislature which have already become law, for which, as in times past, so also in the future, it is well to be prepared by a strong trade organization. Also, the altered position of our apprentices and assistants, renders it needful that those who have the responsibility of masters, should take counsel together and unitedly adopt the best means to secure their advancement in those branches of knowledge which it is imperative they should study. To this end, an agreement to shorten the hours of business seems to me a desirable thing for all parties concerned, and I cannot see any valid reason why uniformity throughout the town should not be sought.

Not only the wide-spreading progress of education in general, but the rapid advances which are taking place in chemistry, pharmacy, therapeutics, and the allied arts and sciences, should, I think, stir us all up to activity, and lead us to recognize the absolute necessity of using every means within our reach to keep abreast of the times, and maintain a leading position amidst the growing intelligence of the age. I may say, without fear of contradiction, that no other business has undergone greater changes during the last twenty years than that to which it is our privilege to belong.

The objects contemplated at the formation of our association are still as pressing, important, and desirable as ever; and although we cannot congratulate ourselves on the attainment of all we set before us, yet we have some degree of satisfaction arising from the fact of having attempted to do good, and help forward a better state of things; the general feeling of mutual esteem and respect which has been enkindled amongst us as a body, and also the number of our young men who have successfully passed the Preliminary, Minor, and Modified examinations aided by this association, are the silver linings to any discouraging clouds that may occasionally darken our horizon.

Time passes on apace, and leaves its mark behind. Great will be the consolation to those who have during a long period freely contributed both time and money for the purpose of defending the trade from injurious legislation, and raising the educational and scientific status of chemists and druggists, to find that as they have to retire from the more active duties of life, their places are taken up and more efficiently occupied by the younger members of the trade; it is to those who have passed the required examinations that we look for a vigorous maintenance of the good work which we have inaugurated. I hold that it is the duty and interest of all registered chemists in this town and neighbourhood to rally round the standard of this association, but more especially do I think it incumbent on the junior men to come forward and throw their energies and intellect into its operations.

The greatly advanced prices of chemicals, and indeed of most articles in which we deal, together with the increased cost of all kinds of labour and merchandise, have, no doubt, produced in many of your minds a strong argument for raising in self-defence our scale of charges. Perhaps we are not yet sufficiently united throughout the town to attempt a local price-list, such as obtains in the midland counties and some other parts of the country; yet the necessity being so pressing, I hope it may not be too much to ask and expect that each of our members will endeavour in every possible way to accomplish this desirable object. Thus our mutual endeavours financially will tend to strengthen our feeling of union; and the small subscription we contribute will yield us far better interest than any other investment we can find.

Allow me to draw your attention for a moment to the Pharmaceutical Society and its Benevolent Fund. Whatever views any gentleman may entertain respecting one or more clauses of the Pharmacy Act, it must be regarded and treated as a reality more or less affecting every one of us. It seems to me, therefore, very desirable that country chemists in great numbers should obtain membership in that Society, in order to have a vote in the election of Council, and also a right to take part in the proceedings of its annual meeting. Politically, we find men regard it as a very important thing to have a vote for a member of Parliament or town councillor, and will frequently subscribe large sums of money to promote the opinions of a party in which their personal interests are very remote; but how much more important is it to the chemist that he should be able to exert a direct influence on questions continually cropping up which affect him personally to a very serious extent! The outlay is but small when we deduct from the annual subscription the price of the Journal, which all should possess, for it is a kind of microcosm, embracing in its pages a synopsis of the thousand-and-one things with which it is necessary every man engaged in the business should be familiar. Besides, each member is entitled to a vote for annuitants on the Benevolent Fund. The objects of this fund are so good and its charities so beneficent that, amidst the differences of opinion on other matters, I have never heard a word of censure or disparagement of the operations of this noble institution; its advantages are not confined to members of the Pharmaceutical Society (as we have in this town a proof), but its sympathies embrace the whole trade; and wherever a case of destitution and distress is found worthy of commiseration, it is proposed as far as possible to administer succour and relief. The benefits of the fund are available also for the widow and orphan.

I am happy to be able to congratulate you that we have had no reappearance of the obnoxious Poisons Bill, which last year gave us so much trouble; but in consequence of the numerous cases of criminal poisoning by vermin killers which have taken place, and the continued complaints and threats of coroners from various parts of the kingdom, the subject has been brought before, and fully discussed by, the Council of the Pharmaceutical Society, and it recommends that all vermin killers containing poison in No. 1 schedule shall be sold under the same regulations as apply to the articles named in No. 1. This will entail considerable additional trouble on chemists in registration, and probably do away with the sale of the smaller-sized packets; but it is hoped this recommendation will be duly observed, lest those in authority should have a pretext to visit us with a more stringent law.

During the last Parliamentary session a new Juries Bill was brought forward, which, on the one hand, excited the hopes of the chemist and druggist that he might be privileged with exemption from service; and, on the other, the fears of the pharmaceutical chemist lest his freedom should be curtailed; in consequence of the press of other business the Bill was withdrawn, but in all probability it will reappear next session. Both parties will do well to keep an eye on this movement. The Adulteration Act is one of the measures of the last Parliamentary Session, and as drugs are included in its range, it may be regarded as of considerable importance to us. Very much depends upon the mode and spirit in which it is administered; if judiciously, we may hope for good results both to ourselves and the public; if otherwise, it may be made the occasion of much vexation, annoyance and expense. I have not a word to say on behalf of the man who willfully stoops to the adulteration of medicines, on the proper action of which perchance a human life may depend. The practice where it obtains is reprehensible in the highest degree, and merits not only our contempt, but any penalty the law may inflict; however, it is well known by those who have had an opportunity of forming a correct judgment, that for many years past there has been a steady improvement in the quality of drugs, etc., sold by chemists, and at no former period was there displayed amongst us a higher tone of sound moral principle in trading. An ambiguity in the wording of this Act in reference to one of the needful qualifications of the analyst, occasioned some uneasiness amongst chemists, but through the prompt action of the Pharmaceutical Council in obtaining the opinions of the Attorney-General, the Solicitor General and Mr. Langley, all doubt and uncertainty must be for ever set at rest.

I would now call your attention to one clause of the Pharmacy Act (viz. the 16th), which has, I think, been misunderstood, and, I am told, been the occasion of much anxiety and pecuniary loss to certain widows whose husbands have died intestate. It has been supposed that in such a case a widow cannot carry on the business, not even with a legally qualified assistant, but is bound to dispose of it at any sacrifice. Now, what I wish to say is this, a widow may take out letters of administration to her late husband's estate, and thus come within the provisions of the law, and who is there to say when her office ceases? If so, who is there to prosecute? I think I may speak confidently of the Council of the Pharmaceutical Society, that not a man of it would take such a step, and I doubt if any one else could do it. This view of the case has, I confess, been a relief to my own mind, and I offer the same to your notice.

In my intercourse with the members of this association, I have frequently heard murmurings that the Pharmaceutical Society had not taken active steps to enforce the Pharmacy Act, by more frequently prosecuting persons who, to such an injurious extent, are illegally retailing poisons. Perhaps it would not have been quite dignified or liberal to have shown hot haste in bringing offenders under the lash of the law; but now, after so long forbearance, the time for action seems to have arrived, and I believe the authorities in Bloomsbury Square are prepared (after giving due warning) to take up and prosecute any clear case of infringement of the law. It rests with those who feel aggrieved to make and substantiate their complaint.

I am sure you would think this address incomplete, were I to omit to mention the subject of provincial education, which for years past has been of absorbing interest to us. I think you will agree with me when I remark that the leading idea in the formation of this association was not personal advantage to ourselves as masters, but that we might thereby afford increased facilities to our young men in the acquisition of suitable knowledge, to enable them to pass the examinations required by the Pharmacy Act, and get a fair start in that progressive course of acquirement to which a higher education leads. Our desire was to emulate and further the aims of the metropolitan school; like that establishment, we soon found the need of a little subsidiary aid, and should have been glad of a few crumbs from the rich man's table That, however, was denied us; our lectures in consequence had to be suspended, and our youth, to a great extent, left to seek preparation at the hands of grinders. It was not to be expected that the young men would all at once realize their new position, and all take advantage of our arrangements. Although for a time thwarted in our purposes, yet we still indulge the hope that in a few years we shall again be able to resume our classes, and lay a suitable foundation for a noble superstructure of sound knowledge, which shall in part remedy that system of cram which is so much complained of in high quarters.

In conclusion, I desire to congratulate my young friends on the movement which they have set on foot for mutual instruction and improvement; let me assure them it will yield the Council the highest satisfaction to render them assistance, and any suggestions they may make from time to time will have the most careful and favourable consideration. Let me advise you in the pursuit of knowledge to be careful to lay the foundations broad and deep, get firmly implanted in your minds the elementary principles of the things you study, try to understand the rudiments of science, cultivate habits of observation and patient research. Do not carelessly pass over the difficulties that present themselves, but seek to get at the philosophy of common things, aim at discharging all your duties in the best manner possible, and then the feeling of drudgery will give place to that of pleasurable interest. I hope none of you will look forward to passing the examinations as the *summum bonum* of your career, as the goal at which you may rest, but that you will consider them as only the portals to a still wider sphere of attainment and usefulness, honourable alike to yourselves and your profession. Let me commend to your careful perusal and study the address of Mr. Stoddart given to the students at Bloomsbury Square on the 2nd of the present month; it is rich in wise counsel, and fraught with valuable instruction, to which you will do well to take heed.

I think I cannot better close than by reminding you of the lectures that are kindly promised during the coming winter; the ability of the lecturers, as well as the interesting subjects chosen, ought surely to command a numerous audience.

An interesting discussion followed on various subjects remarked upon by the President; after which a vote of thanks, proposed by Mr. E. Wilson, and seconded by Mr. Horncastle, was unanimously accorded to Mr. Radley for his able and comprehensive address.

Several specimens of new medicines, etc., were placed on the table for inspection, for which the contributors were duly thanked.

Proceedings of Scientific Societies.

AMERICAN PHARMACEUTICAL ASSOCIATION.

(*Concluded from p.* 317.)

The fourth session was held on Thursday morning.

Mr. O. Eberbach, of Ann Arbor, Michigan, read a paper on elixirs, in answer to a query in which he gave the results of a number of examinations of various elixirs in market, showing quite a diversity in the medicinal values of elixirs called by the same name, but prepared by different manufacturers. After detailing his experiments, he suggested the following formulæ:—

SIMPLE ELIXIR.

Fresh orange-peel	120 grains.
Star anise	30 „
Cardamom	20 „
Alcohol	
Water, each	6 ounces percolate.
Simple syrup	6 ounces.
Caramel	10 grains.
Mix.	

ELIXIR OF CALISAYA.

Unbleached alkaloids of cinchona	48 grains.
Citric acid	12½ „
Simple elixir	16 ounces.
Mix.	

FERRATED ELIXIR OF CALISAYA.

Elixir calisaya	16 ounces.
Pyrophosphate iron	128 grains.
Mix.	

FERRATED ELIXIR OF CALISAYA WITH STRYCHNIA.

Ferrated elixir calisaya	16 ounces.
Sulphate strychnia	2 grains.
Mix.	

FERRATED ELIXIR OF GENTIAN.

Gentian root, liquorice root, each	1 ounce.
Fresh orange-peel	120 grains.
Star anise	30 „
Cardamom	20 „
Alcohol, water, syrup, of each	6 ounces.
Pyrophosphate iron	128 grains.
Mix.	

ELIXIR OF VALERIANATE OF AMMONIA.

Valerianate of ammonia	256 grains.
Simple elixir	16 ounces.

Water of ammonia to neutralize the acid.

After the paper was read a discussion occurred upon it, and the views and feelings of members were freely expressed. The annoyance of the many various manufactures in the market, and that medical men will one day designate one manufacturer, and at another time some other maker will be preferred, obliging pharmacists to keep a great variety of the same professed article, was alluded to, and the members described their modes of meeting this trouble.

Dr. Squibb stated that he opposed the whole class of elixirs as wrong in principle and practice. It presupposed a "case" for which a certain formula was devised, a popular name is now given to it, and the elixir is to be the cure-all for all ages, classes and conditions.

Professor Moore said that he kept no elixirs but those of his own make, and dispensed them invariably when elixirs were ordered, no matter what name might be designated.

Mr. Shinn thought that the intention of the physician should be regarded and his views carried out.

Mr. Hancock said he kept all the different manufacturers' elixirs, and dispensed which ever kind was directed, believing if he followed the direction of the physician he had done his duty in the matter.

Dr. Squibb said every man was a law to himself, and no man could lay down absolute laws to which all could be expected to conform. The physician was a law to himself, and if he chose to order things of a certain manufacture because he had confidence in their character, he had a right to do so. If the pharmacist thinks he can produce an article as good or better than that specified, let him show it to the physician and persuade him to use it, but otherwise he should give the kind ordered.

Mr. Procter said, to him the case was very plain; the prescription designated a certain article of a certain make; the pharmacist's duty was to give that and no other; adhere to the prescription or decline to prepare it.

A special session was held on Thursday afternoon.

A volunteer paper by Mr. B. Lillard, of Nashville, Tenn., on the "Culture of the Poppy and Production of Opium in Tennessee," stated that imported seed was planted in the spring of 1871 with good success, large and vigorous plants being the result, while the flowers and capsules were unusually large. The seed is sown about the same time as oats, in soil prepared as for cotton. It is planted in drills, the young plants are thinned out to from four to six inches apart, and cultivated similarly to cotton. Soon after the flowers drop off (this year it occurred in June), the capsules are cut horizontally *on one side*, early in the morning. (The knife used resembles a cupping lancet.) The milky exudation coagulates rapidly—becoming first pale red, and then a rich brown soft mass. The next morning it is scraped off and dried in the sun, and the following morning the other side of the capsule is similarly scarified. Great care must be taken that the knife does not penetrate the capsule, destroying the production not only of the opium, but also of the seed. By this process a yield of opium was obtained averaging from thirty to fifty pounds per acre.

The opium shown with the paper was of a smooth texture, tenacious, firm, dark brown colour, rich odour (resembling the odour of Egyptian opium).

An analysis of the opium gave 17 per cent. of moisture, 11 per cent. of insoluble matter, and 10 per cent. of alkaloids.

Mr. George C. Close sent a paper on "Japan Wax," in which he stated that it presents no advantages over beeswax for pharmaceutical purposes.

Professor Maisch read an exhaustive paper on the "Cantharis in all its Species," with especial reference to the vesicating properties of the Chinese variety lately introduced. Having examined them for the purpose of determining the amount of cantharidin they yield, he compared it with the published results of those who have examined the ordinary cantharis in use, and states that the yield in his experiments were two and a half times greater than the previous records, and nearly twice (1·78) as much as the best yield heretofore recorded. He has not finished his examinations, but expects to report further next year.

A paper by Professor Edward Parrish, on the preliminary education for young men who expect to qualify themselves for the business of druggist and pharmacist, and what preliminary examination, if any, should be required by the Colleges of Pharmacy, was read by Mr. William Procter, jun. This paper was one of exceeding interest, especially at this time, owing to the agitation of this question, both in the United States and abroad. It is felt to be a fact patent to all, that there is much room for improvement in many of the pharmaceutists of the present age, while many of the young men who are aspirants for the calling are unfit for it. The true remedy is preliminary education, and sooner or later the colleges of pharmacy must compel a preliminary examination before admitting students to their lectures.

A paper by Charles W. Grassly, of Chicago, Ill., on "Seidlitz Powders," and how far those in the market agree in quantity and quality with the formula of the U. S. P., was read by W. Procter, jun. The paper created no little merriment by some of its personal allusions and sarcastic remarks, and disclosed the fact that (in many cases intentionally—in most cases from want of proper care), nearly all the samples of seidlitz powders examined, fall below the weight of the U. S. P. standard. It was stated that in the majority of stores the powders are put up by measures which are inaccurate, or soon become so. Even with the most careful persons, it is impossible to fill these measures uniformly, and if the measures were originally correct, they soon, by attrition, wear away and lose their accuracy. Weighing, and giving just weight, was, therefore, the only remedy. Another source of error in measuring is, that various lots of seidlitz mixture may vary a little, owing either to fineness of powder, moisture, or compactness of the powder. No ingredients were found as adulterants. It was stated in the discussion that in London many years ago, under the name of "Improved Seidlitz Powders," it was customary with certain stores to add one grain of tartar emetic to each box of powders, and that in a very few stores in this country the same practice was observed.

Dr. Squibb read an exceedingly interesting volunteer paper on "A Modified Process of Percolation," which had been perfected by his son. Without an illustration it would be useless to attempt to explain it in the brief space at our command. We can only state the percolator is simply a jar of glass, conical-shaped, and supported by a foot, without any opening at the lower extremity. The material having been previously brought to the proper state of fineness, is moistened and placed in the percolator, which has been previously prepared as follows: a glass tube a little longer than the interior height of the percolator, and about half an inch internal diameter, has tied over the lower end a piece of filtering paper and muslin cloth. A glass tube of 1-16th inch internal diameter of sufficient length is bent twice at right angles, having one leg as long as the larger tube, a connecting length a little longer than the upper diameter of the percolator, and the other leg is to be long enough to bend up the lower end about half an inch or so, and leave the two legs of the siphon thus formed of an equal length, so that it forms a self-supplying siphon. The plain leg of the siphon has a narrow piece of india-rubber tubing around it at the lower end, so that it will fit quite loosely in the larger tube; while near the upper part of the same leg, rubber tubing has been slipped upon it to keep it firmly in its place when in use. The material being now within the jar, it may be covered with the menstruum, when the denser liquid which percolates the mass will filter through the paper and cloth into the interior of the larger glass tube, and finally find its level. When maceration has been continued long enough, the siphon tube is introduced, and the flow is induced by suction. As soon as the flow is established, the siphon is raised in the tube nearly to the upper portion of the liquid, and after the first few minutes the flow should only be by drops.

At the fifth Session, held on Friday morning, it having been reported that an album containing one hundred and forty-four portraits of members of the Association had been obtained, a resolution was passed authorizing the Secretary to take charge of it, and also the album presented by Mr. H. B. Brady on behalf of the British Pharmaceutical Conference. Directions were also given that they should be produced at future meetings for inspection.

Several papers were read. Amongst others one by Dr. E. R. Squibb on Aloes, in which he discussed briefly the characteristics of the several varieties of this drug, and insisted that the socotrine variety alone should be used in the medication of the human family. Allusion was made to the impurities, accidental and otherwise, and a choice specimen of animal and vegetable matter, sand, and other articles was shown, which had been separated by straining from some specimens of socotrine aloes. He also exhibited a goatskin bottle, made after the fashion of the *goat itself*, which had been found in a case of aloes, and also a curiously shaped knife, probably used in cutting the plant, which had been imbedded in the aloes.

In giving some statistics about aloes, Dr. Squibb stated that socotrine aloes lost from 5 to 10 per cent. in straining; and if dried and strained, from 15 to as high as 27 per cent. During the past year 22,000 lb. of the various grades of aloes were entered at the custom-house of New York.

Dr. Squibb read a volunteer paper on "Ammonic-Citrate of Bismuth." This salt is not uniform in its solubility, which it is asserted is caused by the loss of ammonia in heating it to obtain the product in scales. Dr. Squibb suggested that it will readily crystallize, and in that way a more uniform and soluble preparation can be obtained. Dr. Squibb read still another paper, the subject being "Triplex Pill," originally introduced by the well-known Dr. Francis, of this city. The original formula was afterwards modified, and as prepared for Dr. F. in his later years, was as follows:—

Socot. aloes, in powder.
Powdered virgin scammony.
Blue pill, each one troy ounce.
Croton oil, twenty drops.
Oil caraway, one drachm and a half.
Tinct. aloes and myrrh, q. s. To make 400 pills.

Considerable discussion ensued as to the next place of meeting, and it was at length decided that the Association should at its rising adjourn to Richmond, Va, where it should reassemble on Tuesday, September 18, 1873.

A list of thirty-nine queries, and the names of gentlemen who had undertaken to supply answers was then read and approved of; as was also a list of subjects yet unaccepted.

Professor Robert Bentley, of London, England, and M. Stanislaus Martin, the President of the Paris Société de Pharmacie, were elected honorary members.

Various votes of thanks were then passed, and the proceedings terminated.

During the continuance of the meetings of the Association the galleries of the building in which they were held, were appropriated for the exhibition of articles pertaining to pharmacy, and presented a very interesting and showy appearance.

Parliamentary and Law Proceedings.

Serious Charge against a Druggist.*

Edwin Eastwood, chemist and Druggist, of Dukinfield, was on Thursday, October 24th, brought up at the Stockport court, on remand, charged with causing the death of Ann Jones. The deposition of deceased was put in evidence, in which she stated that prisoner had given her medicine to cause a miscarriage, and identified a bottle produced as one of two that he had given her. The sister of deceased deposed that, in consequence of something deceased said, she had taken two bottles from her about five months before her death. Deceased vomited very much every day until the bottles were taken from her, but not afterwards.

Professor Crace-Calvert said that he had examined the contents of a bottle produced and found it to contain a quantity of the essential oil of savin, and of the extract of the leaves of savin, together with sulphate of magnesia, sulphate of iron, and chloride of iron.

Mr. Moore, surgeon, who had previously stated that death had resulted from puerperal fever, said that, in his opinion, such a mixture taken in June last might have produced the state of body which would have rendered the person susceptible of puerperal fever.

The magistrates decided upon committing the prisoner for trial at the next Chester assizes on the charge of wilful murder.

At the coroner's inquest held upon the body, the jury also returned a verdict of wilful murder.

* See *ante*, p. 338.

The Alleged Poisoning by Arsenic.

The trial of Ellen Kettle, for the murder of the former wife of her husband by poisoning, which was adjourned from July last* in consequence of the prisoner having been delivered of a child, was resumed at Chelmsford on Thursday, October 24th, and resulted in an acquittal. As a report of the evidence for the prosecution has already appeared in this Journal, it will suffice to recapitulate the chief points.

The prisoner, who is now only about twenty-one years old, is the daughter of a small farmer living at Great Bromley, near Manningtree. She appears to have conceived a passion for a middle-aged labourer, employed by her father, but who was already married; and whilst the wife was yet alive alluded in pretty plain terms to her early death. On the 5th of October, 1871, the deceased was in the fields with her children, where they had been eating sloes, when the prisoner brought them some beer in a bottle. After drinking some they all suffered from sickness; but the woman, who had previously been unwell, took to her bed, and five days afterwards she died, having previously fallen through weakness and cut herself severely. The doctor, in his certificate, stated that death resulted from "liver disease and exhaustion;" but, being informed of the accident, gave his opinion that death was caused by syncope and loss of blood; an opinion he reiterated in evidence upon the trial. At the beginning of December prisoner was married to the widower, and on the 16th of July last was delivered of a full-grown child. Meanwhile, the prisoner's hasty marriage and some remarks that she made had caused considerable excitement in the neighbourhood; the body was ordered to be exhumed, and the prisoner and her husband were taken into custody, the husband being afterwards discharged. In the body was found five grains of arsenic. At the trial it was proved that the prisoner had had access to arsenic, but it was arsenic mixed with verdigris and hogs' fat.

Respecting the arsenic found in the stomach, Dr. Stevenson, Lecturer on Chemistry at Guy's Hospital, said that he had found slight traces of copper in the viscera; that from one portion,—three-fourths of the liver, weighing 12 oz.,—he only extracted one-fifteenth of a grain; but from the other portion he got "no indubitable proof" of the presence of copper. In cross-examination he said that he had found tea in the stomach, in which there were sometimes traces of copper, and copper was sometimes found in various articles of diet. Reminded that in his report he had said that "the entire freedom from copper of the particles of arsenic found in the stomach, while not entirely negativing, does not tend to support the hypothesis that the arsenic had been mixed with verdigris," the witness admitted this to be so, and also admitted that he could not say he was satisfied that the arsenic in the body came from the bottle containing the verdigris mixture. He thought it possible, and even probable, but could not say more. In a mixture of arsenic and verdigris, the taste of the verdigris would predominate, arsenic being nearly tasteless. It would be difficult to conceive of such a disgusting mixture being taken in food without being at once rejected.

Mr. Serjeant Parry, for the defence, urged that the question the jury had to answer was not whether the prisoner was innocent, but whether she was guilty.

* See *ante*, p. 55.

There was no evidence that poison was present in the beer given to deceased by the prisoner, or to connect her in any way with the arsenic found in the stomach of deceased. The sayings attributed to the prisoner, he said, might be unintentionally coloured by the witnesses.

The Judge in summing up pointed out that, according to the evidence, there was undoubtedly more than sufficient arsenic found in the stomach of deceased to account for death, but he considered the prosecution had utterly failed to show how it came there, or that the prisoner had anything to do with it. The case was surrounded by very suspicious circumstances; but unless the jury were satisfied that death resulted from poison, and that the prisoner administered that poison, they must give her the benefit of the doubt and acquit her.

The jury, after a few minutes' consultation, returned a verdict of "Not Guilty."

Double Suicide by Strychnine.*

On Monday, October 28th, Mr. Bedford resumed the inquiry respecting the deaths of two unknown persons in Soho. Dr. Slight said he had made an analysis and found a very large quantity of strychnia in both stomachs. He had not the slightest doubt as to the cause of death. The police reported that they had been unsuccessful in their attempt to discover the names of the deceased. A verdict was returned that the deceased came by their deaths from strychnia, but how or under what circumstances it came into their stomachs there was not sufficient evidence to show.

Since the inquest a paragraph has appeared in the 'Times' stating that the deceased had been identified by several persons as Captain and Mrs. Douglas, of Richmond.

Review.

A Treatise on the Origin, Nature and Varieties of Wine: Being a Complete Manual of Viticulture and Œnology. By J. L. W. Thudichum, M.D., and Auguste Dupré, Ph.D. London: Macmillan. 1872.

The consultation of two hundred works upon a certain subject by an intending author would not always qualify him or leave him in a fit condition to write another on the same topic. But when it is stated that four hundred others were left unconsulted, strong grounds exist for doubting the likelihood of anything very original being said; at any rate it would be fresh proof of the wisdom of Solomon when he said that "of making of books there is no end." And yet, it must be acknowledged that the effects of recent legislation have given a wider interest to the history of wines which certainly justified Drs. Thudichum and Dupré in attempting to supply a good English manual of viticulture and œnology.

That on the book before us a vast amount of labour has been spent by the authors is very evident, and that they have brought together a great deal of information —much of it being the result of personal investigation in many lands—cannot be denied; but, probably, before it will be able to take its place as the standard work upon the subject, it will require considerable modifications. At present some parts, except as they assist in qualifying the reader for the better comprehension of certain special sections, seem to have little in common with œnology, and appear to have undue prominence given to them; whilst information that would be of special service under present circumstances is almost entirely wanting. For instance, the section on the optical methods for the estimation of sugar in wines is introduced by a treatise several pages long on polarization of light, which, however good in itself and appropriate in a work on physics, gives a *soupçon* of bookmaking to one on wines, while, on the other hand, little is said towards correcting the ignorance in this country respecting the characteristics of good wine; such ignorance, to wit, as gives rise to the brandying of wines destined for this country on the plea of suiting the English palate. In fact, we are not sure but that in one place at least the authors assist to disseminate a very false taste.

As might be expected, the book opens with a dissertation upon the origin of the various vines. The opinion formerly held that all European vines were derived from one particular species, *E. vinifera*, a native of Asia, which had been introduced into Europe in prehistoric times, is, after a review of the adverse evidence, discarded by the authors, the conclusion at which they arrive being that "all those European countries which possess the climatic conditions have in their flora many species of the genus *Vitis* in a wild state, with such botanical characters as leave no doubt that the plants are indigenous, produced by natural selection, and not derived from imported cultivated races of vines, or degenerated by natural selection from previously cultivated races."

In the section on the mineral constituents of the vine we are told that the soluble portion of the ash obtained by combustion comprises potassium and sodium, combined with carbonic and sulphuric acids and chlorine; the insoluble portion contains calcium, magnesium, iron and manganese, combined with carbonic, phosphoric and silicic acids, the proportions of these bases varying considerably according to the soil; but it is somewhat doubtful science to state that it has been proved that where the vine cannot find a particular kind of base which it ordinarily wants for its development, it takes another instead, substituting a chemical equivalent of that which happens to be available for that which it cannot have, the sum of the oxygen combined with them being always the same or undergoing but slight variation.

The second chapter deals with the general principles of viticulture. We must content ourselves with noticing a curious calculation as to the amount of manure required by the vine. We are told that if five litres of dung be yearly dug into the soil round a six-year old plant, it will be maintained in sufficient strength to produce every year twenty grapes of at least fifty grams weight. Who will say after this that agriculture cannot be included among the exact sciences?

Perhaps in no other instance has there been such a tendency to *stare super antiquas vias* as in the manufacture of wine. It is astonishing that in these days of machinery, the grape in many places is still crushed by the foot of man in the same rude manner that it was thousands of years ago. There is nothing more repulsive in the manufacture of the West Indian "piwarrie," which is the fermented saliva in which cassava bread has been masticated, than is to be met with at the present day in the manufacture of Burgundy wine. In that district the crust formed on the top during fermentation is mixed with the wine beneath by men who get bodily into the wine and work it thoroughly in all directions for half an hour; "perspiring freely, not only from the intense labour they perform, but also from the poisonous effect of the carbonic acid gas exhaled from the fermenting mass," while the favourite "luting" is a mixture of loam, clay and cowdung.

However, it must not be supposed that there is nothing novel in the wine manufacture, for in 1852 M. Petiot appears to have discovered that a liquor could be produced by adding to the expressed grape juice an equal volume of sugar and water, or by exhausting the squeezed husks even to the fifth time with successive quantities of sugar and water, which he claims to be "wine in the full sense of the word." On the whole, the authors appear to agree with him, for, although in summing up the results, they speak of the product as a "beverage," they generally term it a wine. In this manner Petiot obtained 285 hectolitres of "wine" from the quantity of grapes which ordinarily yielded only 60 hectolitres. But then Dick Swiveller's "Marchioness" knew how to make wine without any grapes at all.

The chemistry of wines is elaborately dealt with in a series of chapters. Commencing with a description of the physical characters of alcohol and the elementary constitution and chemical character of alcohol and its homologues, the different methods of alcohol determination in wines are next described. Then follow the acids in wine, the ethers in wine, the varieties of sugar and methods for their determination, and afterwards the fatty, colouring, albuminous, astringent, extractive and mineral constituents of wines, and a series of analytical tables. In this section there is an evident desire to meet the wants of various classes of readers, for, while one with but little scientific knowledge will find nearly a page of elementary description of dialysis, the more advanced student is furnished with percentages calculated to six places of decimals, and such specific gravities as 999·99! Some idea of the intricacy of the subject may be formed if it be remembered that "by the influence upon each other of the alcohols and acids known to be present in wine a considerable number of compound ethers may be produced. Supposing five acids and five alcohols to be present, they might produce twenty-five compound ethers, some or all of which might be present and contribute their share to the flavour, such flavour altering as one or other ether predominated. All these ethers occur in wine in extremely minute quantity, and almost entirely elude ordinary analysis."

Where there is so much that is valuable, it may seem trivial to criticize minor details; but there are several points of orthography in this division against which we much protest. The old dispute between "oxide" and "oxyde" has now almost universally been decided in favour of the former; there seems, therefore, no sufficient reason for continuing such forms as "suboxyde," "binoxyde," "oxydizing," etc., especially in the same book as "oxidizing" is used. Neither are we aware of any rule that prohibits a final "e" to "mannit" and "dulcit," and yet allows of its use in "aldehyde." "Baryum" and "chromealum," too, are, to say the least, unusual. There are also one or two cases where the omission of a figure has rendered a formula incorrect. And in a book where almost everything is explained, how is it that we meet with such a word as "hydrothion?"

There is, however, one subject alluded to in this section in a manner that appears open to justifiable criticism. After describing the ordinary operation for the making of vinegar, and the part which *Mycoderma aceti* plays in acetous fermentation, the authors say, "If the alcoholic liquid employed in the vat is free from albuminous matters, it is converted into vinegar by simple oxidation, without the intervention of the mycoderma, and even in the course of twenty years of constant use, no fungus is deposited on the wood shavings in the vat. If, however, the alcoholic solution contains albuminous matter, the *Mycoderma aceti* makes its appearance." Now this is in direct opposition to the view entertained by M. Pasteur, who, in a recent debate in the French Academy, said that he did not believe there existed in any country a single drop of wine acidified spontaneously in contact with air without the previous presence of the *Mycoderma aceti*. He backed up his opinion by two challenges; first, that if Baron Liebig would obtain some of the beech shavings referred to, dry them quickly in a stove, and send them to Paris, he would engage to demonstrate the presence of the mycoderms on their surface; and, secondly, that if a vat in work were filled for half an hour with boiling water, no more vinegar would be produced until sufficient time had elapsed for a fresh growth of mycoderms to appear on the shavings. Now, Drs. Thudichum and Dupré may be right, and M. Pasteur may be wrong; but the statements of the latter will not be disproved by simply ignoring them. Although controversial matters would be out of place in the present book, opinions that have been put forth with such ability and supported by many high authorities appear at least worthy of notice in "a complete manual." Moreover, there is the fact—also not noticed by the authors—that vinegar is now made in France by the direct sowing of the mycoderm on the surface of the wine. This method, while it does not prove that acetic fermentation never takes place without the mycoderms, is based on M. Pasteur's theory; and it has been reported by M. Breton-Langier,* who has worked it practically, to offer many advantages, a very suggestive one being that vinegar is produced at the end of ten days; the time required by the old method to put in work a fresh *mère* being from two to three months.

The latter half of the book is taken up by descriptions of the principal wine districts and the pecularities in cultivation and manufacture. There is much here to interest the ordinary reader, but it appears to be a vast store of information for the œnologist. We must be content with culling a few sentences here and there. One of the problems for the scientific viticulturist of the future to solve occurs in the Médoc and other districts where the "variation of the soil causes a great variety in its products, so that the best and most inferior vines grow frequently side by side. As the vines are the same and the cultivation identical, the soil alone can explain the difference; but the special conditions of this difference are yet wrapped in mystery." The soil appears also to affect the duration of the vine, which in some places has to be replanted every twenty or thirty years; in others it lives sixty or seventy years. Indeed, a sketch is given of a vine at Malines which produced seventy-three branches of grapes when upwards of one hundred years old. Another vine, which in M. Brouner's vineyard at Wiesloch had overgrown a pear-tree, brought a harvest that took two men two days to cut down.

We get one glimpse of the "good old times," when we are told that a most potent agent towards the perfection of vinification in the Gironde has been the liberty which the Girondese won in the great revolution to gather their own grapes when they pleased; and another in the law existing in Portugal so late as the year 1833, which subjected a person adulterating wine in any manner, or a farmer possessing an elder tree on his land, to transportation for life. This is rather further than our modern anti-adulteration legislators would go, and probably would require an increase of penal settlements. There is ground for hope, however, that the day may come when a pure wine may be had for a moderate price, through capital and science being brought to bear in the development of comparatively unproductive districts. For instance, an excellent Dalmatian wine is sold at $1\frac{1}{5}d.$ per litre, while yet the culture of the vine in Dalmatia is confined to the neighbourhood of the sea in consequence of the want of means of transport.

Here, however, we must close this interesting book, which is got up in first-rate style; the illustrations are excellent, and the paper and printing very superior.

Obituary.

Notice has been received of the following death:—

On the 25th of October, Mr. David Mennie Anderson, of Kirriemuir, Forfarshire.

BOOK RECEIVED.

Payment of Local Secretaries.

Sir,—I am glad to see the above subject is beginning to attract attention, and as I am not now a local secretary, I feel that I can speak the more freely upon the propriety of paying local secretaries for at least some part of their services. I need not enter into detail regarding the duties of the office, but may state generally that a secretary who studies the constitution and interests of the Society is of great value, and renders services which it would be impracticable to repay in money, but which may be considered to be met by his own consciousness of doing good, by the status (small though that may be) which his office gives him, and by any acknowledgment on the part of the Society, such as that Mr. Hills proposes, *i.e.*, paying his railway fare to and from London on the occasion of his attending the annual meeting. I do not think that there is any fear of the meetings being inundated in consequence of such an arrangement; most provincial chemists are too much tied to their counters to think of spending a day or two on a journey to London, simply from having their railway fare paid by the Society.

But as regards examinations, or any other definite work which is required from local secretaries, I think it is only just that it should receive a fair remuneration. The Board in London receive pay for their work, and I am not aware that any one outside of the Board grudges them their well-earned fee, nor do I suppose that any on the Board feels it *infra dig.* to accept it. I once received a guinea for six or seven hours spent in the Board-room (I believe the fee is now two guineas), and though I acknowledge that the work was more laborious and responsible than that of superintending the writing of papers by a student or two, it was also occupation of a much more interesting character, and one to which more honour was attached. If superintendents of Preliminary examinations are in future to receive a fee of half a guinea (or five shillings a student when there are more than two), I have only to regret that in most cases the payment will be so small, considering that the day and hour are fixed, without reference to the individual convenience in each case. I would rather see the whole subject of local secretaries reconsidered and their duties rearranged and defined. Looking over the list of towns at which examinations were held (page 331), we find there were fifty-eight in which one student only was present for examination.

I do not know any reason why the single student in Gateshead should not have walked a mile to be examined along with the three in Newcastle, and so economize the examining power. Nor do I think there is any reason why those at Shields, Sunderland, and Durham, should not also have come to Newcastle, in which case the examiner in the latter town would have had ten students under his superintendence, and might reasonably have received a fee of a guinea and his expenses if he required to hire a room, etc. When in office I repeatedly had candidates from small towns twenty or thirty miles distant, and if it is practicable for them to travel so far, I think it would be equally practicable, and in many respects advantageous to arrange that all within a certain radius should meet at some convenient centre. The secretary at Leeds, whose time was devoted to two unsuccessful candidates, might just as well have had those from Ripon, Harrogate, Knaresborough, and perhaps some other towns. Five-and-twenty or thirty large towns might be selected in England that would afford all reasonable facility to candidates for the Preliminary. A fee of a guinea per examination to the secretaries in these towns would put the Society to only a trifling expense, and if perchance any of these gentlemen should feel, like your correspondent this week, that it was *infra dig.* to receive money he had earned, there is always the Benevolent Fund ready to relieve him and profit by his dignity.

Barnard S. Proctor.

Newcastle, October 28th, 1872.

Sir,—As one of the local secretaries of the Pharmaceutical Society, may I be allowed to enter a protest against the kindly-intended suggestion of Mr. Sutton, that "The secretaries should receive some remuneration for their services." I think the proposition would be favourably entertained by very few of those now holding office.

Mr. Hills' proposal would, however, I think, be generally acceptable, and would be a courteous and sufficient recognition of their services.

I believe, too, that the local secretaries' presence at the anniversary meetings would be found useful to the pharmaceutical body, as many suggestions might be offered by them of a practical and instructive character.

I do not think the Council need to fear that too many would accept the invitation; we all know the compulsory tie that binds every pharmaceutist to his business, so that, even under such a persuasive call to Bloomsbury Square, a large majority would be compulsory absentees.

Thos. Witherington.

Worcester, Oct. 28th, 1872.

Sunday Closing.

Sir,—In regard to the present agitation in favour of early closing, what is meant by "Sunday closing?" I see that some of my friends in this city, in the neighbourhood of Broughton and Cheetham Hill, include the latter in their programme. Is it meant that not even medicine is to be supplied on Sundays, and no attendance given at any time during the day for that purpose expressly? It would be a very delightful thing to me if I could dismiss my young men to their friends every Saturday evening, and enjoy a day's quiet repose in the bosom of my own family, without the dread of that *eternal bell;* feeling as entirely untrammelled with regard to shop duties as my neighbours Smith the greengrocer, and Jones the shoemaker. The very thought of such a state of bliss makes one's mouth water. But I can't see how it is to be done. Here is a family who are regular customers. A member of it is dangerously ill, the doctor attends every day, and every day for a week, I have supplied the medicine prescribed by him; Sunday comes, the patient is worse, and a new prescription is written and sent to me. What is to be done? Is the patient to wait till Monday, or may I expect my customer will send to some other chemist who does not close on a Sunday, and then return to me on the Monday? I should be glad to see my way clear as to this matter, and respectfully ask what is meant by "Sunday closing."

J. T. Slugg.

Manchester, October 25th, 1872.

Patent Medicine Licences.

Sir,—I cannot agree with either of your correspondents relative to the amount they would recommend as an uniform rate throughout the country. Where I am in business, 5*s.* is the price of the licence. The idea of raising that to £2 seems a monstrous proposition, and I am sure your correspondent, Mr. Ellis, is mistaken if he thinks "most of the trade" would agree with him. I differ also from him in supposing that the amount, if even raised to £2, would deter our grocers and others from selling patent medicines. An uniform 10*s.* would not be objected to by the country, if it were intended as a relief to the town chemists, but beyond that, I trust no suggestion will be made to the Chancellor of the Exchequer, who does not need stimulation to put on the screw.

An old Country Pharmacist.

Sir,—With your permission, I will state my objections to raising the licence to £2, as proposed, and offer another course for consideration.

If, instead of the three present rates of charges, we had an uniform one of 10*s.* for retailers, it would relieve our London friends; and those who pay 5*s.* now would not complain. By raising all the licences to £2, you might, perhaps, benefit a few chemists by diminishing competition in their particular neighbourhoods, but it would not affect our worst competitors, the co-operative stores. Supposing the advance of £2 took place, I believe you would soon find that those people who discontinued their licences would push the sale of Dinneford's, De Jongh's, Möller's, Condy's and Goddard's preparations, and everything that was not stamped. It is also a question whether they would not open packages of Holloway's and other Pills, Steedman's Powders, etc., to sell them out in small quantities, and so evade the licence.

Should any alteration take place, I propose two separate licences. A £2 licence for wholesale dealers, and a 10*s.* one for retailers.

Vendors who sell both wholesale and retail to take out both licences.

This would tend to check the local chemists supplying the small shops in many parts of the country.

I would make an exception in favour of proprietors of stamped articles, who supply only their own *bonâ-fide* manufactures to the trade, and let them come under the head of retailers' licences. If the licences and stamps were entirely abolished, as proposed in the 'Medical Times and Gazette,' my idea is that such a course would only have the effect of increasing quackery as well as competition.

GEORGE BROWN.

Sandown, I. W., Oct. 28th, 1872.

EXAMINATION FEES.*

Sir,—Paper wars are generally unsatisfactory campaigns, and but seldom secure the desired end. My original object in writing upon this subject was, not to provoke discussion on the numerical strength of the Pharmaceutical Society as regarded members in the aggregate, but, to urge the importance of devising means by which to increase its strength in that particular class of members which the Society desires to encourage, viz., pharmaceutical chemists, *i.e.*, men who have passed the Major examination.

Mr. Carteighe on the other hand has taken hold of a single statement in my letter, and, having separated it altogether from the context, has been led into an entirely false line of argument, having no reference whatever to the main subject. He is arguing the numerical strength of the Society in its broad sense as a corporate body; whilst my statement refers to it in the more limited view, as a Society of Pharmaceutical Chemists; entirely and purposely ignoring both chemist and druggist members, and associates in business, not through ignorance either of their existence or privileges, but because they did not represent that phase of the Society which I desired to bring into prominence.

That this is correct will, I think, be evident to any unbiassed reader of my letters. In my first, *educational qualification* will be found the pith of the whole; whilst in my second, although reference is of necessity made to other points in order to meet the assertions of my friend, yet the gist of the whole is as before, examination and membership flowing therefrom.

Regarded from this point of view the statement to which exception has been taken will, I venture to repeat, prove correct, that whilst our strength, *as a society of pharmaceutical chemists* is decreasing (or at best but very, very slowly inclined to increase) the numerical and therefore political strength of outsiders, *that is those who simply pass what the law compels them to*, is largely increasing. That this is borne out by facts is, I think, clear, when we see that in 1871, out of 566 associates of the Society, only 67 had qualified themselves for membership as pharmaceutical chemists by passing the Major examination, whilst 262 were satisfied with the Minor qualification, and will doubtless in due time help to swell the number of associates in business, for whom your correspondent seems to have peculiar affection. On the other hand, as regards the strength of the Society in pharmaceutical chemists we see that whilst in 1870 the aggregate number was 1802, in 1871 it was but 1797, showing a *decrease* of five in that year.

Having, I hope, sufficiently proved the accuracy of my position, I do not think it will be necessary for me further to discuss this point, preferring by far that some of your readers personally interested in the future examinations and the welfare of the Society should, in anticipation of the subject shortly having to occupy the attention of the Council, be induced to give expression to their views as to the best means of securing a larger number of candidates for the Major examination, and their direct union with the Society as the result of such examination.

Thanking you for your courtesy in giving space to our somewhat lengthy correspondence.

EDWIN B. VIZER.

63, *Lupus Street, Belgravia South, October 26th*, 1872.

Sir,—As no one from this district (except our councillor Mr. Frazer) has ventured to express an opinion on the above subject, I beg to offer a few remarks, considering, as I do, that Scotland has been too backward in expressing her views on matters of such vital importance to the welfare of the Society and the trade at large.

My first thought, Mr. Editor, is, that in the question of Examination Fees will be solved the broader, and consequently much more difficult, problem of pharmaceutical education. I have come to this conclusion, from the intimate connection I have had with our local society here since 1868, as well as from a careful study of the various theories that have been promulgated within the last few years on the question. I am of opinion, however, that the solution of the problem will not be in Mr. Vizer's scheme for raising the fees, as given in the Journal of August 31st, nor even in the modified proposal of Mr. Carteighe's in to-day's Journal. The raising of the Examination Fees may suit the ideas of some of our high-class London pharmacists, but I venture to say that such a proposal will receive but little support from the members of the trade throughout the country. I sympathize very much with some of Mr. Vizer's motives in bringing forward his proposal. It is no doubt a great anomaly, that a body of men which are numbered by the thousand, should be under the control of a few hundreds of the same class in many respects. Some maintain it is the fault of those outsiders, in not taking the advantages offered by connection with the Society; but whether it is their fault or not, I would decidedly say, let the present members of the Society show their anxiety for having a united trade and a united Society by adopting some broad and liberal policy, not only towards those at present in the trade and outside of the Society, but that will induce intending pharmacists to make it their first anxiety, after passing the examinations, to become connected with the Society. Of course I approve of Mr. Frazer's motion which was discussed at last Council meeting, and published in the Journal of October 5th; and here I must take exception to a remark of Mr. Vizer's regarding it. He says (PHARM. JOURN. No. 114, p. 179), "Whether the resolutions proposed by Mr. Frazer do not go too far, and would not be fraught with untold difficulties and inconveniences to the Board of Examiners, I seriously doubt; to say nothing of the almost pauper class implied by the conditions suggested." And further on he says, "My earnest desire is to see the whole trade as far as possible united into one body, each member as such holding a responsible position, to be used for the benefit of the whole. It has been with this desire that I have ever advocated a liberal policy towards those we are in the habit of regarding as outsiders, and it is for the furtherance of the same object that I desire now to see a radical change brought about in the Examination Fees."

There seems to me something strangely inconsistent in these two expressions. He wishes a "liberal" policy adopted, and a "radical" change made, yet he would fix the examination fees at such a high rate that they would debar a certain class (whom he terms the almost pauper class) from entering in. But what is the effect of the present scale of fees that they should be reduced? I can only speak for Glasgow, but while doing so I believe I express the experience of many other large towns. It has been impossible for us to get a class of twenty students together in either of the pharmaceutical classes we have attempted, although we offered the double advantage of reduced fees, and text-books at a reduced rate, simply because our young men are looking quietly about for something better, and I do not exaggerate when I say that not more than forty per cent. of the present apprentices and assistants in this city, will attempt to pass the pharmaceutical examinations. Mr. Frazer has already given instances of young men having left the trade, no doubt to better themselves both now and hereafter, but I can point to others who are sacrificing both time and money at present to gain the higher profession of physician, not to speak of numbers who have left and intend leaving the country altogether for America and elsewhere, where the prospects are better, who, I am sure, would not think of doing so if the examination fees of the Pharmaceutical Society were a little more reasonable; the result of this is, that assistants of the right sort are not to be had at present. And the only way in which I can see this state of matters can be rectified is by adopting Mr. Frazer's proposal at once; and if adopted, I venture to predict that the education question will be comparatively easily settled afterwards. If our young men were settled upon remaining at the business, it would be a comparatively easy matter in large towns to establish schools of pharmacy. No doubt some assistance from the Pharmaceutical Society would make these all the more efficient, and for this purpose I would cordially support Mr. Frazer's motion regarding the distribution of the surplus funds of the Society. Mr. Schacht's scheme, I think, is far too elaborate for our present wants, and I am inclined to think, that if adopted, it will be as much

* See PHARM. JOURN., present vol., pages 179, 240, 279, 339.

a dead letter as Mr. Reynolds's. I would be more inclined to support, in conjunction with Mr. Frazer's motion, that proposed by Mr. Giles in to-day's Journal, viz., the establishment of another School of Pharmacy for higher pharmaceutical education in Edinburgh. I am convinced these are the only practical schemes that have yet been proposed; there has certainly been too much theorizing on the question of pharmaceutical education; as a friend of mine here said the other day, "There has been too much talk about how to cook the soup, while the much more important matter of how to catch the hare, has been almost entirely neglected." I trust the country members will speak out on this matter of increasing the examination fees. It is so mixed up with the question of education that I fear it must be settled first, and if they do not let their voice be heard in support of a reduction from the present scale, an increase will in all likelihood be resorted to, which to my mind would be a sad calamity to the business of pharmacist in this country.

J. M. Fairlie.

Medicines Afloat!

Sir,—In glancing over your leader on "Physic Afloat," the thought struck me that some "practical" difficulties experienced by me might be useful to illustrate the point in question.

In the first instance, I received an order for the ordinary forty-man Board-of-Trade chest. Happening to be away from home before it was shipped, I received a telegram saying that additional medicines were required for from 80 to 100 passengers, as the steamer was chartered for the Cape of Good Hope passenger traffic; and further, that the arrangements were to be completed forthwith, as she had to be on the berth in London on a very short date from that time. I was not long in getting to business, and now my troubles began. Naturally enough, I supposed that for a steamer which had to be specially surveyed and licensed by the Board of Trade, to see that her hull was seaworthy and properly supplied, when the souls on board were increased at once from 40 to 140 or more, there would be some provision made for their well-being—something to stem the tide of disease, mayhap some malignant epidemic; but I was woefully mistaken. My first step was to apply at the shipping office, but I came away as wise as when I entered. I next went to the Custom House, where the same fate awaited me. The officials were polite, and did their best to find anything to help me; but all was blank. I then wrote up to the Board of Trade, and in due course received one of their characteristically laconic epistles written on any amount of paper; but still the same result. "There is no provision made for such cases as you describe." Lastly, I applied to "Her Majesty's Emigration Commissioners," when I did get two lists and a very polite note, saying that they hoped I should find what I wanted in the enclosed lists. Now I do not consider the Board of Trade list for seamen all that could be desired in that line, but compared with the lists of "Her Majesty's Emigration Commissioners," it is simply perfection. For example, for 100 passengers for 100 days and upwards, they order, amongst other things, acid. hydrocyan. dil. ½ oz.; chloroform, 2 oz.; po. borax, 1 oz.; morphiæ mur. 1 dr. Then the other list for 600 men for 100 days and under, argent. nit. 4 drs.; quiniæ sulph. 1¼ oz.; cer. cetacci, 8 oz.; and lint 14 oz., etc.

I managed to extract some wheat from the chaff, and after a good lot of planning, and with the assistance of one or two medicals who understood such matters, I got it fitted up and stocked, and in this my maiden attempt I flatter myself I succeeded moderately well, as the surgeon who joined her (at Gravesend) was so far satisfied on his return that he could only suggest some six or eight articles that were wanting.

My next order was for a steamer going to India, "*viâ* Suez Canal," upon which I set to work at once, as I knew from experience what I had to rely on from extraneous sources. But I hope and trust that now the Board of Trade have taken it in hand, we shall ere long have a thoroughly useful and comprehensive list for voyages of the longest description, and for any number of passengers.

There is one most important matter I should like to touch upon, and that is concerning the survey of ships' medicine-chests. A most salutary law exists regulating the purity of the drugs employed, but, unfortunately for the benefit that ought to accrue to the sailor, it is in most ports a dead letter; and I hesitate not to say that there is not one case in five hundred where a chest is opened by an inspector. What is wanted is a skilled inspector attached to every shipping port in the kingdom, a thoroughly practical pharmaceutist, whose duty it should be to examine every chest that leaves the port; pay him well, but let one of the qualifications for the office be that if elected he himself shall not fit a chest during such time as he holds the appointment. This would deal a death blow at the cheap and nasty compounds that are put into the box and sent to sea as medicines "of the finest quality only," and give the upright conscientious pharmaceutist a chance not only of getting a remunerative price for a genuine drug, but would tend to uphold the credit of British pharmacy.

Sunderland, Sept. 23*rd*, 1872. David B. Sharp.

Pharmaceutical Examination.

Sir,—It will perhaps satisfy 'Quærens' if I remind him that admission has been publicly made that, by a system under which candidates, "no matter how backward," are prepared for the Minor in about a month, no less than one hundred and thirty have been annually passed since 1868.

I do not think, as 'Quærens' seems to insinuate, that the examiners are ignorant of their business; but I do think that they have not time to carry on their business properly. More time is required, greater change in the mode of examination, and, if possible, in the examiners; the practical portion should be much more extended, and a certificate of apprenticeship of at least three years' duration should be required. For affording any further information in support of the statements contained in my letter, I should be glad of an opportunity of communicating personally with "Quærens."

Frederick Andrews.

23, *Leinster Terrace, W.*,
October 15*th*, 1872.

J. Winn, A. B. and J. Richardson.—Your letters, with enclosures, have been forwarded to the publishers, Messrs. Churchill and Co.

A. P.—A species or variety of *Veronica*, probably *Veronica Hendersoni*; but specimen arrived much shrivelled.

H. W. Harris.—(1) *Ground Pine* (*Ajuga Chamæpitys*, Sm., from Gr. *chamai*, ground, and *pitus*, pine), so called, according to Prior, from its terebinthate odour. He says also that it was the forget-me-not of all authors till the beginning of this century. It is found in the chalky districts of Kent and Surrey. (2) White oxide of antimony, prepared by heating metallic antimony in a vessel freely exposed to the air, and furnished with a cool surface for the condensation of the oxidized vapour, is termed "Flowers of antimony." (3) Dr. Hassall's is the best-known book upon the subject.

G. L.—See the regulations respecting Naval Dispensers printed in the first volume of the present series of the Journal, pp. 44 and 828, and also in the Society's Calendar.

"*A Registered Student of the Society.*"—There is no rule prohibiting the admission of such specimens as you describe; but in awarding the prize, the degree of perfection in the specimens would undoubtedly be taken into consideration.

"*In Embryo,*" *and G. C. Bunn.*—Apply to the Secretary for copies of the pamphlets entitled 'Hints to Students,' and 'Regulations of the Board of Examiners.'

J. L.—We do not quite understand your question. If the new Adulteration Act be referred to, we do not think it would interfere with the sale of the article you refer to for the purpose specified.

W. R. H.—We do not think the opinions you express are well founded, or that your letter generally is suitable for publication.

C. Crampton, Coventry.—Your letter does not contain anything calculated to convince us that the necessity of passing the 'Preliminary examination' is to be regarded as a hardship for any one desiring to carry on the trade of a chemist and druggist with credit to himself and benefit to the public. But we feel sure that if our correspondent's energy were directed into a proper channel, the ordeal of the 'Preliminary' would have no terrors for him, and that he would agree with us in ceasing to sympathize with those 'unfortunates' who regard it with dread.

B. B. B., "*Zarefi,*" "*Pharmaceutist,*" *and A. P. S.* are referred to the rule respecting anonymous correspondence.

Communications, Letters, etc., have been received from Mr. Parkin, Messrs. Howard and Sons, Mr. W. A. James, Mr. J. Leare, Mr. Daniel, Dr. J. L. Soubeiran, Mr. Goodfellow, Mr. J. B. Clarke, Mr. J. D. Alkmann, W. R. H., W. D. S., A. B., M. P. S., "An Assistant."

TINCTURE OF ORANGE-PEEL.

BY A. F. HASELDEN, F.L.S.

Tincture of orange-peel has often furnished a topic for conversation, but I do not remember seeing any written communication upon it published in our Journal, hence one reason why I have thought it worthy of being brought to your notice this evening; secondly, whilst the Pharmacopœia directs the dried peel to be used, there are pharmacists who consider that the fresh peel, or peel cut in England, and not allowed to dry, is to be preferred in point of flavour. Again, there are others who admit the superiority of the fresh peel when the tincture is unmixed, but consider it a matter of secondary importance, in the eyes of their patrons, when mixed with other ingredients, as in tincture of quinine, or when added to other things in prescriptions, the supposed delicate flavour of the fresh peel is inappreciable. Again, there are pharmacists who look upon the peel cut, dried abroad, and imported into this country for the purpose of tincture, equal to that cut and dried here, although the Pharmacopœia describes orange-peel as "The dried outer part of the rind of the bitter orange, Citrus Bigaradia, Risso, 'Histoire Naturelle des Orangers,' plate 30." From the ripe fruit imported from the South of Europe I can hardly imagine it would exclude the same, because it was cut and dried abroad.

"*Characters.*—Thin, of a dark orange-colour, nearly free from the white inner part of the rind, having an aromatic bitter taste and fragrant odour." As regards colour, the foreign-cut peel I have generally met with is darker than the English cut, but not so thin. Upon the table are five samples of tincture, four of which were prepared by maceration (B.P. proportions). Maceration was chosen as being less liable to the little accidents which sometimes attend percolation, and they could all be prepared at the same time, without requiring four percolators of the same size, and one was prepared by percolation.

To those who hitherto have not paid attention to the subject, it may be interesting to know that the fresh peel cut here, not being as thin as I wished it, upon being recut by myself, lost just one-fourth of its weight, that is, I removed one fourth of the white inner part of the rind; secondly, this, upon drying, lost two-thirds of its weight, *i.e.*, eight ounces out of twelve, and even then was not as dry as the commercial article. This, dried by myself, cost 5*s.* per lb., the commercial dry English peel costs from 2*s.* 2*d.* to 3*s.*, and the foreign from 9*d.* to 1*s.* Of these five examples, the one by percolation was made with foreign imported dry peel; of the others, one with foreign, one with the English commercial dry peel, one with the peel recut and dried by myself, and one with the fresh peel recut; of this last six ounces were required as an equivalent of two ounces dry. In preparing the tincture with fresh peel, I made one oversight. I tell you this because non-success is sometimes as useful as success. The oversight was this: although I calculated the quantity of the fresh peel required as an equivalent for the prescribed quantity of dry peel, I omitted to calculate the amount of moisture, and that I should require less water to make the spirit proof. However, I do not think that that circumstance has at all interfered with the flavour of the article produced. The specific gravity of each has been taken, and there is considerable variation, running thus:—·944, ·938, ·936, ·926, and ·922. This I shall be happy to explain presently, as in my opinion it does not affect the odour or flavour which is the point which I should be glad if you could decide this evening; and that I may in no way bias your opinion, I refrain at present from giving my own. I feel that it may be difficult to taste or smell one after the other without being in some measure confused, but we expect as much sometimes in our examinations; at any rate, any great difference either in colour, fragrance or flavour, I may naturally expect to be readily detected.

[*The discussion upon this paper is printed at p.* 369.]

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, November 6, 1872.

THE PROPOSED "UNIVERSAL PHARMACOPŒIA."*

BY PROFESSOR REDWOOD.

One of the questions submitted to the "International Congress of Pharmaceutical Associations and Unions," at the meeting held at Vienna on the 9th and 10th of September, 1869, was as follows:—

"What should be done to effect the greatest possible uniformity in the strength and composition of the remedies used in all countries?" A continuation of the universal codex question.

When this question came before the Congress, Mr. Waldheim, of Vienna, stated that the Société de Pharmacie of Paris was then engaged in preparing a small work which would contain the remedies most generally used in all countries, and especially the most important and powerful remedies, such as hydrocyanic acid, tincture of opium, Fowler's solution, the mineral acids, etc. The formulæ for the preparation of these medicines would be given according to the principal pharmacopœias, and questions put as to the reasons for having different forms, and for preferring any one of these to the others. He said the work would in a short time be ready for publication, and would as soon as published be sent to the different pharmaceutical corporations with a request that it might be circulated among medical men and pharmaceutists, and their remarks made on blank pages with which it would be interleaved.

This announcement appeared to the Congress to dispose of the subject, at least for the time, very satisfactorily, and accordingly a resolution was passed thanking the Société de Pharmacie of Paris for having undertaken the work, and encouraging them to proceed with it and get it finished as soon as possible.

Although three years have now elapsed since that announcement was made, I am not aware that any further information has been published with reference to the promised work, nor do I know what progress has been made towards its completion.

In the current number of the 'Chemist and Druggist,' a notice appears headed, "Universal Pharmacopœia," in which it is stated that Dr. Phoebus, of Giessen, conjointly with some other chemists and pharmacists of high standing, privately undertook,

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, November 6, 1872.

in 1869, to draw up an international pharmacopœia, the object of which would be to establish uniformity in pharmaceutical preparations all over Europe. Among the active workers in this enterprise are mentioned Signor Cantini, Naples; Herr Flückiger, Berne; M. Planchon, Paris; Herr Schneider, Vienna; Dr. Thudichum, London; and M. Trapp, St. Petersburg. The notice further states that the work is progressing, but is not yet finished.

When I first read this statement I thought it might possibly refer to the work that was brought under the notice of the Congress at Vienna, and I applied to Dr. Thudichum for further information on the subject.

Dr. Thudichum has kindly consented to attend here this evening, and to explain the general character of the work on which he is engaged. There are two or three questions connected with the preparation of such a work which appear to possess sufficient interest to members of the pharmaceutical body to justify their introduction here. Thus, for instance, it would be interesting to us to know what language the work is intended to be published in; how the question of weights and measures is to be dealt with, whether quantities are to be represented by reference to specified weights, or simply by the use of proportional numbers: and whether the book, when ready, is in any way to be used in the manner proposed by the Société de Pharmacie of Paris, with the view of eliciting the opinions of medical men and pharmacists as to the best processes for the preparation of medicines.

The primary idea involved in the proposition for having an universal pharmacopœia is that all medicines bearing the same names should be of the same strength and composition in whatever country they are used. This is the first and most important object contemplated. But there are other objects which are more immediately susceptible of accomplishment. While the medicines used in different countries differ, a work describing them all, and comprising formulæ for the preparations included in the various authorized pharmacopœias, would afford a comparative view of the pharmacy of different nations, the study of which would be beneficial to those using the work. Such a work would also afford to pharmacists the information they require in dispensing foreign prescriptions. The two last named objects may be realized at once, while that first named can only be carried into effect by slow degrees.

I believe we are entitled in this country to the credit of having made the first successful attempt to abolish the anomaly of the co-existence among people of the same nation, of authorized processes for the preparation of medicines bearing the same names but differing in strength or composition. Germany has recently followed our example by establishing one uniform standard in the place of several standards for the composition of medicines used in that country. Sweden, Denmark and Norway have gone even a step further, and have attempted, although as yet with only partial success, to effect the assimilation in strength and composition of the officially authorised medicines of the three nations, thus establishing a sort of international standard.

All this evidently tends toward the adoption of a universal pharmacopœia with the primary object realized; and although it may be a long time before the difficulties in the way of superseding our national pharmacopœias by such a work can be overcome, if they can be at all, the adoption of the means best calculated to bring about that result appears to present collateral advantages which ought to insure its being put into operation.

No doubt can be entertained as to the desirability of having such a work as that described at the Vienna meeting in 1869, and if the work now announced, and of which Dr. Thudichum is one of the editors, has similiar objects, and is likely to supersede the other, we should be glad to have some more definite information with reference to it. It is with a view to the attainment of that result that I have introduced the subject here this evening.

[*The discussion upon this paper is reported at p.* 370.]

LORD GRANVILLE AND THE BISHOP OF WINCHESTER ON THE OXFORD LOCAL EXAMINATIONS.

The distribution of prizes and certificates in connection with the Ramsgate centre of the Oxford local examination, took place on Tuesday, October 29th. The report showed that 44 candidates out of 99 were entitled to certificates and 8 to prizes.

After the distribution, in the course of some remarks, Lord Granville said that of late years he had been intimately connected with the London University, and he was proud of the progress that institution had made both as regards numbers and in extending the curricula of education in this country. He could not forget, however, that he had spent two very pleasant years of his life in the older University of Oxford, where he graduated at nineteen, perhaps too early. It was most agreeable to him to assist at a distribution of prizes consequent upon the examination instituted with such success by that old university upon a system which at the time he was an undergraduate would have been difficult, if not impossible. If they looked at the report, at the number of subjects included in the examinations, and at the names of the candidates, who, he was informed, belonged to almost every possible creed in that district, they would see the liberal manner in which the examinations were carried on, and that they owed a debt of gratitude for the course the old university had taken. He believed that these examinations were of use in almost every possible way. They gave a great stimulus to the interest taken by parents in the education of their children, enabled them to form a judgment as to how and where their children could be best educated. With regard to the teachers themselves, he believed they would all agree with him that in their work of teaching they received most valuable lessons from the examinations, as they showed them the faults of their modes of teaching. It was the examination which taught a boy to know his own deficiencies and when he succeeded better than anything else could do. Unless they brought these things to some sort of test, they were not sure whether they had knowledge or not, and there was no test more sure than that of being examined by capable and intellectual men, thoroughly versed in the subjects, who did their best to ascertain, not whether a boy was merely crammed, but really understood what he had studied.

The prizes given by the committee of the local centres for London, Finchley, Streatham Hill and Southwark were distributed on October 30, in the Theatre of the London University, by the Bishop of Winchester. His Lordship, after expressing the pleasure he experienced in distributing the prizes, said if the great universitiee of the land were to do the work for which they were founded, they must reach the different ranks of society and of education to an extent which of late years these never have reached. If they merely educate those who give themselves for life to professions which depend entirely upon absolute brain-work, such as the law, medicine, and divinity, and also the class above these, who need not resort to a profession for their existence, they will fall vastly below the idea of their founders, and they would fall vastly below the reasonable expectation of the age in which we live. And yet it was a problem to know how they were to reach all the rest of the thinking part of the community. It was quite evident that the necessary expenses of a regular university career could not be met by numbers to whom God has given talents, natural and intellectual gifts, and also the higher desire which is above those gifts, to use them well. It was evident that it was impossible, because of the necessary expense of a complete university curriculum, that that curriculum should be opened to numbers of those who yet might come under the influence of a university education, and it was one of the happiest thoughts of these later times, which has, through these local examinations, united our ancient universities with all the young blood of England; not of those only who can reside for a regular time in the colleges of the universities, but of those who are to fill up the vast area of places and employments which in this great country require intellectual education and the formation of moral habits. He was convinced that, in giving to those classes the advantages of a searching examination, the universities had imparted a great part of their benefit. After all, education, for a great number of those educated, will have its high level fixed by the examinations which now and then test it. The benefit of that examination was that it possessed all the elements which make examination really valuable. In the first place, it was very real and searching. The examination of this year lasted four days and a half for the juniors, and for the seniors seven days and a half. Therefore, the first element of this examination is that it was very searching. It had this further element, that, from its very breadth and width, it must be a very fair examination. An examination conducted in a very small place, upon a very few people, before few examiners, upon a very narrow scale of examination, was very much like the point of a needle pricking the skin of a man—it does not scarify the whole creature thoroughly; but this examination, applied to the whole country, administered by the two great universities themselves, with every one of their leading men taking a part in it, and each having a rub at the poor examined creature, does scarify the whole intellectual and moral being of the poor wretch subjected to it in a way which undoubtedly makes it a very fair examination. Those who are examined know very well that no little tricks will do, that there is no possibility of getting out of the way of the scarifier, as they might get out of the way of a single needle, and that they will be caught somewhere, held fast, and well scrubbed till it appears what their real mental condition is and what it is when they are subjected to this very perilous analysis. Therefore an examination so complete is nationally educating; it does really test what is in those who come up to be examined; and it is, upon the whole, a most useful, a most enlivening, and a most enlightening process. Of those who do fail, far more fail in the necessary subjects than fail in the optional subjects; indeed, scarcely any fail in the optional. That showed that there would be still fewer failures if more attention were given to that which is expressively spoken of as grinding in the necessaries and less to the optional subjects. It must be a disagreeable thing, of course, to grind and to be ground. But the process is very necessary; there is no coming to any good result without it. You cannot get imperfectly ground flour to make fine bread. I say again, then, grind more upon the necessary than upon the optional subjects; that will have a further effect. The percentage of passes to the total number examined is 67; in the London district it is 62.

JOHN CARGILL BROUGH,

For Ten Years Editor of the 'Chemist and Druggist,' and the First Appointed Editor of the "Year Book of Pharmacy."

It is proposed to raise by subscription a fund for the maintenance and education of the five children who have been left unprovided for, by the untimely death,—at the age of thirty-eight,—of this well-known representative of Science and Pharmaceutical Literature.

The late J. C. Brough commenced his career, while yet a boy, on the staff of the 'Illustrated London News," on which journal his father held an appointment. He was subsequently engaged as a writer for the daily press, and was the author of a large number of articles, stories, essays, and scientific papers, for various popular magazines and periodicals.

Among the best known of these earlier works is a delightful volume, entitled 'Fairy Tales of Science," which is still regarded as one of the most charming examples of his peculiar ability to impart scientific knowledge to the young. He, at the same time, devoted himself to scientific pursuits and inquiries, in which he always took a lively interest, and eventually became the editor of the 'Chemist and Druggist,' as well as editor, and indeed, originator, of the 'Laboratory,' a weekly journal of physical and chemical science, which was held in high repute by leading scientific men both at home and abroad. In August, 1869, Mr. Brough, in conjunction with two friends, produced 'Exeter Change,' and was appointed sub-editor of 'Nature' at about the same time. He was also engaged in the preparation of new editions of Cooley's Encyclopædia and other standard works for above ten years.

In July, 1870, he was appointed Principal Librarian of the London Institution, an office for which both his literary and scientific acquirements, and his geniality of disposition, eminently qualified him. In 1867 he had lost his wife, and shortly afterwards a widowed sister, whose two orphan children he and another sister adopted, and continued to support. He was thus left with five children dependent on his exertions. Although the serious illness, which was ultimately the cause of his death, had begun to affect him painfully during the last year of his life, he, through all his weakness and pain, fulfilled the duties of his office in a most exemplary manner. The managers of the Institution in their annual reports, bear ample testimony to his indefatigable energy and ability.

In July of this year he went to stay for a time at Esher, in the hope of rallying his strength, but became rapidly worse, and finally sank on the 7th of September. The orphan children on whose behalf this appeal is made are:—

Bennett Hooper Brough, aged 12 years.
John Watkins Brough, aged 9 years.
Mary Elizabeth Brough, aged 5 years.
Mary Chilton, aged 10 years.
Arthur Chilton, aged 8 years.

NAVAL DISPENSERS.

The following Order in Council has been issued, containing New Regulations for the appointment of Dispensers at Her Majesty's Naval Establishments, a copy of which has been forwarded to the Editor of the PHARMACEUTICAL SOCIETY by the Director-General of the Medical Department of the Navy:—

AT THE COURT OF BALMORAL,
The 15th day of October, 1872.
Present:
THE QUEEN'S MOST EXCELLENT MAJESTY IN COUNCIL.

Whereas there was this day read at the Board a memorial from the Right Honourable the Lords Commissioners of the Admiralty, dated the 9th of October, 1872, in the words following, viz.:—

"Whereas we have had under our consideration the pay and position of dispensers in your Majesty's Naval Hospitals at home and abroad:

"And whereas we are humbly of opinion that it would be for the advantage of your Majesty's Naval Service to cancel the regulations affecting these officers now in force, dated the 24th day of June, 1870, and to improve their position by granting, in certain cases, increase of pay, and by placing them on the list of civil salaried officers.

"We do therefore beg leave to submit that your Majesty will be graciously pleased by your Order in Council to establish the following regulations for the appointment, pay, and allowances of dispensers in your Majesty's Naval Hospitals at home and abroad, in lieu of those now in force, and to direct that the establishment of such officers to whom the said regulations shall apply shall be as follows in the various Naval Hospitals:—

Haslar	3	Cape of Good Hope	1
Plymouth	3	Jamaica	1
Yarmouth	1	Bermuda	1
Haulbowline	1	Ascension	1
Chatham	1	Hong Kong	1
Malta	1		

"*Proposed Regulations.*

"1. Candidates for the office of dispenser must make a written application to the Director-General of the Medical Department of the Navy, and, as vacancies occur, they will be ordered to attend at his office at the Admiralty.

"2. The age of dispensers on entry shall not be less than 20, or more than 25 years.

"3. Candidates must be in good health, and of good character, and must possess certificates of either the Major or the Minor qualifications of the Pharmaceutical Society of Great Britain. Those who are entered, possessing only certificates of the Minor qualification, will not be permitted to receive the allowance for the charge of stores named in paragraph 9 of these regulations, until they have obtained the Major qualification.

"4. Candidates will be required to obtain certificates from the Civil Service Commissioners, in accordance with the terms of the Superannuation Act of 1859, and of the Order in Council, dated 4th June, 1870, published in the 'London Gazette' of 7th June, 1870. The Commissioners will satisfy themselves as to the age, health, and character of the candidates by personal communication; their physical fitness will, however, be determined by examination at the Medical Department of the Admiralty, where certificates of fitness will be granted for the information of the Civil Service Commissioners, who will also accept the certificates of the Pharmaceutical Society in proof of the candidates' knowledge and ability, without further examination.

"5. Dispensers will be required to serve in any of Her Majesty's Naval Hospitals to which they may be appointed, either at home or abroad.

"6. Dispensers will be included in the list of salaried officers with all the advantages pertaining thereto, and will be entitled to Superannuation under the Act of Parliament of 1859.

"7. Dispensers will be paid at the following rates:—

	Daily Rate. s.	d.
Under 5 years' service	5	0
" 8 "	5	6
" 11 "	6	0
" 14 "	6	6
" 17 "	7	6
" 20 "	8	6
And for each additional year of service after 20 years, 6*d*. a-day extra, until the maximum is reached, namely	10	0

"8. Dispensers will be provided with quarters, and will be granted an allowance of 6*d*. per day in lieu of fuel and lights.

"9. Dispensers in charge of stores will be granted the following additional allowances, viz.:—

	Daily Rate. s.	d.
At Haslar, and at Plymouth Hospitals	2	0
At any other hospital at home or abroad	1	0

"10. Dispensers serving at the following stations abroad, will be paid a further allowance to meet the increased cost of living, viz.:—

	Daily Rate. s.	d.
At Malta, and at the Cape of Good Hope	2	0
At Jamaica, Bermuda, and Ascension	3	0
At Hong Kong	4	0

This allowance, however, will not be included in the pay and emoluments on which civil superannuation will be granted.

"11. Dispensers serving at home will be granted twenty-eight days' annual leave, exclusive of Sundays, subject to such arrangements as the Public Service may require. Those serving abroad are to be allowed the same annual leave, with liberty to reserve it from year to year, so as to obtain a lengthened period of absence; such reserved leave is not in any case to exceed six calendar months, and arrangements must always be made for carrying it into effect without putting the public to any expense in providing substitutes.

"12. In cases of sickness, dispensers will not be permitted to remain absent on sick leave more than twenty-eight days in the aggregate in any year, without the sanction of the Lords of the Admiralty, who will grant an extension of leave in such cases as they may think fit, but not exceeding a total period of twelve calendar months. When sick leave has been granted, full pay will be allowed for six calendar months from the first day of absence from duty on account of sickness, after the expiration of which time, half-pay only will be granted, except when the dispenser would, if superannuated, be entitled to a higher amount, in which case he may be paid at the superannuation rate.

"13. Dispensers now serving, who entered the Naval Service before the Superannuation Act of 1859, and who since their entry have served continuously, shall be entitled to the benefits of these regulations without being required to obtain any qualifications of the Pharmaceutical Society. Those who entered subsequently to the passing of the Act, must qualify themselves in accordonce with these regulations, if serving at home, within twelve months from the date hereof, or if serving abroad, within twelve months after their return to England. Those who do not so qualify, will be superseded by others who are qualified.

"The Lords Commissioners of your Majesty's Treasury have signified to us their approval of this proposal."

Her Majesty having taken the said memorial into consideration was pleased, by and with the advice of Her Privy Council, to approve of what is therein proposed. And the Right Honourable the Lords Commissioners of the Admiralty are to give the necessary directions herein accordingly.

EDMUND HARRISON.

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 9, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

DEODORIZERS, DISINFECTANTS AND ANTISEPTICS.

So much has been written on the genuine or assumed merits of agents professing to possess deodorizing, disinfecting and antiseptic qualities, that we are not surprised to find in them, as in other matters, science and commerce joining hands, and working somewhat too closely for the benefit or convenience of the general community. Chemists have been endeavouring for many years, assisted to a greater or lesser extent by the practical experience of doctors, to find out an innocuous and efficient destroyer of bad smells, a neutralizer of the baneful products of decomposition, and an arrester of that process, but with comparatively ill-success. Our leading medical and chemical authorities appear still to give carbolic acid the first place, for though highly poisonous, safety ought to exist in its smell. For, in spite of the accidents recorded, we take it that none but drunkards or lunatics would ever think of swallowing it, and as Mr. DISRAELI observed, "it is impossible to legislate for the unaccountable eccentricities of stupidity." The solution of chloride of zinc has lately got into disfavour among the "patent safety" organizers, as it is not only poisonous, but colourless, and comparatively inodorous. The permanganates and the perchloride of iron are good in some respects, and convenient, but are costly; and chloralum, chloride of calcium, the "marvel" fluid, the "Eureka" fluid, the "chlozone disinfecting fluid," and, for aught we know, many more, are still untried, but are all being pushed into the market with marvellous persistency and assiduity. Meanwhile, we have been favoured with another (a very lengthy) communication from "One of the Laity," who demurs to the editorial remarks appended to his letter that appeared on the 28th of September, and again attacks the official scale of the Board of Trade. He is probably ignorant of the fact that the amiable rulers at Whitehall, doubtless with a view of conciliating as many "deodorizers" as possible, have (wholly unmindful of shipowners' pockets) ordered three varieties of purifiers to be carried, viz., Condy's fluid, carbolic acid, and chlor-alum. This, which may be called the C process of disinfection, affords the charm of variety to the bewildered captain, and should afford at the same time consolation to our discursive correspondent. But, in spite of asseverations to the contrary, we find, as a result of much practical experience afloat, that carbolic acid is still generally used. Our correspondent says that "carbolic acid has caused the death of more people in the last seven years than chloride of zinc has occasioned since the time (now many years ago) when Sir WM. BURNETT was permitted to foist his fluid on the Royal Navy, much after the style wherein carbolic acid has since been foisted on the public by certain occult pseudo-scientific influences." We cannot, in the absence of categorical proof, accept the first statement as gospel. We neither know, nor care to know, the particulars of "foisting" so successfully pursued by the late Sir W. BURNETT. But if "One of the Laity" can suggest some harmless and efficacious variety of carbolic acid, "occult pseudo-scientific influence" will not be required in order to foist it on the public.

THE JOHN CARGILL BROUGH FUND.

WE have much pleasure in directing attention to the announcement respecting this subject, which will be found elsewhere. Mr. BROUGH'S many literary and scientific claims to our respect need not be mentioned, as they are sufficiently well known. To Mr. BROUGH we are largely indebted for the exercise of influence over those, once called "outsiders," whom by his example and his writings he persuaded to advance the general good, and to unite with one heart and soul in promoting the interests of pharmacy. In healing the unhappy disputes which then prevailed, Mr. BROUGH had no minor nor inconsiderable share. He was the originator of those monthly written examinations on chemistry which have so effectually aided the progress of the pharmaceutical student: and he would have been formally numbered in our ranks, had not constant ill-health and pressing occupations hindered. The influential names on the Committee are sufficient guarantee that the fund may be cordially supported. Probably no one in his lifetime was more eager to help others to the utmost of his ability than Mr. BROUGH: he was indeed conspicuous for his daily kindnesses. We feel sure that the five children who were dependent on him for support will not be left unprovided for by that large circle of pharmacists to whom the late JOHN CARGILL BROUGH was so much endeared, and amongst whom his name was a household word.

THE number of candidates entered for the Cambridge University Local Examinations in December next is 3075, being an increase of 242 as compared with last year. The examinations commence on Monday, December 16, and are held at 44 centres for boys, and 34 for girls.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

November 6th, 1872.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

MR. W. SCOTT BROWN, VICE-PRESIDENT.

Present—Messrs. Atherton, Betty, Bottle, Frazer, Greenish, Hampson, Hills, Owen, Radley, Sandford, Savage, Schacht, Shaw, Stoddart, Sutton, Urwick and Williams.

The minutes of the previous meeting were read and confirmed.

North British Branch.

Mr. Frazer reported that the furnishing of the offices of the North British Branch was being proceeded with under an estimate which he considered very moderate.

The President reported that the coroner of Norwich, who had been communicated with, in accordance with the resolution passed last month, had acknowledged the receipt of the Secretary's letter, and stated that he had no power to direct the prosecution of any person for such an offence as that alluded to, unless a verdict of murder or manslaughter were returned by a jury.

The letter was ordered to be entered on the minutes.

Appointment of Analysts under the New Adulteration Act.

The President submitted the opinion of the Attorney-General, the Solicitor-General and Mr. A. G. Langley on this subject, which has already appeared in this Journal at p. 293.

Appointment of an Examiner.

The President said the next business was to elect an Examiner in the place of Mr. Bird, whose retirement was previously reported. Five gentlemen having been nominated, a ballot was taken, resulting in the election of Mr. William Martindale, of University College Hospital. It was then resolved that Mr. Martindale's name be submitted to the Privy Council for approval.

Three members of the Society having paid their arrears of subscription, together with the subscription for the current year, were, upon payment respectively of a nominal fine of one shilling, restored to membership.

A former associate was also restored on payment of arrears and a fine of one shilling.

Election of Members.

The following Registered Chemists and Druggists were elected Members of the Society:—

James, Kirby .... Beverley.
Priest, Edward Raven .... Cromer.

In addition to the above, the name of a lady was proposed by Mr. Hampson, and seconded by Mr. Urwick, for election to membership of the Society, she being a registered chemist and druggist.

Mr. Bottle asked under what section of the Act or what clause of the bye-laws it was proposed to elect a lady to membership.

Mr. Hampson said he considered that the 18th section of the Pharmacy Act, 1868, made the applicant eligible as a member. The word "his" in that clause, as in many others, evidently was synonymous with "her." A lady applied for membership and was refused three times in 1869, on the ostensible ground that she was not in business on her own account at the time she applied. He thought it very desirable that this matter should be definitely settled; the lady whose name he had proposed was on the Register; he understood she was in business, she had been mentioned to him by a medical man of some standing, and she had been properly proposed and seconded, and he conceived it was their duty to elect her as a member. Having already decided on admitting lady students to the lectures, it was very probable that they would hereafter pass the Major examination as pharmaceutical chemists, and seek to become members, and therefore he wanted the Council to be consistent and admit those whom he considered properly qualified to membership.

Mr. Sutton inquired if this lady was really in business.

Mr. Williams said she was not. She was dispenser to a hospital for women.

Mr. Hampson said he had understood she was in business; at any rate she was on the Register.

Mr. Sandford said that as Mr. Hampson had referred to a former case, he begged to say that it was not entirely on the ground that the lady in question was not in business, that her application was rejected; but because there was a feeling amongst the members of Council that they did not want ladies as members. The non-election of a lady to membership would be no reason at all why ladies should not be registered as pharmaceutical chemists. This was a private Society, entirely apart from the Register, and it was for them to decide as a Society whether they wished to admit lady members or not; and in fact whether a lady should occupy the presidential chair. For if ladies were admitted to membership, they could of course be elected as members of Council.

Mr. Hampson: Certainly.

Mr. Sandford said he should oppose the election of ladies, for the reasons he had given.

Mr. Owen thought the Council ought to be consistent. They had just passed a resolution to admit ladies to the lectures and classes, and he did not see how they could deny them the privilege of becoming members.

Mr. Savage said that on the previous occasion to which reference had been made, he had certainly voted against the election of the lady, simply on the ground that she was not in business on her own account. At the same time, while he did not object to ladies receiving the educational advantages of the Institution, he saw no necessity to elect them to membership.

Mr. Betty said this this was a matter which required very careful consideration. He could not compete in gallantry with Mr. Hampson, and was not prepared on such short notice to decide on so important a matter. Theirs was a voluntary Society, and they could elect whom they pleased; and he feared they might find themselves in a false position if they adopted this principle. The Edinburgh University had admitted Miss Jex Blake to some of the privileges of the University, and now they could not get rid of her.

Mr. Williams suggested that the decision of the question should be postponed for the present.

Mr. Brown thought they ought to know for certain whether this lady was in business or not. In the absence of any definite information, he should advise the postponement of the question.

Mr. Williams said there was no doubt that the lady was not in business for herself.

Mr. Brown remarked that in that case he should vote against her election.

Mr. Savage said he should take the same course, and for the same reason.

The President said he remembered the case before referred to, when he voted against the election of the lady on the ground that the founders of the Society never contemplated the admission of ladies to membership, nor did the framers of the Pharmacy Act, or the words "or her" would be inserted after the word "his" in the various clauses.

Mr. Schacht also advocated a postponement of the matter in preference to a decided rejection of the claim at present, which seemed likely to be the case if the vote were pressed. He did not think the matter should be treated in a jocular spirit, nor did he see any reason for alarm if ladies were elected to membership. It did not at all follow that they would be elected to the Council table or the presidential chair; though if the majority of the members desired to confer that honour upon them, he saw no reason why they should not be elected. There was no possibility of this being the case at present, and he thought that was all the answer such an argument deserved. The question was one of abstract right. If a lady had a right to occupy the position of a chemist and druggist, it certainly seemed rather small on their part to deny them the privileges and great advantages of belonging to the Society if they wished. He would suggest to Mr. Hampson to withdraw the name for the present, and perhaps when the matter had been more looked into, it would be seen that it was not so alarming a proposal as some gentlemen seemed to think.

Mr. Hampson said he would accept this suggestion, hoping that the matter would be reintroduced before long.

Mr. Urwick acquiescing, the motion was withdrawn.

Election of Associates.

The following gentleman having passed the Modified examination, and being in business, was elected an Associate in Business of the Society:—

Platt, William..............Stonycroft, Liverpool.

The following gentlemen, having passed their respective examinations, were elected Associates of the Society:—

Minor.

Capstick, John William ......Lancaster.
Culverwell, John Sayer ......Windsor.
Cunnington, Richard Elliott ..Bristol.
Davidson, William ....Edinburgh.
Dymott, Frank ....Southampton.
Farr, Joseph ....Peterborough.
Flinders, Matthew Tom ......London.
Kershaw, Joseph Henry......Manchester.
King, Horatio Alfred ....Norwich.
Lester, Henry ....Northampton.
Lindsay, George William ....Sunderland.
Litten, Henry ....Sittingbourne.
Marjason, John Morriss ......Dublin.
Norton, Thomas ....Stafford.
Parrott, John ....Norwood.
Smith, Thomas Henry........York.

Modified.

Barton, Septimus William.....Manchester.

Election of Apprentices and Students.

The following having passed the Preliminary examination, were elected Apprentices or Students of the Society:—

Collier, Philip Davies ....Reading.
Gibbons, George ....Adwy.
Gilling, John Thomas........Ripon.
Hitchcock, James............Whittington Moor.
Sainsbury, Allan Fox ....London.
Stables, William Skilbeck ....Scarborough.

Finance.

The report of this committee was received and adopted, and sundry payments, including £100 for furnishing the new premises of the North British Branch, were ordered to be made.

Benevolent Fund.

The report of this committee was received and adopted.

The result of the election of annuitants on the fund, which took place on the 25th ultimo, was reported to be as follows:—

Henson	2557
Wilkes	1811
Kennett	874
Informal Votes	118

The Treasurer was directed to pay the two annuitants recently elected their annuities to Christmas.

A grant of £10 was made to a registered chemist and druggist at Hamilton, Scotland.

A similar grant was made to George B. Kennett, of Clapham, the unsuccessful candidate at the last election of annuitants.

Library, Museum and Laboratory.

The report of the Library, Museum and Laboratory Committee was received. The following books were ordered to be purchased:—

Wagner's 'Chemical Technology.'
Simmonds's 'Science and Commerce.'
Cooley's 'Cyclopædia of Practical Receipts.'
'Jahresbericht über die Pharmacognosie,' 1871.
'Pharmacopœa Rossica.'
'Farmacopœa Española.'
Ferrand's 'Aide Mémoire de Pharmacie.'

Appointment of Curator of the Museum.

It was resolved that the salary attached to this office be £150 per annum, and that the duties be as follows:—

"Hours nine to five, continuously. Saturdays, nine to two.

"To arrange the Museum, and keep the same in good order.

"To be responsible for the securing and safe keeping of all the specimens.

"To mount all specimens which the Committee may direct.

"To clean and label the bottles, drawers, etc., and renew the specimens as often as may be required.

"To examine the specimens for the students, and to keep them in proper condition.

"To prepare and maintain in full efficiency a catalogue for the museum."

"To form and keep in order an Herbarium of medicinal plants.

"To be present at the evening meetings, and assist as far as possible in preparing for them, in conjunction with the Professors.

"To report monthly to the Committee upon all matters connected with the museum."

Three gentlemen who had been selected by the Committee out of a large number, were then called successively into the council-room, and after a few questions had been put to each by the President, a ballot was taken, which resulted in the election of Mr. Edward Morell Holmes, of London, pharmaceutical chemist, to the office.

Jacob Bell Memorial Scholarships.

The following were the recommendations of the Committee appointed to consider this subject:—

"1. Eligibility. — Candidates must be Registered Students or Apprentices of the Society under twenty-one years of age, and have passed not less, or been engaged for not less, than three years in the pharmacy of a Registered Pharmaceutical Chemist or Chemist and Druggist.

"2. Subjects of Examination.—*Latin*:—Virgil; the three first books of the Æneid; Latin prescriptions; translations of Latin into English and English into Latin; translations from any Latin pharmacopœia, and parsing. *French* or *German*. *English*:—Composition and parsing. *Arithmetic*:—The four first simple and compound rules, fractions, and decimals; the British and metrical systems of weights and measures. *Elementary Chemistry*, *Pharmacy* and *Botany*.

"The examinations to be wholly in writing, and in the case of any candidate unable to attend No. 17, Bloomsbury Square, to be conducted under the same conditions as the 'Preliminary,' and such safeguards as the Council may from time to time deem expedient, and that the papers written by the candidate be numbered, *not named*.

"The examination to be conducted by two members of the Board of Examiners, and the award made (subject to the approval of the Council) by a Committee of the President, the Vice-President, and the two said examiners."

Mr. Stoddart said he supposed those who were eligible for these scholarships must have passed the Preliminary examination, and be registered as apprentices or students.

The President said that was so.

Mr. Atherton did not think these regulations necessarily excluded persons who had passed the Minor examinations.

Mr. Williams said they were intended to do so, and he believed had that effect.

The President said that French or German had been added to the subjects of examinations since the recommendations were formerly before the Council, and also Elementary Pharmacy and Botany.

Mr. Savage rather objected to the age being limited to twenty-one; many were apprenticed at sixteen for four years, and would then be in a position to compete, but if they thought they would have a year in which to prepare, it might lead to idleness during their apprenticeship. He should prefer not limiting the age, but simply providing that no one who had passed the Minor examination should be eligible.

The President said the regulation only provided that the candidates should not be over 21. It did not say how much under they might be.

Mr. Williams said a man might not pass the Minor examination until he was 24, or even later, but it was not desirable that men of that age should compete with those under 21, for whose benefit the scholarship was intended.

Mr. Schacht said the Board of Examiners were about to propose that the Minor examination should not be passed under the age of 21. He suggested that students should not be compelled to enter on their studies at once, because in some cases they were not out of their apprenticeship.

Mr. Urwick said many young men now entered on their apprenticeship late, so that it did not expire until they were 21, when they would be unable to take advantage of this Scholarship.

Mr. Hills said they could not keep the Scholarships open, because a vacant bench was left in the laboratory for the scholars, and the next session it would be wanted for some one else.

Mr. Williams thought the regulations in this respect could not be altered. If a young man were not able to avail himself of the Scholarship, why should he compete for it?

Mr. Sandford suggested the addition of the words "No person who has passed the Minor examination shall be eligible to be a candidate" to the first paragraph.

Mr. Frazer did not at all agree with the recommendations of the Board of Examiners as to age, for he began his apprenticeship at the age of 10, and he had assistants now in his employ who were thoroughly qualified at 20 for their duties, and he thought such men should have an opportunity of passing the Minor examination.

Mr. Schacht said he saw no necessity for the addition of the words suggested, which he thought would be tautology, inasmuch as the first part of the paragraph stated that candidates must be registered students and apprentices of the Society, and they would cease to be such on passing the Minor examination.

Some discussion ensued as to whether this was really the case, but as it appeared on reference to the bye-laws, sec. xi. clause 3, that on passing the Minor examination a registered student was immediately taken out of that class, Mr. Sandford withdrew the suggested amendment.

The recommendations of the Committee were then unanimously adopted.

Parliamentary.

The report and recommendations of the Committee were received and adopted.

Mr. Hampson proposed the motion of which he had given notice:—

"That the names of the voters for or against any resolution submitted to this Council be published in the Journal reports of the proceedings."

He thought that as the members of the Council represented the Society and the whole trade, it was a necessity that the members at large should be made acquainted with the way in which the votes were given, in order that they might form an opinion as to the character of their representatives. He could scarcely believe that any gentleman present wished his vote to be concealed, and he therefore brought forward this resolution.

Mr. Betty seconded the resolution, saying he believed it was already the rule that the name should be published, and if it had been omitted on one or two occasions, he supposed it was done inadvertently.

Several members of Council expressed their thorough concurrence with the view of Mr. Hampson, that where a division took place the names should be published, and that where this had not been done, it was simply a matter of pure inadvertence. But as it seemed the general opinion that it might prove inconvenient to lay down a rigid rule, it was suggested that the resolution should be withdrawn, to which Mr. Hampson assented.

Report of the Board of Examiners.

October, 1872.

ENGLAND AND WALES.

Examination.	Candidates. Examined.	Passed.	Failed.
Major	7	3	4
Minor	71	35	36
Modified	45	30	15
Preliminary	258	173	85
	381	241	140

Certificates received in lieu of the Preliminary Examination:—

University of Durham	2
" " Cambridge	2
" " London	2
" " Oxford	1
College of Preceptors	1
Incorporated Law Society	1
	11

SCOTLAND.

Examination.	Candidates. Examined.	Passed.	Failed.
Major	1	1	0
Minor	9	6	3
Modified	4	4	0
Preliminary	24	17	7
	38	28	10

General Purposes.

The report of the General Purposes Committee was also received, but, owing to the lateness of the hour, was not discussed.

The President reported that a letter had been received from Mr. Dymond containing a suggestion for securing a greater interest in local associations. The matter was referred to the Provincial Education Committee.

Two applications from chemists' associations at Aberdeen and Leicester for grants were also referred to the Provincial Education Committee.

Lady Students.

The Secretary said he had received a letter from Mrs. Garrett-Anderson and two or three other ladies, requesting to know whether at the end of the session lady students would be permitted to compete for the usual sessional prizes.

Mr. Brown suggested the consideration of this matter should be postponed until next month.

Mr. Williams said he saw no reason why they should not be admitted.

The further consideration of the question was deferred.

PHARMACEUTICAL MEETING.

Wednesday, November 6th, 1872.

MR. A. F. HASELDEN, F.L.S., IN THE CHAIR.

The following donations to the Library were announced, and the thanks of the Society were voted to the donors:—

Transactions of the Clinical Society of London, Vol. V., from the Society; St. Bartholomew's Hospital Pharmacopœia, 1773, MS., with notes, etc., and Haslar Hospital Pharmacopœia, 1777, MS., both from Mr. J. Fisher, through Professor Attfield; Thesaurus Zeylanicus Burmanni, from Mr. W. Young; Statistical Tables of Patients, 1871, from St. Bartholomew's Hospital; University College Calendar, 1872–3: from the College.

Mr. Hanbury called attention to some leaves of *Rheum officinale*, Baillon, a plant recently described in the Pharmaceutical Journal as the source of the true Chinese rhubarb.

Messrs. Hopkin and Williams exhibited fine specimens of Monobromo-Camphor and Carbazotate of Ammonia. Mr. Williams said, Monobromo-Camphor has lately been brought prominently before the medical world by Professor Deneffe, of Ghent, and quite recently to the notice of pharmacists by Professor Maisch, of New York; it is produced by replacing one atom of hydrogen in camphor by an atom of bromine. The body was first discovered by Perkin, and originally made by the action of bromine upon camphor under pressure in a glass tube; for bromine at ordinary temperatures simply forms the so-called bromide of camphor, which is not a substitution product. At about 130° Cent., however, bromine replaces hydrogen in camphor even at ordinary temperatures, and the product of the reaction dissolved in petroleum oil, as recommended by Professor Maisch, or in hot benzol, deposits the bromo compound as it cools, retaining the unaltered camphor in solution. Two or three recrystallizations from alcohol yield the new product in beautiful crystals, and perfectly pure, although still possessing a smell resembling camphor. It is, medicinally, a new sedative, and has been recommended in delirium tremens, and various other disorders, in doses of two grains frequently repeated.

The Carbazotate of Ammonia, Mr. Williams said, had lately been recommended as a substitute for quinine. It is intensely bitter, but, from the results of experiments made many years back upon a corresponding salt, the carbazotate (or picrate) of potash, he thought it somewhat doubtful if it would be found to be of great value. He also pointed out that care should be taken in manipulating it, as, under certain circumstances, it was violently explosive.

Mr. Bland called attention to a specimen of adulterated cochineal, remarking that such samples were common enough in commerce years ago, but it was many years since he had seen any of it adulterated to anything like the extent of that before them. The cochineal in this instance was loaded with about 20 per cent. of foreign substance, consisting principally of sulphate of barium.

Mr. Greenish drew attention to a very beautiful study of the common foxglove, which had been photographed and presented to the Society by Mr. Frank Good, the son of a member. Specimens of Gill's 'Triangular Poison Bottle' were exhibited, and also some asthma pastilles, presented by Mr. Hustwick, of Liverpool, and prepared from the following formula:—

Asthma Pastilles.

Pasteboard, broken down with hot water, 4 oz.
Nitrate of Potash, 2 ounces.
Belladonna.
Stramonium.
Digitalis.
Lobelia Inflata, all in powder, each 20 grains.
Myrrh and Olibanum, of each 2 drachms and a half.

Incorporate all these with the paste, divide the mass in shape little pastiles. Burn them in a saucer in a well shut room.

Tincture of Orange Peel.*

The President (Mr. A. F. Haselden) then read a paper on "Tincture of Orange Peel."

[The paper is printed at p. 361, and gave rise to the following discussion.]

Mr. Sandford, referring to a specimen of the tincture made by himself, said he had used fresh peel, cut extremely thin. He had not used rectified spirit but proof spirit, and had allowed it to macerate for a long time to get the fine colour it presented. The specific gravity of the specimen before them was ·935. He certainly thought that this was very much better than any tincture made from the dried peel. It had been objected that the tincture made in this way changed by keeping, but he had kept some of it for a long time, and never found any appreciable difference between the old and the new. He did not think there was any loss of tincture at all.

Mr. Groves said he had made experiments with fresh peel, peel recently dried, and old peel, and he found in the case of the fresh peel that in making a vinum quiniæ there was a precipitate formed, and after that had been taken off, there was in a day or two another precipitate, which was white. At first he had some suspicion that it was derived from some impurity in the quinine. He examined the quinine, and then went back to the tincture, and he found that that which was made from the undried peel contained a soluble salt of lime, which when mixed with the quinine became deposited. There was another objection against the use of fresh peel. He dried his fresh peel, ascertained exactly the quantity of water, and then made allowance for that amount in the proof spirit. He found that in cold weather this tincture threw off a considerable quantity of essential oil, and was rather unmanageable on that account. The result of his experiments was that recently dried peel was better than either fresh or old peel.

Mr. Sandford mentioned that if they bought the oranges, and cut the peel themselves they should be very particular to get the true Seville oranges. He was once deceived by some Palermo oranges, which were like Seville oranges in appearance, but made a very different tincture, and left an after taste in the mouth something like that of quassia.

Mr. Williams asked whether there was any distinctive mark or method of distinguishing between the two sorts.

Mr. Sandford said they could hardly tell except by tasting the peel, when they could distinguish directly the Palermo oranges by the peculiar bitter taste.

Mr. Greenish remarked that in some continental pharmacopœias a much stronger proof spirit was recommended than that used in this country for making tinctures, and double the quantity of peel.

Mr. Umney asked Mr. Haselden whether he could give them any idea why fresh peel was discarded in the Pharmacopœia of 1836, whilst it was ordered in that of 1824. Mr. Greenish had asked what would be the loss of spirit in making the tincture. If tincture of lemon made from fresh peel be taken as an example, then a gain rather than a loss might be expected. The objection to the foreign dried peel was, he believed, its adulteration with sweet orange peel, and the taste was the only means by which one could be distinguished from the other. Referring to specific gravities, he should expect there would be great difference with a tincture prepared with spirit strictly proof and a spirit diluted with such variable proportions of water as would be contained in fresh orange peel. He imagined that the compilers of the Pharmacopœia had discontinued the use of fresh peel merely on account of the difficulty there was at all seasons in obtaining the peel. Seville oranges were not always to be had at any time of the year, whereas dried peel could be always procured. After making the tincture from the fresh peel for a period of forty years, the house in which he was engaged had, upon his recommendation, discontinued the use of the fresh peel on account of complaints that had reached them that the tincture from the fresh peel, when diluted with water, had a much more milky appearance than that made from the dried peel. They now prepared tincture from dried peel as directed in the British Pharmacopœia.

Mr. Haselden, in reply to Mr. Umney, said he believed that the reason dried peel was ordered in the B. P. was out of regard to convenience, as it could be purchased at any time of the year. His object in bringing forward the paper was not to support any opinion of his own, but merely to show what his results had been in preparing samples from dried peel and from fresh peel. He appeared to have been unfortunate in the fresh peel he obtained, inasmuch as he believed it would be decided against the tincture from the fresh peel which he had made. He could not imagine how Mr. Sandford in making his tincture did not get rather more tincture when finished than the amount of proof spirit he commenced with.

Mr. Sandford repeated that there was no loss whatever, but rather a gain.

Mr. Haselden said that in making the tincture from the fresh peel, he really obtained two ounces in the pint more than he ought to have had, the moisture in the peel having produced that result; whereas, in the tincture made with the dried peel he lost about two ounces in the pint. That accounted in some measure for the difference in the specific gravities. The tincture made with the fresh peel was ·944; that made with the fresh peel dried by himself was ·936; whereas that made from the dried peel was only ·926 from the English cut peel, and only ·922 from the foreign cut peel. The specific gravity of that made from the dried foreign cut peel by percolation was ·938, exactly the same specific gravity as that which Mr. Stoddart mentioned in his paper at the Pharmaceutical Conference. He (Mr. Haselden) could only account for its going up to ·938 from the fact that in percolation, when they displaced by water, they got some of the water mixed up with the spirit, whereby the specific gravity was altered.

Mr. Bland said they were apt to overlook the fact that tincture of orange peel was desirable on account of two distinct properties. One was its fine aromatic perfume, and the other its bitter, which caused it to be regarded as a slight tonic. If they wanted a fine aromatic flavour, he was satisfied that fresh peel must be used, and not only that, but rectified spirit. A single drachm of the tincture made with rectified spirit from fresh peel would give as much of the aromatic flavour as a couple of ounces of tincture made with proof spirit from the dried peel. If they wanted a light bitter, then dried peel and proof spirit were the things to use.

Mr. Brown said he had had some considerable experience in making tincture of orange peel for flavouring purposes, and he entirely differed from the statement just made—that rectified spirit with fresh peel made a better flavour than dilute spirit. He should assuredly prefer dilute spirit as taking more of the flavour from the peel than the rectified spirit, and as being more manageable afterwards. He endorsed what Mr. Sandford had said, that the peel must be fresh, and must be cut most carefully so as to remove the white without injuring the vessels containing the essential oil. It required a considerable length of maceration, much longer than most other tinctures. Generally speaking, he had not found that a satisfactory result had been obtained in less than a month or six weeks.

The Proposed Universal Pharmacopœia.

Dr. Redwood read a paper on the proposed Universal Pharmacopœia.

The paper is printed at p. 361. After it was read—

Dr. Thudichum said the proposal of publishing a European pharmacopœia originated entirely with Professor Phoebus, of Giessen, in 1869, although it had been communicated to him (Dr. Thudichum) in 1867; so that the proposition made at Vienna was subsequent to the initiation of the enterprise. In speaking on this subject, he should have the advantage of referring to a memorial, which Professor Phoebus in the course of last year handed to the Commission appointed by the Imperial Government of Germany to perfect a general German Pharmacopœia. The first great reason for having a universal pharmacopœia was that there might be introduced into medical literature a uniformity of statement as to the medicines which were used by various physicians in different parts of the world. The second reason was, that the dispensing of medicines and prescriptions which had been carried from one land to another, frequently caused even to the most accomplished pharmacist great difficulty and loss of time; often loading him with a responsibility for which he was not prepared. In the third place, physicians sojourning in various parts of the world, were called upon to treat strangers and sojourners who congregated in climatic and hygienic places, such as those on the borders of the Mediterranean. In those places a great variety of people from all nations were brought together, and required that the local physician should administer to them medicines, and frequently aid them in getting the prescriptions properly dispensed which they carried with them from their native places. Under these circumstances, great difficulties often arose, because the physician of the locality was unable at first sight, and without great preparation, to appreciate the purport of the prescription which the patient brought with him. These three classes of difficulties caused misunderstandings and mistakes, and the patient might to some extent suffer in consequence of them. A careful selection of the most necessary items to be received in the European Pharmacopœia had numbered above two thousand, and it was utterly impracticable for a man to command any knowledge of two thousand drugs. So, too, when a physician went from one country to another, and found a different pharmacopœia, he could not immediately follow the footsteps of his predecessor. The differences of remedies in the different countries were in most cases justified by no practical necessity. Certainly from his (Dr. Thudichum's) point of standing as a physician, he could say, that so far as he was concerned, he would adopt any of the various formulæ which were given in the pharmacopœias if he could attain uniformity. It was not a question of great scientific moment which formula they adopted, so that they had uniformity throughout the whole of the pharmacopœias. During the last 200 years many men had tried to realize the idea of a general pharmacopœia, and the most frequent experiments had been made by single physicians and single pharmacists, each of whom had endeavoured to carry out his own idea in his own way, without any sort of co-operation with others. The first was Nic. Lemery, who wrote a Pharmacopée Universelle, and published it in the year 1697. There was further, Triller's Dispensatorium Pharmaceut. Universale, published in 1764; then Spielmann's in 1783; then Reuss in 1786; Mayr in 1798; Swediaur in 1803; Roeber in 1803; Brugnatelli, an Italian pharmacist, in 1807; and then Von Mons in 1821-2. In these most remarkable works the authors confined themselves to the collecting of various formulæ from different countries. They did not make any selection, nor indicate remedies which might be more or less worthy of recommendation. Only the latter one amongst the works he had mentioned had made such an attempt, and that only in the slightest degree. Jourdan's Pharmacopée Universelle, published in 1828, began to make a selection. All these works had a remarkable success, most of them passing through several editions, or were published in various countries in translations. Some of them reached four editions. In 1835, Geiger commenced the Pharmacopoea Universalis at Heidelberg, but dying before its completion it was finished by Mohr. The authors of this work made a selection of articles, and described the value of them by means of three classes of type. The most valuable medicines were printed in large type, the less valuable in smaller type, and the useless medicines in still smaller type. The same principle was adopted in the Baden pharmacopœia. The articles which were selected by the Commission of Baden being distinguished by particular signs, so that the Baden pharmacists had a sort of universal pharmacopoeia to refer to. The next important treatise that appeared was the Codex Medicamentarius Hamburgensis, in the year 1835, which stated that from international reasons, which had particular value at that great trading place, it offered a rich selection of remedies to its readers; and therefore this Hamburg pharmacopœia might in some measure replace a general pharmacopœia. In 1846, the idea of a general pharmacopœia was taken up in Italy, but it came to nothing. In 1847, the pharmacopœia for the kingdom of Würtemberg appeared, and this was distinguished by a great selection of remedies, many of which it had taken from the Codex Hamburgensis. It distinguished the value of remedies by differently sized letters in the printing, but it had not had any influence upon pharmacists out of the country. In 1864, there appeared a General Pharmacopœia by an author of the name of Strum, who merely collected, and entirely resigned all criticism. They had, then, in this country in 1867, the most excellent British Pharmacopœia, which effected a great simplification in this kingdom. In Germany a similar desire for this simplification of the various codexes led to the appointment of a Commission, which elaborated a Pharmacopœia Germaniæ in 1865; second edition, 1867. This pharmacopœia was no doubt a considerable progress upon what had formerly existed; and he believed it was now introduced as the Imperial Pharmacopœia in Austria. The Danish Pharmacopœia of 1868, and the Swedish of 1869, and the Norwegian of 1870, had agreed to give the same composition for all articles having the same name, which was a very great progress. In the years 1865–7–9 the question of this universal pharmacopœia was mooted at the International Pharmaceutical Congress; but he thought it would be very difficult for a reunion, as it were, of men who were not delegated by any other powers behind them, who might come together again or not, to do so serious a work as that of the general pharmacopœia. Now the Pharmacopée Française of the year 1866 also recognized in its preface that a universal pharmacopœia, or, at least, a European pharmacopœia, was a very desirable thing. The pharmacopœia itself was stated to be intended to help to prepare such a transition, such a union or harmony, and to have adapted itself in many details to the pharmacopœias of other countries. There was also another attempt at a universal pharmacopœia in Hager's 'Pharmacopoeæ Recentiores Anglica, Gallica, Germaniæ, Helvetica, Russiæ inter se collatæ.' He (Dr. Thudichum) had on the table a proof page of the proposed new pharmacopœia, in which several classes of type had been used; the important medicines being in large type, then the second class being smaller, and lastly, a small print for the common drugs. The value of the remedies was thus distinguished by the size of the print. That was the great principle introduced by Geiger and Mohr, and it was of the utmost consequence that it should be upheld. It would be easy for any pharmacopœia anywhere to exist in its integrity by upholding a certain kind of print for its own individual medicines, and yet embodying the whole of the remedies from the other pharmacopœias by giving them in different type. Therefore there was not the slightest difficulty for each country having its full and complete pharmacopœia, and, as it were, mixed up with it in a logical and alphabetical way, a universal pharmacopœia, so that the pharmacists and physicians would only have one book to refer to. Supposing that this work were not successful in being adopted by the public authorities of any country, he, nevertheless, claimed for it a very high scientific value, inasmuch as it would always, under all circumstances, be useful to any one as a book of reference. The society for carrying out the new pharmacopœia began with eight members, and they had latterly been happy enough to add several other international gentlemen to it, and these gentlemen now constituted what they called a "Pharmaconomic Society." The name had been adopted in order to indicate that the intention is not to produce a book for teaching, but strictly a book of law; that was to say, a book which could be followed by any one, and be to him a full and satisfactory exponent of prescription and justification of pharmaceutical action. The first condition was conciseness, and they hoped not to exceed fifty sheets of printing. He questioned whether any single man, no matter with what power endowed, would be capable of accomplishing such a work. It required the zealous and hearty co-operation of men distributed over all the countries concerned, men who could meet on common ground and mutually accord their experiences. He had no doubt that although the proposed work would not teach in words, it would teach by simple classification of the remedies. There were some medicines which were of cardinal importance to the healthful existence of man, and they were as old as history. In old historical works whenever they found mention of remedies, aloes was in the account, and there were digitalis and similar drugs. They would best see the difference there was between a country which was well treated by its physicians and well supplied by its pharmacists and one that was so far behind civilization that its pharmacy and medicine were both at a low standard by visiting such countries. Nevertheless, it was necessary for them, even in the best of circumstances, to constantly remind the mass of physicians and the mass of pharmacists what were the remedies of cardinal value, what were the remedies of subordinate value, but still useful remedies, and those which were mere trash, and which were therefore not only to be treated with indifference, but to be positively rejected. Although these latter remedies were to be discarded, they would still be found in the new Pharmacopœia, and the fact of their having to be rejected would be indicated. He hoped that it would be understood that in anything he had said, he did not in any way commit the Pharmaconomic Society. In some cases there were three or four alternatives presented to them, and it would depend greatly upon the opinions they could obtain from such bodies as the Pharmaceutical Society of Great Britain, which way their decisions in matters of detail were given. If, therefore, he had stated any principle which they should subsequently find changed, he hoped they would not think it inconsistent, as these matters of detail were now under consideration.

The meeting was adjourned to the 4th of December.

Provincial Transactions.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The first meeting of the association for the present session was held in Anderson's University, on Wednesday evening, October 30, at half-past eight o'clock; Mr. Davison, President, occupied the chair. He was supported on the platform by Messrs. Frazer, Currie, Kinninmont, Fairlie, and the lecturer of the evening, Mr. Betty, of London.

The minutes of the last meeting, together with a brief account of work done during the recess, in connection with certain motions carried at the last meeting, having been read, the Secretary stated that he had received a letter from the treasurer, Mr. Young, in which he intimated his resignation of the treasurership. It was also mentioned that Dr. Moffat had written to the Secretary expressing his regret that, owing to the pressure of professional engagements, he will be unable to render any assistance to the association this session. Several new members were then elected.

Mr. Young's resignation having been accepted, the President proposed that the Secretary should undertake the duties of treasurer *pro tem.*, which was agreed to. The Chairman then introduced Mr. Betty, who delivered the following address:—

Mr. President and Gentlemen,—Neither as a form nor a precedent, but strictly as a necessity, would I preface the substance of my address to you by a word of apology for my appearance amongst you this evening. To be frank, in my readiness to accept an invitation so cordially given by my brethren in Glasgow, and affording me the opportunity of becoming personally acquainted with the gentlemen who would welcome me as a guest and visitor in Scotland, I lost sight of my incompetence for the task attaching to my visit. Accord me, therefore, I pray you all the indulgence I require at your hands.

The question I purpose enlarging upon has been treated of on similar occasions to the present by many of our fellow-members, whose addresses doubtless you have read, and whilst it is not easy to avoid the repetition of what has been better said, it is easy to pass unnoticed much of practical value; yet though the subject remains a wide one, it has been shorn somewhat of its former amplitude. It has become unnecessary to dwell upon the advantages of application to the subjects of botany, chemistry, or materia medica. The syllabus of our examinations makes the study of these subjects imperative, and whoever would falter in his resolve to face that issue may take for himself the chiding of King Henry to Westmorland, "That he who hath no stomach to this fight, let him depart; we would not live in that man's company;" but I am much mistaken if you are not earnestly resolved to enter the lists (shall I add, to excel among your compeers and competitors?) and the aims of these sessional reunions are to give you words of encouragement, and to aid as far as we can your endeavours. It would be more than superfluous were I to detain you with remarks on your professional studies in connection with the nature of your daily employments, after Mr. Stoddart has exhausted the subject. He has urged students to use their powers of observation, so that many a work that otherwise would be irksome or mechanical may excite interest, lead to investigation, and reveal to the mind some hitherto hidden secret of nature. Upon the arrangement of your studies I quote the original. "There is one warning I am desirous to impress upon you with great earnestness, viz., the incalculable advantage of a systematic arrangement of your studies. I speak from experience when I say that a loose, indiscriminate manner of study is so much time lost. If you have ever so extensive a library, and dip at random into your Attfield, Bentley, Lindley, Fownes, and Royle, you will make a terrible mistake, and totally put a stop to profitable study. Should any of you attempt to pursue so erroneous a course, however industrious you may be, you will feel extremely uncomfortable when you have to face the Board of Examiners. A method I have always found to work extremely well is to draw up a tabular arrangement according to circumstances. Botany for one day, chemistry for another, materia medica for the third, and stick to it. If you are prevented from enjoying the half-hour allotted to Bentley, pass it over and work with Attfield on the appointed day, but never upset the arrangement. Use every spare five minutes. You will never know till you try what a large amount of work can be performed in a few odd moments. Do not think because you cannot have a couple of hours at a time that you are therefore debarred from study. Where there is a will there is also a way. Not one of your predecessors ever had the advantages you possess, the books you have, or the class-instruction now offered." And Mr. Stoddart adds, "Don't be without a microscope." You are thus warned of your prospects when before the Examining Board you are thrown on the results of random reading; nor can you supplement such unsystematic application by spasmodic efforts at learning just before "going up." Do not lend too ready an ear to captivating announcements; for recollect always the profitable result for you to attain is not to pass an examination, but to be educated up to its standard; avail yourselves of what assistance you can in your work, but expect no royal road to successful study. Consult rather the interesting statistics of our examinations for the sessions 1870–71, 1871–72.

	Total No. examined.	Passed.	Failed to pass.	Per cent. of failures.
Total number of examined candidates	694	436	258	37·70
Of these were connected with the Society's school	181	130	51	28·17
Not connected with the Society's school . . .	513	306	207	40·30

Conceded that the systematic teaching in a pharmaceutical school does aid education, and that our recognized school does educate, these figures prove conclusively that our examiners bring out the fact in the percentage of failures; and hence that our examinations do test a candidate's real knowledge.

And when you take into consideration the number of those who pass self-prepared; of those who, though prepared, hesitate to face the Board without some special help; of those who having failed by a few points only, seek private instruction, the aggregate will, I am convinced, show you that a fair preparation is the passport to a pass examination.

It would be dispiriting to our educational efforts were it otherwise; that, is if we had any reason to suppose that the efficacy of our examinations fell below that standard of excellence which prevails elsewhere. Many of us have a vivid remembrance how much examiners did possess of that fatal facility to discover, and that perverse propensity to follow up what we politely call "a partial knowledge of the subject." If I am not much deceived by what I hear, and my experience of its matriculative examination, the London University may be said practically to set cram at defiance; that monster cram which many more denounce than refuse to coquet with, and of which in our pious horror it becomes us not to magnify the proportions.

Reposing in our Board of Examiners a confidence shared in by the Government Assessor, I should judge it to be inconsistent not to resist any attempt to impose on your method of study conditions, such as compulsory attendance at lectures, which are not a necessity for a pharmaceutical examination. Raise the standard of examinations, if so you will, but allow free trade in learning. Whatever the advantages of class teaching, they are not a necessity. It may not surprise, yet must encourage many a beginner thrown on his own resources, to know that there were nine candidates for the first Bell Scholarship, and that the first was Mr. Talbot, who was located in a small provincial town, and had no help but class-books; that the present holder of the prize was self-instructed. How would it have fared with these students had they, in addition to proof of their talents, been required to demonstrate by their tailors' bills the extent of broadcloth or of tweed they had worn out on the forms of a class? The proposition how the Pharmaceutical Council can most effectually aid local efforts in affording means of professional education amongst us, has become the question of the hour, and presuming the subject comes within the scope of this address, I would not pass it by without comment.

We possess but one considerable school of pharmacy, that of London; that school is also singular as being subsidized largely out of the funds of the Pharmaceutical Society. This fact presents for our consideration the two main questions, Shall the Pharmaceutical Society cease to be an educating body, and withdraw its contribution to the cost of the London school? and, If the time has not yet arrived for the Society to declare itself an examining and registering body only, in what way shall it continue to exercise its double functions?

That a corporation empowered to examine should at the same time permanently supply that education which it is its legal duty to appraise, would be contrary to our usages. In your University of Glasgow, I am aware, examinations are conducted and education supplied, but the offices are held by distinct corporations.

The voice of a majority having pronounced for a continuance of the present system, and its extension throughout our country districts, the Council will be called upon shortly to decide upon the best means of carrying out this object. It will thus take a decided step towards the eventual dissociation of its examining and educational functions; for as this extension of provincial instruction is justified on the ground of its utility, it becomes part of our educational scheme to link metropolitan and provincial education into one system,—that is to say, so long as the Pharmaceutical Council decide to support by grants pharmaceutical education, so long must that assistance be apportioned between the metropolitan and provincial schools. At least, so it appears to me. I do not see any grounds on which you can reasonably subsidize a London school and refuse the demands of country associations for similar help. Our records from 1852 to 1868 prove most positively that the encouragement to provincial schools of pharmacy was an object dear to the hearts of the founders and the promoters of the Pharmaceutical Society, and this has ever been a tradition amongst us. Nor can I regard the pharmaceutical area as a desert containing one spring, but dammed up at its source, whither those who thirst for instruction must travel to drink; its waters should rather flow as far and wide as our present needs extend, at least, till impassable obstacles arrest their course. We should expect provincial schools to flourish rather than to witness our seats of learning confined to capitals. What obtains with us in common with other nations in Europe?

For centres of teaching must we seek their capitals? On the contrary, in Portugal we find Coimbra; in Spain, Valladolid, Salamanca, Seville; in Germany, Leipsic, Wittenberg, Heidelberg, Prague; in Sweden, Upsala; in England, Oxford and Cambridge. The University of Bologna, though proximate to Rome, flourished, and boasted of professors whose fame was European. One old medical school which will ever excite interest among students of medicine and pharmacy, and whose axioms so quaintly declared will never be forgotten, was that of Salerno. How many times have we run over in our minds the diagnosis of a cold,—

> "Si fluit ad pectus, dicitur rheuma catarrhus,
> Ad fauces bronchus, ad nares esse coryza;"

or in discussing with a keen appetite some culinary triumph redolent of the sage bush,—

> "Cur morietur homo, cui semper crescit in hortis
> Salvia salvatrix, naturæ conciliatrix?"

Though Abelard attracted, by his expositions of philosophical theology, that immense concourse of listeners in the university of Paris, we are told that France, on the other hand, *en revanche*, as they express it, possessed numerous provincial universities. St. Andrew's, Glasgow, and Aberdeen led the way for Dublin, Edinburgh, and London. The men who watched over our early institutions were not forgetful of these facts, as testified by their enduring desire to foster country schools of pharmacy. They raised in the metropolis an edifice destined to be the regal home of pharmacy, the source of all titles and honour, but with the example before them of the astute and patriotic Wolsey, who built his palace in Middlesex, but founded a college at Oxford.

One great result of academical teaching must not be overlooked, that *esprit de corps* which grows up and strengthens between young men associated for the same object, producing emulation, esteem, and frequently enduring friendships. What advantages are thus conferred on the young pharmacist over his predecessor, who too frequently regarded every other man in the same business as a stranger or a rival? In its coming attempts to set provincial education on a secure basis, I believe the Council will succeed by a scheme thorough, well considered, and liberal to the verge to venture. To have attempted is not enough; it must attempt and attempt again, so that it may at any future time confidently point to the share it bore in the trial. If I may draw any inference from facts, a good school, or good pharmaceutical teaching, will be a permanency in Glasgow, for here I find myself in a city, the commercial importance of which is of somewhat recent date, yet boasting of an university whose foundation dates almost within the range of mediæval history, of a school still more ancient, and which, at the present day, maintains both in increasing efficiency. Having so far treated of your professional curriculum, allow me, in speaking now of your general education, to remind you that just as working up so much subject matter as will pass you in a pharmaceutical examination, without such an interest in your work as begets the continuance of your exertions, is not true pharmaceutical education, so will the aims of your school-instruction be frustrated by a non-continuance of reading and application to the subjects of your scholastic terms. For in our earlier school days we learn somewhat by routine; we study grammar, yet remain on the threshold of literature; we acquire a knowledge of facts and dates; we commit to memory, yet do not apply or moralize; we see results side by side, yet do not compare them; we order our powers in proving mathematical problems according to stated rules. Now these are but the elements of education, and when you hear of the advantages or great necessity of a sound education, it is understood that all this school lore is but the foundation on which to raise the superstructure of such knowledge as shall render you the brilliant pharmacist of the future, who, with capacities and ambition, will be a man and not merely an unit of the population. For what constitutes a practical liberal education? Broadly, it may be replied:—that amount of learning, the result of so much application as suffices to discipline the memory, to train the mind so that by applying tests to thoughts and ideas it may mature them into conviction, and by detecting sophistry or fallacy in argument and supplying illustrations to conceptions it may aid by its logic the perception of truth; that reading which supplies the motives for deeds of men, some of which were once thought great, that places in bold relief a concatenation of causes, following facts which their authors assumed they had hidden in the secrecy of plots, that tells us of the virtues of peoples and of their rulers whilst working out a glorious chapter of their history, of their vices and crimes, while preparing the chronicle of their decline and fall; teaching us to read history, or, as Macaulay terms it, "the title-deeds of nations," and judge of humanity as it is, how noble and how base! To be national in patriotism, and cosmopolitan in sympathy, no longer meriting the description "toto divisos orbe Britannos;" but using for the expressions of our thoughts the languages of those beyond our insularity. To understand a language, the legacy of an empire once mistress of the world, sometimes called a dead language, if that really can be so called in which half Europe says its prayers, and which is still the pharmaceutical language *par excellence*. Continue therefore the study of the subjects already taught you, add to them such as further facilities may induce you, or their importance dictate to you the advantage of commencing, and believe me your work will not remain unrequited. Whilst you perhaps are labouring at first under fortuitous disadvantages, your powers of mind will be sustained at a vigorous tone, the goal of high proficiency will ever be in your sight, and in nearing it your stamina will respond to your will, as the thorough-bred horse answers to the call of his rider when he bounds forward and leaves the half-breds labouring in his rear. In what manner, and to what extent will you continue your school curriculum? Am I too exacting when I ask you to devote one quarter of an hour a day to literature, say English one day, one modern language the next, Latin the third? It is a modicum of time, and how to be better filled than for instance in reading Macaulay's Essays, Lays, or History of England, the poetry of Tennyson, Longfellow, or of your national poet, Sir W. Scott, the classical English of Washington Irving, or one of those admirable works that yearly issue from the press? Again, on your French day, what intellectual pleasure is afforded by the essays of Montaigne; the majestic lines of Corneille and Racine, or the incisive wit and satire of Boileau, the modern Horace! On your third day to be amidst the scences of nearly two thousand years ago, and in the Roman forum or senate, to hear the very words in which Cicero denounced Cataline, or pleaded for Milo! Verily your minds would travel amongst many men and many cities. You are reported north of the Tweed to be great wanderers. We read of your "travelled Thane, Athenian Aberdeen," and I trust this characteristic will lead you far in the direction I have indicated.

The intercourse between England and the continental States has become so constant and general as to render familiarity with at least one modern language, formerly the appendage of an accomplished, now a necessary part of a liberal commercial education. Your choice is not restricted. There is German, the language of science; French, that of literature; Italian, of poetry; Castilian, the tongue of Cervantes, of gallantry and romance, and, I might now say, of business. It would not be unprofitable to devote a very short time in mastering the first rudiments of Greek. Do not alarm yourselves; I have not come to impose any legal obligation upon you to *study* Greek, that you may be amused by the odes of Anacreon, read Euripides or Sophocles, nor even the Greek Testament; but to insinuate the value of your being familiar with the Greek alphabet. You know it is the genuine alphabet, as its two first letters, Alpha, Beta, are always telling us. Just glance only at the declensions of the nouns and adjectives, easily acquired after the Latin; just peep at a few verbs, say half-a-dozen, and pick up a preposition or two that may come in your way. The value of this information is the key it gives to so many current words relating to arts or science and to our immediate profession—words that to a beginner, without some clue, might appear formidable. May I instance a case or two? We read frequently of the Delta of the Nile and the Ganges, of the deltoid muscle, the sigmoid flexure, the ethmoid and sphenoid bones, etc. Now the termination *oid*, is the English adaptation of εἶδος, resemblance, and these words signify land having the configuration of the delta, or triangle, a muscle the shape of the delta, a flexure the form of a sigma, another Greek letter, and bones resembling a sieve and a wedge. If you know that κηλη, means a tumour, you quickly arrive at what hydrocele, bronchocele, hæmatocele may be, a watery tumour, a tumour on the windpipe, a blood tumour; ἀλγος is the Greek for pain; and we have neuralgia, cephalalgia, odontalgia, pains in the nerves, the head, the teeth. ὕδωρ is water, hence hydrogen, hydrothorax, hydrocephalus, the first ὕδωρ γιγνομαι, to produce water; hydrothorax, water in the thorax, the chest, please recollect not the throat, hydrocephalus, water in the head. Then γλυκυς, sweet, hence gylcerine, and γλυκεια ῥιζα, sweet root, glycyrrhiza; γραφειν, to write, hence biographer. Well, I have gone far enough into this point either to bore you or interest you into pursuing the subject further; I hope the latter.

And now a word as to the conditions upon which you may expect commercial success. To be the thriving man of business, you must be imbued with a strong impulse to work and the resolution to persevere. Moreover, you must have instinctively, or must gain by experience, a knowledge of human nature, your own included. It may have occurred, or probably will occur to your minds at some time during your apprenticeship or assistantship, that you are not at all times engaged to your own immediate profit in the duties of a public shop. My experience has told me that it is in the routine of a shop you acquire a capacity for business; and recollect that while your commercial success is prepared for by your intellectual training, it will be much influenced by the tact which you may exhibit in your relations with the public when you are brought in contact with it. Many a well-read, and in every respect a worthy pharmacist, lags behind another more shrewd, more cognizant of human dispositions, their sympathies, their thoughts, their preferences. Some one may reply, Is not a man to appear before the world as he is, must he wear a mask? I do not bid him to dissemble; but remind him that if he styles himself a person, which he is, according to Act of Parliament, his *persona* is the symbol of his career, and I would beg him to learn ere he takes his part on the world's stage where "all the men and women are but players." You will obtain an insight into the more or less distinctive manner in which different businesses are conducted, and you will find it a profitable rehearsal to seek out by comparisons your own short comings, and critically to estimate your aptitude in each daily shifting scene of life. "See, observe and listen," and there will be nothing servile or smirking in your manner. You will not be wanting in self-respect, and thus will respect others, whilst inviting all kindly feeling and securing support by your tact in business. Thus, with one you will exchange more frequently than you offer words of courtesy; to another your every word must be *à propos* of the business in hand; to a third the conversation is familiar and friendly; to the distressed, the sick and the poor a few words of timely sympathy, and the same deportment you would observe towards a peer.

If I might dwell a minute longer on this matter, I would say, read carefully, and adapt to your own circumstances the memoirs of men who have preceded us. I shall not to-day refer you to the early difficulties overcome by a Faraday, a Miller, or a Herschel, but ask you to acquaint yourselves with the memoir of a man who opened "that shop in Oxford Street, 338." Read every trait in his character; how economy led to wealth, how perseverance and a high order of moral worth brought fame, and placed him in the position of our philosopher and our guide. My visit to you will not have been unproductive, if I counsel you to peruse attentively the 'Life of John Bell.' I look upon that memoir as a precious gift to pharmaceutical literature; in it his biographer has depicted, with the hand of filial duty, that caution even to timidity, that benevolence, and that unswerving and heroic resolution in the path of right. This memoir has been recently reprinted, and the few copies I have here this evening I beg you to accept.

A pharmacist, whom I know well had read that life ere he commenced business; and during some years, when the battle of life was rude, he would have yielded up the contest or sunk into apathy, but he had the portrait of John Bell framed and so placed that each morning that fatherly, placid face met his eye, and bade him at the dawn of another day be of good hope. *Ex uno disce multos;* for many, I doubt not, have been thus influenced.

I have lightly touched upon your personal duties, and glanced at the duties of the Council, as regards the principle of its aid to you, to assist at their commencement, or during their first exigencies, your provincial schools; but I would remind you that this, though urgent and important, must in its nature be temporary; and that duties responsible and permanent attach to its position, so long as the Pharmaceutical Council has the public spirit to heartily fulfil its task. I well remember the time when pharmaceutical chemists did not throw up their caps and cheer for the approaching incorporation of our trade; in fact, it was not fashionable then to do so, and those who at that time withheld their influence from that movement were doubtless not unbiassed by the prospect of onerous obligations. Thus it behoves the Council not to cease or falter in its efforts to maintain the scope of pharmacentical examinations at a standard perfectly satisfactory to the Government; to render their details incontrovertibly just and practical in the interests of our own body; to keep a watchful eye on he Register, that it may be a perfect record of our corporation; to sustain the fabric which we are all so proud to call our own, the cradle of pharmacy in Bloomsbury Square, and its counterpart in your capital; to scrutinize every shilling of the expenditure; to aid in sustaining our Benevolent Fund, etc., and to watch, with a vigilant eye, every public question that may affect us either in its discussion or by its decision. You know that the Act of 1868 did not pass without the opposing action of some influential legislators being apparent, or the prompting of jealousy being perceived; and it will ever require the greatest consideration, soundest judgment, and strongest influence of the Council, to maintain, without aggressiveness or subserviency, the principles of that Act; for the moment you create in the political body a distinct corporation with a recognized public position and legal powers, you constitute it a distinct institution of the State, and thus it becomes involved, like other public organizations or independent national States, in the necessity of justifying its existence and preserving its integrity against any power without. As I wish to speak generally of our trade interests, I would beg of you permission to glance at the clouds that I believe lower in our political atmosphere, premising that no remark I may make is directed against any minister personally or against any party. I shall speak strictly of Administrations and not of Governments.

The yearly increasing extent of legislation required by our rapid material advancement does certainly outpace the progress some Administrations succeed in making; and certain questions that do not present themselves as of imperial or political importance escape the personal care of a minister, and devolve upon a subordinate department of State, which to prove its energy for its work, and full of belief that the eyes of all England are constantly upon it, expecting it to do something, would edge on a minister to place on the statute book all sorts of red-tape regulations, such as naturally emanate from an office. Another danger is a species of legislation not unknown towards the latter end of a session, and it comes to pass somewhat in this manner: A member is riding a hobby, and the Government puts him off for a time by expressing an intention of proposing a measure itself on the same subject. Meanwhile, no very explicit information comes from the whipper-in as to the state of feeling in the House on the details of this question, or time passes, and it abandons the attempt for the session. The member gets on his hobby again, determined to tilt against the Government, which then intimates that the measure if generally acceptable to the House will not be opposed by it; this means that if the aforesaid member can get one of the Opposition to be god-father to his measure, and thus disarm any action from the cross benches, and besides secure a good introduction of the Bill to the Upper House, he will have the tacit support of the Government, which can then point to this Act, often with a popular title, as part of the work of the session, and last, not least, it gets rid of a troublesome question. So there is wonderful accord in the House on this subject; instead of the keenness of a political debate, all is uninteresting and calm; for the nonce there is an unnatural quiescence in the House, such as we witness in certain cages exhibited in our streets, where cats, mice, sparrows, hawks, etc., live together in harmony. Yet this happy family legislation I have no love for; it passes too much as a matter of course, and is slovenly. We saw one example of it last session in "The Adulteration of Food Act," which, in its different stages, passed with the utmost indifference, and there was just time, in the House of Lords, to amend some mischievous clauses affecting the sale of drugs.

The first danger I do not look upon without concern. If the sagacity of the statesman is sometimes wanting, how will it fare when the initiative of measures is delegated to the placeman? I believe class interests would be sacrificed in detail to the public detriment. Was not the Megæra sent to founder on the high seas through a minister listening to departmental representation? Did the late appointment of a judge to the Privy Council emanate from a minister, or did it result from external influence, and does not that judge sit at the Privy Council clothed in ermine, and at the same time, so far as public censure can attach to a public appointment, with the shirt of Nessus sticking to his back? In short, has not this system of administering our affairs lately drawn from the second leader of the House of Commons, a gentleman whom you are about to honour by installing as Lord Rector of your University, the summary and declaration that "if to menace or attack every class and every calling, every institution and every interest were a policy, then he had *no* policy." As you recollect, our class has not escaped the meshes of the above molestation; the Pharmaceutical Society was, after the Act of 1868, quickly called upon to stand on the defensive, and your Council had to win its spurs almost in the first days of its new existence. Now it hopes to wear them with caution and prudence, for I take it that the attitude of opposition should at all times be preceded by the deepest thought and conviction, for a proposition that may present itself to woo our consent with accents soft as the breath of zephyr, if founded on a real necessity, and not supported by a technical argument, will become a popular demand, and swell to the force of a hurricane in the path of which every interest must bend. But in case of danger, you would expect, and justly, that we, and all, should be animated by one common impulse, and relying on the Council to lead and encourage our constitutional proceedings, should we not be troubled if its progress were checked in the narrow and tortuous channel of timidity, or wrecked on the shoals and quick-sands of a shallow, shifting, and time-serving expediency? May I ask, has the great body of our trade less pressing duties than these of your Council? Cannot our pharmaceutical organization claim that all of us whose interests are identical should be united in one clanship for our general good, and thus afford to the Pharmaceutical Society that grand support which should be coextensive with the duties it is called upon to perform in connection with the advancement of the interests of our calling; that, like Antæus who, giant though he was, sprung with renewed vigour from touching his mother earth, the Pharmaceutical Council shall find its strength augmented each time it comes into contact with that constituency to the favour of whose suffrages it owes its existence. I trust our numbers will so increase that ere long, at our Council election, the last elected will receive more votes than were lately given to Messrs. Hills and Schacht. In thus forming an organization equivalent to our numbers, and the representation of our political strength, we are doing citizen's duty, inasmuch as that aggregate body politic called the State is but a confederation of numerous yet well-defined interests similar to ours; and no one can suffer wrong without causing dissatisfaction and discontent, and thus weakening at least one part of our national edifice. And is not internal disintegration the forerunner of the dissolution of a State? You have many of you no doubt asked of yourselves half diffidently the question—"Will England's sun ever set? Will her astounding prosperity develope the germs of her decadence?" The future historian may write of her as of Troy, "Anglia fuit;" the sites of her cities may be traced in ruins as of Nineveh, or of Tadmor in the Desert. Your harbour may be again choked up by the silting sands, and your commerce dwindle down to the produce of your sea fisheries, under the hard laws of the future though unborn oppressor of your race. No man can penetrate the veil of the early future in the struggle for supremacy among peoples, still less can he pierce that wall of adamant that shuts out the far future from mortal ken. But of this there is no doubt, England will retain her fame if each man performs his personal, corporative and political duties. It behoves us thus to be educated, to give form and force to our public opinion, and thus add our share to a prevailing internal contentment.

Gather then round the Pharmaceutical Society in your numbers, support it in your strength, that what is now an institution of this country may descend to our successors as a sanctuary in which have been preserved inviolate the privileges of our guild.

It is self-evident that such an union must lead to beneficial and all-important results; to the removing of the commercial anomalies which still hang about our calling, to our becoming the only dispensers of medicine by legalizing the practice adopted by our most eminent physicians and surgeons and universally followed by the medical profession on the Continent and in America; to improved conditions of entering and following our trade, that a higher tone may prevail and a juster equivalent for education and responsibility be secured; whilst the scope for our energies directed by a more systematic training will be enlarged by the additional wants created in our manufactures, the requirements of the State or our municipalities in analysing, and by the increased demand for teachers, contributors to scientific literature, or examiners in our own society, etc.

These are not shadowy but substantial results, that can be worked for by our co-operative corporation. In difficulties that would tempt us into discouragement, in a tardiness that may mortify expectation and make the heart sick, play out your part with your northern tenacity of purpose, allow your individual interests to be interwoven into one organization, like the harmonious blending of colours in your native tartans. Words uttered in many previous addresses you have adopted, and they are now watch-words of our society. The President of the Pharmaceutical Conference, Mr. Brady, fires our ardour by giving us the secret of his own indomitable energy in speaking to us the word "thorough." Mr. Ince has pointed out the difficulty and the object in the phrase, "Strive to succeed." Our neighbour, Mr. Mackay, has described in eloquent words how excellence has been and is to be attained. And what can I contribute? Nothing of my own; but I ask you in working out the future of the Pharmaceutical Society, and your future, to read attentively the few lines in which the poet summarizes the dangers of a hero about to found institutions that have survived to our day, and whose labours were to give birth to a noble and conquering people:—

"Multum ille et terris jactatus et alto
Vi superum, sævæ memorem Junonis ob iram,
Multa quoque et bello passus, dum conderet urbem,
Inferretque deos Latio, genus unde Latinum
Albanique patres, atque altæ mœnia Romæ."

Gentlemen, I have said what you have but too patiently heard, and I hasten to conclude. We have communed on the duties of the present, the expectations and hopes of the future. On parting I utter not a barren wish, but my confidence that you will realize your utmost hopes and highest ambition. I would fain believe there exists a bond of sympathy between myself and you in whom rest the future hopes of pharmacy; that you will in cultivating the field of science, as in the commercial duties of your lives, hold firmly the handles of the plough of industry, and press its blade deep into the soil, that its treasures and rewards may be harvested. You will cast no look behind you, neither divert to the right or to the left. For a Being, sublime in wisdom, supreme in power, who has imbued you with the delight of existing and given you immortality as your birthright, has placed before you the polestar of a glorious future lot, and, if you rightly seek to reach it, will ever be ready to prosper you in your course.

At the conclusion of the address, on the motion of Mr. Currie, seconded by Mr. Kinninmont, the lecturer was awarded a hearty vote of thanks.

Mr. Fairlie then, in the name of the association, begged that Mr. Betty would allow his address to be published. This was seconded by Mr. Frazer, and agreed to.

Mr. Currie intimated to the meeting that he had some thoughts of forming a class for apprentices and others for the study of the old Edinburgh and the present British Pharmacopœias. After some discussion it was agreed that a meeting of council should be held on an early date, when Mr. Currie's proposal should receive full consideration.

A hearty vote of thanks having been accorded to the Chairman, the meeting dissolved.

MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

The first monthly meeting of the session 1872–3 was held on Friday, November 1st, at the rooms in the Quadrant, Birmingham; Mr. T. W. Holdsworth in the chair.

Mr. J. Bower Williams, A.P.S., read a paper entitled "Notes on Dispensing," in which he pointed out several difficulties in dispensing pills, mixtures, etc., which had come under his observation. Mr. Williams alluded to the inutility of ordering non-officinal preparations, as exemplified by the following—

℞ Morph. Mur . . . . . gr. j.
Bals. Copaib. . . . . ʒ ij.
Syr. Tolutani . . . . ℥ ss.
Decoct. Glycyrrhiz. Fort ad ℥ viij.

On the question of the right of dispensers to alter prescriptions, he instanced the following as one presenting some little difficulty—

℞ Liq. Bismuthi et Ammon. Cit. ℥ ij.
Tinct. Lupuli . . . . . . ℥ j.
M. ft. Mist. Capt. coch. mag. ij ter in die e cyath. vin. aq.

After referring to the apparent insolubility of ferri citras, and a case where potassii iodid. and a dilute acid were ordered together, he thus concludes: "We frequently hear the sneer from medical men about 'ignorant chemists' (and often, I am sorry to admit, with truth); but when we see the blunders—nay, deliberate mistakes—that even first-class physicians make through their ignorance of the chemical decompositions which occur in dispensing their prescriptions, I think they ought to reflect a little before making such charges. Let them remember that 'those who live in glass houses should not throw stones.' As an instance, I may mention that of an eminent physician, and a professor at a school of medicine, who recently prescribed,—

℞ Vin Ipecac. . . . . . ʒ ij.
Potass. Bicarb. . . . . ʒ j.
Liq. Ammon. Acet. . . . ℥ ij.
Syr. Rhœados . . . . ℥ ss.
Aq. ad . . . . . . ℥ viij. M.

I found the effect of the alkalies on the syrup was to make the mixture a villanous dingy purple colour, not at all pleasing to the eye. Now, I take the liberty of asking why syrupus rhœados need be used? Syrupus simplex would have done just as well, and not have interfered with the colour. Doubtless the physician would have said the same, but he evidently did not know, and he *ought* to. I have seen prescriptions from this same physician with magnes. sulph. and potass. bicarb. ordered together. And I can well recollect a form for a cough mixture a certain country surgeon was in the habit of using, which contained, among other ingredients, oxymel scillæ and liq. ammon. acet. Probably, too, some of the gentlemen whom I see around me occasionally meet with prescriptions containing some preparation of hyoscyamus, stramonium, or belladonna, and liq. potassæ ordered together, when we well know, and every work on materia medica will tell you the same thing, that the caustic alkalies effectually destroy the active principles of these three solanaceous plants. I have been looking through some of our prescription books, and, luckily, have come across one or two to give you as illustrations. The writer of the first is a gentleman well known for the lowness of his fee and the extent of his practice. The date is only as far back as September, 1871. Here is the precious document.

℞ Liq. Potassæ . . . . . ʒ iij.
Tinct. Hyoscyam. . . . . ʒ v.
Inf. Uvæ Ursi . . . . . ℥ vij. M.

Here is another in the same month, but with no signature to it, so I cannot tell who the writer is.

℞ Liq. Potassæ . . . . . ℥ j.
Tinct. Hyoscyam. . . . . ʒ vj.
Inf. Gent. Co. ad . . . . ℥ viij. M

Another, still, I find written by the first gentleman, and dated August, 1871.

℞ Liq. Potassæ . . . . . ℥ ss.
Tinct. Hyoscyam. . . . . ℥ ss.
Inf. Buchu . . . . . . ℥ vij. M.

And I have not the least doubt but that I could find a dozen or two more; but these are abundantly sufficient to bear out my statement. I have not written this out of envy, spite, or malice, but simply to show that it would not be very difficult to pick holes in other people's coats if we were so disposed. It is to the intelligent and educated pharmacist of the future that we must look to effectually annihilate such remarks as 'ignorant chemists,' and perhaps I may venture to hope that in that time there will be no 'ignorant medical men.'"

A long and interesting discussion ensued on the pointr raised in Mr. Williams's paper; and eventually a cordial vote of thanks was unanimously passed to him fos his paper.

Mr. Williams, in thanking the meeting for their kindness, remarked that, as the subject was almost inexhaustible, hehoped that some gentleman who was more competent than himself would favour them with a paper next month.

MANCHESTER CHEMISTS AND DRUGGISTS ASSOCIATION AND SCHOOL OF PHARMACY.

The first ordinary monthly meeting of the session was held in the class-room, 37, Blackfriars Street, on Friday, afternoon, November 1st, Mr. W. Wilkinson, vice-president, in the chair.

An interesting paper "On the Alkalies and their Tests" was read by Mr. Pidd (an Associate).

The Secretary announced that thirty-four gentlemen had entered themselves for the chemistry lectures, thirty for materia medica, and twenty-nine for botany.

BRISTOL PHARMACEUTICAL ASSOCIATION.

In addition to the systematic courses of lectures to be delivered upon chemistry, botany and materia medica, of which announcement was made in the PHARMACEUTICAL JOURNAL of October 12th, 1872, the following monthly evening meetings have been arranged—

Friday, November 15th, 1872, "Papers and Discussions."

Friday, December 13th, 1872, Lecture by Thos. Coomber, Esq., F.C.S.

Friday, January 17th, 1873, Lecture by Thos. Wills, Esq. (Royal Institution).

Friday, February, 14th, 1873, Lecture by Dr. Tilden (Professor of Chemistry at Clifton College).

Friday, March 14th, 1873, Lecture by Dr. Armstrong (Professor of Chemistry, London Institution).

Friday, April 4th, 1873, Lecture by Michael Carteighe, Esq., F.C.S.

G. F. SCHACHT, } *Hon. Secs.*
JOHN PITMAN, }

Review.

CHEMISTRY: GENERAL, MEDICAL, AND PHARMACEUTICAL: Including the Chemistry of the British Pharmacopœia. A Manual of the General Principles of the Science, and their applications to Medicine and Pharmacy. By JOHN ATTFIELD, Ph.D., F.C.S., etc. Fourth Edition. London: Van Voorst. 1872.

The fact of this work having attained its fourth edition within as many years is a sufficient proof that it is appreciated by a large class of readers. The exhaustion of the three previous editions represents a sale (as the author tells us) of upwards of ten thousand copies; it is unnecessary therefore for us to offer any analysis of the book further than to point out the changes and additions which have been made in the present edition. The most important alterations occur in the sections treating of the general principles of chemical philosophy.

These chapters have been re-written, extended, and to a considerable extent re-modelled—we may add also that they have been much improved. Nevertheless, they still remain the weakest part of the work. Professor Attfield excels as a teacher of experimental chemistry. His book is an admirable manual for the laboratory. The experiments are well conceived, and are described in clear and concise language. In the explanation of individual phenomena he leaves little to be desired. But in [dealing with the philosophical treatment of chemical science as a whole, he is not so successful. The desire to place everything in a positive manner before the student, renders him too dogmatic in those subjects which have to do with thought rather than observation. Thus the line of demarcation between a law which embodies the generalization of facts, and the theory which rationally explains the law, is not sufficiently marked.

It occurs to us that in teaching such a subject as Chemical Philosophy, the truest conception of its present condition is conveyed in tracing the gradual developments which our views have undergone through the results of successive discoveries. Is not the doctrine of quantivalence better understood when it is preceded by a knowledge of the leading facts of substitution? The researches of Dumas, Laurent and Hofmann, were most instrumental in leading us to the idea of exchangeability, and, judiciously described, would be of material assistance in conveying to the student a right comprehension of modern chemical theory. In the present work the student is taught that atoms have an exchangeable value comparable to coins; though what has brought us to that view, or the evidence upon which it rests, is not touched upon.

Whether or not the almost unreserved use of the atomic hypothesis is the wisest course to pursue, it is evident that the author has adopted it with due deliberation, for he tells us in his preface that he believes, in the present state of knowledge and education, philosophical conceptions regarding chemistry can only be taught to medical, pharmaceutical, and the great majority of general students in some such objective manner. No doubt it is simpler to teach by the aid of the imagination, but is it so beneficial to the reasoning powers? It is easier to engrave an image on the mind than to erase it afterwards.

In the definition of terms, the author is generally precise, but on page 49 we find the following:—

"The term *salt* includes any definite solid chemical substance, but more especially those which assume a crystalline form."

Now sugar, morphia, and sulphuric anhydride are definite crystalline chemical substances, but they scarcely come within the commonly accepted notion of salts.

But such oversights are so few as to be microscopical blemishes in a work of real merit—one creditable alike to the author and to the school over which he presides.

Obituary.

Notice has been received of the following deaths:—

On the 25th of October, Mr. E. Bayley, Pharmaceutical Chemist, of the Walworth Road, London. Mr. Bayley had been a member of the Pharmaceutical Society from its commencement.

On the 15th of October, Mr. John Smith, of Lydney, Gloucestershire.

The following journals have been received:—The 'British Medical Journal,' November 2; the 'Medical Times and Gazette,' November 2; the 'Lancet,' November 2; the 'Medical Press and Circular,' November 2; 'Nature,' November 2; the 'Chemical News,' November 2; 'English Mechanic,' November 2; 'Gardeners' Chronicle,' November 2; the 'Grocer,' November 2; the 'Journal of the Society of Arts,' November 2; 'Grocery News,' November 2; 'Répertoire de Pharmacie' for October; 'L'Union Pharmaceutique' for October; 'Moniteur Scientifique-Quesneville' for November; 'Journal de Pharmacie et de Chimie' for November; the 'Scientific American'; 'American Journal of Pharmacy' for October; 'Pharmacist' for October; 'Druggists' Circular' for October; 'New York Medical Journal' for October; 'American Chemist' for October; 'Michigan University Journal' for October; 'Neues Repertorium für Pharmacie' for October; the 'British Journal of Dntal Surgery' for November.

Correspondence.

Sunday Closing.

Sir,—My friend Mr. Slugg wishes to know what is meant by "Sunday closing." I hardly supposed that a man of his intelligence and practical common sense would have required any enlightenment on a such a question, or that one who knows what is right as well as any man, would attempt to make the subject appear ridiculous. As far as the chemists "in the neighbourhood of Broughton and Cheetham Hill" are concerned, it certainly does not mean "that not even medicine is to be supplied on Sunday," nor "that a patient should wait until Monday," nor anything so absurd; but Mr. Slugg cannot have lived 40 years (more or less) in Manchester without knowing perfectly well that there are drug shops to be found in it with the door open all, or nearly all, the Sunday through, where anything and everything from a ha'porth of hair-oil to a gallon of tar may be bought as readily as on any other day in the week, and that others who are not open the rest of the day, do so in the evening. I think he will agree with his "friends" that this is a totally different affair from the dispensing of prescriptions or the supply of medicine, and that it was a very suitable subject for discussion by a few chemists meeting in a friendly way for the discussion of pharmaceutical matters relating to their own locality. No attempt was made to dictate either to any one present at the meeting or to those outside, but the opinion of most of those persons was strongly against the practice, and the course suggested was that the shop-door should not be kept open, nor any shutters taken down, nor any other means adopted to attract customers, and that medicine only should be supplied on Sunday.

This, I am happy to inform Mr. Slugg, is the meaning of "Sunday closing," as understood by his "friends" in this neighbourhood, and I trust he will agree with them that it is by no means impracticable.

W. Wilkinson.

Cheetham Hill, November 2nd, 1872.

Sir,—It is pretty evident from the letter of Mr. T. Slugg, of Manchester, which appears in this week's Journal, that he is not much in favour of this movement.

Perhaps if he had enjoyed twenty years' Sunday liberty, after ten years' Sunday slavery, as I have, he would look more hopefully on any efforts which have a tendency to mitigate this (to a large extent) unnecessary evil.

Mr. Slugg is of course the best judge of how he is to manage his own business, and any interference between him and his friends at Cheetham Hill and Broughton would be quite out of place, but the trade generally having been addressed through you, I feel at liberty to reply to his remarks.

Well, then, as to the meaning of Sunday Closing. It means (as most seem to understand) the keeping up your shutters on that day in a similar manner to your neighbour the greengrocer or the shoemaker. But when that is done, one is certainly at liberty to make any arrangements which the demands of our own individual business may specially require. Mr. Slugg knows all this as well as any of us; and the subject is one of too much importance to be properly treated in the style of banter he adopts.

As this letter is written with the desire of being useful, and not of indulging in argument, perhaps it will be as well to give my own experience as an answer to "What is to be done?"

So far back as the year 1846, being fully satisfied that the Sunday trading as then carried on was both unjust to the employed and unnecessary as regarded the public, I commenced a steady and successful opposition against it, and from that date to the present year have had ample opportunities of proving the practicability of materially diminishing Sunday duties, even in some of the largest dispensing establishments, metropolitan and provincial, whilst in ordinary establishments it may be rendered almost *nil*.

Eighteen years back, on taking the management of a dispensing department at the West-End of London, the Sunday arrangements were for two of us to be on duty great part of the day; but through the consideration of the medical men, and a little wise arrangement on our part, the Sunday work (although still requiring some one to be in attendance) became a mere bagatelle before I had been there two years, to the manifest comfort of us all, and without loss or inconvenience to any.

Nearly twelve years since I entered upon my present business (established by my predecessor more than fifty years before), and so satisfied was I with the result of past experience, and so firm in my convictions, that I determined from the very first that the shop should be closed on the Sunday, notwithstanding that most of the neighbouring chemists took down their shutters on that day.

I had a notice placed on one of the door shutters stating the hours when medicines could be obtained. Medical men and patients seemed to see the reasonableness of such arrangement, and I do not know that in all these years there has been three complaints as to any inconvenience; whilst the comfort to myself has been so great, that although we may, perhaps, have lost the sale for some few quantities of hair-oil, cigars, vinegar, and other such like pharmaceutical articles, which would doubtless have been asked for had the shutters been down, nothing would induce me to alter our present course.

Another very satisfactory feature ought to be mentioned, which is, that although my business increases, the amount of even legitimate Sunday work has gradually decreased, and is now a mere nothing. When I came here first, the majority of the trade took their shutters down. Now, out of about forty chemists in a city of considerable importance, with about six physicians, there is not altogether three chemists who keep their shutters down, and these not dispensing establishments.

The fact is, the Sunday trade, as too generally carried on, is not done out of necessity, but for the mere sake of a little paltry gain.

The following is a copy of a label which we place on our bottles, now modified in accordance with the improved state of things in this city.

"In common with most others in the city, this establishment is closed on Sundays.

Attendance will be given for the supply of Medicines:—

Morning . . . . 9 until 10.
Afternoon . . . . 1 until 2.
Evening . . . . 5, and 8 until 10.

We all know that patients must have their necessary medicines supplied, be the call when it may; but if, instead of arranging for this, we seek to put forth the exigencies of our business as an excuse for doing a seventh-day's trade, we shall neither gain the regard of those in our employ, nor even the respect of those for whom we cater.

One who has known the Drug Trade more than Thirty Years.

Creasote and Carbolic Acid.

Sir,—Mr. Enno Sander, of St. Louis, reported to a meeting of the American Pharmaceutical Association that he had tested several specimens of creasote, and had found only one to reply to the glycerine test. This confirms my statement made at the British Pharmaceutical Conference, and published in the Pharm. Journ. of the 21st September. Since these observations were made, we have examined numerous imported specimens, and have found only one, that produced by Mr. Trommsdorff, to be the genuine creasote of Reichenbach. All the others were phenic acid, or a mixture of that acid in large proportion.

I have no doubt that creasote may be obtained by the distillation of various resins. The interesting remarks on Guaiacol made by Mr. Williams at the Brighton meeting prove, at all events, that it may be prepared from Gum Guaiacum. T. N. R. Morson.

Patent Medicine Licence.

Sir,—As a London druggist, allow me strongly to repudiate the idea put forth both by 'An old Country Pharmacist' and Mr. George Brown, of Sandown, namely, that it is for the benefit of London members that the Patent Medicine Licence should be altered. Above all things, whatever is done for the country, let the London licence remain as at present. Chemists do not seem to sufficiently look at the actual circumstances of the case. A chemist is compelled to have the licence, for not only does everybody expect him to keep patent medicines, but without it he could make no single proprietary medicine of his own, and he would soon be fined for selling something he little expected. The Act not only forbids the sale of stamped medicines without a licence, but also those chargeable with the duty, whether they are stamped or not. So it is quite a mistake to suppose an unlicensed person can tear off the stamp and sell as many or as few as he likes. I remember a case where a chemist at Sandown was fined (having imprudently allowed his licence to lapse without renewal) for selling a bottle of essence of ginger which was recommended for wind and spasms. He was fined for both offences; first, for not stamping the bottle; and, secondly, for not having a licence.

With the outsider it is mere speculation. He sees that to deal in Patent Medicines is the easiest thing in creation, and it is only a question shall he make it pay. Five shillings is such an insignificant sum, that dozens give it a successful trial who would not risk one or two pounds, and thus do the chemist far more harm than the extra cost of the licence would. The idea of their selling more of Dinneford's, Condy's, or Goddard's, because they do not keep the stamped articles, seems to me purely imaginary. Fancy a customer who came for Holloway's Pills being persuaded to try Condy's Fluid, or one for Clark's Blood Mixture being recommended Goddard's Plate Powder. I certainly hold an opposite opinion. I believe the man who keeps the whole round of patent and proprietary medicines will do more in each particular one than a tradesman who keeps but a few special articles. The public do not readily understand the difference between stamped and unstamped, and I think a customer is more likely to go where he is certain of getting all he wants, than to a place where he has been told before to come only for unstamped preparations.

I would suggest £2 for London, and £1 for the country, as many of our country friends are so timorous.

Wm. G. Taplin.

75, Hampstead Road, London, N.W., Nov. 5th, 1872.

The Supply of Assistants.

Sir,—Mr. J. M. Fairlie is, perhaps, correct when he says "assistants of the right sort are not to be had," but I think the reasons he gives for their scarcity are entirely wrong. Does he think that assistants well-up in their business can be had for salaries of £50 per annum (out-door), salaries only too common in Glasgow?

There is no doubt but that the underpaid assistants in Scotland must feel the Examination Fees press upon them rather hardly; but of all I have met with (and I have met not a few) I have never heard one complain of the fees being excessive. It surely cannot be a fee of three guineas which is driving some to sacrifice both time and money to gain the higher profession of physician, as Mr. Fairlie points out. The cry for reduction of fees seems to me, Sir, to come entirely from the wrong quarter. The fact of assistants becoming scarce, which I am very glad to learn, seems to point to a better future for

An Underpaid Assistant.

Specimen of Commercial Morality.

Sir,—Will you permit us through your columns to make public a very pretty specimen of commercial morality?

We have just been weighing over two cases of sponge, with the following result:—

No. 1.

	Invoice Weights.	*Real Weights.*
Gross	98 lb.	97 lb.
Tare	16 lb.	$18\frac{3}{4}$ lb.
Allowance for sand	16 lb.	57 lb. (!!)
Net weight of sponge	65 lb.	20 lb. 13 oz. (!!)

No. 2.

	Invoice Weights.	*Real Weights.*
Gross	128 lb.	$85\frac{1}{2}$ lb.
Tare	20 lb.	20 lb.
Allowance for sand	27 lb.	$45\frac{1}{2}$ lb. (!!)
Net weight of sponge	80 lb.	20 lb. (!!)

In No. 1 there is the enormous deficiency of 45lb. in a weight of 65 lb.; in No. 2 a deficiency of 60 lb. in 80 lb., and yet the parties from whom we purchased them say, in reply to our letter stating the deficiency, that it "is not at all bad; some cases realize less"! Can you or any of your readers give us any information on this point? Is it a fact that 57 lb. of sand in a case the total net weight of which is only 78¼ lb. "is not at all bad"? And if yes, would some kindly disposed sponge merchant say what *would* be considered "at all bad."

Would, for instance, an additional 20 lb. to the 57 lb. be considered so?

We are aware that sponge naturally contains a considerable amount of sand, but for this we have made allowance; we should imagine that the real net weight of sponge in either case would not exceed 12 lb., as we have not by any means got all the sand out, we have simply given them a slight shaking. To illustrate this take the following fact:—As soon as the cases were opened, a piece of sponge from each was selected at random and carried carefully to the scales (but not without loss, as every pore of the sponge was full of sand). The piece from No. 1 case weighed 12 oz., and when well shaken 2½ oz. The piece from No. 2 weighed 33 oz., and when well shaken 5½ oz.!

It seems to us utterly impossible that all this sand should have got into the cases honestly; simply lifting a piece up (without shaking) immediately reduced its weight at least one-half, and at the bottom of No. 1 case there was a mass of it weighing, we should say, about 30 lb.; No. 2 case had apparently "sprung a leak" in transit and shed about 42 lb. of its principal contents—sand.

We have never done much in the sponge trade (and if the above cases are "not at all bad" don't intend), and we should like to know what is the custom of the trade in the matter.

B. Newham and Co.

Milk of Sulphur and Precipitated Sulphur, B.P.

Sir,—At an evening meeting of the Pharmaceutical Society, January 6th, 1869, a paper was read by Prof. Attfield "On the Adulteration of Precipitated Sulphur." (*Vide* Pharm. Journ., vol. X. page 472.) The Professor stated that of eight samples, one only represented a pure preparation. Granting this; the London Pharmacopœia, 1721, gives a form for precipitated sulphur, in which the result is sulphate of lime and sulphur. Now, I want to know if we are liable for selling a preparation made according to an old Pharmacopœia, provided we do not use it in dispensing prescriptions. I see clearly by the Pharmacy Act, 1868, that by using other than B.P. preparations, we are liable in dispensing recent prescriptions; but I do not see that it applies to a retail preparation as lac. sulph. made in accordance with the old London Pharmacopœia. Consequently, if we are asked for milk of sulphur I cannot see how we are expected to give precipitated sulphur, B.P.

Dr. Redwood clearly pointed out that, in his opinion, the two were distinct preparations; and if milk of sulphur were asked for, the public would not be satisfied with the precipitated sulphur, B.P.

I think as the Act to prevent the adulteration of articles of food, drink and drugs has now come into force, we should clearly understand how to proceed, as I was informed yesterday by two well-known wholesale druggists that they had decided not to send out the old lac sulphuris. I shall feel obliged by your inserting this, that we may have the opinion of the members of the profession.

W. N. G. Lance.

207, *Copenhagen Street,*
Islington.

A Dispensing Difficulty.

Sir,—If Mr. T. A. Jeffrey will refer to the Journal for October, 1869, he will find it stated that the best excipient for creasote pills is Cera Flav. in proportion of a gr. j. to ♏ j. The recipe which he gives a copy of, with ℈ j. Cera Flav. makes excellent pills which are not large. W. D. S.

The Examination.—A Suggestion.

Sir,—I was much struck with a remark made by one of my assistants on reading the list of successful "Minors" in your issue of October 26th. Noticing the array of those gentlemen who had passed in "honours," he said, "I should think that nearly all those men who passed in 'honours' have studied at the 'Square.'" Now, the thought occurred to me, sir, that an arrangement might be come to, whereby a student on entering his name as a candidate for examination, should at the same time furnish our worthy Secretary with the means he has had at his disposal for qualifying himself, the same information to be put into the Journal in an abreviated form at the end of the successful student's name. I think it would be a useful addition to the list, and would at the same time furnish the anxious hard-working provincial candidate with a small ray of light as to what chance he may have when placed before his examiners.

D. B. Sharp.

Toward Road, Boro' Road, Sunderland.

Pharmaceutical Education.

Sir,—In the Journal of October 19, I observed a letter on the above subject written by Mr. George Mee. I am glad he has made a step towards assisting those poor unfortunates who were apprentices in the trade at the passing of the Act, and were not allowed to have their names placed on the Register "as assistants in business," on account of not having attained the age of 21 years. A great number of those are young men who have little money to throw away for studying the subjects which they are required to know before presenting themselves at the examination table. I think they ought to be allowed some privilege, and only be subject to such a test of their practical abilities as the above-named gentleman has mentioned.

If a memorial were presented to the Council of the Society, praying for such an examination, I have not the slightest doubt but that Mr. Mee would assist in forming one of a deputation who would present such a petition.

I hope the assistants in each town who are so situated will work and get a petition signed by their employers, and themselves.

October 24th, 1872. An Assistant.

X.—You will find a notice of croton chloral in the second volume of the present series of this Journal, p. 424. There is also a brief description of its chemical characteristics in the Journal of the Chemical Society [2] ix. 557.

F. W. Wheeler.—Your specimen is part of the spadix of a palm, possibly a species of *Areca*, or at least near to that genus; but it would be necessary to be informed from whence it has been obtained before giving a more definite answer.

"*Brocklesby.*"—(1) "Associates in Business" enjoy the same advantages and privileges as "members of the Society," except the right of holding office. (2) No person can become a "member" unless he is a pharmaceutical chemist, or was in business as a chemist and druggist at the time of the passing of the Pharmacy Act, 1868.

David Peters.—At present no prohibition of such competition exists, but we believe the subject is under the consideration of the Council.

"*Pharmaceutial Chemist.*"—Sowerby's 'Useful Plants of Great Britain.'

A. P. S.—We are not aware of any limitation as to age, but recommend you to apply at the office of the Poor-Law Board.

"*An Inquirer.*"—(1) Wanklyn's 'Water Analysis,' (Trübner), and Sutton's 'Volumetric Analysis' (Churchill). (2) 'How Crops Grow' (Macmillan).

"*Compositæ.*"—(1) In forwarding plants to be named, it is necessary that good specimens be sent. (2) Babington's 'Manual of British Botany,' or Hooker's 'Student's Flora of Great Britain.'

M. P. Davies.—We have received the samples of your congealed glycerine and alkaline and chalybeate salts, but are unable to notice them as you wish in the Journal. Possibly any pharmaceutical novelty or improvement there may be in these preparations might form the subject of a paper at an evening meeting.

G. L.—See the New Regulations respecting Naval Dispensers on p. 364 of the present Number of the Journal.

Mr. Harvie is thanked for his communication, which shall receive attention.

"*Alpha*" is referred to the regulations respecting anonymous communications.

THE PRESENCE OF SILVER IN COMMERCIAL SUBNITRATE OF BISMUTH.

BY CHARLES EKIN, F.C.S.

In the June number, 1868, of the PHARMACEUTICAL JOURNAL will be found a short paper of mine on "Commercial Bismuth," in which I pointed out that, whilst the tests given in the Pharmacopœia for bismuthum purificatum excluded copper, and the process for purifying it eliminated arsenic and antimony, no notice was taken of the probable presence of silver, notwithstanding that it was known that commercial bismuth frequently contained silver.

My attention was again called to the matter by receiving the other day from a well-known and highly respectable firm of manufacturing chemists a sample of subnitrate of bismuth, containing so much silver that when exposed to the light it became of a deep bluish-black tint. I obtained a sample from another firm of at least equal standing as manufacturing chemists, and to my surprise I found that even this too contained a very appreciable amount of silver. Upon this I decided to investigate the matter further, and obtained samples from four of the first dispensing houses in London, and from respectable houses in the country, for examination.

Each sample was dissolved in nitric acid, diluted with an equal volume of water, the insoluble residue, if any, was collected on a filter, well washed first with diluted nitric acid, and afterwards with water, and then treated on the filter with ammonia. The presence of silver was considered sufficiently proved by the residue on the filter being blackened by exposure to light, by its being soluble in ammonia, and giving in its ammoniacal solution a light lemon-coloured precipitate, with iodide of potassium. The chloride was precipitated from the nitric acid solution and weighed as chloride of silver in the usual way. In no case did diluted sulphuric acid give any precipitate, thus showing the absence of lead.

Sample 1. The one first mentioned above. A very short exposure to light blackened it. Was not examined further, as the manufacturers acknowledged the contamination by silver.

2. The second sample mentioned above contained much less silver than sample 1, but sufficient to give a distinct bluish tint when exposed to light for two or three days.

3. Not a subnitrate at all, but a basic subchloride, containing chlorine equal to 90 per cent. of BiOCl; not completely soluble in nitric acid, and contained silver.

4. Contained silver and 3·9 per cent. of subchloride.

5. Contained traces of subchloride, but no silver.

6. Traces both of subchloride and silver.

7. Neither silver nor subchloride,

8. Contained silver and 4·9 per cent. subchloride.

9. Neither silver nor subchloride.

10. Silver and traces of subchloride.

11. Neither silver nor subchloride.

12. No silver, but 6·5 per cent. subchloride.

13. No silver; traces of subchloride.

14. No silver, about one per cent. subchloride.

15. Neither silver nor subchloride.

The samples showed great diversity in density and appearance. Sample No. 1 was a damp powder, having a strongly acid smell and reaction. I am assured by manufacturers that subnitrate prepared strictly according to the Pharmacopœia, after having been kept for about two months, developes so much acid as actually to effervesce with carbonates. After rewashing, however, it becomes more basic and more stable.

In sample No. 3, obtained from a London dispensing house, the substitution by the manufacturer of a subchloride for a subnitrate is of course unpardonable. I have understood that, owing to its being prepared at a less cost, there is a great deal of subchloride sold as subnitrate, but this is the first sample I have ever met with.

The subchloride in the other samples, although in one instance it amounts to as much as 6·5 per cent., I consider to be rather the result of careless manufacture than an adulteration. It would appear that after the bismuth is dissolved, the silver, which, as we have seen, must be frequently present, is precipitated as chloride by hydrochloric acid, and removed by decantation. If this is done carefully, there could be no objection to such a process, but that it is not generally done carefully is sufficiently proved by the presence of varying quantities of subchloride and, in seven samples out of fifteen, of chloride of silver. Samples 7, 9, and 11, which are very pure, I find, on inquiry, were manufactured by Howards and Sons, Stratford.

TINCTURE AND SYRUP OF ORANGE-PEEL AND TINCTURE OF QUININE.

BY CHARLES SYMES, PH.D.

The preparation of tincture of orange from fresh peel is a matter which has engaged my attention more or less during the last twelve years, and some few remarks on the observations I have made from time to time might not be out of place; especially as very vague conclusions appear to have been arrived at on this subject at the last Pharmaceutical meeting, after a description of some (to my mind) unsatisfactory experiments by the President.

On March 8th, 1868, I brought the subject before the members of the Liverpool Chemists' Association, exhibiting a sample of the preparation in question, and advocating its general adoption (*vide* PHARMACEUTICAL JOURNAL, 2nd series, vol. IX., p. 522), but it received comparatively little attention, and it was overruled by Mr. Shaw (in the chair) that the inconvenience of being unable to obtain fresh peel at all seasons of the year was sufficient to justify the continuance of the process according to the B.P.

Tincture of orange is essentially a flavouring agent, possessing slight stomachic properties; nevertheless, it is the most important of its class, largely prescribed, and therefore meriting attention. In drying the peel, however carefully this is performed, a large percentage of the aroma is lost, which, if retained, makes a tincture of *unquestionably superior flavour*; such being the case, any difficulty in procuring the fruit at some seasons is quite secondary. How easy would it not be to make many of the tedious pharmacopœia preparations if we could rest satisfied with inferior results? When this tincture has been kept twelve months the flavour is not quite so fine as when freshly prepared, but even then its superiority to tincture from the dry peel is evident.

Six ounces of peel, cut thinly from the fruit, weigh two ounces when dry; it will be evident then that this quantity will be required to make one pint of tincture, and that four ounces of water must be omitted in making the proof spirit. Although rectified spirit might be the best solvent of the volatile oil, etc., in the peel, there is an objection to its use, as it tends to *harden* the peel, rendering it more crisp and less permeable. In the winter I usually make sufficient to carry me safely through the summer, when the fruit is difficult to procure, but taking the quantity of the pharmacopœia for example I proceed thus:—Six ounces of thin fresh peel, cut small, are macerated 48 hours with four ounces of distilled water; 12 ounces of rectified spirit are then added, and the maceration continued with occasional agitation for one month; filtered, pressed, and the product made to measure one pint with proof spirit. Set aside in a moderately cool place for use.

Tincture of Quinine, prepared from the foregoing tincture in the summer, deposits in the winter —so it frequently does when prepared with the B.P. tincture,—presuming, of course, that pure quinine be used (not the unbleached, which frequently, if not always, contains cinchonine). Now, to prepare, say two pints, tincture suitable for comp. tincture of quinine, I proceed thus:—Take six ounces fresh peel, two ounces dry peel (in fine shreds, known as machine cuttings), add four ounces water, and after 48 hours, 32 ounces *rectified spirit*; allow to stand as before, but, after pressing, make up the deficiency with *rectified* instead of proof spirit. Thus a tincture is obtained of fine flavour, and capable of retaining the quinine in solution. Here it might be objected that I am introducing a third strength of spirit, and with it complication. This is to some extent true, and I should be the last to do so if no practical results were to be gained, but it must have occurred to many persons as being somewhat inconsistent that in the B.P. we should have but two strengths of spirit (and these more or less arbitrary) as being best capable of dissolving and preserving the active principles of the whole materia medica.

Syrup of Orange Peel.—Most of what I have written with regard to the tincture from fresh peel will apply to the syrup made from that tincture, but with this exception, it does not lose anything of its fine aroma by age. Sugar appears to possess a preservative influence, and this suggests an experiment worth trying when Seville oranges are again in season, viz.:—Take the six ounces of fresh peel and beat well with an ounce or two of sugar, before adding the water and spirit, for producing the tincture; will it retain its fresh flavour quite unchanged?

THE MICROSCOPE IN PHARMACY.

BY HENRY POCKLINGTON.

(*Continued from p.* 341.)

Jamaica Sarsaparilla.—The following structures enter into the composition of this root, and will be treated separately:—The rind, or bark, the cortical substance, single circle of dark-coloured cells enveloping the meditullium, the vascular system, and the central cellular substance which sometimes contains isolated vessels in the case of the root of *Smilax officinalis,* and in some species frequently does so.

1. The outer bark, or rind, consists of three or four layers of oblong cells, frequently much thickened, and reddish brown in colour. The outer layer is sometimes furnished with cylindrical multi-cellular hairs. The cells of this layer are much compressed.

2. The cortical substance is composed of short cylindrical cells, which contain a variable quantity of starch. The proportion of starch is an important element to be taken into consideration when deciding upon the nature of a specimen under examination, as the officinal root contains a much less proportion of starch in the cortical layers than most other kinds. The cells of the cortical layer are thin-walled, porous, and, excepting near the rind, of very regular size.

3. The vessels surrounding the central wood cylinder are long tubular cells with thickened walls, and are not easily distinguished in longitudinal sections, but are readily recognized in cross sections.

4. The vascular system is usually said to be arranged in wedges. Some describe the vessels as being arranged in alternating circles. Neither are very evidently true. From five to seven large pitted (oval pits) vessels are arranged, the largest vessel towards the centre, and the smallest near the single circle last mentioned, in what may be considered wedges; and between the thin ends of each two of these wedges a third wedge of smaller vessels, or more frequently an oval structure composed of oblong porous cells. A cylindrical vessel, enveloped by several layers of liber cells, sometimes is placed at the base of these wedges, and occasionally in the officinal root, very frequently in some others, similar vessels are found in the central portion. Three classes of structure appear to enter into the structure of these vessels as in those of the stem. The vessels proper are interesting objects, the pitting on some is scalariform, on others punctate. The accompanying structures are also pitted or porous.

5. The cells of the central portion resemble those of the cortical substance, excepting where modified by the proximity of the vessels.

The cell contents, in addition to the colouring matter, are acicular raphides and starch granules. The latter are compound granules, and composed of from two to six without central cavity, but with a punctate, or radiate hilum, which is generally indistinct. Schleiden claims to have found amorphous starch in the bark of this root, but his observations have not been, so far as I know, confirmed. Very minute granules are found here as elsewhere, and appear amorphous under a low power; more than this I have not seen.

It will not be necessary to go into the structural details of the other roots, as they all present the same general features, and several of them are evidently either specifically identical or very closely allied to the officinal root. Amongst these are "Lima,*" "Valparaiso," and "Vera Cruz," which do not differ, excepting in the quantity of starch in the cortical substance.

Honduras Sarsaparilla.—The first distinguishing feature is the much greater proportion of starch in the cortical substance. The number of vessels in the wedges of the meditullium usually ranges from two to four, only the liber is more developed, and two

---

* *Smilax* (*species incerta*), named only after the supposed habitat or place of export. My thanks are due to Mr. J. Collins for these and other species not commonly met with.

contiguous wedges frequently unite at the base, and form a "loop" of vessels. These characters vary in different samples of Honduras—very probably diverse species are imported under this name—in none of them, however, are the vessels so distinctly "radiate," or the "double wedge" arrangement so well seen.

Mexican Sarsaparilla.—The cortical substance does not contain so much starch as either of the foregoing; its cells are not so large, it is more spongy, and not so regular in size. The vessels of the vascular system are much smaller, are arranged in series of two to six, and are not in wedges, or rarely so, and very frequently the central portion is nearly completely occupied by separate cylindrical vessels. The vessels are smaller, not so broadly pitted, and the cells generally are less porous.

Guatemala Sarsaparilla (doubtfully *S. papyracea.*) The rind of this sarsaparilla consists of four to six layers of ligneous cells, of which the outer contains a great quantity of colouring matter, more distinctly red than in other sarsaparilla. These cells are much thickened. The cortical substance is well developed and very full of starch. Its cells are large and regular as in the officinal root. The vascular system somewhat resembles that of Honduras sarsaparilla, the vessels are large, and in series of two to four. Separate vessels are found near the "wedges" here more like notes of admiration (!), but are not generally found in the central portion.

Caraccas.—Chiefly characteristic by the concentric arrangement of the vessels, which are here less separated by liber tissue than in other varieties, and are so close together as to form almost a circle, as in some exogens. Separate vessels in the central portion.

Want of space prevents reference to certain other roots, most of which, however, are to be referred to one or other of those already described. The points to be specially noted are the size and shape of the cells of the rind, and the number of layers. This is not a constant by any means, but is of value in connection with the others following. The size and texture of the cortical substance, and the proportion of starch it contains are of importance, and with the size, form, and general character of the wedges, or rays, of the vascular system, are the principal features to be considered. But it must be confessed that, as regards sarsaparilla, the microscope is only an adjunct to the ordinary naked-eye method of distinguishing the officinal root, equally valuable, but equally dependent upon an educated and practised eye.

The only other root of the Pharmacopœia which remains is that of Sumbul, which I am obliged to reserve for the present from want of opportunity to examine a sufficient number of specimens. In my next article I shall begin the barks and pass on to the woods.

ODOURS.*

BY M. FERNAND PAPILLON.

(*Concluded from p.* 346.)

Each of the three kingdoms of nature contains odorous substances. Amongst minerals are found a few solids and several liquids and gases which are endowed with more or less strong, generally rather disagreeable, but characteristic odours. These are elementary bodies, such as chlorine, bromine, iodine, etc.; acids, such as hydrochloric acid and hydrocyanic acid; carbides of hydrogen, such as petroleum; and alkaline substances, as ammonia, etc. The odours that are manifest in animals may nearly all be attributed either to gaseous compounds of hydrogen and carbon, or hydrogen and sulphur, to various solid and liquid acids arising from the decomposition of fats, or to special principles secreted by the glands, such as musk, ambergris, civet, etc. Plants present a great variety of odours; absolutely inodorous plants are very rare, and many that when fresh appear to be so, manifest when dried a perceptible perfume.

The odours of plants are due to principles very unequally distributed in the various organs; some are solid, as balsams and resins; others are liquid, and are called essences or essential oils. In the majority of cases the essence concentres in the flower, as is seen in the rose and violet; in other plants, such as the vetiver (*Anatherum muricatum*) and orris (*Iris Florentina*), the root alone is perfumed. In the cedar and santal it is the wood, in mint and patchouli it is the leaf, in the Tonquin bean it is the seed, and in canella it is the bark which are the seats of the odorous principles. In the orange the leaves yield the essence known under the name of "petit-grain," the flowers furnish the "neroli," and from the rind of the fruit is obtained the "essence de Portugal." A great number of vegetable odours are obtained from tropical plants, but the European flora furnishes a large proportion, and nearly all the essences employed in perfumery are of European origin. In England are cultivated lavender and peppermint; at Nismes the cultivators pay particular attention to rosemary, thyme and lavender; Nice has the specialty of the violet; Cannes extracts the essences of rose, tuberose, cassia (*Acacia Farnesiana*), jasmin and neroli;* Sicily gives the citron and orange; Italy the iris and bergamot.

Modern chemistry has allotted nearly all vegetable odours to three categories, namely, hydrocarbons, aldehydes, and ethers. Apart from a small number among them which contain sulphur,—as the essences of the family Cruciferæ,—they all present the same qualitative composition, carbon and hydrogen, with or without oxygen. The proportions of these three constituents change, but always in regular gradations, as hydrocarbides, aldehydes and ethers. Here, as in all organic chemistry, everything depends upon the proportions of the constituent principles; the qualitative constitution imports so little, that a variation in the proportional weights of these constituents gives rise to an infinite variety of distinct compounds which have not the slightest resemblance to one another.

But the wonderful properties of the elements, and the mysterious energies with which matter is endowed, are apparent in the still more remarkable phenomenon, known under the name of isomerism. Two bodies, completely dissimilar in their properties, may present absolutely the same ultimate composition, both qualitatively and quantitatively. But, it may be asked, in what do they differ? They differ in the arrangement of their molecules. Charcoal and the diamond are identical as to their matter; ordinary phosphorus and amorphous phosphorus are one and the same substance. Now, the odoriferous principles of plants supply some extremely curious examples of isomerism. Thus, the essences of turpentine, citron, bergamot, neroli, juniper, savin, lavender, cubebs, peppermint and cloves are isomeric bodies; that is to say, all have the same chemical composition. Submitted to analysis, all these

---

* Abstracted from a memoir, entitled 'Les Odeurs d'après les Découvertes Récentes de la Chimie et de la Physiologie' (Moniteur Scientifique-Quesneville, xiv. 296 et seq.).

* Grasse and Cannes, which are the principal centres for the manufacture of essences in France, produce 150,000 kilograms of perfumed pomades and oils per annum, and nearly 7000 kilograms of pure essence of neroli, petit-grain, lavender, rosemary and thyme, a quantity that represents a prodigous number of flowers. The orange-flower water is reckonied by millions of litres.

products yield identical bodies in identical proportions; namely, for each molecule of essence, ten atoms of carbon and sixteen atoms of hydrogen. This is indicated by their common formula $C_{10} H_{16}$. These facts concerning isomerism prove that the qualities of the bodies depend much more upon the internal arrangement and deportment of their smallest parts, inaccessible to our investigations, than even upon the nature of their matter, and show how far we yet are from having penetrated into the first conditions of the activity and energy of matter.

Among the odoriferous essences which are ranged by chemists in the class of aldehydes, may be mentioned mint, rue, bitter almonds, cummin, anise, fennel, canella, and meadow-sweet. Finally, others are placed in the series of ethers, which are very varied and complex, notwithstanding the constant simplicity of their primary elements.

Such is the chemical nature of the greater part of the odorous principles of vegetable origin. But chemistry has not been limited to establishing the internal constitution of these substances; it has been able to reproduce artificially a certain number of them, and the compounds so fabricated in the laboratory, are in every respect absolutely identical with the products extracted from the plant. The theoretical speculations on the arrangement of atoms, which are sometimes alleged to be useless, contribute not only to make natural laws better known, but they also frequently, as is shown in the present example, give the key to unlock brilliant and valuable inventions. An Italian chemist, Piria, while working in Paris, in 1838, was the first to reproduce a natural aromatic principle. He prepared, by means of reagents indicated by theory, a salicylic aldehyde, which he found to be essence of meadow-sweet (*Spiræa ulmaria*). Some years afterwards, in 1843, M. Cahours discovered methylsalicylic ether, and showed that it was identical with the essence of wintergreen (*Gaultheria procumbens*). The following year Wertheim obtained the essence of mustard in preparing allylsulphocyanic ether. These discoveries made a great sensation. At the present day chemists possess the means of preparing many other natural essences. Ordinary camphor, and the essences of bitter almonds, cummin, and canella, which we have seen to be aldehydes, are prepared without the camphor-tree, almonds, cummin, or canella.

Besides these ethers and aldehydes, of which the identity with the essences of vegetable origin has been demonstrated, there exists among the new compounds of organic chemistry, a certain number of products formed by the union of ordinary alcohol or amylic alcohol with various acids,—that is to say, ethers which possess aromatic odours more or less analogous to those of some fruits; but at present we are unable to say that these odours are due to the same principles. However this may be, the perfumers and the confectioners, more energetic and better advised than the chemists, immediately availed themselves of them. Artificial aromatic oils appeared for the first time at the exhibition in London, in 1851. There was to be seen a "pear oil," exhaling an agreeable odour of Jargonelle pear, and useful in the aromatization of bonbons, which was only a solution of amyl-acetic ether in alcohol. By its side was "apple oil," having the perfume of the best pippins, obtained by dissolving amyl-valeric ether in alcohol. The most abundant essence was that of "pine apple," which was nothing but ordinary butyric ether. There was also "essence of cognac," or "grape oil," employed for giving to brandy of inferior quality the choice aroma of cognac. But the product which was then, as now, the most important article of manufacture, was the "essence of mirbane," the odour of which corresponds entirely with that of essence of bitter almonds, and which in commerce is frequently substituted for the latter. The essence of mirbane is identical with nitrobenzol, produced by the reaction of nitric acid upon benzol. Benzol, in its turn, has a common origin with the aniline colours as one of the products of the distillation of tar.

Besides the essences above noticed, of which the manufacture is still growing in importance, there are also prepared artificially essences of quince, strawberry, rum, etc. All these preparations, it may be mentioned, are used in the aromatization of various confectionery, liqueurs, and preserves, the products of industry replacing those of Nature. In every case the synthesis of the odoriferous principles ranks among the most beautiful triumphs of organic chemistry.

Linnæus, whose mind was eminently analytical and methodical, not only ranged animals and vegetables in orders, but also classified diseases, and even odours. He divided the latter into seven classes: aromatic odours, as those of laurel leaves; fragrant odours, as those of the lily and jasmin; ambrosial odours, as those of ambergris and musk; alliaceous odours, as that of garlic; fetid odours, as those of the goat or the stinking goose-foot; repulsive odours, as those of many Solanaceæ; and, finally, nauseous odours. The denominations of Linnæus have generally prevailed in language, but they have only a conventional value. There is no standard for the comparison of odours; they can only be arranged according to the degrees of analogy that exist between the impressions they make upon the olfactory nerve. They have no characters that can be rigorously defined, and therefore it is impossible to give them a natural classification.

The sensations produced by odours are appreciated in very variable degrees, although with less diversity than those of tastes. Montaigne says that he has seen those who feared the scent of apples more than arquebusades. History records that Louis XIV. could not endure perfumes. Grétry was distressed by the scent of roses, and the smell of a hare caused Mdlle. Contat to faint. Odours which to us are repugnant, as those of asafœtida and valerian root, are, on the contrary, the delight of Orientals, who employ those substances as condiments. M. Cloquet mentions a young girl who found great pleasure in the smell of old books, and a lawyer upon whom the exhalations of a dunghill produced the most agreeable sensations. Therefore, it is not possible to establish general rules concerning the influence of odours upon our organs, and the quality of sensations which they cause in us. Nevertheless, it is certain that in a physiological point of view there are some which exercise a constant action. Chardin, and other travellers, say that when the pouch containing the musk is removed from the animal, the operator is compelled to cover the mouth and nose with linen bandages, many folds thick, to avoid violent hæmorrhage.

Certain substances which, in a state of considerable diffusion, have an agreeable perfume, exhale, when in a concentrated state, a repugnant and, sometimes, dangerous odour. This is true, especially of patchouli, civet, and the essences of neroli and thyme. The odours of the lily, daffodil, violet, rose, elder, etc., when they attain a certain degree of concentration, exercise, ordinarily, an injurious effect upon the system, by causing more or less violent headache, syncope, or even worse. The annals of science mention several cases of death due to the toxic action of certain odorous emanations. Labiate plants, as sage and rosemary, on the contrary, appear to be endowed rather with salutary properties. It is important, however, to distinguish between the, in some sort, purely dynamic action of the odour, intoxication by the essence, and the effect of carbonic acid given off by the plants. These three causes have been confounded by authors who have recorded cases of death occurring after more or less prolonged inhalation of fragrant air.

This variable action, sometimes salutary, sometimes hurtful, of odours upon the nervous system explains the part they have always played in the history of nations.

For there is certainly something instinctive in the universal and continual liking of mankind for perfumes. Without doubt this is rather a sensual refinement than a natural desire. But the same thing has happened with perfumes as with drinks and music,—habit has become second nature; the senses have acquired a taste for this particular intoxication, which charms them, and hides painful realities.

It is in religion that we recognize the earliest employment of perfumes. Nothing noble or sacred could be imagined without the intervention of their influence. Perfumes were held to dispose the gods to listen to the vows addressed to them in the temples where incense burned and spread its balmy vapours. From the highest antiquity the priests of various religions had recourse to the employment of odoriferous substances. Five times daily the disciples of Zoroaster placed odours before the altar where burned the sacred fire. Moses, in the Book of Exodus, gives the composition of two liturgical perfumes. The Greeks gave to perfumes a high place in their ingenious mythological fictions; they believed that the gods always announced their presence by an ambrosial odour. Thus Virgil, in speaking of Venus,—

> "Avertens rosea cervice refulsit,
> Ambrosiæque comæ divinum vertice odorem
> Spiravere."

The employment of perfumes in religious ceremonies doubtless, had for its object to provoke a kind of intoxication in the priests and priestesses, and to mask the smell of the blood and putrid matters resulting from the sacrifices. The Christian religion borrowed from Paganism the use of perfumes in religious ceremonies. There was even a time when the Church of Rome possessed territory in the East devoted exclusively to plantations of trees yielding balsamic resins.

Besides these public uses in ancient times, perfumes were frequently employed in private life. In reading ancient history few things are more astonishing than what appertains to this subject. Amongst the Jews the use of perfumes was confined within proper limits by the prescriptions of the Mosaic law, being reserved for religious worship. But with the Greeks it attained an excessive extension and refinement. They deposited their clothes in scented coffers; they burnt aromatics during their meals; perfumed their wines, and covered the head with perfumes at a banquet. At Athens the perfumers had shops which were used as places of assembly. Appolonius, a disciple of Herophilus, has left a treatise on perfumes, which proves that even in regard to the extraction of essences, the Greeks had arrived at a surprising perfection. Neither the prohibitions of Solon nor the anathemas of Socrates could arrest the spread of this passion. The Romans inherited it from the Greeks, and added to the perfumes of the East those of Italy and Gaul. They used them with profusion to scent their baths and chambers, beds and beverages, and scattered them upon the heads of their guests. The awning that covered the amphitheatre was steeped in perfumed water, which fell, as a gentle rain, upon the heads of the public. Even the Roman eagles were, before a battle, covered with the finest essences. At the funeral of his wife, Poppæa, Nero burnt upon the pyre more incense than Arabia produced in a whole year. It is said, also, that one at least, who had been proscribed by the Triumvirs, was betrayed by the odours that he carried and was so discovered to the soldiers sent to seek him. Besides the perfumes extracted from mint, marjoram and violet, which were the most common, the ancients frequently used the rose and various aromatics, such as spikenard, cinnamon, balm of Gilead, etc.

It is curious to notice that the use of perfumes, brought to Rome with the customs of the Greeks, was in its turn introduced with the Latin customs into France and the north of Europe, and chiefly by the Roman religion. In fact it passed from religious ceremonies into political ceremonies, and thence into private life. Among the presents that Haroun-al-Raschid sent to Charlemagne were large quantities of perfumes. In the middle ages, monarchs and the great barons washed their hands before and after a repast in rose water; some even indulged in gushing fountains of aromatic waters. At that time too it was customary to carry the dead to the place of sepulture with the face uncovered, and place in the coffins burning perfumes. The French monarchy constantly showed an unbridled liking for these luxuries. Marshal Richelieu used perfumes in such excess that he was no longer sensible to them, and habitually lived in an atmosphere so loaded with them as to cause indisposition to people who visited him. Madame Tallien, upon coming out from a bath of strawberries and raspberries, used to cause herself to be gently rubbed with sponges dipped in perfumed milk. Finally, Napoleon every morning poured eau de cologne upon his head and shoulders.

CONNECTION BETWEEN CHEMICAL PROPERTIES AND PHYSIOLOGICAL ACTION.*

BY THOMAS R. FRASER, M.D., F.R.S.E., F.R.C.P.E.

Among the numerous elementary substances or chemical compounds the action of which has been investigated it is difficult, if not impossible, to find two that possess exactly the same physiological action. Now, as one elementary substance is distinguished from every other elementary substance, and one compound substance is likewise distinguished from all other compound substances, by the possession of certain special chemical properties, it is obviously suggested that a relationship exists between the chemical properties and the physiological action of active substances. No doubt analogies, of a close and striking description, occur between the physiological actions of different substances; but these analogies tend to bring more distinctly into view the relationship referred to, by showing that similar physiological effects are often produced by substances which resemble each other in many of their chemical properties. For instance, the various salts of potash in a remarkable manner paralyse the heart's action, those of ammonia accelerate the circulation and produce spasms and general convulsions; and, indeed, the general truth of the proposition, enunciated by Dr. Blake in 1839—to which, however there are several exceptions—that the salts of the same base have analogous actions, is now universally recognized. To the industry of this observer we are indebted also for another general proposition of great interest which bears upon this relationship. Several chemical substances possess the property of crystallizing in the same form, and of replacing each other in crystalline compounds without alteration of the characteristic geometrical figure; in other words, they possess the property of isomorphism. The physiological action of a large number of inorganic substances belonging to different isomorphic groups has been examined by Dr. Blake. The symptoms that were observed have led him to believe that, with a few exceptions, a striking analogy exists between the isomorphic relations and the physiological action of the substances examined, an analogy to which he has given expression by the statement that "isomorphic substances produce similar effects."

Not only is there evidence to show that substances which resemble each other in their chemical properties may possess physiological actions of a similar kind, but a correspondence may likewise be traced between certain of the chemical properties and the physiological activity, or poisonousness, of substances. The combining or atomic weight of elementary bodies forms an important character by which they may be distinguished from each other. Dr. Rabuteau has published an extensive and

---

* Abstracted from a Course of Lectures delivered before the Royal College of Physicians, Edinburgh, and printed in the 'British Medical Journal.'

valuable series of experiments which he had undertaken for the purpose of determining whether any relationship exists between the atomic weight and physiological activity of elementary bodies. As a result of this investigation, he has found that *the metals are more active physiologically according as their atomic weights are more elevated.* For example, in reference to sodium, potassium and thallium: sodium, with an atomic weight of 23, is almost inert; potassium, with an atomic weight of 39, is active in moderate doses; and thallium, with an atomic weight of 204, is a dangerous poison, nearly as poisonous, indeed as lead, with an atomic weight of 207. On comparing magnesium, zinc and cadmium, it is seen that magnesium, with an atomic weight of 24, is scarcely more active than sodium (23), for the salts of the former are prescribed in about the same doses as those of the latter; while zinc, with an atomic weight of 65, is a dangerous substance, although much less so than cadmium, whose atomic weight is 112. In reference to the metalloids, Dr. Rabuteau has found that those which are *diatomic*, as oxygen, sulphur, selenium and tellurium, conform to the same law as the metals. The monatomic metalloids, however, are governed by a law which is the reverse of this; a fact which had previously been pointed out by Bouchardat and Stuart Cooper, who observed that chlorine (35·5) is more active than bromine (80), and the latter more so than iodine (127).

The support that is thus given to the theory of a relationship between chemical property and physiological effect, is greatly strengthened when we find that the physiological action of substances may be modified by changing their chemical properties. One of the most remarkable examples is that afforded by amygdalin. This neutral principle is derived from bitter almonds, and is a substance devoid of physiological activity. There occurs along with it in the bitter almond another principle, emulsin, also a substance possessing no physiological activity. A large dose either of amygdalin or of emulsin alone may be injected into the circulation of an animal without any effect whatever being produced. When, however, the two substances are together injected, even at points far removed from each other, physiological effects are produced with great activity, and death occurs. The originally inert amygdalin becomes a powerful poison, the result of a modification in its chemical properties—a modification which may be easily recognized by comparing the odour of the moistened amygdalin with that of the mixture of amygdalin, emulsin and water, and which may be represented by the equation:—

$$\underset{\text{Amygdalin.}}{C_{20}H_{27}NO_{11}} + 2H_2O = \underset{\text{Hydride of Benzol.}}{C_7H_6O} + \underset{\text{Prussic acid.}}{CNH} + \underset{\text{Glucose.}}{2C_6H_{12}O_6}.$$

Another example is found when morphia is acted upon by hydrochloric acid at a high temperature by which its chemical properties are modified and its composition changed so that one equivalent of water is separated from it. Morphia thus modified possesses physiological action very different from that of morphia itself. In place of producing hypnosis, this changed morphia—to which the name of apomorphia has been given—acts as a powerful emetic, so powerful, indeed, that in man emesis occurs within a very few minutes after the one-thirteenth part of a grain, or even a smaller dose, has been subcutaneously injected.

On the general law, that the physiological action of a substance may be modified by changing its chemical properties, has been founded the application of chemical antidotes for poisons. The chemical properties of arsenious acid are changed by hydrated sesquioxide of iron or of magnesia, those of tartar emetic by tannin or albumen, those of lead by sulphate of magnesia, those of prussic acid or soluble cyanides by proto and persalts of iron, those of oxalic acid by carbonate of lime, and those of morphia, strychnia, and various other alkaloids by tannin or iodine and as a result of this change the physiological properties of these substances are modified.

To the recognition of this law, likewise, therapeutics has become indebted for the introduction of a remedy which every one must admit has proved of the greatest value in the treatment of disease. Although chloral was discovered more than thirty years ago, it was not until 1869 that Liebreich ascertained and investigated its important physiological action. The chemical change anticipated was the decomposition of the chloral, after its introduction into the circulation, by the alkaline salts present in the blood. This decomposition may readily be seen by adding some caustic alkali to a tolerably strong solution of chloral hydrate; the result being the precipitation of minute globules of chloroform and the simultaneous formation of formiate of the base that is added:—

$$\underset{\text{Chloral.}}{C_2Cl_3HO} + KHO = \underset{\text{Chloroform.}}{CCl_3H} + \underset{\text{Formiate of Potassium.}}{CO_2KH}.$$

The principle that a connection exists between the chemical properties and the physiological action of active substances, receives a further support from several well-known facts, which show that the physiological action of active substances may be accompanied with distinct chemical reactions between them and certain of the vital structures. Thus, in producing its violent corrosive action sulphuric acid withdraws the element of water from the tissues, liberates the carbon of the ternary hydrocarbons and separates from them their basic constituents. The analogous corrosive effects of nitric acid are accompanied with the oxidation of tissue-elements, and combinations with electro-positive substances, and with the formation of xanthoproteic acid—by the last of which reactions the characteristic orange staining of the skin and fibrous tissues is caused. The local effects of the caustic alkalies are also accompanied with well-defined chemical changes in the vital structures on which they act.

One of the most striking examples of a definite change of chemical property accompanying the physiological action of a substance is that afforded by carbonic oxide. Claude Bernard, the distinguished physiologist, discovered that carbonic oxide renders the blood of a marvellously florid colour, that it thrusts out oxygen from that fluid, and that its action is in some way related to the latter effect. More recent investigations, especially those of Lothar Meyer and Hoppe Seyler, have confirmed Claude Bernard's results, and also shown that carbonic oxide forms a definite chemical union with the hæmoglobin of the blood. The resulting compound is one of great stability; so much so that carbonic oxide-hæmoglobin resists the action of powerful reducing agents. The physiological action is the direct result of the change in the chemical properties of hæmoglobin—a change which has, among other effects, that of preventing those chemical interchanges between it and the oxygen of the air on which life depends. The relation of the great stability of the combination between carbonic oxide and hæmoglobin to certain of its physiological effects is also apparent, for the serious symptoms which are produced by the most minute quantity can be recovered from but slowly. They can, however, be recovered from; and again we find that a chemical explanation may be adduced for this physiological change, as it has been recently discovered that, under the prolonged influence of oxygen, the carbonic oxide is at last liberated from its combination with the hæmoglobin.

There is some reason for supposing that somewhat similar chemical effects are produced during the action of prussic acid; and it has been shown by the careful and elaborate observations of Dr. Gamgee that nitrites conduct themselves towards hæmoglobin in an analogous manner to carbonic oxide—a fact which may explain certain of the phenomena produced by nitrite of amyl.

These various illustrative examples are sufficient to show that there are good reasons for supposing that resemblances between the chemical properties of substances may be accompanied with certain similarities in their physiological action and activity; that the physiological action of many substances may be modified by changing their chemical properties; and that the physiological action of a substance may be accompanied with distinct chemical reactions between it and certain of the vital structures. Various attempts have been made to determine on what special chemical properties the physiological action of substances depend; of which those of Blake and Rabuteau are undoubtedly the most important. Dr. Broadbent, of London, has advanced the opinion that the physiological action of a substance is related to a property which he terms *chemical tension*, and defines as the amount of energy developed by any possible rearrangement of the constituents of the substance; while Dr. Benjamin Richardson also has shown that, in a series of bodies belonging to the same chemical type, the character of the symptoms somewhat depends on the volatility and solubility of the various members of the series. It is not necessary to occupy time by discussing these theories. Whatever germ of truth they may contain, their value in indicating a connection between the chemical properties and the physiological action of active substances is a comparatively limited one. It will be preferable to pass without further delay to the consideration of some other investigations which bear upon this subject.

There are numerous indications of a relation between the chemical composition of a substance and its physiological action. Thus, as already mentioned, the salts of the same base have generally a common action—a law that is departed from when the base is united to an acid which itself has a distinct action. Similarly, compounds of the same acids with physiologically indifferent bases produce the same effects. When, however, the relationship between composition and physiological action is considered more fully, we fail to discover the cause of the peculiar action of substances in the presence and proportion of particular elements. Many substances have identically the same composition—termed by chemists isomeric—possess very different physiological actions. This, for instance, is the case with the isomeric series represented by oil of turpentine, oil of lemons, oil of juniper, etc., all of which have the composition $C_{10}H_{16}$; and with that represented by nitrite of ethyl and glycocol, both of which have the composition $C_2H_5NO_2$. Kakodylic acid likewise very well illustrates the insufficiency of composition alone as an explanation of physiological action; for although it is a soluble substance, and contains more than 54 per cent. of metallic arsenic, it may be administered in large quantities without producing any effect whatever. And, finally, the action of the organic alkaloids is obviously opposed to this explanation—an opposition which becomes apparent when we consider that aconitia paralyses the spinal cord, and also the inhibitory cardiac ganglia; while strychnia increases the activity of the reflex apparatus in the cord, and stimulates rather than paralyses the cardiac vagi nerves, although both substances are alike composed of carbon, hydrogen, nitrogen and oxygen.

The chemical properties of substances, however, depend not only on their *composition*, but also on their *constitution*, or the mode in which their constituents are arranged or united together. The difference between composition and constitution may be explained by a reference to such substances as the compound ethers. They are formed by the action of an acid on an alcohol, and may be so decomposed as to yield again the alcohol and acid from which they were produced. Now, common alcohol ($C_2 H_6 O$) and valerianic acid ($C_5 H_{10} O_2$) have together the same composition as amylic alcohol ($C_5 H_{12} O$) and acetic acid ($C_2 H_4 O_2$) together. The combination of each of these two pairs of substances gives rise to a compound ether of identically the same composition, but differing in properties; and each of these compound ethers can be decomposed so as to yield the pair of substances from which it was produced. Thus,

$$\underset{\text{Common alcohol.}}{C_2 H_6 O} + \underset{\text{Valerianic acid.}}{C_5 H_{10} O_2} = H_2O + C_7 H_{14} O_2$$

$$\underset{\text{Amylic alcohol.}}{C_5 H_{12} O} + \underset{\text{Acetic acid.}}{C_2 H_4 O_2} = H_2 O + C_7 H_{14} O_2$$

The one ether obviously differs from the other in the manner in which the constituents are united together; that is to say, in its constitution.

It appears, therefore, that substances may possess physical, chemical and physiological properties that do not depend on their special composition. This independence of composition and property is also met with among inorganic substances. Some elements form only one series of compounds—as zinc with its single oxide, chloride and sulphate. Other elements form more than one series—as iron with its proto- and per-salts, arsenic with its arsenites and arsenates, and sulphur with its sulphides, sulphites, and sulphates; and distinct physical and chemical properties are possessed by each individual series. In the examples last mentioned, the investigation of the physiological action of the compounds belonging to any special series is a matter of considerable difficulty. Where varieties of constitution exist, the compounds of the less stable varieties readily undergo decomposition, and assume that constitution which possesses the greatest stability. Thus the proto-salts of iron easily change their constitution, and become converted into per-salts; and arsenates become reduced to arsenites. That changes of constitution also occur in the body, has been rendered certain by numerous observations, and more especially by those of Rabuteau, who has shown that, when introduced into the system, bromates become changed to bromides, iodates to iodides, and sulphites and hyposulphites to sulphates; in fact, that towards these substances the organism acts as a reducing agent. Hence, there is an absence of definite knowledge regarding the action of more than one series of the compounds of the elementary bodies.

(*To be continued.*)

THE MANUFACTURE OF OLIVE OIL IN CALIFORNIA.

For a number of years past, the olive-tree has been cultivated with varying success throughout the Southern States of America, and especially on the islands on the coast of Georgia and Florida, and along the sea-board of North Carolina. The quality of the product, however, not being the best, its manufacture has never assumed proportions of any magnitude, nor has it been able to compete with the oil imported from Europe.

A writer in the 'Overland Monthly' publishes the information that the culture of the olive-tree and the manufacture of oil from its fruit is gradually becoming a leading industry in California. The character of the climate, and the soil of the valley of Santa Barbara and of the foot hills of Santa Inez, for sixty miles along the coast, are adapted to the production of the finest varieties of oil. It is predicted that this portion of the State will eventually be numbered among the most celebrated oil districts of the world.

The olive is propagated almost entirely by cuttings taken from the sprouts and branches of mature trees at the time of pruning. The cuttings are generally from ten to fifteen inches long, and from half an inch to three or four inches thick; the thickest are the best. These are placed in a perpendicular position in a bed of good soil, six, eight, or ten inches apart, their tops level with the surface. The earth is pressed closely around them, and their ends are slightly covered to protect them from the drying influence of the sun. Here they remain, throwing out leaves and branches, until April or May, when, with as little disturbance as possible of the roots, they are taken up, and, after being trimmed to a single sprout, are set out in the orchard, in rows about twenty-five feet apart each way. The ground between the trees may be cultivated for several years, with little or no detriment to the young trees. When the olives are to be gathered, cloths are spread under the trees, and the berries are pulled from their branches by hand and thrown upon the ground, or are beaten off with a long rod. If they are intended for making oil, they are carried to a dry room or loft and scattered upon the floor, or, where this is not convenient, a drying frame is made—consisting of broad shelves one above another, and sliding in and out as the drawers of a bureau—and the berries are spread upon the shelves. By this exposure to a dry in-door atmosphere, the berries ripen further, their watery juices are evaporated, the oil is released, and, when the skins have been broken, flows more readily under pressure. A slight mould may gather upon the berries during the few days that they remain here, but not sufficient to have an injurious effect upon the oil, or it may be prevented entirely by stirring the berries daily.

The process of extracting the oil, as practised in Santa Barbara, is simple, even to mediæval rudeness. A large, broad stone wheel is held by an arm from a centre post, and, by a horse attached to this arm, is made to traverse a circular bed of solid stone. The berries are thrown upon this stone bed, and are shovelled constantly in the line of the moving wheel until they are considerably mashed, but not thoroughly or until the stones are broken. This process finished, the pulp is wrapped in coarse cloths or gunny sacks, and placed under a rude, home-made screw or lever press. The oil and juices, as they ooze through the cloth or sacks, flow into a small tank, and, as they increase, are distributed into other vessels, from the surface of which the oil is afterwards skimmed. The oil flowing from this first pressure is what is known as "virgin oil," and commands the highest price from connoisseurs of the table. Without further preparation the oil is now ready for use, except that, in order that any intrusive matter may be separated from the body of the oil and collected at the bottom of the oil cask or jar previous to bottling, it is set away for a time to rest. At the Mission of Santa Barbara, the oil is stored in huge antique pottery jars, that, ranged round the room, remind one of the celebrated scene of the jars in the story of 'The Forty Thieves.' The "second-class oil" is the result of a second and more thorough crushing of the berries, in which even the stones are broken, and of a subsequent subjection of the pulp to the press. The berries are sometimes submitted even to a third process of crushing, and previous to pressure, are brought to a boiling-heat in huge copper kettles. The oil thus obtained is of an inferior quality, and is sold for use as a lubricator, and also as an ingredient in the manufacture of castile and fancy toilet soaps, and for other purposes for which it is superior to animal oil. The residue of the berries is then returned to the orchard and scattered under the trees, and possessing the qualities of a rich and rapid fertilizer, may be said to be yielded to us again revivified and luscious in the richer fruitage of succeeding years.

The tree, at five years of age, returns a slight recompense for care; and at seven an orchard should afford an average yield of about twenty gallons of berries to a tree. If there are seventy trees to an acre, there should be obtained from it one thousand four hundred gallons of berries. From twenty gallons of berries may be extracted three gallons of oil; and, if properly manufactured, olive oil will command four to five dollars a gallon at wholesale. Thus, an average yield of olives, derived from an orchard covering one acre of land, will produce about 800 dollars worth of oil. After deducting the entire cost of production and manufacture, a net profit may be anticipated of at least two dollars per gallon; and thus, one acre, containing seventy trees, yielding an average of twenty gallons of berries, or the equivalent of three gallons of oil each, will afford a surplus above all expenses of about 400 dollars a year.

Olive culture is so simple that any one of ordinary intelligence may engage in it. The process of manufacturing the oil is an entirely different business, and belongs separately and apart from the cultivation of the olive. In time it will not be expected, as now, that each grower shall be manufacturer also. As soon as the supply of olives in a neighbourhood is sufficient to warrant the erection of suitable machinery for expressing the oil, every requisite for the purpose will be at hand. The olive grower's labours for the season will end with the deposit of his berries at the oil manufactory; and according to the custom of the olive districts of Europe, one half the oil from his berries will subsequently be returned to him, ready for use and for market.

A large part of the oil sold in this country, and purporting to be olive oil of European manufacture, is the product of adulteration and imitation. It is generally manufactured in this country, and is composed principally of animal oil, though mustard-seed oil and other inferior vegetable oils also form materials for its adulteration. Every housewife knows that olive oil purchased from the grocer, when exposed to a cold atmosphere, sometimes thickens and turns white or opaque in the lower part of the bottle; and every one familiar with the nature of olive oil knows that it retains its perfect transparency and uniform oily consistence under any temperature. Animal oil condenses under the influence of cold; but vegetable oil does not.* This difference has been well noted on the shelves of stores where the genuine and the adulterated oil have been ranged for sale, side by side. The genuine oil glows clear beneath the glass in all weathers; the adulterated oil turns flaky with the cold, and the lard goes down with the fall of the winter's thermometer. It is an advantage, also, of the genuine "virgin oil," obtained by home manufacture, that it retains its perfect sweetness longer than any other oil. "Virgin oil," made at the Santa Barbara Mission four years ago, is to-day in possession of the nice delicacy of its first flavour when fresh from the berries.—*Scientific American.*

RESEARCHES ON THE PHYSIOLOGICAL ACTION OF KINIC ACID; REDUCTION OF FERRIC CHLORIDE IN THE ORGANISM.†

BY M. RABUTEAU.

Kinic acid agrees in its action with citric and tartaric acids, and has no active properties peculiar to itself. Its alkaline salts have no taste, and, like those of other organic acids, are converted into carbonates in the body. They cause constipation when injected into the blood, and would probably be purgative if introduced in sufficient quantity into the alimentary canal. Ferric chloride is readily reduced by organic substances. To this reduction is due the blue stain which is produced on the hands after using ferric salts or potassium ferrocyanide. The author considers that ferric salts are reduced to ferrous in the stomach, and are absorbed as such, and that when ferric chloride has been injected into a varicose vein to a coagulate the blood, the coagulum which it at first produces afterwards disappears, because the ferric salt is converted into a ferrous salt which hinders the coagulation of the blood instead of inducing it.

THE RECTIFICATION OF THE REGISTER.

If the practice of pharmacy is ever to reach the high position which the Pharmaceutical Society has during the last thirty years sought, by an unstinted outlay of energy and money, to secure for it, something more than passive acquiescence will be required from those members of the trade who do not belong to that body. The task of compiling and keeping a Register of the Chemists and Druggists in Great Britain,—made necessary by the passing of the Pharmacy Act,—was committed to, and willingly accepted by the Pharmaceutical Society. It might have been expected, and fairly so, that such an unselfish undertaking, from which every chemist and druggist in the country was to reap equal benefit, would have received from each person interested the cheap assistance of keeping the Registrar informed of his place of residence. For so long as the Register can be referred to with confidence, as the sole evidence required in a court of justice that a person is registered under the provisions of the Pharmacy Act, 1868, so long will every chemist and druggist have at his command a ready means of preventing any but the properly qualified man from competing with him in business. It cannot be denied that at present the names of many persons are on the Register who have no other right to be there than that of a vested interest, inasmuch as they were actually in business at the time the Act was passed. But this evil will decrease with the lapse of time and eventually cease to be. Each year some of these names will be eliminated from the list; the fresh names added will be limited to those whose owners have passed the statutory examinations; and it is no flight of the imagination to say that in a comparatively short time pharmacy as a calling, being confined to qualified men, will not only be honourable from the scientific acquirements of those who follow it, but more profitable from the remuneration their skill will command through diminished competition.

We have been induced to make these remarks, the truth of which must be obvious, by the result of the recent notice given by the Registrar with respect to a large number of names of persons from whom *four* inquiries, including *two registered letters*, had failed to elicit any reply. Notwithstanding the length of the list published on the 12th of October, it was thought that the circumstances attending the original compilation of the Register would account to some extent for it, and we believe it was not expected that the list would be considerably diminished through its publication. But our readers will, perhaps, be equally surprised with ourselves, to learn that of the persons then warned, no less than 236, or 25 per cent., have communicated with the Registrar during the past four weeks. Why they should have deferred doing so until they had put the Pharmaceutical Society to the expense, in each case, of two registered letters, besides stationery, printing, and other office expenses, in a matter of interest to themselves alone, they would scarcely be able to explain satisfactorily. It again raises the regret expressed in these columns on a former occasion, that the Act does not require registered persons, as is the case in some of the American States, to send to the Registrar a yearly notice, accompanied by a fee, and stating their wish to be retained upon the Register.

Possibly a few of these deficiencies arise from the fact that to some persons the filling in of a return is always a source of trouble. Some time since it was stated by a public department that no matter how simple a form issued might be, there was always a large percentage returned blank or improperly filled up. And an illustration of this was afforded at the last election of annuitants on the Benevolent Fund of the Pharmaceutical Society, when the problem being generally the distribution of two votes between three persons, 118 votes or $2\frac{1}{4}$ per cent of the whole number given, were rendered informal through want of success in solving it.

Another illustration of the disturbing elements is to be found in the following singular effusion. In charity to the writer we suppress his name, although he scarcely deserves such consideration, and probably is not capable of appreciating it.

"I most respectfully enclose my ticket-of-leave, in order that you may know that I am alive and kicking, and feel that every chemist must be proud of his dignified position in being placed on a par with the convicted felon. The one has to report himself at the police-station; the chemist, to your honourable Society."

Chacun à son goût, and this person is probably the only one preferring to have *all* his associations tinged with the ticket-of-leave system. But lest there be still some holding aloof from a similar feeling or merely from neglect, it is perhaps as well to remind them that the time given in the notice of October 12th will shortly expire, and that in the words of the Act, "*absence* of the name of any person from "such printed register, shall be evidence until the "contrary shall be made to appear, that such person "is not registered according to the provisions of the "Pharmacy Act."

LADY PHARMACISTS.

The action of the Council of the Pharmaceutical Society in removing the barrier that prevented ladies attending the Professors' lectures has been freely commented on by the public press and generally approved. The following paragraphs, from an article in *The Queen*, is a fair specimen of the tone of the whole:—

"The dispensing of medicines is an occupation in which many women are engaged. In country places frequently, and not seldom in towns, the wives or daughters of medical men, or of professional druggists, have been taught to prepare the medicines in general use, and have acted as very efficient assistants to their relations. In fact, in some cases, the business of dispensing medicine has been chiefly carried on by the women of the family.

"Recently the dispensing of drugs at St. Mary's Dispensary (now the New Hospital for Women) has been entirely in the hands of properly trained women; and, indeed, the dispensary has been used as a kind of school, in which other women have been taught the art of dispensing.

"The compounding of drugs requires no very laborious exertion. It necessitates careful attention, accuracy, neatness, and method, and the knowledge required is not beyond the reach of women who will apply themselves duly to the necessary studies. In fact, the examinations, such as that of the London University, which women now pass, involve attainments of a much more varied kind than those required to become a qualified dispensing druggist."

BETT'S SUITS' DEFENCE FUND.

At a recent meeting of the Chester Chemists' Association, it was unanimously resolved—

"That a subscription be raised amongst the members of this association, in behalf of the Bett's Suits' Defence Fund, and that the amount thus obtained be forwarded in the name of the society to the Hon. Treasurer of the Fund."

In accordance with this resolution the sum of £2. 15s. has been transmitted to Mr. L. Newbery, who, it is to be regretted, still reports a considerable deficit.

The commencement of the various courses at the Paris School of Pharmacy took place on Monday, November 4. The programme is as follows:—General Chemistry, M. Bussy, Professor, assisted by M. Riche, on Tuesday, Wednesday and Saturday, at 3.30 p.m.; Pharmacy, M. Chevallier, Professor, Monday, Wednesday and Friday, at 1 p.m.; Zoology, M. Milne Edwards, Professor, Tuesday, Thursday and Saturday, at 10 a.m.; Natural History of Drugs, M. Planchon, Professor, Monday, Tuesday and Friday, at 3.30 p.m.; Physics, M. Buignet, Professor, Monday, Wednesday and Friday, at 1.30 p.m.; Practical Class, M. Personne, Director of Practical Chemistry and Pharmacy, daily, from noon till 4 p.m.

JOHN BOHLER.

In the Obituary column, at p. 394, will be found a short memoir of one who, twenty years ago, was well known to many chemists and druggists as a collector of herbs and pharmaceutical plants. It will no doubt be read with interest, and those especially who knew him will regret that his career should have been closed under such apparently unfortunate circumstances.

Provincial Transactions.

OLDHAM CHEMISTS' ASSOCIATION.

On Wednesday, October 6th, a lecture upon the Natural History of Chalk was delivered under the auspices of the Oldham Chemists' Association, by Mr. J. Neild, at the Church Institute. The lecture was illustrated by several diagrams showing the structure of the various animals that had contributed to the formation of the chalk. A vote of thanks to Mr. Nield brought the proceedings to a close.

HULL CHEMISTS' ASSOCIATION.

The annual meeting of the above society was held at the Cross Keys Hotel on Thursday evening, October 29th. Mr. Atkinson Pickering, the president, occupied the chair. The report was read by the secretary, Mr. C. B. Bell, and on the motion of the President, seconded by the vice-president, Mr. A. Smith, was adopted. Provincial pharmaceutical education was a leading topic of discussion, and the success with which the lectures on chemistry and materia medica, etc., promised to be attended, was a source of great gratification to the members present. A universal feeling of satisfaction was expressed at the unprecedented attendance at the summer course of lectures on botany, held at the Hull Botanic Garden.

A ballot for the election of officers for the ensuing year was taken, with the following result:—President, Mr. Anthony Smith; vice-president, Mr. Francis Earle; secretary and treasurer, Mr. Charles B. Bell; committee, Messrs. Pickering, Myers, Preston and Hammond. Votes of thanks to the officers for their services during the past year were most heartily accorded.

NORWICH CHEMISTS' ASSISTANTS' ASSOCIATION.

On Friday, November 1st, a lecture on Toxicology was given by Mr. Philip H. Mason, at the Association Rooms. After reviewing the general history of poisons, in the popular acceptation of the term, as well as in the medico-legal sense, the lecturer divided them into two principal classes, irritant and neurotic, and, reserving the latter class with its sub-divisions for a future lecture, proceeded to discuss the following inorganic poisons, and the methods for detecting them in organic mixtures and in different parts of the animal economy:—Arsenic, antimony, mercury, the mineral acids, alkalies, the salts of lead, zinc, barium, copper, potassium, bichromate, etc. etc. Oxalic and prussic acids were also glanced at. The lecture was illustrated by numerous experiments.

MANCHESTER CHEMISTS' ASSISTANTS' ASSOCIATION.

The last ordinary meeting of the above was held at the Lecture-room, 37, Blackfriars Street, on Monday evening, November 4th, the president, Mr. Lane, in the chair.

An instructive paper was read by Mr. Saunders, on Arsenic and Antimony with their Sources and Modes of Separation. The various tests were also shown, including Marsh's and Reinsch's; also Fleitmann's test for arsenic in the presence of antimony, with other conclusive tests shown by actual experiment. Afterwards a vote of thanks was awarded to the reader for his very useful and interesting essay. A paper on Volumetric Analysis has been kindly promised by Mr. Siebold for Monday evening, November 18th.

BRIGHTON ASSOCIATION OF PHARMACY.

The opening meeting of this association was held in Hanover Lecture-room, Church Street, on Friday evening, November 8th. There was a fair attendance, and, without any preliminaries, the president, Mr. W. D. Savage, read the following paper:—

Gentlemen,—At the commencement of a new undertaking, or the resuscitation of an old one, it would seem to be, by practice, the proper thing to say something as to the *objects* likely to be obtained by the organization, and what efforts will be necessary to secure their accomplishment.

The second rule of the association defines the *object* to be the mutual improvement and general advancement of the interests of all its members; and the *tenth* rule indicates the way by which this is to be attained, viz., by lectures and reading of pharmaceutical papers. In practice we may find it necessary to transpose the position of these, and so begin with the reading of suitable papers, feeling our way by degrees to higher things as opportunity and means become available. I contemplate, however, a much wider sphere of usefulness in the whole being brought together (apart from social gatherings arising out of these associations), the interchange of thought and the force of example will go a long way either to sustain or mar the efforts of the leaders of the undertaking. It too frequently happens that by a spasmodic effort an association is formed which soon withers and dies. This mainly arises from relaxed energy on the part of the promoters; or more frequently, perhaps, from the removal of some one who had the necessary time and perseverance to uphold it. The principals and assistants engaged in this renewed effort, must feel mutually bound to aid each other, and to support by their presence at the meetings, and to take such part in the proceedings as to justify the belief that they are anxious for the success of the undertaking. The mere formal acquiescence in the establishment of such an association is not enough,—to become a member is essential. But unless some little sacrifice on the part of the principals is made, it must sooner or later end in failure. The parties more immediately interested in the success of this association are the apprentices and assistants; the former, by the means at their disposal, will be enabled to advance their pharmaceutical education, and the latter to strengthen and enlarge that which they have already obtained. But I cannot help thinking that *all* who are connected with the trade must rejoice at the opportunity that this association affords of removing a stigma from our town, and of being able to help those who are desirous of helping themselves; and thus it is that the originators of this undertaking have wisely (I think) combined the interest of employers and employed in having associated on the committee of management principals and assistants. It may be thought by some that such a combination is injudicious and will prove impracticable in working. As the majority of our establishments have but one assistant, how can principal and assistant leave at the same time? This of course cannot be; but the difficulty may to a certain extent be removed by an arrangement that the principal should attend monthly, or other meetings where his presence and experience would be most required, whilst the weekly meetings for *practical* instruction would be most advantageously promoted by the attendance of assistants and apprentices. By a little concession and mutual desire on the part of both that such arrangements should be carried out, beneficial results must follow, until the good time comes when our shops can be closed and business engagements cease at eight o'clock, so that all may then be free to attend such gatherings. In the meantime we must make the most of our opportunities; and when we contemplate the limited means at the disposal of such men as Faraday, with the noble results that he achieved, we have no cause of despair, but on the contrary, grea encouragement to persevere and avail ourselves of the many facilities placed within the reach of all who will but use them, in every department of science or commerce. Education is the cry, and in none just now is the appeal made more urgent than in that of Pharmaceutical Education. We have the various schemes propounded by Messrs. Reynolds, Schacht, Attfield, Wootton, and Redwood, and locally we have our friend, Mr. Schweitzer's suggestions, read at the Conference. Amidst such a variety of plans and opinions you cannot wonder at the perplexity of the Pharmaceutical Council, and their hesitation to adopt any scheme until the difficulties that at present surround the question are cleared away, and more experience acquired to enable them to decide equitably. On reviewing the different proposals we may perhaps be permitted to consider some of the distinctive characters of each plan, beginning with that of my esteemed friend, Mr. Richard Reynolds, of Leeds; for although his views, as enunciated at the Leeds Association (see the Journal of March of this year), are later than those of the Provincial Education Committee of the Council, which appeared in the proceedings of Council, March 2nd, 1870,—yet, as a member of that Committee, we may fairly infer, that if not the author, he was the promoter of those suggestions of having in large towns the *means* of acquiring technical education. And whilst the parent Society could not initiate such schools of pharmacy as the report indicates as necessary, and as Mr. Reynolds advocates, still they could materially aid the same after their formation and having furnished evidence of their vitality and usefulness. It is said that the plan is analogous to that of the medical profession, whose wants are supplied by the eight schools of medicine established in the principal towns of England. Such a provision connected with the Pharmaceutical Society (although entirely independent of it so far as management is concerned) would place those favoured towns in somewhat the same position as London, so far as to enable students to attend lectures and receive practical instruction. It has been argued that places like London would then be resorted to by apprentices and improvers. This, to a certain extent, would prove to be so, but the parent Society remaining as now an examining body would be all the better off by such institutions preparing the students to pass creditable examinations; and the students themselves would not require to be so far from home, nor, consequently, to incur such a large expenditure. Mr. Schacht again deserves much credit for the elaborate scheme which he proposes for provincial education, and its general principles were approved by the Council. Without, however, entering into every particular, especially as the details have not been furnished, certain propositions based on the science and art programme of Kensington, of payment for results, seem to me impracticable. As at present propounded it is imperative that 25 lectures on chemistry and botany shall be given by *competent teachers*; that they shall be on different days, and be of one hour's length; and that the student do attend at least 20 of these lectures. How is it possible that such an arrangement can be carried out? Mr. Reynolds, in a letter to the Journal of July 27, very ably suggests difficulties that would arise in attempting to carry out Mr. Schacht's scheme. Amongst others, he points out the awkwardness of having two examining bodies, for the Pharmaceutical Society are to send examiners. Suppose, for illustration, that we had a class arrangement on Mr. Schacht's principle, and one of our students did so well that he obtained a prize for himself and £2 for the Association. The same young man, under a different system of examination, goes up for his Minor, and is plucked! How disagreeable and unsatisfactory such a state of things would be, and still there is nothing improbable in such a result. But I must pass on to consider the next proposition suggested by Professor Attfield, which he read at the Conference meeting, and it is so well known that it scarcely needs reference, beyond that of pointing out some of the more important parts. There is much in the professor's scheme that commends itself to my approval; indeed, I am not certain that on the whole it is not the best scheme for provincial education as yet suggested, embracing, as it does, some of Mr. Reynolds's proposals. It stands thus:—1. To increase the fees of teachers of chemistry, materia medica, pharmacy, and botany; 2. To pay one half the salary of curator and lecture assistant; 3. To distribute such duplicate specimens from the Society's museum as might be available; 4. To make grants to libraries; 5. To grant loans of materials for class teaching, with power for making them absolute grants. These are parts of the scheme of the Provincial Education Committee, adopted by the Council on November 2nd, 1870, but from the stringent regulations imposed on the local associations they were virtually impracticable. When the local committees applied for loans the individual responsibility imposed by the regulations was so great that, as was the case with Nottingham, they declined to avail themselves of the offer. The part of Professor Attfield's scheme differing materially from the others is the imperative attendance at lectures at some recognized school; this very desirable course would be found inoperative in practice, at least for many years to come. How can the village or small town apprentice find time or means to accomplish it? I cannot help thinking that Professor Redwood's proposition would be an excellent one for immediate use, viz., that candidates should be required to state *where*, *when* and *how* their education had been conducted. This suggestion if carried out, would at once enable the examiners to see where *cram* would be likely to occur, and so regulate by varying their course of examination to test the efficiency of the professed teachers of *cram*. I cannot leave this subject without adverting to the observations at the Conference of our friend Mr. Schweitzer; he thinks the aid given in money or books to provincial societies is so much money thrown away, whilst the establishment or maintenance of a number of regular schools would be equally ineffective, and tend to cripple the parent Society; that apprentices should have passed their Preliminary previous to entering on the trade; that masters should not take apprentices unless they are able to instruct them, so that at the end of their term, with very little study, they may pass the Minor examination. Our friend thinks that the Preliminary or classical examination is evidence of a youth's fitness for entering the business; that the Minor should only represent an assistant's qualification, whilst the Major should be a necessary qualification for becoming a principal, and that no more suitable place for the attainment of these objects is to be found than Bloomsbury Square. If the Society, after paying their officers, should have any funds to spare, let them open the whole establishment gratuitously for a limited period to apprentices and assistants. Whilst I am ready to concur in many of the views enunciated by Mr. Schweitzer, I also think they may probably apply more forcibly to the future than the present, but our thoughts are for the present, and for some time to come. I have great faith in self-reliance; but a little help in time of need is like lightening the burden of a fallen horse, which he will carry well enough after he has risen. The proposals of Mr. Schacht seem to me as likely to be of very limited application, as none but the largest towns could get the necessary organizations. Mr. Reynolds's plan seems necessary if Professor Attfield's requirements were carried out, inasmuch as attendance at recognized schools could not be confined to London. I have dwelt so much on this subject that I am afraid you will consider me very prosy, but provincial education is of such vital importance just now that more than ordinary reference seemed to be required. My own ideas are simple; and I think with Mr. Schweitzer that the days of the uneducated amongst us are numbered. An apprentice henceforth must be able to pass his Preliminary, or furnish evidence that he has passed one or other of the local university examinations. The master must not object to concede at least one hour each day for study; and to my mind the morning is by far the best part of the day for such a purpose. In the evening (where more than one apprentice or assistant is kept) an arrangement, when practicable, should be made so that each one might have alternate hours, say from seven, until closing time, being within call if required. Such an arrangement on Mr. Stoddart's plan of systematic study would, I am sure, enable any young man with ordinary application to pass his Minor examination within two or three years, and do away with the necessity of attendance at any recognized school, whilst half, or at most, a session at Bloomsbury Square *afterwards* would complete the "Major," and do away with much complexity that now surrounds the question. I would not discourage such an association as this, because I believe them to be important auxiliaries; but in small towns where no such co-operative aid can be obtained, I believe the means which I have indicated capable of accomplishing the object; but the masters must not only allow the necessary time, but assist in procuring chemicals for experiments. I do not think the indiscriminate run of your chemicals and chemical apparatus without any charge or restraint the best course to adopt, but to purchase *at cost price* all the apparatus required by an apprentice or assistant, and an equitable return for all unbroken utensils at the end of the term. No principal could object to supply every facility for the improvement of those under his care. On the other hand, the engagement must be one of mutual interest, and the *employé* must show by attention and care that he merits the privileges conceded. I must here observe that in too many cases there is a spirit of estrangement betwixt the principal and assistant, which, in a rightly established concern, should not exist, if we properly realize the fact that our apprentices and assistants are to be the future masters; and as we impress them by our conduct, so will they probably act. It is important that our example should be worthy of imitation. Some of the large establishments in London are governed on equitable principles, whilst, on the other hand, others seem so exacting and selfish, with the coarsest living, the maximum of work and the minimum of domestic comfort, that it is no wonder that frequent changes occur, and those who submit to such treatment do so grudgingly, and only to obtain experience, without any of those pleasing reminiscences that ought to subsist after leaving the service. We should all try, I think, to bear in mind the wise maxim "to do unto others as you would they should do unto you"; and whilst I am anxious to impress upon my brother principals the *suaviter in modo* treatment to those in their employ, I would none the less most urgently appeal to every apprentice and assistant to consider their responsibility, and endeavour by a proper regard for their principals' interest to merit the confidence and kindness reposed. I recollect that Mr. Stoddart, at one of the Conference meetings, when he was presiding, saying that he on one occasion required a large parcel to be conveyed a short distance to the carrier, in the absence of the porter; when the assistant seemed to hesitate, he placed it on his own back and took it without a word, and the lesson was so salutary that he never had occasion for future complaint. It is true assistants should not be treated as menials, but occasions will arise when a little deviation shows a right feeling, that cannot be otherwise than thoroughly appreciated. Those of us who can look back to the last generation of chemists and druggists, know what a change has taken place, and how different things are now as compared with what they were. Our apprenticeship was one of drudgery, and with few exceptions the provincial town and city druggist combined tea, tobacco, oils, paints, colours, and in some cases were seed merchants. Some of these combinations exist now in the northern counties, and a young man coming south finds that he has a new trade to learn, less physical and more mental energy is required; but when an assistant has graduated in the two kinds of trade, and become master of each, he is usually a valuable assistant. I would here remark the importance of a knowledge of the kind of trade mentioned to rightly estimate the recent agitation of the poison question. It is a serious matter to those chemists who live in agricultural or manufacturing districts, to have additional duties imposed upon them, and anything like registration of poisons at certain seasons of the year would necessitate an additional assistant on market day, when usually as much business is done as on all the other days put together. We who live in the south know nothing of the bustle and confusion arising from multiplicity of orders given and required to be executed on market day; we must therefore look charitably on some of the shortcomings of our country friends; and whilst public security against unnecessary risk should be guarded against, we ought carefully to avoid imposing burdens that would be honoured in the breach rather than in the observance. Legislative enactments can never supersede individual responsibility, and no greater incentive to proper precaution will be found equal to self-interest. By a single accident (to which the most careful of us are liable) might follow the loss of business and reputation. One of the greatest safeguards will be found in our educational status, and I would here call attention to some important alterations contemplated to come into force in October of next year, and to remind my young friends that they must, if they desire to avail themselves of the present mode of preparing for the Minor examination, make the best use they can of the ten months before them, for after then a new order of things will prevail. On the evening of Tuesday last I attended a meeting of the General Purposes Committee in Bloomsbury Square, when a deputation of five members of the Examining Board met us, and Mr. Carteighe, as their exponent, went most fully into the proposed change, whereby the Minor after this year will become the principal practical examination. It will stand thus:—"Candidates for this (the Minor) examination must have passed the first or Preliminary examination, and must produce certificates of having attained the *full age of* 21 years, and of having been employed for three years by a pharmaceutical chemist or a chemist and druggist, in dispensing and compounding prescriptions." I tried to alter the proposal about age, thinking it more satisfactory that a youth should be able to pass his principal examination whilst apprentice, but this was overruled by my colleagues, and made to dovetail with the Bell scholarships, which for the future will exclude those who have passed their Minor, and are *under* 21 years of age. This is much more equitable than the previous arrangements, which placed the ordinary candidate at a disadvantage, having to compete with an examined man. The Committee having arranged with Mr. Parkhurst to give you a course of ten lectures, I do hope that the efforts of the committee to promote the interests of the association will be appreciated, and that the classes will be numerously attended. Nothing tends so much to depress the energies of a lecturer or teacher as an empty room; let the seats be well occupied and the audience attentive, and a good result is sure to follow. I have already adverted to the views entertained by Professor Attfield on provincial pharmaceutical education, and the anxiety manifested by him at the alarming extent to which "cram" prevails; but few of us could anticipate the fact, as stated by Mr. Andrews in a letter which appears in the Journal of Nov. 2nd, that for the last four years no less than 130 each year have passed the Examiners' Board by "cram." Some persons will be disposed to say that there must be some defect in the mode of the examination, or so large a number could not elude detection, but only let such persons consider the limited time—say twenty minutes or half an hour at most—which each examiner can detain a candidate, and, of necessity, to ascertain the relative merits of each by asking the *same* questions, termed, by Mr. Carteighe, "stock questions," you will at once perceive the difficulties which beset the question, and, to judge the examiners fairly, all these things should be considered. Men who pass by such means as a *month's* preparation can never feel perfectly satisfied; and I do hope that none of our Brighton young men will sully the prestige of our town by a back-door entrance whilst the front portals of Bloomsbury Square are wide open, and ready to welcome legitimate effort and honest work with the enduring title of M.P.S. I cannot conclude this address without mentioning the kindness of our friend Mr. Hills in presenting through the secretaries of the Conference the portraits of Jacob Bell, Wm. Allen and Dr. Pereira, men whom we have reason to be proud of, and whose virtues may we emulate! We must not omit to express our gratitude to the executive of the Conference for their handsome and valuable gift of suitable books (to be selected by ourselves) to the value of £10. Last Sunday I had the privilege of hearing an excellent sermon preached from the words "Beginning at Jerusalem," a most suggestive text—the apostles starting from the place where they were best known on their universal mission of mercy. So let us say to the young men beginning at Brighton, avail yourselves of the advantages of this association, and wherever your future lot may be cast, let your character and conduct reflect credit on the Brighton Association of Pharmacy.

The paper was listened to with the greatest attention and its conclusion was greeted with applause. Mr. Savage said he should be glad to hear the remarks any member might have to make.

A short discussion then ensued, and a vote of thanks to Mr. Savage for his able and interesting paper brought the proceedings to a close.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

The first meeting of the season was held on Thursday, 7th November, 1872. In the absence of Dr. Frankland the chair was taken by Professor Williamson, F.R.S., vice-president. The meeting was well attended, and after the termination of the usual business several interesting papers were read. Two by Mr. E. C. C. Stanford, F.C.S.; the one, "The Action of Charcoal on Organic Nitrogen," being an account of his experiments to ascertain the value of a method of deodorizing and utilizing fish offal and other offensive matters, by mixing them with charcoal; the other "On Iona Pebbles." A communication entitled "Mineralogical Notices," by Professor Storey-Maskelyne and Dr. Flight, was then read by the former, giving a short description of several minerals mostly new or from fresh localities. Mr. J. R. A. Newlands gave a brief explanation of "A Means of Preventing Explosions in Coal Mines," which the author proposes to effect by erecting air-tight chambers over the upcast and downcast shafts, and forcing air through the workings by powerful air pumps or ventilating fans. There were also papers "On the Specific Heat of Occluded Hydrogen," by W. C. Roberts, F.C.S., and C. R. A. Wright, D.Sc., and "On some Probable Reactions that yielded Negative Results," by Dr. C. R. A. Wright. The meeting finally adjourned until Thursday, 21st, when a paper "On Anthraflavic Acid" will be read by Mr. W. H. Perkin, F.R.S., etc. During the evening a beautiful specimen of bromocamphor was exhibited by Mr. Williams, of the firm of Hopkin and Williams, who stated that it was used medicinally as a nerve sedative in such diseases as delirium tremens.

Parliamentary and Law Proceedings.

Child Murder and Suicide in Manchester.

An inquest was held on Monday before Mr. E. Herford, the city coroner, concerning the deaths of Annie Gurlin, aged 29, widow, who lived in Cross Street, Thompson Street, Oldham Road, and her daughter Ada Millicent Gurlin, aged about 2½. The first witness called was Ann Lawrence, residing in Rochdale Road, who deposed that the deceased Annie Gurlin was her daughter. The latter had been in a very melancholy way for some months, fretting about her husband, who died eight months ago. She seemed very cross with everybody, and was quite different to what she had previously been. Upon various occasions she had told witness that she should like to poison herself and her children. One day last week she took some laudanum, and it made her very poorly. She said that she intended to kill herself. Witness left her at her house about ten o'clock on Saturday night in her usual health. Witness took the other children home with her, leaving only the younger deceased there with her mother. On Sunday morning witness went back to the house, unlocked the door and passed into the bedroom, where she found them both lying in bed together, dead. She started off for a doctor and the police, and when she returned she found the police in the house. She had not the least doubt that her daughter was out of her mind.

Police-constable William Hawkins received some information, in consequence of which he entered the house. Upon the floor near the bed, where the two deceased lay, he found a bottle and spoon.

Mr. J. Jordan, assistant to Mr. William Bentley, druggist, Shudehill, stated that about a fortnight ago the deceased, Annie Gurlin, came to his employer's shop and asked if she could have an ounce of prussic acid for her husband, who was a photographer. He asked some questions, upon which the deceased fetched a woman, who supported her statement, and said that her husband was not dead. The prussic acid was then supplied in a bottle similar to the one produced.

Mr. William Walls, surgeon, Oak Street, said the bottle found by the policeman contained prussic acid. Upon making a *post-mortem* examination of the two bodies he discovered indications of the presence of prussic acid which had caused death. On the Wednesday previously the elder deceased had called upon him and complained of pain in her left arm, and she wanted it bled, saying it had bled through a scratch she received a few days before, and it relieved her. He told her to bring her mother with her. She went away, but did not come again. He thought that she wanted him to open a vein, and that she was not sane.

The jury returned a verdict to the effect that Annie Gurlin poisoned herself and her child, Ada Millicent Gurlin, whilst in an unsound state of mind. It transpired that the woman who supported the statement made by the elder deceased to the druggist was named Mary Walker, and she was present at the inquest. The jury, in censuring her conduct, expressed their opinion that proceedings ought to be taken against her.—*Manchester Courier.*

Death by Misadventure.

On Wednesday, October 6, Dr. Hardwicke held an inquest at 13, Devonshire Terrace, Paddington, touching the death of Harriet Scott, aged 74. It appeared that a chemist who prepared an injection ordered by her physician, inadvertently put in a double quantity of morphia.

After deliberating for a considerable time the jury returned a verdict of "Death by misadventure."

Obituary.

JOHN BOHLER.

A recent obituary in the Sheffield *Daily Telegraph* contained a notice of the death of Mr. John Bohler, at the age of 75, and from a later issue we take the following interesting particulars:—

Although neither a native nor a settled inhabitant of Sheffield, the late John Bohler was so well known to many of our townspeople, especially the older members of the medical profession, and to the students of botany in general in various parts of the kingdom, that a few words of record seem due to his memory. We believe he was born at South Wingfield, in Derbyshire, of a very humble stock, and of parents to whom he owed nothing beyond "the accident of his birth." He learnt to read and write, after a fashion, at the village school, and as early as possible was put to stocking-weaving, the common employment of the neighbourhood. From his earliest boyhood he had a taste for collecting and identifying plants, heaps of which were piled up in his lodging-room.

In due time he found that certain plants had not only medical virtues, but a selling price, so he became a collector for the apothecaries and druggists, and probably no man in England was better acquainted with the habitat of every officinal herb, infusions of which are recognized in the Pharmacopœia or adopted in empirical practice. Hyoscyamus, colchicum, daphne, etc., continued in use, but decoctions were giving way to alkaloids. He tried his hand at these, but he was no chemist. Curiously enough the disciple of Culpepper, Thornton and Hill never sank into that most arrant of quacks, the modern "herb doctor."

His vocation of collector led to a loose, rambling, but sober and studious life. His means of purchasing books were exceedingly limited, but he borrowed and read most of the popular works on botanical science, of which he acquired a competent knowledge; these, added to his experience as a collector over a very wide field, made him a welcome visitor to the closest naturalist.

About thirty years ago his name appeared on a work entitled 'Lichenes Britannici,' several *facsimiles* of which were published by the late Mr. Ridge; the specimens being collected and mounted by Bohler; and the description written by Dr. Deakin, author of 'The Botany of the Coliseum of Rome.' These "time stains," as they were somewhat poetically called by our forefathers, are mostly found growing on the barks of old trees, or on walls or rocks; they are sometimes rich in colour, and curious in their structure, especially as seen under the microscope. One arboreal species is known as *Lecidea Bohleri.*

We believe he one year delivered the sessional lectures on botany at the Sheffield Medical School, besides giving private lessons. Perhaps the most complimentary and only compensating employment he ever met with, was being engaged some years ago by a Committee of the British Association to assist in a botanical exploration of Snowdon, North Wales. He wrote the account of local plants in Dr. Aveling's 'History of Roche Abbey.'

Of late years he has devoted his attention to the cryptogamic races, especially fungi, for mounted collections of which he usually found purchasers. But toadstool collecting was a lean pursuit, most persons caring little about any except the esculent ones. Nor was pondering in damp places and in the winter time, at his age, and often, it is to be feared, with an empty stomach and an insufficient supply of clothing, favourable to health, to say nothing of comfort. And so, from little to less, and, we are afraid, from that to nothing, the substance of the poor old man fell off.

He was until about twelve months since one of the most untiring walkers in the kingdom, England and

Ireland having added their botanical varieties to his research. But his familiar beat was Sherwood Forest, and there within a few weeks he took a last farewell of scenes so long and delightfully familiar. He had personal peculiarities, failings, perhaps faults. A vagrant life, however picturesque, is rarely favourable to the *res angusta domi*. In aspect, manners and conversation he was the very personification of an unaffected simplicity; and his old friends in Sheffield concur in the regret that a man so modest and interesting, who may be considered, perhaps, the last example of a character once better known as the old English simpler, should have closed his life in indigence and obscurity, if not actual destitution.

Notice has been received of the following death:—On the 31st October, Mr. Thomas Percival Mucklow, chemist and druggist, of George Street, Aston, Birmingham.

Reviews.

QUALITATIVE CHEMICAL ANALYSIS. By Dr. C. REMIGIUS FRESENIUS. 8th ed. Translated by A. VACHER. London: J. and A. Churchill. 1872.

Fresenius' works on qualitative and quantitative analysis hold so high a place in the estimation of English students of practical chemistry that the reviewer approaches his task of meting out praise, or of finding fault with a standard work like the new eighth edition of the qualitative analysis, with considerable hesitation. Most of our readers will learn with satisfaction that the liberties which Mr. Vacher took with the last English edition have not been repeated, and that the author's wish and *injunction* to adhere strictly to the original text have been faithfully complied with. On the score of justice to the German author, and in view of the advantages accruing to the English student, we congratulate the editor that he abandoned "the broad view of his duty" and contented himself with becoming a mere translator.

Fresenius divides his book into two parts, each consisting of several sections. Every one familiar with laboratory teaching will know that the first two sections, comprising eighty pages of the work, descriptive of divers chemical operations and of reagents, are, as a rule, passed over, and that the student is set at once to practise the reactions for bases and acids. The information they convey—admirable of its kind—is usually glanced at only when a reference to any of the manipulatory operations described has to be made, or when some information about reagents is wanted. The plan of the book evidently assumes that a general knowledge of chemistry, such as is obtainable by attending a course of lectures, has been acquired previously to the study of qualitative analysis. If so, the value of the elaborate and detailed instructions consists in being useful matter of reference. The section treating of the reactions of the bases and acids has by general consent always been looked upon as the most useful part of Fresenius' qualitative course. The accuracy and fulness of the information collected during many years by the author is beyond praise; and if it were for nothing else, the book should be in the hands of every chemical student. The additions comprise, among other things, careful instructions regarding the spectra (illustrated by a new spectrum table) of the elements which can be studied by means of a Bunsen flame, and the results of Bunsen's experiments on the deportment of bodies at a high temperature. Spectrum analysis has made such rapid strides during late years that it may be questioned whether the meagre information conveyed to the student, by tacking on to the qualitative laboratory course a description of some of the more easily obtainable spectra of the metals of the alkalies and alkaline earths, satisfies the cravings of an earnest student; and whether it may not be advisable to reserve spectrum analysis, with the application of an induction coil, for a separate course of study. It is to be hoped that some of our masters of spectral analysis will soon supply a want felt by laboratory students of a short and concise treatise on the new branch of chemical analysis.

Fresenius is sometimes carried away in his desire to supply as much information as possible, as is evidenced, for instance, on p. 103, where we are told that in respect to the detection of traces of alumina by an alcoholic solution of morin, the analyst should compare Goppelsroeder, Zeitschr. f. Anal. Chem. 7, 208. We are afraid this injunction will be as frequently disregarded as not. In fact, throughout this section of the book it becomes noticeable that much of the new information conveyed by the author will remain mere matter for reference; and this tendency of expanding and taking account of matter which cannot be looked upon as absolutely necessary to an elementary course of qualitative analysis had, no doubt, induced Mr. Vacher—and we own with much justice—to apply the pruning-knife. It would have been well if the author had distinguished the more important from the less valuable reactions by means of small type, as is done now in many text-books. In fact, the student gets, on first acquaintance, utterly bewildered with the host of reactions and injunctions regarding solubility in water, alkalies, acids, salts; and lasting discouragement results from not being able to grope his way through this labyrinth of disjointed facts. Throughout the whole book there is not one hint how best to overcome the difficulty of fixing the numerous chemical changes upon the memory; the analyst is simply told to perform certain operations and to note certain changes. No such help as may be derived from proper methods of generalization of results of a similar kind is even so much as hinted at. There is no attempt made at explaining or giving a reason for the chemical changes propounded, or at showing the analogy and natural connection between the various reactions. These omissions have always been looked upon as serious defects in the work; defects which the new edition does nothing to efface.

The second part, comprising directions for the analysis of simple salts and complex bodies, exhibits even in a more marked degree the painstaking nature of Fresenius' teaching, but if bewilderment seized the pupil on studying the reactions given in the first part, he becomes utterly demoralized by the intricacies of the directions how and what to do in the second. It is evident that the attempt to guide the analyst through the numerous phases of *possible* complications has misled Fresenius into unnecessary repetition and into constant references backwards and forwards. Instead of being guided how to work out for himself methods of separation based upon the knowledge of the properties of bodies which he has acquired, the analyst has to be constantly led by leading-strings, and to be told how to move, step by step, on the chess board of qualitative analysis, and hence when left to his own resources he becomes as a rule utterly helpless. The distinction between the few leading experiments and mere confirmatory experiments involved in the preliminary examination of substances does not become sufficiently apparent. We hold, with all due deference to the eminent author, that it is highly objectionable to adopt separate analytical courses whether the substance under examination be a simple or compound body,—a solid or liquid,—a metal or an alloy,—neither a metal nor an alloy,—whether it be soluble in water or acids, or insoluble in either,—whether organic acids be present or not. There is scarcely a commercial salt which does not contain sufficient discernible impurities to advance it from the division of simple salts into that of compound bodies. Telling the analyst what to *expect* is not a method conducive to lead him to use his own judgment correctly, and is liable to work much mischief. Moreover, an earnest student does not want to be told constantly what to do. Part of the interest attached to chemical analysis is destroyed. A carefully compiled analytical course should provide for every contingency that may arise without involving tedious and fatiguing repetitions. A student may surely be supposed to have learned *ex gr.* by the time he arrives in compound analysis that a yellow sulphuretted hydrogen precipitate may consist of sulphides of cadmium, and arsenic, as well as stannic sulphide; and to tell him (p. 237) that in that case he should look for these substances *only*, may well be treated as an act of supererogation. Instructions of a similar nature will not teach the analyst to think for himself and to learn to draw correct conclusions from the facts he observes.

Testing specially for silicic acid among the substances precipitated by chloride of ammonium and ammonia, also for oxalates, etc., as Fresenius still does, instead of removing silicic acid by evaporation and filtration, and decomposing oxalates, etc., previous to proceeding to groups III. and IV. uselessly complicates the analysis of these groups, already rendered sufficiently difficult by the presence of phosphates which cannot be eliminated with equal facility.

As might be expected from the experienced author, part II. abounds with numerous interesting explanatory notes which will be especially valued by private students. An appendix treats in a comprehensive manner of the deportment of the most important medicinal alkaloids with reagents.

It is to be regretted that the author still adheres to the old notation (O = 8). He should have been made aware that, in this country at least, the unitary system of notation is all but generally adopted by chemists.

In conclusion we may say that every one interested in analytical chemistry will hail this book with pleasure, and it is to be hoped it will not be long before a much wanted new edition of Fresenius' quantitative analysis will make its appearance.

BOTANY FOR BEGINNERS, AN INTRODUCTION TO THE STUDY OF PLANTS. By Dr. M. MASTERS, F.R.S. Bradbury, Evans and Co.

Introductory works on botany have not been infrequent of late, and this is one that will be perused with interest by many, especially by those who, having a fondness for flowers, are desirous of knowing something of the scientific story of the lives of plants which is here told in an agreeable and attractive manner.

With regard to the value of the work to pharmaceutical students, we must say a few words. Originally appearing in the pages of a newspaper it is somewhat desultory in form, and the author has adopted what is to our thinking the objectionable plan of commencing with expositions of imperfect flowers. The willows, poplars and ashes, were probably in flower when the first chapters of the work appeared, but it is only during a very few weeks in the spring that these are to be met with. When a student takes up a work and his attention is directed to plants or trees none of which are at the time in flower, although there may be plates which to a certain extent supply their absence, he loses the practical value of an examination, and very probably misses the thread of the discourse. The real value of a work like this consists in its leading the student onwards by practical acquaintanceship from one step to another; and the material required to work upon should be ready to his hand during as many months of the year as possible. Further than this, we doubt the propriety of commencing with the study of imperfect flowers. Is the first lesson best learned from an imperfect type? Does not the examination of a common buttercup give a better groundwork to the study of the relation of the floral organs than can be acquired from a willow catkin?

Let the student work first upon such a plant as that, becoming thoroughly acquainted with the organs common to most flowering plants which are there clearly represented, and he will afterwards take more interest in and better understand those forms of vegetation in which certain organs are suppressed or merely indicated.

We have also a controversy with the author's use of the word *inseparate*, to express the union of parts, instead of the accepted terms cohesion and adhesion. He apologises for the use of a word "as yet not in common use," but the word is as old as Shakespeare's time, and was used by him in a sense quite different, namely that of indivisible,

> "this is, and is not, Cressid!
> Within my soul there doth conduce a fight
> Of this strange nature, that a thing *inseparate*
> Divides more wider than the sky and earth;
> And yet the spacious breath of this division
> Admits no orifice for a point as subtle
> As Ariachne's broken woof to enter."

Surely this cannot be the right word to express, as our author says, "an apparent union,"—a case of mild attachment. Botanical terms are sufficiently multiplied without further additions, and unless new definitions are clearly shown to hit the mark we are better without them. In this case we think the shaft flies wide, and the reasons for its being launched are not clearly given. We are told at page 28 "that the terms cohesion and adhesion imply that parts originally separate became subsequently united; but this is not in the generality of cases a true expression of the state of affairs. Such a union does take place sometimes, but very rarely."

So far so good; but the antidote to this statement had been given a few lines before, where it is stated,—"But more than this, the stamens are free above, but *inseparate* from the tube of the perianth below. They too began life as independent stamens, but the isolation ceases after a time, and in adult life they appear as if joined to the tube of the perianth." The "beginner" will not easily reconcile these statements, and a want of precision is confusing to any one who reads carefully for the purpose of study. Whilst thus differing from Dr. Masters, it gives us much pleasure to draw attention to the merits of his little work. His descriptions of plant life are simple and efficient, written in so lively and pleasant a style that we should judge the book could by no possibility be dull to any one who has a taste for the study. Without making much pretension it covers a good deal of ground, and each subject is so touched upon as to give a picturesque view of some aspect of plant story. The book is enlivened and made more useful by the presence of a number of woodcuts, some of which are new and very good, whilst others are old friends, and although the work cannot be taken as a Primer, it is one that will do both "beginners" and others good to read.

CHEMISTS AND DRUGGISTS' DIARY AND PHARMACEUTICAL TEXT BOOK. 1873.

Amongst the numerous diaries which are issued at this period of the year, the above presents features of peculiar interest to the chemist and druggist, and the Chemists and Druggists' Diary for 1873 is calculated to keep up the reputation won by its predecessors. The portion devoted to the diary proper seems to be printed on finer quality paper than heretofore, and several new features have been introduced into the skeleton pages. There is some useful letter-press at the end, although not so much in quantity, we think, as last year. The collection of recipes will no doubt prove useful for reference. For one or two of these a source nearer home than a general reference to three American journals might have been given; and here and there some of them present a slovenly appearance, as for instance in the reproduction of a statement that half a pound of Ung. Hydrarg. Oxidi Rubri made eighteen months ago presents at this time just as fine an orange-chrome colour as when first made, which, though correct when it appeared in a dated periodical nine or ten months since, may have been scarcely suited for indefinite repetition. These, however, are minor defects; and besides these recipes there is a very useful dictionary of incompatibilities, together with the usual, as well as some unusual, almanac matter.

Notes and Queries.

[323.] GLASS LABELLING.—I should be glad if any reader would inform me how to affix glass labels to drawers, as the whole of mine are falling off, notwithstanding I have only recently had my shop entirely refitted.—A Chemist.

[324.]—EMULSION OF WINE AND OIL.—Can any of your readers give me the process for "Uniting Oil and Wine" without any intermediate substance? I understand this is done by the medical profession and chemists at Hastings, and is a favourite remedy in consumption.—A.S.

[325.]—LYCOPERDON GIGANTEUM.—Will any of your readers inform me, (1) whether the unripe *Lycoperdon giganteum* plant is wholesome as food, and (2) at what period of its life it becomes useful (on combustion) for taking bees.—L.

CHLORAL HYDRATE AND BROMIDE OF POTASSIUM.—Dr. James Thompson, of Leamington, states in the *Lancet* that he has found a combination of chloral hydrate and bromide of potassium very useful in *delirium tremens*, and that in many cases where sleep was not produced by chloral hydrate alone, it was obtained by the addition of an equal proportion of bromide of potassium to each dose.

DELICATE TEST FOR AMMONIA.—M. Lex proposes to take advantage of the fact that liquids containing only traces of ammonia are coloured green if treated first with carbolic acid and afterwards by chloride of lime in testing for ammonia.—*L'Union Pharmaceutique.*

PRESERVATION OF PENCIL AND INDIA INK DRAWINGS.—To accomplish this object Erckmann recommends that the drawings should be placed upon a glass plate or smooth board and covered with collodion, containing two per cent. of stearine. When dry they may be washed with water without being injured.

BOOK RECEIVED.

The Beginnings of Life: being some account of the Nature, Modes of Origin and Transformations of Lower Organisms. By H. Charlton Bastian, M.A., M.D., F.R.S. With numerous illustrations. London: Macmillan and Co. 1872.

The following journals have been received:—The 'British Medical Journal,' November 9; the 'Medical Times and Gazette,' November 9; the 'Lancet,' November 9; the 'Medical Press and Circular,' November 9; 'Nature,' November 9; the 'Chemical News,' November 9; 'English Mechanic,' November 9; 'Gardeners' Chronicle,' November 9; the 'Grocer,' November 9; the 'Journal of the Society of Arts,' November 9; 'Grocery News,' November 9; 'New York Druggists' Circular' for November; the 'Dublin Journal of Medical Science' for November; 'Scientific American'; the 'Indicator,' November 9.

Payment of Local Secretaries.

Sir,—As an old student I have the greatest affection and respect for everything associated with Bloomsbury Square, and for several years past I have contrived a pilgrimage to the Annual Meetings. A variety of circumstances this year deprived me of my usual treat, but an announcement in the Journal that, in connection with the meeting for distributing the sessional prizes, etc., on October 2nd, articles of novelty and interest would be exhibited, induced me to be present. I enjoyed the meeting; saw several old friends, and grasped the hand of our beloved Professor Bentley, but I must express my disappointment at finding not a single exhibit. Clearly no great pains had been taken to secure any, or is it really to be understood that at present pharmacy is so developed that no scope remains for further extensions and improvements in appliances and apparatus, or have the questions associated with poison regulations, and the Preliminary examination swamped all other energies?

I am a local secretary, and in speaking for myself I doubt not I express the sentiments of others. Whatever time or trouble is devoted to the interests of the Society and the trade is a labour of love, and no money payment in any shape is expected or wished, but I do ask that the Society will make it worth our while to make an occasional journey to London as pharmacists. I shall shock some when I state my preference for the old style of conversazione to the more modern entertainment at South Kensington. Continue this as a social gathering and to please the ladies, but do not let it and the politics of the Annual Meeting absorb the occasion.

I ask that something may be done for the further education (pharmacists never cease to be students) of those who have perhaps long ago done with examinations, and who, as a rule, will not care to pore further over the contents of our present museums, valuable as these may be. What we want is opportunity of inspecting in a focus the latest and most improved forms of the tools we use, whether in practical pharmacy, experimental chemistry, analysis, or microscopy

I hope ere long to see space secured for a permanent collection of laboratory apparatus and trade appliances, but until this is realized, cannot we have a temporary display at the time of the Annual Meeting?

The provincial local secretary will most likely wish to spend a morning in the library of the Society, conning over the books to see what volumes he can with profit add to his own shelves at home, and examining the latest edition of standard works. Until recently a table was spread with a rich selection of scientific periodicals, English, Continental and American. Why does this arrangement no longer exist?

John Whitfield.

Scarborough,
November 5th, 1872.

Examination Fees.

Sir,—Several of your correspondents in debating the educational question, demur alike to an increased stringency in the examinations to the Society, demanding from candidates proof of their having passed through a curriculum of previous study, and to the continuance of the present very moderate amount of examination fees, on the ground that fewer persons are entering the business than formerly, in consequence of the barriers which already exist; and they who demur deprecate any increase in the difficulties which bar an entrance on the legal practice of pharmacy, apparently dreading in the immediate future a famine of legally qualified pharmaceutists and chemists and druggists.

There is, however, one point which seems to have been much overlooked in the discussion of this subject, and that is the fact that there is at present—and for some years to come there is likely to be—a great many more legally qualified chemists than can possibly obtain a living by the practice of pharmacy; hence a large proportion are compelled to eke out a subsistence by adding other trades to their own legitimate one, by counter prescribing, and sometimes by even less excusable incursions on the domain of medicine and surgery. This is the direct result of there being many more persons embarked in the calling than there is any need for. Many of these persons—in the country especially—have as boys picked up a rudimentary knowledge of drugs in apothecaries' surgeries, or as porters in the service of druggists, and from their social position and antecedents, are tolerably satisfied if they can clear from their business as much as a skilled mechanic receives as wages. Others have been indeed apprenticed to a druggist of some sort or other, but either through their own apathy, or through lack of opportunity, their knowledge of pharmacy and its allied sciences is little or nothing in advance of the first named. Now it is to be expected and desired that both these classes of persons should gradually disappear; and I do not hesitate to say, that if pharmacy is to be made worth the attention of educated young men as a business career, that the number of "chemists shops" in proportion to the population must greatly decrease, their place being taken by a much small number of pharmacies, and a considerably increased number of oilmen, Italian warehousemen, booksellers, photographers, etc. This gradual separation of incongruous businesses will of course be a work of time, but the sooner it takes place the better for the public and ourselves. There will be in the future a difference both in quantity and quality; and there is urgent need that the first decrease and the second improve. Meanwhile there need be no "searchings of heart" for some time to come with regard to a falling off in the number of registered practitioners of pharmacy.

Wm. H. Hayward.

Trowbridge.

Sir,—Anonymous correspondence, as a rule, does not deserve the same attention as if authenticated by name and address of the writer; but I cannot allow the remarks of 'An Underpaid Assistant' to pass without calling in question their correctness. There are few, if any, assistants "well up" in their business here who would accept a salary of £50 or even £60 per annum. I know many, anything but well up, receiving higher salaries; but this is, to some extent, beside the question at issue, as there are other reasons, as well as those given, why assistants are leaving the business, such as long hours and confining employment, as compared with other businesses. My statement, however, I adhere to, viz., that the present scale of examination fees has not only pressed heavily on some who have gone forward to the examinations, but has deterred others from going forward at all. And I gave this as a reason, among others, why the fees should be reduced instead of raising them as proposed by Mr. Vizer and Mr. Carteighe; but 'An Underpaid Assistant' seems to doubt this. I have to remind him, however, that it is not a question of "three guineas" at all, but five guineas, and in some cases eight and nine guineas, and with Mr. Carteighe's addition would perhaps be twelve guineas, some of our young men having had to pay one and two guineas additional for the Preliminary and the same for the Minor. Of course, they were "plucked" once or twice; but this is a contingency always to be looked forward to, and I do not think the Society should make capital out of it. Then the fee for the Preliminary is two guineas of itself, while the medical Preliminary here is only 10*s.* 6*d.* It is little wonder therefore that a young man preparing to study should choose the cheapest, especially when the future prospect is better. Your correspondent thinks the cry for a reduction of fees comes from the wrong quarter; I should like to know from whence it should come, and when. I do not think there is much prospect of it coming from the assistants who are leaving the trade in disgust; and it will certainly not be time for employers to do so when the business has been drained of its best hands.

17, *St. George's Cross, Glasgow, Nov.* 12*th*, 1872. J. M. Fairlie.

The Sale of Poisons.

Sir,—I shall be glad if you will be kind enough to inform me through the columns of your Journal whether or not grocers are allowed to sell chlorodyne and Winslow syrup.

It has recently been decided (Pharmaceutical Journal, page 94), that the sale of Battle's Vermin Killer must be registered; and as it is equally as well known that the two preparations I have named owe their sudorific effects to morphia as it is that the active ingredient in Battle's Vermin Killer is strychnine, it seems to me that the Sale of Poisons Act must be applied to all patent medicines containing poison, if applied to one; and in that case chlorodyne and Winslow's syrup must be classed under part 2, schedule A, Pharmacy Act, 1868.

If my supposition is correct, I shall be obliged if you will further inform me if it is the duty of the Pharmaceutical Society to take steps against parties contravening the Act.

Thos. Brewis.

Amble, September 30*th*, 1872.

Pharmaceutical Education.

Sir,—As one of the "poor unfortunates" mentioned in the letter of an assistant in last week's Journal, I would suggest that instead of spending time and energy in trying to obtain "some privilege," they should take for their motto, "Nil desperandum," and qualify themselves for the existing examinations.

I must confess that at one time I might have added my voice to his, in pleading for privilege, but that now I write from the other side the hedge, and if the following brief sketch will prove a stimulus or encouragement to any assistant, my letter will not be in vain. The only schooling I was fortunate enough to receive was obtained at a small village school, where Latin was indeed a dead language. At the age of fourteen years, I was apprenticed for five years to a chemist in a country town, and during the whole term, only studied very little by fits and starts, never dreaming of a compulsory examination. My term having expired, I took a situation in one of the large manufacturing towns in the north, and when within three months of my 21st birthday I was informed by a commercial friend that I had two examinations to pass, I could hardly believe him; but having ascertained that it was a fact, I set to, and without losing a day at business (with the exception of half a day for the Preliminary and two days for the Minor), with scarcely any aid, and at a cost of under £12, including fees, travelling expenses, etc., within a year I was so fortunate as to receive a star in the Minor, and can now look back on the compulsory examinations as among the good things of life, seeing that knowledge is power and I may add pleasure too.

An Associate in Business.

The Annual Subscription.

Sir,—Attention has been drawn to the fact, that a great number of those who have qualified themselves as Pharmaceutical Chemists do not become members of the Society; one cause is, doubtless, that many cannot afford the extra half-guinea; for the young Major, from want of practical knowledge, or it may be years, often finds himself compelled to accept a junior's berth and salary. I venture to suggest, as a remedy, that Major associates not in business be admitted to membership without extra subscription; this would be an addition to the few inducements offered to students to take this qualification.

A Young Major.

London, November 6*th*, 1872.

The Library.

Sir,—In the interest of provincial pharmaceutical education, may I suggest the desirability of bringing under the notice of the Council the rules which at present regulate the use of the library of the Society by country members.

The rules for the issue and retention of books apply equally to all, and, as a consequence, while to the town member they merely regulate the use of the library, to the country members they almost close it. The postage to and fro of any book of moderate size, and this doubled if the book be retained beyond the fortnight, forms a tax which is almost prohibitory.

What I would suggest is, that to remove in some degree the disadvantage under which country members labour with regard to the library, the Society pay the outward postage of books to the provincial members, and that they be allowed to retain them three weeks instead of a fortnight. By this means the extra expense now incurred by them would be reduced to 50 per cent. and the benefit would be correspondingly increased. The result would be that they would be placed, with regard to their use of the library, more on a par with their London brethren.

The country members may fairly claim the consideration of the Council for this matter, the use of the library being the principal direct advantage they derive from their connection with the Society.

A. H. Claypole.

Early Closing.

Sir,—I am always happy to say a few words on early closing, as I have found from experience that chemists are open much longer than there is any necessity for. The reason people go to a chemist's late is generally because they expect to get in, whereas if the public knew chemists finally closed at a certain time there would be very few late customers. I am quite willing to admit in large towns medicine from a prescription may occasionally be required late; but even this more often is because the patient or prescriber knows it can be dispensed at any hour. I think if chemists were asked if things served after 8 oclock were really necessaries, the majority would answer in the negative. Pennyworths of pills, twopennyworths of castor oil, and seidlitz powders could as well be had before eight as after it, and therefore calls for such trifling remedies—which every one ought to have in their house—cannot be looked upon as a sufficient reason for keeping open so late. I recollect a few years ago writing on the same subject to the 'Chemist and Druggist,' and while I was penning the letter a woman called me up for something for her husband, who, on inquiry, had been poorly a fortnight, and had just then, at 20 minutes to ten P.M., thought he had better take something. This is only one case out of many.

Neither medical men nor the public are unreasonable; and if we are disposed, our working hours *may* and *ought* to be much shortened; for how can we expect our young men to study if they have to work until ten?

Again, Sunday trading many also be reduced to a minimum by a little discretion and pains. Eleven years ago, when I came here, people used to come for all sorts of things on Sunday, but by degrees they have all dropped off, and so have most of my would-be-late customers; and yet my business has increased yearly. I now lock up and turn off the gas at nine every evening, excepting Saturday, and myself and young men either go out or sit at home and read, and on Sunday I do not open at all, and find this arrangement not in any way unpalatable. At the same time, if anything urgent is required, the public have the willing services of

Alfred W. Smith.

93 & 94, *High Street, Rye, Sussex.*

Sunday Closing.

Sir,—Kindly allow me the opportunity of replying to Mr. Wilkinson and 'One who has Known the Drug Trade Thirty Years.' To the latter I say that he is quite mistaken in supposing that I am not in favour of what he calls Sunday closing. In proof of which I assure him that I am fifty-eight years of age, and never in my life opened my shop on a Sunday in his sense of the words; that never since I was my own master have I sold anything on a Sunday that was not required strictly for medical purposes; and that for more than twenty years I have only required the attendance of my assistants in turn, from 12.30 to 1.30; from 4 to 5, and from 8 to 9.

To Mr. Wilkinson I reply, that as no glossary was provided with the announcement of the new agitation, I really did expect something more, or rather something less, was intended than what is described by my friend, which is not Sunday closing. By "closing," a place of business is always understood ceasing to transact business there. If a notice were placed on the door of a broker's office, stating "this office will be closed every day at four o'clock," and one or two clerks always remained behind to receive telegrams, or money, and transact other business, any one being admitted on knocking at the door, say till six o'clock, it would not be true that the office closed at four. Or if a number of clerks were employed at a telegraph office from Monday to Saturday, and on Sundays one or two were in attendance to despatch messages, etc., it could not be said that the office was "closed on Sundays."

I am delighted to find that my brethren are agitating for the establishment of the practice I have adopted for more than a quarter of a century, and heartily wish them success; but I don't "close on a Sunday." I wish I could.

J. T. Slugg.

November 11*th*, 1872.

Patent Medicine Licences.

Sir,—Instead of debating the question of the various prices of a patent-medicine licence, I think we ought boldly to "rise as one man," and ask that licences to sell stamped medicines be only granted to registered chemists and druggists. Now that laudanum is being sold by grocers (Pharm. Journ., Oct. 26th, 1872, p. 339) under the guise of a patent (?) medicine, I should think the Legislature would, if the matter were properly put before them, readily grant this privilege.

When I came into this part of the kingdom I was much surprised to find the regular price of a 1*s*. 1½*d*. patent to be 1*s*. At first I would not believe that the more respectable of the profession would be guilty of lowering the prices; but alas, for the noble science of pharmacy, I found it only too true! Yes; gentlemen who had acquired the higher qualification required by the Major examination, and gentlemen with letters after their names indicating fellowship with learned societies, were doing that which many a greengrocer would scorn to do, namely, selling 1*s*. 1½*d*. puffs at the starvation price of 1*s*. After making inquires, I was informed that the 1*s*. price was started by a local newspaper proprietor, who had to take out the charge for advertising the precious stuff partly or wholly in the patent stuff itself, instead of coin. Whether this be the true solution or not I cannot say, but this much I do know, that patent medicines are regularly sold by my neighbours all at 1*s*., much to my loss and theirs too.

Now, if the trade in patent medicines were confined to chemists and druggists, this terrible state of competition might be done away with, while the public would in no way suffer. I know it would make very little difference to the *élite* of the trade—those who have their dispensing establishments—yet I think the Pharmaceutical Society should look a little to the interest of the more numerous and humble of her children, those poor country druggists whose scanty subsistence is eked out by the sale of sundries, including a very large proportion of patent medicines, and who seldom see a prescription.

Why should one man before he can sell a pennyworth of paregoric, be compelled to spend time, money and talent in passing the ordeal of the Pharmaceutical Society, while another is allowed, for 5*s*. per annum, to dispense such blessings as soothing syrups, laudanum, etc., *ad lib.*? I pause for a reply.

A Village M.P.S.

Sir,—The question of patent medicine dealers and licences has more than once been thoroughly ventilated; and as it can be proved, no doubt, to the satisfaction of anyone, that restricted articles are being supplied to the public by persons who are not registered chemists, and in nowise qualified to deal in the same except under cover of the medicine licence, it is time some action should be taken in the matter. The suggestion of Mr. Alexander Ellis to raise the duty to £2 would probably shut up his opponents, but it would not deter very many unqualified persons from pursuing their present course. Whatever arrangements be made relative to the amount of duty, I hold that this large department of the chemists' business ought to be secured to the properly qualified man. He has little enough compensation for the legal requirements upon his attention; besides which, it is a farce to prohibit a non-registered person selling laudanum, etc. under heavy penalties, when, by paying 1½*d*. in the 1*s*. to Inland Revenue, he can do so with impunity; further than this, it is well known that large numbers of country shopkeepers continue to deal in prohibited articles without in the least disguising the fact.

A Country M.P.S.

Sale of Patent Medicines.

Sir,—I have always been given to understand it to be illegal to open Patent Medicines and retail the contents in small quantities; I find, however, this is largely done in Bristol. Chemists open packets of "Steedman's" and sell the powders singly, or in any quantity; and hairdressers and hucksters sell Whelpton's Pills in pennyworths. One hairdresser purchases £5 or £10 of Whelpton's at a time for this purpose. This sale seems to me to defraud the Revenue, since every 2*s.* 9*d.* box so opened would, if sold in 7½*d.* boxes, produce 9*d.* instead of 3*d.* duty; and were the sale I describe stopped, a far greater number than six 7½*d.* boxes would be sold in place of each 2*s.* 9*d.* It also seriously affects the sale by chemists in the neighbourhood, and they naturally ask, "What can be done to alter this state of things?"

W. H. T.

Totterdom, Bristol, Nov. 3rd, 1872.

SPECIMENS OF COMMERCIAL MORALITY.

Sir,—In your issue for November 9th appears a letter headed "Specimen of Commercial Morality," and signed 'B. NEWHAM AND Co.' With the difference in weight between the invoice and real weights I am not now concerned, but I think your correspondents are not aware of the "doctoring" sponge undergoes before reaching the English market. Perhaps, like myself, your correspondents assumed the sand contained in the sponge was derived from the bottom of the ocean. Some years since, however, I met with a naval officer who had been for some years on the Mediterranean Station. He had watched the sponge fishery closely, and I gathered from him that the value of sponge on the spot where collected had immensely increased. A sponge that ten or fifteen years ago might have been purchased on the spot for a shilling, could not now be purchased for less than five shillings. But as regards the sand, he informed me that the pieces of sponge when procured by the sponge divers were placed separately around their little gardens and were watered daily (once or twice), according to the humidity of the atmosphere, with water in which fine sand was suspended, the sponge, acting as a filter, retained the sand, while the water soaked away. This process was repeated till the sponge would retain no more sand. It was then carefully packed in cases for the English market. It is reasonable, therefore, that as your correspondents observe, the bottom of the case should contain a large quantity of sand. The shaking in transit would naturally produce this result.

Your correspondents probably purchased sponge in original cases, and we all know how large is the quantity of sand in them. Many respectable houses now send out sponge free from sand (at greatly increased prices), and I think it is a fair question for the consideration of the retailer whether such a system is not to his advantage. If I have been misled in my information as to the source of the sand, perhaps some of your correspondents will kindly put me right.

W. JUDD, F.C.S.

Leamington, Nov. 12th. 1872.

W. Cathcart.—Everlasting Chlorine.—The sulphuric acid is added upon the assumption that it causes a concentration of the other acids, as will be seen by the following, which has been kindly furnished to us by the exhibitor, Mr. Septimus Piesse, of New Bond Street:—"One of the actions of concentrated mixed nitric and hydrochloric acids is to evolve chlorine. The addition of sulphuric, by absorbing the water originally with the acids, and also that produced by their decomposition, keeps the acids in a perpetual state of concentration, under which condition they alone act when cold. Theoretically the action is thus—

$$2HCl + 2HNO_3 = 2H_2O + 2NO_2 + Cl_2$$

but this does not represent entirely the reaction which occurs; for at times, unless the temperature be kept down, oxides of chlorine, etc., come over; the addition, therefore, of the sulphuric acid to the nitro-muriatic acid must be very gradual. The everlasting chlorine, as exhibited, was made by mixing the acids of commerce,

Hydrochloric Acid	2 parts.
Nitric Acid.	2 „
Sulphuric Acid	1 „

The first addition of the sulphuric acid to the other acids merely causes evolution of hydrochloric acid. This arises from the sulphuric taking away water at point of contact. Further addition of the acid soon, however, changes the colour of the liquid, and Cl is evolved quite regularly, sparkling like champagne after the first effervescence is over." Your other question we are unable to answer.

"*Methyl.*"—We have no doubt the word applies to the spirit as well as to any preparation containing the spirit; but if you have a licence for keeping methylated spirit, and do not use such spirit for any of the purposes prohibited by the Act, we do not suppose that using it for burning would be interfered with. Ask the supervisor of your district to write to the Inland Revenue authorities.

"*Verbum.*"—1. The word is accented pā′tent or pat′ent by various authorities; some give both. We are not prepared to say which is the more correct. 2. Iodi′dum.

A. G. M.—Numberless recipes for the articles mentioned have been given in former numbers of this Journal, where you will find a mine of information upon these and similar points.

W. B.—No certificates are given to Associates.

"*Elementarius.*"—There is no limitation as to age at present.

A. J. Rayson.—A person who has once passed the Minor examination may at any subsequent time carry on the business of chemist and druggist.

A. B. Daniell.—We should recommend you to ascertain with certainty if there be any silver at all in the lead in question, for if the chloride precipitate is entirely soluble in water, it is pretty clear that silver is not present.

"*Juno.*"—Phosphorus may be administered dissolved in ether; or, still better, in oil. See Pereira's 'Materia Medica.'

"*Verus.*"—(1) According to 'Storer,' 1 part of phosphorus is soluble in 320 parts of cold alcohol, sp. gr. ·799. (2) The same authority gives the solubility of acetate of morphia in cold water as 1 part in 17.

R. Modlen.—We know of no such work as that described by you.

M. P. S.—Mix the spirit of chloroform gradually with the bulk of the water and shake after each addition; the mixture will then be formed free from any separation of chloroform.

"*Kino.*"—We are unable to give an opinion. You should apply to the Inland Revenue authorities.

"*An Apprentice.*"—Huxley's 'Lessons on Elementary Physiology' (Macmillan), or Carpenter's 'Principles of Physiology' (Churchills).

F. Adams.—According to the strict letter of the law, any medicine advertised as a remedy for the relief or cure of any disorder is liable to stamp duty. But the Commissioners interpret this provision with some leniency. With respect to the labels forwarded, you had better apply to the Secretary of Inland Revenue at Somerset House. See an article in the PHARM. JOURN. [1] xiv. 145, and the Calendar of the Pharmaceutical Society.

Co-operative Stores.—"*Disappointed*" sends an account of his experience resulting from taking an engagement at a co-operative stores, which he offers as a "warning." Having left the stores after a short stay, he applied with good credentials for a situation at a West-End house, where, upon his replying to a question as to the name of his last employer, he was simply shown the door. The same result has followed forty-three other applications, with the slight variation that in one case "the person raised his foot and literally kicked me out of his premises." "*Disappointed*" appears to think that having repented of his false step, and been somewhat severely punished, it is time that he were forgiven. Perhaps some of our readers will think so too.

Sunday Closing.—We have received a communication from "An Assistant" who appears to have misunderstood the purport of our remarks on p. 348, since he writes, "According to your view, where a dispensing trade is done, the assistant must be in waiting to dispense any prescription that may turn up. Now, it is this confinement which is the obnoxious thing. It matters very little whether the door be opened or closed as long as I am confined to the place." We do not think that what we wrote is open to this construction. Our statement that it was intended to have "some one in attendance capable of dispensing or selling medicines" refers to an undoubted necessity, but does not imply that the person must always be the assistant. Arrangements would have to be modified according to the circumstances of each establishment; and in some localities it would perhaps be practicable to limit the Sunday dispensing to one or two establishments, each taking its turn.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. P. L. Simmonds, Mr. MacDowell, Mr. W. L. Jones, Mr. A. W. Smith, Mr. D. Hanbury, Mr. G. Dudgeon, Mr. Marshall, Mr. Morris, Mr. Lindley, Mr. O. A. Reade, Mr. Clifford, T. C. H., "Verbum," "Nil Desperandum," "Spongia Usta."

SPECIFIC GRAVITIES OF THE LIQUIDS OF THE BRITISH PHARMACOPŒIA, 1867.

BY CHARLES UMNEY.

The insertion of the specific gravities of most of the liquids in the British Pharmacopœia of 1867 was one of those prominent features which made it surpass its predecessor of 1864, and also the previous editions of the London, Edinburgh and Dublin Pharmacopœias.

The compilers undoubtedly regarded a determination of the density of the officinal fluids, when compared with their behaviour with various reagents, as one of the most rapid methods by which the value of such liquids could be estimated.

Had the "characters and tests" of the Pharmacopœia been enumerated without the addition of the specific gravities of the liquids, then they must have been considered as incomplete; on the other hand, if the specific gravities only had been given without the tests which have been wisely appended by the authors, then such data might have induced some to view a density determination as an infallible method of determining real value.

To the pharmacist, the record of these specific gravities is of vast importance, as he is thereby enabled to make a comparison of the density of those liquids he receives in a manufactured form with those published in the Pharmacopœia, and thus judge approximately of their strength and purity.

Again, to the pharmacist, whose chief aim is to vouch for the value of every preparation he dispenses, no better means can be found for checking the accuracy of his work than a determination of specific gravity, and comparison of the results with the data of the Pharmacopœia.

In order to test the accuracy of the specific gravities given in the Pharmacopœia, I have from time to time since its publication made notes of numerous determinations, and more especially in those cases in which I have found deviations from the officinal density; the discrepancies noticed are but few, taking into consideration the numerous figures there given.

Thinking the publication of those specific gravities, which in my hands have seemed to differ from those of the Pharmacopœia, would not only be interesting to the readers of the Journal, but also give other workers an opportunity of testing their accuracy, I have arranged side by side in the following table the specific gravities as noted by me and those of the British Pharmacopœia.

	B. P. Sp. Gr.	Sp. Gr. Found.
Acid. Sulphurosum (9·2 pr. cnt.)	1·040	1·048
Ext. Cinchonæ Liquidum . .	1·100	1·122
Liq. Bismuthi	1·122	1·134
Liq. Calcis Chloratæ	1·035	1·050
Liq. Ferri Perchlorid. Fort. .	1·338	1·445
Liq. Hyd. Nitratis Acidus . .	2·246	2·130
Liq. Plumbi Subacet. . . .	1·260	1·270
Liq. Sodæ Chloratæ.	1·103	1·090
Syr. Ferri Iodidi	1·385	1·400
Syr. Mori	1·330	1·298
Syr. Papaveris	1·320	1·330
Syr. Sennæ	1·310	1·320
Tinct. Ferri Perchloridi . . .	·992	1·007

It cannot be too much impressed upon every pharmacist that, in order to ensure the uniformity so much to be desired in medicine, it is absolutely necessary that he should make frequent specific gravity determinations of those liquids which pass through his hands.

To the manufacturer a knowledge of specific gravities is invaluable; having once verified the divisions on the scale of his hydrometer, he uses it without reserve; for by its indications he is enabled to judge of the care and diligence bestowed upon the fabrication of a solution, the component parts of which have previously come under his eye, even although he had no opportunity of watching the process.

Acid. Sulphurosum.—It has been shown (PHARMACEUTICAL JOURNAL, vol. X. p. 516, and Proceedings of the Pharmaceutical Conference, 1869, p. 77) that a solution containing 9·2 per cent. of sulphurous anhydride will have a specific gravity of 1·048 and not 1·040, and that a solution of 5 per cent., the strength now generally adopted, is of specific gravity 1·027.

Extract. Cinchonæ Liquid.—It is directed to evaporate the aqueous extractive from one pound of Calisaya bark to three fluid ounces, or until the specific gravity be 1·200, and to this add one ounce of alcohol (·838). The resulting liquor is said to be 1·100 (about).

I have found that a mixture of fluid extract of cinchona and spirit of wine of the density described will be of specific gravity 1·122. I would modify, therefore, these directions, not only because of this discrepancy, but because they are wholly based upon an error, for it is assumed that *three fluid ounces* of liquor can be obtained from one pound of bark, a yield much beyond the average, and which would be defined with more accuracy as *two fluid ounces.* If the present proportions of volume of cinchona extractive and spirit of wine are to be adhered to, then the Pharmacopœia should direct that one-third of its volume of spirit of wine should be added to the fluid extract of cinchona, when the specific gravity would be 1·122. If, however, a 1·100 density be as concentrated as it is thought necessary to prepare the fluid extract of cinchona, then the directions should be amended thus: Evaporate the liquors to *two fluid ounces,* or until the specific gravity be 1·175; to this add one-third of its volume of rectified spirit, when the resulting liquor will have a specific gravity of about 1·100 (1·102).

Liq. Bismuthi.—Although perhaps the officinal method is seldom resorted to for the production of the liquor, still it would be well to amend the specific gravity as it now stands in the Pharmacopœia, to 1·134.

Liq. Calcis Chloratæ.—In this preparation we have an example of specific gravity being no indication of strength, as the chlorinated lime from which this solution is prepared, is a mixture of variable proportions of hypochlorite, chloride and hydrate of calcium, the specific gravity being chiefly influenced by the chloride of calcium present. I look upon the specific gravity 1·035, identical as it is with that of the Dublin Pharmacopœia, as an error; for in my hands using 30 per cent. chlorinated lime the specific gravity has not been less than 1·050, and in taking good commercial chloride of lime I have found the specific gravity to be 1·057. Good commercial chlorinated lime never contains less than 33 per cent. and sometimes as much as 37 per cent. of available chlorine. My experience has taught me that chlorinated lime is sent into the market for the use of the druggists, of such a low chlorine value as would not be accepted as bleaching powder in any manufactory where purchase is preceded by analysis, unless offered at a reduction in proportion to its real value. I should suggest that in future chlorinated lime should be described as containing *one-third* of its weight (33·3 per cent.) of available chlorine. I append the results of a recent examination of specimens of Liq. calc. chloratæ, B. P., of pharmacy.

	Spec. grav.	Available Chlorine per cent.
Brit. Pharm.	1·035	2·958
No. 1	1·045	1·830
No. 2	1·049	2·780
No. 3	1·042	·590
No. 4	2·600	1·053

These show that anything but uniformity exists, and that the maximum chlorine value is seldom or ever attained. In all probability, were the standard of the chlorinated lime raised to 33·3 per cent., then we might have a liq. calcis chloratæ containing 3 per cent. of available chlorine.

Liq. Ferri Perchloridi Fortior.—It has been shown by Abraham (PHARM. JOURNAL, vol. IX. 2nd series, p. 272) that the specific gravity of this liquor should be 1·445 and not 1·338, and this I can corroborate. While writing upon this solution, I would suggest that in future a somewhat smaller quantity of nitric acid be used than is at present ordered, as the great excess over and above the theoretical quantity acts powerfully upon the spirit of wine with which the liquor is diluted for tincture, and renders the tincture most unacceptable to those who were accustomed to the tincture made by the London Pharmacopœia process.

Liq. Hydrarg. Nitr. Acidus.—In my hands the directions of the Pharmacopœia have been insufficient to ensure a uniform result.

We are told "to boil (the solution of the mercury in the acid) gently for fifteen minutes, cool, and preserve the solution in a stoppered bottle. Specific gravity, 2·246." No mention is made of making up the product to a given weight or measure.

On the several occasions on which I have made the solution, I have never obtained it of the officinal density, 2·246. The greatest gravity I have noted after fifteen minutes' gentle boiling has been 2·130, sometimes it has been much less. I would suggest that the following clause be added to the directions:—"Let the product be made to measure 5 oz. 1½ fluid drachms, or to weigh eleven ounces. The specific gravity should be 2·130."

Liq. Plumb. Subacet.—The directions for preparing this liquor are almost identical with those of the London Pharmacopœia, although the proportions are somewhat varied—

	Pharm. Lond.	*Brit. Pharm.*
Acetate of Lead	2167 grains.	2187·5 grains.
Litharge	1280 grains.	1531·2 grains.
Water	20 oz.	20 oz.

The increase in the acetate of lead is unimportant, but the proportion of litharge is nearly 20 per cent. (19·6) greater in the British than in the London Pharmacopœia. In Phillips's translation of the London Pharmacopœia, 1851, the specific gravity is described as 1·260; and although the proportion of litharge has been thus augmented, in the British Pharmacopœia the solution is still said to be of specific gravity 1·260.

Now I have found that it is possible to obtain a solution when making a large quantity with the greatest ease at 1·285, and even in making a quantity of one pint, which I imagine is seldom done, the resulting liquor will have a density of 1·270. This, I should suggest, should be the recognized minimum gravity of the officinal solution.

Liq. Sodæ Chloratæ.—Although I have scheduled this solution, and have given a specific gravity which, I think, would represent a solution of carbonate of soda, 12 oz. in 36 oz. water (1·100), into which chlorine (not dried) has been passed to saturation and increased thereby in weight 3·3 per cent,—still I have never been able to obtain a solution containing 2·535 per cent. of available chlorine by this officinal process, neither have I been fortunate enough to meet with any manufacturer who has ever been more successful.

The strongest solution I have produced has contained 2·02 per cent of available chlorine when examined immediately after production, with specific gravity 1·090, but this has rapidly decreased in value, on account of free chlorine being present, which, decomposing the bicarbonate of soda, is converted into chloride, and consequently unavailable chlorine. As far as I can estimate, this very nearly corresponds with the theoretical quantity that would be contained in the hypochlorite of soda formed, presuming the liquid to be in addition saturated with free chlorine. If the statement be true, that when the chlorine comes in contact with the solution of carbonate of soda, there are formed hypochlorite, chloride and bicarbonate of sodium; then the 12 oz. (5250 grains) of carbonate of soda ordered in the Pharmacopœia would require 651·6 grains of chlorine, 325·8 grains of which would be transformed into hypochlorite, and would be always available in the proportion of 1·469 per cent. of chlorine in the perfected solution.

Let us presume the addition to this of the quantity of chlorine in an aqueous solution, which is about ·606 per cent.,

Then 1·469 Chlorine (as Hypochlorite)
+ ·606 Chlorine (as free Chlorine)

= 2·075 per cent. of available chlorine,

closely corresponding with the result I obtained in practice (2·02). It may be argued that this is rather speculative, but if we turn to Pereira's 'Materia Medica' (page 556), we find at any rate one part of this corroborated as far as the hypochlorite is concerned, by the composition of the chlorinated soda of the London Pharmacopœia being expressed as,

Hypochlorite of Soda	3·11
Chloride of Sodium	2·44
Bicarbonate of Soda	6·26
Water	88·19
	100.00

Now as hypochlorite of soda has 47·7 per cent. value of available chlorine, the quantity of hypochlorite in the solution of the London Pharmacopœia will be equal 1·48 per cent. of available chlorine, free chlorine being altogether ignored. It is difficult to understand why there should be such a different statement as to strength in the two Pharmacopœias, when the same proportions of ingredients are given in both formulæ.

To confirm my opinion upon the impossibility, or at any rate the impracticability, of preparing this solution by the officinal process, I examined specimens of "Liq. Sodæ Chlor. B.P." of pharmacy, with the following corroborative results:—

	Spec. Grav.	Available Cl. per cent.
Brit. Pharm.	1·103	2·53
No. 1	1·041	2·40
No. 2	1·070	1·72
No. 3	1·093	4·05
No. 4	1·047	2·08
No. 5	1·080	·71

A qualitative examination convinced me that most, if not all, had been made by a process of double decomposition between chlorinated lime and carbonate of soda; indeed, with some the decomposition had been so imperfect, that considerable quantities of lime salts were left in solution. To remedy this very unsatisfactory state of things, I should suggest that in future the chlorinated soda be made by a double decomposition process, as in the Dublin Pharmacopœia and French Codex, altering the proportions, however, thus—

"Take good commercial Chlorinated Lime, (33 to 35 per cent. Cl.)	16 oz.
Carbonate of Soda	24 oz.
Water	1 gallon.

"Dissolve the carbonate in two pints of the water, and triturate the chlorinated lime with the remainder, allow the solution to stand three hours, then filter; add the carbonate of soda solution, separate the precipitate by a second filtration," or the whole might be accomplished by one precipitation and filtration as in the French Codex. The specific gravity of such a solution will be 1·054, and will contain at the least 2·53 per cent. (the present Pharmacopœia quantity) of available chlorine.

This process has also the advantage that the solution can be made in three or four hours by any pharmacist, whereas the British Pharmacopœia process is only suited for a chemical factory, and the result very unsatisfactory.

Syrupus Ferri Iodidi.—If the directions of the Pharmacopœia are strictly followed, and the weight of syrup there ordered to be made from two ounces of iodine be made up to *two pounds eleven ounces*, then the specific gravity of the syrup will be 1·400 and not 1·385.

If the syrup of 1·400 specific gravity be put aside for a few days, it will soon be found that the sides of the bottle will be studded with crystals. I have placed several bottles, taken at various times, aside for the purpose of noting the change. In all, crystals of sugar well defined, as large as crystals of sulphate of soda, can be seen. It is also worthy of remark that in all these specimens of 1·400 specific gravity, in which the crystallization of sugar has been going on, the upper part of the liquid is tinged with free iodine, whereas in a syrup of the 1·385 density placed side by side with the other specimens, no such colour has made its appearance, neither is there the least sign of crystallization.

It would be well, therefore, to amend the Pharmacopœia directions, thus, "The product should weigh when cold *two pounds eleven ounces and three quarters*, and should have the specific gravity 1·385.

Syrupus Mori.—If the directions for preparing syrup of mulberries be strictly followed, the spirit added, and the product made to weigh *three pounds six ounces*, then the specific gravity will be 1·298, and not 1·330. It can be seen by a comparison of the proportion of sugar ordered for this syrup, with the quantity directed to be used for syrup of lemons, or even some of the other officinal syrups, that if 1·330 be the correct specific gravity of the mulberry syrup, then the other syrups are incorrectly described in density. It would be well to amend the formula thus:—

Mulberry Juice	(sp. gr. 1·060)	1 pint.
Refined Sugar	,,	2 pounds 3 ounces.
Rectified Spirit	,,	2½ fluid ounces.

The product should weigh *three pounds six ounces*, and have the specific gravity 1·330.

Syrups of Poppy and Senna.—The slight variation is of little importance. In all probability it is due to the better exhaustion of the senna and poppies.

Tinct. Ferri Perchloridi.—As this tincture is a mixture of one fluid part of solution of perchloride of iron with three fluid parts of spirit of wine, it is obvious that if the specific gravity of the Liquor Ferri Perchlorid. Fort. is incorrect, then the tincture prepared from it will also be incorrect. From *a liquor* of 1·445 *the tincture* will be of specific gravity 1·007.

Having then given these criticisms upon the specific gravities of the Pharmacopœia, it would, perhaps, be interesting to append a list of some other specific gravities I have noted, which are not figured in the Pharmacopœia at the present time, and although they are but of little importance. These, with the exhaustive schedule of specific gravities of tinctures, lately published by Stoddart and Tucker, will leave but few liquid officinal preparations the densities of which have not been published.

Acet. Scillæ	1·038
Ext. Filicis Liquid.	1·000
Liq. Ammoniæ Acetatis	1.022
,, Ammoniæ Citratis	1·062
,, Zinci Chloridi	1·460
Mist. Sennæ Comp.	1·115
Mori Succus	1·060
Rhamni Succus	1·070
Spiritus Ammoniæ Fœtidus	·847
,, Armoraciæ Comp.	·920
,, Camphoræ	·850
Syrupus Aurantii	1·282
,, Ferri Phosphatis	1·305
,, Rhei	1·310
,, Rhamni	1·320
,, Scillæ	1·345
,, Zingiberis	1·312

Upon these but few remarks are necessary.

Ext. Filicis Liquid., if carefully prepared, will have a specific gravity of at least 1·000. It is to be regretted that much of the oil of male fern of pharmacy, and more especially that imported, is of much less specific gravity, on account of about 20 per cent. of ether being either mixed with the fluid extract, or from the imperfect evaporation of the ether.

Rhamni Succus is seldom met with in a state of purity; generally it contains 50 per cent. of additional water, and sometimes more. True juice will have a specific gravity of 1·070, and sometimes, when expressed from berries in a dry season, it will be of the density 1·075. (This year the crop of buckthorn berries has been a total failure on account of the late spring frosts.)

Spiritus Armoraciæ Comp.—It is necessary in distilling one gallon, as directed in the Pharmacopœia, to add *three* pints of water instead of *two* pints. If two pints only be used, it will be found, that so much water is absorbed by the dried orange peel and horse-radish, that the gallon of distillate will be at least deficient some *fourteen* or *fifteen* ounces.

Syrupus Rhei.—It would be an improvement to continue the evaporation of the percolate to *fourteen* fluid ounces only instead of *thirteen* fluid ounces, or until the specific gravity be 1·026; and also to add, "The product should weigh *two pounds seven ounces*, and should have the specific gravity 1·310."

Syrupus Rhamni.—Although this is perhaps the least important of the syrups, still, since it has a place in the Pharmacopœia, it is advisable that the best and most uniform preparation possible should be made. The present formula I fear, on account of the various dilutions of buckthorn juice, and also from "five pounds of sugar *or a sufficiency*" being ordered, and from no weight being given for the perfected syrup, but merely a specific gravity 1·320, is scarcely the best that could be devised. I would suggest the following:—

Buckthorn Juice	4 pints or a sufficient quantity.
Ginger, Pimento, of each . . .	¾ ounce.
Refined Sugar	5 pounds.
Rectified Spirit	6 fluid ounces.

Evaporate the juice to two pints and a half, or until it is of specific gravity 1·100; add the ginger and pimento and digest at a gentle heat for four hours and strain. When cold add the spirit; let the mixture stand for 14 hours, then decant the clear liquor, and in this dissolve the sugar with a gentle heat. The product should weigh *seven pounds twelve ounces* and have a specific gravity 1·330.

INDIAN OPIUM.

From the higher price which Indian opium has realized at the public sales in Calcutta, there is likely to be a considerable increase on the estimated revenue to be derived by the Indian Government from this source. The sums realized at the monthly sales have been as follows:—

	Rupees.
April	5,170,250
May	5,186,513
June	4,926,325
July	5,099,875
August	5,196,250
	25,579,213

Equal to £2,557,921, or an increase of more than £400,000 thus far on the estimated amount in the Indian budget. The budget estimate was framed as follows:—

	£
44,175 chests Behar, at 1200 rupees	5,301,000
37,420 ,, Malwa, at 600 ,,	2,245,200
Opium supplied for retail sale in North India	152,000
Miscellaneous receipts, Bengal . .	1,800
	£7,700,000

The average prices realized at the opium sales in August in Calcutta were for 2000 chests Behar, 1470 rupees; for 1575 chests Benares, 1432 rupees, being a considerable advance upon the previous month's rates, which were 1439 and 1409 rupees respectively, and a little above the highest prices of the last five months. This narcotic drug brings into the Indian Government a larger revenue than tobacco does to the British exchequer.

CONNECTION BETWEEN CHEMICAL PROPERTIES AND PHYSIOLOGICAL ACTION.*

BY THOMAS R. FRASER, M.D., F.R.S.E., F.R.C.P.E.

(*Concluded from p.* 387.)

Among the organic compounds, however, a large class of substances may have their constitution modified in such a manner that a change to the original or any other form is effected only with the greatest difficulty, namely, the natural alkaloids. Their constitution is not fully known; but it is sufficiently known to prove it to be of the same type as that of ammonia, and to show that they resemble that substance in containing triatomic nitrogen. Thus ammonia = $N\left\{\begin{matrix}H\\H\\H\end{matrix}\right.$; strychnia = $N \equiv (C_{21}H_{22}NO_2)'''$. Like ammonia, also, they are converted by union with acids into salts having a different constitution—a constitution in which the nitrogen, in place of being triatomic, becomes pentatomic. For instance, in the formation of hydrochlorate of strychnia, the originally triatomic nitrogen takes up chlorine and hydrogen, and becomes pentatomic $N\left\{\begin{matrix}(C_{21}H_{22}NO_2)'''\\H\\Cl\end{matrix}\right.$, united by three bonds to carbon, by one to hydrogen, and by one to chlorine; just as the triatomic nitrogen of ammonia unites itself by two additional bonds to chlorine and hydrogen, and so becomes pentatomic in hydrochlorate of ammonia $N\left\{\begin{matrix}H\\H\\H\\H\\Cl\end{matrix}\right.$. But, by this change, hydrochlorate of strychnia is not rendered permanently or stably pentatomic; it easily loses the chlorine and hydrogen which it has acquired, and returns to the triatomic state. The action of alkalies, or, in many cases, even of alkaline carbonates, is sufficient to effect this, and to set free the alkaloid. It is obvious, therefore, that the change of constitution effected by the addition of an acid does not permit us to discover the corresponding change in physiological action. But if, instead of an acid, we make use of such a substance as iodide of methyl, we find that, while the triatomic nitrogen takes up methyl (CH_3) and iodine, and becomes pentatomic (just as in the former case it took up hydrogen and chlorine), it does not lose these

* Abstracted from a Course of Lectures delivered before the Royal College of Physicians, Edinburgh, and printed in the 'British Medical Journal.'

newly acquired atoms when treated with alkalies, but remains pentatomic even when subjected to attacks more violent than any to which it could be exposed in the system.

The type of the natural alkaloids is that of ammonia, but certain varieties of constitution are met with. In ammonia, the nitrogen is united to three equivalents of hydrogen. Now, one or two or three of these equivalents may be replaced by one or more radicals, and in this way we have amine, imine, and nitrile bases. Thus, one equivalent of hydrogen is replaced by $C\,H_3$ in the amine base, methylamia, $N \left\{ \begin{matrix} (CH_3)' \\ H \\ H \end{matrix} \right.$; two equivalents by the diatomic radical $(C_8\,H_{14})''$, in the imine base, normal conia, $N \left\{ \begin{matrix} (C_8\,H_{14})'' \\ H \end{matrix} \right.$; and three equivalents, by the same diatomic radical, and by $C\,H_3$, in the nitrile base, methyl-conia, $N \left\{ \begin{matrix} (C_8H_{14})'' \\ C\,H_3 \end{matrix} \right.$, or, to take another example of a nitrile base, by one equivalent of the triatomic radical $(C_{21}\,H_{22}\,NO_2)'''$, in strychnia, $N \equiv (C_{21}\,H_{22}\,NO_2)'''$. These various bases are distinguished from the bases derived from them in which nitrogen is stably pentatomic (called ammonium bases) by certain chemical characters common to them all. Their salts, for instance, are decomposed by caustic potash, so that the base is set free, and water and a salt of potassium formed; and a similar effect is produced by moist oxide of silver. The salts of the ammonium bases, however, are not acted upon by caustic potash, and, when treated with moist oxide of silver, a hydrated oxide of the ammonium base (in which nitrogen remains pentatomic) is formed, and the acid unites with the silver.

The powerful decomposition action which caustic potash is able to exert, does not, therefore, change the chemical constitution of these ammonium bases. It, indeed, has no effect upon their salts; and even when these salts are treated with moist oxide of silver the characteristic pentatomicity of their nitrogen is retained. In the living body, they cannot possibly be subjected to the influence of such powerfully decomposing agents; and hence, by studying their action, and comparing it with that of the nitrile or other base from which they are derived, the relationship between physiological action and a certain form of chemical constitution may be discovered.

It was owing to this consideration that Dr. Crum Brown and Dr. Fraser resolved to examine the action of a number of the ammonium bases derived from the vegetable alkaloids. Their experiments were made with the methyl, and, in a few instances, the ethyl, derivatives of strychnia, brucia, thebaia, codeia, morphia, nicotia, atropia, and conia, and more especially with their iodides and sulphates. The results obtained may, perhaps, be best illustrated by describing, with a little detail, several of their experiments with iodide and sulphate of methyl-strychnium.

It is well known that strychnia acts on the living economy in a distinctively defined and characteristic manner, and that it is one of the most active of poisons. When administered subcutaneously, doses varying from one-twentieth to one-fiftieth of a grain produced in rabbits the most violent tetanic convulsions, and in a few minutes killed the animal. Few poisons have been more carefully studied, and it is now almost undoubtedly established that the phenomena produced by strychnia are due to a localization of its action on the spinal cord.

The effects of iodide of methyl-strychnium were first examined by subcutaneous injection. It was administered as a fine powder suspended in warm distilled water, in which menstruum it is but sparingly soluble, though more so than in water at the ordinary temperature. In this way, by a series of progressively increasing doses, it was found that as much as twelve grains could be given to a rabbit, weighing three pounds, without any effect whatever. Fifteen grains, however, produced serious symptoms, though followed by recovery; and death was caused by the administration of twenty grains. In none of the experiments, not even in the fatal cases, were the symptoms those of strychnia-poison; no starts nor spasms occurred, nor did stimulation give evidence of the slightest increase of reflex activity. In fact, a condition exactly the reverse of that produced by strychnia was caused by iodide of methyl-strychnium. In place of violent spasmodic convulsions and muscular rigidity, the appearances were those of paralysis with a perfectly flaccid condition of all the muscles. The limbs of the animal first yielded; its head gradually sank until it rested on the floor; by-and-by, it lay in a perfectly relaxed condition; and when death occurred, it was due to stoppage of the respiratory movements. In the necropsies, further evidence was obtained to distinguish the effects of iodide of methyl-strychnium from those of strychnia. The heart was found acting with nearly its normal rapidity; the spinal motor nerves were either paralysed, or nearly so; and, in place of the early or almost immediate occurrence of rigor mortis that follows the action of strychnia, the muscles continued flaccid, contractile, and alkaline for many hours.

Administered internally, suspended and dissolved in warm distilled water, no effect was produced, although as much as thirty grains was given at one time. One-tenth of a grain of strychnia, however, also administered by the stomach, quickly produced violent tetanic convulsions, and in a few minutes killed the animal.

Sulphate of methyl-strychnium being a very soluble salt, it was anticipated that it would act with much greater activity than the iodide, and experiment confirmed this anticipation. One grain dissolved in water and injected under the skin of a rabbit caused its death in eighteen minutes. Half a grain, however, produced no marked effect. When eight-tenths of a grain were similarly administered, symptoms of a most serious character were produced, but death did not result. Some days afterwards, one-twentieth of a grain of strychnia, dissolved in very dilute sulphuric acid, was administered to this rabbit by subcutaneous injection; and it produced symptoms of strychnia action, followed by death fifteen minutes after the injection. Eight-tenths of a grain of sulphate of methyl-strychnium contain about six-tenths of a grain of strychnia; the effect of converting this nitrile base into an ammonium base by adding to it sulphate of methyl had been, therefore, to reduce its poisonous activity at least twelve times.

The symptoms produced by sulphate of methyl-strychnium were the same as those produced by the corresponding iodide, and suggested a close resemblance between its action and that of curari (wourali)—a resemblance, indeed, which had previously been pointed out by Professor Schroff, of Vienna. Dr. Brown and Dr. Fraser accordingly extended their research for the purpose of studying the exact causation of the paralysis, and found that in experiments where iodide of methyl-strychnium was substituted for sulphate, the results were the same, and that their mode of action is identical with that of curara. This result is an extremely curious and interesting one. It is difficult to imagine a more decided modification in the action o any substance than is produced by the change of chemical constitution resulting from the addition of iodide or sulphate of methyl to strychnia. The striking characteristic of the action of strychnia is the great and uncontrollable activity of the muscular system; that of curara, of iodide and sulphate of methyl-strychnium, and, as was also found, of other similarly modified alkaloids, is the flaccid and motionless condition caused by the impossibility of exciting muscular action through the nervous system. So opposite are their effects, that many physiologists look upon curara as a powerful counter-agent to strychnia, while physicians have employed it in the treatment of strychnia-poisoning and of tetanus.

The other vegetable alkaloids examined, all possess, though in varying degrees, the same peculiar spinal-stimulant action as strychnia. Brucia and thebaia exert this action with great energy; codeia and morphia with somewhat less power; and nicotia, atropia, and methyl-conia, in a still slighter degree, though quite obviously. The result of the combination of each of them with a salt of methyl is, as in the case of strychnia, to change their chemical constitution from that of nitrile bases with triatomic nitrogen, to stable ammonium bases with pentatomic nitrogen; and the change of physiological action following this change of chemical constitution has been found to consist of a removal of spinal-stimulant action, and addition of paralysing action restricted to the terminations of the motor nerves. The important general fact indicated is, that a change of chemical constitution, even when it is of a simple kind, may produce a very essential change in physiological action; and, although perhaps evidence is as yet insufficient to warrant any positive assertion, it is extremely probable that all the stable ammonium bases have a curara-like action.

It is necessary, however, to guard against the impression that the compounds of pentad nitrogen act simply as nerve-paralysers; their action is not necessarily restricted to these structures. In several cases it is, no doubt, so restricted; and notable examples of this are found in the salts of methyl-strychnium, methyl-brucium, and methyl-thebaium, whose nitrile bases have probably no other decided action than a spinal-stimulant one. In those cases, however, in which the salts of ammonium bases are derived from alkaloids that produce complicated effects, a restriction of action to the terminations of the motor-nerves does not occur. The original actions of the alkaloid, excepting the spinal-stimulant one, are retained by the salts of its ammonium base; and thus the salts of methyl-atropium not only act like curara, but they likewise paralyse the cardiac inhibitory fibres of the vagi and dilate the pupils, while the salts of dimethyl-conium retain the paralysing action on the vagi that is possessed by conia itself.

In considering how these various facts bear upon the connection between chemical constitution and physiological action, it is no doubt essential to remember that a change of composition as well as of constitution has been produced by the conversion of the nitrile into the ammonium bases. In the substances examined by Dr. Brown and Dr. Fraser, the composition of the original alkaloids was changed by adding to them a salt of methyl. Are, then, the subsequent changes of physiological effects produced by the action of the added salt of methyl? This hypothesis Dr. Fraser thinks so improbable as scarcely to deserve consideration, being opposed to the result of various experiments.

It might also be asked, if the processes by which these ammonium bases are prepared do not so profoundly modify the chemical nature of the alkaloids from which they are derived, that no actual relationship exists between the new substances and their original sources; that, for example, sulphate of methyl-strychnium, though derived from strychnia, is in no special manner related to sulphate of strychnia—the elements of the latter substance having been so disarranged in its conversion into the former, that the strychnia has been altogether destroyed. As an answer to this conjecture Dr. Fraser points out that the ordinary colour reactions of the alkaloids are retained by their methyl derivatives.

These various facts confirm the opinion that chemical composition bears some relation to the physiological action of active substances, and they also prove that this relationship is to an important extent due to the arrangement of the atoms in the substance. They appear, likewise, to point to the conclusion that physiological action is often, if not always, the result of a chemical reaction between the foreign body and certain of the constituents of the vital structures whose action is modified by it. The results of investigation with such substances as carbonic oxide show, indeed, that physiological action may be chiefly the result of chemical reactions. The effects of other substances have not been connected with chemical action in so direct a manner, but this is to a great extent explainable by the difficulties attending the demonstration of a connection of this kind. Although experimental research, in many cases, has discovered the exact histological elements which are acted upon, the chemical characters of these elements have not yet been sufficiently ascertained. We have no means of determining their normal conditions with the delicacy that is required, and we are, therefore, unable to investigate the chemical reactions that almost certainly accompany modifications of their normal physiological condition during the operation of active substances. Thus, although we know that the normal physiological condition of the terminations of motor nerves are modified by the salts of the ammonium bases derived from strychnia, brucia, thebaia, etc., and that this modification is produced by substances that have definite chemical properties, we cannot discover what chemical change is produced so long as we are ignorant of the special chemical properties possessed by these structures. The trustworthy observations of Kühne have shown that a recognizable change occurs in the physical characters of the nerve terminations—a change which renders their outlines more distinct; but we are unable to connect this change with any definite chemical reaction. In the course of time, reactions of a more delicate kind than any we yet possess will, no doubt, be discovered, not only for these structures, but likewise for each of the special structures on which the physiological action of active substances is localized.

PREPARATION OF THE BROMIDES OF QUINIA, MORPHIA, STRYCHNIA AND CALCIUM.*

BY GEORGE MACDONALD.

The bromides of the alkaloids may be readily prepared in small quantities by precipitating a solution of their neutral sulphates with bromide of barium.

Bromide of barium is not met with in commerce, but it can be made by saturating solution of hydrobromic acid with freshly precipitated carbonate of baryta. The following is a good method:—

Put 1 oz. by weight of bromine and 8 fluid ounces of water into a pint jar. Attach a sulphuretted hydrogen apparatus, being careful to so place the end of the delivery tube that it will touch the surface of the bromine, and pass a stream of sulphuretted hydrogen slowly through until the bromine is entirely converted into hydrobromic acid. Filter the hydrobromic acid solution into a capsule, and warm gently until it has lost all sulphurous odour.

To make the carbonate of baryta, to a boiling solution of 2 oz. of chloride of barium in a pint of water, add solution of carbonate of ammonia (to which a little ammonia has been added) in excess, wash the precipitate three or four times by decantation, and afterwards transfer it to a filter, and continue the washing until the filtrate ceases to produce any turbidity on the addition of a solution of nitrate of silver, to which a few drops of nitric acid have been added. Then remove the precipitate from the filter, and mix it with sufficient water to bring it to the consistence of thick milk.

To make the bromide of barium, add to the hydrobromic acid solution small portions at a time of the mixture of carbonate of baryta and water, until rather more than three-fourths of the mixture has been added. When this quantity has been added, apply a gentle heat and shake vigorously. Then filter a small portion and test

* From the 'American Journal of Pharmacy.'

with litmus paper. If it shows an acid reaction, more carbonate of baryta must be added until the reaction is neutral. When a sufficient quantity of carbonate of bartya has been added, filter and evaporate to 4 fluid ounces. It is not necessary to proceed to crystallization, as the salt is very soluble, and therefore difficult to crystallize in small quantities, and a solution of it is really what is wanted after all.

Bromide of Quinia.—To make this salt, dissolve 1 oz. of medicinal sulphate of quinia in 32 fluid ounces of boiling water, and add solution of bromide of barium until a precipitate ceases to be produced. (A little less than 5 fluid drachms of the solution of bromide of barium made by the formula given above, will be about the proper quantity.) Filter a small quantity of the solution, acidulate it slightly with nitric acid, and test for baryta with a few drops of diluted sulphuric acid. If a whitish turbidity is produced, it is an indication that too much bromide of barium has been added, and enough sulphate of quinia must be added to entirely decompose it. If, on the other hand, the presence of baryta in the solution was not indicated, slightly acidulate another portion of the filtrate with nitric acid, and add a drop or two of solution of bromide of barium. If this produces a whitish turbidity, it shows that there has not been enough bromide of barium added, and more must be *very carefully* added, until the sulphate of quinia is all or *nearly* all decomposed. It is better, of course, to have a little undecomposed sulphate of quinia in the solution than *any* bromide of barium.

When the precipitation of sulphate of baryta is completed, filter the solution, while still warm, into a capsule, and evaporate at a gentle temperature, until crystallization begins to set in. Then remove from the fire and set aside to crystallize. The bromide of quinia will be found to be aggregated in *globular clusters* of brilliant silky needles, and the singularly beautiful appearance of the crystallization is alone almost ample compensation to any one for the little trouble he may go to in making it.

Drain the crystals well, remove them from the capsule, and place between sheets of bibulous paper and set aside to dry. The crystals are soluble in about 40 parts of cold water, and appear to be anhydrous. At least I have had a small quantity exposed to the air for a couple of weeks, and they do not show the slightest appearance of efflorescence. I have not made accurate weighings, and cannot speak positively.

Bromides of Morphia and Strychnia.—These salts may be prepared after the same method as bromide of quinia, with slight modifications, which will readily suggest themselves. They both crystallize well, and are quite as soluble as the corresponding sulphates.

Bromide of Calcium.—The process of Mr. James R. Mercein, in the March number of the Journal,* is probably as good a one as could be devised. The majority of apothecaries, however, will find the following to be a more ready and convenient way of making it:—

Dissolve 4 oz. of bromide of ammonium in a pint of water. Put in a flask and bring to the boiling-point. Keep boiling, and add milk of lime† (made from *pure* calcined lime), in small quantities, until ammoniacal vapours cease to be evolved. The operator can easily tell when this point has been reached, by the sense of smell. Filter the solution, evaporate to a syrupy consistency, remove from the fire and stir until cold. This salt is quite deliquescent, and requires to be kept in well-stoppered bottles. In preparing this salt, care must be taken as to the quality of lime used, as some limestones contain a large percentage of carbonate of magnesia, and the salt obtained by using a lime burnt from limestone of that quality, would necessarily contain a correspondingly large percentage of bromide of magnesium.

* Pharm. Journ. [3] vol. ii. p. 878.

† In a note appended to this article, the Editor of the *Amer. Journ. Pharm.* points out that in decomposing bromide of ammonium by caustic lime, care must be taken to avoid an excess of the latter, since a basic bromide (oxybromide) of calcium is very readily formed, having a strong alkaline reaction. The term *bromide of quinia* has of late been frequently used in medical journals, but is incorrect. The salt being a combination of *hydrobromic acid*, with the alkaloid *quinia*, should be called hydrobromate of quinia. Its composition is analogous to that of hydrochlorate (muriate) of morphia, and its proper name is formed correctly only in perfect analogy with that of the latter.

VANILLIC ACID.*

BY M. P. CARLES.

After being preserved for a certain time vanilla generally becomes covered with crystalline needles. As this crystallization is considered to be a mark of good quality, sometimes it is sought to impart it to inferior vanilla, and this is done by simply putting some of the crystals already formed into the case containing it. The chemical composition of this efflorescence does not, however, appear to be perfectly understood.

Formerly, and the error has been repeated in recent works, Vogel asserted that it consisted of benzoic or cinnamic acid; Wittstein thought it to be coumarine. M. Vée,† comparing the melting-points of these various substances, detected the error and showed that it was a peculiar acid. About the same time, M. Gobley‡ investigated the chemical characters of these crystals, compared them with coumarine, and proposed for them the name vanilline, or aromatic principle of vanilla. Later, in Germany, Stokkebye§ took up the subject. He fixed the melting-point at 82° C., instead of 76° C. (Gobley), or 78° C. (Vée), and in virtue of its acid properties called it vanillic acid. Finally, while Gobley had attributed to it the formula $C_{20}H_6O_4$, Stokkebye represented it by $C_{34}H_{22}O_{20}$.‖ These differences in the formulæ and melting-points attributed to it seemed to show that even if their authors examined the same crystals, they were at least not of equal purity. M. Carles was therefore induced to undertake the present investigation.

Instead of extracting the vanillic acid directly from the vanilla, M. Carles preferred to purify the deposit found at the bottom of the cases in which vanilla had been kept. From a mixture of specimens from various sources he made a concentrated aqueous solution by boiling, and after the addition of animal charcoal, passed it through a moistened filter. Upon cooling, the acid was deposited, and it was submitted to two or three successive crystallizations. If cooled slowly the crystals appeared as colourless transparent prisms, sometimes more than two centimetres long. When fresh and very pure their odour was very feeble, but was increased by heat, and their taste was piquant. Vanillic acid, so obtained, melts at between 80° C. and 81° C. Heated on platinum foil it volatilizes without decomposition, but it distils with difficulty in a retort at about 280° C. It is very soluble in cold alcohol, ether, chloroform, sulphide of carbon and the fixed and volatile oils. Water at 15° C. dissolves 1·2 per cent., but in boiling water it is very soluble. It decomposes the bicarbonates with effervescence; and saturates perfectly the alkaline bases in the cold, and the earth bases with heat. Pure concentrated sulphuric acid turns it yellow in the cold, but if the acid contain traces of nitric acid a scarlet colour is produced, and the same result follows with pure sulphuric acid and resinous crystals. Dilute nitric acid attacks it feebly, but concentrated quickly converts it into oxalic acid. Chlorine, bromine, and iodine yield products of substitution. It is precipitated by acids from concentrated aqueous or alcoholic alkaline solutions

* Abstract of paper in 'L'Union Pharmaceutique,' xiii. 294.

† Journ. de Pharm. et de Chimie, [3] xxxiv. 412. ‡ Ibid. 404.

§ Zeitschrift für Chemie, 1865, p. 467.

‖ These formulæ are according to the old notation.

with little evident modification, even after being exposed for several hours to a temperature of 100° C. It colours the persalts of iron blue, reduces nitrate of silver and is precipitated plentifully by the acetates of lead. Its formula is given by M. Carles as $C_{16}H_8O_6$ ($C_8H_8O_3$).

	Found. I.	II.	Calculated.
Carbon . . .	63·14	63·13	63·15
Hydrogen . .	5·55	5·69	5·26

The author describes the following compounds of vanillic acid obtained by him:—

Vanillate of Lead ($C_{16}H_7PbO_6$).—Tufts of white crystals radiating from a common centre, deposited upon cooling after mixing a hot aqueous solution of vanillic acid and a solution of neutral acetate of lead.

Vanillate of Magnesia ($C_{16}H_7MgO_6$).—Colourless, inodorous crystals slightly soluble in cold water, insoluble in alcohol and ether. Obtained easily by double decomposition between fresh vanillate of baryta and sulphate of magnesia, or by saturating a boiling solution of vanillic acid with magnesia hydrate or carbonate, and allowing to cool slowly.

Vanillate of Zinc ($C_{16}H_7ZnO_6$).—Deposited in white crystals upon cooling a hot solution of vanillic acid, saturated by oxide or carbonate of zinc. Slightly soluble in boiling water.

Iodine Compounds ($C_{16}H_7IO_6$ and $C_{16}H_6I_2O_6$). — The first consisting of white pearly crystals of faint odour, slightly soluble in alcohol and ether, melting at 74° and subliming without decomposition, was deposited after some hours from a mixture of 2 grams of vanillic acid dissolved in 50 grams of water and 1·5 grams of iodine dissolved in 50 grams of alcohol. The second was obtained when iodine was used in excess, also as pearly crystals. It is slightly soluble in boiling water, insoluble in cold chloroform, soluble in hot ether and alcohol.

Bromine Compound ($C_{16}H_7B_2O_6$).— Pearly, yellowish, odourless crystals, very slightly soluble in water, more so in alcohol, ether and chloroform, obtained by gradually adding slight excess of bromine to a concentrated aqueous solution of vanillic acid, and crystallizing the precipitate first from alcohol and then from boiling water.

Vanillic acid being ignited with potash, and the mass afterwards treated with water, hydrochloric acid and ether, yielded small white inodorous prismatic crystals, which product the author considers to be a new acid, and proposes to call oxyvanillic acid, with the formula $C_{18}H_8O_3$. When vanillic acid was heated in a sealed tube with hydriodic acid, the methyl-hydriodic was obtained.

From these experiments M. Carles is led to conclude that the efflorescence on vanilla is neither of the substances that have heretofore been described, but is a peculiar acid, isomeric with anisic, formobenzoic, methyls alicyclic, creasotic oxytoluic, and many other acids.

MEDICAL EDUCATION OF WOMEN.*

We have seen it laid down as an axiom that the noblest principle of life is change. All things change. The steadfast mountain crumbles down and its particles of soil are carried away by the hillside torrent to refresh and fertilize the plains below. Man changes from the child to the adult; from manhood to old age; from the mortal to the immortal. Kingdoms, dynasties, and forms of social life change and alter their condition. To remain without change is impossible; changes constantly occur even under our own observation. Old things are passing away,—nay, in many instances, they have passed away. We do not now find the home-industries described to us by our elder relatives. The progress of arts and manufactures has rendered unnecessary the home arts of spinning, baking, and brewing. All these things are better done on the principle of division of labour, by organized agency specially trained for the purpose, each in its appropriate manufactory, in place of the individual efforts of the women of the family. No one would now don a homespun coat, or wear a knitted sock, when he can obtain a superior article at a less cost. Even were this not the truth, it is a fact that our girls are no longer educated with a view to the same after-life as was lived by their grandmothers. Some sixty or eighty years ago a woman was amply educated for an ordinary position in life could she read her prayer-book and write a letter. No doubt, in many ways, woman was then, as she has ever been, a "help-meet" for man; but how many a man must have regretted that the very one whose affection and respect would best fit her in every way to be his *alter ego*, was utterly unacquainted with even the elementary principles of the art, profession, or trade by which he made the daily bread of the household! Man has an intellectual as well as a physical and a moral nature. He needs sympathy with each part of his character and vocation to make his life substantially happy; and it certainly cannot conduce to his happiness to find his partner utterly unable to appreciate his labours, to exult in his successes or to sympathize, with true womanly tenderness, in his failings. Hence arose a desire among men that their daughters should be better educated. The old ideas passed away, and in a short space of time the girl's curriculum was well nigh as arduous as the boy's course of study, while it was a good deal more varied. Our daughters were taught to know and appreciate their own language, to read the history of their own and other lands, to converse in French and other modern languages, and to cultivate the accomplishments which serve as the recreation of life. Recently, during the past ten years or so, lectures have been given at all first-class schools on the elements of geology, botany, chemistry, and other physical sciences. The seed thus sown fared like other seed; in some "it yielded an hundredfold," springing up with such vigour as to beautify and adorn all the girl's future life. Henceforth she had ample resources within herself; no place could be dull; no time hang heavy on her hands; the stones, the flowers, the silent stars all suggested thoughts which were companions in any solitude or leisure hour. The thirst for knowledge once awakened is insatiable; and where the seed takes root thus kindly, the woman is a better, because a more intelligent, member of society, a fitter wife to her husband, a more capable mother and guide to her children. In other cases, of course, we shall find that the good effects of the impression once received remain all but passive in the mind, and yet the woman is fitted to sympathize with her husband, even although she may not have the power actually to aid him. Thus, something has been gained. The power, though passive, is still real; and it is clearly an improvement on bygone days.

The progress of manufactures and the changes in social economy have buried with the past the spinning, knitting, and sewing that filled up the leisure hours of our grandmothers, and that made their lives happy and useful in their day and generation. Our girls are no longer fitted for this work; nor is there any scope for such ability did the knowledge exist. The result is, in some cases, very sad. Our daughters are, in too many instances, aimless, idle, and unhappy. They have no proper or beneficial occupations; and the time which is so valuable, the young fresh hours of life, when every faculty is well strung, the imagination most vivid, and the physical constitution at its best, are frittered away in an objectless existence, or in the pursuit of so-called pleasure. This is not the case with our sons. Their school career, their college course, and the business of actual life demand their best energies. They become useful, earnest, and self-reliant; while the very girls who are to be the companions, the wives, and the mothers of the future, have no other device to wile away their precious time but the perusal of empty novels or

* From the 'Madras Journal of Medical Science.'

the absurd imitation of birds, beasts, and flowers, called "fancy work;" or, perhaps, they are driven to effervescent fits of pseudo-piety, the only alternatives to which are reckless flirtation and the slow poisoning process of uncontrollable ennui. There must be something essentially wrong in such a state of things. Why should all other labour have a definite end; all other seed-time an abundant harvest, and only the long years and hard earned money spent on a girl's education have no fruition? These considerations, even were there no others, should lead the present generation to seek some useful and honourable career for its daughters as well as for its sons. In some cases, perhaps in many, there is an absolute necessity for the girls of a family to aid in the common effort to earn the household bread. The daughters of our English mechanics, labourers, and small farmers know well that they must turn out into the world and do their best to maintain themselves in decency and comfort. They have no false shame in using, to the best of their ability and knowledge, the heads and hands that nature has given them. They are, as a general rule, diligent in their calling and faithful in the exercise of the little committed to them by the Great Master. It is when we come to a step higher in the social scale that we meet with sad instances of the want of an acknowledged career for the girls and women of the day. Perhaps one girl, braver or better endowed by nature than the rest, tries a situation as governess, but, notwithstanding all its drawbacks, the profession of governess is much overstocked in England, and there is no room for it in India. To take the lowest view of it, in the language of the old Jew, it does not pay. For many years, however, no other opening could be thought of at home; and thousands of ladies, well-born, well-bred, and well-educated, were sacrificed in this profitless manner. We are aware that these remarks are more applicable to the circumstances of England than to those of India, but the principles of education and its good or ill results are the same there as here. We are most thankful to find that there are now several openings at home to a useful and happy career for women, whose birth and education would render unbearable and irksome the duties of domestic servants, shop-girls, or needle-women. England, conservative and tenacious to the back-bone, hesitated long ere she followed the example set by foreign nations; but the real misery caused by want of means and want of employment has, at last, told its lesson, and we now find English women busy in printing-offices and book-binding rooms, directing the wondrous telegraph, or copying hard-worded folios in lawyers' offices. Many doors of honest and hopeful toil are thrown open to them; and the women of England, to their credit and advantage, have proved themselves both willing and able to avail themselves of these several sources of industry and honest bread-winning.

There is another sphere of usefulness to which we would now specially call attention,—one which, in its appeals to the best attributes of a woman's nature, far excels all others: one which has claimed the attention of women since the earliest historic ages, and of which one branch, at least, was under the direct protection and patronage of the ancient queen of heaven, Juno Lucina! We refer to the most humane of all—the healing of the sick, the soothing of the anguished, the comforting of the distressed. The medical profession is one of the noblest that man or woman can be called on to exercise. It appeals to our three-fold nature, and every one who, even in the humblest of its grades, exercises this calling aright should be better, more learned, and holier from the daily ministrations to suffering humanity. In the preliminary scientific examinations the mind of the embryo physician is strengthened, cultivated, and trained to a degree far beyond the mere book-knowledge he may acquire. In the subsequent course of lectures delivered by the heads of his profession, he is directed how to apply this knowledge, and by clinical experience, by patient watching and accurate observation by the bedside of the sick, and in the diligent prosecution of *post-mortem* studies he gains that insight into the construction of man and the workings of nature which truly fit him to be a high-priest of the healing art. "The eye only sees what it brings the power of seeing." From sharing in the labours, trials, and honours of this profession women have long been debarred—debarred, no doubt, as much by their own ignorance and want of system as by the objections raised against them by the members of the medical profession. All this is easily understood if we remember the class of women who professed to have any medical knowledge. They were, for the most part, aged women, to whom age had taught neither sobriety, honesty, nor the power of governing their tongue. They were utterly uneducated, and prejudiced to a fearful degree; women who eschewed cold water and fresh air, and who, in the hour of emergency, were altogether unfitted to aid the medical man in the simplest of operations. No wonder that the highly educated and refined doctor shrunk from being associated with those wretched specimens of womanhood, devoid of knowledge, ordinary sense, and common good-feeling. These women seldom set up, as the village barber did, to be "bone-setters," or "bleeders," or domestic surgeons; they confined themselves to midwifery and the nursing of the sick. How they were ever tolerated by medical men as their co-adjutors is a matter of marvel, but we must suppose that they were put up with simply because no fitter helpers were forthcoming. The case is altered, or, rather, is altering now; women of all ranks show themselves eager for medical tuition, from the uneducated woman, whose highest ambition is to be a good nurse, to the highly educated and well-born women who swell the ranks of the Sisters of Charity, sincerely desirous to render help in as intelligent and as perfect a manner as possible.

There have been many objections raised against the admission of women to a medical career—some of them, no doubt, of great weight and deserving of serious consideration: others, again, merely frivolous, and sprung from mistaken notions of propriety or from desire to let things be as they are. Some of the faculty are opposed to the medical training of women on the ground that they must share the class rooms of the male students, and that it by no means beseems a woman's modesty and delicacy of feeling to acquire from a male teacher, and amid male fellow-students, any knowledge of anatomy, midwifery and other kindred subjects. This is an objection that comes home to every woman desiring tuition; to every father who would like his daughter trained to the most noble of professions. We hold, however, that this objection is founded upon a mistaken notion as to what is and what is not true delicacy of feeling. We would put our opinion forward with due respect for the opinions of others, but to our mind the whole body is a monument to the greatness and wisdom of Him who made it; and no right-minded man or woman could make the highest manifestation of God's creative might the subject of unseemly jest, unholy thought, or undesirable allusion. We think that the evil, if evil there be, exists only in the imagination of the morbid, not in the subject which demands the best efforts of the mind. Further, we do not see how, in a properly conducted class-room, under the supervision of a teacher who himself felt the solemnity and responsibility of his profession, the pupils could ever behave in any but a becoming manner. Another objection frequently urged is that women are deficient in nerve and strength; as to the latter, we believe that skill is more in request than strength in a doctor; and for nerve, or quiet, silent stedfastness of purpose we think that women are, at least, as well endowed as men—if not more so. No doubt we shall find individual women, as well as individual men, who feel faint at the sight of a streaming wound or a repulsive sore. Perhaps more women than men might plead guilty to this charge; but no one chooses a profession without some regard for his, or her, personal feelings, and we may feel assured that a woman who willingly undergoes all the study and all the practical work demanded in hospitals may be trusted to have nerve enough for even an alarming crisis in after practice. Then, as to moral courage, as to whether a woman can have the heart to resolve on some painful treatment, and to carry it out firmly, steadily, and tenderly withal, not ceasing for the trying cries of her patient or the possible entreaties of those around her, we believe that there are many such gentle, yet firm-minded, women who will not shrink from duty merely on account of its disagreeableness. Again, few medical men, even those who bear the highest reputation, ever undertake an operation of extreme difficulty without the advice and co-operation of a brother professional, and we cannot suppose that any medical man would refuse his counsel and assistance because the individual seeking it was a woman instead of a man. Another objection frequently urged is that the training and profession of a doctor are utterly incompatible with the duties and responsibilities of a wife and mother. We are quite willing to admit the force of this objection in many cases; nor can we conceive a more undesirable and pitiable state of things than exists in the home where husband and children are neglected while the wife and mother, forgetful of her duties and truest pleasures, is engrossed with other pursuits, studies, and cares. We contend, however, that this is no valid objection against the admission of such women as desire it to a medical career. We know that all women do not marry, some, perhaps, never have the chance, and some, by a peculiar idiosyncracy, have no inclination. Now there can be no possible objection to these women entering the medical profession, and throwing into this channel all the energy and enthusiasm that will otherwise be frittered away in profitless pursuits, that can give no solid pleasure, but which tend more than any other circumstances to make them those peculiar, crabbed, and disappointed specimens of humanity called "old maids." Supposing, however, that a female medical student or a lady-doctor marries. Will she be a worse wife or a worse mother? Have her studies made her more or less competent for the general duties of life? We assume, of course, that she gives up all special prosecution of the profession as a matter of gain or constant occupation. We believe that she will make a better wife and be a better mother. The knowledge of the healing art will still remain, and husband, children, and friends may be the gainers by her kind and gentle ministrations. The arguments in favour of giving women a medical education are many. A sick man longs for the gentle touch and friendly sympathy that none can bestow so well as a woman. Woman, indeed, is man's natural nurse; she is the first that soothes his infant ailments; she is the one who composes his limbs and closes his eyes for the last long sleep. A woman's hand is peculiarly adapted for some operations, those especially where a small soft hand is preferable, and less liable to entail injury than one of larger size and rougher mould. In all circumstances knowledge is power, and in some cases the mere tying of a handkerchief and tightening the impromptu ligature with a twig may suffice to stay inordinate hæmorrhage from a divided artery, when the patient must assuredly die were assistance delayed many minutes. We do not mean that all women who study medicine should practise for gain; in the higher ranks it were most undesirable that a woman should do so; but no one is the worse for knowing what should be done in cases of emergency and knowing how to do it. No one will be more thankful than the doctor to have all things made ready to his hand. The last argument we shall adduce to-day is, that taught or untaught women will ever be employed, especially by the poorer classes, in one most important branch—midwifery. It is only necessary to look back on the past annals of midwifery in England, and the constant mal-practices by native midwives in this country, to make us all agree that, so far as this branch at least is concerned, women must be scientifically and thoroughly taught. A series of articles published in 'The Lancet' for April, May, and June last, will show us something of the horrible barbarities common in England so long as midwifery was practised by the so-called midwives. Here, in India, there is scarcely a medical man who could not confirm a well-known practitioner's statement to us, "They bring here women whom they have actually killed by their ignorance and cruelty, and then expect us to deliver them in safety, though the womb is ruptured, or other fatal injuries inflicted!"

DEODORIZATION OF EXCRETA BY SEAWEED CHAR.—CONFERENCE AT SOUTHSEA.

On the invitation of Colonel Synge, Commanding Royal Engineer at Gosport, a party of gentlemen assembled at the Southsea Pier Hotel on Thursday, for the purpose of considering a scheme for the removal and utilization of refuse by carbon.

Among the propositions laid down by the promoters of the scheme are these:—That a dry deodorant is preferable to water, inasmuch as the former transmutes the obnoxious and dangerous substances to which it is applied; that the application of water to refuse is extravagant in practice and erroneous in theory; that the difficulties and objections to the earth system (such as its un-remunerativeness and the tendency to attract worms and flies) disappear with the use of charcoal; that by the use of charcoal bulk is diminished, and application and removal are thus facilitated; that deodorization is instantaneous and complete; that the use of charcoal is more remunerative than that of earth, the material possessing an intrinsic value, and taking up completely and within a limited compass all the valuable qualities in the refuse; that charcoal may be obtained at about 30*s.* a ton, and that after use the compound can be sold for manure or re-burnt; and that by proper appliances for burning the mixed contents of closets, etc., in closed retorts, and saving the volatile products, the supply of charcoal, after the first, can be kept up without any fresh importation. All that is necessary in the application of charcoal is a layer of carbon to receive the deposit and another to cover it. With regard to the value of the refuse, it is alleged to be, according to the best authorities, 8*s.* 4*d.* per head per annum, while the carbon by which it is carried retains its own value.

The closet is in the first instance charged with seaweed or peat charcoal. When collected in sufficient quantity, the mixed compound is distilled in a retort; ammoniacal liquor, tar, and gas are yielded; and from the former, sulphate of ammonia and acetate of lime are obtained. Animal charcoal remains in the retort; and with this the process is carried on. The produce of a year's working on a population of 20,000 is estimated at £4680, and the expenses at £2530, which would leave a balance of £2150 to cover management, sales, incidental expenses and profit.

In the discussion which took place, the disadvantages of the water-closet system were pointed out by several speakers. Mr. Stanford and Mr. W. R. W. Smith said that the carbon system had been applied in a ship-building yard in Glasgow, and the latter gentleman said he had been in the vault and found it entirely free from smell; the excreta disappeared; the whole mass became black, and could not be distinguished from the charcoal, and when it was dry it was inodorous. It was also stated that when char was used, there was an absence of the flies and insects that accompany the earth system. On the other hand, it was urged by one or two speakers that some of the evils arising from the water-closets are capable of being remedied, and that the carbon system required more care than would be given by servants and uneducated people.

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 23, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE ADMINISTRATION OF PHOSPHORUS.

THAT medicinal remedies are subject to the rule of Fashion is well known, and judging from numerous inquiries which have lately been made respecting the methods for the internal administration of phosphorus, that substance is about to have its turn of more or less lasting popularity as a remedy. A short notice of the principal preparations will therefore probably be of service.

And first, to correct an error. A few weeks since Mr. S. M. BRADLEY, of Manchester, writing to the 'British Medical Journal,' described a case of neuralgia which, after having been unsuccessfully treated by himself with every remedy he could think of, was immediately relieved by a homœopath with two drops of "mother-tincture of phosphorus." Mr. BRADLEY—apparently misled by the fact that the "mother-tinctures" of the Homœopathic Pharmacopœia are usually calculated to contain all the soluble matter of one grain of a drug in ten minims of the tincture, and that saline solutions are made up to a strength of 1 in 10—went on to say that this "mother-tincture" was "phosphorus dissolved in alcohol in the proportion of 1 to 10," a statement which has been reproduced in a contemporary circulating among chemists and druggists, and sometimes providing them with homœopathic news. Mr. BRADLEY has since found out that in using this remedy, he has only been giving his patients a preparation containing 1 per cent. of phosphorus instead of 10 per cent., and he has published a correction of his former statement. However, since many persons may see the original statement and not the contradiction, it will be as well to give the following from the Homœopathic Pharmacopœia, by which it will be seen that there are two recognized solutions of phosphorus, one in ether and one in absolute alcohol:—

"*Preparation.*—Trituration, using moist sugar of milk at first, and bruising the chips of phosphorus rather than rubbing them. Solution in ether, which, if very pure, will dissolve nearly 1 per cent. Solution in absolute alcohol. When making these solutions, the phosphorus should be cut into small chips, and, in the case of alcohol, at any rate, the mixture, in its bottle, with the stopper loose, should be plunged in hot water till the phosphorus melts, when the stopper should be made firm, and the melted phosphorus well shaken with the alcohol. The solution should be well secured in stoppered bottles and kept in the dark."

Phosphorated Oil (Huile phosphorée) is a preparation of the French Codex, of which the following is the formula:—

"Phosphorus	2
Oil of Sweet Almonds	100

"Put the oil into a bottle which it will nearly fill, and introduce the phosphorus. Heat in a water-bath for 15 or 20 minutes, agitating briskly from time to time. Keep the bottle closed during the operation, except at the commencement, when a passage for the air inside should be made by means of a paper placed between the neck of the bottle and the stopper. Let the solution cool and deposit, and then decant the clear oil into small well-stoppered phials exactly filled."

There is also an "Oleum Phosphoratum" in the new German Pharmacopœia, similarly prepared, in which, however, the proportions are "phosphorus, well dried, 1; oil of almonds, 80." The preparation should be "limpidum, fumans, phosphorum redolens."

The subject of the solvent of phosphorus best suited for internal administration was studied by M. DUJARDIN-BEAUMETZ in 1868.* He pointed out that phosphorus is soluble in sulphide of carbon, ether, chloroform, and oil. Of these the first, notwithstanding its great solvent power (according to VOGEL† dissolving eighteen times its own weight of phosphorus without losing its fluidity) is excluded in consequence of its effects upon the system. Alcohol, also, he rejected, in consequence of the small proportion it dissolves (according to BUCHNER, 1 part in 320 cold alcohol, sp. gr. ·799). Solutions in ether, chloroform, and oil, were tried in the form of capsules, made to contain 1 milligram of phosphorus in each. The quantity of ether required was found to produce injurious effects, and was quickly abandoned. It may be remarked here that a case was mentioned at the meeting of the Société de Pharmacie, in April, 1870, where severe symptoms of poisoning followed the administration of 4 grains of phosphorated ether.‡ It is also stated by BRUGNATELLI that the ethereal solution undergoes decomposition in the course of time. Chloroform, according to M. BEAUMETZ, dissolves easily two per cent. of phosphorus, and, therefore, 1 milligram doses could be administered in capsules containing 10 centigrams of the solution. Continued use of these capsules led, however, to considerable disturbance of the system, a result which, although at first referred to the phosphorus, he afterwards believed to be due to the chloroform. He considers the phosphorized oil to be the best preparation, and as many as twelve or thirteen capsules of this oil have been taken daily by patients without inconvenience. But an objection exists in the deposit of insoluble phosphorus which gradually forms in them; and M. BEAUMETZ has proposed to use phosphide of zinc, pre-

* 'Gazette des Hôpitaux,' 30 Mai, 1868, and Journ. de Pharm. et de Chimie, viii. (1868) p. 227.

† Neues Repert. f. Pharm. xvii. p. 449; Journ. de Pharm. et de Chimie, ix. (1869) p. 237.

‡ Journ. de Pharm. et de Chimie, xi. (1870) p. 416.

pared by bringing phosphorus vapour into contact with melted zinc in an atmosphere of dry hydrogen.

The deposit that occurs in the phosphorated oil of the French Codex was investigated by M. Méhu. In a paper read before the Société de Pharmacie, at Paris, in May, 1861,* he states that it is the result of the action of the phosphorus upon the albumen, resin, and other organic matters present in ordinary oil of almonds. These deposits are yellow, becoming reddish by exposure to light, and vary in quantity with the temperature and the quality of the oil; and since they carry down some of the phosphorus, the strength of the preparation is thus liable to variation. He proposes, therefore, to submit clear almond oil to a temperature of 150° C. in a porcelain capsule for about a quarter of an hour; then for ten minutes to 200° C. or 250° C. By this means water is at first driven off, and then instable organic matters are destroyed or volatilized. The superheated oil deposits slightly after standing some time, or it may be filtered; it will then produce an absolutely clear and stable solution of phosphorus.

According to M. Méhu, sweet almond, olive or poppy seed oils will dissolve easily one-eightieth of their weight of phosphorus. He therefore proposes that only one part of phosphorus to 100 parts of oil, instead of the two parts of the Codex, should be used. Phosphorated oil of this strength is strongly luminous in the dark; but this luminosity may be entirely destroyed by the addition of a small quantity of ether, or of any of the essential oils not containing oxygen, such as bergamot, citron, copaiba, lavender, mace, mustard, rosemary, turpentine, etc. Colza, rape, beechnut, linseed, and brown cod-liver oils each dissolve one-seventieth of their weight of phosphorus. Castor oil dissolves one part in one hundred and five.† Cacao butter dissolves one per cent.; but if a colourless product be required, it should be treated as recommended for the oil of sweet almonds.‡

Dr. Radcliffe has recommended the following formula for gelatinized phosphorus pills:—§

"Phosphorus	6	grains.
Suet	600	"

"Melt the suet in a stoppered bottle capable of holding twice the quantity indicated; put in the phosphorus, and when liquid agitate the mixture until it becomes solid; roll into 3 grain pills, and cover with gelatine. Each pill will contain [illegible] of a grain of phosphorus."

The following formul by Soubeiran of a "Potion phosphorée" is given by Dorvault as the best method of administering phosphorus internally:—

"Phosphorated Oil	8
Gum Arabic	8
Peppermint Water	100
Syrup	60

Make an emulsion."

§ Pharm. Journ., 2nd ser. vol. VII. p. 615.

The phosphide of zinc before referred to is a compound easily decomposed by weak acids, such as lactic acid, yielding phosphuretted hydrogen. It contains one-fourth of its weight of phosphorus; but it is said that experiments have shown that physiological effects equal only to half the weight of phosphorus result from its use, and that consequently it is necessary to use eight parts of the phosphide to obtain the effects of one part of phosphorus.

Professor E. S. Wayne, who, on the occasion of his presence at the recent meeting of the British Pharmaceutical Conference, was elected an Honorary Member of that body, has since his return to Cincinnati been entertained by the members of the College of Pharmacy there, of which he is President. Professor Wayne gave an interesting account of pharmacy in Europe as it had come under his notice.

THE CANTOR LECTURES.

The first course of the Cantor Lectures, in connection with the Society of Arts, for the coming session, will be commenced on Monday next, November 25th. It will consist of five lectures on "The Practical Applications of Optics to the Arts, Manufactures, and to Medicine," by C. W. Meymott Tidy, M.B. A second course on "The Energies of Gravity, Electricity, Vitality, Affinity, Light, and Heat, especially with reference to the Measurement and Utilization of them," by the Rev. Arthur Rigg is announced.

THE ROYAL INSTITUTION.

The following lecture arrangements at the Royal Institution for 1872–73 have been announced:—

Prof. Odling, M.A., F.R.S.—Six Christmas lectures (adapted to a juvenile auditory), "On Air and Gas," on December 28 (Saturday), December 31, 1872; January 2, 4, 7, 9, 1873.

Prof. Rutherford, M.D., F.R.S.E.—Twelve lectures "On the Forces and Motions of the Body," on Tuesdays, January 14 to April 1.

Dr. Debus, F.R.S.—Three lectures "On Oxidation," on Thursdays, January 16, 23, 30.

Dr. H. E. Armstrong, F.C.S.—Four lectures "On the Artificial Formation of Organic Substances," on Thursdays, February 6 to February 27.

Prof. A. Vernon Harcourt, F.R.S.—Five lectures "On the Chemistry of Coal and its Products," on Thursdays, March 6 to April 3.

Edward A. Freeman, Esq., D.C.L.—Six lectures "On the Comparative Political Institutions of Different Nations," on Saturdays, January 18 to February 22.

Prof. W. K. Clifford, M.A.—Three lectures "On the Philosophy of the Pure Sciences," on Saturdays, March 1, 8, 15.

Prof. Max Müller, LL.D.—Three lectures "On Darwin's Philosophy of Language," on Saturdays, March 22, March 29, and April 5.

John Morley, Esq.—Three lectures "On the Limits of the Historic Method," on Tuesdays, April 22 to May 6.

J. H. Parker, Esq., C.B.—Four lectures "On the Evidence for the Traditional History of Rome from Existing Architectural Remains." on Tuesdays, May 13, 20, 27, and June 3.

Prof. Tyndall, LL.D., F.R.S.—Six lectures, on Thursdays, April 24 to June 5.

Prof. Odling, M.A., F.R.S.—Four lectures, on Saturdays, April 26 to May 17.

Edward Dannreuthner, Esq.—Three lectures "On the Development of Music in Connection with the Drama," on Saturdays, May 24, 31, and June 7.

The Friday Evening Meetings will commence on January 17th.

Friday Evening Discourses during the season will probably be given by Wm. Spottiswoode, Esq., the Rev. Prof. T. R. Birks, Edward Dannreuthner, Esq., Robert Sabine, Esq., Sir H. Rawlinson, K.C.B., Prof. Clerk Maxwell, James Dewar, Esq., E. J. Reed, Esq., C.B., J. Emerson Reynolds, Esq., Prof. W. K. Clifford, Prof. Tyndall, Lord Lindsay, Prof. Odling, and others.

THE ROYAL SOCIETY.

The Royal Society has this year awarded the Copley Medal to Professor Friedrich Wöhler, of Göttingen, for his numerous contributions to the science of Chemistry. Royal Medals have also been awarded to Professor Thomas Anderson, M.D., for his various chemical researches, and to Mr. Henry John Carter, F.R.S., for his valuable and long-continued researches in Zoology. The Rumford Medal, given every two years, has been awarded to Angers Jonas Angström, for his researches on Spectral Analysis. The annual meeting of the Fellows for the election of officers and Council for the ensuing year will be held on the 30th inst. On that occasion a successor to Dr. Sharpey—who resigns his office after a long period of service as Secretary—will have to be appointed. Professor Huxley is nominated by the Council as his successor.

The vacancy in the faculty of the Philadelphia College of Pharmacy occasioned by the death of Professor Parrish has been filled by the appointment of Professor William Procter, jun., who formerly held the same chair (Pharmacy) for many years, but resigned it in 1866.

We have great pleasure in referring to the inauguration of a Chemists' Association at Carlisle (see p. 414). We understand that the movement has had a generous financial assistance from the employers in the town, and it is to be hoped that this will be supplemented by the exercise of their personal influence in supporting the new society. Rooms have been taken, and it is proposed to hold a class in chemistry and pharmacy, under the tuition of Mr. J. Hallaway, and one in materia medica under the care of Mr. W. Moss, the secretary.

The question of the medical education of women having a direct bearing upon a subject still under discussion in the pharmaceutical body, we desire to call attention to an able article from the 'Madras Journal of Medical Science,' printed at p. 408.

Mr. E. C. C. Stanford's scheme for deodorizing and utilizing sewage by means of seaweed char was recently the subject of an interesting Conference at Southsea. We may mention that Mr. Stanford is an old pupil of the school of pharmacy at Bloomsbury Square, and was at one time Demonstrator in the laboratory.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The second general meeting was held at the Royal Institution on the 24th of October; the President, Mr. E. Davies, F.C.S., in the chair.

Messrs. Pearson, Chambers and W. P. Lake were elected members of the association.

Mr. Charles Sharp presented to the museum a section of a Cycas stem from Queensland, and of Adelaide bark, used for tanning purposes. Mr. A. Redford presented a bark from Queensland, known there as the "bitter medicine."

The President invited members to subscribe to the John Cargill Brough Fund, remarking on the object and merit of the fund.

A discussion followed on the subject of Pharmaceutical Education, which was adjourned to the next meeting.

The third general meeting was held on the 7th of November; the President in the chair.

Messrs. E. H. Parnell and S. Wilde were elected members, and Messrs. Henry Case and Charles Clark Burman were elected associates of the association.

The adjourned discussion on Pharmaceutical Education was resumed by Mr. Shaw, but no definite resolution on the subject was proposed.

LEEDS CHEMISTS' ASSOCIATION.

The second meeting of the present session was held in the Clergy-room, Church Institute, Leeds, on Wednesday, Nov. 13, 1872; the President, Mr. E. Brown, in the chair.

The minutes of former meeting having been read and confirmed, Mr. R. Reynolds, F.C.S., read the paper of the evening, entitled "A Short Notice of some Leeds Worthies in Science," and afterwards gave some information respecting the proposed Yorkshire College of Science, shortly to be commenced in Leeds.

Mr. George Ward, F.C.S., was glad to hear that the scheme was being carried on. He should hail with pleasure the inauguration of such a college, and had pleasure in proposing the following resolution:—

"That this meeting desires to record its gratification at the proposal for a Yorkshire College of Science, and believes that it would materially assist in the education of students in pharmacy."

Mr. E. Thompson seconded the resolution, which was carried unanimously.

On the motion of Mr. Smeeton, seconded by Mr. S. Taylor, a cordial vote of thanks was given to Mr. Reynolds.

NORTHAMPTON PHARMACEUTICAL ASSOCIATION.

The monthly meeting was held on Friday, Nov. 8. The first business was to fill up the vacancy caused by the resignation of the President, Mr. Masters, and resulted in the election of Mr. C. Hester. A vote of thanks was passed to Mr. H. J. Masters for his valuable services during his term of office as president.

Mr. C. Hester returned thanks for the honour conferred upon him. He said he would do all in his power to serve the best interests of the association, and much regretted that his business duties compelled him to be so frequently absent from their meetings.

Mr. Druce then read some correspondence, and said they had received a specific gravity bottle from Mr. Armitt, Ralph's 'Botany' from Mr. Tearle, Ilfracombe, and a number of prescriptions from local friends which were extremely acceptable as their book was not yet completed.

After some business connected with the working of the association had been transacted,

Mr. Druce read a paper on Chemistry, and the following note on Chlorate of Carbon:—

"Under the above rather sensational name a dark grey powder was sent for examination, which had been procured from New York for use in eclectic medicine. It appeared to be a mixture of a coarse white powder with some black substance, the mixture being very imperfect, patches of white powder being very plentiful, showing that a sieve had not been used in its preparation. Upon analysis it proved to be a mixture of chlorate of potash with about 10 per cent. of vegetable charcoal. As the price of this compound was twenty-one shillings per pound, an amount of profit almost equal to that on corassa was obtained by the person who prepared this 'elegant compound.'"

A vote of thanks to Mr. Druce was passed, and the meeting terminated.

CARLISLE CHEMISTS' ASSOCIATION.

The first general meeting was held in the rooms of the association in Barwise Court, on Friday evening, the 15th instant; Mr. Councillor A. Thompson, President, in the chair.

The report of the committee having been read by the Secretary, Mr. W. Moss, was unanimously adopted.

The President then called upon Mr. Hallaway, who proceeded to address the meeting as follows:—

Gentlemen,—It having devolved upon me to deliver an address at this the first meeting of the Carlisle Chemists' Association, I feel that I am not competent to deliver such an address as is worthy of the occasion; but as some one must take the initiative in all such associations, rather than it should not be done I have taken upon myself the responsibility. I beg of you that you will not look for nor expect anything great or grand, but look upon me as being one anxious to further the interests of pharmacy, and on what I shall say as an inducement and stimulus to our youths to acquire that knowledge which is essential, and without which it is impossible to carry on successfully our business.

Nearly all trades and professions have either their unions or associations, the objects of which are chiefly to look after trade matters and to further and protect the interests of their respective trades or professions, and I trust that this association, which we are now met to inaugurate, will be the beginning of a new era in Carlisle; that it will be the means of consolidating as a body the chemists and druggists of this town, and uniting us as it were into one friendly family. The medical profession of our two northern counties have their medical association, which association meets at stated periods, and at which meetings papers are read by members upon professional matters, to the advantage and edification of the whole association, and without in any way detracting from the dignity of, or yet in any way interfering with the private interests of its individual members, but, on the contrary, uniting together the profession more closely. Such, I trust, will be the case with the Carlisle Chemists' Association; its members have no private interests to serve more than to do that which they can to look after the interests of the trade as a whole, and in imparting and receiving information which in the end benefits the whole community.

One of the objects of this association is to advance pharmacy, and as a means to that end, the committee propose there should be a monthly meeting for the reading of papers, whether original or extracted, the discussion of subjects specially connected with the trade of pharmacy, and the bringing under the notice of its members new medicines. If each member will contribute a little of his time and experience, I believe we shall carry on the association successfully. I also trust that in the course of time we shall be able to have a museum and a library; and in order to do this, the committee will thankfully receive anything in the shape of books or specimens for that purpose, so that the youths who may come to Carlisle to learn their business shall not have to complain of want of facilities for so doing, and also that they may be places of reference in pharmaceutical matters for the whole town.

The other object of this association is for the mutual improvement of its members and the helping and stimulating of our apprentices to acquire a sound, thorough and practical knowledge of the higher branches of our business, so as to enable them in the first place to get through their examinations creditably, and, secondly, to fit them for filling the positions that may devolve upon them in the future with credit to themselves and honour to their old masters, an object which I am sure we all agree in and wish to promote.

Pharmacy is a trade that demands a great degree of conscientiousness. Just think for one moment what very often depends on us,—an issue of life or death. What does it avail how clever our medical men are, or what amount of skill they may possess, or how long they may have anxiously considered and pondered over what is the best remedy to give, if their prescriptions are not accurately prepared in accordance with the wishes of the prescribers? And it behoves us all, young and old, so to fulfil the important duties that fall upon us, that the profession may have confidence in our skill and conscientiousness, and that the public may rely upon us doing our duty faithfully. Here I would bring before the masters the necessity of so conducting their businesses,—I refer especially to the preparing and dispensing of medicines, taking the pharmacopœia as their guide and standard,—that a youth may have always clearly set before him the duty of a pharmacist to prepare and send out medecines in conformity with the instructions of the Pharmacopœia and the wishes of the prescriber; and may learn to have a horror of secret formulæ. By secret formulæ I mean the formulæ that are used when nostrums are prepared, such as preparing vin. ipecac. with spirit; the constant use of concentrated infusions and decoctions for fresh, and the use of half-and-half (spirit and water) for the true proof spirit, 5 of spt. and 3 of water; and a host of other abuses that I am afraid still retain their old places up and down the country,—bringing to my mind what a friend in the drug trade once told me, that he thought in old times when he was an apprentice, the thing was not how to make things properly, but how not to do it. The apprentice should be taught that he ought not to think how preparations can be cheaply made, but how they can be best made, and that he has a duty to perform that requires a great amount of conscientiousness.

Pharmacy, in its earliest ages, was in the hands of the physicians, who professed the healing art in all its branches, and prepared their medicines themselves, or superintended the preparation of them. I should neither like to make nor superintend such messes as were made in the period referred to; and I wonder what the youths here present would think if we set them to work upon such things as the fat and grease or suet of a duck, goose, eel, boar, heron, dog, capon, beaver, wild cat, stork, hedgehog, hen, man, lion, hare, kite, wolf, mouse of the mountain, hog, serpent, badger, bear, fox, vulture, album græcum, east and west bezoar, stone taken out of a man's bladder, viper's flesh, the brain of hares and sparrows, the rennet of a lamb, kid, hare, and a calf, and a horse too; the excrement of a goose, of a dog, of a goat, of pigeons, of a store horse, of swallows, of men, of women, of mice, of peacocks, etc.? What I have just read form a portion of the remedies enumerated in the Pharmacopœia of 1653; the science of medicine was so little understood, and so imperfectly cultivated, that it was in general practised empirically, and was often confounded with sorcery and witchcraft. No laws existed for the protection of the public from ignorant practitioners, and it was not until the year 1511 that in this country the practice of the profession was regulated by law. It is uncertain what time physicians gave up practising pharmacy, but we find that in 1617 the apothecaries, who were previously incorporated with the grocers, were separated from the latter, and obtained a charter which gave them the privileges of practising pharmacy, viz., the selling of drugs, and the preparing and compounding of medicines according to the physicians' orders and instructions. The first pharmacopœia was published by the college in 1618, and subsequent editions at various times, until we reach the last, and, I believe, the best that has been yet published, the 1867 British Pharmacopœia. The Edinburgh and Dublin Colleges also published pharmacopœias, but in the year 1864 a pharmacopœia was published that superseded the three pharmacopœias then in use, the London, Dublin, and Edinburgh, called the British Pharmacopœia, and which did away with the uncertainties and anxieties that so often troubled us, as to how a prescription was to be dispensed (not knowing by whom or where it was written) when it contained a medicine that was ordered to be prepared of different strengths by the different colleges. On the 18th of February, 1843, the Pharmaceutical Society of Great Britain became a corporate body, and in 1868 obtained from Parliament the object for which they had so striven and worked, the compulsory education of all who practise pharmacy on their own account.

The law has now said that every one who keeps open shop for the sale of such articles as are enumerated in certain schedules must pass an examination; and although it does not prevent any one from keeping open shop for the sale of three-fourths of what we do sell, still the one-fourth that is prohibited from being sold by any one who has not acquired the necessary privilege for selling is a total preventive to any one following the business of a pharmaceutical chemist.

As the law has said in its wisdom that all who keep open shop must pass an examination, I say before such examination can be passed, it is an essential requisite that every one must be educated, and the first thing, therefore, for any one going into the business to do is to begin to acquire the necessary education.

There are many schemes put forth for educating future pharmacists, and which have been fully explained and discussed in the PHARMACEUTICAL JOURNAL; they all have their friends and admirers, and I dare say they might be brought into practical working order. Still, I hold that it is the duty of an apprentice to pay for his own education, and that good practical pharmaceutical chemists can be made if young men will themselves study and make use of the advantages offered by such associations as this we are now met to inaugurate, with the practical training behind the counter, if with the help thus given they help themselves. Certainly they do not pretend to make a young man a pharmacist without his own help, but they offer rooms to read in, the assistance, help, advice, goodwill, and experience of their seniors, and, I trust, also, some practical and theoretical instruction in chemistry, pharmacy, materia medica, and botany that is not always met with behind the counter.

I wish to bring before your notice the desirability and the necessity of not taking apprentices without their having first passed the Preliminary examination, or, at any rate, it being made an essential feature in the agreement that it has to be passed within three, or at the latest, twelve months after entering upon their apprenticeship.

I think you will at once see the force of this when I say that a youth fresh from school is in a much better position with everything fresh in his memory to pass such an examination, than when he has been from school, say, two to three years, and perhaps forgot a good deal of what he did know. It also would have the effect,—which is the thing desired and inculcated by every one who wishes to see pharmacy occupy its proper position in our land,—of weeding out the uneducated, keeping out of our ranks those whose education has not fitted them for entering them, thus giving tone to, and elevating the whole body also. It will have the effect of lessening in the course of time the great number of businesses that at the present time abound, by putting greater difficulties in the way of, and increasing the cost to, those who wish to practise pharmacy, and eventually making our businesses more remunerative by their becoming so much larger. The time of the youth is taken up with the preliminary studies, if he does not pass before he enters, or immediately after, to the total exclusion of what he ought to be doing so as to enable him to get through his Minor after serving his apprenticeship.

In the few words more I have to say, I wish specially to address the youths whom I now see here, and for whose benefit this association has been chiefly got up. I wish to impress upon them the necessity of studying during their apprenticeship; not in a random way, but by hard downright work, being in earnest and determined to overcome all difficulties, using all the spare time that they have for the furtherance of their studies. And here I would remind them that they may consider themselves well off, as they will find very few towns in England that adopt such an early closing hour as we do here, which they will find a great boon, and as such, should prize it.

The examinations comprise a knowledge of chemistry, pharmacy, botany, materia medica, with the practical manipulation of the laboratory and dispensing counter; also the modes of ascertaining the strength and purity of drugs, the tests and antidotes for poisons, the doses of ordinary medicines and an acquaintance with the language of prescriptions. Rather a formidable programme, I fancy I hear my young friends say; but it is a programme that must be mastered by every one who wishes to pursue the calling of pharmacy and aspires to be in business for himself. And I can assure them, if they will only give their time, and take for their motto '*Labor omnia vincit*,' they will master it. I also wish to impress upon them the necessity of having a regular routine of study, to have nights or portions of nights set apart for particular subjects; say one night for chemistry, one for materia medica, another night for botany, another for history or general literature, and lastly, and I believe of the greatest importance, one night for reviewing what you have done in the preceding nights. And remember that the great secret of being successful and accurate as a student, next to perseverance and being thorough in all your studies, is the constant habit of reviewing, by which means you fix in your memory faithfully what you have learned. Here I would recomend a few books to your notice, and which, I think, you ought all to possess, viz., Attfield's 'Chemistry,' Oliver's 'Botany,' Roscoe's 'Chemistry,' Scoresby-Jackson's 'Materia Medica,' Fownes' 'Chemistry,' and Selecta è Prescriptis.' Now you must not let those nights that are set apart for particular subjects be interfered with. Make yourselves a programme, and stick to it; it may be irksome at first, but if you will only persevere you will find you will be as anxious to get to your studies, and be as annoyed if you are interfered with, as you are for getting to your dinner when you are hungry and called off before you are done. Practical pharmacy, not high scientific pharmacy, will engage a good deal of your time in the shop. I fancy at this last I hear my young friends saying, "All very well to say so, but, you know, we don't get much practical pharmacy in the shop." In answer to that I say, the shop is where you will get, although at present you may think to the contrary, most useful knowledge, and that practically, which will enable you at a future time to manage a business either for yourself or some one else. And it has been proved to be a fact, that without the practical training in a shop, it is almost an impossibility for a young man, no matter how full of theoretical knowledge he may be, to pass his examinations. For the want of practical knowledge gained in a shop, young men who have attended laboratory practice at Bloomsbury Square, who have been well up in all but practical experience in a shop, have been plucked. Professor Attfield inculcates the desirability of making it compulsory that before a youth presents himself for examination he must have been apprenticed a certain number of years to the trade; indeed, a young man who has received his education in a school of pharmacy, without any practical experience in the routine of a shop, would be unqualified to conduct a business, and not likely to succeed if he were to make the attempt. The judicious combination of the profession with the trade is the great object to be attained, for while it is of the highest importance that those who dispense medicines should be duly qualified as chemists, it is equally necessary to sustain their commercial character as druggists. Professor Redwood says the subjects involved in the Minor examination, and the extent of knowledge implied by the description of it given in the bye-laws, appear to him to be such as young men of average ability, with the scholastic acquirements indicated by the Preliminary examinations, ought to be able to acquire in a three or four years' pupilage with a competent master, and attendance during part of the time at lectures or classes for systematic instruction. Even without lecture attendance, if the pupil be properly aided in his studies, he may, as many do, successfully prepare for this ordeal; and to corroborate this view of the Professor's we have instances of young men not only passing the examinations, but seizing upon the highest prizes the Pharmaceutical Society has to bestow. Amongst such examples Mr. Betty, when addressing the chemists at Glasgow last week, mentioned the name of Mr. Talbott, who was the successful candidate for the first Bell Scholarship, and who resided in a small country town and had no help but his class-books; also Mr. Betty informed them that the present holder of the prize was self-instructed. Professor Redwood also says the examinations are not intended for the discovery of the extent of the candidate's knowledge so much as his want of knowledge; they are designed rather as a test of his weak points than of his strong points. "It is not," he says, "a high degree of scientific attainment in any of the branches of knowledge comprised in this curriculum that is most wanted, but a general proficiency in all, and great ignorance in none." In conclusion, I wish to impress upon my young friends that they must not expect too much from Mr. Moss or myself (but I can assure them we are both willing and anxious to assist them and to do all that we can to help and direct them so far as we are competent—still, they must bear in mind, that they who help themselves are best helped) and to thank you all for the patience with which you have listened to me.

The address was received with much applause, and at its conclusion, a cordial vote of thanks was given to Mr. Hallaway.

The thanks of the meeting were also voted to Messrs. Southall, of Birmingham, for their present of a collection of specimens of materia medica.

A vote of thanks to the president closed the proceedings.

Obituary.

Notice has been received of the death of the following:—

On the 21st of October, Mr. Frederick William Sanders, chemist and druggist, of Great Hampton Row, Birmingham.

Parliamentary and Law Proceedings.

Alleged Violence in Administering Medicine.

On Monday, November 11, an inquest was held at the Wandsworth Union Workhouse, before Mr. Carter, on the body of Rhoda Williams, aged 72, who died on the previous Wednesday evening shortly after a sleeping draught had been forcibly administered to her by the nurses. A patient in the next bed but one to the deceased stated that the nurses attempted to give deceased a draught on Wednesday evening. She spat it out. Nurse Ward then fetched another, and pinched or held deceased's nose and put the feeder in her mouth while the other nurses held her down. Deceased was conscious, and struggled to prevent the medicine being given. It was not more than five or ten minutes after the draught was given that death took place.

Dr. Ceely said deceased was suffering from dropsy, diseased heart and lungs in an advanced stage. Saw her on Wednesday afternoon. She was delirious, talking rapidly and incoherently. Prescribed for her a stimulant. Ward came to witness and described the patient's state, wishing to know if she should give her a night draught. It was not laudanum, but a sedative. Witness ordered her to give one. It was customary for the nurse to have a bottle of the draught under lock and key. It was a preparation of opium, supplied from the dispensary. Ward had a bottle. Witness supplied it, but did not make it up. Twenty minims was ordered to be given. It was in solution, containing tincture of opium. Ward did not come again till after the death of deceased. She said she had given the medicine, but did not say anything about the first draught. Witness understood from her there had been some difficulty in administering the dose. First heard about the second dose on Thursday following from Ward, who said she had attempted to give the first dose, that it was spilt, and she then administered the second. Witness saw deceased a few minutes after death. There was no appearance of violence. About two tablespoonfuls of water was added to the quantity of medicine ordered. Had made a *post-mortem* examination. Found no evidence of violence on the external parts. The stomach was empty, and there was no appearance of opium having been taken. The two doses, if taken, would have been a large, but not a dangerous quantity.

Mary Ward, the nurse, said deceased was in bed in a very bad state, delirious, and very noisy. She attempted to get out of bed, and made use of bad language. Witness went to Dr. Ceely, and asked if he would allow her to give deceased a night draught, as she was delirious. He consented, and witness obtained twenty drops of laudanum, which she measured in a minim measure, and added two tablespoonfuls of water. Attempted to administer it, but it was upset; none of it went into deceased's mouth. Prepared another draught, put some in her mouth, but she spat it out. Nothing was done by any one to make her swallow it. Her nose was never touched: her hands were held to prevent her knocking the feeder out of witness's hand. The coroner summed up, and the jury returned a verdict of Natural Death.—*Wandsworth and Battersea District Times.*

Attempted Suicide by a Chemist and Druggist.

On Saturday, November 9, Mr. Hannaford, chemist and druggist, of Irthlingborough, was found in a drowsy and partially unconscious state, he having taken a quantity of laudanum. The usual treatment was had recourse to, and on Monday morning he had nearly recovered. After being left for a short time, however, he was found with his throat stabbed in four places, and the bed saturated with blood. The wounds were at once dressed, and it is thought probable that he will recover.

Reviews.

A Manual of Chemical Physiology, Including its Points of Contact with Pathology. By J. L. W. Thudichum, M.D. London: Longmans. 1872.

An English work on Physiological Chemistry has long been wanted. The Cavendish Society's translation of Lehmann's excellent Manual was not accessible to all, and is now, moreover, out of date, and no other of anything like equal merit has succeeded it. It is true that the student who reads German can find several good books to aid him, and, in particular, Kühne's "Lehrbuch," which we rejoice to hear will shortly be published in an English dress by Professor M. Foster. But the fact remains that the English student has not hitherto had any trustworthy and sufficient guide in the difficult work of physiologico-chemical analysis. At the present time, even Kühne is out of print.

Such is the juncture at which Dr. Thudichum's book has appeared, and it would indeed have been satisfactory if it had supplied the want that students are feeling so keenly. But this want, we are sorry to find, is still unsatisfied. We are anxious to do full justice to Dr. Thudichum's ability and industry, and we gladly admit that there is much that is valuable in his book; but its faults of arrangement, selection and nomenclature are so grave, and its errors, and still more its omissions, so glaring, that it is not likely to be of much use as a text-book.

The first sixty pages of the book are occupied with a general outline of physiological chemistry, reprinted almost *verbatim* from one of the appendices to the tenth report of the medical officer to the Privy Council. Many of our readers are, no doubt, familiar with these annual reports, and will remember the lengthy and finely-illustrated memoirs which Dr. Thudichum has contributed to them in successive years under the title of "Researches Intended to Promote an Improved Chemical Identification of Diseases." Somehow, these researches have been received with not a little distrust by the medical profession. Perhaps the very number of the discoveries announced and the slender proof adduced in support of many of them are sufficient to account for this; but the feeling was certainly strengthened by the tone of originality—often too much like self-conceit—which induced the author to change many of the common names of chemistry, and to explain facts according to hypotheses of his own—hypotheses which had not received the adhesion of chemists, and which were often crude and improbable. It was felt that a public health report was hardly the place in which to re-write elementary chemistry. Such dogmas as that "all atoms possess chemism, dynamicity and polarity," and the constant use of such words as "chemolysis," "physiolysis," "hydrothion," for sulphuretted hydrogen; "rhodanate" for sulphocyanate, and "hydroxyde" for hydrate, are clearly out of place in a work of the kind, and are evidence of bad taste in the author.

The portion of Dr. Thudichum's reports here reproduced is interesting and suggestive, and much of it is valuable. But it has the great fault to which we have before referred; it is untrustworthy. No student in reading it could distinguish well-ascertained facts from the hypotheses, often mere guesses, which the author mixes with them. Difficult points in physiology are disposed of in a few lines, with dogmatic explanations, which would be most satisfactory if they were certain, but which as things stand are sure to mislead the student. Thus, the escape of carbonic acid from the lungs is explained (p. 30) by the assumption of a "hematic acid," which passes into the serum from the corpuscles and decomposes the carbonates "at the very moment when the blood-corpuscles arrive in the small breathing cells of the lungs." This idea, or one very like it, was started a few years ago by Kühne, and has some probability; but it surely is not right to give it to students as matter of fact. Elsewhere (p. 15), the formation of hydrochloric acid in the glands of the stomach is described as a simple reaction between water and salt, by which hydrochloric acid and caustic soda are simultaneously formed. Of course this *may* be the case, but considering the strong *à priori* improbability, who but our author would have ventured to state it dogmatically?

For examples of simple errors of fact, we may point to page 41, where neurine and choline are described and formulated as different substances, whereas they have long been known to be identical, and where the acid $C_{16}H_{32}O_2$ is described as margaric, instead of palmitic. It is, however, right to add that errors of this kind do not appear to be numerous.

The second portion of the work is an analytical guide, and is, therefore, wisely made "prescriptive, in the style and manner of pharmacopœias." But, most unwisely, it has been arranged in alphabetical order, so that the unhappy student who wishes to work systematically will find himself carried from acetic acid to albumen, from albumen to alcohol, from alcohol to allantoine, and so on throughout the book. Separate headings are of course given for such substances as bile, blood, milk and urine, but as the proximate constituents of those substances are scattered throughout the book, it is a work of some labour to collect the methods necessary for their examination. And the headings themselves are imperfect and arbitrary. Bodies as important as Viteline, choline and glycerine are omitted, whilst luteine gets six, and cruentine nearly three pages. In the separate articles too, we notice many remarkable omissions. Only one kind of albumen, globulin or lactic acid is mentioned. No allusion is made to the important researches of Miescher on pus, Städeler and Obolensky on the mucin of the submaxillary gland, or Jaffé on the bile and urine pigments. And, finally, in the article on urine, no notice is taken of the fermentation test for sugar, or to any necessity for purification of the urine before the application of the copper test.

It is no great compliment certainly to Dr. Thudichum to say that his book is at the present time the best the English student can use, but considering its manifold imperfections, we cannot help hoping that it will, ere long, be superseded by a more trustworthy, if less ambitious text-book.

Note Book of Materia Medica, Pharmacology and Therapeutics. By R. E. Scoresby-Jackson, M.D., Second Edition. Edited by Dr. Angus Macdonald, M.A.

Few students who make this, the second edition of Dr. Scoresby-Jackson's Materia Medica, their text-book, will complain that the difficulties of the British Pharmacopœia are not most thoroughly explained, and their path otherwise made easy and interesting.

In our review of the former edition* we quoted one or two extracts from it, which give a very good idea of the general method of treating the subject, and Dr. Macdonald has strictly adhered to his author's plan.

Nevertheless, much had to be rewritten and rearranged, especially the chemistry, of which the symbols are now in the new notation, the old formulæ being retained, as in the Pharmacopœia, "to facilitate reference to older works."

The work is divided into three parts; the first of which is introductory to the whole subject, and includes descriptions of pharmaceutical operations, together with a very useful list of officinal formulæ, with each preparation under its proper heading. Then follows an article on magistral formulæ or prescriptions, which contains

* Pharm. Journ., 2nd Ser. vol. VIII. p. 423.

much useful information, but in which too many long and comparatively obsolete words are used, as in the following description of one of the methods of exhibiting medicines, "*The Iatraleptic Method.*—This process requires more than mere opposition; the term signifies *to cure by anointing* (ἰατρεύω and ἀλείφω). It has also been called the *epidermic method, anatripsologia* (ἀνατρίβω, *to rub in*) and *espnoic medicine*." Under the heading of mental causes modifying the action of medicines, some lines of poetry are given, which seem strangely out of place so near to elaborate chemical formulæ.

The second part of the work includes the drugs from the inorganic kingdom, and the explanations of the preparations and tests of the Pharmacopœia are excellent. The long list of synonyms for each substance hardly deserve the importance given them; it can be very little good to know that hyposulphite of soda has been called "natrum oxidatum subsulphurosum," or that citrate of potash once went by the name of "salt of Riverius." No such objection can be made to the foreign synonyms, which are not sufficiently well known in this country.

Following the description of each drug is an account of its therapeutic qualities, and here, as in many other works on the same subject for the use of students, there is a want of definiteness, even more than the present state of therapeutics justifies; all the possible actions of the substances under consideration are put down one after the other, and no great stress is laid on the particular properties of each drug, which a small practical experience enables any one to obtain. For instance, ammonia is "medicinally employed as a diffusible stimulant and restorative, antacid, antispasmodic, diaphoretic, sudorific, expectorant, antidote, counter-irritant, vesicant, etc. It has been recommended in the later stages of febrile and inflammatory diseases, and in other cases where there is great nervous prostration; also to hasten the cold stage of intermittent fever and to promote the eruption in febrile exanthemata; in the later stages of pneumonia and in chronic bronchitis; in atonic dyspepsia, with acidity of the primæ viæ, and flatulence; in syncope; in spasms; to avert fits of epilepsy; in hysteria; in amenorrhœa and chlorosis; to dissipate the effects of alcohol; in delirium tremens; as an antidote to sedative poisons, such as hydrocyanic acid, digitalis, etc." And this is not all. This instance, taken at random, would seem to indicate to the commencing student that ammonia is a universal panacea; and yet how unfrequently does liquor ammoniæ appear in prescriptions, so that a very false idea is obtained of its importance.

Considerable stress is laid on the objection to the presence of nitric acid in the solution of citrate of bismuth and ammonia, but the acid is not free, the solution being generally alkaline, and it has never been shown that the presence of a nitrate is in any way injurious.

The third part of the work is occupied with the consideration of organic materia medica, and is brought up to the times by the introduction of the recent researches of Drs. Brunton, Frazer and Harley. Considerable space is occupied by botanical descriptions of the plants referred to, and the obsolete Linnean names are still retained.

The same remarks that have been made with regard to the therapeutics of the second part of the book apply to this one also in many of the articles. Some of the descriptions seem also to mislead. Thus, in discussing the use of quinine in simple intermittent fever, our author says, "it is only after visceral disease, or other complications when present, have been suitably treated by other remedies, that these remedies can be safely or profitably applied." This statement is peculiar, and though it may be true, does not give a clear idea as to the general way in which the drug is employed.

Notwithstanding the peculiarities above pointed out, this work cannot but prove a useful one to students of the subject.

Correspondence.

Commercial Morality.

Sir,—Will you allow me to reply through your Journal to the letter signed by Messrs Newham and Co., which appeared in No. 124, on the 9th of November. It is headed "Specimen of Commercial Morality," and refers to their purchase of two cases of sponge, of which they give full particulars as to their being deceived in the weights charged and actual weights, and also in the net produce of sponge when the sand was abstracted.

Now, Sir, allow me, as a sponge merchant of very many years' standing, to inform your correspondents that if they will buy original packages as imported, and turn dealers themselves, they must put up with the consequences. They cannot reasonably expect to buy fairly cleaned goods, such as a respectable firm would supply them with, at the same rate as that with the full complement of sand in, as received from Smyrna.

Any druggist can ascertain through the wholesale houses or drug brokers in London in what state the sponge is received from abroad, and he will then find where what he would term the "immorality" proceeds from. If he wants to purchase sponge, let him give the fair market value for it, and not buy the sand and sponge as it is imported; and if he finds too much of the former and too little of the real article in the package, cry out that he has been taken in. I am sorry to say that too many parties who retail sponge think, when they are offered the original goods at a low price, that they had been previously paying very long prices, and consequently give an order and then find their mistake out.

J. W. Pyke.

4, *Great Prescott Street, Goodman's-Fields, London, November 10th*, 1872.

Sir,—The reply of Mr. W. Judd in your impression of the 16th, to the letter upon Commercial Morality in that of the 9th, states very clearly and truly the process of loading sponge with sand.

Sponge in its natural state is found growing to the rocks, no doubt sometimes near a sandy bottom, but the sand is all (or nearly all) washed into it by those who find it to their advantage to do so.

Having visited some of the centres of the heavy sponge trade in the Mediterranean, and seen the sponge being prepared for the English market, we clearly see the advantage which the dealer gains over the English buyers; the former knows how much sand he has washed into his sponge, the latter has only to guess at it. It is a fact that you may purchase sponge at the average commercial weight, which is about 70 lb. of sand and 30 lb. of sponge to 100 lb. You may then order it to be doubly weighted, so that the 100 lb. contains only 15 lb. of sponge.

In France the custom is to have sponge perfectly light, and to "wash out" every impurity, instead of "washing in" sand. Having had considerable transactions in light sponges dressed after the Paris fashion, we arranged at the time of the Franco-German war to bring into our own factory workmen from Paris, accustomed to the process of cleansing sponges.

Many are still greatly prejudiced against it, and having been so long accustomed to the sanded sponges at from 2*s.* to 12*s.* per lb., they are with difficulty convinced that light sponge at 16*s.* to 40*s.* are decidedly cheaper. In purchasing light sponges, buyers see exactly what each piece costs.

All this is done to make the sponge nominally cheap per lb., and the retailers of this article are answerable for this state of things, for they too dearly love a cheap quotation. The light sponge reaches England direct from the fisheries in bales, with little freight, for it is tightly compressed, whereas the sanded sponge is opened and packed in cases at a far greater bulk, and consequently freight. Again, the labour of sanding is greater than that of washing, and requires considerable space to place each piece separate, and great patience to wait till the sand dries into it.

It remains only to be stated that the finer the texture of sponge, the lighter it will weigh, and that sponge that has once been sanded, requires greater time and labour to render it entirely free of sand, but the honest sponge which has not undergone the process of sanding, but has arrived in this country in its virgin state, requires but little washing, and not one grain of sand will be found in it. There is therefore now no difficulty whatever in avoiding the speculation which always attends the purchase of sanded sponge.

G. B. Kent and Co.

11, *Great Marlborough Street, Regent Street,*
November 18*th*, 1872.

Sir,—I wish to add my experience to that of Messrs. Newham and Co., in the purchase of sponge in sand. I have just cleaned a case and find the result to be far less favourable than theirs.

Invoice Weights.	Real weights.
Gross 138 lb.	136 lb 8 oz.
Tare 17 lb.	17 lb.
Allowed for sand 30 lb.	82 lb. 14 oz.
Net weight of Sponge 91 lb. . .	8 lb. 2 oz.

I would recommend chemists to avoid all such purchases however plausibly the case may be put before them. It would be well for all who have paid for experience in the same way to make the fact known, that the system may be at once put a stop to.

Spongia Usta.

Worcester, November, 12*th*, 1872.

Sir,—A grocer lately had some sugar returned to him with the following polite message:—"Too much sand for domestic but not sufficient for building purposes," and with some such message should your correspondents B. Newham and Co. have returned those wonderful cases of sponge which they describe in your Journal. B. Newham and Co. labour under a popular delusion when they say that they "are aware that sponge *naturally* contains a considerable allowance of sand." I respectfully beg to differ from them. It *naturally* contains nothing of the sort. I bought a short time since some pounds of compressed sponge, from a firm in London, which was absolutely free from sand, and more, it never had any sand in it; every pound of it was equal in quantity and saleability to 4 lb. as usually bought and weighted with sand. I no longer go to "the Children of Israel" for sponge. I buy it free from sand, and thus know exactly what I am buying. Newham and Co. should take the bull by the horns, and not be deterred from doing a legitimate trade because they have been once bitten.

November 13*th*, 1872. Nil Desperandum.

Early Closing.

Sir,—When is a chemist's shop closed? The question suggests itself after perusing the correspondence in late numbers of the Journal. As to Sunday closing, I have always considered Mr. Slugg's practice the correct one; and ever since my first situation, where from inexperience I made no special inquiries on the subject, and where in consequence I remained three weeks, I, for several years, invariably refused every offer of a situation (and I had several very desirable offers) where anything beyond work of genuine necessity was required on a Sunday. Since I have been in business I have had customers on Sunday who have looked at articles of perfumery, etc. while a prescription has been preparing, but when they have desired to take them, they have been courteously informed that such orders would be gladly executed on the following day. I have never had occasion to regret this line of conduct, and cannot trace to it any case of pecuniary loss.

But what is early closing? I know some chemists who "close at eight o'clock," but their door shutters are down until ten. Now my customers come in at the door, and hence it makes no difference to them whether the window shutters are up or down, so long as there is free ingress and egress through the doorway. Some of these early closing chemists are not averse from signing an agreement to close on holidays, and while their neighbours act upon the agreement *bonâ fide*, their door is open all day long, and they take all the gleanings. In tkis new movement, is early ciosing genuine? Would that the secret of combination for this and many higher purposes would reveal itself to us who live in country places.

Nov. 16*th*, 1872. Henricus.

Remuneration of Assistants.

Sir,—The view brought forward by your correspondent 'An Underpaid Assistant' as to the cause of the scarcity of assistants of the *right sort* is very different from those which we usually see advocated.

There has been a great cry through the trade, especially from the employers, for pharmaceutical education, and a great number of schemes and plans have been brought forward, in some of which it is sought to persuade, and in others to force the rising generation to study and qualify; but if it be true that there is no demand and proportionate remuneration for the trained and educated assistant, it is evident that we have begun at the wrong end of the matter. In order to see whether such be the case we have only to look through the advertisements for assistants in the Pharmaceutical Journal, and there the requirements we find as a rule to be "state height and salary required." Let the *former* be rather high and the *latter* very low, and a certificate of competence is of little more use than waste paper, unless one is prepared to take a salary which a carpenter or stone mason would look down upon with contempt.

Create first the demand, and then the supply will follow without any difficulty, as any man of ordinary ability can prepare by self-help for the examinations without any extraneous assistance; only show him that he will have a probability of being repaid for his time, trouble and expense. Before asking for more assistants of the right sort, it would be well to provide suitable employment for those we have, instead of compelling them to seek for it in foreign situations, hospitals and the like, where they are to a great extent lost to British pharmacy.

O. A. Reade.

Sir,—The difficulty of the assistants' co-operative question, which has never been underrated in these columns, does not diminish by examination. The more the matter is discussed, the more wide does the gulf appear to yawn between the just and the expedient. Months ago was sounded the note of warning against the pernicious counsels of professional agitators, and the warning is not less requisite at this date, though the circumstances of the case are changed.

Chemists generally have met reasonable demands by reasonable advances. It is an accomplished and indisputable fact that the assistant is distinctly better off than he was twelve months ago, and the denunciation of professional agitators is met with the reply, that the assistant has obtained an amelioration of his condition by the thorough ventilation which his grievances have obtained from time to time through the medium of your valuable Journal.

To say that justice would not have been done but for extraneous pressure, is to advance an assertion incapable of proof, and to malign a body of men who are certainly not more selfish than their neighbours in the transactions of business. The people who content their limited understandings with jargon about supply and demand, and labour being worth what it will fetch in the market, have yet to learn, and will be difficult to convince, that the chemist has raised the assistant pecuniarily, without knowing where he will recover the increased outlay, and with the prospect of having to pay it out of profits, which at the best are insignificant compared with the average profits of commerce. Yet this is strictly true, and where the master has spontaneously given a rise to competent men, we are hopeful that the work will be done with so much more care and diligence, that the bargain will prove profitable to both parties.

There is no better solution of the difficulty to offer than this, mutual forbearance and consideration, sympathy and toleration, instead of distrustful antagonism.

104, *The Strand.* A. Courtenay.

Sir,—In reply to "Underpaid Assistant," allow me to say that the fault is our own; I have often wondered why it should be tolerated when the remedy seems so simple. Why not have a society of our own, by which we could claim our rights? "Unity is strength;" let us be united. This society might be termed the "United Chemists' Assistants' Society." Through its influence many benefits might be derived, viz., providing for old age and illness, etc.

Wm. W. Lindley.

[*** Such a society as that suggested by our correspondent, provided its efforts were devoted to proper objects, might undoubtedly render great services to its members and to the trade generally.—Ed. Pharm. Journ.]

Patent Medicine Licence.

Dear Sir,—In reply to Mr. Taplin, I will pass over his *reductio ad absurdum*, and merely ask the name of the chemist at Sandown, and the date when he was fined for selling Ess. Zingib.

Personally, I have no wish for any alteration in the licence, but if any change should be made, I appeal with confidence to the majority of the trade for support of my scheme.

George Brown.

Sandown, I. W., November 11th, 1872.

*** [We have communicated with Mr. Taplin respecting the above question, and have received information from him which has satisfied us that his statement was correct.—Ed. Pharm. Journ.]

Sir,—The flagrant injustice manifest in the imposition of this tax has been freely commented on by several of your correspondents.

All are agreed that the sale of patent as well as officinal medicines legitimately belongs to chemists and druggists, and the assumption of this business by stationers, grocers and others ought to be put a stop to.

While residing in a large manufacturing city the amount of trade I did in these articles was about £300 per annum, the licence being 10*s.*; now, however, as I live within a certain distance from the metropolis, and the amount done in patent medicines is comparatively small, I have to pay two pounds for the privilege.

It should be remembered that wholesale dealers, whatever the extent of their transactions, are placed on the same footing with the retailers as regards the medicine duty—the princely (!) Holloway pays no more—and country wholesale manufacturers and wholesale dealers may sometimes be exempt from the payment of 10*s.* or even 5*s.* per annum.

Would it not be possible for Government to make a more equitable adjustment of the duty, still realizing a satisfactory return?

Sirius.

Educational Labelling.

Sir,—Seeing many letters in the Journal upon Pharmaceutical Education, I take the liberty of sending you from Dieppe a few labels similar to what we have upon all our bottles. When I arrived in France I was quite ignorant of the contents of the French pharmacopœia, and not having any time to study (our hours being from a quarter to seven a.m. till nearly eleven o'clock p.m., the early closing not having yet arrived here) have been obliged to read up as best I could, but with the help of the labels I have been enabled to learn the composition of most of the various wines, pommades, and syrups, which are very numerous.

The labels contain nearly all the information (with the exception of the compounds they enter into) that is required for the materia examination. First you have the plant, then the family to which it belongs, then the natural order, if poisonous or not, the mode of employment, dose, and if poisonous, the antidote.

With regard to wines, syrups, etc., you have the composition, if poisonous, mode of employment, dose, etc.

I think, could these labels be placed upon the bottles, that apprentices and all desirous of learning would be greatly facilitated, as I have been.

P. Vincent.

[*** The labels forwarded by our correspondent are printed in black on white paper, $2\frac{1}{2}$ by 2 in. or less. We give translations of two of them for specimens.—Ed. Pharm. Journ.]

LEAVES OF PURPLE DIGITALIS.

Digitalis purpurea.
Family.—Scrophulariaceæ.
Source.—Europe.
Poisonous in large doses.
Properties.—Diuretic, sedative.
Not sold without "ordonnance."
Used internally in *infusions*, in the proportion of 1 to 4 grams to a litre of water, for dropsy, palpitations, etc.

Cost, per 500 grams.		To sell at
per gram.	per 5 grams.	per 30 grams.
per 125 grams	per 250 grams.	per 500 grams.

Observations—

PASTILLES OR TABLETS OF IPECACUANHA.

Formula.—Ipecacuanha powder, 30; sugar, 1470; mucilage of gum tragacanth with orange-flower water, q. s. To be made into tablets weighing 6 decigrams.
Properties.—Emetic, expectorant.
Sold with "ordonnance."
Used internally.
Dose.—3 to 6 daily as expectorant. (Each tablet contains 12 milligrams of Ipecacuanha).

Cost per 500 grams.		To sell at
per gram.	per 5 grams	per 30 grams.
per 125 grams.	per 250 grams.	per 500 grams.

Observations—

Condensed Milk.

Sir,—It would, I think, interest some of your readers to learn that so far from condensed milk being a new preparation, a kind of condensed milk was in constant use by the army of Chinese Tartary in the thirteenth century, as this paragraph from Marco Polo's Travels will show:—

"They also have milk dried into a kind of paste to carry with them; and when they need food they put this in water, and beat it up till it dissolves, and then drink it.

"It is prepared in this way; they boil the milk, and when the rich part floats on the top they skim it into another vessel, and of that they make butter, for the milk will not become solid till this is removed; then they put the milk in the sun to dry, and when they go on an expedition, every man takes some ten pounds of this dried milk with him, and of a morning he will take a half pound of it and put it in his leather bottle, with as much water as he pleases, so as he rides along, the milk paste and the water in the bottle get well churned together, into a a kind of pap, and that makes his dinner."

Doncaster, October 23rd, 1872. C. Parkin.

C. D. P.—The loss is only one-eighth the quantity of phosphate of iron which is held in solution. We are not aware of any better mode of precipitating it than the Pharmacopœia process, where the soda of the acetate neutralizes the sulphuric acid in which the phosphate of iron is dissolved. The acetic acid thereby set free scarcely dissolves any phosphate of iron, and consequently it is precipitated.

L. W. Marshall.—We think both your preparations of iron must have contained some basic oxide in solution—probably not the same quantity in each. This we find is easily precipitated by many salts and by acids, except hydrochloric, unless these be added in excess.

H. H. Pollard.—It is intended that the Bell Scholar should avail himself of all the privileges provided for him; he must therefore commence his studies at the commencement of the session. See the resolution of the Council recorded on p. 188 of the present volume.

"*Bluff.*"—*Succus Taraxaci.*—We have never seen the juice of dandelion after one-third of its volume of rectified spirit had been added to it become so solid that it could not be poured from the bottle. Such an appearance might have been brought about either by an unusual amount of Inulin being present in the Taraxacum root, or by the roots being much drier than usual, and consequently the expressed juice stronger. The specific gravity of expressed juice of Taraxacum from autumn gathered roots should be about 1·080, and when the spirit is added (before filtration) 1·035. Have these specific gravities been determined? Try to remove the liquid from the solid by placing in a cloth and applying the gentle pressure of a screw press.

"*Piper.*"—(1) We know not what is meant by the term "Nepaul Pepper." Capsicum is sometimes called "Indian Pepper." (2) "Phu" is an old name for Valerian.

"*A Pharmaceutical Chemist.*"—We are unable to find any record that it has been used medicinally.

"*Fair Play*" is referred to the rule respecting anonymous communications.

Editor of the 'Wandsworth and Battersea District Times.'—We are obliged for your communication.

The report of the meeting of the Sheffield Pharmaceutical and Chemical Association, on the 13th inst., and that of the meeting of the Bristol Pharmaceutical Association, on the 15th inst., have been received too late for insertion this week.

ON CALABRIAN MANNA.

BY DANIEL HANBURY, F.R.S., F.L.S., F.C.S.

Read before a meeting of the British Pharmaceutical Conference at Brighton, August 14th, 1872.

Manna, it is stated in the *British Pharmacopœia* (1867), is a concrete saccharine exudation from the stem of *Fraxinus Ornus*, L., and *F. rotundifolia*, DC., which trees are cultivated for the purpose of yielding it chiefly in Calabria and Sicily. Of the method of collecting manna in Sicily there are tolerably exact accounts; and the manna plantations of that island have also been fully described.*

Having never heard of manna plantations in Calabria, nor seen any modern account of manna-gathering in that region, I wrote in 1868 to my friend Colonel Yule of Palermo to inquire if he could furnish me with any particulars. Colonel Yule being unable to answer my questions, communicated them to Mr. Grant, British Consul at Brindisi, who in his turn sought to obtain the desired information from some of the British Vice-Consuls (Italians) in Calabria. But except the statement that the site of its production was the province of Calabria Citra, and especially the territory of Rossano on the shores of the Gulf of Taranto, I was unable to gain any very precise knowledge on the subject.

Here I may remind you of an investigation into the history of manna which I made in 1869,† and that one conclusion to which it led was this,—that manna was collected in Calabria for hundreds of years prior to its being a commercial product of Sicily, and that the earliest accounts of manna-gathering in the latter, only date from the second half of the 17th century.

It will be well now to consider some remarks that have been made by travellers regarding manna as an object of industry in Calabria: though they are only passing allusions, they suffice to show that this drug was at least a well-recognised production of the country in question.

Baron Riedesel, a German nobleman who made an interesting journey through Sicily and Southern Italy about a century ago, and whose travels have been published both in German and English,‡ travelled from Cotrone to Cariati, small towns on the eastern coast of Calabria. Of the latter he remarks that "it is a bishopric of Calabria, * * "round which they collect the best manna and "in the greatest quantity. The owners of the "manna-trees are obliged to sell their manna to the "king for a fixed price: the better sort, or what is "commonly called *in cannole*, for 2 *carlini* [8*d*.], and "the worse, or *in frasca*, for 8 *grani* [3¼*d*.] the "pound. These revenues are farmed for 32,000 "ducats [£5533] per annum. The greatest quan-"tity is collected about Cariati and Strongoli."

About 20 miles west of Cariati is the small town of Corigliano, where, says the Baron, they also collect "*vast quantities of manna*."

Half a century after this traveller, an English-man, the Hon. Richard Keppel Craven, made a journey through Calabria, visiting among other places Cariati, the vicinity of which was at that period still famous for manna. The following is from his published journal*:—"The mountains near "Cariati abound with game, and the forests which "richly clothe their summits furnish quantities of "that species of ash which produces the manna, a "considerable branch of commerce in this province, "and more particularly esteemed from this district."

The foregoing notices, scanty as they are, are yet of interest as coming from eye-witnesses, or at least from inquiries on the spot. Let me now add a few observations of my own, the result of a short journey during the present year through a portion of the province of Calabria Citra.

First, when at Florence I inquired for *Calabrian Manna*, addressing myself to the principal firm of wholesale druggists in that city:—the answer I got was that Calabrian manna was an article they never purchased, but that if I wished to see the drug it was possible, as it so happened that a small keg of it had been sent to them for disposal. Of this offer I availed myself: I found to my surprise that the drug was a soft viscid mass containing small tears, mixed with fragments of leaves, sticks, and dirt,—in fact I regarded it of such very bad quality that I declined a sample which was kindly offered me. I thought also that if I travelled into Calabria I should easily obtain much better, as well as all desired particulars respecting the trade in manna, of which, according to the latest edition (1868) of Murray's *Handbook for Southern Italy*, Calabria Citra is the "principal seat." I accordingly proceeded southward.

Around Florence I may remark, and especially between that city and Pisa, the manna ash (*Fraxinus Ornus*, L.) is frequent, being one of the small low trees grown as a support for the vine. Except these examples I hardly saw the tree until I reached the shores of the Gulf of Taranto, when I observed some very tall specimens in the strip of humid forest a little south of Policoro.

Journeying onward I arrived at Rossano, a town in Calabria Citra, of about 10,000 inhabitants, situated 3 or 4 miles from the sea. Here I learnt that the manna trees, which are called *Ornelli*, grow on some of the adjacent mountains,—that they are of large size, and are *not* cultivated,—that manna is obtained from them by incisions in the trunk made by the peasants in July and August,—that the manna got is mostly of the soft or fatty kind, very little of it being obtained in long white pieces or *cannoli*, and in some seasons none at all.

The collecting of manna about Rossano is at present, I was assured, a very small and insignificant branch of industry. Few persons among those from whom I sought information knew anything of the gathering of manna, or even of the existence of the manna-ash in the neighbourhood. One gentleman a principal inhabitant of the town and holding an official position, to whom I had a letter of introduction, assured me that the incising of the stems of the trees had been since the last four or five years forbidden by the Government; and the same statement was made by others. It is plain, however, that manna *is* still gathered about Rossano though

* See in particular a paper by Dr. Cleghorn on the Botany and Agriculture of Malta and Sicily—*Transactions of the Botanical Society of Edinburgh*, vol. x. 1868–69.

† PHARM. JOURN., XI. (1870) 326.

‡ *Travels through Sicily and that part of Italy formerly called Magna Græcia*, translated from the German by J. R. Forster, F.R.S., London, 1773.

* *Tour through the Southern Provinces of the Kingdom of Naples*, London, 1821.

the amount is quite insignificant, for I obtained from a pharmacien in the town a specimen, being part of some he had purchased from a peasant the previous season.

Hoping for more information and that I might at least obtain better specimens, I went to Corigliano, a small town, the mountains around which produce according to Murray's Handbook, "the finest manna in Calabria,"—a fact without doubt perfectly true a century ago. Here I was told that no manna is now brought in for sale, the collection having entirely ceased. I called on five pharmaciens in the town: three of them had in stock no manna whatever; the fourth had some which he had purchased in Naples, but the fifth (Signor Giuseppe Guidi) had a box containing a pound or two of manna of the country, of which he kindly gave me a sample. He told me that it was old, none being now collected. This manna is a moist, semifluid, saccharine mass, of a dirty yellowish grey.

On the 5th May (1872) I reached Cosenza the the capital of the province, situated at the head of the valley of the Crati, in passing through which I observed a few trees of *Ornus*. The locality was anciently renowned for manna. Here I repeated my inquiries in several pharmacies, but in vain. At length I found one, the proprietor of which showed me some soft manna which he said had been got near Cotrone. I discovered also in another pharmacie manna of two qualities, *scelta* and *in pasta*, both of which the pharmacien stated he had bought of peasants who had collected it at Rossano. The collecting of manna about Cosenza was quite ignored by most of the persons whom I asked for information. Those who had any acquaintance with the drug declared it was no longer an object of industry in that part of Calabria. One pharmacien asserted that the collection of manna had been prohibited for the last six or seven years.

The course of my journey having led me to Messina, I had the pleasure of making the acquaintance of Mr. Robert Sanderson, a merchant of that city of long standing, whose business in Italian produce includes the shipment of manna. On asking this gentleman about Calabrian manna, he informed me he was ignorant of such a commodity; and on my showing him some of the drug in the soft form in which I had procured it at Cosenza, he expressed much surprise, and declared it to be unlike any Sicilian manna he had seen.

No specimen of Calabrian manna was contributed to the Italian Exhibition held at Florence in 1861; but there appear to have been three samples from Rogliano in the London Exhibition of the following year.*

From what I have already stated, the conclusion is I think irresistible,—that Calabrian manna as an article of commerce has practically ceased to exist, and that the collection of manna in that part of Italy is on the verge of extinction.

I regret that when at Rossano I was unable to visit the woods of *Ornus* which undoubtedly exist in that vicinity. But the habits of the Calabrian peasantry are such that it is impossible for travellers to quit the high-roads without personal danger.

The better to inform myself of manna-industry, and especially that I might become well acquainted with the tree, I afterwards paid a visit to the manna plantations at Capaci near Palermo. I also inspected the trees which are cultivated at the *Istituto Agrario Castelnuovo* near that city*, and in the park of La Favorita. But as the time of my visit (May 16–22) was not that for collecting the drug, I have no details of particular novelty to communicate.

Respecting the manna-ash itself, however, I wish to say a few words. It has often been stated, as in the *British Pharmacopœia* (for which in this case I presume the *Prodromus* of De Candolle is the authority), that there are two species of manna-ash, namely, *Fraxinus Ornus*, L., and *F. rotundifolia*. Many modern writers on pharmacology admit but a single species, *F. Ornus*, L., of which *F. rotundifolia* is stated to be a cultivated variety peculiar to Calabria and Sicily, and propagated by grafting.

I do not think either statement satisfactory. *F. Ornus* is very variable even in its wild state, and in the same locality. As to the tree which is cultivated in Sicily, and of which I have examined specimens from all parts of the island†, it likewise presents great variations, but no special form that can be singled out as deserving the name *rotundifolia*, or even that can be recognised as *par excellence* a cultivated variety. It is true that the tree in some manna plantations is occasionally grafted, certain trees yielding a poor supply of saccharine matter being thus replaced by others of a more productive nature. But I observed no grafting at Capaci where the trees are grown like coppice oak in England, and where such a plan of treatment would therefore be hardly worth the trouble.

[The paper was illustrated by several specimens of Calabrian manna procured at Rossano, Corigliano and Cosenza, and by a large suite of botanical specimens of *Fraxinus Ornus*, L., and a stem of the latter showing the incisions for manna.]

EXAMINATION OF SOME SAMPLES OF FERRUM REDACTUM.‡

BY A. N. LITTLE.

Ferrum Redactum, defined in the British Pharmacopœia to be "metallic iron with a variable proportion of magnetic oxide of iron," is described as a fine greyish-black powder soluble in hydrochloric acid, with evolution of hydrogen. Ten grains digested at a gentle heat in an aqueous solution of fifty grains of iodine, and fifty grains of iodide of potassium, leave not more than five grains undissolved, which should be entirely soluble in hydrochloric acid.

In consequence of the difficult nature of the preparation of this substance, the pharmacopœial authorities have permitted an adulteration, or rather a sophistication, with the magnetic oxide of iron to the extent of 50 per cent. The quantitative test of the Pharmacopœia is based upon the insolubility of this oxide in a strong solution of iodine and iodide of

---

* They were contributed by Signor Giovanni Morrelli of Rogliano, Calabria.

* A most interesting agricultural college founded by private munificence, where 22 lads are studying scientific and practical husbandry under the able directorship of Professor Inzenga.

† Many of them courteously presented to me by Professor Todaro of the Botanical Garden, Palermo.

‡ Read at a meeting of the Bristol Pharmaceutical Association, Nov. 15, 1872. See *post*, p. 437.

potassium, which attacks only the metallic iron; any larger proportion of magnetic oxide than that allowed being thus detected.

In accordance with the pharmacopœial directions, ten grains were digested in the solution of 50 grains of iodine and 50 grains of iodide of potassium for about fifteen minutes and filtered; the residue was then dried, and in order to ensure uniform results slightly ignited, dissolved in hot hydrochloric acid, sufficient nitric acid being added to oxidize any protosalt; the solution was boiled, and ammonia added in excess; the precipitated ferric hydrate was then dried and ignited, and from the resulting ferric oxide the weight of magnetic oxide originally present was calculated. By this method the following percentage amounts of magnetic oxide were obtained:—

No. 1. 49·16.	No. 3. 58·40.	No. 5. 69·75
„ 2. 52·60.	„ 4. 59·32.	„ 6. 90·75

or negatively, the percentage amounts of uncombined iron (the standard being 50 per cent.) were as follows:—

No. 1. 50·84.	No. 3. 41·60.	No. 5. 30·25
„ 2. 47·40.	„ 4. 40·68.	„ 6. 9·75

Nos. 1 and 2 agree with the Pharmacopœia in being of a greyish-black or slate colour; Nos. 3, 4, and 6 are of a dull black, and No. 5 of a chocolate brown colour.

If, in the manufacture of Ferrum Redactum, the temperature be not raised sufficiently high, the reduction of ferric oxide to metallic iron does not take place, which probably accounts for the brown colour of No. 5.

Traces of sulphates, chloride, sulphides, and carbides were found in each. Cyanide of potassium, an impurity mentioned in the 'Year Book of Pharmacy,' as resulting from the reprehensible practice of preparing Ferrum Redactum from the residue of the ferrocyanide of potassium manufactories could not be detected. Lead, also mentioned as an impurity, was absent.

The colour of the majority of those samples which have come under my notice is distinctly black, which, if my experiments be correct, is due to the increased admixture of magnetic oxide of iron; hence, most reliance is to be placed in those specimens of a slate or greyish-black colour. An excessive proportion of magnetic oxide in any sample is readily shown by dissolving a little of the suspected substance in dilute sulphuric acid, filtering if necessary, and adding ammonia in excess; if the specimen contain much magnetic oxide, it dissolves with very feeble effervescence and gives a black precipitate on the addition of ammonia, but if prepared according to the B.P. it effervesces briskly, and ammonia produces a dirty green precipitate. Ferrum Redactum, from its liability to become oxidized, should be preserved in well-stoppered bottles.

WOMEN AS CHEMISTS.*

If there is one thing more than another which may be predicated with tolerable certainty it is that commerce, with agricultural and other scientific industries, is destined to attain to a comparatively greater importance than the professions, and will be preferred to them or to salaried service as affording a more ready outlet for energy and application, as being more elastic in development, and as promising larger and quicker pecuniary returns. As instruction becomes more general, it will be less distinction than it now is to be known as an educated man, and the difference between employments which are "genteel" and those which are supposed to be otherwise will cease to be sharply defined. Perhaps we may attain to the condition of things which prevails among the Vril-ya, and our retail shops will be served by children of all ranks "exceedingly intelligent and courteous, but without the least touch of importunity or cringing." Many young men of birth have done very rough work indeed in the colonies, and have enjoyed doing it, and there is even now a good deal of blue blood engaged in wholesale trade. If mental cultivation is worth anything, it ought to fortify the reasoning powers and develope the habit of sagacious foresight. It is, therefore, probable that while the sons and daughters of butchers, bakers, agents, etc., will still continue to swell the ruck of needy professionals, clerks, secretaries, or salaried Government employés and governesses, where, in the nature of things, incomes are fixed and hope lags behind, those who are poor, but better born and more highly educated, will apply themselves to trade, agriculture, and industrial pursuits.

We noticed lately that a new business, at once scientific, privileged, and profitable, is open for the acceptance of educated women who choose to avail themselves of the opportunity. The Pharmaceutical Society has voluntarily offered to admit women to its lectures and examinations. As the subjects treated of are botany, chemistry, and the knowledge of drugs, there are no objections worth naming against the sexes being instructed together. Henceforth any young woman who passes her examination obtains her first-class pharmaceutical certificate, and is free to establish herself in business as "Pharmaceutical chemist and druggist." It is true that this calling, which may be described as science and trade combined, requires method, exactitude, knowledge, great carefulness, and sense of responsibility; on the other hand, it is lucrative, and sufficiently scientific to be highly interesting to intelligent persons. But the shop? Whether woman's good sense will float her over that obnoxious word remains to be seen; and yet between penurious gentility and education, respectability and an established independence in trade, there seems to us no sort of comparison. Of shops kept by druggists and chemists there are two kinds. Those who study the physiognomy of our streets must have observed that in poor and densely populated districts druggists' shops spring up with amazing rapidity, and appear to meet with a tolerably uniform success. One which is at first represented by a few bottles, plasters, and half-a-dozen tooth brushes may be seen before long adorned with plate-glass, coloured jars, etc. This is an "over-the-counter business." Proprietary or patent medicines, pills, plasters, horse medicine, rat poison, and specific remedies for every known disease are sold; but the pennyworth or two-pennyworth of physics are paid for on the spot, and form the staple of the trade and profits. The men who keep these shops are often exceedingly ignorant; but they, nevertheless, prescribe largely for the poor, the advice being as it were thrown in gratuitously with the medicine, and paid for in ready money; it need hardly be said that young and needy medical men are in this way very heavily handicapped. But by the recent change in the law certain drugs may not be sold at these shops, nor may the owners assume the title of pharmaceutical chemists. The other class is that presided over by those who pass the prescribed examination of the Pharmaceutical Society, and is chiefly employed in compounding and dispensing the prescriptions ordered by medical men. To these persons certain privileges are secured, and they are legally entitled to announce themselves as pharmaceutical chemists.

Women are generally very neat and handy dispensers. They may be supposed to have more sense of responsibility than the doctor's apprentice or the druggist's boy

* Reprinted from the 'Pall Mall Gazette,' Nov. 11.

and, as a matter of fact, the wives of many country medical men do almost regularly compound for their husbands' patients. To commence business in the higher branch of the drug trade may require from £200 to £400 in the provinces, rather more in London; but the stock of a druggist has this advantage over many others, it does not eat, it is not perishable, and, if stored in proper vessels, and carefully looked after, it loses none of its qualities by keeping. We have said that it is a lucrative trade. Take, for instance, a prescription containing six doses to be made up in a six-ounce phial; for this the druggist charges 1*s.* 6*d.* or 2*s.*, according to the style and standing of the shop. Now in all mixtures of this kind the proportion of actual physic used is one fourth or one-sixth, but generally much less, the rest being made up of distilled water, of which the cost is almost nominal; and the profit on the drugs generally ranges from 400 to 600 per cent. Again, pills are charged 6*d.*, 9*d.* or 1*s.* per dozen, but there never yet was made a pill of a size to be swallowed by mortal man which could possibly contain one halfpennyworth of drugs. Soda, in nearly all its forms, is bought by the gross, and retailed by the ounce or by the pennyworth, and the same with other substances. There is still another road open to the really intelligent and industrious chemist, by which he may reduce his expenses with the wholesale dealers to a minimum, *i.e.*, by the skilful use of instruments, such as the hydrometer, microscope, etc., by which to test the strength and purity of drugs, and by himself preparing his own infusions and decoctions. If he chooses to advance further, and becomes a proficient in practical analytical chemistry, his assistance will almost certainly be sought in questions of professional research affecting the public health, sanitary reform, river pollution, and so on. All this may now be obtained by any pharmaceutical chemist, whether male or female. Such being the facts of the case, we do not wish to charge the sex with a general perversity and a deficiency of good sense; but if, while women continue to knock at the closed doors of the hospital lecture-room, they decline to avail themselves of the open portal of the Pharmaceutical Society, we shall think it looks very like both one and the other.

THE ADULTERATION OF FOOD ACT.

At a recent meeting of the Commissioners of Sewers for the City of London, Dr. Letheby, the Medical Officer of Health for the City of London, was requested to draw up a report upon the provisions of the Adulteration of Food, Drugs, etc., Act, and the method of enforcing them. He has, therefore, in conjunction with Mr. Baylis, the solicitor to the Commissioners, prepared the following Report, which will be taken into consideration at the next meeting of the Commissioners:—

Gentlemen,—In accordance with your request, we have the honour to report to you on the subject of the Adulteration of Food Act, 1872. The Act was passed on the 10th of August last, and it is entitled 'An Act to Amend the Law for the Prevention of Adulteration of Food and Drink and of Drugs.' The Act differs in several important particulars from the Adulteration of Food Act of 1860, of which it is an amendment, and with which it is incorporated. The chief points of difference in the two Acts are the following:—

First.—In addition to articles of food or drink, as mentioned in the old Act, the adulteration of drugs is strictly prohibited, and the sale thereof is the subject of severe penalties. Besides which, the Pharmacy Act, 1868, is incorporated in the new Act, and with it all the provisions relating to the sale of poisons and the adulteration of drugs.

Second.—In the old Act of 1860 the question of adulteration is confined to the sale of adulterated articles in fraud of Her Majesty's subjects, and to the great hurt of their health; but in the new Act the person who admixes, or causes others to admix, the adulterating ingredient with any article of food or drink or drug is subject to penalty; and a clause is introduced which gives a very precise meaning to the kind of adulteration—namely, the fraudulent admixture of any substance with any article of food or drink or drug for the purpose of increasing its weight or bulk.

Third.—The penalties for adulteration are very different in the two Acts, for in the old Act of 1860 the penalty—for selling any article of food or drink with which, to the knowledge of the dealer, any ingredient or material injurious to health has been mixed, or for selling as pure or unadulterated any article of food or drink which is adulterated or not pure—was for the first offence a sum of money not exceeding £5, together with the costs of the conviction, and for the second offence the publication of the offender's name, place of abode, and offence, in any manner that the justice might deem desirable, and at the expense of the offender, while in the new Act of 1872 the penalty for this offence is increased to £20, and it likewise applies to those who are convicted of selling adulterated drugs. Again, in the old Act, there is no penalty for mixing, or causing others to admix the adulterated article, but merely for selling it; whereas, in the new Act, the persons actually engaged in the process of adulteration are subject to a higher penalty than those who sell the adulterated article; for the penalty for the first offence is a sum of money not exceeding £50, together with the costs of conviction, and for the second offence he shall be guilty of a misdemeanour, and be imprisoned for a period not exceeding six calendar months.

Fourth.—The execution of the Act by local sanitary authorities is no longer permissive, but is compulsory whenever the authorities named in the 5th section of the Act are required to put it in force within their respective districts by the Local Government Board in England; and thereupon the local authorities shall appoint and remove in their respective districts one or more persons possessing competent medical, chemical, and microscopical knowledge as analysts of all articles of food, drink, and drugs purchased within the said districts, and shall pay to such analyst such salary or allowances as they may think fit, but such appointments and removals shall at all times be subject, in England, to the approval of the Local Government Board. For the City of London and the liberties thereof the authorities are the Commissioners of Sewers.

Fifth.—The method of procedure in the new Act is greatly enlarged from what it was under the provisions of the old Act of 1860, for in the latter case the power of prosecuting rested entirely with the purchasers of articles of food or drink, who were entitled, on payment to the analyst of a sum not less than 2*s.* 6*d.*, nor more than 10*s.* 6*d.*, to have any such article analysed by the analyst, and to receive from him a certificate of the result of his analysis, specifying whether in his opinion such article was adulterated, and also whether it was so adulterated as to be injurious to the health of persons eating or drinking the same, and such certificate, duly signed by such analyst, was, in the absence of any evidence to the contrary, sufficient evidence in any court of justice of the matter therein certified, and the sum paid for such analysis and certificate was to be deemed part of the costs of the proceedings. But in the new Act of 1872, in addition to this method of procedure, which is still retained and even extended to drugs, the local authorities must institute proceedings. This is to be done through the inspector of nuisances, or the inspector of weights and measures, or the inspector of markets, one or all of them, as the local authorities appointing them shall think fit to determine; and such inspectors shall procure within their districts, by purchase or otherwise, samples of articles of food or drink and drugs suspected to be adulterated, and shall submit them for analysis to the analyst appointed for the district, and shall, on receiving a certificate stating that the articles in question are adulterated, cause a complaint to be made before a justice of the peace, and thereupon such justice shall issue a summons requiring the seller or the adulterator to appear before the justices in England to answer such complaint, and such summons shall be served by delivering the same, or a true copy thereof, upon the premises where such articles were obtained or sold; and the expense of such prosecutions, if not ordered to be paid by the party complained against, shall be deemed part of the expense of executing this Act. Certain precautions, however, must be taken by the inspector or the purchaser in the conduct of their proceedings, for as proof will be required of the identity of the article purchased and analysed, it is necessary that directly the article suspected to be adulterated is obtained from the dealer, and before it is removed from the place of sale, the purchaser or inspector shall give notice to the dealer or person serving him of his intention to have such article analysed, so that the dealer may have the opportunity of accompanying the purchaser to the analyst, or of securing the article in such a manner as to prevent its being tampered with by the purchaser or inspector. This is especially provided for in the 3rd clause of the Act of 1860, and in the 8th clause of the Act of 1872. Again, in the 10th clause of the new Act the mode of retaining samples for further analysis is prescribed, inspectors being required to receive all articles of food, drink, or drugs, to be analysed by the analyst appointed under the Act, and in the presence of the analyst to take samples from such articles, and having sealed them in his presence, to retain them, and produce them in case the justices shall order other analysis to be made by such skilled persons as they may appoint, in accordance with the provisions of the 5th clause of the old Act of 1860.

Sixth.—In case the dealer considers himself aggrieved by any conviction of the Justices under these Acts, he can appeal to Quarter Sessions, in accordance with the provision of the 6th and 7th clauses of the old Act of 1860, or he can, even when convicted of selling an adulterated patented article of food, drink, or drugs, have a case stated for the opinion of a superior court.

Seventh.—The new Act provides that the analysts appointed under the Act shall report quarterly to the local authorities appointing them the number of articles of food, drink, or drugs analysed by them under the Act during the foregoing quarter, and shall specify the nature and kind of adulteration detected in such articles, and all such reports shall be read at the meetings of the aforesaid local authorities.

Lastly.—The expense of executing the Act within the City of London and the liberties thereof is to be borne out of the consolidated rates raised by the Commissioners of Sewers of the City of London.

Reviewing, therefore, the provisions of the new Act, it appears to us that the following points are deserving of notice:—

A. The third section of the Act declares that "any person who shall sell any article of food or drink, or any drug, knowing the same to have been mixed with any other substance with intent fraudulently to increase its weight or bulk, and who shall not declare such admixture to any purchaser thereof before delivering the same, and no other, shall be deemed to have sold an adulterated article of food or drink or drug, as the case may be, under this Act." Now, the question which, in our opinion, is open to considerable doubt, is the exact meaning of the words "such admixture;" and by way of illustration we will take the case of the following articles, which are notoriously and almost universally the subjects of admixture with other substances for the purpose of increasing their weight or bulk—tea, coffee, cocoa, mustard, and milk. In some cases the admixture is undoubtedly fraudulent, as when exhausted tea, or spurious leaves, or iron filings, are mixed with tea; or when chicory or other roasted vegetable substance, is mixed with ground coffee; or when water is added to milk; but in others—as when cocoa is mixed with sugar, or farinaceous matter, for the purpose of reducing its fatty constituents, which are not always digestible in the pure and concentrated state; or when mustard is mixed with flour or other harmless substances in order to make it an acceptable condiment—it can hardly be said, unless the proportions of the diluents are excessive, that such admixtures are made with intent fraudulently to increase the weight or bulk of the articles. Assuming, however, that they are, is it enough for the dealer to declare at the time of sale that the article is a mixture, or must he name the several ingredients of which it is composed? Or must he even go further, and state the proportions of the several ingredients of the article? It is manifest that until these questions have been settled by some competent legal tribunal, it will not be possible to proceed with any certainty of conviction against those who admix, or cause others to admix, or who sell an adulterated article; or, if it be, that by the mere declaration at the time of sale that the article sold is a mixture, without specifying approximatively the proportions of the constituents, the fraud of adulteration may evidently be practised to any extent and with perfect impunity.

B. As to the adulteration of drink, it is proper to mention that in the Licensing Act, 1872, provision has been made in the 19th and following clauses for the analysis of adulterated intoxicating liquors, and for prosecution thereon, the analyst being a person appointed by the Commissioners of Inland Revenue, and the persons who are to purchase, or otherwise obtain, samples of such liquors for analysis are the police, acting under the orders of the Commissioners of Police or other police authority, or any officer of Inland Revenue. It is a question, therefore, whether the analyst appointed under the Adulteration of Food Act can undertake the analysis of any drink that can be called an intoxicating liquor. Again, the examination of chicory, coffee, and tea for adulterations already committed to the Excise by various Acts of Parliament, dating from the 11th of George I., cap. 50, to the 26th and 27th Vict., cap. 22, and the relation of their powers and the duties of the food analyst is somewhat uncertain.

C. With respect to the appointing of an analyst under the 5th section of the Act of 1872, it is proper to remind you that the medical officer of health was so appointed by the Commissioners of Sewers on the 2nd of October, 1860; but, as from that time to the present, notwithstanding the inducements offered to the public by your extensively circulated notice of the first of February, 1861, there have been but 57 analyses made by him under the provisions of the Act of 1860, if the provisions of the Acts of 1860 and 1872 are to be carried fully into operation it will, in his opinion, be necessary to reconsider the original appointment with the view of providing for the additional work it will entail.

D. It will also be necessary to give instructions to the inspector of nuisances, or the inspectors of markets, or all of them, to obtain samples of articles of food, drink, and drugs, under the direction of the analyst, and in accordance with the provisions of the Acts of Parliament.

NATIONAL CHAMBER OF TRADE.

The adjourned meeting of the chemists and druggists' section of this association was held on Tuesday last at the offices of the chamber, 10, Duke Street, St. James's, to confirm the resolution passed at the previous meeting on the 10th October last, and to adopt measures accordingly.

Mr. A. F. Haselden took the chair.

Mr. F. Morrison, the Secretary of the National Chamber of Trade, having read the minutes of the proceedings of the previous meeting, Mr. Haselden said, as some misconception had arisen in consequence of his title as President of the Pharmaceutical Society having been introduced into the advertisement and notices of the meeting, he wished it to be distinctly understood that he took part in this and the former meetings in his private capacity.

The meeting was numerously and influentially attended,—amongst the number were Messrs. Newbury, Sainsbury, Crispe, Matthews, Pope Roach, Greenish, Carteighe, etc. etc.

The question before the meeting being the action of certain wholesale houses in reference to their supplying the Civil Service Co-operative Societies, it was resolved, after a lengthy discussion, upon the motion of Mr. J. Crispe, seconded by Mr. Hemingway,

"That this meeting use every endeavour in its power to induce the wholesale trade not to supply the co-operative stores, and to solicit their assistance in support of the retail traders."

Mr. Robert Hampson moved, and Mr. Greenish seconded, that the foregoing resolution be sent to all the wholesale houses and manufacturers supplying the retail trade, which was also carried unanimously.

A vote of thanks to the chairman concluded the meeting.

THE BROUGH FUND,

For the Maintenance and Education of the Five Children who have been left unprovided for, by the untimely death,—at the age of thirty-eight—of

JOHN CARGILL BROUGH,

For Ten Years Editor of the 'Chemist and Druggist,' and the First appointed Editor of the 'Year Book of Pharmacy.'

Subscriptions by cheque (crossed London and Westminster Bank), or P. O. Order, are invited, and will be received by Mr. Bremridge, 17, Bloomsbury Square, London, W.C., or they may be forwarded to the honorary secretary, Michael Carteighe, at 81, Mornington Road, London, N.W.

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 30, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE ADULTERATION ACT.

So far as it is possible to judge from what has been made known as to the steps hitherto taken with a view of carrying this Act into operation, it would seem merely to have given rise to a multitude of doubts, difficulties and questions, without offering any prospect of being serviceable to the public. In the report to the City of London Commissioners of Sewers, published at page 424, it will be seen that Dr. LETHEBY, the Medical Officer of Health for the City, and Mr. BAYLIS, the solicitor to the Commissioners, raise a very important question as to the meaning of the words "such admixture," in the third Section of the Act, and they express their opinion that the meaning it conveys is open to considerable doubt, illustrating their view of the case by reference to the articles, tea, coffee, cocoa, mustard and milk. Some of these articles, notoriously, always contain admixtures, and it might become matter of opinion whether or not they were added with the intent of fraudulently increasing the weight or bulk of the article sold. The provisions of the Act do not appear to offer any assistance in settling this question, nor do they indicate the limits within which such well-known cases of admixture are permissible.

Again, it is suggested in the report that if it be sufficient for a dealer, in selling such articles, to declare they are mixtures, the fraud of adulteration might evidently be practised to any extent and with perfect impunity. These are, indeed, most startling obstacles to the working of the Act, and it would appear they alone offer more than usual opportunity for the proverbial coach-and-four being driven through this Act.

But the difficulties of the case are far from being exhausted; there is still the important question as to who shall be the analysts. Medical Officers of Health have, in some instances, with questionable eagerness, put forward the opinion that they should seek and accept the appointments of food analysts; and a proposal has been made to establish two laboratories in London where all the analyses required for the metropolis should be conducted. It is satisfactory, however, to find that the medical press has in nowise favoured either proposition; and the *Lancet* has, with commendable courage, declared that "Medical officers of health are not, as a rule, properly competent to perform the chemical and analytical work required without special assistance." We may also add that even under these circumstances, it would be impossible for them to perform the duties appertaining to the office of analysts under the Act; for supposing analyses were made by competent chemical assistants, the lack of competent chemical knowlege would render the official analysts unfit to appear in court and undergo examination in cases of prosecution.

Doubtless there are exceptional instances of medical men being fully competent to carry out all the duties of analyst under the Adulteration Act, and in such instances we readily acknowledge no one could more advantageously occupy the office; but we protest altogether against the notion of making medical officers of health analysts under the Act without regard to such considerations. Moreover, there are besides the point of competence, very many other reasons which render the tenure of such an office by medical men undesirable; and as regards some of these, we cannot do better than quote the words of a medical man, Mr. R. S. POWER, of Dartmoor, who writes to the *Medical Times and Gazette* as follows:—

"If analysis is to constitute part of the duties of our future health officers,—and without analysis I do not see how they could venture to recommend measures which would frequently entail considerable expense,—it appears to me that the combined duties of medical officer of health and general practitioner are incompatible. The number of hours that the most energetic man can work is limited, and already the profession is overworked without any additional duties. Analytical processes involve a large expenditure of time, perhaps more than may be generally supposed; and if it be so with the professed chemist in a well-ordered laboratory, how much more with an amateur (for the majority of general practitioners must be amateurs in chemical manipulations)! As an example—suppose water is the suspected source of disease,—a scientific man would scarcely venture an opinion on its quality without at least applying the simple permanganate test. Yet see what this involves to approximate accuracy! There is the preparation of a test solution (for the permanganate will not keep at a constant strength, and must be frequently re-made), and the testing of this by another standard solution to ascertain its accuracy before use. Then, suppose the test ready, the suspected water must be raised to a certain temperature (testing cold water is most tedious), not by boiling in the tea-kettle, but with the aid of a spirit-lamp in a clean glass vessel—a process that occupies a good deal of time, as a small quantity of water will not be expedient to operate on. The dropping in of the permanganate follows, and is necessarily tedious; when, perhaps in the midst of the most anxious part, a peal of the bell—Mrs. Smith is in labour, and must be attended at once! No more analysis that day; and worse, the whole must be recommenced with a new sample.

"But our conscientious Health Officer may not be content with this general analysis should he have time to perform it. Comparatively innocent matter may decolorize the permanganate; and, before condemning the water-supply of a house, street or town, he naturally is anxious to know what is this oxidizable matter which he has detected. It may be nitrites; ammonia, indicative of poisonous water, or it may be of vegetable origin, comparatively innocent; perhaps some chalybeate spring is at the bottom of it. The investigation must be carried further, and evaporation, incineration, the application of other tests—and probably their manufacture—take up a great portion of the day; for be it borne in mind that these delicate testings must as a rule be completed without interruption—they cannot be taken up and put down to suit convenience.

"Let any one who has a doubt on the matter take a litre of water and evaporate it in a glass or earthenware vessel to dryness, and note the time it takes—not, of course, requiring the constant presence of the operator, but necessitating frequent looking after.

"Besides the consideration of time comes that of apparatus; and it is surprising the number of appliances such a simple analysis requires.

"But water, though probably the item most frequently needing investigation, is but one of a long list; and when the question involves the possible condemnation of food, implicating perhaps a tradesman's character, one would feel very chary indeed of giving an opinion unless supported by the unchangeable evidence of scientific facts.

"In making these remarks, I speak from practical experience; and every practical man will, I feel, concur with me—that, short and easy as a simple analysis appears in print, it needs apparatus, care, and time in performance.

"Now, with the general practitioner apparatus is purchasable; care is voluntary; but what about the time?"

The justice of these remarks will, we are sure, be recognized by every one at all conversant with the technical details of chemical analysis; and we trust that the Local Government Board will not fail to exercise a careful discretion in confirming the appointments of analysts made by local authorities, so as at any rate to ensure the efficient performance of the duties they may be called on to perform, and at the same time prevent the very possible misapplication of the Act, as a means of persecution, quackery, or mere trade purposes of advertising.

Adopting the view that this Act will be generally brought into operation, it seems that some greater attention should be paid to its prospective working from the tradesman's point of view than has hitherto been the case, and in the first place the thorough fitness of the analysts appointed seems to be especially important in that respect, for it would be impossible to over-estimate the amount of injury which might be suffered in consequence of frivolous or unfounded charges being made. Moreover there seem to be very great and grave defects in the provisions of the bill as to procuring samples of food, drink, and drugs, and submitting them to analysis. We should like to see the power of "suspecting" entrusted to some more definite and responsible authority than the Act indicates, and some better guarantee of *bona fides* on the part of "any purchaser" than the mere payment of a sum ranging from two shillings and sixpence to half a guinea.

As regards the readers of this Journal more especially, we may point out that the incorporation of the Pharmacy Act and the Act to Regulate the Sale of Poisons in Ireland with the Adulteration Act, would seem to have some graver possible effects than appear on first sight of this provision, and we think this aspect of the matter well worthy the consideration of the trade.

In connection with this point it is somewhat curious to note what were the reasons for incorporating the Pharmacy Act, given as follows by Lord Eustace Cecil, one of the active promoters of legislative enactment against adulteration.

"A definition of articles injurious to health was thought to have been sufficiently provided by the incorporation into the Act, of the Pharmacy Act which contained a schedule of poisonous ingredients."

This would seem to leave a wide field still for adulterators, and fully justifies his Lordship's suggestion that, if there was any difficulty as to the interpretation of the statute, a case should be stated for the decision of one of the superior courts. The Pharmaceutical Society has already adopted this course in regard to the question of eligibility for the office of analyst. In so doing it seems to have roused the indignation of the Executive Council of the South-Eastern Branch of the British Medical Association, and to have induced that body to pass a resolution that the ordinary dispensing chemists and druggists of the county are not qualified for the offices of analysts, as well as to decide upon sending a deputation to Mr. Stansfeld, the President of the Local Government Board, with the object of impressing upon him the importance of this and other resolutions they had passed. This proceeding, which seems to have had in reality much of the "hole and corner" character, has, however, been magnified into appearing as a deputation of the entire British Medical Association, and was so reported in the *Times* of Friday, 22nd inst., without this mistake having as yet been rectified, so far as we are aware.

It would not be difficult to point out that it is scarcely pertinent for a small knot of medical men to constitute themselves judges as to qualification for an office which they are admitted to be unfit to fill; but we refrain from entering upon a *tu quoque* controversy on this subject. We must, however, express our surprise that Mr. Stansfeld should so readily have acquiesced in this resolution, and still more that he should have done so as a matter of course. We freely admit that under existing conditions the qualification for conducting analytical work is not universally possessed by members of the trade; but we can at the same time assert without fear of contradiction that in its ranks there are very many who are in every respect qualified to hold the office of analyst under the Act, and to perform its duties with benefit to the public as well as credit to themselves. We trust this apparently very foolish ebullition of jealousy will meet with the repudiation it deserves from medical men in general, and that it may in no way lessen the mutual cordiality existing between two classes so closely connected together.

The next Evening Meeting of the Pharmaceutical Society will be held on Wednesday, December 4th. The following papers are announced to be read on that occasion:—"Note on a Macerating Stand," by Mr. R. W. Giles; "The Extracts containing Chlorophyl," by Mr. J. B. Barnes; "Dispensing Note on Chloral Hydrate," by Mr. J. G. Plumer; "Sulphurated Antimony, Official and Commercial," by Mr. John Moss, F.C.S.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

November 20th, 21st, and 22nd, 1872.

Present on the 20th—Messrs. Allchin, Barnes, Carteighe, Cracknell, Davenport, Edwards, Gale, Haselden, Ince and Martindale. Dr. Greenhow attended on behalf of the Privy Council.

Present on the 21st—Messrs. Allchin, Barnes, Carteighe, Cracknell, Davenport, Edwards, Gale, Haselden, Ince, Linford and Martindale. Dr. Greenhow again attended.

Present on the 22nd—Messrs. Allchin, Barnes, Carteighe, Cracknell, Edwards, Gale, Haselden, Ince and Martindale.

Major Examination.

Five candidates were examined. *One* failed; the following *four* passed and were declared duly qualified to be registered as Pharmaceutical Chemists:—

Butterfield, Edward.......... London.
Saunders, Thomas Bealby .... Cheltenham.
Clarke, George Ernest ...... Stowmarket.
Robertson, Fred. Freer Leslie London.

Minor Examination.

Sixty-five candidates were examined. *Twenty-six* failed; the following *thirty-nine* passed, and were declared duly qualified to be registered as Chemists and Druggists:—

*Mackinna, John .... Dumfries.
*Tearle, Walter.............. Ilfracombe.
*Anthony, David .... Cardiff.
*Colley, John................ Ripon.
*Bothamley, William Parkinson Nottingham.
*Faraker, John Joseph........ New Brighton.
Equal. { *Davies, Richard Morgan, jun. Carmarthen.
{ *Sumner, John Joshua........ London.
*Butler, John Harsant .... High Wycombe.
Manlove, Richard Joseph...... Slough.
Weeding, William Samuel .... Hastings.
Russell, George Hannah...... Frome.
Equal. { Pattinson, Dan .... Whitehaven.
{ Wardle, James .... Bootle.
Allen, Charles Bowen .... Penzance.
Taylor, George William ...... Louth.
Elmitt, John Henry .... Horncastle.
Markham, William Charles.... Bristol.
Horrax, John .... Keswick.
Equal. { Duncalf, Thomas Henry...... Macclesfield.
{ Stibbs, James .... London.
{ Young, Horatio Thos. Barmby Hull.
Parris, Thomas Watkin ...... Taunton.
Morton, Henry.............. London.
Equal. { Chesterton, William Peter .... Walsall.
{ Crew, William Thomas ...... Manchester.
{ Johnson, Fletcher Atkinson .. Driffield.
{ Williams, Thomas .... Welshpool.
Griffiths, Evan .... Cardiff.
Ferriday, William............ Ardwick.
Urwin, Matthew .... South Shields.
Shakerley, Benjamin .... Liskeard.
Vigis, Joseph Lewis.......... Shepton Mallet.
Equal. { Birrell, George .... Kensington.
{ Wilkerson, William James.... Epsom.
Crundall, Augustus Horton .. Cirencester.
Gatenby, Robert .... Beverley.
Buswell, Arthur .... Winchester.
Sale, Thomas John .... Ipswich.

The above names are arranged in order of merit.

* Passed with honours.

Preliminary Examination.

The Certificates of Examination of the undermentioned were received in lieu of the Preliminary:—

Certificates of the University of Cambridge.

Bothamley, William Parkinson Nottingham.
Dear, Theophilus .... Hornsey Rise.
Marson, William .... Stafford.

Certificate of the University of Oxford.

Wood, Henry Thomas Gibbons .. Hull.

Certificate of the Society of Apothecaries.

Hart, Alice Marion .... London.

Certificates of the College of Preceptors.

Bellingham, Sydney .... Worcester.
Colling, Herbert .... Brighton.

NORTH BRITISH BRANCH, EDINBURGH.

The first meeting for session 1872–73 took place in the Society's new rooms, St. Giles Street, on Friday evening, February 22nd, at 8.30. There was a good attendance; Mr. H. C. Baildon, president, in the chair. Apologies for absence were read from Professor Balfour and Professor Archer.

The following introductory address was delivered by the President:—

Although I should have preferred to have seen the presidential chair of the North British Branch of the Pharmaceutical Society occupied this year by some one more able than myself to fulfil the duties devolving upon the occupant of this honourable office, yet, as a mark of your continued confidence, I return you my best thanks for the honour you have again conferred upon me.

In my address at the opening of the last session, I alluded to the prospect we had of obtaining a suite of rooms worthy of the position of the North British Branch. The Council found it no easy matter to obtain premises in all respects suitable, and after a very exhaustive search the rooms we are now in were, all things considered, thought the most eligible for our purpose. The situation is central; and if there is a difference in the convenience to our members, it is in favour of the Old Town, and this the Council thought a recommendation, as hitherto the rooms occupied have been situated at a considerable distance from the places of business of our friends on the south side. These rooms were originally taken to be entered last May, but at that time they were found in such an unfinished state as to determine the Council to postpone taking them until the present term. This has necessarily delayed the formation of an enlarged museum, and considerable additions to our library, but immediate steps will, I hope, now be taken to supply both, when we have ascertained the accommodation afforded by our cases for the proper reception of books and specimens, and when we have reported the same to the London Council. I hope this session will be quite equal to its predecessors in the arrangements for our evening meetings for scientific purposes. Our indefatigable honorary secretary informs me that Professor Crum Brown has promised a paper for our December meeting, Dr. Stevenson Macadam a lecture in January, Dr. Mackendrick in February, Professor Archer in March, and Dr. Arthur Gamgee for April, when our session closes. This arrangement by no means precludes our own members from reading papers between those periods. That vexed question, "What is the best mode of providing for the education of the rising generation of pharmacists has been discussed both at the Pharmaceutical Conference at Brighton, and in the Pharmaceutical Journal by the numerous letters which have appeared in its pages, but I do not think the problem is yet solved. I have carefully read the various and conflicting schemes proposed for effecting this most desirable object. For my own part I should be sorry to see any steps taken by the Society which would place our students in a position of dependence upon external pecuniary aid. If taken from the right class in society, I cannot see why they should not be as able to obtain a proper knowledge of pharmacy in the same way as the students in medicine, and of the other professions do. And although the expense of attending lectures may prevent a few from selecting pharmacy as their profession, I can see no disadvantage in this, but on the contrary, those who enter will be drawn from a class who have had a better preliminary education, able at once to pass the initiatory examination, and whose parents and friends are able and willing to provide the means to enable them to acquire a theoretical as well as practical knowledge of pharmacy.

It appears to me that the only legitimate way in which the London Council could assist pharmaceutical education in the provinces, whilst preserving the independence of the student, would be by providing rooms, a museum, and library in convenient centres, and even in smaller towns, when an earnest desire existed to make good use of these expensive but necessary accessories. To go beyond this would tend to enervate rather than brace the generality of our students. Self-help and self-reliance should by every means be encouraged. As a rule what costs nothing is little valued. As you will have seen by the programme, an opportunity will be given this evening of having this important subject discussed, and it will be introduced by Mr. Mackay reading a short paper expressing his own views on this vitally important subject.

No city out of London affords greater facilities for acquiring knowledge than does Edinburgh, and the arrangement made by our honorary secretary as to lectures should be taken advantage of to a much greater extent than has been the case in previous years. Mr. Mackay reports that at this date he has issued fourteen tickets for Dr. Macadam's lectures, one ticket for analytical and three for practical chemistry.

I am very pleased to see the example first set, I believe, in Edinburgh, of making it incumbent upon all youths to pass the Preliminary examination before the indenture is prepared, is now being acted upon in other places. It not only affords a test that the youth has been sufficiently educated to fit him for his future career, but it relieves him from a weight of anxiety which would otherwise press upon his mind until he passed this examination, and enables him at once to enter upon studies directly connected with pharmacy. I would also suggest that every indenture, in cities where they can be obtained, should make it imperative for the apprentice to attend during its continuance a class of chemistry, materia medica, and botany, which, with the practical knowledge acquired in his place of business, should enable him to pass the Minor examination at the termination of his apprenticeship.

The Act of Parliament for preventing the adulteration of food, drinks and drugs, which passed on the 10th of August, renders it doubly imperative on our members to test carefully every drug and chemical before taking them into stock. The time has long since passed away when with some wholesale houses adulteration might be said to be the rule, especially as regards essential oils and powders. Still there are ample reasons for testing the more expensive class of chemicals. A good many years since a parcel of one of our most important alkaloids, the muriate of morphia, upon the purity of which human life frequently depends, came into my hands direct from the manufacturer, and answered all the usual tests satisfactorily, except the test of experience. A lady, who had long been obliged to have recourse to it, having obtained her usual supply, after taking a few doses, declared it was adulterated, and was so positive that I placed a sample in the hands of one of our largest and best makers of morphia here, and although they were satisfied there was adulteration, still it was not discoverable by the usual tests. But upon separating the morphia, it was found to be adulterated to the extent of 25 per cent. The adulterant was eventually proved by an eminent London maker to be white sugar.

In 1842, the 'Journal de Chimie Médicale' offered four silver medals to be awarded to the authors who should furnish to the journal the best notices on adulteration not yet made known, and on the means of detecting them. I believe adulteration in America has been, and still is, practised to a great extent. In this country some articles of large consumption, such as tea and spirits, have been found in London and Glasgow to be frightfully adulterated. Nay, in some instances, deleterious *substitution* was practised—neither tea nor spirits being found in the samples analysed. It is to be hoped the present Act will be so carried out as to greatly lessen, if not remove this evil.

I would now submit to the inspection of the members some interesting vegetable products of the East, sent to me from Singapore by my friend Mr. Jamie, and I shall simply read extracts from Mr. Jamie's letters, describing them in his own words. He writes, "The first specimen is a stump of what I fancy is a tree-fern (*Cibotium*), which the natives on the east coast of the Malay peninsula, at a place called Sangora, use for the stopping of bleeding. It was brought to me by a gentleman who was in that direction prospecting for tin, etc., where it was exposed for sale in the Sangora bazaar."

In reference to this specimen I would refer you to two very interesting papers contributed to the 1st series of the PHARMACEUTICAL JOURNAL, vol. XVI. by Mr. Daniel Hanbury and Professor Archer. It is known by the name *pengawar-djambi* or *pulu*. By some of the old authors it is considered to be the 'Scythian Lamb,' 'Frutex Tartarus,' or 'Vegetable Lamb.' "It was said to spring from a seed like a plant, and be attached to the earth by a root, whilst in its animal nature it rejoiced in a sort of flesh and blood, browsed upon the surrounding herbs by turning round upon its axis, or root, until, having devoured all within reach, it perished a victim to hunger." It has a place in the Dutch Pharmacopœia. As a styptic, the hair of the stipes may be employed in the same way as cotton, wool, tow, or the nap of a beaver hat. The styptic action is supposed to be simply mechanical. Professor Archer says, "The most striking feature is the abundant clothing of long, sparkling, golden-brown, moniliform hairs, with which the outer part of the stipes is thickly covered, and which, at the first glance, suggest for the drug an animal rather than a vegetable origin."

The second specimen "is a bottle containing the hairy down of the leaves of a jungle-tree." Mr. Jamie writes, "I am very sorry indeed that my botanical education will not enable me to send you the regular orthodox description, but I have done the next best thing, that is, I have sent you by post some of the leaves, from which I think any botanist will readily class it. As far as my knowledge goes, I should say it belongs to the Thalamifercus class. The tree, or rather sapling, I took the leaves from was not high, but it grows to a large tree. This hairy down only grows on the young branches and leaves. As the tree grows so does the down leave it. To see the hairy down on the trunk of the tree just reminds me of a hare's foot; to the feel it is exceedingly soft, and if burnt puts one in remembrance of amadou burning, or somewhat like nitre paper, for it scintillates. It is a good styptic, and might become useful in stopping bleeding. I have prepared a little with carbolic acid, and use it for slight cuts, which it heals quickly. Under the microscope it has very much the appearance of cotton fibre. Whether it could be put to any economic use will greatly depend on whether quantities could be got. I have no doubt the tree grows all over India and Java, as well as in the Malay peninsula. The leaves yield large quantities, for what is in the bottle came off six leaves. One day, being in the jungle, I observed the same kind of leaves, but very much destroyed by being full of round holes, and as I was wondering what could have produced such an effect, I saw an insect come and cut a piece out of a leaf and fly away, probably to build a house for itself; so that the hairy down is useful to insects, whether it is or not for animal life." I submitted these leaves to Professor Balfour, who, however, was unable to classify them, although he took great pains to do so. I then forwarded them to Professor Bentley, who, in reply, writes, "I am sorry I can give you no positive information as to the plant yielding the leaves you forwarded to me. I did not recognize the leaves, but thought they were derived from a species of *Ficus*. I therefore went to the British Museum, and submitted them to Mr. Carruthers and his assistants, but no one could identify them. Mr. Carruthers thinks they are derived from *Ficus tomentosa*, but as there were no specimens of this plant in the British Museum herbarium, no positive data existed by which they might be traced to that plant. Unless, therefore, some botanist from India could recognize them at sight, the only way to trace their botanical source would be to obtain specimens of the flowers, etc., with the leaves of the plant. Judging from the down from the leaves, it seems to be probable it might be useful." Since receiving Professor Bentley's letter I requested Professor Archer to examine them, and he has pronounced them to be the leaves of *Ficus lasiophylla*, from a young plant. The hairy down decreases with the age of the tree.

Mr. Jamie takes great interest in our Society, and he fully expected to have made a very interesting contribution for the opening of last session. He wrote me, "You will be sorry when I inform you that I am unable to forward you an article to read when you are president, which is disappointing to myself, as I made every effort and went to considerable expense to be able to send you something both new and rare. It was to be on essential oil as an article of perfumery; but not getting a sample of it made through not knowing the nature of the flowers, I thought it useless to write an account of it without being able to place before the Society a sample of the oil. Now that I am on the subject I shall just mention the plant of which I thought the oil would be a valuable product. The natives here call it Champaka Putch. 'Putch' is Malay, and means white. There is another kind called Champaka Kiming (yellow), the flowers of which have a strong and not unpleasant smell, and are very much used by the natives in the East for the perfume, for which they pay a high price. The white flowers are still more valuable, and give a far pleasanter perfume. In 'Gray' you will find a very short account of it under the Sanskrit name, and in the 'Treasury of Botany,' under the botanical name *Michelia champaka*, you will find a condensed account of it. In these I think the yellow is meant. The yellow is propagated from seeds, but the white is cultivated from grafts. I had collected about 50 lb. of flowers of the white, and expected a beautiful sample of oil; but before I could get them distilled, fermentation began and completely destroyed the whole. I hope better success will attend my endeavour next time if I should again venture on the same experiment. I do think it would be worth the while, and shall try to keep it in mind. The Ilang-Ilang of Manilla, in my opinion, cannot be compared to it."

Mr. Jamie, in his last letter, writes, "I am very sorry to say that I have had no opportunity of again trying the flower of the Champaka for the oil, as this year we have had no flowers, nor has anything occurred to my observation worth communicating through you to the society. I suppose the museum is not to be confined entirely to one branch, but that every branch of the animal and vegetable kingdom will be represented as well as inorganic specimens. In the expectation that minerals will be acceptable, I have bespoke a specimen of galena found on the east coast of the Malay peninsula, between Sangora and Patani, from the gentleman who brought me the tree-fern. He was successful in discovering three mountains of galena (sulphide of lead), rich in silver. It is said on very good authority that ten years will not take away one of them, though wrought night and day. A gold company also has been formed in Malacca. The assay of gold to the ton is 4¼ oz. I shall try to obtain a piece of the quartz. A tin mining company has been formed also near to the gold. When once they have begun I shall try to obtain a specimen of it. Should you think the tree-fern and the hairy down and leaves worth presenting to the museum, by all means do so."

Thus far Mr. Jamie: I am sure you will agree with me that it is very gratifying to find a zealous worker in so distant a place as the Malay peninsula. I shall no longer trespass upon your time, but ask our honorary secretary to read his paper on "Pharmaceutical Education."

At the close of the address Mr. Mackay proposed that a hearty vote of thanks should be tendered to Mr. Jamie at Singapore, who, though so far distant, yet had remembered the Society's museum here, and that Mr. Baildon should be asked to transmit the same on the first opportunity when writing to Mr. Jamie. This was carried by acclamation, and the President said he would have much pleasure in acceding to the wish just expressed.

Mr. John Mackay then read the following paper on "What course ought the Society to follow in reference to Pharmaceutical Education?"

There is no subject of more importance at the present time than the question of pharmaceutical education. So much has been said and written regarding the best means of giving an impetus to the educational department of pharmacy, that it occurred to me as a right and proper thing, on this the opening night of our session, to give the members of our society an opportunity of expressing their opinion in connection with what has been for so long a keen object of discussion.

I do this all the more readily that while so much has already been written, printed, and circulated, no fixed plan has, up to the present sime been received, adopted, or recommended by the London Council.

My remarks will not extend to any great length, because my desire is chiefly to draw the attention of those hearing me to the leading facts in connection with this question, and by so doing induce a discussion, in the course of which some new views may be evolved, and thus add to the existing and expressed ideas as to the best mode of improving the means of educating those whose daily work is connected with pharmacy.

In very shortly reviewing our position, let me remind you, that the primary object sought for in establishing the Pharmaceutical Society was that of advancing chemistry and pharmacy, and thus promoting an uniform system of education among those who carried on the business of chemist and druggist. With what energy this has been done, and what amount of success has resulted from the anxieties and labours of the founders and their successors, is known to many of you. I am one of those who think the Society has done its work ably and well. But I also believe that the time has now come, when the system hitherto pursued ought to be modified and changed. At the opening of the session last year in London, I ventured to hint that ere long our Society would cease to be an educating body, and I fancy that prediction will ere long be fulfilled.

Glancing at the Acts of 1852 and 1868, and the bye-laws formed in accordance with them, we have very specific and stringent clauses, not only regarding the appointment of examining boards, but also indicating the nature and extent of the powers so conferred. Now, I admit freely, that during the early part of our existence, under the operation of the laws just referred to, there existed a real necessity that the funds of the Association should be spent, and that freely, in furnishing opportunities and appliances of which all those requiring to prepare themselves for examination might, if so disposed, fairly take advantage. At the period to which I have referred, schools of pharmacy were unknown, and lecturers or teachers in the requisite sciences were comparatively few, while the difficulties in the way of attending chemistry, materia medica, and botany was considerable. Hence lectures, and paid lecturers, in connection with the Society in London, were established, and, along with an excellent laboratory, have existed up to the present time. I do not stop to inquire the amount of money which has been thus spent during the last thirty years as a part of our own school in the metropolis, because good fruit has been borne from the seed implanted by the labours of such men as Thomson, Pereira, Redwood, Bentley, Attfield, and others; but leaving the past, and looking to the future, the great question now almost forced upon the members of our Society is—Are we to continue in perpetuity the machinery which has been kept in motion so long, or are we to make a change; and, if so, of what character, and to what extent, and in what form, are we to carry this out?

In connection with this subject, the nature of existing fees and subscriptions promises to open up a field for argument and debate. The money now accumulated, belonging to the funds proper of the Society, and amounting to many thousands of invested capital, is considerable, and I am quite ready to admit that there is no necessity for us to go on increasing this sum; but I feel there is as little call to diminish either examination fees or annual subscriptions. Our weekly Journal is almost self-supporting, notwithstanding so many thousand copies are sent free every week throughout the year to all parts of Great Britain. But the feeling becomes stronger and stronger that, without encroaching at all on our funded capital, we are bound in the same way out of our yearly profits—if I may be allowed to call the annual balance by such a name—to make provision for and assist those who are disposed to help themselves, or who may be prepared to take advantage of certain proposed arrangements, by annual grants of money. Now we come to the difficult and knotty point, and I hope many here will express their feelings freely upon it.

Several propositions have already been made, but as yet no one course has been considered sufficiently correct or practical to be acted upon. Let me summarize the principal of these:—

1. It has been proposed that several central schools of pharmacy should be formed in various towns throughout the provinces, and money voted for this purpose from the Society's funds.

2. That certain examinations should be conducted simultaneously throughout the country, and that payments as well as prizes ought to be made according to certain results.

3. That two great schools ought to be formed, one in London, and the other in Edinburgh, and that pharmaceutical students be urged to find their way to one of these centres, and there prosecute their studies.

4. That sums of money be voted in cases where a certain local amount is subscribed, and the money so given be spent in any way thought best, by those in the locality, so long as it promotes and assists pharmaceutical education.

5. That compulsory attendance at certain courses of lectures should be insisted upon before any candidate be admitted for examination, and that proof of such attendance be given by the exhibition of class tickets, comprehending chemistry, materia medica, pharmacy and botany.

Other ideas have been promulgated, but the foregoing will serve to bring to your recollection some of the leading features of schemes long before us. I do not quite agree with any of these proposals.

Referring to London, I think we would do very wrong to give up our habitation in Bloomsbury Square. Among the very first steps taken in connection with the foundation of our Society in London was the formation of a library and museum. Both these departments have been carefully tended, and in point of value and interest continue a credit to our Association. These, therefore, I would continue to foster and increase. Plenty of space and accommodation must also be secured for examinations, as well as for the operations of our Council Government, Secretary and Registrar. I would further grant the name of professor to our lecturers in London, but would abolish their annual salaries. The use of the lecture-room might, however, be given free. All pupils who attend the prelections, or who occupy benches in the laboratory, ought, I think, fairly to pay such fees as would render each department self-supporting. By such an arrangement young men resident in or visiting London, would always be sure of good sound instruction at a fair remunerative value, with the immense advantage and privilege of having the free use of a good library and excellent museum.

But having referred to our great centre, we now glance at the position of the provinces. How are they to be treated? I submit the following for consideration:—

Let all towns, large and small, where chemists and druggists are to be found, be looked upon as places requiring some assistance, more or less, in aid of pharmaceutical training. Admit this as a principle differing only in degree, but taking our London establishment as a type of what might be fairly imitated. Books, specimens, and a place of meeting ought, I think, to be accessible to all connected with pharmacy, in every place were there are a few connected with our business, who express a desire to keep pace with the advancing state of pharmaceutical literature, as well as doing justice to those young men, who, if they follow out their daily occupation, will require to fit themselves for their examinations.

I know many young men who go up for their Minor are often puzzled with some of the drugs submitted to them for recognition. For instance, I have heard more than one declare he never saw jalap root, and and others equally at a loss when ipecacuanha was presented to them. Some may smile at this, but these parties on being asked from what source they obtained material for preparing the tincture of the one and the wine of the other, promptly replied that in both cases they used the powder. And so with many other articles, but more especially botanical specimens. Now, if sets of the various substances in materia medica and chemistry were made available, it is not, I think, too much to believe, that the examination of many of the articles externally, might lead to the getting up of the habitat and other particulars, such as uses and doses of root, plant or gum. Again, there are many establishments in country towns, and even in large cities, where there is a great paucity of books. In all such cases, I conceive a well-assorted library might prove of very considerable advantage. Further, accommodation might fairly be given free to any gentleman who was disposed to give a short series of instructive lectures, on the understanding that so far as his own remuneration for such services was concerned, he would be paid by the fees of those who attended his demonstrations.

But the cry with many is still give us lectures, and let the funds of the Society be spent in paying, or, at all events, assisting to pay gentlemen for giving lectures in different places. No one can more appreciate the advantages of such instructions than I do, yet I am equally certain that in many, I would almost venture to say the majority of instances, young men have not the opportunity, while others have not the inclination to attend such courses of lectures. I refer, of course, to the great mass of our apprentices and assistants scattered up and down the country throughout England, Scotland and Wales.

Further, we must remember some do not go to the lecture-room at all, and that though attendance there is *desirable* yet it is not a *necessity*, for we have constant proof of young men who with books and specimens and earnest study fit themselves for our Minor and Major examinations, passing both, not only creditably but sometimes in honours. And it is for this reason I enter my protest against making it *compulsory* to attend certain courses of lectures and producing certain tickets of attendance on such lectures, before candidates can be admitted to examinations. To insist on this, as has already been seriously proposed by a most able and intelligent teacher, would be to destroy altogether the present constitution of chemists and druggists. Not only so, but I have great doubts whether if such a course were acted upon, the desired end would be obtained. The earnest pupil who has opportunity would doubtless be much benefited by attending classes; but I feel assured that there would be many cases where a ticket for regular attendance might be produced without a corresponding benefit. In other words, I would rather have the application of a diligent student at home, than the mere attendance under compulsion, of the careless or indifferent youth. Cases have been known where young men not caring to study, but compelled to go through a stated course, have spent their time in the lecture-room otherwise engaged than paying attention to their teachers, but yet entered an appearance in order that class-ticket and certificate of attendance might not be wanting when called upon. I do not detract in any way from the value of scientific teaching either in lecture-room or laboratory, for I consider it a most laudable and praiseworthy thing for any young man, who from position, inclination and circumstance can take advantage of systematic study and class teaching to do so to the full, as by so doing he is in the highway, not only to improve himself, but also raise the standard of true pharmacy. What I demur to, is making certain courses of such study not optional but compulsory. Now I trust I am not misunderstood in what I have just enunciated. I am desirous that legislation should be effected more for the present than for succeeding pharmacists. The constitution of our body is such, that until many things change in regard to our daily occupation, we can scarcely at the present time dare to compel a higher scientific standing than what has been, and still is, insisted upon as being possessed by all who wish to be placed upon the Government register. The day will doubtless come, and that perhaps sooner than many expect, when the true value and position of a dispensing chemist may be properly and duly recognized. But we all know the almost miserable pittance which at present many of our brethren make, even though they toil from early morning till the latest hour of night. Go where you will, in large city or country town, and you will find that the very few have comfortable incomes, while the many have just enough to do. It is, therefore, I submit, self-evident that no increase in compulsory education will in the meantime be a cure for this state of things. Prices as a rule must advance, assistants must be better paid, and druggists' shops must become fewer before even the commencement of this improved condition of things; and I would, therefore, ask for a gradual improvement in these points before insisting on such a radical change in the education of our young men as I know many are desirous of making.

In connection with pharmaceutical training, I may mention what I believe will interest all here. In lately glancing over the minute-book of our North British Branch, I found the following which I give *verbatim* as it is to be there found. It refers to a meeting held in Edinburgh in 1853 to discuss the operation of the Pharmacy Act of 1852. Jacob Bell was present, as will be seen from the following:—

Extract from minute of meeting held in Edinburgh in March, 1853.

"Mr. Mackay moved the following resolution:—

"'That it is expedient, in order to assist in carrying out the provisions of the Pharmacy Act, to render it imperative that all future apprentices to pharmaceutical chemists in Edinburgh, Glasgow, Aberdeen, St. Andrew's, and other places where lectures are delivered, shall attend at least one course of materia medica and one course of chemistry; and resolve that this meeting strongly recommends an especial clause in each indenture to that effect.'

"This was seconded by Mr. Bremner, and agreed to.

"It was further proposed by Mr. Jacob Bell—

"'That this meeting recommends that pupils attend a course of instruction in practical chemistry and botany wherever they have an opportunity of so doing.'

"This was seconded by Mr. Flockhart, and agreed to."

Here let me remark, judging from the above in regard to educational requirements, our position does not much differ at the present time from what it did twenty years ago, for had the above recommendation been carried out, cramming and other forced modes of instruction would not have bulked so largely as they do at the present day.

I dare say many of you have read the excellent address of our friend Mr. Savage, at the opening of the Brighton Association of Pharmacy, which appeared in the Journal of the 16th inst. The remarks speak for themselves, but you could not fail to be struck with that portion where he says that "in the evening of Tuesday last I attended a meeting of the General Purposes Committee in Bloomsbury Square, when a deputation of five members of the Examining Board met us, and Mr. Carteighe, as their exponent, went most fully into the proposed change, whereby the Minor after this year will become the principal practical examination, etc." Now it appears to me that you only require to increase the stringency of your examination as thus hinted at, and at the same time increase your money payment as I believe is already contemplated, to cause many to leave the business, and also prevent many others from entering it. I do believe the existing Minor and Major examinations as conducted in London and Edinburgh are fair tests of the ability of the candidates to be admitted to the higher or lower grade of our Society; and I unhesitatingly affirm that I for one will oppose so far as I can increased stringency or additional money payments in connection with either examination. No young man can go through the Minor in less time than three hours' constant and unceasing work, while the Major requires at least seven or eight hours to complete the examination. Let us know our business well, practically and fairly, but do not insist upon a knowledge far above and beyond what Minor or Major examined man may be expected to possess.

I promised at the outset that my remarks would be short, and I dare not therefore extend them, for I trust the whole subject will be fairly discussed. I may, therefore content myself with simply indicating what I think the course of all pharmaceutists ought to be at the present moment, keeping in view, that the time may yet come, when there will be a necessity both for extension and change in the system at present followed in training our youthful friends.

1. I think every master is bound to see that his apprentices pass the Preliminary examination of the Society before they become bound by indenture.

2. In every indenture there ought to be a mutual obligation between master and parent or guardian, that the former will afford time to the apprentice to attend at least one course of chemistry, materia medica, pharmacy, and botany, while the latter becomes bound to furnish the necessary funds to enable the youth to take advantage of the time so given.

3. As such a system could only be carried out where

lectures are delivered in connection with University, College, or School of Pharmacy, time should be given in the absence of such opportunities in country towns for the systematic study of these important subjects, either in the morning or evening, as might be found most convenient with business arrangements.

4. As a rule, let the term of apprenticeship be five years.

5. That the study of the different departments should be aided as much as possible by the use of books and specimens of drugs and chemicals.

6. At the close of such an apprenticeship, let each young man devote as much time as he can to the study of practical chemistry, and by keeping up his reading, so fit himself to pass his Minor examination.

Now these propositions are very simple, and will at once convey an indication of the kind of aid which I think the parent Society ought to extend to her children, especially if it can be proved that they are in want of, or desire such needful assistance. I have already plainly hinted my own feeling as to the direction in which the funds of the Society should for the present be spent, and if thus taken advantage of, I feel that with our examinations continuing as they now are, there can be little fear that either uneducated or illiterate men will ever be found filling up the ranks of the pharmaceutical army, and so bring down, as many have feared, disgrace upon all connected with our profession.

Already we have in our pharmaceutical horizon many bright constellations, men well known for high intellectual and scientific attainments; but I conceive it is equally certain that with facilities already given, and still to be acquired, young men generally may be fairly educated, and with ordinary application and perseverance, prepare themselves to occupy their important and responsible position of dispensing medicines to the sick, and thus carefully and correctly fulfil the intentions of the prescriber.

A discussion then followed on the subject of the paper.

Mr. D. R. Brown (Macfarlane and Co.), said he was now of the same opinion that he had been all along—that a thoroughly furnished pharmaceutical chemist required a much wider and more extensive education than the great majority had hitherto got. He thought a very great advantage might accrue to them if they looked to what was past. In former days, the apothecary had a much wider education, and a much better pay than the ordinary pharmaceutical chemist of the present day. He held a very respectable position, indeed, and if they just recollected, there was scarcely a branch of science but took its origin from the old apothecary. The present degraded position of pharmaceutical chemist arose from the fact that they permitted science to be taken out of their hands by men more competent than themselves. There was not an article in the possession of the old apothecary—if it were plant or mineral—but had been gathered by himself, and if it were a pharmaceutical preparation, but had been prepared by himself. The pharmaceutical chemists of the present day had permitted all these things to be taken out of their hands. They went to the manufacturer and bought an article, and, very much like the grocer, they sold it in retail. The result of that was, that an uneducated class of men had come amongst them whose only object was to live and make money. That was all very right and proper when carried on in moderation, but those he spoke of pursued it too eagerly, and tried to do it at the least possible expense to themselves. He held that progress was absolutely necessary for them. The world was progressing, and what had happened, had happened because they allowed themselves to remain stationary, whilst others were moving forward. He believed the time would come when the making up of prescriptions would pass from their hands if they did not take better care of themselves. Medicine just now was in a transition state, had become a science, and knew that chemistry was one of its best handmaids. Medicine had been investigating the healthy condition of all the organs of the body, examining their secretions, knowing what was in them in their normal condition, and learning what they became in their abnormal. Another step in the practice of medicine, and the pharmaceutist will vanish. No such a thing as pharmacy will then be in existence. It would become a dead art; and the reason was this, that the physician having the science at his finger ends would not be content to work on uncertainties. He would compel the pharmaceutical chemist to eliminate the active principles of everything he dealt with, and to put them into his hands that he might measure them with perfect accuracy. To prevent all this, he held that pharmaceutical education should be a much wider one than it was at present. He acknowledged one of the best steps was the Preliminary examination. He next held that they could not make their examinations too stringent, but he also acknowledged that Mr. Mackay was right in saying that in the present condition of the profession it would be wrong to insist upon it. He thought that if a man took a lad and bound him apprentice for five years, and took his services, as they were taken, for a very few pounds indeed, that master was bound to see that his apprentice was educated in his profession, and educated at his expense too. It was utterly impossible, scattered up and down the country as they were, that many of their young men could attend lectures. He thought that each master should provide his own museum, and spend some time upon his apprentices. Why should he not undertake various pharmaceutical operations for himself, if for no other purpose than that of educating his apprentices? Why should he not undertake some chemical experiments and make a good many of the substances in which he dealt. Multitudes of them were easily made, and did not need to be manufactured in large quantities. The cost would be very little. He saw no other way of educating the profession as it ought to be educated unless the master took the apprentice in hand. It was his duty. In a great many places, such as Edinburgh, Glasgow, Aberdeen, St. Andrew's, where large numbers were to be found willing to attend classes, these should be provided. He was adverse to the Pharmaceutical Society of Great Britain providing anything for the apprentices but examination.

Mr. Frazer (Glasgow), said the difficulty he felt was brought out by Mr. Mackay. It was impossible to hit upon a scheme that would be acceptable to all parts of the country and all circumstances. He had tabled his proposal in the month of March. They had a surplus sum of money of £1500 or £2000. He wanted the Council of the Society to set aside what they could spare for educational purposes. It was impossible for every druggist in the kingdom to go to London for what he wanted. Let them put their hands into their pockets in each locality, and for every 20*s.* which they subscribed, let them ask the Council in London for other 20*s.* or 10*s.*, and spend it on pharmaceutical education as they thought would best suit their circumstances. Mr. Reynolds's scheme was to have educational centres in Leeds, Edinburgh, Liverpool, Bristol, and so on; but he held that was but a modification of the evil of one institute. They had no right to accumulate money as they were doing without applying it to any useful purpose. He thought they ought to spend it in educating their young men; that they ought to reduce their examination fees, for, compared with other and larger learned societies, they were much too large. By these means they would get rid of their surplus funds. He would not reduce the standard of the examinations. It was a wrong thing that they should have to educate their young men. But they had got their young men into a fix. The masters had passed this law for a conservative purpose,—to keep the trade into fewer hands. Whatever was the motive, that was the result of it? They had got their young men into a cage, and they ought to help them out of it. The young men had no means of educating themselves to the standard the masters had raised. They were therefore bound to give them every facility they had in their power to attain this standard. His proposal about the examination fee, which had not been ventilated yet, he should like considered. He proposed that where a young man was able to do it, he should be allowed to take the Minor and Major examinations at one step. Where a young man was able to take it at one step, they had no right to say, "You must take the Minor first," and make him pay for that five guineas, when he was able to take the two for six. He was satisfied that the examination fees, considering the rate at which the young men in Scotland were remunerated, were too high. The effect of this was that many left the trade. The passing through examinations at their time of life had a deterrent effect on many, altogether irrespective of their power to pass them, and therefore the examinations ought to be made as few as possible. If they did as he proposed, they would find a large proportion taking the Minor and Major at once. The Society could only lose about £300 by this being done, and by many more taking the Major than now did, that sum would be made up. He thought the suggestion of Mr. Brown that each chemist should have his own museum was one of the best practical hints that he had heard.

Mr. Mackenzie thought that Mr. Mackay's paper contained some good suggestions. He quite endorsed, he remarked, what that gentleman had said about the present manner of education—that it was contrary to the spirit of the age, and must sooner or later succumb. It should be altered so far, that any young man coming up to be examined, no matter how or where he got his education, should be placed on an equal footing with all others, if he proved himself possessed of the requisite knowledge. He believed that the standards of the examinations were already as high as they prudently should be made. He was not exactly prepared to admit what Mr. Brown had said regarding the present pharmaceutical chemist. The old apothecary was a sort of mongrel. He was neither a druggist nor a doctor, but a little of both. He was an educated man because he had graduated at the university. He thought that Mr. Brown's ideas were rather Utopian regarding the master's duties to his apprentices. He would gladly see this, but where could they find a master, with a good business, who had time to do all this? He thought with Mr. Brown, however, that each master should have his museum; but it could not be expected in many cases that he could turn schoolmaster for his apprentices. It had been asked how were the apprentices in rural districts to be enabled to compete with those who were able from their situations to attend colleges and lectures, for the examiners allowed no difference between the two classes when they came up for examination? They had heard a great deal about the money that the Society had accumulated also. He did not think it wise that this money should be allowed to go on accumulating without any definite or good purpose. He thought the fees should remain as they were, but he would most decidedly have the young men who were prepared to pass both examinations at once permitted to do so. But returning to the question how the young men through the length and breadth of the land were to be put on an equal platform, he suggested that the Society, instead of paying certain learned men to be lecturers, should pay them or other competent men to compose or edit a work of the nature of 'Cassell's Popular Educator,' containing the information imparted in the lectures so that the young men should be able to educate themselves. The lessons might be graduated as in the work he had mentioned, and one number or part might be published every week. The progressive lessons might gradually lead the student up to the Minor and then to the Major examination. This might be done by a system of question and answer, embracing chemistry and botany amongst other things, and leaving to the master that sound practical work which he was bound to teach his apprentices. Let them consider what had been done in all the different departments of knowledge by means similar to those he suggested. It would place the young man in the most secluded part of the country upon an equal platform with those employed in the towns and cities. If they were going to apply the surplus funds of the Society to a general educational scheme, he thought this was the best way they could do it.

Mr. Ainslie (Gardner and Ainslie) said he fully concurred in most of the remarks made by Mr. Mackay. He thought they were sensible and practicable. He had a suggestion to make in regard to the examinations. On the occasion of almost every examination they had young men coming before them who were ignorant of the names of certain drugs and preparations. He believed that one great cause of this was, that these young men had been, perhaps, but a short time at the trade. He thought it would be an improvement if every young man before he came up for examination had been not less than four or five years at the business. He thought the idea of having a museum and library of reference in most towns a very good one, and although it would cost a good deal of money, it would be the best way the Pharmaceutical Society could help the young men in their course of study. A great deal had been said about the difficulty of passing the Minor examination; this was much exaggerated. A young man who went systematically into the study of chemistry, matéria medica and botany need have no fear of the examination. He thought the young men of the present day wished to have too much done for them. He thought they did not exert themselves as they might do, especially with their shorter hours of labour in most towns. He suggested the plan that he himself adopted when an apprentice, of getting up at six in the morning and having about two hours' study before commencing the work of the day. He thought if every young man of average ability were to do so, we would not hear so many complaints of the difficulty of the Minor examination. He thought that examination very well as it was; some thought it not scientific enough, but he thought it was quite sufficient to make them correct dispensers of medicines, as well as persons in whom the public might place the utmost confidence.

Mr. Kemp (Portobello) thought it should be understood in the discussion of that night, that they were not proposing any immediate revolution, but that what they proposed had all relation to the future. Any change that took place would, he believed, reserve all rights, so that those already in the trade would pass under the present examinations. The question before them was, Should the Society expend any money for the education of future pharmaceutists in the provinces? It was admitted that the Society had all along had a desire to do this, had already done something in this direction, and was anxious to discover how it could do more. The question was, Is the education to be brought to the student or the student to go to the education? He thought it would be utterly impossible to have a great many centres of education. As regarded the Minor examination he thought Mr. Mackay was right in saying that the Minor examination was quite within the reach of any young man who was disposed carefully and perseveringly to study his business. They had had many examples of students passing with the greatest credit who had never attended any lectures. But he thought that the two sides of the question did not hang together. Mr. Mackay had admitted that this examination was quite within the reach of the ordinarily industrious student. But then there was a proposal to spend a great deal of money in providing centres of education, and another proposal had been made to make the Minor examination more stringent. If it was made more stringent it would become the Major examination; and if they made the present Major more stringent the students would have to attend lectures. In a letter he sent to Professor Attfield, he hinted that at some future time the Minor examination should be abolished. It was intended as an examination for assistants. Now he thought the employers were the best examiners of their own assistants. The result of the continuance of the present Minor examination was, that they had two qualifications existing amongst those who had set up business perhaps in the same street. By-and-by the public would inquire what was the cause of the difference in their designations, and would discover that the one who had passed the Major examination was the better man. Instead of making the Minor examination more stringent, he thought the students should at once pass to the Major, and in the course of a few years they would have nothing but pharmaceutical chemists.

Mr. Kinninmont, of Glasgow, thought that the best mode of disposing of the surplus money of the Society was to reduce the examination fees. At the present moment they had a surplus of £16,000, and this was the cause of their quarrels and discussions. If this money were capitalized, it would bring £600 a year, which they might employ according to the suggestions of Mr. Frazer. He thought a fee of one guinea for the Preliminary, two guineas for the Minor, and two for the Major examinations were sufficiently high fees. He thought it a ridiculous idea to ask that the apprentices before they were bound should be made to pass the Preliminary examination. If this were enforced, they would find it impossible to get young lads. He should protest against the alteration of the present Minor examination, which, in his opinion, included everything that a druggist ought to know. He might learn as much after as he pleased, but it should not be compulsory. He maintained that the higher branches were not absolutely necessary to a man who had merely to carry on the ordinary business of a chemist and druggist. A voluntary examination they might, however, make as stringent as they pleased. This question of education could be settled very easily by every master minding his own apprentice. There was nothing in the Minor, and scarcely anything in the Major examination, but what private study would enable a young man to pass. But if they made examinations more stringent, they would just prevent young men from coming forward.

Mr. Gilmour (Lindsay and Gilmour), pointed out the necessity for a good Preliminary education for boys coming into the trade, so many having failed to pass the Preliminary education, and so many others having passed it only by the skin of their teeth, as he said; and also the necessity of every assistant making an honest effort for himself. It was proposed to start education centres, but where these centres would be placed were the very places that least require them. The examinations had long been spoken of as the end of a young man's education, but these examinations should show the young man what he was ignorant of. He was suspicious of this whole question of education as brought forward by men in and out of the Society, because he did not think that those who had as yet attempted to settle the matter were in a position to legislate for the great mass of the trade. To aim at a common platform for all in the trade would only end in disappointment. The main thing they should aim at was to establish a higher moral tone among the young men. He thought the present examinations were quite sufficient for the requirements of the present day, and that all they required was the establishment of proper museums, proper libraries, and proper consulting rooms in as many places as possible, without interfering with the independence or the proper privileges and duties of the young men. As to "cramming," he did not think it existed to nearly the extent that was thought, at least in Scotland. The examinations showed that it did not exist. He suggested to put an end to this absurd cry about cramming, that the examiners should publish the questions monthly. He concluded his remarks by again pressing the necessity of a higher moral tone amongst the young men.

Mr. W. Leitch: I beg to state that I coincide generally with the remarks of previous speakers, and homologate most of Mr. Mackay's statements; but I am decidedly of opinion that no great change in the mode or means of education is either probable or desirable. I believe that twenty years hence it will be found as now that chemists will receive their primary education in the country districts, and be naturally drawn as assistants to the great centres where they may have better opportunities of perfecting themselves in their art. At the same time, allow me to remark that, in my opinion, you are very apt to overlook one of the main elements of the case. You speak only of education, but I ask where are you to obtain the pupils? It is well known that even now there is an absolute dearth of apprentices and assistants. This may be due partly to the stringent provisions of the recent Act; but I insist that it is mainly due to the fact that there is no adequate object held out for the student of pharmacy to attain. It is absurd to suppose that young men of good education and position will be found to enter on a career involving such high and varied attainments, and offering so small an ultimate object, so few chances of advancement, and so little opportunity of cultivating the social amenities of life. It is only the favoured few who are fortunate enough to succeed to good dispensing businesses; and the remuneration of assistants generally is so manifestly inadequate to their position, and to the long time and considerable outlay necessary for their due qualification, that many otherwise able young men have already left the profession, and numerous others are deterred from commencing so inauspicious a career. To remedy this state of matters, I boldly affirm that the hours of labour must be considerably abridged, that the remuneration of qualified men must be trebled or quadrupled, and more encouragement given to scientific studies. Now to do this, masters must of necessity receive what they are already entitled to, viz., a very large increase in the present scale of charges; and considering that they have now an almost perfect monopoly in dispensing, there should be no difficulty in at least doubling all their dispensing charges. When this is done, and a due object and position held out for the attainment of any assistant, you will find the right class of youths come forward to the profession; and when once within the ranks, it is for the Society to decide where four or five centres should be established, where assistants may be helped by lecture tickets at recognized schools of pharmacy, so as to enable them to pass the Major examination with at least as much ease and credit as others not superior to them may do the medical curriculum. I may conclude by saying that, unless some such advance as I have advocated be made, the number of those choosing pharmacy as a profession will go on decreasing, as other occupations of greater relative monetary value are of easier attainment and equally honourable. I feel that I have not been discussing the point from a purely educational view, but certainly from one we cannot afford to overlook.

Mr. Young (Macfarlane and Co.) said that at this late hour he would not trespass, important as was the subject under discussion. He had given some attention to the various schemes which had been proposed, and he felt bound to say that the one which Mr. Mackay had that night brought under their notice was the one which commended itself most to his mind. He recognized the importance of the Bloomsbury school as a great central institution, and it would be matter of regret to him that any change should lessen its value. Change, however, of some kind was before them, and he thought no safer mode of transition could be effected than that contained in Mr. Mackay's proposal. It would give a standing to the Society in the principal centres of the country, it would recognize the teaching powers in many localities, and would tend to cement and foster that kindly feeling which is already springing up in connection with members of the medical profession. As to the examinations, he was content with them as they were, though he did wonder sometimes that while the Preliminary examination fee at the universities of Edinburgh and Glasgow was 10*s.* 6*d.*, it was with us £2. 2*s.*; and in the knowledge of this he did feel that when a parent presented himself offering his boy as an apprentice the first demand made was this examination fee. He thought a change might be made here with advantage, for he agreed with Mr. Gilmour in the necessity of a good education, and with Mr. Ainslie in a compulsory term of apprenticeship. Mr. Mackay could tell them that the Minor examination was originally intended as the assistants' examination, and he had no doubt the time would come when it would be held exclusively as such.

Mr. Mackay, in reply, said that the late hour prevented his answering, as he felt quite prepared to do, some of the remarks which had been made. He felt much gratified, however, that the opening of the Society's new rooms had been inaugurated by a discussion on such an important subject. He could not help stating in regard to the £2. 2*s.* fee for Preliminary examination, and to which exception had been taken by more than one speaker, that so long as the existing fees remained, there could be no better division than £2. 2*s.* for the first, and £3. 3*s.* for the second examination, thus making up the aggregate five guinea payment for the Minor examination, because before the classical examination was insisted upon, candidates passing the Minor paid at once the lump sum of £5. 5*s.* One word is also necessary to explain that the Minor examination was originally intended only for assistants and not for masters, but the Privy Council insisted that the Minor should form the test for qualification to admit to the position of chemist and druggist, and thus enable the party who passed to be placed on the Government Register.

A vote of thanks was awarded to Mr. Mackay for having so ably brought the subject of pharmaceutical education before the meeting, and giving an opportunity for free discussion in connection with it.

The following donations to the museum and library were then laid on the table:—

Specimen of leaves of *Ficus lasiophylla*, Singapore, by Mr. Baildon; specimen of hairy down from the leaves, of *Ficus lasiophylla*, Singapore, by Mr. Baildon; specimen of chemically pure bromide of potassium in large crystals (French manufacture), by Mr. Baildon; specimen of Pengawar-djambi or Pulu, *Cebotium*, *Scheidiarum*, by Mr. Baildon; specimen of Bassia nuts the fruit of *Bassia latifolia*, by Mr. Harry Hyne; Pharmacopœia Germanica, Berolini, 1872, by Mr. H. C. Baildon; the 'Pharmacist,' from America; 'The Year Book of Pharmacy,' from the Conference; 'Ashworth's Binder and Pharmaceutical Journal,' from the Society; bound volume of Journal, 1871–72; five volumes of 'The Proceedings of the Royal Society,' by Mr. John Mackay; five volumes of the Journal of the Chemical Society, by Mr. John Mackay.

The Secretary then intimated the arrangements which had been made by the Council in regard to the use of the room as follows:—

On and after Monday the 25th of November, arrangements have been made whereby the museum and library will be made available to all connected with the society, during the day from 10 A.M. till 4 P.M., and in the evening from 6 till 10. On Saturdays the hours will be from 10 till 3.

Any one wishing to examine the specimens in the case may have an opportunity of doing so by applying for the key of the cases to the party in charge of the rooms.

Books will be given out and taken back at any time during the hours above named, but in the meantime no volume will be given out unless by order from the Secretary, to whom application must be made.

The council hope that ere long the library and museum will both be considerably enlarged. In the meantime they have set aside one of the Society's rooms as a reading-room, open to all, and on the table of which will be found constantly lying the following weekly and monthly publications:—The 'Lancet,' Pharmaceutical Journal,' 'Chemist and Druggist,' 'Chemical News,' 'British Medical Journal,' 'Scientific Journal,' 'Nature,' and the 'Food Journal.'

A vote of thanks to the President closed the proceedings.

Provincial Transactions.

BRISTOL PHARMACEUTICAL ASSOCIATION.

The monthly evening meeting for November was held on Friday, the 15th; Mr. Stroud, vice-president, in the chair.

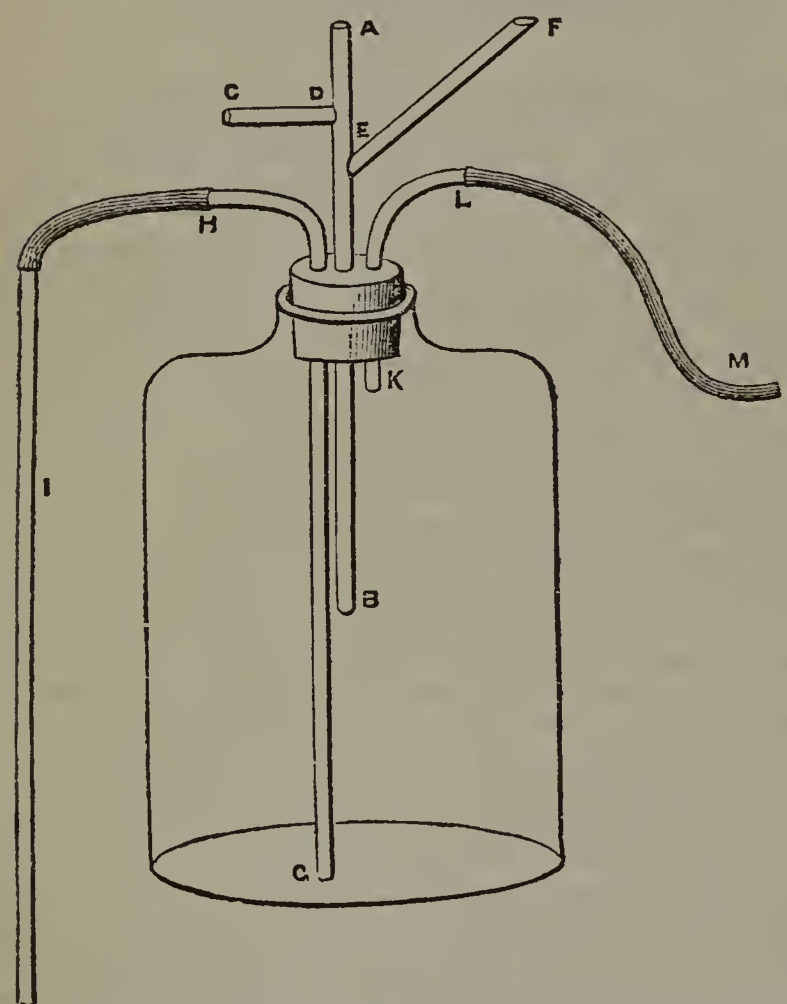
After a few introductory remarks from the Chairman, Mr. Giles read a paper upon the "Syrups of Phosphates," in which he referred to the difficulties sometimes experienced of obtaining a satisfactory and *permanent* solution of the phosphates of which the syrups were composed, and of avoiding a tendency to discoloration. Specimens of syrup of phosphate of iron and syrup of phosphates of iron, quinine and strychnia were exhibited, which had been kept for upwards of a year without material deposit or discoloration. He considered that these inconveniences might be avoided by the following simple precautions, viz.:—To accomplish the process with the greatest possible rapidity of manipulation, to exclude every source of impurity, and to dissolve the sugar without heat. With this object *distilled* water should be used *copiously* for washing the precipitates, which should then be dried by strong pressure, and the purest loaf sugar (in the state of rough powder) should be used for completing the syrup. If likely to be kept long, the syrup should be bottled in sizes convenient for use. In the preparation of syrupus phosphatis comp., Professor Parrish's published formula was stated to produce a syrup harsh to the taste and objectionable to patients, particularly to children, for whom it is largely employed. This appeared to be overcome in the American manufactured syrup by the substitution of a sensible proportion of hydrochloric acid for its equivalent of phosphoric, which equally well retains the phosphates in solution, and gives a soft saline taste to the product. The presence of arsenic in phosphoric acid, to an extent capable of communicating irritating properties to phosphatic syrups, was also stated. The author was indebted for this information to the careful observation of Mr. Randall, of Southampton. The arsenic probably finds its way into phosphorus in consequence of pyritic sulphuric acid (which is commonly contaminated with arsenic) being employed by the phosphorus manufacturers on account of its cheapness.

Mr. Stoddart exhibited two samples of British brandy which he had prepared, one from rags and the other from Iceland moss. They appeared to be exceedingly good imitations of the veritable Cognac and to have a large percentage of alcohol.

Mr. Stoddart then availed himself of the opportunity for showing his method of percolation, because so many had doubted its applicability to those substances that contained much resin. A large glass cylindrical tube was placed upon the table, containing powdered ginger in the course of percolation. The "*dark skin-deep ring*" of resin was seen plainly as it gradually descended, from the spirit being displaced by a column of water.

Mr. Schacht exhibited in action a piece of apparatus designed to supply a continuous blast of air for blow-pipe or other purposes. It consisted essentially of a tin tube (provided with a branch tube open to the air) through which water was driven from a supply tap into a properly fitted bottle. Air was thus entangled with the water in its course through the tube, and carried with it into the bottle. The water was then got rid of by means of a siphon, and the air was conducted by an elastic tube to the blow-pipe.

Mr. Schacht said the instrument was figured in the appendix to Eliot and Storer's 'Inorganic Chemistry,' and some exact measurements for its construction were given in the explanation, but he had found in practice that the length of the tin tube could be reduced by at least one half, and by so doing the apparatus was rendered much more manageable, whilst, as the meeting saw, its efficiency was in no degree diminished.



A.B.=Tin tube, eighteen inches long, half-inch diameter.
C.D.=Do. do., three inches long, one-third inch diameter, inserted at right angles.
E.F.=Tin tube, long enough to reach the level of A, one-third inch diameter, inserted at an angle of 45°.
G.H.I.=Siphon, half-inch diameter.
K.L.=Air tube, one-third inch diameter.
M.=India-rubber tube to convey away the air.

To set the apparatus in action, connect the tube CD with a water tap, by means of a piece of elastic tubing, and turn on the water; pinch the tube M for a few moments between the thumb and finger, until the siphon has begun to act. A blast of air will at once be felt at the extremity of M.

Mr. Little, a student, then read a paper entitled "Results of an Examination of some Samples of Ferrum Redactum." Mr. Little said he felt that he owed some apology for venturing to bring before the Association a subject which was certainly not original, and which probably did not possess that amount of general interest, which it was at least desirable should characterize communications submitted at such meetings. But finding it a difficult matter to produce anything original, he had thought that students, like himself, might do much useful work by examining, from time to time, some of the more important chemical preparations of the Pharmacopœia as they are met with in commerce, with the view of determining how far they correspond with or differ from the standard indicated in that work.

He had been thus induced to make an examination of half-a-dozen specimens of Ferrum Redactum, obtained from different sources, and to bring the results before this Society. [The paper is printed at p. 422.]

SHEFFIELD PHARMACEUTICAL AND CHEMICAL ASSOCIATION.

The second monthly meeting of this association was held on Wednesday, Nov. 13th; Mr. W. V. Radley, president, in the chair.

During the evening a lecture was delivered by W. Baker, Esq., F.C.S., on "Volumetric Analysis and Alkalimetry." The lecturer ably described the apparatus used in volumetric analysis and also the process of standardizing, describing in the course of his lecture several of the most important methods of conducting analysis by those means, during which he performed numerous beautiful experiments to illustrate his remarks. In concluding, Mr. Baker said, "I would urge upon students the importance of making standard solutions for themselves; by so doing they would gain a ready and useful acquaintance with the equations, and also an idea of the importance of accurateness in all processes employed in chemical investigation."

A vote of thanks was unanimously accorded to Mr. Baker for his interesting lecture, when, in briefly responding, he again urged upon the young men to try the processes for themselves, as, in his opinion, there are times when the druggist or dispenser will feel it very necessary to have at hand some such ready method of ascertaining the purity or commercial value of his chemicals.

The election of several associates concluded the business of the meeting.

LIVERPOOL CHEMISTS' ASSOCIATION.

The Convictions under the Adulteration Act.

The fourth general meeting of the session of the Liverpool Chemists' Association was held on Thursday, Nov. 21st, at the Royal Institution, Colquitt Street, Mr. E. Davies, president, occupying the chair. The council of the society had adopted the following resolution:—"That the council of this association, whilst sympathizing with the objects of early closing, does not consider it within its province to call a meeting of the chemists and druggists of Liverpool to discuss the question."

Mr. Abraham, in reference to this resolution, said the members of the council would individually be glad to do anything in their power to promote the earlier closing of chemists and druggists' shops, but they did not consider that the society could take action in the matter. He would gladly see an effort made to obtain earlier closing.

Mr. Shaw expressed a similar opinion.

Mr. Shaw afterwards called the attention of the society to the two prosecutions on the previous day for selling adulterated milk. He suggested that the stipendiary magistrate, Mr. Raffles, was wrong in his interpretation of the Act when he said that persons were liable to a penalty for selling adulterated articles whether they were aware or unaware that there was adulteration. He (Mr. Shaw) understood the third clause to mean that before persons could be convicted of the offence they must be aware of the adulteration.

The Chairman said he had not studied the matter, and, therefore, could not give an opinion on the point. He had always considered, however, that the only way to repress adulteration was to make the seller—whether he had a guilty knowledge or not—liable to a penalty, leaving it to him to take proceedings against the person from whom he had purchased the article.

A paper was afterwards read by Mr. C. Symes, vice-president of the association, on "Pharmaceutical Progress," in which he referred to what had been done by the association for pharmacy.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, Nov. 21st, 1872; Dr. Frankland, F.R.S., president, in the chair.

When the preliminary business of the meeting had been transacted, a paper "On the Standardizing of Acids," by W. N. Hartley, F.C.S., was read by the Secretary. The author finds it convenient to prepare the solution for rapidly standardizing acids by dissolving a known weight of metallic sodium in alcohol, and diluting the solution with water; it is then ready for use. The second communication "On Anthraflavic Acid" was read by the author, Mr. W. H. Perkin, F.R.S., in which he gave the results of the continuation of his investigations on this acid, including an account of two new derivatives, *diacetyl-anthraflavic acid* and *dibenzoyl-anthraflavic acid.*

An animated discussion on some theoretical points indirectly connected with this memoir ensued, and the meeting finally adjourned until Thursday, December 5th, when there will be two papers by Professor C. Rammelsberg "On the reducing Power of Phosphorous and Hypophosphorous Acids and their Salts," and "On Hypophosphites;" also one by Professor A. H. Church, on "New Analyses of some Mineral Arsenites and Phosphates."

Parliamentary and Law Proceedings.

Conviction under the Adulteration Act.

On Tuesday, Nov. 19th, two cases were heard by Mr. Raffles at the Liverpool Borough Police-Court, in which proceedings were taken under the new Act for the prevention of adulteration of food, drugs, etc.

William Smith, cowkeeper, was charged with selling adulterated milk. An inspector in the service of the Health Committee said that on the 7th instant he bought a pennyworth of milk from the defendant, and subsequently gave it to Dr. Brown, public analyst.

Dr. Brown stated that he analysed the sample, and found it to contain less than half the quantity of cream found in the poorest cow's milk; it had been adulterated by adding 30 per cent. of water. Milk naturally contained from 85 to 88 per cent. of water, and to the milk he analysed other 30 per cent. of water had been added.

For the defence it was stated that, if the milk was adulterated, it was adulterated before it came into defendant's possession.

The magistrate said that, by an Act recently passed, any person selling adulterated food, whether aware or not that it was adulterated, was liable to a penalty not exceeding £20; and the person who caused it to be adulterated to a penalty not exceeding £50. This being the first case under the new Act, he was not inclined to inflict a heavy penalty, but future infringements of the law would be severely treated. He would in this case inflict a penalty of 40*s.* and costs.

Edward Elkin, cowkeeper, was summoned under similar circumstances.

Dr. Brown deposed that the sample sent to him of the milk sold by the defendant contained only half the average quantity of cream, and had been adulterated by adding 10 per cent. of water.

The defendant made a similar defence, and the magistrate inflicted a penalty of 20*s.* and costs.

Suspected Poisoning.

An inquest has been held before Dr. Lankester upon the body of Hannah Harwood, who was found dead in bed some time since, and a suspicion of murder existed against a man who lived with her, and who cut his throat at the time.

The Coroner said the woman's body had been examined, and although there was something strange in the man's behaviour, there was nothing on the woman's body to indicate that she had been injured or poisoned.

A juryman said since the adjournment a bottle containing laudanum had been found in the room. The bottle was then produced; it was a two-drachm bottle, labelled "Laudanum—poison."

A witness said she found the bottle on the Saturday following the day the inquest was opened, in the room where deceased lived. She believed neither the man nor the woman were in the habit of taking laudanum. It appeared to be new, as the label was perfectly clean when she found it.

To another witness who went to see the man at the hospital, he said that he took it himself; that he went to three shops and got one pennyworth at each, and took it the day he attempted to commit suicide.

Dr. Stone said the bottle could not contain sufficient laudanum to cause the death of a human being. He had found no traces of laudanum in the stomach of the deceased when making the *post-mortem* examination, and had no reason to believe she was injured or poisoned.

A verdict was recorded that the deceased died from heart disease, accelerated by habits of intemperance.—*Echo.*

Suicide of a Chemist.

An inquest has been held at Buxton on the body of Mr. John Acton, chemist and druggist. From the evidence adduced, it appeared that the deceased had been suffering for some time past from depression of mind, but nothing to cause any alarm to the family. He got up at his usual hour on Sunday morning and came downstairs, but when breakfast was ready he was not to be found. His wife went in search of him and found him partly on the bed and partly on the floor in his bedroom. She procured assistance, but examination showed he was quite dead. A bottle of prussic acid was afterwards found in the room and an empty tumbler glass, which had evidently contained the poison. The jury found "That the deceased had committed suicide by taking prussic acid whilst in an unsound state of mind."

Mr. Acton was seventy-three years of age, and had been in the trade for fifty-five years, first at Sheffield, but for the last sixteen years at Buxton. For some years he had been exceedingly eccentric, but not so as to cause any alarm to his friends.

Obituary.

Notice has been received of the death of the following:—

On the 6th of November, Mr. Richard Thomas Stipling Bray, chemist and druggist, of Pembroke Street, Devonport. Aged 33 years.

On the 17th of November, Mr. John Acton, chemist and druggist, of Buxton, Derbyshire. Aged 73 years.

On the 13th of November, Mr. Joseph Philpotts, chemist and druggist, of Newnham. Aged 70 years.

BOOKS RECEIVED.

A Manual of Elementary Chemistry, Theoretical and Practical. By George Fownes, F.R.S. Eleventh edition, revised and corrected by Henry Watts, B.A., F.R.S. London: J. and A. Churchill. 1873. From the publishers.

Introduction to Inorganic Chemistry. With 82 engravings on Wood. By Wm. George Valentin, F.C.S. London; J. and A. Churchill, 1872. From the publishers.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

Death by Misadventure.

Sir,—In your Journal of November 16th, your report of an inquest held at Paddington is calculated to mislead the public, as it does not contain the facts of the case. The following is a more correct account of the proceedings:—

On the 6th of November, Dr. Hardwicke, coroner, held an inquest at 13, Devonshire Terrace, Paddington, touching the death of a lady named Scott, aged 74. From the evidence it appeared that Mr. Dickenson, a chemist, of Queen's Gardens, Bayswater, prepared a prescription for the deceased without the help of an assistant, and being hurried, he used solution of morphia in mistake for water. The jury, after long deliberation, returned a verdict of death by misadventure.

One of the Jury.

Evasion of the Pharmacy Act.

Sir,—The following case has recently come under my notice:—A man who has proved his inability by "being plucked" carries on the business or profession of chemist, but sheltered from the law by transferring it to another who is on the Register, thus holding out to speculative chemists on the Register an opportunity of making an addition to their income by lending their names to incompetent persons, who could then carry on business in defiance of the Pharmacy Act. Surely we who are duly qualified ought to be protected against such piracies. Am I unreasonable in asking that as the law is so stringent, it should go one step further and prohibit the sale of all medicines for internal use by any but competent persons? We should then probably hear less of accidents from laudanum given for tincture of rhubarb, arsenic for magnesia, or from over-doses of Godfrey.

Many grocers, bakers, and small shopkeepers sell patents and drugs, driving a snug trade with the former, and without a licence, that I really begin to think the time and money spent in obtaining the qualification of pharmaceutical chemist has not been well laid out, and fail to see the advantage of belonging to a Society where such palpable evasions are tolerated either from want of power or unwillingness to arrest the evil. I venture to express a hope that other chemists will take up the subject, and do all in their power to promote the suggestion "that medicines for internal use should be sold by none but qualified persons."

W. Metcalfe.

November 18th, 1872.

[*** We think our correspondent has in his own hands the remedy for such cases as are within his own cognizance.—Ed. Ph. Journ.]

Errata.—"*Specific Gravities of the Liquids of the B.P.*"—Through a printer's error a correction in Mr. Umney's article on this subject in last week's Journal becomes necessary. Page 402, col. i. line 21, the sp. gr. of "No. 4" should be 1·053 and the "available chlorine" 2·600, instead of as it now stands. "*Sirius*," also, referring to his letter on p. 420, col. i, says that he intended to have written the last line of the fourth paragraph "exempt from the payment of *more than* 10*s*. or even 5*s*. per annum."

The report of the meeting of the Manchester Chemists' Assistants' Association on the 18th inst. has been received too late for insertion this week.

"*Occult Pseudo-Scientific Influence.*"—We have received what appears to be a proof-sheet of a work in the press, containing a vigorous attack upon the germ theory and the advocates for the use of carbolic acid and the carbolates.

F. J. Barrett.—The articles mentioned by you are preparations of a poison within the meaning of the Pharmacy Act, 1868, and therefore cannot be legally retailed or dispensed by any person not qualified according to the provisions of that Act. The Act, however, does not interfere with wholesale dealings in such articles.

"*Spes.*"—Apply to the Secretary for a copy of the Regulations of the Board of Examiners.

J. A.—*Pil. Taraxaci.*—The following formula is given by Cooley:—"Extract of dandelion, 1 dr.; powdered rhubarb, q. s.; divide into $3\frac{1}{2}$-grain pills."

"*A Lover of Fair Play.*"—All the information that was in our possession at the time was published, and on our application to the coroner for further particulars he declined to furnish them.

Messrs. Macdougall Brothers.—Your communication has been received and shall have early attention.

J. Goodfellow.—Your letter has not been overlooked, but it was not thought desirable to publish it, inasmuch as you appear to be under considerable misapprehension as to the facts of the case. For instance, it is not in the power of the Pharmaceutical Society to allow a man to pass on to the Major examination without first undergoing the Minor examination, since the latter has been prescribed by Act of Parliament as compulsory upon all who enter the business as chemists and druggists. Again, it is wrong to say that any person who has passed the Major is "excluded from the list of pharmaceutical chemists, simply from not paying fees to become so titled," since every person passing the Major examination becomes thereby entitled to call himself and be placed on the Register as a "pharmaceutical chemist," and this is not at all dependent upon the payment of any fees or joining the Pharmaceutical Society. Some of the incongruities you refer to are unavoidable, having been imposed by Parliament, but they will disappear with the lapse of time.

X. Y. Z.—The deposit referred to is not due to evaporation, but probably to a chemical change which takes place in this and other proof-spirit tinctures, especially under the influence of light.

A. Wright.—Tallow is commonly purified by melting it together with water, or water containing about two per cent. of sulphuric acid. Another plan is to blow steam for some time through the melted tallow. See vol. II. (1871) p. 322.

"*Leeds.*"—Much would depend upon the nature of the substance referred to in the word translated "salt," which could scarcely have been identical with what is popularly called by that name in this country. Possibly it was an earthy matter impregnated with chloride of sodium, which "lost its savour" as the salt crystallized out. We do not know to what Mr. Maundrell refers.

"*Unus ex Alumnis.*"—As the matter is under the consideration of a committee which has not yet made its report to the Council, we think it would be premature to discuss it, but we do not see that there would be any hardship involved in a person waiting until he is twenty-one years of age before going up for the Minor examination.

"*A Minor Minor.*"—The new regulations respecting the Bell Memorial Scholarships, adopted by the Council at its last meeting (printed, *ante*, p. 367) are now in force and apply to the next competition.

Mr. J. H. D. Jenkinson is thanked for his communication.

"*Chemist.*"—The prescription sent no doubt illustrates the frequent disregard of incompatibilities by prescribers, but we do not see how such a case can be dealt with otherwise than by bringing it under the notice of the medical man.

G. Masson.—*Vermin Killers.*—If you refer to the proceedings of the Council at its meeting in August and September (*ante*, pp. 112 and 188), you will see that amended regulations with regard to vermin killers have been prepared, which are ordered to be sent to all chemists and druggists on the Register.

L. V. O.—Phosphate of iron is reprecipitated. Make the phosphate yourself carefully, and keep it suspended in water, and we think that you will obtain satisfactory results. The author of the paper referred to informs us that he has not experienced the difficulties which you name.

R. B. B.—The green precipitate is protoxide of iron, and it is formed because magnesia precipitates oxide of iron from solutions of ferrous salts.

H. E.—No reaction takes place.

"*Pharmaceutical Chemist.*"—The subject of your letter has been already considered, as you will see by this week's Journal.

Communications, Letters, etc., have been received from Mr. G. Masson, Dr. Kernot, Mr. G. B. Clarke, Mr. D. L. Jones, Mr. Shaw, Dr. J. Léon Soubeiran, Dr. Stone, Mr. S. Wylde, Mr. Pearse, Mr. Macdowell, Aberdeen School of Pharmacy, "Chemist," Edinburgh Assistant," "Pharmaceutical Chemist," R. S., N. A. K., R. B.

THE EXTRACTS CONTAINING CHLOROPHYLL.*

BY J. B. BARNES.

In the last London Pharmacopœia it is directed that the extracts of aconite, belladonna, hemlock, henbane, and lettuce are to be prepared by evaporating the juice of the leaves unstrained to a proper consistence.

The British Pharmacopœia directs the juice to be heated to 130° F. "Separate the green colouring matter upon a calico filter; heat the strained liquor to 200° F. to coagulate the albumen, and again filter; evaporate the filtrate by means of a water-bath to the consistence of thin syrup; and then add to it the green colouring matter previously separated, and stirring the whole together assiduously, continue the evaporation at a temperature not exceeding 140° F., until the extract is of a proper consistence."

This is an improvement upon the old method, for the presence of the albumen not unfrequently set up fermentation, nitrous acid was evolved, and nitrites and nitrates formed in the extracts, probably at the expense of the active principles.

With the view of ascertaining if any further improvement can be effected in these preparations, I have made a series of weighings of the insoluble colouring matter contained in different samples of these extracts, obtained from some of the principal pharmaceutical establishments in London. The results are as follows:—

EXTRACT OF ACONITE.

Samples.	Quantity employed.	Amount of Chlorophyll obtained.
No. 1	100 grains	1·5 grains.
No. 2	100 grains	4· grains.
No. 3	100 grains	4· grains.

No. 1 was of the consistence of thick treacle, the filtration went on rapidly and satisfactorily, but Nos. 2 and 3 took some days to filter, and it was found that when warm water was employed in washing out the extract, the filtrate on cooling became turbid; consequently weighings were made of the insoluble matter which had been washed with cold distilled water; they were both firm enough to roll into pills.

EXTRACT OF BELLADONNA.

Samples.	Quantity employed.	Amount of Chlorophyll obtained.
No. 1	100 grains	14 grains.
No. 2	100 grains	17 grains.
No. 3	100 grains	18 grains.
No. 4	100 grains	15·5 grains.

All these were good firm extracts.

EXTRACT OF HEMLOCK.

Samples.	Quantity employed.	Amount of Chlorophyll obtained.
No. 1	100 grains	14 grains.
No. 2	100 grains	9 grains.
No. 3	100 grains	16 grains.
No. 4	100 grains	15 grains.
No. 5	100 grains	8 grains.

Nos. 1, 2, 3, and 4, were tolerably firm, but No. 5 was unusually soft.

EXTRACT OF HENBANE.

Samples.	Quantity employed.	Amount of Chlorophyll obtained.
No. 1	100 grains	16 grains.
No. 2	100 grains	11·5 grains.
No. 3	100 grains	18·5 grains.
No. 4	100 grains	14 grains.

The consistence of the samples was good.

EXTRACT OF WILD LETTUCE.

Samples.	Quantity employed.	Amount of Chlorophyll obtained.
No. 1	100 grains	13 grains.
No. 2	100 grains	1 grain.
No. 3	100 grains	1 grain.
No. 4	100 grains	9·5 grains.

Nos. 1 and 4 were tolerably firm, but Nos. 2 and 3 were of the consistence of thick treacle.

In these experiments, excepting Nos. 2 and 3 of extract of aconite, the colouring matter was separated by dissolving the extracts in hot distilled water; transferred to tared filters, they were washed with warm distilled water until the latter passed through colourless; the chlorophyll was then dried in an air bath at 100 C. until the weight became constant. The insoluble matter in some samples of extracts of aconite and lettuce was very small, amounting to only one and one and a half per cent., and in extract of lettuce was not green but brown; whether this change is due to age or not I am unable to say.

From these varying results it is clear that extracts containing the colouring matter are not of anything like uniform strength; so much so is it the case that I venture to bring the subject before the Society in the hope that discussion will elicit opinion as to the desirability or otherwise of eliminating this cause of varying strength in preparations, which it is so very desirable should be of constant and unvarying strength.

Dr. Harley* has shown how valueless the extract of hemlock of the Pharmacopœia is, and the value he attaches to the preserved juice. It is evident from his experiments that the prolonged application of heat employed to evaporate the juice to the consistence of an extract, dissipates so much of the active principle, conia, that very little of it remains in the extract. It is not improbable that some loss of alkaloid takes place in the preparation of extract of henbane; and it is most desirable that after coagulating and separating the albumen, the evaporation should be carried on at the lowest temperature possible. As far as my experience goes I think that a temperature not exceeding 120° F. should be used, and that the evaporation of the juice should be effected in shallow evaporating pans exposed to a current of dry air, until the proper consistence is obtained.

It is undoubtedly established that the action of aconitia, atropia, and conia are identical with the medicinal properties of the plants from which they are extracted; and it is not improbable that hyoscyamia will be found to possess the properties of henbane in the highest degree.

The objections which I anticipate will be offered to any alteration in the preparation of these substances, is the absence of the accustomed colour, the increased strength, and possibly the greater deliquescence.

My answer to the first objection is that in the case

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, December 4, 1872.

* "On the Preparation of Extract of Conium of the British Pharmacopœia, 1864 and 1867," (PHARM. JOURN., vol. VIII., 1866–67).

of these so-called green extracts, it is not so very easy to distinguish between one and another, as exemplified by the answers of the candidates who come up for examination in pharmacy. I venture to state that it will not be more difficult to distinguish these proposed *purified extracts* than it is with those already in use, for, although the colour will be different, their characteristic odours will be retained.

To the next objection, that of increased strength, any inconvenience which might arise from that source will be more than counterbalanced by the very important consideration of uniformity of strength of these preparations; and in order to facilitate the use of these *pure* extracts I might be allowed to suggest their employment in the form of *liquid extracts;* hemlock, however, should be excluded on account of the volatile nature of its alkaloid.

In order to prepare these fluid extracts, it will be necessary to continue the evaporation until reduced to dryness, before they are converted into the fluid state, and of course the addition of about a fourth part of rectified spirit will be required to preserve them. I have not made any of these solutions, therefore am not prepared to say of what strength they should be made.

They would be more definite in strength than their corresponding tinctures, they would cost less, and the ease with which they could be prepared would, I am sure, be a boon to the pharmacist as well as to the medical man.

The increased tendency of these extracts to deliquesce can be met by making them firmer than those in use at present, and by keeping them in pots better secured than those commonly used. For the dispensing counter, strong glass jars with ground-glass lids would be found to answer well; and when made into pills, the apt dispenser will not be at a loss to protect them from the action of the air.

[*The discussion upon this paper is printed at p.* 458.]

APPARATUS FOR MACERATING.*

BY RICHARD W. GILES.

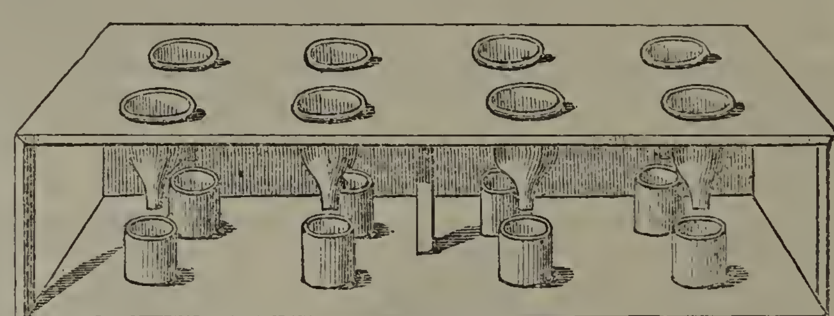
It has been suggested to me that it would be desirable to give some explanation of the model representing the simple arrangement which I have now presented to the museum of the Society, adopted for many years with increased satisfaction, for the exhaustion of drugs in the preparation of extracts, liquors, syrups, etc.; but as this has been already done when the same model was exhibited at Nottingham on the occasion of the Pharmaceutical Conference held there in 1866, I shall content myself with a very brief general description now, referring, for more detailed information, to former notices in the PHARMACEUTICAL JOURNAL,† and supplementing those communications by some unpublished notes on the preparation of extract of rhubarb, in which the present macerating process was employed.

The object of the apparatus is to obtain results similar to those which are effected by well-conducted percolation, viz., the exhaustion of the drug with the minimum volume of solvent by submitting it to successive contact with fresh portions of the menstruum. This is easily done when spirit is the solvent and the drug is in a state of moderately fine powder, but according to my experience it is not easily accomplished with *water*, which will neither penetrate ingredients in the powdered state nor exhaust them by passing through if they are not in a state of powder. A series of cones is, therefore, used, amongst which the total quantity of the substance operated upon is divided, and water is passed through the whole series, allowing sufficient time (determined by the character of the drug) for maceration upon each. When the model was previously exhibited, I thought that eight cones would prove sufficient for all substances; but I have since found it advantageous to employ at least sixteen cones when operating upon cinchona bark, and this number enables me to submit each portion of bark to sixteen macerations, and to effect a very complete exhaustion without using more water than would be required for a single maceration of the whole quantity. The completeness of the exhaustion is shown by the sp. gr. of the several infusions, of which it will only be necessary upon this occasion to quote the first and last taken from laboratory notes of two operations upon different samples of cinchona:—

Sample A.	sp. gr.
1st Liquor after passing through 16 cones	1034
16th „ „ „	1002
Sample B.	
1st Liquor after passing through 16 cones	1086
16th „ „ „	1002

I may mention that although sample B. proved so rich in extractive, the *quality* of the result was not considered satisfactory, and I agree with Mr. Umney, that cinchona barks suitable for fluid extract do not yield these large results.

The relatively small exposure to heat and oxidation during evaporation of the smaller quantity of liquid employed under these circumstances materially affects the quality of the product.



The sketch represents a stand of eight cones, and eight receivers placed beneath the cones to receive the infusions at each running off.

Each cone is about four gallons capacity, and is provided with a movable strainer fitting the delivery end, which is secured during maceration by a cork. When the cork is withdrawn, the liquor flows through the strainer. Cinchona bark is an extreme example of difficult exhaustion. In operating upon other substances I use fewer cones—sometimes ten, sometimes four, sometimes only two. In the preparation of the sample of extract rhubarb now submitted, 4 lb. *sliced* rhubarb were divided amongst four cones and treated in the following manner.

---

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, December 4, 1872.

† See particularly vol. viii. p. 220 (2nd Series).

20 oz. spirit of wine, mixed with 20 oz. of water, were passed through the cones in succession, being allowed to stand for six hours in each. About 26 oz. syrupy fluid were recovered and reserved. The spirituous maceration was followed by a succession of three aqueous macerations, which were recovered and evaporated separately to a syrupy consistence. In this way the rhubarb was efficiently exhausted with 7 pints of fluid (compared with 22 pints prescribed in the Pharmacopœia formula). The reduced aqueous macerates were mixed with the reserved spirituous liquor, and evaporated carefully in water-bath to suitable consistence, yielding as product 1 lb. 11 oz. (42·2 per cent.) of sapid and fragrant extract, which dissolves with facility in water, forming a solution which, in appearance and taste, might almost pass for fresh infusion of rhubarb. Its cost was 10*s*. 9*d*. per lb., including estimated allowance for working expenses. I have not investigated its medicinal activity; but unless it is greatly superior to that of average specimens, the practical result has been to waste 4 lb. rhubarb and a certain amount of time.

It will be seen that the above process, which differs materially from the process recommended by the Pharmacopœia, coincides with suggestions made by the President in recent papers upon the preparation of tinctures; that is to say, that it uses the spirituous solvent and the aqueous solvent consecutively (as in the Pharmacopœia process for extract jalap); and I may take the opportunity of saying that I have frequently availed myself of this mode of exhausting drugs, but I do not think it is applicable to the preparation of tinctures to the extent contemplated in the paper referred to. For example, it would not answer to macerate the ingredients for tincture of rhubarb first in rectified spirit, next in water, and then mix the resulting liquors, but a judicious application of the idea will often enable us to recover the *whole of the spirit* employed and to avoid loss of volume in the product, which, as Mr. Umney has shown in his useful table of the loss in the preparation of tinctures, is sometimes a matter of considerable importance.

[*The discussion upon this paper is printed at p.* 458.]

DISPENSING NOTE ON CHLORAL HYDRATE.*

BY J. G. PLUMER.

There have been many suggestions put forward respecting the dispensing and dose of chloral hydrate. It was first, I believe, introduced on the Continent, and has been given there in doses consisting of only five grains, principally combined with simple syrup and distilled water. But in England it is given in doses ranging from five to fifteen or twenty grains, either in the form of draught, syrup or mixture. It is generally prescribed in the form of a syrup; Tolu and other flavouring adjuncts being employed to disguise the taste. In my opinion the Syrupus Flor. Aurantii, P.B., is the best form of combination with which it can be used. It seems most effectually to avoid the sickly feeling created by the chloral hydrate; I venture to suggest the employment of a concentrated solution which may prove convenient. I find that one fluid drachm of a solution made with distilled water may contain so large a quantity as one drachm by weight of the chloral hydrate. I therefore use this formula:—

℞
Chloral Hydrat. . . . . ℥j.
Aquæ destillat. . . . . . . q. s. ad fl. ℥j.

About five drachms of aqua destillata are found necessary, and the result is satisfactory. Hence in a prescription ordering ʒij chloral hydrate, two drachms of the concentrated solution will be wanted. The convenient applications of this liquor will be obvious. Syrup of chloral hydrate in any combination may be instantaneously prepared. Thus:—

℞
Liq. Chloral Hydrat. . . . ♏ 80.
Syrup. Flor. Aurant. . . . . ʒiv.
Syrup. Simplicis . . . . . ʒiv.

The resulting syrup will contain ten grains of chloral hydrate to the drachm. Should a coloured syrup be desired, as is frequently the case, then the following formula may be substituted:—

℞
Syrup. Rhœados . . . . . ʒss.
Liq. Chloral Hydrat. . . . . ♏ 80.
Syrup. Flor. Aurant. . . . . ad ℥j.

Or,
Liq. Chloral Hydrat. . . . . ♏ 80.
Tinct. Cocci. . . . . ♏ ij.
Syrup. Flor. Aurant. . . . . ad ℥j.

An anodyne draught of any requisite strength may be expeditiously prepared; and the solution has this advantage, that although in so highly concentrated a state, it will keep without decomposition any reasonable amount of time.

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, December 4, 1872.

ANTIMONIUM SULPHURATUM; OFFICIAL AND COMMERCIAL.*

BY JOHN MOSS, F.C.S.,

Demonstrator in the Laboratory of the Pharmaceutical Society of Great Britain.

To prepare sulphurated antimony, the British Pharmacopœia directs that 10 oz. of black antimony shall be boiled with $4\frac{1}{2}$ pints of solution of soda for two hours with frequent stirring, and occasional addition of water to make up for that lost in boiling; then, that the liquor shall be strained off, and slightly acidulated with diluted sulphuric acid added gradually—the precipitate washed and dried.

The same authority describes the product of the above process as "an orange-red powder readily dissolved by caustic soda, also by hydrochloric acid with the evolution of sulphuretted hydrogen, and the separation of a little sulphur. Boiled in water with acid tartrate of potash, the resulting solution is precipitated orange-red with sulphuretted hydrogen. Sixty grains of this preparation, dissolved in hydrochloric acid and dropped into water, give a white precipitate, which, when washed and dried, weighs about 53 grains."

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, December 4, 1872.

The London Pharmacopœia (1851) orders 27 per cent. more of the alkali than the above, and the product is described as "golden-red." The Edinburgh Pharmacopœia also orders 27 per cent. more of alkali (in this case solution of potash) than the B.P. for the preparation of "golden sulphuret of antimony." The United States Pharmacopœia orders 35 per cent. more alkali (solution of potash); the product is called "sulphurated antimony," and is described as a "reddish-brown powder." In the French Pharmacopœia a totally different process is adopted. Sulphide of antimony, flowers of sulphur, dried carbonate of sodium, and vegetable charcoal are to be heated together in a crucible, and when effervescence has ceased, the cooled mass is to be exhausted with as little water as possible, the solution to be strained off, and precipitated with dilute sulphuric acid. The product is *Soufre Doré d'Antimoine.*

Experiments.—Having noticed that our laboratory students, when working the B.P. process, invariably obtained a product of a reddish-brown colour, I made a few experiments with a view of ascertaining the conditions necessary to the formation of the orange-red powder from the B.P. materials, viz., black antimony, solution of soda, dilute sulphuric acid and water.

The B.P. process was first tried in its integrity, and gave a product of a dark red-brown colour, almost maroon, little different in appearance from any that had been previously made by the students. In the next experiment, one lot of materials was boiled in an open dish, and another lot in a flask; otherwise the conditions under which the two experiments were conducted, were precisely similar. It was anticipated that, from the greater exposure of the materials in the dish, the product obtained from them would contain a relatively larger amount of oxide than the product of the flask experiment, and be correspondingly paler in hue. This was found to be the case as regards the colour; the proportion of oxide was not determined.

Several other experiments, 22 in all, were made, in which the B.P. process was modified in various ways, so as to include the proportions of materials ordered in the Pharmacopœias referred to above except the French, but I failed to obtain a product that had the colour mentioned in the Pharmacopœia. The one which most nearly approached the golden red of the Pharmacopœia was got by filtering the solution into diluted sulphuric acid.

In order to compare the dark red product of the B.P. process (which I shall call the B.P. product) with the sulphurated antimony of commerce, four specimens of the latter were procured from well-known establishments. The five samples were submitted to all the B.P. tests except the quantitative one.

B.P. product.—A red-brown powder, easily miscible with water, and rapidly subsiding from the supernatant liquid, which it leaves quite clear. Readily acted upon by solution of soda, but does not dissolve completely till the mixture is gently warmed, when a perfectly clear and colourless solution is obtained. From this solution brilliant crystals are deposited after boiling. Readily dissolves in hydrochloric acid with evolution of sulphuretted hydrogen; the solution is faintly opalescent from the separation of a very minute proportion of sulphur. After boiling with solution of cream of tartar, the filtered liquid gives a slight precipitate with sulphuretted hydrogen. Sixty grains treated as the Pharmacopœia directs gave a precipitate of oxychloride weighing 51½ grains. An examination of the filtrate showed that a little of the oxychloride had washed through.

No. 1.—(Labelled *Antimonium Sulphuratum*). An orange-red or orange-yellow powder, difficultly miscible with water, from which it never subsided entirely so as to leave the supernatant liquid quite clear. On mixing with solution of soda, a pale buff flocculent matter was left undissolved; on boiling, the flocks did not dissolve, but appeared to resolve themselves into a crystalline powder, and after standing for a few hours, brilliant crystals were formed on the side of the test tube; the supernatant liquid was bright yellow, evidently from excess of sulphur dissolved in the solution of sulphide of sodium formed in the decomposition. Partially dissolved by hydrochloric acid with evolution of sulphuretted hydrogen, and separation of much sulphur in flakes coloured bright red,—this colour probably due to undissolved sulphide of antimony. After boiling with solution of cream of tartar, the filtered liquid gave a considerable precipitate with sulphuretted hydrogen.

No. 1*a.*—(Labelled *Antimonium Sulphuratum*). Identical with the preceding in characters and reactions.

No. 2.—A dirty yellowish-brown powder, with pale yellow particles plainly discernible in it. Mixes with water more readily than No. 1, but not so readily as B.P. product. On mixing with solution of soda, very dark, almost black flocculent matter was left undissolved; on boiling, the flocks became paler, and afterwards the substance behaved like No. 1, which it also resembled in its behaviour with hydrochloric acid and with solution of cream of tartar and sulphuretted hydrogen.

No. 3.—Similar to No. 1 in appearance, and also in its deportment towards the reagents, except that the matter insoluble in caustic soda was of a distinct red colour, resembling calamine.

The difference, both in appearance and reactions, between the B.P. product and Nos. 1 and 1*a*, which may be taken as the representatives of the trade samples, was so marked that I made an attempt to ascertain the composition of each. After several experiments, the method finally adopted was as follows:—A weighed quantity of the sample was heated in the air-bath at 212° till it ceased to lose weight; this loss denoted hygroscopic moisture. The sample was then digested for an hour in a saturated solution of cream of tartar, thrown upon a tared filter, washed, dried and weighed; this loss was held to denote oxide of antimony. A weighed portion of the powder insoluble in solution of cream of tartar, was afterwards treated with a measured quantity of bisulphide of carbon, filtered, and the filtrate evaporated to dryness on the water-bath in a tared porcelain dish; the proportion of sulphur removed by bisulphide of carbon was thus ascertained. What remained after this treatment was presumed to be either the tersulphide of of antimony Sb_2S_3, or the pentasulphide Sb_2S_5. To determine which of the two, a weighed quantity of the original sample was dropped, a little at a time, into a long-necked flask containing fuming nitric acid, by which the antimony was oxidized to pentoxide, Sb_2O_5, and the sulphur to sulphuric acid. The contents of the flask were then washed into a porcelain dish, and excess of nitric acid expelled by evaporation nearly to dryness on the water-bath, water added, filtered, and the sulphuric acid in the filtrate determined by precipitation as sulphate of barium. Whether the amount of sulphate of barium obtained after the subtraction of that due to sulphur removed by bisulphide of carbon corresponded to ter- or penta-sulphide of antimony was then ascertained by calculation. Proceeding in this way, the following results were obtained:—

	B.P. Product.		No. 1.	No. 1*a*.	
	1st experiment.	2nd experiment.		1st experiment.	2nd experiment.
	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.
Water	2·97	2·97	1·372	1·272	1·272
Oxide of Antimony . .	3·584	3·258	35·938	38·515	37·013
Sulphur removed by Bisulphide of Carbon	·514	·532	23·975		25·725
	7·068	6·760	61·265		64·010
Ter- or Penta-sulphide of Antimony	92·932	93·240	38·735		35·990
Total	100·000	100·000	100·000		100·000

Sulphide of Antimony.—·812 gram of the B.P. product gave on oxidation with fuming nitric acid 1·538 gram of sulphate of barium, which is equivalent to ·2112 gram of sulphur. Deducting from this ·004 gram as the proportion of sulphur (ascertained by calculation from data given in the table) which would be removed by bisulphide of carbon, there is left a remainder of ·2072 gram. This is equivalent to ·7339 gram of tersulphide of antimony, or 92·189 per cent. of the hydrated salt; or to ·5118 gram of the pentasulphide, or 62·29 per cent. The antimony compound present was obviously the tersulphide.

With No. 1 and No. 1*a*, a different, and it is believed, a simpler plan was adopted. ·492 gram of the powder which remained after treating No. 1 with solution of cream of tartar and with bisulphide of carbon successively, was oxidized as previously described, and yielded 1·058 gram of sulphate of barium. Theory requires that ·492 gram of $Sb_2 S_3$ should give 1·011 gram of sulphate of barium and a similar quantity of $Sb_2 S_5$ should give 1·418 gram of the same salt. Proceeding in the same way with No. 1*a*, it was found that ·218 gram gave ·454 gram of sulphate of barium; theory requires that ·218 gram of $Sb_2 S_3$ should give ·448 gram, and that the same quantity of $Sb_2 S_5$ should give ·628 gram. These determinations show conclusively that what remains after treating the samples with solution of cream of tartar, and afterwards with bisulphide of carbon, is tersulphide of antimony. It does not follow, however, that No. 1 and No. 1*a* contain any tersulphide of antimony at all. On the contrary, I do not believe that they contain a particle of the latter salt, whilst the B.P. product contains above 90 per cent. of it. My reasons for this belief are as follows:—No. 1 and No. 1*a*, together with No. 3, are amorphous and uniform throughout, and must have been prepared by the well-known process which consists in the addition of excess of sulphur to the soda solution of black antimony whilst still boiling. Sulphantimon*ate* of sodium, a sulphide of sodium, ($Na_2 S_5$,) and hyposulphite of sodium, are formed. The first-mentioned salt on decomposition with sulphuric acid yields $Sb_2 S_5$, and sulphate of sodium, whilst H_2S escapes.

$$Sb_2S_3 + S_2 + 3\,Na_2S = \underset{\text{Sulphantimonate of Sodium.}}{2\,Na_3\,Sb\,S_4}$$

$$2\,Na_3\,SbS_4 + 3\,H_2\,SO_4 = Sb_2\,S_5 + 3\,Na_2\,SO_4 + 3\,H_2\,S$$

Sulphur is precipitated along with the pentasulphide of antimony, by the action of the acid on hyposulphite and the sulphide of sodium which are formed during the boiling.

$$2\,Na_2\,S_5 + Na_2\,S_2O_3 + 3\,H_2\,SO_4 = 3\,Na_2\,SO_4 + 3\,H_2\,O + 6\,S_2$$

It is thus that the excess of sulphur over that required to form pentasulphide of antimony finds its way into the product.

If any confirmation of the belief that antimony exists in these bodies as pentasulphide only, were required, it is found in the fact that the residue of the successive action of solution of cream of tartar, and of bisulphide of carbon, which has been shown to be tersulphide of antimony, gives no vapour of water when heated in a long narrow dry tube. For tersulphide of antimony obtained as such by precipitation from a solution, after drying at 212° F., still contains 2 per cent. of water (Fresenius). As would be expected, then, the residue of the B.P. product, treated as above, gives off water on heating.

The cream of tartar used in the above experiments was obtained by filtering a saturated solution of carbonate of potassium into solution of tartaric acid, and washing the precipitate two or three times with cold water.

Bisulphide of carbon, as met with in commerce, always leaves a slight residue on evaporation. A measured quantity of the same sample of bisulphide was used in all the estimations, and the amount of non-volatile matter due to this was deducted from the total residue.

The action of bisulphide of carbon on pentasulphide of antimony, in separating two atoms of sulphur from the rest of the compound, is very interesting, showing, as it does, that these two atoms are not so intimately combined with the antimony as are the remaining three. It also adds another to the many points of resemblance which already exist between the compounds of antimony and those of arsenicum.

From the appearance of No. 2, I believe it to be a mechanical, and not very complete, mixture of the B.P. product, with the commercial article as examined above. It does not give up so much sulphur to bisulphide of carbon as Nos. 1 and 1*a*.

The crystals which separate after boiling a solution of any of the above samples in solution of caustic soda are stated by Heffter (Watts's Dict. vol. i. p. 327,) to be antimonate of sodium $2\,NaSbO_3, 7H_2O$, and are described by him as regular octahedrons. They appear to me to be rather regular cubes or right prisms.

Conclusions.—The B.P. product is evidently the sulphurated antimony intended by the Pharmacopœia authorities to be used in dispensing prescriptions, "sulphide of antimony, Sb_2S_3, with a small amount of oxide of antimony, Sb_2O_3." There seems, however, to be a discrepancy between the product and the description of it, for few persons, I think, would distinguish it as an "orange-red powder." Further, the orange-red sulphurated antimony of trade is not, as a rule, the sulphurated antimony of the British Pharmacopœia, and therefore should not be used in making Plummer's pill, nor in dispensing, unless, of course, it were specially ordered. For these purposes the official article alone should be employed.

[*The discussion upon this paper is printed at p.* 459.]

ABERDEEN SCHOOL OF PHARMACY.

A course of lectures of an elementary character upon the practical study of materia medica, with the chemistry and botany of the Pharmacopœia, to be delivered by Dr. Beveridge, at Hospital Court, 56, Gallowgate, in connection with the Aberdeen Society of Chemists and Druggists, was commenced on Monday, Nov. 25th. The lectures will be continued on each Monday, Wednesday and Friday, at 9.30 A.M., until March 24th, 1873. A summer course of a more advanced character will be given at the same hour and on the same days, commencing on Wednesday, 2nd April, and terminating on Wednesday, the 30th July. Fee for either session 20*s*. Payable during the first week to the officer, Mr. William Adam, at the school. The library, which contains standard works on the above subjects, is open every Friday evening, from 8 to 10 o'clock.

CONVERSAZIONE OF THE NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

A large meeting of the members and friends of this society was held on Wednesday evening, November 25, in the rooms of the association, Exchange Buildings. A considerable number of objects of interest were exhibited, including some choice photographs and pictures lent by Messrs. Allen and Son, and Mr. A. Scott; the ethyl and methyl series of anæsthetics, presented to the museum of the society by Messrs. Hearon, Squire and Co.; several chemical novelties lent by Messrs. Hopkin and Williams; pharmaceutical apparatus, microscopes, and mountings of chemical and pharmaceutical substances, etc. The President exhibited a handsome collection of sponges, and Mr. Ransom, of Hitchin, contributed to the museum a fine specimen of scammony root, with the juice exuding. During the evening, the President, Mr. J. H. Atherton, F.C.S., distributed the prizes awarded to the students of last session classes in chemistry and botany, in connection with the School of Pharmacy. Previous to the distribution, the President congratulated the society on the very pleasant and successful evening they had spent, and hoped that another year they might have a conversazione on a larger scale. The present one was purely a family gathering of pharmaceutists of the town and neighbourhood. He thought that, although their family party had been so very successful, in his opinion they missed the presence of their elder brethren, the members of the medical profession. The science of medicine and the practice of pharmacy ought to go hand in hand together. The medical profession, he felt sure, would cordially respond to an invitation to meet their pharmaceutical brethren on such an interesting and social occasion as the present one. Another year he hoped to have a similar gathering, and invite all interested in pharmacy to be present. Such meetings would be productive of much good.

The prizes were distributed as follows:—

Botany.	Inorganic Chemistry.
Mr. Bothamley, 1st.	Mr. F. Lumley.
,, Isaac Grey, 2nd.	,, Ward.

Prizes from the Science and Art Department.

Mr. J. Stephenson	Queen's prizes.
,, Williamson Widdowson	
,, Reuben Widdowson	
,, Isaac Grey	
,, F. Lumley	Certificates.
,, W. P. Bothamley	
,, Ward	

The President announced that prizes would be given by the Council to the most proficient in Dr. Souter's class at the end of the session, and also that Mr. Williams had offered a prize for dispensing, which would be awarded to the candidate who excelled in neatness and correct manipulation.

THE HULL CHEMISTS' ASSOCIATION.

The annual dinner of the members of this society was held on Monday evening, December 2nd, at the Cross Key Hotel. The chair was occupied by Mr. Anthony Smith (president of the association). The usual prefatory toasts having been duly honoured,

Dr. J. H. Gibson proposed "Success to the Hull Chemists' Association." It was not many years since the chemists and druggists were looked upon as a rope of sand; having no conjoint action or thorough understanding amongst each other. But of late years they had been endeavouring to combine for most excellent objects,—first, that those who entered the trade should be better educated. And he believed the system now laid down by the chemists and druggists of Hull would become more perfect than any line of procedure they had hitherto pursued. Then they combined for self-protection in trade, which was an object he also much applauded.

The President, in responding to the toast, said no one felt more than he did the necessity for association; in this respect the Hull Chemists' Association had worked wonders by establishing a system of education for apprentices not surpassed by any in the kingdom, and he had every reason to believe it was highly appreciated by them. There was not the slightest doubt that it would ere long bear fruit, in sending up some medalist or first-class man who would reflect credit upon the town of Hull. They should, however, not study merely the education question, but study themselves, and cast off that coldness and those petty trade jealousies which had existed so long amongst them.

Mr. Oldham proposed "The Healths of the Vice-President, Mr. Earle; the Hon. Secretary and Treasurer, Mr. C. B. Bell, and the Committee." Mr. Niven proposed "The Medical Profession," associating with the toast the name of Dr. John Hare Gibson. The President proposed "The Healths of the Lecturers, Messrs. Niven and Parsons."

The health of the President was then proposed by Dr. J. H. Gibson, and acknowledged by Mr. Anthony Smith, who subsequently proposed "The Pharmaceutical Society of Great Britain."

The Pharmaceutical Journal.

SATURDAY, DECEMBER 7, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the Editor, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to Elias Bremridge, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. Churchill, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE AMENDED REGULATIONS OF THE BOARD OF EXAMINERS.

We are glad to put before our readers to day, in the report of the Council Meeting of the 4th inst., the altered form of regulations agreed on by the Council, whose duty it is, conjointly with the Board of Examiners, to frame or alter such regulations as may be required from time to time, to be observed in the examinations held under authority of the Pharmacy Acts.

We are the more pleased to be able to do this thus early, because much unnecessary alarm appears to have been raised in some quarters by the rumour that some alteration was about to be made. This was perhaps but natural, as everybody knew that in the early days of compulsory examination the greatest possible leniency had been exercised, on the understanding that as time wore on, the examinations would advance gradually to their proper standard. *It was hoped also that students would progress in a corresponding ratio.* Every change therefore in the examinations must necessarily be upward, and there is always a dread of change under such circumstances. But having looked through the new order, we confess that we see very little to alarm our young friends. The only addition to the "Preliminary" is, "*a thorough knowledge of the British and Metrical System of Weights and Measures.*"

Passing to the Minor, there is apparently more change; and at this we are not surprised, because that is of all examinations the most important, when considered in reference to the relationship in which the Council of the Pharmaceutical Society, as an educative body, stand towards the public. The Preliminary, though not referring to anything specially pharmaceutical, is of the utmost consequence, as securing an adequate foundation on which, and by the help of which, to build up a sound technical education. The Board of Examiners already accept the certificates of other examining bodies, and according to our thinking if all students were compelled to bring such certificates—provided always that the Council approved none but high-class examining bodies—it would be better for the great object of the Society in introducing lads of superior education to the trade. We hold any chemist culpable who signs indentures with an apprentice before he has passed the Preliminary examination. The "Major" is an honour to which every pharmacist who desires to take high rank among his fellows,—and as a fair inference to be more highly esteemed by the public,—must in future direct his course. But when a man has passed the "Minor," he goes to the world certified by the Board of Examiners that he is a fit and proper person to be entrusted with one of the most responsible duties which one man can perform for another. It is here that the Dispensing Chemist ceases to be a mere tradesman, buying and selling for gain only to himself; he has to exercise professional skill and knowledge on behalf of suffering humanity, and on his possession of competent skill and knowledge often hangs the life of his employer. To say then that such a person shall be able to detect *errors* and *unusual doses* and have *a general knowledge* of *Posology*, is saying no more than is absolutely necessary. The expression is a little enlarged from the old regulation verbally; but it really seems to us that when an examiner had the power to put a candidate to the proof as to "*unusual doses*," he must be virtually testing him in *usual* doses. The knowledge required under the head of "Pharmacy" seems an improvement; it is more important even that a man should know how simple substances are compounded, and *why* they are compounded in a certain manner to obtain a proper result, than that he should be able to run off the ingredients of a compound on his finger-ends from mere recollection of what he *read* in the Pharmacopœia. In the matter of Chemistry, it seems to have been deemed necessary to advance somewhat further than in the other subjects of examination, but not further than is desirable now that men may if so minded, stop short after this examination. We incline to the hope that the slight advance in chemical knowledge required at this stage may tempt men onward to further study, and consequently the higher examination, which, by the way, seems under the new system somewhat curtailed.

Taking the whole alterations, we think the framers of these regulations were impressed with the necessity of making the examinations more *practical* than they have hitherto been; and we are particularly led to this conclusion by the proposition to insist on the attainment of full age before coming up as candidates for the Minor examination, the attainment in fact of man's estate before assuming man's rights as a citizen. This we suppose must be a matter of Byelaw, and when to it is added the certificate of having passed three years in the practice of dispensing, a great safeguard for the public will have been secured. It is ordained that the new regulations shall not come into operation until October, 1874. Six years will then have elapsed since the passing of the Pharmacy Act of 1868; and while, on the one hand no apprentice or student who has commenced his career in Pharmacy during that time can say that he entered the business without knowledge that he must pass through a certain ordeal before commencing business on his own account; on the other, we think no assistant who entered previously, and has not yet availed himself of the earlier opportunity to pass, can complain of undue haste in the Council in endeavouring to fulfil their pledge to the public, *that in consideration of the privileges accorded to Chemists and Druggists, a duly qualified class of men should be provided to undertake their important duties.*

There will be an examination for scholarships at Sidney College, Cambridge, on Tuesday, April 1st, 1873. Among the scholarships are two of £40 per annum each, for Natural Science, the following books being recommended:—Heat and Electricity, —Ganot's Physics; Chemistry,—Roscoe and Galloway's Qualitative Analysis; Geology, —Lyell's Students' Elements; Zoology and Physiology,—Nicholson's Manual of Zoology, and Huxley's Lessons in Physiology; Botany,—Bentley's Manual.

The Secretary of the Pharmaceutical Society has received a letter from Mr. Simon, the Medical Officer of the Privy Council, intimating their Lordships' approval of the appointment of Mr. William Martindale, of London, Pharmaceutical Chemist, to be an Examiner in the room of Mr. Augustus Bird, resigned.

It is with pleasure we are enabled to state that the first of Dr. Tilden's pupils who has competed has gained a scholarship of the value of £80 a year for four years' in Natural Science.

At the sitting of the Académie de Médecine, on the 19th November, a commission reported upon a new manuscript work on the Chinese materia medica, by M. Dabry de Thiersant, consular agent of France in China, and M. Léon Soubeiran, Professor at the Paris School of Pharmacy. The work is said to contain not only much that is curious, but also valuable information respecting therapeutic agents in use by the Chinese, which are worthy of further investigation by Europeans. The commission complimented the authors upon having made a real advance upon all analogous works previously published, and recommended that the Academy should request the Minister of Public Instruction to have it printed at the public expense.

The Lord Mayor has appointed Friday next, December 13th, for holding a meeting in favour of the Anti-Income Tax Movement, at the Guildhall.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

December 4th, 1872.

MR. A. F. HASELDEN, F.L.S., PRESIDENT.

Present—Messrs. Atherton, Baynes, Bottle, Betty, Frazer, Greenish, Hampson, Hills, Owen, Radley, Sandford, Savage, Schacht, Shaw, Stoddart, Sutton, Urwick and Williams.

The minutes of the previous meeting were read and confirmed.

The Jacob Bell Memorial Scholarships.

Mr. Atherton asked when the new regulations respecting the Bell Scholarships would come into operation.

The President: In July next.

Mr. Atherton said in that case he feared many cases of hardship, if not injustice, would occur. He knew of one young man at Nottingham who, having communicated with the Secretary, and being informed that his position as a candidate for the Jacob Bell Scholarship would not be affected by his passing his Minor examination, came up for examination accordingly, and passed. Now it appeared that he would be excluded from the Scholarship. There might be other cases of the same kind; and he thought it would be better if the new regulations did not come into operation until 1874.

Mr. Williams thought if the matter were right to be done at all it should be done at once.

Mr. Urwick said he knew of cases in which young men had been preparing themselves to compete for the Senior Scholarship, and were now much disappointed; although, of course, the chief benefit of their studies would still remain to them.

Mr. Savage suggested that the rules should come into operation in July next, but that they should not have any retrospective effect on those who had been preparing for it.

Mr. Hampson said the character of the examination had been entirely altered, so that those who had passed the Minor examination would be almost sure to compete successfully with other candidates.

Mr. Atherton said the young man he referred to was, he believed, just twenty years of age. It was his intention to compete for the Bell Scholarship, and relying on the letter of the Secretary, he had passed his Minor examination.

The Secretary said he was quite under the impression when he wrote that the new regulations would not prejudice the case of the young man who applied to him.

Mr. Sandford suggested that Mr. Atherton should give notice of motion for next month that the regulations should not come into operation until 1874.

Mr. Atherton said he would do so.

Mr. Schacht said it must be understood that the entire change in the regulations should be suspended.

After some further conversation, it appeared that no date had really been fixed for the new regulations to come into operation.

Mr. Bottle thereupon moved:—

"That the alterations in granting the Bell Scholarships adopted by the Council on October 2nd, 1872, and the further alterations adopted on Nov. 2nd, 1872, do not take effect until after the award in 1873."

Mr. Greenish seconded the motion.

Mr. Baynes said he should oppose the motion unless it were understood that the Senior Scholarship was also retained in the next competition.

Mr. Schacht and Mr. Hampson supported the motion, which was then put to the vote with the following result:—

For—Messrs. Atherton, Baynes, Betty, Bottle, Frazer, Greenish, Hampson, Hills, Owen, Radley, Sandford, Savage, Schacht, Shaw, Stoddart and Urwick.

Against—Mr. Williams.

The President did not vote.

PROVINCIAL EDUCATION.

Mr. SCHACHT, in consequence of there having been no meeting of the Provincial Education Committee during the past month, proposed that two applications which had been received from Aberdeen and Leicester should be considered by the Council at once.

Mr. SANDFORD seconded the motion.

Mr. WILLIAMS moved an amendment, which was seconded and carried, for referring the matter to the Committee in the ordinary way, on the ground that it would occupy too much time to discuss these applications at the Council Board.

APPOINTMENT OF ANALYSTS UNDER THE ADULTERATION OF FOOD, DRUGS, ETC., ACT.

DEPUTATION TO MR. STANSFELD.

The PRESIDENT said no doubt the Council had seen a report in the newspapers of a deputation of medical gentlemen to Mr. Stansfeld, one of their resolutions being that chemists and druggists were not competent for the appointment of analyst under the new Adulteration Act. Mr. Stansfeld's reply was that an ordinary chemist and druggist was not competent, and that he did not imagine any such persons would be appointed, He (the President) thought this applied equally to ordinary medical men, that there were among chemists and druggists many quite qualified and eligible for the appointment, and that a deputation on the part of the chemists and druggists should wait on Mr. Stansfeld to urge their view of the matter. The Vice-President, he might say, was also of this opinion.

Mr. SAVAGE thereupon moved that a deputation be appointed to wait upon Mr. Stansfeld on the subject at the earliest possible opportunity.

Mr. HAMPSON seconded the motion, which was carried unanimously, and the President, Treasurer, Messrs. Sandford, Greenish and Betty, the Secretary, and the Society's Solicitor, with power to add to their number, were appointed the deputation.

AMENDED REGULATIONS OF THE BOARD OF EXAMINERS.

The amended regulations, as proposed by the Board of Examiners, were submitted.

Mr. SCHACHT said that as a member of the General Purposes Committee which had met a deputation from the Board of Examiners to consider this matter, he would propose the adoption substantially of the recommendations. All who were present at the large committee meeting would have heard the subject so fully explained by Mr. Carteighe, who perhaps had taken as much interest in the matter as any of the Board of Examiners, that it was not necessary to go into it again. Broadly speaking, however, there were two or three essential points for consideration. In the first place, there was a certain limit of age in the candidate for the Minor examinations, and the necessity of producing a certificate of having been engaged a certain time in the practice of pharmacy. That was one point of the utmost consequence. Then, again, there was a general shifting of the subjects in which the candidates were to be examined—some being taken altogether out of the Major, and thrown altogether into the Minor—and there was an apparent excess of matter urged upon the candidates for the Minor examination. The first topic seemed to be the one of by far the most importance, and to it he felt inclined most warmly to accede. The proposed change seemed a most wise one, and not only wise in itself, but in accordance with the spirit of the Act of Parliament which gave them power to examine at all. In fact, the opposite course seemed to be involved in absurdity; that that Society, in whose hands was vested the power of determining on behalf of the public who was or was not competent to carry on the business of a chemist and druggist, should be able to empower any young man, at the age of sixteen even, to do so was a simple absurdity; and it could not be other than in accordance with the intention of the Act of Parliament, that they should require such persons, who were to be stamped, as it were, with their certificate, to be of the mature age of twenty-one. The necessity, that candidates should pass a certain portion of the previous years in practical pharmacy, was what all recognized as positively necessary when themselves engaging assistants, and it was only fair to insist upon the same thing before allowing any one to practise his profession for the benefit of the public or otherwise. The alterations proposed in the Minor examination were not so great as might appear, and one or two points certainly seemed quite sensible, and only such as ought to be required by those in whose hands the public safety was placed. The small extra modicum of science could not be objected to by any one, and he thought the whole changes were in that direction which had been of late much clamoured for, namely, to prove whether a candidate had a practical knowledge of his business. He believed there was some little difference of opinion whether they had power to make these changes, and with that view he had framed his resolution, so as, if possible, to limit the expression of the opinion of the Council to the principles involved. And as there was also an idea in some minds that by carrying the regulations as they stood, they should be pledging themselves to the existing arrangement of fees, which was quite a different question; he also intended to exclude that subject. If those two elements of difficulty were eliminated from the question he could not but hope that the proposition would be unanimously carried in this form.

> "That the proposed amended regulations of the Board of Examiners with the omission of all words relating to fees, be adopted, and that the question as to the Council possessing the legal power to carry the proposed alterations into effect be referred to the Parliamentary Committee."

Mr. STODDART seconded the resolution with much pleasure. He knew two or three instances at the present moment of young men who had passed the Minor examination, which qualified them to keep open shops as chemists and druggists, who did not really know how to carry on the business at all. The fact was they had been apprenticed to masters who had rather taught them to come and pass the examination than how to carry on their business, so that they really were not qualified. That at any rate showed the necessity for requiring three years' experience before passing the examination, and his own opinion was that a young man ought to know his business first, and then come and pass the examinations afterwards. He had carefully looked over the amended regulations and could see nothing at all to make them too difficult unless it were the few words under the head of botany relating to the "arts and domestic economy." There was nothing there difficult in itself, but it might give the examiner the power of making the examination very difficult indeed.

Mr. FRAZER moved an amendment,

> "That the proposed alterations in the character of the present examination be not adopted."

He said he did not do so without serious consideration, and he was very sorry Mr. Mackay was not present, because he knew he took the same view. He would not go into the minutiæ of the matter, but he did not think any circumstances existed at present warranting a change. He was not aware that the present examinations had proved inefficient, though of course, isolated cases might occur, just in the same way as medical men occasionally proved inefficient to perform the responsible duties cast upon them, even although they might have passed a stringent examination. Generally speaking, however, he did not think the public safety had suffered from the inefficient conduct of their businesses by those who had passed the Minor examination, nor did he think the Privy Council would permit any increase in the stringency of the examination. At the time the Act of Parliament was passed, the Minor examination was intended for assistants, but the Privy Council stepped in and insisted that men who passed it should be allowed to conduct business on their own account, and he believed the same motives which actuated them then, would operate now to prevent what he maintained was a very considerable increase in the stringency of the examination. If changes were to be introduced, there was no doubt there would be a considerable diversity of opinion as to what the changes should be, as there had been with regard to the educational question. Some time ago this matter had been very much discussed in Manchester, and great difference prevailed as to what should be done. Even with the present examination, it was well known there was a great difficulty in getting apprentices. This was found to be the fact in Glasgow, and it was the same in Edinburgh, and he had the testimony of men all over the country to the same thing. Of course there might be exceptions as there were to every rule, and there was also a difficulty in getting young men at the termination of their apprenticeship on account of the stringency of the examinations and the expense of the fees. It had been stated that at the present time there was a much larger number in the trade than was either profitable or necessary, but there could be no doubt, if these changes were carried out, by-and-by it would be found that men could not be obtained to conduct the business, and they would have to take down their shutters themselves. The reason was very plain. The classes from whom they had hitherto derived their apprentices and assistants could not afford to give their sons the education necessary to fit them for these examinations, and the classes above them would not put their sons to such a business. He himself was giving his own son a university education, but he questioned if there were more than three or four young men in Scotland preparing for the business who enjoyed the same advantage. No doubt the business was rising in importance, but so were others in equal proportion. The present regulations had only been four years in existence, and he certainly thought it was too soon to make any change. In confirmation of what he had said with regard to the difficulty of getting assistants, he might add that he had recently heard from one of the large wholesale London houses that even they had now a difficulty in getting assistants, and had to look to the country for them, instead of having a list of applicants to select from, as had formerly been the case. He had no objection to any amount of science being introduced into the profession, and, for himself he regretted that the Senior Bell Scholarship was to be abolished; but still he did not want the compulsory examinations to be higher than the safety of the public demanded. Some persons might think there were too many in the trade, and that if there were less it would be better for those who remained, but still they were bound to act in accordance with the views of their constituents, and not to exclude young men who were not prepared for such stringent examinations, especially considering that even now the Senior Bell scholars were leaving the business and getting into better occupations. Very recently there had been a meeting in Edinburgh of some of the most highly qualified men in Scotland, when there was but one feeling, that the present examination should not be interfered with.

Mr. Hampson, in seconding the amendment, said he was one of the last men who objected to any real advance in pharmacy, or to do anything which would prevent its development in this country; but besides the advancement of pharmacy they must look at the matter from another point of view, not only as pharmacists but as traders; and he wished the Council to pause before sanctioning the great step proposed in the contemplated alterations. Only three or four years had elapsed since a very great change took place, viz., the passing of the Pharmacy Act, which of itself was a very important step as affecting the trade, and he thought it very unadvisable that another change should be made so soon. The examinations as at present conducted, he believed, were not inefficient to test the qualifications of men who had to conduct our business; and it must be borne in mind also that they were not legislating for Prussians or Frenchmen, where the whole influence of the State was exercised to support pharmacy, and to give it a proper status. In the majority of businesses throughout the country a very small amount of pharmacy proper was transacted in a chemist's shop; and until there was a larger amount of real scientific work to do, it was exceedingly premature to take such a step as this. No doubt these regulations had been proposed by the examiners with a good object, and were very suitable for the purpose they intended, but notwithstanding that he believed they were unnecessary and unadvisable. Then, again, the legal obstacle had been referred to, and had not yet been cleared up. It was intended to exclude all who had not passed a period of pupilage; but this, in his opinion, was a retrogressive step. Medical men were now doing away with the system of pupilage, considering it unimportant; and considering that about 99 per cent. of the candidates had passed through an apprenticeship, which was the natural inlet to the trade, he did not think it necessary for the sake of the hundredth to tie their hands in such a way. The London trade were well represented in the Council, and in consequence of the large amount of pharmacy which passed through their hands, they might be disposed to take a partial view of the question; but they must bear in mind the character of the trade throughout the country, and he believed if all country chemists were obliged to pass these examinations, the test would be altogether out of character with the condition of things. There was another important point to be remembered, the number even now leaving the trade. It will be said from a selfish and purely interested point of view, that it would be a good thing for those who remained; but the interests of the public must also be borne in mind. Rather than come to a decided vote on the matter that day, he should much prefer the question being postponed; for he did not think they were competent to settle it in a hasty manner, and most certainly he thought any such change was unadvisable for some years to come.

Mr. Savage said there was one point which presented an obstacle to his mind, namely, the age being fixed at twenty-one. If a boy were apprenticed at sixteen he seldom continued more than four years, which left him one year before he could pass his examination; and he was never so likely to succeed after that interregnum as he would be during his four years of apprenticeship. He thought if a boy were qualified after four years of apprenticeship to pass his examination, it was rather hard that he should be prevented doing so. In the main, however, he agreed with the amended regulations. With regard to the difficulty of getting apprentices, it was probable that under the new state of things there might be even less than there was at present, in consequence of the profession being more appreciated.

Mr. Baynes, as a country member, said while there was much that commended itself to his own mind in the new regulations, he did think they were attempting the alteration much too soon. They had already postponed the operation of the amended regulations with regard to the Bell Scholarships lest they should do injustice to individuals, and it was quite as likely there were many persons to whom this change would also prove a great injustice. The Pharmacy Act of 1868 took by surprise many young men who never expected to have to submit to an examination at all, and an increased stringency would not only be an injustice to these young men, but would arouse a feeling throughout the country that as alterations were being made so soon, others would be made later, and altogether young men would be deterred from turning their attention to the business at all. It must be remembered that in many country places the amount of pharmacy proper was very small indeed, not half a dozen prescriptions, perhaps, being seen in the course of a week, so that a great part of the work of the chemist's shop might as well be done by a porter. If these examinations were made too strict, the result would be the calling into existence of a class of men, not calling themselves chemists, who would retail drugs. Even at the present time, many grocers were selling drugs and chemicals, and the trade was being cut up not only by co-operative stores but by other traders. Making the qualifications too high would be only holding out a premium for irregular trading. He should be glad, therefore, if the question could be postponed *sine die*, especially as all those to whom he had privately mentioned the subject agreed that it was quite a mistake to attempt any further alteration at present.

Mr. Atherton, as another country member, did not think there would be any objection raised within the district he was acquainted with to these regulations being passed almost as they were. In fact, they were not increasing the rigidity of the examinations, but only making them more practical. He did not see that the passing of the Pharmacy Act was any injustice at all, but a very proper measure; and it really had the effect of lowering the examination, because the qualifications which now enabled a man to conduct a business were previously only intended for assistants, those who intended to carry on business themselves being expected to pass the Major examination.

Mr. Urwick did not think sufficient weight had been given to the opinion of those who had proposed the alterations, namely, the Board of Examiners, who were, perhaps, the best qualified to form a judgment on the matter. They seemed to think that the time was come when rather more should be required of those who presented themselves for examination, intending to carry on business, and he could not agree that men did not know they would have such an examination to pass. Most of those who had entered the trade ever since 1844 or 1845, should have looked forward to passing the Major examination; the Minor, which now qualified a man to commence business, was not so stringent as the Major. It was only proper that the public should be protected by a severer test being imposed, and he did not see that the complaint could be raised by those who were chemists and druggists and conducted country businesses, inasmuch as they had time given them to give notice of their intention to pass the modified examination. In his opinion, also, the examiners had the power of requiring almost as much (save the practical part) from the candidates under the present regulations if they thought fit; and the alterations appeared to be proposed more with the idea of making the change public, so that young men might see what would be required of them. At the same time, he agreed with Mr. Savage that the age might be reduced one year, for he thought any one might learn the business in three years if he had common sense and application.

Mr. Williams said that these new regulations really arose through the past action of the Council itself. About a year and a half ago the Council were forcibly impressed from what occurred out of doors, as well as what they heard in other ways, that the examinations were not anything like what they ought to be; Mr. Siebold, of Manchester, for instance, expressing an opinion that they were a sham. The consequence was that a deputation of the Council met the Board of Examiners, who were then of opinion apparently that no alteration was required; but the question being argued at some length, the Board of Examiners took a different view, and the result was that, after much consideration, these improved regulations had been proposed. The attempt had been, not to make the examinations more stringent, but to make them more consistent; and he believed this was their real effect. The present regulations required a man who went up for the Minor to be examined in prescriptions; but there was no power of examining him as to unusual or poisonous doses or in mistakes. Now, it was certainly very inconsistent to give a man the power to carry on business, when he had not completed his examination in such a necessary subject. The Council had impressed upon the Board of Examiners that they should make the Minor as purely practical as possible, so that a man who had passed some time behind the counter of a good house of business ought to be able to come and pass his examination without the necessity of cramming or resorting to other extraneous sources. At the same time, it was felt that the Major should be made if possible the test of scientific acquirements, whilst the Minor was the test of practical knowledge. In that way he believed they would be carrying out the intention of the Act of Parliament and doing their duty both to the public and to themselves, which, he believed, with the present examination they did not do. He would only add that he might take exception verbally to some of the regulations; but he would not do so considering that the whole matter had been carefully gone into by the Board, who were really the best judges of the matter.

Mr. Owen said, though he did not wish in any way to oppose the advancement of pharmacy, he could not forget what had been said by Mr. Baynes and Mr. Hampson, who had an extensive knowledge of country businesses. He could also speak as to the difficulty of getting assistants, particularly juniors, and thought any further restriction would be a great mistake, especially considering the short time since the Act was passed.

Mr. Radley, as a country member, said the new regulations recommended themselves very strongly to his judgment, and he did not anticipate any difficulties whatever being raised in the country, for he believed they would meet with general approval. The certificate given to a young man entitled him to commence business, and there was certainly nothing in the new regulations which was not necessary for him to be examined in, nor did he see anything to be objected to. He had spoken to some of his friends in the country on the matter, and they agreed that it was perfectly right that the examination should be improved.

Mr. Shaw said it always appeared to him that the Act of 1868 was defective in certain respects, especially in allowing a young man to be examined at any age, either fifteen, sixteen, or seventeen. It might, however, be a question whether twenty should not be substituted for twenty-one.

Mr. Williams said there were reasons why it could not be done.

Mr. Shaw said that requiring three years practical experience was a very good feature, for he had it on the authority of Professor Attfield that those who had had no practical experience in a shop were the very persons who endeavoured to get through their examinations by means of cramming. In his opinion it was desirable that the Minor examination should be made as stringent as possible, seeing that the passing of it entitled a person to undertake the dispensing of medicine. It was true at the time the Act was passed the Government did not wish that the Major examination should be a business qualification, but it did not necessarily follow that that should be understood to apply to all future time. Under the head of chemistry in the Minor examination there was the word "practical" in italics, which he should like to have some definition of, because, as it stood there, it appeared to him that it might be construed to mean that the candidate must have been practically engaged in a chemical manufactory.

The PRESIDENT said he did not suppose any such thing was intended, but it only meant that the candidate should possess a knowledge of how certain articles, such as quinine or bicarbonate of soda, were produced.

Mr. SHAW said he only wanted it made clear, so that there might be no mistake about it. With regard to the objections which had been made, he thought the change would improve the *status* of the profession, and induce young men to come into it, knowing that they would occupy a higher position than they had hitherto done. In that way he hoped they might in time arrive at a greater unanimity in charges for the greater benefit of the whole trade. If, on the contrary, they enabled young men to come in on very easy terms, they would only be perpetuating the evils which had been in existence for the last thirty years. He should therefore vote for the adoption of the new scheme, especially considering that the Board of Examiners so strongly recommended it.

Mr. SANDFORD said a great deal had been said about its being proposed to change the examination at the present time, but in October, 1873, when the new regulations would come into force, the Pharmacy Act of 1868 would have been in operation five years, and therefore they could scarcely expect any young man who was apprenticed at that time would be injured by them, and any who had entered the trade since had come in knowing that such examinations must be passed. Still, he should have no objection to the date being altered to 1874, if it were desired, which would give them six years. He should advocate the adoption of the resolution, especially considering that Dr. Greenhow, the Government visitor, had expressed himself in these terms in his Report: "In my first report on the Examinations of the Pharmaceutical Society I stated that the Minor examination was in my opinion as stringent as could with fairness and practical advantage be enforced at that time. Three years have, however, now elapsed since the provisions of the Pharmacy Act came into operation, and there could be no hardship provided due notice were given beforehand, if at the end of another year candidates for the Minor examination were to be examined practically as to their ability to determine by means of the proper tests, the presence of the acid and base in solutions of one or more of the salts commonly used in medicine, or to ascertain the purity and strength of some of those officinal articles most likely to be impure or to vary in strength. This addition to the present subjects of examination seems the more desirable when it is considered that candidates who have passed the Minor examination and been registered as chemists and druggists, are thereby qualified to keep shops for the retailing and dispensing of medicines." Now that was a very important point. The position was altered altogether. A young man was now sent out into the world as a safe dispenser to be trusted by the public, and that altered the question very much. It had been proposed that the age should be twenty, but their solicitor informed them that it was really a question whether a man before the age of twenty-one had any right to be examined at all. Until that age he was only an infant, and was not entitled to the privileges of a "person" as mentioned in the Act. He believed twenty-one would be a very good age, because it would almost ensure a certain period of practice in dispensing. It had occurred to him as a desirable regulation, that three years, or four, might be required between the passing of the Preliminary examination and the passing of the Minor, which would also have the effect of ensuring only properly educated youths coming into the business.

Mr. SUTTON asked if that would be legal.

Mr. SANDFORD said he did not know of any illegality in it. They already provided that a man could not come up for the Major until three months after passing the Minor, and it would be just as legal to say three years as three months. He merely threw out what seemed to him a good way of securing the Preliminary examination being passed at the commencement of the apprenticeship. With regard to the alterations themselves, he could not see very much difference between them and the regulations in the Calendar which he held in his hand, and he agreed with what had been said, that the examiners might have made the examinations just as stringent under the old as they could under the improved regulations. They had transposed a certain part of the old rule headed "Practical Dispensing" to "Reading Prescriptions," and had added 'to detect errors, discover unusual doses, and have a general knowledge of posology; also to render in good Latin prescriptions written in English." In the old form it was to translate prescriptions, and detect unusual doses, and to render literal as well as appropriate translations of the directions for use. Now here they had to render in good Latin prescriptions written in English. All that was perfectly necessary, for it was well known that errors did occasionally occur in prescriptions, and the detecting unusual doses was the same thing as detecting errors. That, therefore, was very little more than there was before. Then in the pharmacy clause, they had added and to give "the best excipients and methods of manipulation for forming emulsions, pills, etc.," and also "to give the proportions of the active ingredients, and possess a practical knowledge of the processes" for making certain preparations. Formerly they were asked to give all the ingredients in certain preparations, but it was of much more importance that the student should know as well as the principal ingredient in what way the preparation is made. For instance, to take confection of senna it was more important that the young man should know how to make it than that he should know the exact weight of figs to be used. The materia medica clause stood as before. In the botany clause Mr. Stoddart took exception to the words "domestic economy," and he believed any little matters like that the examiners would only be too glad to alter if necessary. The clause relating to chemistry did seem stiffer than many would like; it stood "to determine practically, by means of tests, the presence in solution of the chemicals in common use, and explain the reactions which occur in each case. To possess a general knowledge of the laws of chemical philosophy" (which seemed a rather wide expression), "and a practical knowledge of the means of determining specific gravities, densities and temperature, and of the instruments appertaining thereto, and the physical and chemical constitution of the atmosphere." He did not know how that could be modified in any way, it was at any rate not more than a man ought to know. He had certainly met with such lamentable errors in the examiners' room as perfectly startled him. He had heard from the President the other day that in a prescription put before the young men who came to be examined, the word *incipiens* occurred, and coming under one of the examiners there was only one man who translated it correctly.

The PRESIDENT: And that prescription has been before the candidates for the last ten years.

Mr. SANDFORD said in his own experience he had met with the most gross errors in translating directions for use, which showed very clearly that they wanted better educated youths in the first place, and that after a certain time they should pass a good examination before they were entrusted to dispense medicines for the public.

Mr. WILLIAMS said that at a late meeting of the Board of Examiners he understood one of the questions put was this, something was to be evaporated in a water bath, and the question being asked what was the temperature of the water, the young man said he did not know, he did not expect that question.

Mr. BETTY said he was sorry the regulations had not been taken clause by clause, so that whatever was open to objection might be pointed out and everything considered on its own merits, especially as it would be most invidious and distasteful to reject *en masse* the whole scheme. However, Mr. Sandford had gone through most of the details, and said exactly what he should have done if necessary, and therefore he would only add, that he hoped they would vote almost unanimously in favour of the new regulations, which he believed would thoroughly stand the test when they came to be applied.

Mr. Bottle said the time had now arrived when it was the duty of the Council to vary the examination in accordance with what was palpably the intention when the Act was obtained. The 6th section of the Act of 1868 stated that the examinations should be such as were provided for and contemplated by the Act—there were no assistants under that Act—"or as the same may be varied from time to time by any bye-law to be made in accordance with the Pharmacy Act as amended by this Act." So that clearly the Legislature intended at that time to adopt what was then held to be the qualification for assistants, in order that they might not take any one by surprise in being called upon to pass an examination, but that they should have reasonable time to prepare for something better. The preamble of the Act said, "Whereas it is expedient for the safety of the public, that persons keeping open shop for the retailing, dispensing, or compounding of poisons, and persons known as chemists and druggists, should possess a competent, practical knowledge of their business;" and further, that they should be duly examined as to that practical knowledge. He maintained that the alteration proposed was nothing more than asking men to show that they were practically acquainted with the business, and all this might fairly be expected of them. Mr. Sandford, however, had taken up the position which he was about to take in asking to defer, until 1874, the introduction of this new regulation. He thought that was only fair, and would give longer notice to those who were now preparing for examination. As to the observation that it was utterly impossible to expect the pupils of country chemists to pass the improved examination, he thought that if any pupils ought to pass such a one, they were the pupils of country chemists, for if their masters knew anything at all, they had more time to teach it than those engaged in business in London or large towns. Then it was said that twenty-one was objectionable, but he did not think so. He remembered the first apprentice he took was the son of a friend of his who had been broken down by over exertion, and at the earnest request of the boy's mother he took him when thirteen and a half years of age, being apprenticed until he should be twenty-one, and he stayed two years afterwards as an assistant. He maintained that the very fact of this arrangement as to twenty-one would be a great advantage to masters taking apprentices, inasmuch as it would enable them in many cases to retain them until twenty-one, and they would thus get over the difficulty which had been spoken of as to getting junior assistants. His best assistants he had always found had been his own apprentices whom he had himself trained. Therefore the very fact of a man knowing that he could not pass his examination till he was twenty-one, would lead in many cases to his binding himself for five years instead of four.

Mr. Hills asked the proposer and the seconder of the resolution if they would agree to alter the date to 1874 instead of 1873. By that means they would be acting perhaps more fairly towards those who came into the business.

Mr. Sutton said he had been talking to Dr. Odling and Professor Williamson in regard to the nature of the examinations which they conducted, and how they dealt with those questions which referred to the processes going on in large chemical manufactories—such as alkali works. They told him that they always incorporated these things in the examination; and he asked them how they provided for the case of a man who came up from some locality where he could know nothing at all about these things. They told him they did not make any strong point of such questions. If they happened to have a man from a locality where he had an opportunity of obtaining a knowledge of these processes they passed it to his credit, and if he did not, they passed it by altogether. That appeared to him the only way of doing it; for otherwise it simply resolved itself to this—a man must have lived in a certain place or he could not know anything about such matters.

Mr. Baynes said if the year 1874 was substituted for 1873, it would meet the views of many of the Council.

Mr. Schacht, in replying on the amendment, said he had not made the alteration just referred to for this reason, that he should be rather disposed to suggest after the discussion that had taken place, that still greater liberty should be taken with the resolution, namely, that the regulations should be referred to a committee for the purpose of discussing every line and word, and if needful of making here and there a verbal alteration. If it were thought by such modifications the principle would in any way stand in jeopardy, he should adhere to his original resolution. But still he should like to make the alterations to meet the views which had been suggested if possible; and in doing so he knew that they would not be acting contrary to the feeling of the Board of Examiners. For instance, if there was a strong objection to the introduction of the words "domestic economy," he knew the examiners would be willing to expunge them. Their intention, however, in introducing them was merely that the candidates' knowledge should not be absolutely limited to medical botany. If, however, it was supposed that the words referred to included an examination upon all subjects connected with the words "domestic economy," of course it would be better to expunge them altogether. He, however, wished it to be understood particularly, that the Board of Examiners considered the general arrangement of the paragraphs as essential to their scheme, and that to alter the balance of the subjects would spoil it altogether. To each of these subjects a certain number of marks were assigned, and they were carefully arranged so as to convey a general result to the minds of the examiners. Any material alteration, therefore, would be mischievous. For his own part he regretted the suggestion of postponement for a year, for he did not see why it should not come into operation at the end of the current session. At the end of that time he saw no injustice to anybody if the new regulations came into force. At the same time he felt quite sure that the Board of Examiners were the last body who would wish to insist on their own views, but would be willing to explain them if that were felt to be necessary. He would remind those who thought there was an extra stringency in the regulations, that the full number of marks which could be obtained by a candidate were not required in order to entitle him to a certificate. As to altering the age, he thought there would be equal difficulties in the way, and on the whole he should prefer the matter being referred to a committee who should confer with the Board of Examiners.

Mr. Stoddart, as the seconder, said he should be glad to consult with Mr. Schacht. He was only anxious that they should have the Minor made a good and practical examination. He had been rather misunderstood as to his objection to the words "domestic economy," his only object being that he might be able to advise young men who frequently came to him as to the course which their studies should take.

Mr. Greenish said that the words were simply inserted in order that the examiners might have an opportunity of ascertaining whether the young men knew anything of botany generally. In other words, to give the examiners more scope.

The President said he believed the Board of Examiners had no other view in framing these regulations than to carry out the wishes expressed by the Council some time ago, and also the wishes of the Government; and he believed they had also framed them with a view to the convenience of the candidates. They had taken from the Major such portions as seemed useless and unnecessary, having been already tested in the Minor. Thus, the determination of unusual doses, etc., being now provided for in the Minor, together with the reading and translating of prescriptions, these subjects were removed from the Major altogether, as it was evident that if a man could translate prescriptions and detect errors well enough to carry on a business, it was unnecessary to test him further. Again, with practical dispensing, as it was called, in the Major examination, the candidate was only required to give the strength of certain solutions, and the supposed best way of making pills, emulsions, etc., which was in reality theoretical dispensing; and this having been now provided for in the Minor, was removed from the Major. Looking at it as a whole, he did not think there was anything more difficult than the examiners might make the present examination if they saw fit. With regard to fees, they had been simply inserted as a piece of information for candidates, as the Board of Examiners had nothing whatever to do with regulating them. Nor did he think there would be any objection to removing the words "domestic economy," the reason for the introduction of which had already been explained. All the examiners were in favour of the age being fixed at twenty-one; and with regard to the supposed difficulties of their country friends, he could only say that all their best assistants came from the country. He must say he hoped the regulations would be passed at once, for if sent back to a committee, it would only cause delay. He should prefer the resolution terminating at the word "adopted," leaving the legal question for a separate resolution. With regard to the time, he was rather in favour of 1874, because it would take two or three months at the earliest before the necessary bye-laws could be legally passed and go to the Privy Council for approval, at the end of which time candidates would have only six months to prepare themselves. He should be glad if Mr. Frazer could see his way to withdraw his amendment.

Mr. FRAZER regretted that he could not do as the President suggested, but he had not proposed his amendment without serious consideration, and he had heard nothing in the course of the discussion to induce him to alter his mind. He must say, also, he regretted that a vote had not been taken on the scheme as it stood, without any alterations being suggested. It had been stated that the character of the examinations as a whole had not been altered, but his complaint was that so much of the Major had been imported into the Minor as to render it much more difficult. He could not for one moment agree with Mr. Savage, that by rendering the examinations more difficult would remove the difficulty of getting apprentices, for he was convinced the result would be quite the reverse. In conclusion, he desired to add that he yielded to no one in his respect for the Board of Examiners, who had no doubt prepared what in their judgment was an improved scheme, but he could not agree in the expediency of introducing it at the present time.

The amendment was then put to the vote with the following result:—

For—Messrs. Frazer, Hampson and Owen.

Against—Messrs. Atherton, Baynes, Betty, Bottle, Greenish, Haselden, Hills, Radley, Sandford, Savage, Schacht, Shaw, Stoddart, Sutton, Urwick and Williams.

The amendment was therefore lost.

Mr. SCHACHT again expressed his readiness to modify his resolution, so that the matter might be referred to a committee, who should confer with the Board of Examiners as to verbal alterations.

After some further discussion, however, it appeared to be the general feeling that any further delay was unadvisable, and the motion was put in this shape:—

"That the proposed amended regulations of the Board of Examiners, with the accompanying slight alterations, and the omission of all words relating to fees, be adopted."

The vote being taken, gave the following result:—

For—Messrs. Atherton, Baynes, Betty, Bottle, Greenish, Haselden, Hills, Radley, Sandford, Savage, Schacht, Shaw, Stoddart, Sutton, Urwick and Williams.

Against—Messrs. Frazer, Hampson and Owen.

The resolution was therefore carried.

The AMENDED REGULATIONS are as follows:—

"*Regulations of the Board of Examiners, for the Examination and Registration of Pharmaceutical Chemists, Chemists and Druggists, and Apprentices or Students, in accordance with the Pharmacy Acts,* 15 & 16 *Vict. cap.* 56; 31 & 32 *Vict. cap.* 121; *and* 32 & 33 *Vict. cap.* 117.

"The Board of Examiners in London meets for conducting the Minor and Major examinations every month, except in August and September. For the Modified examination, the Board meets as often as required. Candidates must give notice to the Registrar of their intention to present themselves and pay the fee, on or before the first of the month in which the examinations are held.

"The Board of Examiners in Edinburgh meets for the Major, Minor, and Modified examinations as often as required. Notice is given in the PHARMACEUTICAL JOURNAL when meetings take place.

"Secretary to the Board in Edinburgh, John Mackay, 119, George Street, Edinburgh."

"*The First or Preliminary Examination.**—(For Registration as Apprentices or Students.)—This examination is held throughout Great Britain on the first Mondays in January, April, July, and October in every year. Candidates for this examination must give not less than ten clear days' notice.

"The examination is a written one, and comprises

- Latin,—translation into English of a paragraph from the first book of Cæsar ('*De Bello Gallico*'), or a passage from each of the following works: Pereira's 'Selecta e Præscriptis,' and the last edition (Latin) of the London Pharmacopœia.
- Latin Grammar.
- English Grammar, Composition.
- The first four rules of Arithmetic, simple and compound, Vulgar Fractions, and Decimals, and a thorough knowledge of the British and Metrical systems of Weights and Measures.

"In the case of candidates residing in the country and unable to attend in London or Edinburgh, the Registrar shall send the questions, under seal, to the person appointed to superintend the writing of the answers,† with instructions that they be opened by him in the presence of the candidates, who shall write the answers forthwith in his presence in a given time.

"*Minor Examination.*—(For registration under the Pharmacy Act, 1868, as chemists and druggists.)

"Candidates for this examination must have passed the First or Preliminary examination, and must produce certificates of having attained the full age of twenty-one years, and also of having been employed for three years by a pharmaceutical chemist, or chemist and druggist, and in dispensing and compounding prescriptions.

"The following form the subjects of examination:—

"Prescriptions.—The candidate is required to read without abbreviation autograph prescriptions; translate

"* Certificates of having passed the Local Examinations of the Universities of Oxford, Cambridge, or Durham, the Examination of the College of Preceptors; or those of any legally constituted examining body previously approved by the Council, *provided Latin and Arithmetic be included in the subjects*, are accepted in lieu of this examination.

"† The Council have appointed the Local Secretaries to undertake this duty.

them into English; and render a literal as well as an appropriate translation of the directions for use. To detect errors, discover unusual doses, and have a general knowledge of posology; also to render in good Latin ordinary prescriptions written in English.

"Practical Dispensing.—To weigh, measure, and compound medicines; write the directions in concise language in a *neat and distinct* hand; to finish and properly direct each package.

"Pharmacy.—To recognize the preparations of the Pharmacopœia which are not of a definite chemical nature, and have well-marked physical characters, such as extracts, tinctures, powders, etc.; to give the proportions of the active ingredients, and possess a *practical* knowledge of the processes, and the principles of the processes by which they are made, and of the best excipients and methods of manipulation for forming emulsions, pills, etc.

"Materia Medica.—To recognize specimens of roots, barks, leaves, fruits, resins, gums, animal substances, etc., used in medicine; give the botanical and zoological names of the plants, etc., yielding them, and the natural families to which they belong; name the countries and sources from which they are obtained, the officinal preparations into which they enter, and judge the quality and freedom from adulteration or otherwise of the specimens.

"Botany.—To recognize the more important indigenous plants used in medicine. To possess a general knowledge of the elementary structure of plants, and the structure and distinctive characters of roots, stems, leaves, and their parts. To name and describe the various parts of the flower.

"Chemistry.—To recognize the ordinary chemicals used in medicine. To possess a *practical* knowledge of the processes by which they are produced, the composition of such as are compound, and explain the decompositions that occur in their production and admixture, by equations or diagrams. To determine practically, by means of tests, the presence in solution of the chemicals in common use, and explain the reactions which occur in each case. To possess a general knowledge of the laws of chemical philosophy, and a *practical* knowledge of the means of determining specific gravities, densities and temperature, and of the instruments appertaining thereto, and the physical and chemical constitution of the atmosphere.

"*Major Examination.*—(For registration as pharmaceutical chemists under the Pharmacy Act, 1852.)

"Candidates for this examination must have passed the 'Minor' examination at least three months previously.

"Materia Medica.—This comprises a *practical* knowledge of the methods of estimating the value of important drugs, of obtaining their active proximate constituents in a separate state; of identifying them and ascertaining their purity or impurity by tests.

"Botany.—This comprises an intimate acquaintance with the parts of the flower, fruit, and seed; the functions and mode of arrangement of the different organs of plants; a knowledge of the general principles of classification, and of the Linnæan and De Candolle's systems. The candidate must be able to distinguish practically between each of the following natural orders:—Ranunculaceæ, Papaveraceæ, Cruciferæ, Malvaceæ, Leguminosæ, Rosaceæ, Cucurbitaceæ, Umbelliferæ, Compositæ, Gentianaceæ, Convolvulaceæ, Solanaceæ, Atropaceæ, Labiatæ, Schrophulariaceæ, Polygonaceæ, Euphorbiaceæ, Orchidaceæ, Iridaceæ, Liliaceæ, Melanthaceæ, Graminaceæ; and refer to their respective Orders such specimens as may be shown to him.

"Chemistry.—This comprehends an intimate knowledge of the laws of chemical philosophy, a *practical* knowledge of the nature and properties of the elements and their compounds, both organic and inorganic, especially those used in medicine or the arts. The different combinations and decompositions must be explained by equations; also the *qualitative* analysis of the more important chemicals, *e.g.* nitrates, chlorides, carbonates, sulphates, phosphates, oxalates, tartrates, etc., and the detection of impurities in them, and the *volumetric* estimation of the strength of all pharmacopœia preparations in which standard solutions are ordered to be used.

"An elementary knowledge of the properties of light, heat, electricity, and magnetism is also required."

To come into force, October, 1874.

Examination Fees.

Mr. Williams also moved, and Mr. Urwick seconded a resolution—

> "That the consideration of the fees to be paid in future by candidates at examinations be remitted to the Parliamentary Committee."

This was also put and carried.

On the motion of Mr. Williams, the names of Messrs. Fraser, Greenish and Urwick were added to the Parliamentary Committee.

Proposed Alterations in the Bye-laws.

Mr. Hampson said, in the absence of Mr. Brown, he wished to propose a resolution to this effect:—

> "That no resolution by which the legal position of members of the Society, or the legal position of chemists and druggists, whether members of the Society or not, may be altered, shall be passed at any meeting of the Society unless fourteen days' previous notice shall have been given of the intention to propose such resolution."

Mr. Williams said he was going to propose a resolution which he thought would render that unnecessary, and he would bring it forward now:—

> "That the Parliamentary Committee be instructed to examine the bye-laws generally, and to prepare and report upon such alterations as may be deemed expedient, more especially as regards the conduct of the general meetings of the Society."

Mr. Urwick seconded this motion, which was carried unanimously.

Elections.

Pharmaceutical Chemists.

The following gentlemen, being duly registered as Pharmaceutical Chemists, were granted a diploma, stamped with the seal of the Society:—

Butterfield, Edward ....London.
Clarke, George Ernest........Stowmarket.
Robertson, F. Freer Leslie....London.
Saunders, Thos. Bealby ......Cheltenham.

Associates.

The following, having passed the Minor examination, were elected Associates:—

Birrell, George ....Kensington.
Buswell, Arthur ....Winchester.
Butler, John Harsant ....High Wycombe.
Chesterton, Wm. Peter ......Walsall.
Crundall, Augustus Horton....Cirencester.
Faraker, John Joseph ....New Brighton.
Gatenby, Robert ....Beverley.
Griffiths, Evan ....Cardiff.
Johnson, Fletcher Atkinson ..Driffield.
Maitland, Pelham Christopher Launceston.
Parris, Thos. Watkin ....Taunton.
Urwin, Matthew ....South Shields.
Vigis, Joseph Lewis..........Shepton Mallet.

Finance.

The report of the Finance Committee was received.

"The Committee recommended the purchase of £1000 Stock New Three Per Cents. on the general fund, etc.

"*Collector for* 1873.—Mr. L. S. Hughes was recommended for re-appointment as collector of the subscriptions to the Society and to the Benevolent Fund for London and the suburbs.

"*Annual Subscriptions.*—The Committee also recommended that the accounts of the Local Secretaries and the London Collector's account with the Registrar for subscriptions received for the current year be closed at end of March.

"That all subscriptions remaining unpaid after that date be applied for by the Registrar direct.

"That a copy of these resolutions be sent to each Local Secretary and printed in the Society's Journal and Transactions.

"*The Register for* 1873.—Messrs. Butler and Tanner's estimate for printing the Register was recommended to the Council for acceptance.

"*The Calendar for* 1873.—Messrs. Taylor and Co.'s estimate for printing the Calendar was also recommended for acceptance."

The Report and recommendations of the Committee were adopted.

BENEVOLENT FUND.

The Report of the Committee was received and adopted. It stated that the Secretary had received a communication from the executors of Mrs. Jane Lyons, of Albert Terrace, Knightsbridge, stating that that lady had left a legacy of £500, free of duty, to the Benevolent Fund. It also recommended the grant of £10 to the widow of a late annuitant on the Benevolent Fund.

LADY STUDENTS.

Mr. HAMPSON moved in accordance with notice—

"That lady students attending the classes or lectures are eligible to compete for the Sessional Prizes and Certificates, and for all prizes and scholarships given for proficiency in this Institution."

He said that when he asked the Council to admit ladies as students, and received a unanimous assent, he did not dream of any doubt arising as to whether such students would be entitled to compete for class prizes. He thought there was no doubt that lady students might claim this as a matter of right; but it appeared there was some doubt existing, as evinced by a letter received from Mrs. Garrett-Anderson, and in order to remove it he had brought forward the resolution. He would not weary the Council by adducing self-evident reasons in support of the claim of the lady students, for he thought a moment's reflection would decide every one to vote unanimously in favour of it. The professors, as well as the present and prospective lady students, were waiting the decision of the Council of the Society, and to refuse them the same privileges as gentlemen, after so freely admitting them to the lectures, would be to deceive, disappoint, and use most unfairly those who were entitled to fair play, impartial treatment, and courtesy.

Mr. SCHACHT said he was very happy to second the resolution, but he thought the latter clause must be omitted, as it would include the Bell Scholarship, which, as it included laboratory instruction, was already decided against by the previous vote of the Council.

Mr. HAMPSON said he would confine the resolution to sessional prizes and certificates.

Mr. SANDFORD said the students could already claim certificates by law.

Mr. HILLS said he was at the Royal Academy on the previous night, when he found a large number of young ladies and young gentlemen studying together with no difficulty whatever being apparent. There were many large establishments in London where both sexes were thrown together without any disadvantage.

Mr. BETTY said this was a very important question, and he should like to ask the mover and seconder of the resolution if they had any ulterior object in view, or if they merely confined it to the resolution proposed. If so, he should have no objection to vote for it; but if it was meant as an encouragement to ladies to enter the business, he should contest it as a matter of principle and expediency.

Mr. SCHACHT said he would candidly state that he meant what was contained in the resolution and nothing more. The future would take care of itself.

Mr. BOTTLE called attention to the existing regulations as bearing on the matter. Mr. Hampson's resolution proposed to throw open the door to ladies to compete for everything which the Council had to give away. Now, however, it was proposed to withdraw the Bell Scholarships; and it would be found on referring to section 4 of the Rules and Regulations for Prizes that the "Prize of Books" and "the Pereira Medal" could only be given to associates or registered students of the Society. He took it that ladies who were permitted to attend the lectures on botany and chemistry were not associates, and consequently were not entitled to compete for these prizes. He had no objection to ladies attending the botanical classes and receiving the prize which entitled them to admission to the Royal Botanical Society's Gardens; but with regard to the other prizes, much as they might desire to be generous to the female sex, they must not forget to be just towards the male. Now it must be remembered that ladies who entered for the chemical or botanical lectures would probably be able to devote a great deal more time to them than young men who were at work in the laboratory as well, and it would be hardly fair to the latter to put them on the same footing with a young lady who had nothing whatever to do but study the particular subject in which she wished to gain a prize. He had, therefore, sketched out an amendment which he thought would meet the case, to the effect—

"That lady students attending the chemical or botanical lectures are entitled to receive certificates of such attendance, but are not eligible to compete for the prizes now offered by this Council, and that it be referred to the Library, Museum and Laboratory Committee to consider and report upon the expediency of offering special prizes to be competed for by lady students."

Mr. STODDART said he would second the amendment. One reason in favour of altering the bye-laws was, that in his opinion the Herbarium prize ought to be restricted to those actually engaged in the business. It was impossible for a young man in business to compete on fair terms with another who had the whole of his time at disposal.

Mr. HAMPSON said he had certainly counted on Mr. Bottle's support, knowing him to be both just as well as generous. With regard to lady students attending only one or two classes, and therefore being able to concentrate their energy on the particular subjects they studied, it must be remembered that the same argument applied to gentlemen students, but no alteration of the rule was made to meet their case. Of course lady students would be ineligible to compete for prizes which were restricted to associates, and that he did not propose to deal with. He believed, however, that one lady was already an associate, and no doubt one or two more would become so. Lady students did not want special prizes, but the opportunity to compete with male students under precisely similar circumstances. The law permitted ladies to become chemists and druggists, and therefore, in the interests of pharmacy and common sense, they ought to grant them the same privileges as male students.

Mr. SANDFORD thought it was a mistake to suppose that any lady was an associate.

Mr. HAMPSON said he referred to a lady who had passed the Preliminary examination.

Mr. SANDFORD said that was another matter.

The PRESIDENT said the sessional prizes and certificates were open to all students, and were not restricted to associates,

Mr. HILLS thought the subject required a good deal of consideration, and though he did not wish to be so ungallant as to vote against the ladies, he should like to give the matter more consideration before he could vote for the resolution. He therefore hoped that consideration would be deferred for another month or so.

Mr. SHAW said this question of female pharmacy was constantly coming forward, month after month, which he thought was a very great pity, and should much prefer they should come at once to some decision with regard to it. Referring to the Act of Parliament, there were several clauses in which the term "person or persons" occurred, and it must evidently be meant to include both sexes, and it had already been so determined with regard to the registration of females who were in business prior to 1868. According to the bye-laws, he considered that ladies were eligible to be elected as associates if they passed the proper examinations; and if that were so, they were not placed on a fair footing if the opportunities of studying were not placed at their disposal, and the same advantages given to them as to the other sex. There might be many circumstances in which it would be proper and desirable that females should study pharmacy.

Mr. URWICK saw no objection to Mr. Hampson's resolution, and thought the fact of ladies competing for the prizes would stimulate young men.

The PRESIDENT thought it would be very hard if a lady like Mrs. Garrett-Anderson were allowed to compete and take away the prizes from the other students.

Mr. HAMPSON said Mrs. Anderson did not propose to come there herself, but she applied on behalf of the lady students.

After some further discussion Mr. HAMPSON said in the interest of the ladies themselves, and also of the better reason of some of the members present, he would withdraw the resolution for a time.

LIBRARY, MUSEUM AND LABORATORY COMMITTEE.

The Report of this Committee was presented. It recommended the purchase of the following books for the Library:—

Bloxam's 'Chemistry, Inorganic and Organic,' second edition.
Bouchardat's 'Nouveau Formulaire Magistral,' seventeenth edition.
Dorvault's 'L'Officine,' eighth edition.
Fresenius's 'Qualitative Chemical Analysis,' eighth edition.
Hofmann's 'Modern Chemistry.'
Nicholson's 'Introductory Text-Book of Zoology'; 'Advanced Text-Book of Zoology'; and 'Manual of Zoology,' second edition.

It also stated that Professor Attfield had suggested the desirability of appointing an Assistant Demonstrator in the Laboratory in consequence of the great number of students at present engaged; but the Committee were not able to recommend such an appointment without further information.

The report and recommendations were received and adopted.

A letter from Professor Attfield was also read on the subject, and the President reported the result of a conversation he had had with him. After some conversation, it was resolved that a temporary engagement be entered into for three months only, and that Mr. Shenstone, one of the Junior Bell Scholars of last session, be offered an appointment for that period.

HOUSE.

The Report of this Committee was received and adopted. It contained nothing calling for report.

PARLIAMENTARY.

The Report of the Parliamentary Committee was read, advising, amongst other things, the taking of proceedings against several persons who, it was alleged, had infringed the provisions of the Pharmacy Act with regard to the sale of poisons, etc. It also contained correspondence with the solicitor, reporting the proceedings which had been already taken in cases previously under consideration. The Report was received and adopted.

GENERAL PURPOSES.

The Report of this Committee was received and adopted.

REPORT OF THE BOARD OF EXAMINERS.

November, 1872.

ENGLAND AND WALES.

Examination.	Candidates. Examined.	Passed.	Failed.

PHARMACEUTICAL MEETING.

Wednesday, December 4th, 1872.

MR. A. F. HASELDEN, F.L.S., PRESIDENT IN THE CHAIR.

The following donations to the Library and Museum were announced, and the thanks of the Society were voted to the donors:—

'The Lichens and Scalemosses of Devon and Cornwall,' by E. M. Holmes; 'The Mosses of Devon and Cornwall,' by E. M. Holmes and F. Brent, from the Curator; 'Medico-Chirurgical Transactions,' vol. LV., from the Royal Medical and Chirurgical Society of London; the 'American Dispensatory,' by J. King, M.D., eighth edition, from the author and publishers, per Professor Wayne, of Cincinnati, and Mr. Umney, of London; 'De la Respiration Végétale,' per A. Guillaumet, from Dr. Soubeiran; Specimens of Amyl Hydride, from Mr. J. Robbins; section of Baobab Tree, from Mr. T. Baynes.

Professor BENTLEY drew the attention of the meeting to a section of the baobab-tree, which had been forwarded to the Society by Mr. Baynes, who was formerly the artist of the Livingstone expedition. Mr. Baynes stated that the bark was used as a substitute for quinine. In most manuals treating of the properties and uses of plants, the bark of the baobab-tree was reputed to be used medicinally, and as an authentication of that, Mr. Baynes' contribution was of value.

Dr. PAUL asked the attention of the meeting to a table which had been forwarded by Mr. Ekin, of Bath, in which the nutritive values of various articles of food were represented on the basis of the respective percentage of carbon and nitrogen. This mode of valuation was somewhat hypothetical, but it afforded a fair ground of comparison between different articles of food within certain limitations. The table was constructed in such a way as to show these comparative values graphically. Though the use of graphic formulæ in chemistry were not to be recommended or regarded as very serviceable, he thought that in a case like the present, and within certain limits, a table of that kind with the graphic method of representing fact might be of use.

Professor REDWOOD called attention to an apparatus which had been placed in the room for the inspection of the members. It was a form of apparatus which was very generally used by pharmacists in Germany, and had at his suggestion been imported by Messrs. Zimmermann and Co., of the City. The apparatus provided in a small compass means for conducting the various pharmaceutical operations of boiling, distilling, infusing, digesting, etc.

Mr. COOPER exhibited a specimen of effervescing lozenges, which, he said, he had been some years endeavouring to produce. He was in hopes that by means of these lozenges certain medicines might be administered in a more pleasant way than by the present methods.

Professor REDWOOD remarked that Mr. Cooper seemed to have made an important step in the direction of elegant pharmacy.

Mr. COOPER added that if these lozenges had been produced twenty years ago, homœopathy would not have held its own.

Mr. WOOTTON described several specimens of French elegant pharmacy, which, he observed, were perhaps not very important, though interesting for the excellent manner in which they were made. Among these he referred especially to some sulphovinate of soda (prepared as described in the PHARMACEUTICAL JOURNAL of last June). There was also on the table a drop measure, which he said was the neatest thing he had ever seen, and was mathematically correct. The section of the tube was three milligrams in diameter. There was also a table showing the number of drops to the gram of various liquids, varying from water 20 drops, to ether 98 drops to the gram.

Mr. WILLIAMS said that within the last two months considerable demand had arisen for croton chloral hydrate, which, although not a new thing, having been introduced two years ago, had not hitherto been much used in medical practice in this country. It was stated to be of great value in nervous diseases affecting the face. It was made by passing dry chlorine into aldehyde, but the first experiments failed; it was found to be a very difficult body to manufacture, in consequence of the bad quality of the aldehyde. That prepared by the process usually given was a very impure body, and, in fact, quite unfit for the purpose of making croton chloral. He had, therefore, brought a specimen of what he believed to be nearly pure aldehyde, a thing he had never seen before, and of which he thought few in the room had any knowledge. It was a powerful body, and probably might be recommended for medicinal use. In the first place, it had great affinity for oxygen. If a stoppered bottle were half filled with it and left for a short time, the stopper would be held so tight that there would be a difficulty in removing it, for the whole of the oxygen left in that portion of the bottle was absorbed by the aldehyde. They knew very well that the spirits of nitre was a very favourite remedy. The Edinburgh Pharmacopœia a few years ago ordered spirits of nitre to be made with nitrite of ethyl. He believed he was right in saying that that preparation did not give satisfaction, and was not looked upon as a good medicinal article. An opinion had been held that aldehyde played an important part in the medicinal action of spirits of nitre. Medical men could now determine for themselves whether aldehyde had any important medicinal action or not, but if they breathed this specimen, he thought they would agree with him that it was likely to be a very potent one indeed. Speaking theoretically, he thought it ought to prove one of the most powerful anæsthetics known. The croton chloral hydrate smells of lemon. It is formed by two moduculcs of aldehyde, less one moducule of water, the three atoms of hydrogen being replaced by three atoms of chlorine; croton chloral was the result, the hydrate forming the beautiful crystalline body before them.

The PRESIDENT mentioned that Mr. Robbins had presented the Society with a specimen of amyl hydride, but Mr. Robins was not present to explain it.

Mr. CARTEIGHE read a paper by Mr. Giles on an "Apparatus for Macerating."

[The paper is printed at p. 442, and gave rise to the following discussion:—]

The PRESIDENT remarked that Mr. Giles had in some measure misunderstood what he stated at the time referred to. He stated that in certain tinctures, such as tincture of calumba, it was desirable to macerate the root first of all in a small quantity of water.

Mr. UMNEY felt very much indebted to Mr. Giles for bringing such an excellent arrangement of displacement apparatus before them. Some three or four years ago he had a conversation with Mr. Giles, from whom he took one or two hints, and since that period he had experimented upon cinchona bark, but with a modification of the form of apparatus before them. He had used cucumber glasses, which were cylinders having a diameter of 2 or 2½ inches, with a length of probably twenty inches or two feet. He had ten of these glasses, and had taken 100 ounces of cinchona bark, dividing the bark into ten portions, and percolating with successive pints of water, the percolate of the first being put upon the second, the second on to the third, and so on to the tenth. It was found that when 100 fluid ounces of percolate had been obtained, the bark was almost wholly exhausted. These evaporated, and one-third of its volume of spirit added, produced 20 per cent. of fluid extract, which was a good average quantity of completed liquor.

Mr. GERRARD suggested that it would be an improvement if each cone were divided by four, and only to have one receiver. There was by the present plan a considerable loss by spontaneous evaporation.

Mr. UMNEY said the last speaker seemed to forget that it was necessary to put the percolates on to each other successively, and therefore it was impossible to have one for four, or they would do away with the chief part of the process.

Mr. BLAND corroborated Mr. Umney's statement as to the advantage of the cucumber glasses, and said he had been in the habit of using them for the last eighteen or twenty years.

The PRESIDENT believed with Mr. Bland that there were no percolators much better than cucumber glasses, only sometimes they were not perfect, not being of the same diameter throughout. They, therefore, got an uneven pressure; but he had had one made upon the principle of a cucumber tube, and it was as perfect as a good glass syringe should be, being even all through.

A paper was read by Mr. J. B. BARNES "On the Extracts containing Chlorophyll."

[The paper is printed at p. 441, and gave rise to the following discussion:—]

The PRESIDENT said that this subject was one which ought to elicit considerable discussion. For his own part, he never could see the advantage of retaining the chlorophyll, because although a nice bright green when first made, the colour very soon became brown,—certainly before they could have a fresh supply in the following year. It was a question whether the extract deprived of the chlorophyll would be as manageable when put into a pill as when the chlorophyll was present. With regard to a making liquid extract from the extract reduced to dryness, he thought it was open to a good deal of question whether the extract would not suffer considerably during the process of drying, in order to be in a good condition afterwards,—whether it would not be possible without so much reduction to reduce the extract to a certain specific gravity, and then add the spirit that might be desirable to keep it. They had two or three instances of liquid extracts in the Pharmacopœia in the Succus Conii and the Succus Scoparii, which he thought were fair illustrations of what might be done in that way. Of course they were comparatively weak as compared with what might be made under Mr. Barnes's idea. The subject was well worthy their consideration, and Mr. Barnes had done a service to pharmacy in bringing it before the Society.

Mr. HANBURY thought the author had rather overlooked the fact that the raw materials employed in these preparations are not of uniform composition,—that henbane and belladonna not being definite chemical substances, it is unreasonable to expect they will afford preparations of unvarying composition. He also thought that the author had rather assumed than proved that the portion of the extracts insoluble in cold water consisted wholly of chlorophyll.

Professor Attfield said that Mr. Barnes had alluded to the evolution of nitrous fumes in certain cases during the preparation of extracts, and had suggested that some nitrous acid might be produced at the expense of the nitrogenous principles, notably, of course, the active principles of the plants. Considering how commonly nitrates were found in the juices of plants, it was not unlikely that the source of the nitrous fumes would be nitrates reduced by the organic matters present. He had found crystals of nitrate of potassium imbedded in a certain specimen of extract, but no nitre in a similar specimen from the same drug, which had undergone decomposition.

Mr. Umney could quite corroborate what Mr. Barnes had stated, upon the unmistakable odour of nitrous fumes in making the extract of henbane. Mr. Giles strongly advocated at the Pharmaceutical Conference at Brighton the omission of the chlorophyll in these green extracts. They had a great deal to learn from the Americans as regarded fluid extracts.

Professor Attfield asked Mr. Umney whether he had ever noticed these nitrous fumes from senna. He had observed them, and he should like to know whether anybody else had done so.

Mr. Umney replied that he had not.

Professor Attfield remarked that fresh henbane juice, pressed from a plant within half an hour of its being cut, was rich in nitre.

Mr. Fryer believed that a large proportion of the loss in these extracts could be avoided by applying less heat. He thought the process of the Pharmacopœia was quite needless in the separation of the chlorophyll. It was much better prepared without separating the chlorophyll, and by this means a good deal of waste could be avoided. Of course, it took a longer time; but he believed the result was more satisfactory.

Mr. Umney said that such an extract would be contaminated by the very body that they wished to get rid of—the albuminous matter. The authors of the Pharmacopœia had in view the raising of the juice to the boiling-point, in order that the nitrogenous principles should bo rejected, as they looked upon that as the most damaging ingredient in the extract.

"A Dispensing Note on Chloral Hydrate," by Mr. J. G. Plumer, was then read by Mr. J. Ince.

[This paper is printed at p. 443, and gave rise to the following discussion :—]

Mr. Barnes mentioned that he had recently had occasion to take chloral hydrate, and he found it exceedingly disagreeable, even with syrup of orange-peel. He found it greatly irritated the throat; but with the addition of a little mucilage of tragacanth, that was almost done away with.

A paper by Mr. J. Moss, F.C.S., on "Sulphurated Antimony, Official and Commercial," was then read.

[The paper is printed at p. 443, and gave rise to the following discussion :—]

The President remarked that this was an interesting paper, which might be the means of inducing them to test some of their preparations to ascertain whether they were B.P. preparations such as they ought to be; and he rather thought this was doubly necessary now after the passing of the Adulteration Act.

Professor Redwood said this subject was one which had come under his notice for a great many years. As long as he could recollect anything of laboratory experience in that Society, the preparation of sulphurated antimony had presented to those engaged in making it a great deal of difficulty. The process given in the present Pharmacopœia did not materially differ from the processes previously given. It was true that the quantity of alkaline solution directed to be used with a given quantity of black antimony was now smaller than it used to be, but that did not practically affect the result, for in none of the cases was the whole of the antimony taken up in solution. He could entirely confirm what had been stated by Mr. Moss, that, as a general result, proceeding as strictly as possible according to the instructions given in the Pharmacopœia, the product was rather a reddish-brown than a yellowish-red powder. Nevertheless, they knew that in commerce what had been sold as sulphurated antimony was either golden-yellow, as it had been sometimes called, or yellowish-red,—lighter and brighter in colour than that generally obtained by adopting the process given in the Pharmacopœia. He had felt a great deal of interest in the results which were represented as having been obtained by Mr. Moss. He regretted, however, that Mr. Moss had not been able to indicate a method of manipulation by which, without materially altering the composition of the product, they might be able to obtain a result nearly coinciding in appearance with that which pharmacists had been accustomed to use. He believed that if such a preparation as the one before them were sent out by wholesale houses, the trade generally would reject it; and he should be glad to see a method indicated by which they could obtain uniformly a product of a yellowish-red colour rather than a brown, and which, nevertheless, should have a composition such as the Pharmacopœia preparation was directed to have. He quite agreed with Mr. Moss, that it would be incorrect to use the golden sulphuret of antimony which was commonly met with in commerce, and which appeared to contain a large proportion—according to Mr. Moss's analysis, 37 or 38 per cent.—of oxide in the place of the $3\frac{1}{2}$ per cent. of oxide which Mr. Moss found in the preparation made by himself, strictly according to the Pharmacopœia. There could be no doubt whatever that the active constituent of this preparation was the oxide which was contained in it. If they now had to consider whether this preparation of antimony was the most satisfactory which could be proposed, he had no doubt they would come to the conclusion that it was not, and that they could replace it by some other which would be much more satisfactory, because more uniform in its composition and more to be relied upon. But suppose they were to omit this preparation from the Pharmacopœia, what would be the consequence? It would not be omitted from medical practice. They would go on using it without anything in the Pharmacopœia to indicate what its composition even approximately ought to be, and, therefore, they were bound to retain it because it was so firmly fixed in medical practice. Since Mr. Moss had kindly given him a copy of his paper a day or two ago, he (Professor Redwood) had repeated the Pharmacopœia process. Having made the solution by boiling the antimony with the alkali, he took one portion of it while it was still hot at nearly boiling temperature, strained it, and precipitated it with dilute sulphuric acid, and it came out as dark as the darkest specimen which Mr. Moss had placed before them. He took another portion when the cooling had taken place to a greater extent, and treated it in the same way, and it came out of a much lighter and brighter colour, nearly coinciding with the description in the Pharmacopœia.

Professor Attfield said that his colleague had almost exhausted the subject from a pharmacopœia point of view. It seemed that, as regarded the colours of the substance, if it was manufactured by the commercial process, it included penta-sulphide of antimony, and was more or less of an orange-red tint; if by the official process, it contained tersulphide of antimony, but had not the official colour—it was brownish, not "orange-red" at all. The question then arose as to the amount of oxide of antimony that should be present. Professor Redwood had suggested that, if an article could be obtained having the colour of the commercial article and the official proportion of oxide, that would be the best that could be employed. No doubt that Mr. Moss could, by continuing his researches, produce such an article. The Professor rose, however, rather to speak on the chemical aspect of the matter. It was well known to chemists that the so-called pentasulphide of antimony and the pentasulphide of arsenicum were by no means definite chemical substances. By adding an acid to a sulphantimonate, they necessarily obtained a precipitate containing proportions of sulphur and metal which corresponded with the true pentasulphide, but it by no means followed that it actually was a true pentasulphide. In the case of pentasulphide of antimony the mere application of a temperature such as would be sufficient to volatilize sulphur gave a sublimate of that element and a residue of a tersulphide. The action of hydrochloric acid also was to give not pentachloride of antimony, as might be expected, but terchloride. Then the pentasulphide of arsenicum gave up two-fifths of its sulphur to dilute solution of ammonia. Hence chemists would look with considerable interest to Mr. Moss's paper, with the object of ascertaining whether it threw light upon the constitution of the so-called pentasulphides of antimony and arsenicum. Well, they first came across the observation that bisulphide of carbon, which was an excellent solvent of sulphur, took away two-fifths of the sulphur from the pentasulphide of antimony and left the tersulphide. Here was a fact which seemed to indicate that the article was not a true pentasulphide. On the other hand, the tersulphide thus obtained contained no moisture, which certainly was a somewhat characteristic component of this substance when precipitated from a solution of the ter-compounds of antimony. Professor Redwood had remarked that there was room for more pharmaceutical research in connection with this subject; and he (Professor Attfield) would suggest there was also a good deal of room for more chemical work in the matter.

Mr. Martindale remarked that this article would be much better expunged from the Pharmacopœia, especially as it was used almost entirely for one preparation.

The President announced that the next meeting would be held on the 5th of February.

Parliamentary and Law Proceedings.

Poisoning by Chloral Hydrate.

On Wednesday evening, November 27th, Mr. C. J. Carttar, held an inquest at Greenwich, concerning the death of Mr. David Gower Silva, who was found dead in his bed on the previous Monday morning.

Mrs. Silva said the last time she saw him alive was at eight o'clock on Sunday evening. About six o'clock in the evening he went out to Mr. Part, a chemist, in Church Street. He had been in the habit of going there, but not during the last three months, for the purpose of obtaining sleeping draughts. At a quarter to twelve the same night she went upstairs to bed, and seeing deceased, as she thought soundly asleep, in order not to disturb him she slept in another room. The next morning she found him lying in the same position and quite dead.

In answer to questions, Mrs. Silva said the deceased had an empty phial in his right hand and another empty phial was found near him. On Saturday last the deceased sent his son to Mr. Part for a sleeping draught, but he came back and said that Mr. Part was then very busy and could not make it up, and that as his father (the deceased) had already had one draught he did not want another then. The deceased insisted upon the servant girl going for a draught. The deceased took this draught, and slept until eleven o'clock on Sunday morning.

Mr. Edward James Part, chemist, of Church Street, Greenwich, said about two years since the deceased came to him and wanted a sleeping draught, which he prepared of laudanum. He made a second draught of laudanum, but the deceased complained that they were not strong enough, and witness then prepared a draught containing 20 grains of hydrate of chloral, with a compound of cardamoms. This was witness's own prescribing. Witness afterwards found deceased was suffering from excessive drinking, and he had prepared him many draughts, increasing the strength at deceased's request, up to 100 grains of hydrate of chloral. On some occasions, when deceased sent for the draughts, he had sent him merely coloured water instead. On Friday last the servant of the deceased came for a draught, and witness prepared one containing 80 grains of the hydrate of chloral. The next morning the deceased came in as usual, and said it was no use sending him a draught under 100 grains. The draughts given on Saturday contained each 100 grains, and at that time and also about a year ago, he expressly cautioned deceased as to the taking of the draughts.

This being the whole of the evidence, the Coroner said that there was no doubt that death resulted from taking the poison named. The questions for the jury were, whether the same had been taken in mistake, or with any wilful intent. They would also probably consider the propriety of selling poison in such quantity. With regard to the serving of the deceased with two draughts on the Sunday evening, he (the Coroner) did not view that fact as some of the jury appeared to do, because a bottle specifying a "sleeping draught" would be supposed to be for one taking; but he did think that the bottles ought to have contained a label bearing the word "poison," because a bottle might have found its way into the hands of another person than whom it was intended for.

After a short consultation, the jury returned a verdict "That deceased died from the effects of an overdose of hydrate of chloral, taken in ignorance of its fatal effects."

The Coroner then called Mr. Part forward, and said it was the unanimous wish of the jury that he should caution him against selling poison in such a quantity, the danger of which he knew. Referring to the new Licensing Act, he observed that a publican was held responsible if he supplied a drunken person; and in the case of serving poison to a person suffering as deceased, greater caution should have been taken. He hoped the present inquiry would act as a caution in the future.

Mr. Part said there had never before been any mistake in conducting his business, and the draughts would not have been prepared but through the deceased urging him, and his promise that he would be careful in not taking both draughts served to him on Sunday evening.—*Kentish Mercury*.

[*** In reference to the comments upon this case which appear in the *Lancet* and *Medical Times and Gazette*, we must remark that the latter journal is so far in error that chloral hydrate is not included among the poisons enumerated in Schedule A of the Pharmacy Act, 1868.—Ed. Pharm. Journ.]

*** In consequence of the great length of the report of the Society's proceedings, we are compelled to defer the publication of several communications.

Communications, Letters, etc., have been received from Messrs. J. J. Nicholson, J. A. Clark, Brown, Pickup, Bland, Crundall, Fitzhugh, Bennett, Druce, Laird, Brown, Bascler, Burnett and Co., Lord, M'Master and Hodson, M'Neil, Symes, Jones, Watson, Crozier, Baildon, Young, Batting. An Associate, Justitia, A Chemist, Excelsior, Proctor Jones, Cecil, Datura, Persevero, Agitator, Z. V. Z., A. P. S.

PHARMACEUTICAL PROGRESS.*

BY CHARLES SYMES, PH.D.

The subject which I have hurriedly chosen is a wide one; my notes contain thoughts as hurriedly strung together, but I trust they will lose nothing of their genuineness on that account. It is one which looked at by different individuals, or even the same individual, under different conditions, will necessarily appear very different, therefore I can only be responsible for depicting it as it appears from my own point of view.

Were I so disposed, I have not the time to search out and bring before you all the minor circumstances connected with the dawn of pharmaceutical history, neither will I bore you with statistics and figures to prove simple facts of which you have a general idea already in your minds. We must necessarily have some starting-point, and probably cannot do better than take the foundation of the Pharmaceutical Society for our commencement; doing so, we will, if you please, divide our subject under these heads—the immediate past, the present, and the immediate future.

The Immediate Past.—There are some still living amongst us who first moved in constituting the Pharmaceutical Society, others who joined it in its early days, and consequently became also its founders. Those who are desirous of going into the details of its history from the commencement will find them fully set forth in the pages of the PHARMACEUTICAL JOURNAL. Suffice it to say that a number of earnest men, desirous of seeing a better state of things than there existed, with a large-heartedness well worthy our emulation, gave their time and their money to bring about the desired results. Some of these men have passed away in comparative obscurity, but their work remains, and let us, who are reaping the reward of their labours, honour their memory, rather than as has been occasionally done, make disparaging remarks as to their professional skill and knowledge; they did the work that came to their lot to do, let us do the same.

At first a considerable amount of energy was thrown into the matter; brilliant and rapid progress was anticipated. But it soon became evident that however correct and good the object in view, the immediate results were over-estimated; that there was no room for the continual display of this great energy. The same lesson has constantly to be learnt over and over again by individuals, communities and nations. Nature cannot be so easily pushed out of her course; matters of this kind will rarely proceed and become matured as rapidly as our wishes; in this particular the old maxim "festina lentè" prevailed, and it was over a quarter of a century before the hopes of the founders were realized.

It is true that in 1852 the Society got an Act of Parliament to confirm their charter of incorporation; but this only served to shut out from it many good and worthy men, who for reasons probably not known to themselves had not previously joined; the outsiders, as they were called, were in considerable majority, and jealousy gradually sprung up between these two bodies—a rival society being started. This society did some good of its kind; it gave this large outside majority a desire for organization, which the Pharmaceutical Society, from the very nature of its constitution at that time, could not do; and it finally treated with that Society for conditions on which, not only itself, but the whole trade should become one in certain common interests. We all remember how, amidst the strife of tongues, much written controversy, and after several failures, the Pharmacy Act was ultimately passed in 1868, and we were ushered into a new state of existence.

The Present.—Taking all things into consideration, the new Act is working as well as might be expected. It is true, we still have cases of poisoning as of yore; and both magistrates and coroners occasionally censure chemists quite undeservedly, by threatening to fine them for not registering the sale of such articles as laudanum, etc. This latter error will become less frequent in course of time, when the Act is better understood by these dignitaries. But the poisoning cases, when they will cease, who can tell? Education is a subject which at present is engaging much attention, not only amongst the pharmaceutical body, but throughout the civilized world; and it sometimes appears as though w had none of the great men of talent living amongst us now as in years gone by. But reflection tells us that things have changed; that in the past ignorance — dark, black ignorance prevailed; and wherever talent existed this darkness formed a background from which it shone resplendent. In the present, education more generally prevails; the background is not nearly so dark; there is more half tone, and, consequently, our educational picture is not so bold or striking. In nations and also in communities, we can usually judge of general progress by educational progress; and no one looking at pharmacy as it is in the present day, and as it was thirty years ago, can doubt for a moment that we have considerably advanced. The large number of excellent books which have been published during that period, in chemistry, pharmacy, botany, materia medica, etc.; the improvement in the purity of our drugs and chemicals; the better facilities for detecting adulteration are evidence of this. We have the pharmaceutical establishment in Bloomsbury Square, with its extensive museums, library and laboratories; also other schools of pharmacy, both metropolitan and provincial; we have the Pharmaceutical Conference holding its meetings in different parts of the country, for the purpose of interchange of thoughts, etc.; we have our provincial associations; and last, though not least, two excellent journals devoted to our interests.

In the past a five or seven years' apprenticeship was often spent in mere drudgery instead of intellectual culture, but there is a growing tendency to substitute mechanical for bodily labour. I grant you that some of those who were educated under difficulties turned out first-class men, but that goes for very little; might they not, with better facilities, have been still better men?

Then there are signs of decided improvement in shortening our hours of active labour in the business.

The Immediate Future.—I do not propose to enter the domain of prophecy, not even to suggest the possible position of pharmacy in the year 1900, but simply to make a few remarks as to certain progressive conditions and improvements which we might hope for and reasonably expect during the next few years.

Well, I have said there is a tendency to shorten the hours of active labour. Perhaps it might be

* Abstract of a discourse delivered at a meeting of the Liverpool Chemists' Association.

thought I attach too much importance to this; but, has it not been a curse to this business for many years, a bar to enlightenment and progress, the spoiler of social and home comforts, and a barrier which impedes the progress of associations such as this? When will men of pharmacy merge their petty jealousies, forego their inordinate desire for gain, and regulate their hours of employment more in accordance with Nature's laws rather than according to the arbitrary and absurd ones which they have prescribed for themselves? I believe there is in every individual a certain amount of energy,—different in different individuals of course, but in all there is this energy, partly mental, partly physical, partly active, partly passive,—and that a great portion, if not the whole of this active force, is transmutable. Just as a given quantity of motive power might be developed as heat, light or electricity, so this active energy is capable of being put forth either as mental or physical force. If you exhaust all this active force in physical development, or if you squander or trifle it away, where do you find power to cultivate the mental capacity? You might draw, it is true, on the latent energy; but this done too often, health is impaired. I should like to see our hours of business nearer to those of the merchant at his office, say from nine to six at the most, and during those hours should like to see business done as a merchant does it. None of that important time should be lost, the amount of work accomplished by any one individual would be little less than if extended over the larger number of hours, but the expenditure of energy decidedly so.

Well, gentlemen, when the day arrives that this is accomplished, what a large amount of time and energy we shall have at our disposal, and how much might be expected from us! Surely there will then be no grounds for Dr. Attfield charging our students with *superficial cram.* Cram you always will have if you choose to call it so, but if what is crammed is retained so as to be useful, cram as much as you like. The professor is doubtless correct when he says that the bulk of the students in the present day aim merely at passing the examinations, and do not study purely to gain knowledge. If we consider for a moment who they are that constitute the bulk of those presenting themselves for examination in the present day, we shall see that they entered the business never expecting to pass an examination at all. The present long hours of business only leave these young men very little time in which to prepare for the examinations. After they have done with these, we can still hope that some prosecute their studies for the love they bear towards them.

With all due deference to those who have been pushing forward educational schemes, it implies want of faith in the progressive condition of things which they have been instrumental in bringing about. There is a time to be active, and there is also a time to be *passive.* Two or three years hence things will have approached nearer their proper level; then, and not till then, shall we be able to fairly judge of what is necessary to be done for education. We are told that competent men get plucked,—that incompetent men pass the examinations; and the only reply seems to be "that the time is too short to examine in." Well, why not give more? It is surely unfair to send a man away half examined, when he pays well for it.

I anticipate, too, the day is not far distant when we shall all more fully value our time. I could say much on this point, but my friend Mr. Delf so thoroughly exhausted the subject in a paper which he read before you some time since, that to add thereto would be superfluous. In the future, too, we can hope that some of the provincial associations will give us some better evidence of their usefulness. Liverpool is considered to stand amongst the first of these—but does it? Is there the same difficulty amongst other associations, in getting papers for the evening meetings? We have a good library; but (with a librarian none too well paid) it costs about fourpence per volume per annum for each that is circulated. We have an excellent museum; but it is a rare thing to find any one in it. A school of pharmacy; but where are the pupils? Are these signs of a healthy condition? Can we not hope for something better?

We could wish, too, that the Pharmaceutical Conference would make some real progress; that its numerical strength were not the chief evidence we have of its progressive condition. It publishes a good Year-Book, and I should be pleased to see its proceedings form a more important feature in that volume. Some of the papers read at the annual meetings are good, some are trash. Just fancy a man reading a paper for the purpose of explaining that whenever tinct. ferri perchlor. is ordered he always uses the liquor!

Finally we reach Bloomsbury Square. There, as I have said, we have a grand institution, and good professors, and at the head of all the Pharmaceutical Council.

You remember the Executive Committee of the Chemists and Druggists' Society, and you also remember the old Pharmaceutical Council, embracing men whose names have become, if not household, certainly pharmacy words with us; men whose judgment we esteemed; men in whom we had confidence that, whilst they were at the helm, the ship would sail safely. Now, I speak with all due deference to the present Council, but I feel that I am speaking the truth when I say that it too much resembles the Executive of the Chemists and Druggists' Society—too little the old Pharmaceutical Council. Do not misunderstand me. There were some good men in the former body; but, as a whole, they were loosely strung together; uncertain in their action; they did not represent pharmacy of the first class; and this I maintain a governing body like the Pharmaceutical Council ought to do.

IODIZED ALBUMEN AND IODIZED ALBUMEN WITH FERRIC CITRATE.*

Professor Luigi Guerri, of Florence, has been studying the question whether it be possible to employ the white of egg to prevent the decomposition of ferrous iodide, and to obtain a combination which should contain one part of iodine to five parts of oxide of iron. In order to investigate the action of iodine upon albumen, Professor Guerri saturated it with dilute phosphoric acid, collected the liquid, evaporated the solution of albumen to 3° Beaumé, and afterwards added finely divided iodine, obtained by precipitating tincture of iodine with water. This

* From 'L'Union Pharmaceutique,' vol. xiii. p. 289.

caused the albumen to turn red, but after some time, when stirred, it regained its primitive colour. These changes of colour occurred repeatedly after additions of iodine until at length the red colour remained persistent and mucilage of starch was coloured blue. When this point was attained the liquid was agitated, and, after standing ten or twelve hours, it again regained its original colour; it then no longer gave the reaction with starch, except under the influence of chlorine water or nitric acid containing hyponitric acid. Even these were not sufficient to set free some portion of the iodine, it being necessary to incinerate with potash in order to obtain it in the state of iodide of potash. Professor Guerri found afterwards that even during the evaporation of the albumen to dryness the iodine remained in combination, and that during the process some white flakes appeared, which separated upon standing, and redissolved in a very small quantity of potash.

According to careful experiments of Professor Guerri, 100 parts of this iodized albumen, that had been dried at 60° C., contained 3·132 parts of iodine; and 474 parts of solution of albumen of 3° Beaumé density when so evaporated yielded 31·928 parts of iodized albumen, whilst 31·928 parts of iodized albumen contained 1 part of iodine. The iodized albumen forms yellow transparent scales, soluble in water, with the exception of a few flakes which are not dissolved by acetic acid or phosphoric acid, but are dissolved by alkalies. The solution is precipitated by alcohol; is neutral, and gives no iodine reaction.

In order to obtain a ferruginous preparation of the strength before mentioned, Professor Guerri dissolved 18 parts of ferric citrate,—corresponding to five parts of ferric oxide,—in 474 parts of solution of albumen, 3° Baumé density, previously iodized, and evaporated the solution at a temperature of 60° C. to dryness. This gave 50 parts of a compound containing one-third of ferric citrate and two-thirds of iodized albumen. The product so obtained has the appearance of ferric citrate, but is a little yellower. The solution comports itself similarly to the iodized albumen. The iron is not separated from it by alkalies, or by ferrocyanide of potassium, but is separated by the alkaline sulphides.

Each of these preparations is easily formed into a pill mass with simple syrup, as well as with extracts not containing much tannic acid. They can also be administered in powder.

THE CHEMICAL PROPERTIES OF EUCALYPTUS LEAVES.

BY M. RABUTEAU.

In a note presented at a recent session of the French Academy,* M. Rabuteau describes the result of an attempt to ascertain whether the leaves of the *Eucalyptus globulus*, now frequently employed in cases of intermittent fever, contained any basic principle analogous to the alkaloids of quinine.

Brunel, in a memoir upon the effects of eucalyptus, speaks of an undefined substance obtained from it which he calls eucalyptine; and in Corsica the medical men have administered, with success, a saline residue, obtained by treating an alcoholic extract of eucalyptus bark with sulphuric acid. If, however, the eucalyptus had contained a febrifuge alkaloid, M. Rabuteau thinks it would scarcely have escaped M. Cloez in his researches on eucalyptus leaves and eucalyptol; and a direct search for such an alkaloid by M. Rabuteau has led him to the conclusion that one does not exist in the leaves.

Having evaporated some alcoholic tincture of the leaves to half its original volume, the addition of water caused a plentiful precipitation of yellowish resin, which blackened upon exposure to the air. A few drops of hydrochloric acid considerably favoured the separation of this resin, which was soluble in alkalies, and formed with them resinates. The slight alkalinity of the saliva was sufficient to dissolve it, with extreme slowness, but in appreciable quantity. A preparation might therefore be made from it analogous to certain medicinal tars, soluble upon the addition of an alkali.

The liquor, separated from the resin and filtered, contained tannin, which imparted astringency to it, and was removed by a salt of iron. It was then treated with a solution of iodine in iodide of potassium, to precipitate an alkaloid if present; also with phosphomolybdic acid, but without success, although the latter reagent is said to be such a delicate test for an alkaloid that it gives a plentiful yellow precipitate when caffeine is present in a solution in the proportion of 1 part to 20,000, and a yellow turbidity with 1 part in 80,000.

A decoction of powdered leaves of *Eucalyptus globulus*, in water acidulated to separate all the resin, treated with the same reagents, yielded no trace of an alkaloid.

* 'Comptes Rendus,' lxxv. 1032.

CERTAIN UNDESCRIBED PROPERTIES OF THE CONCENTRATED SOLAR RAYS.*

BY GEORGE ROBINSON, M.D.,

Fellow of the Royal College of Physicians of London.

Some thirty years since, I accidentally noticed that the sun's rays, concentrated by an ordinary lens and directed upon the hand immersed in water, produced immediate pain with burning heat and vesication. This experiment, varied and repeated at intervals on different living animal tissues and under different circumstances, always led to the same result. But if the concentrated rays were fixed for an instant upon the head of a small aquatic animal, death immediately resulted before vesication occurred. On dead animal matters similarly treated, no perceptible effect was produced.

The physiological action was, as I have stated, always instantaneous, but when a thermometer having a bulb of black glass was immersed in water, and the rays concentrated on the bulb for some time, the instrument at the end of ten minutes only indicated a rise of temperature from 60° to 80°. A few years since I happened to mention these observations to my venerated friend, the late Dr. John Davy, and at his request I prepared a short account of them, which he communicated to the British Association for the Advancement of Science, at its meeting in 1867.

The rationale of the results witnessed in this simple experiment always seemed to me obscure, and to indicate the possible existence in the sun's rays of some property or force that had not hitherto been investigated. Under this impression, and being myself engaged in practice, I took advantage of an opportunity to draw the attention of the illustrious Faraday to this subject some fifteen years since, in the hope that he would apply his powerful mind to its elucidation. But in a kind letter

* From the 'Scientific American.'

he told me that he was then overwhelmed with work and could not undertake the inquiry.

Happening to be in New York during the recent hot summer, I have performed a few additional experiments; and so far as they go, they certainly tend to confirm my belief in the existence of a hitherto unrecognized property or force in the solar rays.

In attempting to ascertain the precise nature of this force, I could not rely on ordinary thermometers, for they are actuated gradually and slowly while the pain and sensation of heat are instantly felt. Neither would the usual thermo-electric apparatus meet the difficulty, as my observations must be made in water as well as air. I finally concluded to rely on Nature's own instrument, the nerves of sensation as they exist in exquisite perfection in the integuments of the finger. In the propriety of this course, I was confirmed by a remark of Professor Tyndall that the optic nerve is more sensitive to the heat rays present in light than any thermometer.

In experimenting, I generally placed on the end of the forefinger of my left hand the substance under observation, steadying it with the thumb, and dipping the hand when necessary into water so as to have a layer of that liquid at least an inch thick above the skin. The lens employed was of seven inches focal distance; and in using it, I always threw the focus behind the object examined so that the rays should traverse it instead of being concentrated upon it.

Whenever in experiments in air there was the slightest appearance of singeing or other action of heat on the substance examined, the observation was rejected. Care was taken not to press the finger firmly against the substance, but merely to maintain the slightest possible contact. Under these conditions, a burning painful sensation was felt when the concentrated solar rays were transmitted through the following substances both in water and air, namely, two layers of blue glass, black leather (glazed and unglazed), green leaves, thick white cardboard, the same covered with blue or red paper, six layers of pink paper, earthenware, oilcloth and common brown glue a quarter of an inch thick.

Now taking only these substances into consideration, it is not easy to explain on the views now current how rays could pass through an opaque non-conducting substance like oil-cloth, so as to pain the finger placed beneath it even when both were immersed in water. But my observations came still more into collision with received opinions. Thus it is generally stated in scientific works that a crystal of alum is athermanous, that while allowing the rays of light to freely traverse it, those of heat are arrested. But on directing the concentrated rays through a crystal of perfectly transparent alum, I found that it produced a burning sensation in the skin, both in air and water. It is evident, therefore, that Melloni's conclusions with reference to athermanous bodies do not apply to the concentrated solar rays, if the pain were produced by heat. Another still more curious and unexpected result was obtained. It is generally believed that metallic surfaces reflect heat rays of all degrees of refrangibility, and are consequently impenetrable to them and absolutely athermanous. But I found that a burning heat was felt in the finger when the concentrated rays were transmitted through double tin-foil and thin sheet-iron. The following experiment illustrates this point very clearly: I took a mirror formed of plate-glass a quarter of an inch thick, silvered in the usual way with tin amalgam, on the back of which was a thick layer of red paint, well dried. I let the painted back part of the mirror rest upon my finger both in air and water; and on concentrating the rays upon the glass, throwing the focus as usual behind the mirror, the burning pain in the finger was instantly felt by myself and others. The mirror itself was in no way affected by the experiment.

Here the light rays were of course excluded, and those of radiant heat were, according to the generally accepted laws of physics, prevented from penetrating to the finger by the intervening metallic coating of the mirror, to say nothing of the layer of red paint; and yet rays capable of producing pain and inflammation in the integuments of the finger undoubtedly passed through, 1, the water; 2, the thick plate-glass; 3, the layer of tin amalgam; and, 4, the coat of red paint.

Now what were these rays?

They were very refrangible, they possessed great penetrating power, they acted instantaneously, and energetically upon the tissues of the living animal body. These are obvious and palpable conclusions, but without additional facts we cannot go much further in reasoning on the subject.

That the concentration or mere convergence of the sun's rays does really increase their penetrating power is, I think, highly probable, and this may partly explain some of the facts observed. But I still cling to the belief that the conditions present, for instance, in the last-mentioned experiment, rather point to the presence in the sun's rays of a force acting specially and as a powerful stimulant or irritant on living matter. It may be that the more refrangible heat rays thus exercise on vital structures a special influence analogous to the actinic or chemical power of the more refrangible rays of light. I append other experiments, which also tend to render it probable that the irritation and pain in the living tissues, observed under these circumstances, are not induced by common heat. Ordinary albumen being coagulated at a temperature of about 150° F. might, I thought, serve as a test of the presence of common or thermometric heat in the sun's rays, and so assist in determining the question whether the burning pain was really due to heat or to some other force.

Some perfectly transparent egg albumen, placed on glass or on white earthenware, was not at all changed by the concentrated sun's rays; on any dark surface, however, it was instantly coagulated, and this effect occurred both in air and water. Thus when poured on dark purple paper and the rays concentrated upon it in the slightest degree, the albumen presented at once an opaque clot.

I took some of this purple thick glazed paper, and wrapped it round my finger. On the purple surface I placed some albumen, and on the latter a second layer of the purple paper. I then carefully concentrated the sun's rays so as to avoid burning or injuring in any way the paper, throwing the rays through it and the albumen; I instantly felt the burning pain in the finger, and then withdrew the lens and examined the albumen placed between the two layers of purple paper. *It was not at all coagulated.* Here the irritating rays passed through two layers of purple paper and a film of albumen without producing any effect on those substances, but instantly caused pain in the skin beneath. A little of the same albumen placed upon the same paper was at once coagulated by the same condensation of the sun's rays, so that, if any rays of heat had passed through the first layer of paper, they ought to have produced coagulation in the albumen resting upon the second layer of purple paper. As they did not do so, the probability is that the pain was not occasioned by ordinary heat.

In another experiment the mirror above-mentioned was placed upon the finger, a layer of egg albumen intervening between the skin and the back painted surface of the mirror. The rays were then gradually concentrated upon the upper glass front of the mirror until a burning pain was felt in the finger beneath the latter. The albumen, being then examined, was *not* coagulated.

In leaving this subject for the present, I shall merely remark that the phenomena of "sun stroke" are probably due to the peculiar rays producing the pain and other physiological and pathological effects noticed in my experiments. This inquiry may therefore not be without some practical interest to the members of the medical profession.

In the hands of more skilful investigators, aided by the refined scientific appliances of the present day, there is every reason to hope that the obscurity still surrounding this subject will be dispelled, and that we shall hereafter be enabled to recognize more fully the nature of the intimate and beneficent connection undoubtedly existing between the solar and vital forces.

INDIAN RESINS AND GUMS.*

BY P. L. SIMMONDS.

The progress of our manufactures and chemical industries leads to increased demand for gums and resins, which are only received in any quantity from two quarters, India and Africa, where they are abundant and labour is cheap. In soluble gums, Arabic, etc., there has been a small increase in the imports in the last few years; but, notwithstanding the large employ of dextrine and gum substitutes, the natural gums, at moderate prices, are still much wanted; of the various lac products, for which we are solely dependent on India, the supply is decreasing; and of the resins for varnish, copal and kowrie are the only ones of which steady supplies are maintained; animi has fallen off considerably. In view of the growing deficiency in the supply of gums and resins for commerce, the Government of India has set on foot, through its officials, inquiries as to the yearly amount that could be obtained of the more easily procurable kind of gums and resins, and the price per ton at which they could be put down at the provincial commercial centre most convenient for export to Europe, or for transmission to a suitable port. The exportation of these products, and especially of gums proper, has only to a very small extent engaged the attention of traders. They are now generally gathered for local consumption merely. A large foreign demand would develope the trade in each kind to an immense extent, as gum-producing trees are abundant all over the provinces. We have not all the replies before us, but from the report of the Commissioners of the Central Provinces, some useful facts may be gleaned.

About 180 tons of dammar or *ral*, at from 160 to 190 rupees per ton, could be put down yearly at Nagpur or Jabalpur. This would come from the district of Mandla, Balaghat, Raipur, and Bilaspur. Formerly, a good deal of ral was procurable. It is easy to get. The hillman selects the finest trees, hacks a circle on the bark round each, and removes the ral when formed. This process, though, kills the tree, and entire forests have been destroyed by it. Of late years a stop has been put to the practice in the Government jungles, and but little ral now finds its way into the market, and that is procured from the Malguzari jungles. In addition to the above, a large quantity could be exported yearly from Sambulpur, and put down at the port of False Point, at 135 rupees a ton. The vast extent of sal forests (*Shorea robusta*), Government and zemindari, in these eastern districts, would admit of enormous quantities of ral being produced, were there a call for it, at a fairly remunerative price. The hill tribes would readily carry on the industry, and, could they be induced to tap the trees judiciously, the timber would not suffer. These provinces, at a rough guess, could readily supply 25,000 tons of stick lac. The price at which it could be put down on the railway, and a part of it at False Point, is from 280 to 500 rupees per ton. All districts produce lac, but it is particularly abundant in the eastern ones. Large quantities of it are consumed in the different towns in the making of bracelets, etc.; but most districts also export it, to a greater or lesser extent.

In Jabalpur there is a European lac factory that consumes most of the lac produced in the district. It comes, too, to Jabalpur and Mirzapore in large quantities from Raipur, Bilaspur, Sagar, and Mandla. In the last-named district, the Jabalpur lac firm has bought the right, for the next three years, of collecting lac in the Government jungles, for 950 rupees a year. In the Sambulpur district, a European firm, from Mirzapore, has for a long time held practically the monopoly of the lac collection. Burhampur and Bombay receive supplies, though of less quantity, from the Narbada and Nagpur divisions. The whole exports of the Central Provinces for the year 1868–69 amounted to 1492 tons, and for 1869–70 to 1348. Of this amount in the two years respectively, 1417 tons, valued at 386 rupees a ton, and 1290 tons, at 269 rupees a ton, were exported to Mirzapore and Central India; 66 tons, at 540 rupees, and 53 tons, at 350 rupees, were exported towards Bombay; and nine tons, at 205 rupees, and five tons, at 252 rupees a ton, were sent down to the eastern coast.

Stick-lac is procurable in immense quantities all over the provinces. In years of excessive heat the out-turn is said to be less. The low price at present paid for it hardly repays, it is said, the cost of collection, and in consequence much that is in existence is not gathered. A large demand at a good price—and this it is confidently expected will not be long in coming—would call all this at once into the market. Moreover, by inducing better methods of cultivation, collection and cleansing, it would vastly increase the supply, which would be limited only by the extent of the demand and the size of the forests. The valuable industry, too, that it would establish would tend to develope the resources of the most backward parts of the Central Provinces. The increase of the supply by artificial propagation thus becomes a subject of much interest. Major Lucie Smith reports that lac is found abundantly in the zemindaries to the east of the district of Chanda. The incrusted twigs are broken off and sold by the Gonds to the dealers in lac. The people believe that the lac insects are born of the morning mist, and no efforts are made to propagate them artificially. But were there a large demand, the rearing of the insect would be systematically carried on, and result in a very great increase of the product. Mr. Grant, the Commissioner of the Jabalpur division, states that in two places only is the production of lac assisted by human agency in propagating the insect from tree to tree. The great bulk of the lac is produced without any artificial assistance, and left entirely to the unaided exertions of the insect, and its migration from tree to tree. The question whether it would pay the Government to undertake the establishment of lac-producing tracts of forests is one which naturally suggests itself in any discussion of an increased supply of resins. On the practicability of a scheme of this nature, the Deputy-Commissioner quotes a passage from a letter received by him from Mr. Michia, a French gentleman of some scientific attainments, who possesses a very intimate knowledge of the forests of the Jabalpur and Mandla districts, and who is himself the proprietor of a large tract of productive forest land in the latter district. Mr. Michia says the production of stick-lac might be indefinitely increased in the Central Provinces, if more attention were paid to the rearing of the cocoons. If, instead of trusting to chance for the annual propagation of this valuable insect, and relying altogether on the agency of birds in transfering young broods from tree to tree, without which lac would altogether disappear from our forests, we were to establish in the wilds of Balaghat and Mandla lac plantations for rearing the cocoons, the supply would be enormously increased. Palas (*Butea frondosa*) and cusam (*Schleichera trijuga*), the only necessary trees, are found in great abundance all along the whole of that line of country. The plan suggested by Mr. Michia appears feasible, and worthy of a trial.

The Beejasal (*Butea frondosa*) and dhak (*Pterocarpus marsupium*) that yield kino are fairly plentiful in these provinces. At present there is no demand for kino, except to a small extent for medicine. Large quantities could, if required, be supplied for export. The Deputy-

* From the 'Journal of the Society of Arts.'

Commissioner of Chanda considers that 100 tons could easily be raised in his district, and put down at the Wurdha railway stations for 120 rupees a ton. But the valuable timber of the Beejasal would suffer by the process of tapping that is necessary for the production of the resin. The Salai tree (*Boswellia thurifera*), from which *gunda fereza* is produced, is as abundant as any tree in the Central Provinces. At present but little of the gum is brought into market, and that for local use, but very large quantities could be readily supplied. The tree yields the gum abundantly. The value of its timber is very little, nor is it injuriously affected by tapping. From the Chanda district, it is estimated that 10,000 tons could be put down yearly at the Wurdha railway station for 100 rupees a ton. In the Narbada valley, it could be brought to the railway for 160 rupees (£16). Of the Dikamali resin (obtained from the *Gardenia lucida*) it is conjectured that 200 to 300 tons could be brought to the railway from the Chanda and Bhandara districts for about 100 rupees a ton.

Some 4500 tons of the better kinds of gums could readily be supplied on the Great Indian Peninsula Railway at from 100 to 200 rupees per ton. The dhouma (*Shorea robusta*) and babul (*Acacia arabica*) are said to yield the best gum. Good gum is also procured from the char, ber, palas (*Butea frondosa*), saj, ain (*Dipterocarpus* sp.), tendoo, khair (*Acacia Catechu*), etc. There are numberless other gum-yielding trees, the gum of most of which is not of any market value. All these gums are readily procurable in most districts in large quantities. But the different kinds are brought to market so mixed up together that it is impossible to distinguish between them, or to make a guess at the amounts of the different sorts that could be suppled. Gums are generally collected for mere local consumption. Small quantities are, however, exported into the Berars, from Sagar to the north, and from the Narbada division towards Bombay. During the last year or so, two Bombay European firms have sent agents into the interior of the Nimar district, to make arrangements for a permanent supply. They have not as yet been very successful. In some parts the Gonds gain a livelihood by gathering gum, but the price is so low that in most districts men find the cutting of grass and sticks much more profitable. As a rule, women and children are employed on the work. In Nimar, their wages are the weight of the gum collected in wheat, or double its weight in *jowari* (sorghum). A large demand at higher prices than those now offered would not only greatly increase the outturn, but bring into the market a far superior article. At present, as has been stated, all kinds are gathered promiscuously, and offered for sale as gum, not as the product of any particular tree, except, indeed, occasionally, when the gatherers are under contract to supply the dhouma or some other gum for medicine. But these pure gums are procurable in very small quantities. Not only this, but the gum offered for sale always contains a quantity of sand, leaves, and bark. No attempt is made to keep it clean. It is gathered carelessly before it is sufficiently dry to come away of itself, and in consequence pieces of bark are torn off with it. But it may well be questioned whether this industry would ever become a remunerative one in these provinces, so far removed from the sea. Gum-bearing trees grow as extensively on the sea-board, where facilities for export are much greater.

A NEW FILTER.

BY R. ROTHER.

For most pharmaceutical purposes the ordinary plaited filter meets all requirements. But for analytical operations the plaited filter cannot be successfully applied. The numerous folds, while favouring the rapid transmission of liquids, expose too much surface for the convenient collection of precipitates, and at the same time greatly and seriously interfere with their washing. The plain filter is the only practical form for analytical uses, but as it exposes only half as much surface as the plaited filter, the passage of the liquid will naturally be slower; but a very fatal objection to the plain filter is the superfluous fold which in two thicknesses lies under one-half the extended surface of the filter. The interposition of these two extra layers compels the liquid to pass through three thicknesses of paper on the half side of the extended filter, whilst the other half side presents only a single thickness. It is evident that the two hidden layers are a very appreciable impediment to the current, aside from the more important fact that the liquid will traverse this side less rapidly than the other, and thus occasion an imperfect washing of the precipitate, or at least prolong the operation beyond reasonable limits. The writer, recognizing the force of this objectionable feature, resorted to a very simple modification of the plain filter, which, whilst saving 50 per cent. of the paper, removed all the deleterious defects of the old form. This new filter practically presents but a single thickness of paper to penetrate, at the same time preserving an even surface, equal in all other advantages to the plain filter. The strength and general security of the new filter has been thoroughly tested, and has not failed in a single instance. The filtrations are more rapid than with the usual form, and the absence of the superfluous half sheet admits of a more rapid drying, which is an additional gain of the new filter. The most gelatinous, as well as the most compact and heavy precipitates were collected with it from strongly corrosive liquids with the greatest ease. Its particular advantages for analytical operations are unsurpassed.

To make the new filter, cut the circular disc of filtering paper in two through the line of its diameter, take either half disc and fold it across the line of the radius, then turn down the double edge of the cut side and fold it over several times—finally, run a hard, smooth surface along the seam thus produced, to compress it, and spread the finished filter into an appropriate funnel, first moistening it with water before the liquid to be filtered is poured in.—*Chicago Pharmacist.*

SUNDERLAND CHEMISTS' ASSOCIATION.

The annual dinner of the Sunderland Chemists' Association was held on Wednesday, December 4th, in the Palatine Hotel; Alderman Thompson, the President of the Association, occupied the chair. The usual loyal and complimentary toasts were drunk, that of the "House of Commons" being coupled with the name of Mr. Candlish, M.P., who was present and replied.

Mr. Nicholson (hon. sec.), in responding to the toast of "The Sunderland Chemists' Association," said the members of the society had but one object in view, and that was to advance the position of the chemists, which was best done by the formation of local associations.

In reply to the toast of "The Medical Profession," proposed by the Vice-president, Dr. Yeld said he thought that the medical profession should not infringe upon the rights of chemists, and he hoped that few years would elapse before medical men gave up the practice of dispensing. When they did that, however, he hoped the chemists would then give up the practice of prescribing. He hoped that a Sunderland chemist would be appointed to the office of analyst. He had been charged with having stated that there was not a chemist in Sunderland qualified for the position, but he denied that he ever said anything of the kind, as he knew there were gentlemen well able to do the work.

The Chairman, in reply to "The President and Officers of the Association," said it was degrading to medical men that they should have to compound drugs when there was a branch of the medical profession in waiting night and day to do the work. In conclusion, he recommended the members of the trade to unite together for the protection of their interests.

THE ADULTERATION OF FOOD ACT.—DEPUTATION TO MR. STANSFELD.

On Thursday afternoon, December 12, a deputation from the Pharmaceutical Society, consisting of the President, Treasurer, Messrs. Betty, Bottle, Greenish, and Williams, with the Secretary and Mr. Flux (the Solicitor) attended by appointment at the office of the Local Government Board to bring before Mr. Stansfeld their views with regard to the appointment of analysts under the Adulteration of Food, Drink and Drugs Act. They were received by Mr. Lambert and Mr. Lumley, who stated that Mr. Stansfeld regretted very much that he was unable to meet the deputation, having been summoned to a Cabinet Council at such short notice as not to enable him to communicate with the deputation beforehand.

The President stated that the deputation attended in consequence of what had taken place at a deputation of medical gentlemen a short time ago, an account of which appeared in the *Times* of November 22nd last, from which it was feared the inference would be drawn that Pharmaceutical chemists or chemists and druggists would be excluded from competing for the appointment of analyst under the Act referred to. Now, as there were among their body many men quite qualified for the appointment, they were desirous that it should be publicly stated that such persons being so qualified were eligible. He would read three resolutions which had been passed by the deputation that morning:—

"That whilst it is obvious that sanction to the appointment of a dispensing chemist, simply because he happens to be called a chemist, cannot properly be asked, it is equally obvious that sanction to the appointment of a medical practitioner simply because he happens to be called a medical practitioner cannot properly be asked.

"That there are upon the Register of Pharmaceutical Chemists and Chemists and Druggists, persons possessing competent *medical, chemical and microscopical* knowledge for the office of analyst within the meaning of the Act of Parliament, and that it is not expedient for such persons to be excluded from the appointment.

"That competency is a question of fact, to be considered in each case, and that the examinations of the Pharmaceutical Society in a knowledge of chemistry and materia medica are, as a test of competency, at least equal to those necessary for admission to the Medical Register."

Mr. Lumley inquired if there were any examination to as microscopical knowledge by the Pharmaceutical Society, or how that qualification was to be tested?

The President said they did not examine in microscopical knowledge, nor was he aware that medical examinations included that subject.

Mr. Lumley asked if any of their examinations led to the belief that the persons examined had really given any study to the subject of microscopical investigation.

The President said the examinations themselves did not; but it was known as a fact, that there were many gentlemen in the business who were well qualified in that respect, and it would be, therefore, unfair to them that they should be excluded simply because they happened to be called chemists and druggists. Their view simply was, that chemists and druggists who were properly qualified should not be excluded from competing for the appointments.

Mr. Lumley asked how it could be ascertained that a person had acquired the requisite knowledge. With regard to a medical practitioner, the study of anatomy or some other branch of his profession would necessarily or naturally lead to microscopical investigations.

Mr. Greenish (member of the Microscopical Society) said the microscope was very much used at the present time in connection with materia medica, and although it did not form any part of the Society's examinations, yet it was very rare to meet with a pharmacist who was not a tolerably good, if not an accomplished, microscopist. In fact, the use of the microscope was necessary to the proper study of materia medica; especially in connection with starches and similar substances which would constantly have to be examined to detect adulterations.

Mr. Lambert said, as he understood, the resolutions simply went to the effect that a dispensing chemist should not be excluded from the appointment referred to, provided he was properly qualified.

The President said that was their object.

Mr. Flux said he considered it went to this length, that there was a greater inference to be drawn from a gentleman being on the Register of the Pharmaceutical Society that he was properly qualified for this appointment than if he were on any medical register. In lately preparing a case which he had laid before the Attorney-General and Solicitor-General in connection with this matter, he had made many inquiries, but he could not discover that there existed any test as to microscopical knowledge; but it appeared that the test applied by the Pharmaceutical Society as to the knowledge of materia medica went further in this direction than any other he could discover. It appeared that medical men were examined more especially in the application of medicines than in the knowledge of their ingredients, while the examinations of the Pharmaceutical Society were directed more to the composition of the medicine in its original state and its various compounds. What led to the present deputation was the fact that it appeared from several medical publications that a special claim was set up on behalf of the medical body to these appointments by reason of the use of the word "medical" in the statute. Now, in consequence of that, he had laid a case before the Attorney-General and Solicitor-General, and obtained opinion from those gentlemen, and he would ask leave to hand in both the case and the opinion.

Mr. Lumley, after looking at the opinion, said no doubt that when the Legislature wished to point to a legally qualified medical practitioner, they used those words which were not to be found in the present Act.

Mr. Flux said that was as far as the deputation desired to go. They only wished an authoritative utterance to the effect that these appointments were not limited to medical practitioners on the medical Register, and that really the electing bodies had to select the most competent persons within their knowledge and submit the election for confirmation to that office without a foregone conclusion that if the person appointed were not a medical man his election would not be confirmed.

Mr. Lambert said it was quite clear from the opinion of the Law Officers of the Crown that the appointment was not to be confined to medical practitioners, but it appeared that the persons must have some medical knowledge.

Mr. Flux said he admitted that, but contended that that medical knowledge did not necessarily import the practice of medicine.

Mr. Lumley said the difficulty was to see how a gentleman's medical knowledge could be ascertained unless he possessed a medical diploma.

Mr. Flux said there were many gentleman possessing the degree of Doctor of Science from the London University who were examined in all the sciences, including medicine, but they might not possess a medical diploma, and would not be on any medical register. Their contention was that the question of medical knowledge, like any other, was one of fact to be ascertained by the electing bodies without reference to any register, that the knowledge of medicines themselves was as much medical knowledge as the knowledge of their administration, and all pharmaceutical and other chemists did possess a knowledge of medicines, although they were not examined as to their application.

Mr. Lumley said in that case, would not the word "chemical" have been sufficient?

Mr. FLUX said hardly so, because medicines were distinct from chemicals.

Mr. LUMLEY said one consideration was that the articles to be analysed would be drugs supplied by chemists, and thus a gentleman would be analysing articles furnished by persons in his own trade. Was it contemplated that he should give up his business?

Mr. FLUX said that consideration would apply equally to a medical man. They did not contend that only gentlemen on their own Register should be eligible, for there were many men of eminence as practical analytical chemists who were not on the Register. He would also submit that there was no reason to imagine that a practising chemist and druggist would not duly discharge his duty equally as well as a practising medical man; because they might be called upon to analyse medicines. Their contention really came to this—there was no objection applicable to the one body which did not apply to the other, and that in fact a chemist should in respect of these appointments stand on a level with a medical man. A medical man might be presumed to have a kind of medical knowledge which the other did not possess, whilst on the other hand, the chemist might have a kind of knowledge which the medical man did not possess. Again, there was nothing to show that the medical men as a body were examined in chemistry.

Mr. LAMBERT said it appeared to him that before a medical man's election could be approved, some proof would have to be given of his competent knowledge of chemistry. And in like manner, if a chemist was appointed some proof would be required that he had competent medical knowledge.

Mr. FLUX said his contention was that the whole matter was a question of fact. The person to be appointed must have three qualifications, and if he possessed any two without the third, he was not competent; this was to be ascertained, not by reference to any register, but by such evidence as the electing bodies could obtain.

Mr. LUMLEY said he could understand that a gentlemen's medical knowledge could be ascertained by a reference to the Medical Register, and in the same way that his chemical knowledge might be ascertained by a reference to the Register of the Pharmaceutical Society. Could not microscopical knowledge be proved in the same way by reference to the register of some microscopical society?

Mr. FLUX said as far as he could understand, admission to the Microscopical Society was not subject to any test. It was merely a matter of voluntary subscription. The same was, to a certain extent, the case with the Chemical Society.

The PRESIDENT said that in any election which would take place, the persons competing, would bring forward what certificates they could in proof of their qualifications, and the electing body would decide probably from those certificates and any other knowledge they might be able to obtain. With regard to the word "medical," he thought it might almost be left out of the question, because he believed it referred not to a knowledge of medicine in the therapeutical point of view, but to a knowledge of the nature of medicines either to be used as adulterants or as being themselves adulterated; and also a knowledge of the action of these medicines upon the human frame. He contended that chemists and druggists, when properly educated, did possess that knowledge, and probably in a greater degree than ordinary medical men, and he thought this view was borne out by the opinions of the Attorney-General, Solicitor-General and Mr. Langley.

Mr. LAMBERT said he did not quite gather that from the opinion itself.

The PRESIDENT said he thought it would appear so from the opinion when read in connection with the case upon which it was given. He had nothing to say against their medical friends; on the other hand, he did not wish them to be unduly favoured, but that all should be put on the same footing.

Mr. LUMLEY said it must be remembered that the analyst had not only to report as to whether drugs were adulterated, or used to adulterate other matters, but also whether adulterations of other articles were injurious to health. One adulteration might be very slight, and yet very injurious to health, another might be very gross, and yet harmless. Some articles were poisonous in certain quantities, but not in others.

Mr. FLUX said his contention was that the knowledge of materia medica possessed by a chemist and druggist would enable him to deal with such matters. Every chemist had upon his shelves works stating what were the proper doses to be employed of strychnine or any other poisonous compound when used for medicinal purposes, and it not unfrequently happened that chemists were called upon to correct by their own knowledge errors made in prescriptions.

Mr. LUMLEY said he could quite understand that; they had, however, to deal not only with drugs and medicines but with articles of food of all kinds.

Mr. GREENISH remarked that if a medical man studied microscopy, he generally did so in connection with the minute structure of the human body; whereas a chemist used the microscope habitually to detect adulteration in the practice of his business.

Mr. WILLIAMS said there was one point which had not been touched upon, viz., that the main function of the person to be elected was that of analysing. Now analysis was a thing which required great experience, long study and much special knowledge. Medical men were rarely conversant with this branch of science, whilst many chemists were. He held in his hand a cutting from a London newspaper containing the remarks of a medical officer of health declining the office of analyst for his own district, for which he had been proposed, on the ground that he was not qualified. In so saying he was not to be understood as stating that he was not perfectly qualified as a medical officer, but candour compelled him to say that he had never made an analysis in his life, and he even went so far as to add that in his opinion there were only two medical officers in London—Dr. Letheby and Dr. Stephenson—who were really qualified for the office of analyst. This was an honest admission of the truth which the deputation contended for.

After a few remarks from Mr. HILLS,

Mr. LUMLEY asked what were the qualifications of any of the gentlemen appointed under the former Act?

Mr. WILLIAMS said he believed there were only two appointments made in London, one of Dr. Letheby, a medical practitioner, and one of Dr. Muter, who held no medical qualification.

Mr. FLUX said as far as he could gather no inference could be drawn from the appointments made under the former Act.

Mr. LAMBERT said he thought the subject had been very fully discussed, and he and Mr. LUMLEY would submit to Mr. Stansfeld the resolutions which had been drawn up, together with the case submitted to the Law Officers and their opinion, and also lay before him as fully as they could the views of the deputation. He would add that he believed as yet there had been very few appointments, none having been submitted for the approval of the department. The whole question was at the present time under consideration, so that a more opportune moment could not have been chosen for the deputation.

The PRESIDENT suggested in conclusion that the objection to a chemist being appointed because he might have to analyse articles sold by his fellow-tradesmen applied equally to medical men as officers of health, since they might be required to inspect and report upon property in which some of their best patients were interested.

Having thanked Messrs. Lambert and Lumley for their courteous reception, the deputation then withdrew.

The Pharmaceutical Journal.

SATURDAY, DECEMBER 14, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

UNIVERSAL PHARMACOPŒIA.

THE discussion, recently reported in this Journal, relating to the proposed Universal Pharmacopœia, has left undetermined several questions that were then raised, or that naturally suggest themselves on reflection. The principal object contemplated in the proposition made at the International Pharmaceutical Congress was the assimilation in strength and composition of all important medicines used in different countries. This is a result that can only be obtained by slow degrees, after the collection of much varied information, and finally through the intervention of those officially connected with the governing bodies having control over the issuing of authorized pharmacopœias. The first thing to be aimed at is the attainment of the requisite information. It is necessary to direct the attention of medical men and pharmacists to existing differences, often important, in medicines having the same or similar names. Arising from this cause much difficulty and even danger sometimes attends the dispensing of medicines for travellers in foreign countries. If all medicines having similar names were similarly composed, this difficulty would be removed. But how is such an assimilation to be effected? It is not the mere publication of the formulæ of different pharmacopœias, nor the placing of such formulæ in juxtaposition, that would accomplish what is required. The habits and prejudices prevailing in different localities must be overcome, and this, not by the exercise of authority, but by an appeal to facts and arguments. When several forms are adopted in different places for the administration of the same medicine, questions will arise as to the necessity for these differences; and if such necessity, or some sufficient advantage to justify an exception, cannot be shown to exist, then which of the several formulæ should be adopted to the exclusion of the others? These questions can only be settled after opinions have been freely expressed by all parties interested. The book proposed to be issued by the Société de Pharmacie of Paris, and referred to at the Vienna meeting, had for its object the eliciting of this kind of information, and was perfectly distinct and different in its design from the work described by Dr. THUDICHUM as that projected by Dr. PHOEBUS and other eminent medical and pharmaceutical authorities, including himself.

Then again, the book referred to at Vienna, itself emanating from a pharmaceutical corporation, was to be sent to other associations of a similar description, to be used by them at their discretion for furthering the object in view, but not with a view to its sale for profit, or its use for the ordinary purposes of a pharmacopœia.

The question of pharmaceutical nomenclature is one of considerable importance in connection with the attainment of the desired object. If it is proposed to assimilate the composition of medicines used in different countries, the names applied to them should be assimilated also; and then comes the question, in what language should these names be expressed, and further, in what language should the work as a whole be composed. In most countries Latin is the language of prescriptions, if not wholly, at least as far as relates to the names of medicines, and prescribers and dispensers in every country are supposed to have a knowledge of Latin. This is obviously, therefore, the language most suitable for a universal pharmacopœia.

There is also the question of weights and measures, or other means of representing the relative quantities of the ingredients entering into compound medicines, which will have to be determined before the Pharmacopœia is finally prepared.

Some of these questions were asked with reference to the work described by Dr. THUDICHUM; but the doctor's remarks, although conveying much valuable information, did not refer to these points. What we learn from his statement is, that a society consisting at first of eight members, with Dr. PHOEBUS at its head, and called the "Pharmaconomical Society," has undertaken the production of a Universal Pharmacopœia, which is to comprise a description of European medicines, good, bad, and indifferent, and that these are to e classified according to their merits by the size haracter of the type used in describing them, important medicines being in large type, then medicines of less importance in smaller type, and lastly, worthless medicines, which, in the opinion of the authors ought to be discarded, in the smallest type.

With the exception of the proposed classification by means of different types, we presume this work would not materially differ from HAGER'S "*Pharmacopœæ Recentiores Anglica, Gallica, Germaniæ, Helvetica, Russiæ, inter se collatæ.*" It might, no doubt, be a valuable addition to pharmaceutical literature; but from the description given, we fail to discover in it the essential features of such a work as the International Congress evidently contemplated.

AWARD OF PRIZES BY THE FRENCH ACADEMY.

On the 25th November the Académie des Sciences held its annual public meeting, on which occasion the prizes for the last two years were awarded. M. Faye, the Vice-President for 1871, delivered an address in which he alluded to the disasters from which France had suffered, and said that, nevertheless, the sittings of the Academy had been uninterrupted, except on one occasion, when one of the perpetual secretaries having left his home for the Academy was obliged to return in consequence of the erection of barricades and the imminent danger of his house being destroyed by fire. M. Faye also congratulated his hearers upon the fact of the French metre having been recognized in Great Britain and the United States, and adopted in Germany. Amongst the prizes awarded, numbering 34 in the two years, were—(1870) the Jecker Prize, 1700 francs each, to Messrs. Clermont, Gal and Grimaux, for researches in organic chemistry; the Barbier Prize (in the absence of a botanical competitor) to M. Personne, for his researches on chloral; (1871) the Jecker Prize of 5000 francs to M. Schützenberger for his labours in organic chemistry; the Barbier Prize, to M. Duquesnel, pharmacien and author of a work entitled 'De l'Aconitine Cristallisée;'* the Montyon Prize, in experimental physiology, to M. Raulin, for a treatise entitled 'Études Chimiques sur Végétation.'

The system of giving prizes for original research, which is such an important feature in connection with the French Academy, is one that is undoubtedly successful, not only in promoting scientific investigation, but in influencing generale ducation. Many suggestions have recently been made as to the most profitable disposal of the presumed surplus funds of the Pharmaceutical Society, and it would, perhaps, be worthy of consideration whether a portion might not advantageously be applied in a similar manner to assist in the development of pharmaceutical research in this country.

THE ADULTERATION ACT.

At a recent meeting of the Association of the Medical Officers of Health, Dr. Letheby brought forward the subject of the payment of analysts appointed under the above Act, with the object of obtaining the sense of the Association upon the question. He estimated that an average of 250 analyses would be required from each analyist appointed, and he suggested that if paid wholly by salary, each analyst should receive £175 per annum; if partly by salary and partly by fees, then at the rate of £1. 1*s.* each for the first 100 analyses, and 10*s.* 6*d.* each for the remainder; if paid wholly by fees, then the scale should range from 2*s.* 6*d.* to 10*s.* 6*d.* per analysis, that being the scale of fees required by the Act to be paid by any purchaser of articles of food, etc., desirous of having such articles analysed. The suggestion was approved by the Association.

* See Pharm. Journ. [3] vol. ii. p. 602.

Dr. Whitmore has been appointed public analyst for the parish of Marylebone, and Dr. Bernays, of St. Thomas's Hospital, for the parish of Camberwell. So far as we have been able to ascertain, the tendency of the bodies in whom is vested the appointment of analysts under this Act, has, hitherto, been to appoint medical officers of health of their districts, and there is little doubt but that this tendency is encouraged by the Local Government authorities.

DISINFECTANTS AND DISINFECTING.

In our correspondence columns we have inserted a letter from Messrs. M'Dougall Brothers, in refere nce to our remarks upon this subject recently The preparations referred to by Messrs. M'Dougall are known to us, but we have no positive evidence as to their practical utility as compared with carbolic acid. As bearing upon this question, it may be mentioned that the authorities of the Smithfield Club Cattle Show have this year resorted to the use of Sir William Burnett's Disinfecting Fluid.

A society has been formed under the title of the National Health Society, which is to have for its object to help every man and woman, rich and poor, to know for himself, and to carry out practically around him, the best conditions of healthy living. The steps at present proposed are the holding of monthly meetings for the reading of papers; the establishing of classes for instruction in various branches of sanitary science; the delivery of free popular lectures; and the formation of a reference library and an information office.

On Monday last, Mr. J. K. Lord, the naturalist and superintendent of the Brighton Aquarium, died after a short illness. Two days previously the first public illumination of the Aquarium took place with great success.

A meeting of the representatives of the Italian Pharmaceutical College has been recently held in Rome, having for its object an examination of the status of the body, which was found to be satisfactory. Messrs. Rolli, Peretti, Cicconi, Marignani, and De Cesarisi, of Rome; Colleoni, of Venice; Garofoletti, of Milan; De Vecchi, of Umbria; Kernot, of Naples; and Monteforte, of Palermo, were nominated as a committee to inquire into the progress of pharmacy in the west of Europe, and apply the same to Italy; also to draw up a pharmaceutical code of laws and a single tariff.

Provincial Transactions.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The first meeting of the session of this society was held in the new rooms of the association, Exchange Buildings, on Friday evening, the 18th October; Mr. J. H. Atherton, F.C.S., the President, in the chair.

Several members were elected, and donations to the library and museum announced.

The President said that arrangements had been made for a course of lectures on "The Chemistry and Botany of the Pharmacopœia," by Dr. Souter, to be held in the rooms of the society every Tuesday afternoon, and he hoped that all the associates would avail themselves of this opportunity of acquiring the sound and practical knowledge which Dr. Souter was so well calculated to afford. He explained that the time for the classes had been altered from nine o'clock P.M. to the afternoon for several reasons, chiefly because it afforded an opportunity for young men in the neighbouring towns and villages to avail themselves of the lectures and other advantages of the association, many applications from such places having been made; and another reason was, that by holding lectures in the afternoon they had a better attendance of the pupils, and their minds were more capable of receiving instruction in the afternoon than when wearied with the exertions and toil of a day's business.

The President also congratulated the society on having obtained such very convenient and commodious rooms at a more moderate rental. They must now devote their energies to the enlargement of the museum, so as to give every possible facility to the associates for acquiring a practical knowledge of the articles used as medicine.

The President then delivered the "inaugural address" of the session, referring at some length to the question of provincial education, and stating that he still adhered to his original opinion, that the establishment of large centres of education would not at all meet the wants of the country. That provincial societies could not afford, and ought not to be called upon, to defray entirely out of their own pockets all the preliminary expenses of forming museums, libraries, etc. That the question of aid from the Pharmaceutical Society ought to be considered as only of a temporary nature. That the elaborate schemes introduced by various gentlemen during the past year did not at all help the Council in their decision on the subject; that, in fact, their work was retarded in his (the President's) opinion. The matter being only temporary, the more simple the arrangement the better. If pecuniary aid was needed at all, it was needed at once; and he thought the Council should give grants where local societies were doing good work; where the necessity was felt for education, arrangements would be made in other parts of the country either for establishing classes for themselves, or arranging with the nearest provincial association. If the necessity was not felt, there was nothing to be done; even if the masters did not care to face the difficulties of forming an association in populous places, the assistants could form one for themselves, and receive aid where necessary. He thought that pecuniary grants should be given according to the number of young men in the district, and ostensibly for aiding local societies in forming museums, libraries, and the means of carrying on the educational work. He (the President) quite believed that in a few years if there existed a proper means of having good and well-illustrated lectures, a useful museum and a good library, the lectures could be made self-supporting, and in that case the local funds would be adequate for all ordinary expenses; there would then cease to be any necessity for using the funds of the Pharmaceutical Society.

The President then alluded to the method by which the utility of the Society could be spread over an area of thirty miles, at very little more expense to those living in towns a short distance from Nottingham.

Other matters were alluded to, such as the Adulteration Act, the Juries Bill, Co-operative Stores, the Pharmaceutical Conference, the Examinations, and Mr. Atherton concluded by dwelling on the uses and advantages of associations of a like nature, and making a strong appeal to the members to support the society not only by their subscriptions, but to do so by their presence, as an encouragement both to the young men, and to the officers of the society.

After some discussion, a cordial vote of thanks was passed to the President for his comprehensive address.

SUNDERLAND CHEMISTS' ASSOCIATION.

On Wednesday evening, Nov. 13, Dr. Donkin, late Professor of Medical Jurisprudence at the University of Durham, delivered a lecture to the Sunderland Chemists' Association, in the long room of the Athenæum, the subject being "Arsenical Poisoning," with reference to the "Cotton Cases," which have raised much interest on the subject in the country. Alderman Thompson presided. The following is an abstract of the lecture:—

The ancient Greek and Roman physicians were familiarly acquainted with two compounds of arsenic and their poisonous properties; these were the red and the yellow sulphurets of arsenic. To the red they gave the name of sandaracha or realgar, while the yellow was named arsenicum or auripigmentum, now contracted into orpiment. Dioscorides, the father of the materia medica, who wrote towards the end of the first century, as well as his successors Ætius, Actuarius, Galen, and later still, the Arabian physicians, especially Avicenna, have given an account of the symptoms and treatment of arsenical poisoning; and they used the same remedies which are now considered most effectual against this poison, namely, emetics, demulcents, such as milk, and barley water in large draughts, linseed tea and laxatives. Pliny the naturalist also describes the sulphurets of arsenic, and applies the term arsenicum to the yellow variety. Both the red and the yellow sulphurets of arsenic owe their poisonous properties to the large quantity of free arsenious acid they contain, amounting sometimes to 30 per cent. of their weight. Owing to the brilliant colours of these compounds, they are much used at the present day in dyeing, paper staining, and painting, and, what is still worse, in colouring toys and sweetmeats for children. When solid arsenic is found in the exhumed body which has been long buried, it is generally in the form of orpiment, or yellow sulphuret, produced by the chemical action on the arsenic originally administered of the sulphuretted hydrogen generated by the process of decomposition. Arsenious acid, commonly called arsenic, was first produced in the eighth century by Geber, an Arabian chemist, to whom we are also indebted for the discovery of corrosive sublimate, nitrate of silver, and other valuable compounds. To arsenious acid he gave the name of "sublimed arsenic," and Avicenna, an Arabian physician, afterwards named it white arsenic, its common modern appellative; he knew it to be a most virulent poison, and says of it '*interficit homines.*' The native physicians of India administered it internally as a valuable remedy for diseases of the skin, and for intermittent fever, long before its introduction into European medical practice as a therapeutic agent. Arsenic is thus a poison and a medicine of great antiquity, and as such has been long known in China, where the prohibition of the sale of arsenical compounds is somewhat similar to that now in force in this country. But the penalty for infringing the law is somewhat different; inasmuch as both the seller and buyer suffer decapitation if the effect of the poison is fatal; but if not fatal they are obliged to undergo the pleasant alternative of being strangled! Metallic arsenic, like all other pure metals, is innocuous, but most of its compounds are energetic poisons; of these arsenious acid, or common white arsenic, may be studied as the prototype, whether in a free state or in combination with alkalis or other substances. Arsenic occurs in two conditions, either in white enamel looking masses with a shining fracture, or in the state of a white powder. It is perfectly tasteless and inodorous, and this is one reason it is so often employed by murderers, as it can be administered without exciting suspicion. It is very sparingly soluble in water; cold water dissolves it in the proportion of from half a grain to a grain to the ounce; water at the boiling point only a grain and a quarter to the ounce; but if the arsenic is boiled for an hour in water, it is dissolved to the extent of 11 grains to the ounce; and as three grains constitute a fatally poisonous dose, an ounce of this latter liquor might kill three adult persons. An Act of Parliament prohibits the sale of solid arsenic in quantities less than 10lb., unless it is mixed with one-sixteenth of its weight of soot or one thirty-second part of it weight of indigo. If blue or black arsenic, therefore, should be administered to a victim, the matters vomited will be blue or black. This prohibition, however, does not produce an increased security against arsenical poisoning, because by boiling and filtering a strong poisonous colourless solution can be obtained. Arsenic combines readily with potash and soda, and the arsenite thus produced is quite soluble and quite as poisonous as pure arsenic. Arsenic is also readily suspended in a mechanical condition, in mucilaginous and viscid fluids, such as gruel, arrow root, sago, cocoa, or even porter. Arsenic may justly be described as the very Proteus of poisons, so to speak, being capable of producing almost every species of poisonous action, except pure corrosion, and of attacking almost every important organ of the body. Thus, on some occasions, it excites violent inflammation of the stomach and bowels, and so destroys life by this purely local action; on other occasions it leaves the stomach and bowels altogether uninjured, and produces fatal sinking of the heart's action, or death by syncope; while in other instances, again, the patient, without evincing either pain or uneasiness, gradually sinks into a deep sleep, and dies comatose, leading to the belief that he has been poisoned with opium, or has died from apoplexy. Now, in the two latter class of cases, there are no symptoms or indications whereby the most highly-trained and experienced physician can, during life, detect, or even suspect arsenical poisoning. The poisonous energy of arsenic is equally fatal to vegetable and animal life. Plants watered by an arsenical solution fade, wither and die, and thus the vegetation in the vicinity of furnaces employed for the smelting of arsenical ores displays a sickly, wan and withered appearance. When animalcules are watched under the microscope, they are observed to die in the course of from ten to thirty minutes after the addition of a solution of arsenic to the water containing them. The poison is equally fatal to worms, insects, crustaceans, fish, reptiles, birds and mammals. In short, no animal, great or small, is capable of resisting its fatal energy as a poison.

In arsenical poisoning cases occur which are acute and cases which are chronic; the difference arising entirely from the mode of administration. The acute cases are produced by a single large dose of the poison, the object being to kill the victim outright in the course of a few hours, or in a day or two at the outside. Most frequently the poison begins to act in from half an hour to an hour, locally, by producing violent inflammation of the stomach and bowels, attended with very characteristic symptoms, which do not resemble, when studied conjointly, the phenomena produced by any disease. The symptoms are those of what are termed irritant poisoning. The victim is suddenly seized with faintness, depression, nausea and sickness, accompanied with intense burning pain at the pit of the stomach, greatly aggravated by pressure; the pain then extends to the whole of the abdomen, and violent vomiting and purging ensue, the vomited matter being brown or turbid, and sometimes streaked with blood, but black or blue at first if arsenic mixed with soot or indigo has been administered. In some cases a white vomit has been observed when a large quantity of white arsenic has been administered. In cases of suspected poisoning the vomit should be carefully preserved for examination. The vomiting in arsenical poisoning is very violent and persistent and is rendered more intense by swallowing the smallest quantity of any substance or fluid, and, moreover, it is not followed by the slightest relief. The purging, too, is equally persistent and painful, and there is often a discharge of blood. The mouth is parched and there is intense thirst with a sensation of burning and constriction in the throat. The pulse is exceedingly feeble, frequent and irregular, often quite imperceptible, owing to the depressing power exercised by arsenic on the action of the heart; so that the condition of collapse is generally, but not always, induced; the skin becoming cold, clammy, and livid. A case of arsenical poison may, therefore, at first sight, bear a strong resemblance to cholera, for which, however, it cannot be mistaken on a careful examination, even although the calves of the legs may be cramped. There is much jactitation and restlessness, and the countenance is generally collapsed from an early period and expressive of intense torture, anxiety or even despair, and the eyes are injected, red and sparkling. When this congeries of symptoms has lasted for a few hours the brain and spinal cord often become affected, so that convulsive movements of the trunk and extremities begin to be manifested, and then delirium, followed by fatal stupor. But the intellectual faculties often remain clear to the last; death taking place calmly, though it may be preceded by an attack of convulsions. In this category of cases in which a very large dose of the poison has generally been swallowed, death frequently occurs at the end of twenty-four hours, and generally before the end of the third day, although some cases may linger a few days longer, and become subacute. Now these cases are examples of violent and fatal inflammation of the lining membrane of the stomach and intestines, of which all the traces, including ulceration, are detected by dissection, after death. When arsenic kills by its action on the heart, brain, and spinal chord, after being absorbed or taken up into the blood by the minute blood vessels forming a dense net work on the lining membrane of the stomach, the local effect of inflammation on the stomach and bowels, just described, is either entirely absent or very feebly developed. In fact, life is extinguished so rapidly (within five or six hours) that inflammation has not time to become developed. When the poison acts on the brain, after absorption, it produces complete narcotism, with the symptoms of death by opium or apoplexy, namely, a deep sleep, with loss of consciousness and volition. Dr. Moreland, of Bombay, describes a fatal case of this description, in which the victim, a man, was suspected of having taken a large dose of opium. When the poison kills by its action on the heart, producing death by syncope, attended with all the symptoms of collapse and sinking, namely, a faint and almost perceptible pulse, a cold clammy skin and laborious breathing, the intellect may remain clear, or, there may be some degree of stupor, and there may or may not be convulsions. When arsenic kills by its action on the brain and spinal cord, or on the heart, death takes place rapidly; generally at some period between two and eight hours after the poison has been swallowed. In these cases, as I have already stated, there is generally a complete freedom from local inflammation of the stomach and bowels, and its attendant characteristic symptoms. The symptoms of chronic arsenical poisoning may be divided into primary and secondary. The primary are those developed by the local contact of the poison with the lining membrane of the stomach and intestines, and indicate the inflammation excited and kept up by the continuous administration of the poison. They are as follows: constant pain in the stomach, nausea and vomiting, especially after taking food or drink, griping pains, tenderness and distension over the abdomen, and obstinate protracted purging. The tongue is red and dry, and there is urgent thirst. The pulse is frequent, small and feeble. When these symptoms have continued some few days, those of the secondary class become developed and are produced by the absorption of the poison into the blood and the constant saturation of the tissues of the body with it. These are: redness and suffusion of the eyes and intolerance of light, salivation and ulceration of the gums, a discharge from the nostrils, cough and expectoration sometimes bloody, strangury, a peculiar eczematous eruption on the skin, emaciation and great muscular prostration; convulsions, numbness and tingling in the fingers and toes, ending often in paralysis, especially of the lower extremities. As the case progresses, convulsions, numbness, stiffness, tingling and paralysis of the lower extremities (sometimes the upper), and of the lower half of the body, generally permanent, and ending in death. Orfila was the first to prove experimentally on dogs that when a solution of arsenic is injected into the empty stomach, it is absorbed into the blood and diffused or deposited in every part of the body in the short space of an hour and a half. From the rapidity with which the poison destroys life by its action on the brain and heart, there can be no doubt that the absorption and diffusion of arsenic throughout the body is equally as rapid in the human subject as in the dog or other animals, the laws of osmosis being alike in each. Arsenic is not a natural constituent of the human body, and does not enter into the formation of any of the tissues, and no sooner is it deposited in any of them than its removal from the body, or elimination, as it is termed, begins to take place. This is effected by the organs of excretion, more especially by the kidneys, and is no doubt due to the fact that arsenic does not form an insoluble compound by combining with the tissues; but being a crystalloid it is subject to the laws of osmosis and cast out of the body dissolved in water. Orfila first detected by experiment on dogs that the urine becomes impregnated with arsenic in from three and a half to five hours after the poison had been injected into the stomach. Further experiments and actual observation on the human subject have clearly demonstrated that arsenic is gradually and completely removed from the body, after having been deposited in the tissues, in the course of from twelve to fifteen or twenty days after its administration has ceased, consequently it will not be detected in the tissues after death, by chemical analysis, if the victim survives the operation of even a large fatal dose, for a period exceeding fifteen or twenty days, assuming the kidneys to be healthy as well as the other organs of excretion. It follows from the facts just stated that in a case of suspected poisoning by arsenic, and more especially in chronic and subacute cases, when suspicions of foul play have been roused, portions of the urine should at once be secured for chemical analysis, taking precautions, of course, to secure the identity of the specimens procured. This procedure is indispensable in forming a correct diagnosis, and one which should never be omitted by the medical attendant, because, should the case be one of arsenical poisoning, the instrument of destruction will not, with ordinary care, escape detection. A lecture on arsenic would be incomplete if the subject of poisoning by the arsenite of copper —Scheele's green—were to be omitted. This substance enters into the composition, more or less largely, of various pigments, namely: emerald green, mineral green, Vienna green, Brunswick green, etc. It is, therefore, found in the oil paint cakes of water colours, in wafers, adhesive envelopes, and as a green paint for toys. But it has been used most abundantly of all in green decorative paper hangings, especially those called "green flocks," by which so much mischief has been done. So great was the demand for these papers a few years ago that Dr. Taylor stated in the last edition of his work on poisons (1859) that a manufacturer told him that his average consumption of arsenic in making them was two tons weekly. The publicity given by the press since then to the serious injury to health, and even death, caused by these papers, seems to have rendered them much less fashionable in this country. The Prussian Government, after a thorough investigation, prohibited their manufacture altogether.

MANCHESTER CHEMISTS' ASSISTANTS' ASSOCIATION.

The third meeting of the session was held at the new Lecture-room, 37, Blackfriars Street, on Monday evening, November 18th; the President, Mr. Lane, in the chair.

A lecture was given by Mr. Siebold on "Volumetric Analysis." He explained the different modes of quantitative analysis, both by the ponderal and volumetrical methods, and showed the great advantage of the latter both in the saving of time and the increased accuracy of the result.

The lecturer practically tested the strength of acid. hydrocyan. dil., acid sulphurosum, etc., by the volumetric method, and the frequent applause of a large audience testified its thorough appreciation of the explanation and complete success of the numerous experiments.

At the close of the lecture a hearty vote of thanks was given to Mr. Siebold.

The fourth ordinary fortnightly meeting was occupied with the reading of a paper on "Opium," by Mr. R. de Burton. After describing the mode of obtaining it, "its varieties" and "constituents," the reader briefly referred to the large doses of morphia and other active ingredients sometimes met with, which greatly exceeded those of the Pharmacopœia, thereby causing a doubt to exist in the mind of the dispenser as to whether it was intentional or an oversight.

It was thought by the meeting that in all such cases where the dose of morphia and other active ingredients exceeded that of the Pharmacopœia, a mark of some kind attached by the prescriber, confirming his intention, would greatly assist the despatch of the medicine, and relieve the dispenser from much anxiety.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The second general meeting of the association was held in Anderson's University, on Wednesday evening, 27th November, at nine o'clock.

In the unavoidable absence of the President and Vice-President, Mr. Kinninmont was elected chairman.

After the minutes of last meeting had been read and approved of, Mr. Wm. McKenzie was elected as treasurer.

It was stated that the arrangements for Mr. John Curne's class were almost completed, so that the class would start in a few days.

Several members were then elected, after which the Chairman introduced Dr. John Clark, Lecturer on Chemistry, Glasgow, who delivered a very instructive and interesting lecture on the "Oxides of Hydrogen."

At the close of last session a motion was passed instructing the Council to take some active steps to raise the prices by retail of many of the drugs and chemicals that had advanced very much in price, and, if possible, to adopt a complete retail price-list, both for dispensing and general drugs. It was thought advisable, however, to consult the trade generally in regard to such a matter, and, if possible, carry the numerous doctors who keep open shop with the druggists in the movement.

Accordingly in September last a trade meeting was held which was well attended, and a large, influential committee appointed to draw up a complete list. The committee set to work at once, and the list having been completed, and the various districts of the City and neighbourhood canvassed by the members, on Friday evening last the final meeting of the trade was held in Anderson's University, Mr. John Currie, chairman of the committee, in the chair, for the purpose of receiving the report of the committee and giving a formal adoption to the list. The attendance was large, several medical men being present. The report showed that upwards of 130 chemists and surgeons had signed the petition in favour of the list, and with a very few exceptions, they were willing to adopt it. A committee was appointed to wait upon these persons to impress upon them the necessity of acting with the majority in this matter, and that the list gave no latitude for supplying inferior goods at lower prices. After some further discussion regarding the discretionary power to be used by the chemist in reducing prices occasionally to poor people, and it being understood that in such cases the letter "E" should be marked on the left-hand corner of the prescription, denoting *exceptional*, Mr. J. M. Fairlie brought forward the following resolution, viz., "That this meeting of the Glasgow drug trade cordially adopts the 'retail price-list' submitted by the committee; thanks the members for their arduous labours connected with its compilation and canvassing of the trade, and appoints them a standing committee to meet as occasion requires for the purpose of revising the prices of fluctuating articles, and adding to or deleting from the list any articles they think necessary." This having been seconded by Mr. James M'Donald (Glasgow Apothecaries' Company) and supported by Dr. George Smith, was unanimously agreed to.

A cordial vote of thanks brought the proceedings, which were very harmonious throughout, to a close. The list is being sold by the association at 1*s*. per copy.

HALIFAX AND DISTRICT CHEMISTS AND DRUGGISTS' ASSOCIATION.

The fourth annual meeting of this association was held on Thursday, December 5th, 1872. After supper the election of officers took place, with the following result, viz.—President, Mr. Jessop; Vice-Presidents, Mr. Stott and Mr. Hebden. Committee, Mr. Wm. Dyer, Mr. Jas. Farr, Mr. Pollard, Mr. Shaw, Mr. Wood. Treasurer, Mr. J. B. Brierley. Hon. Sec., Mr. Robert Brook.

The President thanked the meeting for the honour it had conferred upon him. He looked with pleasure and satisfaction upon the Pharmaceutical Society, and his connection with it, and was glad to see the Council doing their utmost by educational and other efforts to raise the trade into something more approaching a profession, and thought it was their duty as a local body to assist so desirable an object. He rejoiced to witness a more fraternal feeling of brotherhood apparent amongst them, and believed the result would be rather less of rivalry and competition and more of a desire to benefit one another.

The Honorary Secretary read the annual report, which alluded to the efforts made with respect to early closing, the recommendation of the executive to the members to register vermin killers, the Food and Drug Adulteration Act, the education controversy, the injury to trade from the civil service stores, competition and other trade matters, and which was unanimously adopted. Mr. Stott proposed "The Pharmaceutical Society." Mr. Wm. Dyer, in responding to the toast, said he had always had a profound respect for the Society, and they were now beginning to see and appreciate its value and importance. "Success to the Association," proposed by Mr. Blyton, was responded to by Mr. Hebden. Mr. Robert Brook proposed "The Mayor and Corporation," which was acknowledged by Mr. Councillor Pollard. Votes of thanks to the ex-president, honorary secretary and president brought an interesting meeting to its close.

BRIGHTON ASSOCIATION OF PHARMACY.

The monthly meeting of this association was held at the Hanover Lecture Hall, Church Street, on Friday evening, December 6th; the President, Mr. W. D. Savage, in the chair. There was a fair attendance of members. A paper "On Percolation" was read by Mr. Julius Schweitzer.

[The paper will be published *in extenso* in the next number of this Journal.]

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, December 5th, 1872; Dr. Frankland, F.R.S., President, etc., in the Chair.

Amongst the new members who were balloted for and elected at this meeting, after the minutes had been read, was a Japanese gentleman, Mr. K. H. Yoshida.

The first two papers read were "On Hypophosphites" and "On the Reducing Power of Phosphorous and Hypophosphorous Acid and their Salts," by Professor C. Rammelsberg.

A communication by Professor A. H. Church, entitled "New Analyses of Certain Mineral Arseniates and Phosphates," then followed, giving the result of his examination of the minerals fluor-apatite, arseniosiderite, childrenite, ethlite, tyrolite and wavellite. The last paper was "On the Condition of the Hydrogen Occluded by Palladium, as indicated by the Specific Heat of the Charged Metal," by W. C. Roberts and C. R. A. Wright, D.Sc., being an account of their recent experiments on the specific heat of palladium charged with hydrogen. This interesting compound, which was discovered by the late Professor Graham, Master of the Royal Mint, and supposed by him to be an alloy of palladium and hydrogen, is obtained on making metallic palladium, the negative pole in the electrolysis of water acidulated with sulphuric acid. The authors find, however, that the charged metal cannot be regarded as a true alloy of the two elements.

Parliamentary and Law Proceedings.

Important to Chemists.

Howlett v. *Jones*.

At the Whitechapel County Court on Wednesday, November 27th, the plaintiff, a shopfitter, sued the defendant, a chemist, for £3. 13*s*., for a plan and estimate for fitting up a new chemist's shop, and for polishing up the side of a counter to prepare for the work. Mr. Abbott, solicitor, appeared for the defendant, and informed His Honour that the counter in question did not belong to the defendant. He knew nothing about it.

The plaintiff stated that he had supplied the defendant with a plan and estimate, that the defendant had given him the contract, but, afterwards, had written to say that he had given it to another person.

Cross-examined by Mr. Abbott: He had given the defendant a price verbally, exclusive of extras, but he had not supplied him with a written estimate or specification. He charged three guineas for the pencil drawing. Taking into consideration the time spent upon it, and in attending upon the defendant while visiting other shops, it ought to have been five guineas, and that would be the price usually charged under such circumstances. He always charged for plans and estimates.

The defendant having been called, stated that he simply asked the plaintiff for a price and received a pencil drawing, which he never ordered. He was positive that he never ordered a plan, nor did he give him the contract. His last words to the plaintiff were, "That he would consider the matter over, and let him know in a day or two," which statement was corroborated by the defendant's assistant, who was present and heard it. The plaintiff having asserted that it was impossible for him to give the price required without making a drawing, His Honour allowed him two guineas and 10*s.* costs.

Conviction under the Petroleum Act.

At Sheffield, Henry Rose, oil dealer, was charged by the inspector of petroleum, with having exposed for sale some petroleum, in pint bottles, five of which had no labels upon them as required by the Act. The complainant stated that he met Rose's boys in the street with trucks or handcarts containing petroleum oil and benzoline, and that he seized five bottles holding about a pint each, which were not labelled, though three of them bore some indications of having at some time had labels upon them. The defendant relied upon a proviso to one of the sections in the Petroleum Act, exempting persons keeping petroleum in small quantities and under certain conditions from the necessity of obtaining licences, but the stipendiary ruled that the exemption applied to keeping petroleum only, and not to selling, conveying, or exposing for sale, and fined the defendant (who had been previously convicted for a similar offence) 20*s.* and costs.—*Sheffield Independent.*

Alleged Poisoning by Godfrey's Cordial.

An inquest was held in Hull on Friday, Nov. 29th, touching the death of a child four weeks old. The mother deposed that the day before the child died she thought it had a stomach-ache, and gave it nearly two tea-spoonfuls of Godfrey's Cordial, which she bought at a chemist's in Mytongate, without the admixture of water. The next morning, as it seemed ill, she took it to the doctor and told him what she had done, and he ordered her to give it some castor oil. The child died in the afternoon.

W. L. Loten, chemist and druggist, 31, Mytongate, said he recognized the mother, but did not remember selling her the cordial. Always waited on all the customers himself. Sold about half a gallon of Godfrey's cordial per week, and the greater portion went out in cups, which he did not label. Sold one ounce for a penny. Made the cordial himself of 4 lb. treacle, 40 drops oil of sassafras, 2 oz. sweet nitre, and 2 lb. boiling water. That was not the true Godfrey's cordial, which was a patent medicine. Every druggist had a formula of his own for what he called Godfrey's cordial. His cordial never contained any opiate or any poison whatever. The cordial produced by the police had not been purchased at his shop.

The medical evidence went to show that the child died of pericarditis, and a verdict was returned accordingly. —*Hull and North Lincolnshire Times.*

Alleged Acceleration of Death by a Cough Mixture.

An inquest was held at Sheffield on Wednesday, December 4th, on the body of Mrs. Lowe. It appeared from the evidence that for some time past deceased had been suffering from bronchitis, and for a few days before her death she had been very much worse. On Saturday her daughter went to Mr. Lockwood, druggist, South Street, Moor, for some cough mixture. That night she gave her mother half a tea-spoonful; and in the course of the night her mother herself took a similar quantity. She took some more on the following day. On Monday she was not able to get up, and her daughter in the course of the day and night gave her three doses of the mixture. When the daughter went to bed at night her mother was very ill, and groaned a good deal. On the following morning she found her mother was lying dead by her side.

Mr. Willington, surgeon, who was called to the deceased after death, gave it as his opinion that death had been accelerated by a narcotic. She had been, he said, a woman addicted to intemperate habits, and those habits would accelerate the effects of a narcotic. The mixture obtained from Mr. Lockwood was a narcotic. It was labelled "Essence of Linseed." The label was calculated to mislead, as there was no linseed whatever in it. It was composed of morphia, chlorodyne, treacle, and some other sweet substances.

The jury were of opinion that it was most improper for manufacturers and druggists to put a wrong label upon a medicine so frequently taken as a cough mixture. They returned a verdict to the effect that the deceased died suddenly from debility, accelerated by the administration of a narcotic inadvertently given; and they appended to their verdict that "the sale of narcotics under the name of essence of linseed is dangerous, and should be discontinued, and that the manufacturers of the said narcotic ought to have notice of this case and the opinion of the jury." The coroner promised that he would communicate their opinion to the manufacturers.

[*** In reference to the foregoing report, which is taken from the *Sheffield Independent* Messrs. Kay Brothers, of Stockport, request to be allowed to state that, although the surgeon's statement may be true with regard to the essence of linseed prepared by Mr. Lockwood, they deny its accuracy if applied to their preparation. They state that the amount of narcotic contained in their "essence of linseed" is less than in an ordinary cough lozenge, and that it is really what it is labelled.—Ed. Pharm. Journ.]

Alleged Attempt to Poison by Arsenic.

On Monday last a boy named Hoy, aged twelve, was charged at the Clerkenwell police-court with attempting to poison his step-mother by administering to her a quantity of arsenic. It appeared from the evidence that on the previous Wednesday morning the prisoner, according to his usual custom, took his father and step-mother each a cup of tea which they drank while in bed. Two hours afterwards the woman was seized with vomiting and purging, and a burning sensation in the throat. On Saturday the boy again brought the woman a cup of tea, which, however, she not drinking, afterwards threw away, when she noticed a sediment at the bottom. This roused her suspicions, and the cup was taken to a medical man who pronounced it to be arsenic. The father said he kept arsenic in his shop to poison rats, but he was not aware that anybody but himself knew of it. He saw the arsenic safe in a drawer about two months ago. Since then more than half of it had been removed, as well as the outside wrapper. The wrapper that was left had on it a poison label. The medical man stated that the sediment in the cup was arsenic mixed with a dark powder, probably charcoal. There was sufficient arsenic in the cup to poison more than a dozen persons. It corresponded with the arsenic in the drawer.

The prisoner was remanded.

Adulteration of Milk.—What is an Adulteration?

Several milk-dealers have been summoned before Mr. Raffles at the Liverpool borough police-court for adulterating the milk sold by them. In two cases Dr. Brown deposed that specimens of milk purchased had been adulterated by the addition of 20 and 10 per cent. of water respectively. A penalty of 20*s.* and costs was imposed in each case.

In another case it was alleged that the adulteration consisted in mixing 200 parts of skim milk with 100 parts of new milk. For the defence it was urged that this was not an adulteration within the meaning of the Act; that to prove an adulteration it was necessary to show that some foreign ingredient had been introduced. Mr. Raffles said that he saw the difficulty, but that reading the section as a lawyer he could not say that the milk had been mixed with any other substance. It was not an honest transaction, but he felt he could not convict. He would, however, grant a case if it were applied for. The summons was accordingly dismissed.

Explosion of Gunpowder in a Chemist's Shop.

On Saturday afternoon last a rather serious accident occurred to Mr. Williams, chemist and druggist, at his shop, 124, St. Philip's Road, Sheffield. Towards dusk he struck a match, in order to look for some article, and unfortunately one of the sparks fell upon a small barrel containing about two pounds of gunpowder, a portion of which exploded in his face, burning his hair very severely. A cry of "Fire" was raised, and a neighbour rushed into the shop and threw the contents of a water bucket upon Mr. Williams, whose clothes had been ignited by the explosion.—*Standard.*

Obituary.

MRS. SOMERVILLE.

The following obituary notice of the late Mrs. Somerville is reprinted from the *Times*:—

Mary Somerville died on Friday in the neighbourhood of Naples, where she had of late years taken up her residence. Had she lived to the 26th of the present month she would have attained her 83rd year. Mary Somerville, or, to give her maiden name, Mary Fairfax, was a lady of good Scottish ancestry, being the daughter of the late Vice-Admiral Sir William George Fairfax, who was a cadet of the noble Scottish house of Lord Fairfax, and who commanded His Majesty's ship Venerable at the Battle of Camperdown. She was born on the 26th of December, 1789; her mother was Margaret, daughter of Mr. Samuel Charters, Solicitor of Customs for Scotland. All that is known of her early life is that she was a great reader, even from childhood, and that she was brought up at a school at Musselburgh, in the vicinity of Edinburgh.

Before many of the most distinguished cultivators of physical science were born, Mrs. Somerville had already taken her place among the original investigators of nature. In the year 1826 she presented to the Royal Society a paper on "The magnetizing Power of the more refrangible Solar Rays," in which she detailed her repetitions of the experiments made by Morichini of Rome, and Bérard of Montpelier. The paper had for its object to prove whether solar light is a source of magnetic power. By means of a prism the component rays of a sunbeam were separated, and those which are now known as the chemical or actinic rays were allowed to fall upon delicately poised needles of various sizes which had been previously proved to be devoid of magnetism. In every instance the steel exhibited the true magnetic character after an exposure of several hours to the violet light. Experiments were then made by covering unmagnetic needles with blue glass shades and placing them in the sun, and in all cases they became magnetic. From these experiences Mrs. Somerville concluded that the more refrangible rays of the solar spectrum, even in our latitude, have a strong magnetic influence. This communication was printed in the 'Philosophical Transactions' at the time; it led to much discussion on a very difficult point of experimental inquiry, which was only set at rest some years later by the researches of two German electricians, Riess and Moser, who showed that the action upon the magnetic needle was not caused by the violet rays.

In 1831 or 1832 Mrs. Somerville published her 'Mechanism of the Heavens.' This book, her only strictly astronomical work, which is largely derived from Laplace's celebrated treatise, 'La Mécanique Céleste,' and is understood to have been originally suggested by Lord Brougham, was originally proposed by its author as one of the publications of the Society for the Diffusion of Useful Knowledge; but, being moulded on too large a scale for their series, it was given to the world in an independent shape. A few years later her name became more widely known by her 'Connexion of the Physical Sciences,' which obtained the praise of the 'Quarterly Review' as "original in plan and perfect in execution," and, indeed, "a true 'Kosmos' in the nature of its design and in the multitude of materials collected and condensed into the history which it affords of the physical phenomena of the universe." This she followed up with her 'Physical Geography,' which, as its name imports, comprises the history of the earth in its whole material organization. These two works, in addition to their popularity in this country, as testified by the many editions through which they have passed, have been translated into several foreign languages; and their author's services to geographical science were recognized in 1869 by the award of the Victoria medal of the Royal Geographical Society. In the same year she gave to the world her 'Molecular and Microscopic Science,' a work which, to use the expression of a writer in the 'Edinburgh Review,' "contains a complete conspectus of some of the most recent and most abstruse researches of modern science, and describes admirably not only the discoveries of our day in the field of physics and chemistry, but more especially the revelations of the microscope in the vegetable and animal worlds."

The publication of such a work as that last mentioned by a lady in, we believe, her eightieth year is without a parallel in the annals of science. In it that which most forcibly strikes the reader is the extraordinary power of mental assimilation of scientific facts and theories which is displayed by its author. In it Mrs. Somerville first gives us a clear account of the most recent discoveries in organic chemistry, in the elementary condition of matter, and tells us of the latest researches into the synthesis of organic carbon compounds. She next leads us on to the relations of polarization of light in crystalline form, and, quitting the subject of molecular physics with an account of the phenomena of spectrum analysis as applied to the stars and nebulæ, she begins with the consideration of the microscopic structure of the vegetable world; then passing in review the whole of the organisms from algæ to exogenous plants, she lands us in her second volume among the functions of the animal frame in its lowest organizations, and describes the morphology of the various groups of animals from the protozoa to the mollusc. In thus traversing this immense field of modern scientific inquiry, Mrs. Somerville does not attempt to generalize to any great extent, much less to bring forward any original observations of theories of her own; but, as she modestly hints in her preface, she has simply given in plain and clear language a *résumé* of some of the most interesting results of the recent investigations of men of science.

For some few years before her death Mrs. Somerville was in the receipt of a literary pension, bestowed upon her in recognition of her services to science. This was the nation's tribute to her worth. But among men of science a far higher value than pecuniary grants can have is set upon those rewards which can be bestowed only by such as can appreciate the labours and aims of a toiler in the scientific field. And these Mrs. Somerville received: the Geographical Society, as we have said, awarded her its medal; the Royal Astronomical Society elected her, in 1834, one of its honorary Fellows, the same honour being at the same time bestowed upon Miss Caroline Herschel—the only two ladies on whom such a distinction was ever conferred. The Fellows of the Royal Society also signified their appreciation of her works and their personal regard for their author by subscribing for a bust of Mrs. Somerville, which Chantrey executed, and which the Duke of Sussex publicly presented to the Society in 1842, in his own name and in that of the subscribers. This monument adorns the Library of the Royal Society.

Mrs. Somerville was twice married. Early in life she became the wife of Mr. Samuel Greig, who is described in 'Burke's Peerage' as "a Captain and Commissioner in the Russian Navy." Her union with him became the means of developing her latent scientific powers, as he took great pleasure in mathematical inquiry, and carefully initiated her in both the theory of mathematics and their practical application. Her second husband was Dr. William Somerville, a member of a good old family of Scottish extraction.

Notice has been received of the death of the following:—

On the 23rd of November, Mr. John Whitfield, pharmaceutical chemist, of the firm of Whitfield and Son, Worcester, aged 45. Deceased was one of the earliest examined members of the Pharmaceutical Society, which he entered in 1847.

On the 14th of September, at Perth, West Australia, of consumption, Mr. John Thomas Glass, late of Cheltenham and Bournemouth.

On the 22nd of November, Mr. Richard Constantine Hay, chemist and druggist, of Bond Street, Leeds, aged 79.

Reviews.

SANITARY SCIENCE: as Applied to the Healthy Construction of Houses in Town and Country. By R. SCOTT BURN. Glasgow, etc: Collins, Sons and Co.

This is a work which can be read with considerable interest; but the interest will centre in the value of the subject rather than in the literary performance. It would hardly be possible for an author to write a treatise on sanitary matters which should be altogether free from quotations, because the subject is of the widest; but to borrow too largely of the Egyptians, even if one acknowledges the loan, is doubtful wisdom, in more senses than one. No person in our day can arrogate to himself even a simple branch of one single science; but he can add to the cairn some stone which he has himself dug up and polished, and he only. We are far from saying that Mr. Burn has not heretofore contributed some heavy pebbles to our sanitary landmarks; but we say that he has not done himself justice on the present occasion. A book such as this, moreover, should have given the quoted matter in smaller type than the original matter. This is a healthy rule, and one Dr. Corfield, for example, followed out with great advantage to his readers in his 'Digest of Facts Relating to Sewage.' To bestow upon a work like that before us a title such as 'Sanitary Science,' is surely also a little indiscreet. 'Sanitary Jottings Concerning House Construction' would have been more appropriate to its bulk and general treatment. Perhaps the fault lies with the publishers, who may have urged Mr. Burn to write the work with somewhat of haste. Our author is universally known as a gentleman of good professional practice and extensive research, and we trust that he will be spared to polarize more of his own experiences for us in a future volume.

Mr. Burn has described and illustrated a very useful method of preventing the accumulation of dust in rooms, a matter almost altogether ignored in the construction of houses in the metropolis. This "dust draught" is of the simplest make, and would be a great saving of time to the housemaid, and a great source of benefit to the family if its use were universal. And yet it is nothing more than a tube which leads from the back-hearth into the chimney-flue some distance above the register of the grate. Dampness as a very prevalent source of evil finds also a proper recognition, and several cures for it are mentioned which experience has confirmed as being valuable. The chapter upon cottage accommodation will be especially welcome to the sanitary student, for it is a subject too often neglected by our domestic architectural writers. For the most part these treat of mansions and villas only, and leave the cottage carefully out in the cold. Even when some agricultural society or some philanthropic individual offers a prize for an essay upon the best form of labourers' dwellings, the chief points attended to by the competitors are less those of health and comfort than of cheapness and neatness of elevation.

Mr. Burn considers that a floor superficies of 144 feet is the minimum which should be allowed for a living room, and a 100 feet for a bed-chamber, no room being less than nine feet from floor to ceiling, and attics to be earnestly eschewed. We agree with him in each particular.

We confess our disappointment at the curt manner in which the smoke nuisance is treated, for this is the most crying evil of the day. The eye is weary of pictures of earth-closets and patent filters, and would twinkle with joy at any feasible device for ridding itself of the pungent smoke. That this pest is extinguishable is not to be doubted; but it does not seem to be a branch of Hygiene which "pays," and therefore it has few professors. This is a sober statement—smoke prevention as a business is unremunerative, hence we sit in "smuts" and perambulate in flakes of "blacks." Just notice what follows when the fiat has gone forth that such and such a contrivance is absolutely necessary. Burglary, for instance, is on the increase, and straightway the papers herald in a host of patent sash-fasteners, and the chief of the police placards the metropolis with his idea of the *ne plus ultra*. We have a better example occurring before our eyes at the present moment. The "constant water supply" is imminent with us, and already the lists of "water waste preventers" seeking recognition at the hands of the water companies, are mounting into a score. Let some one devise a means of ensuring a proper combustion which shall benefit the units who practise it, and a combined action in the same direction will soon be made imperative upon us. Our present schemes for the reduction of smoke are too tentative in character, and, in point of invention, too poverty-stricken. It is nigh twenty years since Mr. Spencer Wells pointed out the evils resulting from a constant grimy atmosphere, and cast the foreshadow of a cure. How can we be so dilatory in what concerns our longevity so nearly? And yet after all, it is not long since we separated our postage stamps with a pair of scissors.

We consider Mr. Burn's dissertation upon ventilation to be the most useful part of his book; and in the threescore pages which he has dedicated to this subject he gives the most ample information as to what is usually done in this matter, and why it is done. The chapter on water is practicable, and may be termed an epitome of all that is needed to be remembered by any one outside of the medical profession. We have only one fault to find here, and it is embodied in this sentence—"No overflow pipe should be connected with the drains if it can be at all avoided." Now it always can be avoided, and always should be avoided, for the disease germs often make a highway of such a pipe to reach the cistern, with results such as we all know. The book concludes with some excellent examples of ash-closet and other drainage systems and a short discussion on sewage utilization. Despite our friendly criticisms, we recommend the book as worthy of a place in a library, and wish it a good circulation.

Round the Table. Notes on Cookery and Plain Recipes, with a Selection of Bills of Fare for Every Month. By "The G. C." London: Horace Cox. 1872.

How to Cook. The Principles and Practice of Scientific, Economic, Hygienic and Æsthetic Gastronomy, with Model Recipes in Every Department of Cookery, Original and Selected. By T. L. Nichols, M.D. London: Longmans. 1872.

The sufferings of Sancho Panza, when the importance of his health to the community of the island of Barataria caused his dietary to be placed under the dictation of a doctor of physic, have often been food for laughter. But the reading of a well-written book on cookery enables one to sympathize with the hungry squire when he saw one dish whisked away because it was too watery, another because it was too highly spiced, or heard his plea for a plate of roasted partridges cruelly met with the Hippocratian aphorism, "Omnis saturatio mala, perdicis autem pessima." And since, in a recent pharmaceutical oration, it was strongly insinuated that competent pharmacists were much more numerous than pharmacists with a competency, some apology may be thought necessary for the introduction of a subject in the study of which it is so very difficult to obtain assistance in the shape of "object lessons." For under such circumstances Chispa's problem is very apt to crop up—

"I've heard my grandmother say, that Heaven gives almonds
To those who have no teeth. That's nuts to crack.
I've teeth to spare, but where shall I find almonds?"

But there has always been somewhat of a special connection between the apothecary and the cook, even beyond the evident one that a too free patronage of the latter frequently necessitates the services of the former. Much that is akin to practical pharmacy is found in the art of cookery as practised by a real *chef de cuisine*, and the special qualities required by an expert in both callings are mainly identical. Though at the present day, cookery is too often a preliminary to requiring the aid of the physician, it was in ancient times looked upon as a branch of the healing art; and a revival of this opinion is noticeable in the increased attention that has lately been paid by medical and scientific men to questions of diet. Besides this, medical men have not thought it beneath them to write upon cookery, and Sir Theodore Mayerne in the seventeenth century, Hunter and Hill in the eighteenth, and Kitchener in the nineteenth, have given to the world cookery books that rank among the best of their respective eras.

'Round the Table' is the production of a writer who not only knows his subject, but evidently loves it. One can easily believe the statement in his preface that the recipes are derived from experience. Although lacking the wit that renders Brillat Savarin's 'Physiologie du Goût' so enjoyable, "The G. C." makes the reader feel himself in good company. Starting with a proper horror of "people who on four days out of the seven dine off a joint and potatoes," he gives pleasant glimpses of that Utopia where the price of meat, milk and eggs has no power to interfere with the gastronomic enjoyments of its inhabitants. Indeed, in such company, one is surprised to meet with a "Potage au Pauvre Homme;" and it is quite a relief to discover, from the position of the adjective in the title considered in connection with the nature of the ingredients in the potage, that probably poverty of the pocket is not alluded to. But although there may be many dishes referred to in this book which would only be likely to make their appearance in an expensive establishment where professional cooks are employed, there is also a great deal of sound advice respecting those little points which are so essential to the comfort of the dining-room. Hints as to the number, selection and arrangement of the guests, the ordering of the servants, the decoration of the table and the disposition of the dishes thereon, the temperature of the room, the management of lamps, and a hundred other subjects—all of them marked by good taste, and generally as applicable to a small as a large establishment—meet the reader on almost every page.

It is curious to note how old customs are sometimes confirmed by modern opinion. The Romans said that the number of guests at a table should not be less than the Graces or more than the Muses. "Ten is the very largest number of friends that should assemble at dinner," writes "The G.C." "Good wine," said Sir Theodore Mayerne, at eighty-two years of age, "is slow poison: I have drunk it all my lifetime, and it has not killed me yet; but bad wine is sudden death." "In the matter of wine," echoes our author, "no mediocrity is tolerable; small beer or water is infinitely preferable to bad wine." According to Milton, the first hostess—Eve—was intent

"What choice to choose for delicacy best,
What order, so contrived as not to mix
Tastes, not well joined, inelegant, but bring
Taste after taste upheld with kindliest change,—"

although she was harassed by "no fear lest dinner cool." And the following description of a cook, written when Athens was more than a name, is just as true after the lapse of two millenniums:—

"To roast some beef, to carve a joint with neatness,
To boil up sauces, and to blow the fire,
Is anybody's task; he who does this
Is but a seasoner and broth-maker;
A cook is quite another thing. His mind
Must comprehend all facts and circumstances:
Where is the place and what the time of supper;
Who are the guests and who the entertainer;
What fish he ought to buy and where to buy it."

In this work the importance of using absolutely clean vessels is strongly enforced, and it is truly remarked that in a majority of the kitchens of the middle classes of this country the cooks would pronounce vessels "clean" which no amount of sand, soda and soap could make fit for use.

'Round the Table' supplies many recipes that might be usefully extracted if space allowed, but we must content ourselves with two which have the double advantage of answering a question sometimes put to the pharmacist, and giving a fair specimen of the style of the book.

"*Restorative Broth.*—Slice three onions, and dispose them in a saucepan so as to completely cover the bottom of it; over them place a layer of fat bacon in slices a quarter of an inch thick; over that put three carrots, also cut in slices, so as to form another layer; on this again put the following condiments judiciously proportioned—viz., salt, whole pepper, cloves, parsley, marjoram and thyme. Upon this pile up two calves' feet, chopped in small pieces, and one pound of beefsteak, free from all fat and finely minced. Cover the saucepan and put it on the fire, there to remain for one hour. There should be no fire at the side, it should be fairly under the saucepan. The next step consists in filling up the saucepan with boiling water so as just to cover the contents; and then it is put by the side of the fire to simmer for one hour; after that the liquor should be poured off without disturbing the other contents of the saucepan. The steam, which arises during this operation gives out a most appetizing perfume, which will fill the hearts of those present with gladness. The liquor should now be strained through a napkin; the little fat which will float on it should be removed with the help of some clean blotting-paper; and the broth can be administered to the patient. A teaspoonful of sherry and a small quantity of sugar may be advantageously added to each cupful. This restorative when cold will be a firm jelly, and it can then be administered in a solid form."

"*Beef Tea.*—Take 2 lb. of beef, free from all fat; mince it as fine as you can, and put it into a jar, with one pint of cold water, to stand inside the fender for a couple of hours; now strain off the water, and put it by, replacing it by another pint of tepid water. Put the jar nearer the fire, or on the kitchener, so as to keep the water hot without boiling. After the lapse of another couple of hours strain this off, and mix it with the first pint you strained off. Transfer the minced meat into a saucepan: add one pint of boiling water to it, and let it boil for one hour; strain and mix with the first two pints. Let the whole give one boil; add salt, and the beef tea is ready for use."

"The *théorique* of the above process is this. Meat contains various substances, all of them nourishing; but some, as albumen, are only soluble in cold water, others tepid water alone will dissolve, and others again can be brought out by the action of boiling water alone. By treating the meat with cold, tepid and boiling water separately, all that is to be got out of it is obtained; and the result is, as it must be, the best beef tea that can be made."

As might have been expected, the preserved Australian meat is referred to, and although it was not likely to be quite suited to the taste of "The G.C.," who complains of its being over-cooked, he describes several very appetizing dishes which can be made from it.

An interesting chapter on salads calls attention to a subject very much neglected in this country. Boldly rejecting that great favourite of the British greengrocer, mustard and cress, the author mentions several comparatively unused salad plants, especially the dandelion, and states generally that any vegetable which is not positively unwholesome when uncooked may form the foundation of a salad. Those who wish for further information upon this subject may consult an article, reprinted from *Nature*, in the present series of this Journal, vol. I. p. 167.

One point—too often neglected—that adds to the reader's comfort and confidence in the writer of this book is, that the orthography and accentuation of the French names are generally correct. In one line, however, there is the double trip of "celeri" and "crême."

The second book upon the list is addressed to a different class of readers. Written by an author who has recently been attempting to demonstrate "How to live on sixpence a day,"—a proceeding that might be supposed to do away with the necessity for cooking,—it is not surprising that the recipes as a rule are more suited for persons of straitened means than those in the manual first-mentioned. It would perhaps characteristically illustrate both books, though in somewhat an exaggerated manner, to quote a flavouring from each. In 'Round the Table' the addition of a bottle of sherry to the water a ham is boiled in is recommended; in 'How to Cook,' the final touch to a Poor Man's Potato Pie is a boned bloater cut up with the fat as a nice change of flavour. There is, however, in the introductory chapter of 'How to Cook' a great deal of much-wanted information on the food question, and, considering the low price at which it is published, the book is certainly a good one.

The following journals have been received:—The 'British Medical Journal,' December 7; the 'Medical Times and Gazette,' December 7; the 'Lancet,' December 7; the 'Medical Press and Circular,' December 7; 'Nature,' December 7; the 'Chemical News,' December 7; 'English Mechanic,' December 7; 'Gardeners' Chronicle,' December 7; the 'Grocer,' December 7; the 'Journal of the Society of Arts,' December 7; 'Grocery News,' December 7; 'Bulletin de l'Académie de Médecine for November 19; Evans, Lescher and Evans' 'Monthly Price List,' 'Western Lancet' for October; 'Journal of Applied Science' for December; 'Scientific American,' November 30; 'Neues Repertorium für Pharmacie; 'Milk Journal' for December; 'Moniteur Scientifique for December; 'British Journal of Dental Science' for December; 'Practitioner' for December; 'Food, Water, and Air' for December; 'Michigan University Medical Journal' for November; the 'Hull Packet and East Riding Times,' from a correspondent.

Pharmacy in Germany.

Sir,—Many of your readers are probably aware of the monopoly that exists at the present time throughout Germany, in the acquirement and possession of pharmacies. This is naturally esteemed by many as an injustice to the bulk of the profession. At a meeting on Tuesday, Dec. 3, of the Berlin branch of the German Chemists' Asssistants' Association, the subject was brought forward in the shape of a petition, proposed to be presented next session to the 'Bundesrath,' requesting its early attention to the state of pharmacy in the empire, especially in relation to the principle of free trade. The petition states that in the course of the year 300 men pass their examinations, and that in the same period thirty assistants (at the most) become proprietors by "concession," and about 100 by "purchase." This leaves annually 170 as assistants, many of whom in preference to remaining as such for probably a very considerable period, devote themselves to another calling. This accounts in a large measure for the great scarcity of assistants. The petition also maintains that as the greater portion of prescriptions are dispensed, and the most important operations conducted by the assistants, the public are as much, or even more dependent on them than on the proprietors themselves. Nevertheless, the only men to whom the pharmaceutical profession opens a career of independence, are either those who are already in possession of considerable means for the purchase of the few businesses for disposal, or those who expect a "concession" of a pharmacy from a father or near relative. After looking at the matter from other points of view, the petition closes with the remark, that the longer legislation on the point of free trade is postponed, the more difficulties will it present; as every year by the concessions granted for new pharmacies, there will be a proportionately greater number of proprietors requiring compensation for existing rights and privileges.

How this and similar petitions will be received by the German Parliament will be seen in the course of a short time. Walter Hills.

Berlin, December 6th, 1872.

Disinfectants and Disinfecting.

Sir,—In your editorial article of 9th November on "Deodorizers, Disinfectants, and Antiseptics" you very properly point out the fact that, "In spite of the highly poisonous nature of carbolic acid, it is generally preferred as a disinfectant." You also suggest, that could some harmless and efficient variety of carbolic acid be introduced to the public it would be readily adopted. Permit us to point out that such preparations have for many years existed in the form of "M'Dougall's Patent Carbolic Disinfectants," which are now coming into general use. These preparations, whilst possessing all the valuable antiseptic properties of carbolic acid, have also the powerful deodorizing effects of sulphurous acid, both these substances being in a neutral form, *i.e.*, as combinations of carbolate of lime and sulphite of magnesia.

The public should be informed that carbolic acid acts as a poison simply through its powerful causticity, which destroys the skin and the mucous membrane, and that may be neutralized by admixture with lime, soda, or other alkali.

This causticity, whilst most useful to the surgeon, in no way increases the antiseptic properties of carbolic acid, and the carbolates are as efficacious in this respect as the raw carbolic acid, whilst perfectly free from danger.

We have for many years endeavoured to instil this fact into the public mind; and since carbolic acid in combination with sulphurous acid (in a neutral form) was recommended by the Royal Commission on Cattle Plague as the best disinfectant, it is time that these harmless and efficient preparations should be universally adopted.

It is supposed by many that because the soap prepared with carbolic acid instantly destroys insect life, that it must therefore be poisonous to animals. Such is not the case. It destroys these parasites not by poison, but by coagulating the albumen of which they are chiefly composed (instead of blood), thus stopping their circulation and causing death.

Animals dipped into a solution of the soap suffer no harm, even should they drink some; and many thousands of sheep are yearly dipped in a carbolic dipping.

The fluid carbolate recently introduced is likely to prove an invaluable lotion, gargle, etc., for hospital and domestic use, and is perfectly harmless.

M'Dougall Brothers,

Table of Food Values.

Sir,—I am obliged to you for your, on the whole, favourable notice of my "Table on the Relative Values of Different Articles of Food," at the pharmaceutical meeting of the 4th ult. With regard, however, to your objection that the method of valuation I have adopted is somewhat hypothetical, allow me to say that the method is none of mine, but is to be found in Professor Huxley's 'Manual of Physiology.' If I err, I am content to err in such company.

All I have attempted to do is to expand and to render graphically the lessons given in Professor Huxley's excellent manual and in works by other authorities treating of the same subject.

Charles Ekin,

Bath, Jan. 9th, 1872.

Lady Students.

Sir,—At the last meeting of the Council of the Pharmaceutical Society, Mr. Bottle is reported to have said in the course of the discussion whether lady pharmaceutical students should be eligible to compete for the prizes and scholarships of the institution, that "it would be hardly fair to the male students to put them on the same footing with a young lady who had nothing whatever to do but study the particular subject in which she wished to gain a prize." As Mr. Hampson justly remarked, the same objection is not urged against those of the male students who may have all their time at their disposal. The statement itself, however, does not in any way express the actual circumstances. One of us—the three ladies now attending the pharmaceutical lectures—is engaged from the time she leaves the lecture-hall till late in the evening in dispensing; another has, until very recently, been similarly engaged until a late hour at night, and is now seeking re-engagement; and the third has, besides domestic duties, her time largely occupied by other studies and serious pursuits. Being thus engaged we find but little time to read for the lectures and examinations, and we vainly wish for the opportunities for study and investigation enjoyed by the male students in the laboratory. The Pharmaceutical Society has thus far closed its laboratory to us; and if we shall be able to present ourselves at all for the final examination, it will be at an immense disadvantage as compared to the male students, and by supplying the want of laboratory instruction by personal effort. All that we ask is to be allowed the same opportunities for study, the same field for competition, and the same honours, if justly won. To grant this would complete the just and generous initiative which the Pharmaceutical Society has already taken.

Adulterated Milk.

Sir,—In to-day's and in a previous copy of the Journal you report some cases of conviction under the Food Adulteration Act for selling adulterated milk, when it is said that the milk in question had too little cream. I would esteem it a favour if you would say in a note next week what is authoritatively given as a fair average of cream for *pure* milk. I have some standing by me just now obtained from a large country dairy farm where thirty cows are giving milk. It has 7 per cent. of cream.

Two or three years ago I made a survey of the town's dairies. I examined over thirty samples of milk; the highest percentage of cream I got was 13; the lowest, 3; both being obtained where one cow only was kept for private use. The richest one was attached to a brewery and confined, the other was in the outskirts, and getting out every day.

Some other samples, containing 5, 10 and 20 per cent. of water added, had 10, 7 and 5 per cent. respectively of cream. One sample with 10 per cent. of water had 9 per cent. of cream.

With such a variation I am afraid that it is just possible considerable injustice may be done if the quantity of cream is to be made an element in the case.

Analysis.

Dundee, November 30th, 1872.

[*** The yield of cream in genuine milk ranges certainly from 7 to 14 per cent., and it is unsafe to condemn a specimen of milk sold on account of its yielding little cream. If, however, the percentage of fat in the milk fall considerably below 3 per cent., and the "total solid residue" fall below 11·5 per cent. the milk may be safely condemned as more or less skimmed. In view of the present interest attaching to the question of milk adulteration, we purpose furnishing in early numbers a few facts respecting the characteristics of pure milk and the methods for detecting adulteration.—Ed. Pharm. Journ.]

A. H. Crundall.—We think your communication unsuited for publication. To be patronized is about the last thing that the ladies require.

"*Persevere.*"—There is nothing illegal in the course you describe, and we think it would operate as its own remedy for whatever is objectionable in it.

"*Cinchona.*"—(1) We have no doubt but that we could mention the names of gentlemen competent and willing to undertake the duties, but we consider that it would be far preferable that they should be performed by some one living in the same district as the members of the Association. (2.) We should advise "Fownes" to be studied in addition to the other book mentioned. (3) *a.* The B.P. and any works bearing on analysis and materia medica; *b.* Yes.

C. Crook.—Add the oil to as much water in a bottle and shake well; then add the liquor potassæ, again agitate and pour in gradually the remainder of the water, with the acetate of morphia dissolved in a portion of it, shaking well after each addition until the whole is added.

T. G. Batting.—The sp. chloroformi, B.P., is generally used in dispensing.

"*An Associate.*"—A plan frequently adopted is to add to tinct. iodi a sufficiency of liq. ammon. fort. and filter. Squire gives the following as Sir J. G. Simpson's formula for liquor ammoniæ iodidi:—"Liq. ammon. fortiss., 2 oz.; iodine, 10 grs.; iodide of potassium, 20 grs.; rectified spirit, 1 oz.; dissolve."

"*Justice.*"—In reply to our correspondent, he only is responsible. It is the duty of every person entitled to registration to see that not only his name but his address is correctly set forth in the published Register. Any one failing to ascertain for himself that the Registrar appointed under the Act does enter those particulars has only himself to thank for any inconvenience that may arise from the default.

"*Arte et Labore.*"—We have no qualification for giving advice upon the subject you inquire about.

H. A. K.—(1) "Liquor Vandelliæ Diffusæ." *Vandellia diffusa* is a Scrophulariaceous plant, a native of Brazil and Guiana, used sometimes in diseases of the liver or as an emetic. See vol. II. p. 849. (2) "Liquor Panaceæ." *Arnica montana* is on the Continent sometimes called *Panacea lapsorum.* Some preparation of this is probably referred to; but the prescription is evidently intended to be dispensed by some special or foreign chemist.

S. K. Bennett.—(1) No payment other than the fee for the examination is necessary. (2) The best way of ascertaining the questions set at the Minor or Major examinations would be to present yourself for examination. Apply to the Secretary for a copy of the Regulations of the Board of Examiners.

L. V. Z.—(1) We suppose the examiners would have no objection to chemical testing where it was necessary. (2) We believe not.

A. P. S.—We think your view is the correct one.

J. E. Richardson.—The entire bulk of the mixture, even if it were water, would be insufficient to dissolve the quantity of sulphate of magnesia. The quantity intended must have be ℨ xij. and not ℥ xij., and the mixture would be so dispensed in London.

Communications, Letters, etc., have been received from Professor J. Léon Soubeiran, Messrs. L. V. Rees, Jenkinson, Tichborne, Ekin, Sanger and Sons, Symes, Brookes, Norris, Dr. C. Kidd, Chemicus, Vigil, Silentium, W. J.

COWS' MILK AND THE BEST METHODS OF DETECTING ITS ADULTERATIONS.

BY CHARLES EKIN, F.C.S.

The physical properties of cows' milk are too well known to need description. It is a slightly alkaline liquid, and has a specific gravity varying from 1026 to 1031; according to the most recent analyses, it contains in a hundred parts,

Water	87·55
Fat	3·07
Casein	4·04
Milk Sugar	4·63
Ash	·71
	100·00

Milk has all the essential constituents of food-stuffs, viz., proteids, fats, amyloids and minerals in exactly the proper proportions to form a typically perfect food. These, measured by their carbon and nitrogen percentages, give 6·8 parts per hundred of the former to 0·7 of the latter. The phosphate of lime in milk is especially important to the process of the formation of bone, and this combined with the easy digestibility of milk, and as we have seen, by its containing in proper proportions all the essential constituents of a perfect food, explains why it should and does form the diet, *par excellence*, for the infant stages of life. It would seem a work of supererogation in these days of advanced knowledge to point this out; and, indeed nature has been teaching the lesson from time immemorial; but I have frequently heard mothers boast that their children have been brought up entirely without milk, whether human milk which is better, or its substitute from the cow, and that my experience cannot be altogether singular is sufficiently proved by the number of so-called infants' foods which we see everywhere advertised.

Although for adults the mixing of foods which long experience has justified is no doubt the best, still it is quite possible under certain conditions to live on a milk diet alone; and we have here at all events one instance where theory and practice are perfectly in accord. I have been assured by one whose authority is undoubted, and who has lived several years amongst certain tribes of Arabs remarkable for their fine physique and great strength, that they have but one meal a day, and that that meal consists entirely of camels' milk. The meal, it is true, must be rather a tedious affair, for owing to the stomach not being able to accommodate a sufficient quantity of the fluid at one time, they have to wait whilst they slowly pass the bowl from one to the other, until the casein has been coagulated in the stomach, and there is literally room for another draught. I am not informed whether this process is facilitated, as is reported of children at school feasts, by "standing up."

The white and almost opaque appearance of milk is an optical illusion; examined by the microscope it will be seen to be a perfectly transparent fluid, in which float numbers of transparent globules of fat. These globules are surrounded by an albuminous envelope, and the mechanical breaking of this, as in churning, causes the fat to agglomerate and become what is known to us as butter.

In the process of churning, a portion of the cheesy matter or casein of the milk becomes mixed with the butter, but this can be removed to a great extent by repeated washings in water, and decanting off the particles of casein which are suspended in it.

In the best kinds of butter the cheesy matter rarely amounts to more than one per cent.; in the inferior kinds there is often several per cent. present. As a rule, the more the casein is left in the butter, owing to its liability to putrefactive changes, the more likely the butter is to become rancid.

We have been treated of late years to several sensational articles in the newspapers as to the adulteration of butter, but they have no foundation in fact. The adulterants are almost invariably water and common salt. Good honest butter, if fresh, contains 82 or 83 per cent. of fat, about 1 per cent. of salt., and 16 per cent. of water; if salted, it should never contain more than 7 per cent. of salt. It is sometimes adulterated with as much as 35 per cent. of water. The fat should be estimated by washing with ether and evaporating down the ethereal solution. Where much water is present a rough estimate may be formed by melting the butter at a gentle heat in a graduated tube, and measuring off the proportion of water, which will of course sink to the bottom.

Cheese is made by coagulating the casein of milk; in this country by means of rennet, in other countries by such diverse substances as hydrochloric acid, vinegar, tartaric acid, sour milk, the juice of figs or thistles, etc. etc.; but though the manufacture of cheese offers many points of interest to the chemist, a discussion of them here would be foreign to the purpose of this article.

The cow stands first amongst all animals as a milk giver, both on account of the quantity and quality she yields.

The quality of the milk is much influenced by the age, the breed, the food, and the general conditions under which the animal is kept; and it becomes a point of importance to the analyst to know the extreme limits of this variation.

It used to be the custom to speak as to the purity and goodness of milk from the size and number of the fat globules as revealed by the microscope, but it is needless to say such a test is very unreliable, as is also the test of specific gravity. With regard to this latter test, it is evident that the removal of all or part of the cream, which is lighter than water, would increase the specific gravity, and a milk thus treated would actually in this way be pronounced better than it was before it was deprived of its cream.

Within the last two years, thanks to Mr. Wanklyn, who during that time has made several hundred analyses of milk, the results of which analyses he has published from time to time in the 'Milk Journal' and elsewhere, the assay of milk has been put upon an altogether more satisfactory footing than it has ever been before. Mr. Wanklyn has based his conclusions upon the amount of total solids milk contains; and although this method is not of his originating, it has been brought in his hands to a completeness and degree of accuracy which leaves little to be desired.

In examining a milk according to his plan, small thin platinum dishes containing carefully weighed quantities of milk are to be maintained at a temperature of 212° F. by means of a water bath for three hours. The residue once dried is not found to be very hygroscopic. This, of course, gives the total solids. If it is desirable to estimate the ash as well, the precaution must be taken (to avoid overlooking chloride of sodium, which is slightly volatile) to ignite the residue for as short a time as possible and weigh the ash, then ignite very strongly until the ash is completely whitened, and reweigh.

Four samples of genuine milk treated thus gave per cent.:—

Total solids dried at 212° F.	Ash.
12·12	0·61
12·16	0·63
12·51	0·66
12·47	0·76

Genuine milk of average richness, and neither skimmed nor watered, contains approximately 12 per cent of solids, and gives about 10 per cent. of cream. Milk which has been skimmed, but not otherwise maltreated, contains about 10 per cent. of solids. From the departure from these standards we can judge of the extent to which skimming and watering have been practised, the removal of 1 per cent. of cream lowering the solids of milk by 0·2 per cent.

Analyses extending throughout a whole year were made of the mixed milk of fifteen cows, and they show that the milk scarcely ever varies. In but four instances did the water fall below 86·6, and in four only did it rise above 88 per cent.

In making a complete analysis of milk, the water is found by deducting the weight of solids.

The fat, by treating the total solids with ether, and evaporating down the ethereal solution.

The milk-sugar is dissolved by water out of the milk residue which has been deprived of its fat and moistened with alcohol. The aqueous solution of milk sugar is evaporated in the water bath and dried until constant in weight. The weight of the salts dissolved out of the milk residue by water is ascertained by igniting the dry residue containing the milk-sugar and is deducted; the difference giving of course the milk-sugar.

The casein, coagulated in the usual way and separated by filtration, being on a filter cannot be accurately weighed, and may be found as difference.

Notwithstanding the statements to be met with in works treating of the Adulteration of Food, as to sheep's brains, etc., etc., being occasionally added to milk, water is really the only adulterant that is ever met with. There can be no doubt that in large towns the practice of watering exists to a large extent. In London, especially, according to the 'Milk Journal,' the samples of pure unskimmed milk form only a small minority.

Mr. Wanklyn has lately suggested that his method of limited oxidation by means of a strongly alkaline solution of permanganate of potash may be very well applied to the examination of milk, casein yielding 6·5 per cent. and albumen 10 per cent of ammonia. I am not aware that he has published any experiments bearing upon this, but those who have had experience in the estimation of albuminoid matters in potable waters, according to his plan, will readily understand that it may be adapted with great advantage to the examination of milk.

[⁂ In a letter received from Mr. J. F. Brown, of Dover, in reference to the testing of milk, he suggests that a determination of the amount of sugar present might form the basis of a convenient and trustworthy test. He says, "I remember applying it some years ago, by first separating the casein by heating with 1 per cent. of acetic acid, then diluting the whey to a definite measure and dropping it from a burette into a measured quantity of the solution of cupric potassio-tartrate, kept boiling in a flask until the colour was discharged. This copper solution was made from the directions in Attfield's Chemistry, so that 100 grains was equivalent to 5 grains of lactose."—Ed. Pharm. Journ.]

PERCOLATION.*

BY JULIUS SCHWEITZER.

The subject which I am going to deal with in this paper is a pharmaceutical process for preparing fluid extracts, tinctures or any other liquid preparation; it is the process called percolation. It is not a new process, although only recently introduced into the last edition of the Pharmacopœia. Some thirty years ago, Mr. Deane contributed a long paper about this subject, an account of which is in the first volume of the Pharmaceutical Journal; and so recently as at this year's meeting of the Pharmaceutical Conference here in Brighton, Mr. Stoddart gave us the results which he had obtained in preparing tinctures by this process and by simple maceration.

The different writers on percolation, after referring to the various difficulties which this process presents, usually finish by recommending a proceeding of their own, slightly different from those of their predecessors. I consider it, therefore, not out of place to bring the subject forward once more. I do not pretend to tell anything original or new, but will simply give an account of my proceeding. In working for many years in a large laboratory, I have had opportunities to try nearly every drug used in pharmacy, both on the large and small scale, and I never found any great difficulties to success. I usually carried my experiments on with cold water. The different opinions of the various writers on this subject I consider have principally arisen by their working with small quantities. If you work on the small scale, and if you are careful in the selection of your drugs, and see that they are properly powdered, and if you watch the subsequent process with the desire to produce a good article, you are almost sure to succeed whatever plan you may follow; but if you adopt the same proceeding on a large scale, the results are not near so certain and satisfactory; on the contrary, you find success very doubtful, and failure in many instances unavoidable; and no process can be considered sound and recommendable that is not applicable for large quantities. I consider also, that a certain amount of confusion and difficulty may be caused to a beginner by not keeping the two processes of displacement and percolation more distinct and separate from each other. That there is a difference in these two processes I consider sufficiently proved by their different names.

Displacement.—Displacement means the displacing or the removing of the soluble matter from your drugs and nothing else, and consequently you remove, eliminate or displace this in the highest state of concentration, and by means of the least possible amount of fluid; it is a process more applicable for small quantities where the ingredients are reduced

* Read at a meeting of the Brighton Association of Pharmacy, December 6th, 1872.

to a fine powder, the menstruum or solvent being usually strong or absolute alcohol, ether or chloroform.

Percolation.—Percolation, on the contrary, means simply the flowing through of your menstruum. It is a process specially adapted for large quantities. You usually work with proof spirit or more frequently with water; it is, moreover, a process where you usually have to use more fluid than absolutely necessary for the mere exhaustion of your ingredients.

The Percolator.—After these preliminary remarks let us consider the best form of our percolator. I think it is now generally admitted that the cylindrical form is the best, while the cone, which found many advocates in the commencement, is rejected. The conical percolator was first of all selected, because the ingredients when packed in it can readily rise when moistened and swelling out; consequently there was no danger of blocking the percolator up or bursting it; but the same loose attachment of the species with the sides of the percolator which enabled the solid ingredients to rise, allowed also the fluid to pass without penetrating right through them. Besides this most serious objection, a conical percolator is unnecessarily bulky, while the principal amount of the ingredients is of necessity in the upper and wider part where the fluid exerts the least pressure and has the least solvent action. But whatever percolator may be used, it will be found an additional advantage to have a tap at the bottom for the check and regulation of the outflow of the fluid.

The Species.—With regard to the condition of the ingredients, they must be in a uniform, more or less, finely divided state; the larger the quantities used and the more mucilaginous the nature of the ingredients, the coarser the species may be; while the smaller the quantities worked with and the more insoluble and woody in fibre, the finer the ingredients can be. These are, of course, only general rules, and those who have experience in the process will find no difficulty in percolating a cwt. of finely powdered opium or ergot of rye at one time.

In such cases it is necessary to mix the powder with some inert, insoluble, and light material; in the above-mentioned instances I took the rumex fruit and residue, so abundantly obtained in the preparation of extract of opium, and ordinary rye-husks. In fact, I found husks or straw, either cut fine as chaff or in whole pieces, a most useful help to facilitate in many instances the process of percolation. The ingredients themselves must be of a uniform powder to allow the fluid to pass through every particle at an equal rate; the fineness, as I have stated before, may vary from a powder passed through a sieve of 36 to 144 meshes to the square inch. They ought, moreover, to be moistened with the menstruum used for percolation, and allowed to absorb as much of it as possible, taking care that the single particles retain their shape or individuality, and that the mass does not form a shapeless magma. During this absorption of moisture, some vegetable ingredients will increase very materially in bulk, and this swelling out ought to be allowed to go on to its full extent before packing them in the percolator. If you percolate with water you will find that some ingredients, such as poppy-heads or orange-peel, absorb a great amount; in fact as much as they contained in their fresh condition. The dry vegetable cellular tissue retains the power to fill these cells and vessels with moisture again, and it is of great importance for the process of percolation that this is so; and pains ought to be taken to see that the ingredients are thoroughly impregnated and soaked by sprinkling them from time to time with the menstruum, and turning them over and over.

The Packing.—After the ingredients are brought to the proper condition for packing, a little tow or cotton-wool is placed in the bottom of the percolator, over the tap, and on this the ingredients are packed. Where it is possible it is best to use the hand, to ensure a uniform and close position without jamming or smashing the ingredients, the hand being the best guide for the amount of pressure required to effect this; a little tow or cotton-wool is again covered over the top and some weighty and not acted upon substance placed over it to prevent the floating up of the mass. I have found old glass stoppers very serviceable for this purpose. Sufficient fluid is now added to cover the species, and it is well before starting the process to allow the apparatus to stand quiet for a couple of hours, after which the tap may be turned on so as to enable the fluid to escape drop by drop in quick succession.

The Percolating or Exhausting.—The exhaustion of the species is effected by the means of two agencies, the force of gravitation compels the fluid to descend, and the capillarity of each single particle absorbs the descending fluid and facilitates and enables it to pass right through the mass from particle to particle, carrying with it the soluble portion. The first portions which pass out of the percolator are those most highly charged with extractive matter, and are best kept separate from those obtained last, especially where water is used for percolating, and where the products have to be concentrated by evaporation; in these cases the evaporation ought to commence with the more diluted portions obtained at the end of the process, adding the first products last.

Conclusion.—I cannot leave this subject without throwing out some suggestions. Percolation enables us to separate the active, soluble and volatile aromatic principles of plants in a highly concentrated and natural condition; and from my experiments I have but little hesitation in stating that all our proof tinctures, such as tincture of orange-peel, henbane, cinchona bark, etc. etc., could be made much more uniformly and economically by exhausting the respective drugs simply by water, concentrating the percolated products to such a degree that three parts of it added to five parts of rectified spirit would produce eight parts of tincture of Pharmacopœia strength. Such a plan, if once introduced, would naturally lead a step further; after ascertaining the best solvent for each drug, concentrated standard solutions of each would be made, and from these, by addition of spirit or wine, or by mixing one or more together, all our tinctures and wines, simple and compound, could readily be made at a moment's notice, with the certainty that in each case they really possessed all the soluble active principles of the drugs. A chemist in thus preparing his stock preparations with the least amount of spirit, and in a concentrated form, would usually select the time of the year when orange-peel, henbane, conium and all our indigenous plants are in proper season; in many cases he would buy the fresh plants and dry them himself, instead of, as now, using them whenever wanted all the year round, immaterial whether in or out of season. He would find, moreover, that in many of the present preparations he has to commit great waste of material, throwing many ingredients away before they are half exhausted. I cannot help thinking that by possessing such stock liquors containing all the soluble active portions of our drugs in a simple and definite form, the labour of the physician as well as that of the chemist would be facilitated; the one would readily know what he had to prescribe, and the chemist would better know what he really dispensed; tinctures, liquors and wines would become clear indicators of what they really are, a number of old and obsolete compounds would disappear from our shelves and store-rooms, and make place and throw more light on those preparations of importance that remained behind.

BORATE OF LIME IN PERU.*

BY M. THIERCELIN.

Borate of lime is found in the great pampas of Tamarugal, especially upon the western boundary, in the dry bed of a river which once ran from the north-east to the south-west. It is collected by breaking through the saline crust which covers the soil, and digging up the subjacent sand. The mineral then presents itself in nodules of various sizes, but having an average weight of from forty to fifty grams. There are besides myriads of smaller concretions a few millimetres in diameter, which are neglected because of their size. The pieces are rounded and white, with a brown tint derived from the earth. Their fracture is shining and pearly, and presents a lamellar crystallization, which recalls boracic acid. Small prisms with a yellowish reflection reveal the presence of glauberite. The solubility of the entire mass in water is very slight, varying from one to five per cent., according to the proportion of its elements. Acids, on the other hand, especially hydrochloric acid, dissolve it nearly completely in a short time. Dilute acids only partially dissolve it.

By qualitative analysis the author has obtained from it the following: — HO, BO_3, SO_3, CaO, NaO, Cl, SiO_2, Fe. He has not, however, met with potash or ammonia, the presence of which has been stated by some authors to be constant.

The neighbourhood of the volcano of Isluga, about twelve or fifteen leagues to the north-east, explains the origin of the boracic acid; either it was conveyed in the steam which the ordinary winds would drift towards these parts, or else, dissolved in cold water, it was brought down in the river which formerly ran in the now dry bed. It would also be accompanied by sulphurous acid, which would account for the sulphuric acid now found. The numerous masses of easily disintegrated carbonate of lime that are scattered about upon the soil, would necessarily furnish a base to the two acids vomited from the volcano, and borate and sulphate of lime would thus be formed. But in the presence of a large quantity of common salt which is spread over all the neighbouring country, the sulphuric acid has formed a double salt of soda and lime, or glauberite, which is besides found in nearly every part of the province. Boracic acid, on the contrary, not being able to decompose the chloride of sodium in the cold, would remain free from the soda. This in reality proves to be the case upon analysis.

Various analyses show that the salt contains two equivalents of acid,—that it is, therefore, a biborate of lime,—with eight equivalents of water. If this salt were in a pure state in the mineral, it would have the following centesimal composition:—

BO_3	41·18
CaO	16·47
HO	42·35

* From the 'Bull. Soc. Chim.' and 'L'Union Pharmaceutique.'

But this is not the case, and without speaking of silica, iron, etc., there is always a proportion of glauberite present, and sometimes a considerable quantity. Analyses would therefore give a varying proportion of the different elements, according to the quality of the specimen examined. The following are the results of some analyses made by the author:—

	No. 1.	No. 2.	No. 3.
HO	20·15	28·74	28·78
BO_3	16·42	17·67	25·40
SO_3	21·56	17·80	18·00
CaO	15·15	13·29	17·36
NaO	7·75	6·89	6·97
Insoluble (SiO_2)	10·42	8·37	0·14
Alumina and iron	4·31	5·10	,,
NaCl	4·00	1·95	3·57
	99·76	99·81	100·22

The first two represent two commercial specimens, the last some nodules chosen for their purity, and separated from glauberite and earth. It would appear, therefore, if the first two were of average richness, that boracic acid is present in the mineral to the extent of from sixteen to eighteen per cent. The water found over and above the eight equivalents of crystallization must be considered as hygroscopic; its proportions vary considerably.

The proportion of boracic acid in relation to the lime proves clearly that it is a biborate, and as the rest of the lime and soda are required to constitute the glauberite, it is evident that soda is not present in the borate.

According to the formula of biborate of lime ($2\,BO_3CaO$, $8\,HO$), in which the acid represents 41·18 per cent. it might have been expected that all the specimens analysed would contain less acid than was found in the pure salt. It is astonishing to see in published analyses quantities of acid out of all proportion to the composition of the mineral. For instance, in 'Watts's 'Dictionary' analyses are given in which boracic acid figures as 34, 43, 44, 45, 46, and even 49·5 per cent. These must certainly have been analyses where the determination of the acid has been by difference. If the method is easy, it runs the risk of not being very exact.

It must be admitted that the direct analysis of boracic acid is difficult, and that this circumstance has without doubt influenced the processes employed. In order to render his analyses as exact as possible by working directly upon the acid, the author had recourse to the volumetric method.

It has already been stated that dilute hydrochloric acid does not entirely dissolve the mineral; in fact, it leaves all the glauberite intact, and acts only upon the borate. If, therefore, hydrochloric acid, say of fifty per cent. strength, be dropped from a burette into a vessel containing a determined quantity of borate well powdered and suspended in a little water coloured blue with tincture of litmus, after the acid has decomposed all the borate it will remain free and redden the solution. The quantity of hydrochloric acid employed will indicate the quantity of boracic acid displaced, from which the proportion per cent. may be calculated. This easy method gives very exact results, and allows an analysis of borate to be made in less than an hour.

THE FLORA OF THE QUANTOCKS.*

BY W. TUCKWELL.

The geological formation and the historical associations of the Quantock Hills have been abundantly investigated. Their natural productions, animal or vegetable, have not yet, so far as I know, been described or

* Read before the Somerset Archæological and Natural History Society September 12th, 1872, and reprinted from *Nature*.

catalogued, although they contain specimens in both branches of Natural History singularly rare and sought after, and though more than one zoologist or botanist of note gazes on them daily from the windows of his home. A paper whose conditions are that it should be light and popular, and that it should not exceed ten minutes in the delivery, cannot throw much scientific light upon the plants of the most limited region; but it may reveal sources of enjoyment and raise individual enthusiasm, and it may remind this meeting that the time has possibly come, when our association should use the means at its command to encourage the gradual creation of such a flora and fauna of the county as no single naturalist, unassisted by a public body, can in any case trustworthily compile.

In this beautiful valley, fat with the rich red soil that countless millennia have seen washed down from the surrounding hills, the flora is everywhere so unusually rich as to win the envy and delight of strangers. It has been my lot to pilot botanists from all parts of England in search of local rarities; and I have found their chief raptures given not to the uncommon flower they had come to see, but to the profusion of form and colour which includes almost every English genus; manifest in the common turnpike roads which skirt the hills, but revealed in full perfection to those only who penetrate the interior of the range. In the sheltered lanes of the less wooded combes; in the road from Kilve to Parson's farm, the footpath from the Castle of Comfort to Over Stowey, above all in the lane from the Bell inn to Aisholt, the hedge-banks and the wide grass margins of the road are scarcely surpassed in beauty by the mosaic of a Swiss meadow or an Alpine slope. From the beginning to the end of June the colours are blue and yellow; the blue represented by the ground ivy, the germander speedwell, the brooklime, the late bugle and the early self-heal, the narrow-leaved flax, the long spikes of milkwort, and the varieties of the violet; the yellow by the birdsfoot trefoil large and small, the St. John's-wort, golden mugweed, and hop trefoil, the agrimony, the yellow vetchling, and the countless kinds of hawkweed. In the hedges above are the mealtree and guelder rose, the madder, white campion and lady's bedstraw, half hidden by the twining tendrils, white blossoms, and tiny cucumbers of the bryony; while here and there, where the hedge gives way to an old stone pit or deserted quarry, the tall foxglove and the great yellow mullein stand up, harmonious sisters, to fill the gap. By the middle of July the colours shift. The flora of early spring is gone: the milkwort shows its pods, the speedwell its bushy leaves; the yellow still remains; but the blue has given way to pink; to the lovely musk mallow, the horehound, doves' foot, cranesbill, restharrow, painted cup, and calaminth. With August a third change arrives; the small short clustering flowers are gone: instead of them we have the coarse straggling fleabanes, ragworts, and woodsage: the great blue trusses of the tufted vetch and the pure white trumpets of the bindweed take possession of the hedges; the yellow sagittate leaves of the black bryony and the red berries of the mountain ash warn us that summer is past. Our September visit marks the closing scene. The flowers are few and far between; but the ivy bloom is musical with bees, the hazels put forth clusters ruddy brown as those with which the satyr wooed the Faithful Shepherdess; the arum pushes its poisonous scarlet fruit between the mats of dying grass; and the meadows which slope upwards from the brooks are blue with the flowers of the colchicum.

These are all common flowers, whose names and habits, if education did her work, we should learn in childhood from our mother and our nurse: it is their immense profusion, not their rarity, that calls for notice; and they represent but a small part of the hill flora. To exhaust this fairly we must visit four different regions—the hill tops, the bogs, the coppices, and the slopes toward the sea. Of the first it is difficult to speak without a rapturous digression as their familiar sights and sounds occur to us—the breeze that seems half conscious of the joy it brings, the musical hum of the bees, the warble of invisible larks, the popping of the dry furze pods in the stillness, the quivering air above the heather, the startled spiders with their appended egg-bags, the grasshoppers, the green hair streaks, the gem-like tigerbeetles on the wing, in the distance the Mendips and the yellow sea, or the long rich valley, closed by Dunkery and Minehead.

Heath, furze, bracken, and whortle berries, are the four tetrarchs of the hill tops, giving endless shades of red, and green, and yellow. The heaths are three, and only three—the heather, the cross-leaved heath, and the bottle heath, the last exhibiting rarely a white variety, which in the language of flowers tells the tenderest of tales. From beneath their shelter peep the eyebright, the spring potentil, the heath bedstraw, and the creeping St. John's-wort; amidst them springs the uncommon bristly bent grass; everywhere the green paths which wind amongst them are carpeted with the mœnchia and the little breakstone, and bordered by the red and yellow sheep's sorrel and the pale yellow mouse-ear. On many of the prickly furze beds grows the wiry leafless dodder; every ditch is filled with masses of lemon-scented oreopteris, and every patch of stones is hidden by the pink blossoms of the mountain stonecrop. At 800 feet above the sea we meet with mat grass and the cross-leaved heath. Higher still we find the slender deers' hair, first cousin to the isolepis of our greenhouses; and highest of all grow, for those who know their haunt, two species of the stag's horn club moss.

The bogs are very numerous. They form the summits of the combes; and some of them descend the hill until they join a deep cut stream. All are covered with the turquoise bloom of the forget-me-not and the glossy peltate leaves of the marsh pennywort, and choked with the little water-blinks. They all include liverwort with its umbrella-shape fructification, sphagnum, marshwort, and pearlwort; and on their margins grow the ivy-leaved hair-bell, the lesser spearwort, the lousewort, and the bog pimpernel. In a few of them are found the oblong pondweed and the marsh St. John's-wort; in two combes only, as far as I know, grows, alone of its genus, the round-leaved sundew.

Of the coppices, Cockercombe and Seven Wells are the best known; but their large trees check the growth of flowers; and the botanist will find more to please him in Butterfly Combe and Holford Glen, which are smaller and less frequented. Here in early spring masses of the white wild hyacinth rise amidst last year's dead leaves; here grow the cowwheat, woodrush, golden rod, sheep's scabious, wood pimpernel, wild raspberry, sanicle, and twayblade. The helleborine is found in Crowcombe; in Tetton woods the rare pink lily of the valley; in Gothelstone the adders' tongue and mountain speedwell; in Ashleigh Combe, thelypteris; in Aisholt wood the white foxglove, white herb Robert, and white prunella; while under the famous hollies of Alfoxden, sacred to the memory of "Peter Bell" and "We are Seven," grow the graceful millet grass and a rare variety of the bramble.

On the St. Audries slope the changed soil and the influence of the sea give birth to several new plants. The autumn gentian, the tufted centaury, the round-headed garlic, and the sea starwort are abundant near the cliffs; the perfoliate yellow wort is common; fluellen grows in the stubbles, the lady's tresses near the lime-kiln, the sea pimpernel between the stones, the arrow-grass and hard-grass just above the sea, to which we descend between banks covered, as no other banks are covered, by the magnificent large flowered tutsan.

A few rare plants remain, which come under neither of the groups described. The Cornish money-wort abounds in a small, nameless combe near Quantockshead; the rare white stonecrop is indigenous or naturalized at Over Stowey; the white climbing corydalis is found close to Mr. Esdaile's lodge; the lady's mantle.

goldilocks, and bistort grow in the Aisholt meadows; the stinking groundsel hard by the remains of Coleridge's holly-bower. In the same neighbourhood I have twice found the purple broomrape; and Wilson's filmy-fern, one of the rarest of British ferns, is established in the Poet's Glen.

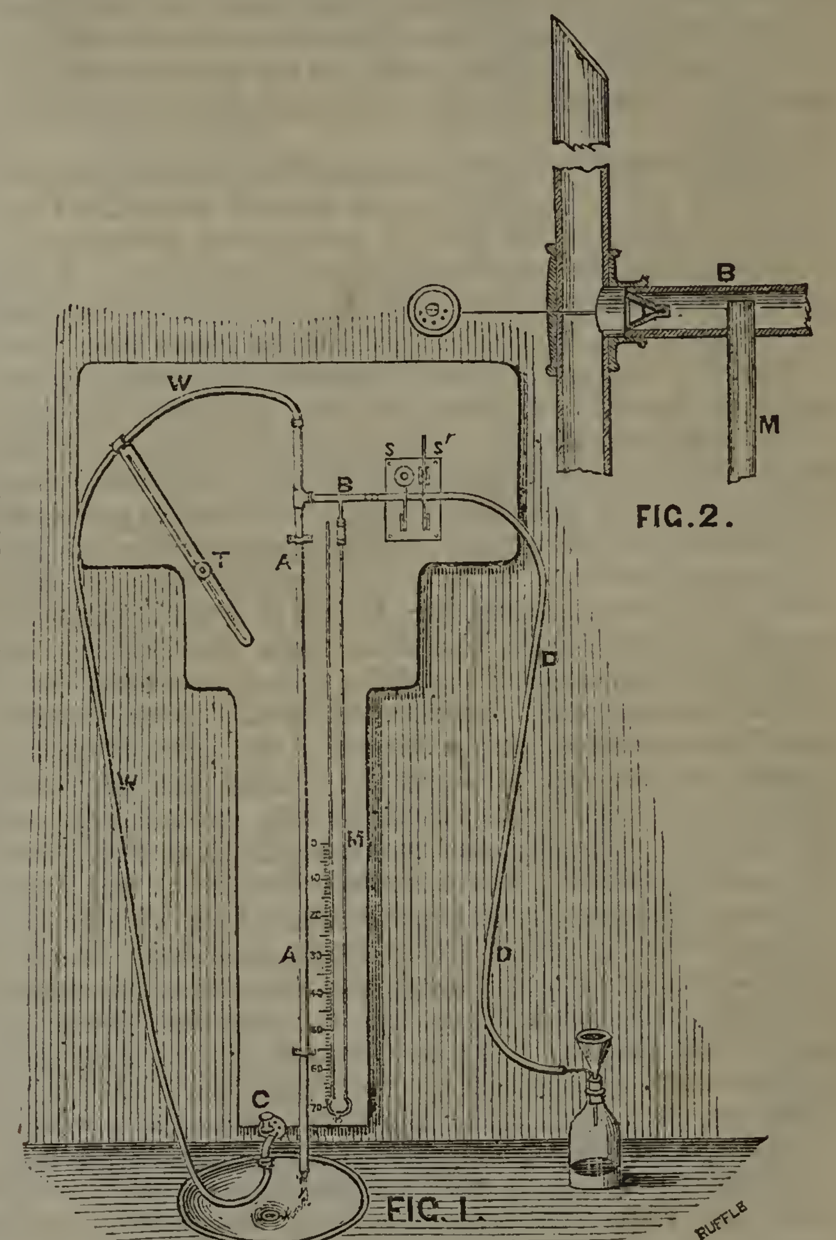
I venture to hope that there is no one present to whom this catalogue of plants is a catalogue and nothing more, Our English wildflowers are so charming in themselves. they awake in all of us so many associations, they hold so large a place in our poetical literature, their popular names reveal so many an etymological secret and recall so many a striking superstition, that almost every one, whatever be the line of his mental culture, is willing to own their interest and to linger over their recital. To the Shakspearian scholar they bring memories of Perdita at the shearing-feast, of Ophelia in her madness, of Imogen sung to her untimely grave, of the grey discrowned head of Lear, with its chaplet of "rank fumiters and furrow-weeds." The lover of Milton points to the "rathe primrose," the eye-purging euphrasy, and the amaranth, which was twined in the crowns of worshipping archangels. The historian of the long-buried past sees in the Cornish money-wort, the filmy-fern, and the Lusitanian butterwort of our hills evidence distinct and graphic of the time when Scotland, Ireland and Spain formed with our own peninsula portions of a single continent. The student of folk-lore tells his tales of the ceremonies which surrounded the vervain, the St. John's-wort, and the rowan, and of the strange beliefs which clung to the celandine, the hawkweed, and the fumitory. The etymologist will elevate the names familiar to us all into records of the origin and habits of our remote forefathers; he will disinter the fragments of myth and history which lie embalmed in the centaury, the pæony, the carline thistle, the flower-de-luce, and the herb Robert; he will tell us how the laburnum closes its petals nightly like a tired labourer, how the campion crowned the champions of the tournament, how the foxglove, the troll-flower, and the pixie-stool, bring messages from fairy land; how the scabious, the lung-wort, the scrophularia, and the wound-wort, bear witness to the grotesque beliefs of a pre-scientific medical community. Of the botanist I need not speak. Not a flower that blows but will furnish him with the text of an eloquent discourse. Forms that yield to other men artistic and sensuous enjoyment only, lay bare before him secrets of structure and of function as wonderful as those which characterize his own bodily frame; suggesting each its truth of design, and natural selection, and adapted change, and mysterious organic force. In the fructification of the orchid, the stamens of the barberry, the hairs of the nettle, the leaf of the sundew, he reads lessons as profound and similes as graceful, as were taught to Chaucer, and Southey, and Wordsworth, by the daisy, and the holly, and the lesser celandine. Year after year he greets the early spring with an enthusiasm which his neighbours know not, as one by one his friends of many years, the snowdrop and the violet, and the crimson hazel stigma, and the stitch-wort, and the daffodil, and the coltsfoot, come back to him like swallows from their winter sojourn out of sight. Year after year, as the seasons die away and the earth is once more bare, he looks back delighted on the pleasant months along which he has walked hand in hand with Nature; for he feels that his intelligence has been strengthened, his temper sweetened, and his love of God increased, by fellowship with her changes, study of her secrets, and reverence for her works.

Persian Saffron.—Dr. Hager reports that he has received under this name some agglutinated cakes having a fatty odour, which contained a few crocus stigmas, but consisted chiefly of narrow yellow petals saturated with a thick oil readily dissolved in ether. He states that it may be easily distinguished from true saffron by its imparting a yellow colour to petroleum ether.

AN IMPROVED FORM OF FILTER PUMP.*

BY T. E. THORPE, F.R.S.E.

In the 'Berichte der Deutschen Chemischen Gesellschaft' (No. 7, 1872), Dr. Mendelejeff is reported to have described a new form of filter-pump devised by M. Jongo, or Moscow, which is so exceedingly simple and efficacious that it will doubtless be universally set up in laboratories. The disposition of the apparatus will be readily understood from the annexed figure,



which represents it in the modified form about to be described. It consists of a tube A A about 1 metre in length and from 8 to 10 millimetres in diameter, to the side of which is affixed a side tube B about 5 centims. in length. The upper end of the vertical tube A is cut slantwise in the manner represented in the enlarged figure (fig. 2), and is connected by means of a strong but sufficiently elastic caoutchouc tube with the stopcock C in connection with the water-supply. In the original apparatus a Bunsen valve was fitted into the side tube; that is, the caoutchouc tube D D was stopped at the upper end with a short piece of glass rod and cut along its length near the end by a smart blow from a chisel. The edges of the slip were thus left sharp; and on applying any outward pressure to the tube they readily adhered, making a perfectly air-tight conjunction. The valve was then pushed within the tube B, which was narrowed at the end so as to retain the caoutchouc tube perfectly air-tight. The other end of the caoutchouc tube D D was connected with the vessel to be evacuated. On allowing the water from the main to flow through the vertical tube, the caoutchouc tube commences to pulsate rapidly as it falls over the upper edge of the tube A, and periodically closes the opening. The Bunsen valve in consequence intermittently opens

* Read before the British Association at Brighton, 1872; reprinted from the 'Philosophical Magazine' for October.

and shuts, and rapid suction is set up; and it is thus easy to obtain a vacuum equivalent to 0·7 metre of mercury. The working of the apparatus is obviously akin to that of the hydraulic ram; so easily and efficaciously does it exhaust, that it will doubtless take the place of the Bunsen filter-pump. It has the great advantage of portability over the older form, since it may be so constructed that it can be transported to any position in the laboratory: it obviates the necessity of a fall of upwards of 30 feet, and therefore requires no alteration in the existing arrangements of pipes and fittings; and, lastly, its cost need not exceed a few shillings.

There are a few disadvantages connected with the use of the caoutchouc valve above described. Owing to the gradual diminution of its elasticity by long-continued working, its efficacy diminishes after a time; it not only then fails to bring about rapid exhaustion, but so soon as the conjunction of its edges ceases to be perfect, it allows the water to flow back into the caoutchouc tube. To obviate these inconveniences another form of valve was devised. A hollow metal cone shaped like a funnel is soldered air-tight into the end of the side tube B (fig. 2). This cone is pierced near its apex with a number of holes, and into it is fitted a piece of unvulcanized sheet caoutchouc shaped like a filter. This is retained in its place by a small screw passing through the sheet caoutchouc and into the apex of the cone. By its elasticity the india-rubber sheet presses firmly against the sides of the cone, and effectually prevents the entrance of air or water from the tube A; but the slightest pressure from within B is sufficient to disturb the adhesion, and to allow of the ready transmission of air through the holes in the cone. This valve is of a more durable and permanent character than the original form, and permits of a more rapid exhaustion. In the modified form of the instrument a manometer M is fixed to B; this allows the degree of exhaustion to be immediately ascertained from the position of the mercury along the graduated scale. The rapidity of the pulsations in the caoutchouc tube W W may be regulated by the moveable arm T, which by means of a screw can be clamped in any desired position. The screw S serves to regulate the rapidity of the exhaustion, or, in cases of simple aspiration, the amount of air passing through the holes in the cone. S' is a clamping arrangement, by which the vacuum within the pump can be maintained without disturbing the screw S if it should be necessary suddenly to disconnect the caoutchouc tube D from the vessel to be exhausted.

This brief account of the slight but serviceable modifications in the original instrument of M. Jongo is made with the object of introducing an exceedingly valuable piece of laboratory apparatus to a more extended notice than it has hitherto met with in this country.

THE AMOUNT OF CAFFEINE CONTAINED IN COFFEE, AND ON ITS PHYSIOLOGICAL ACTION.

BY HERMANN AUBERT.

Although the quantity of caffeine contained in raw coffee is known, no attempt has ever been made to ascertain how much of the alkaloid is contained in a cup of coffee, and it is also uncertain whether the beans should be slightly or strongly roasted, and whether the ground coffee must be boiled to extract its active principles or simple infusion is sufficient. By extracting the coffee with water, either by percolation or decoction, and evaporating to a syrup, which is then treated from five to eight times with chloroform at nearly 60° till all the caffeine has been dissolved out, he obtains a larger quantity than previous experimenters. Raw beans of the yellow Java kind yielded 0·709–0·849 per cent. by this method, while they gave only 0·474 by Garot's method of precipitation with basic lead acetate. When much roasted, coffee loses a certain quantity of caffeine, which sublimes, whereas it loses none by slight roasting. Notwithstanding this, the coffee made in the usual way by percolation from strongly roasted coffee contains rather more caffeine than that made from an equal weight of slightly roasted coffee, as the roasting renders it more easy to extract.

When coffee is prepared in the usual domestic fashion by pouring six to ten times its weight of boiling water three or four times over ground coffee, nearly the whole of the caffeine is extracted, hardly one-fifth of it remaining in the grounds. The quantity of caffeine in a cup of coffee prepared from 16⅔ grams of coffee is about 0·1 to 0·12 gram. A cup of tea prepared in the ordinary way from 5–6 grams of Pekoe tea contains also about 0·1 to 0·12 grams of caffeine. Caffeine acts upon the spinal cord and causes tetanus in doses of 0·005 gram for a frog, injected subcutaneously; for a rabbit, 0·120 gram (injected into the jugular vein); for cats, 0·200, injected in the same way; and the same quantity for dogs. It has a peculiar action on the muscles of frogs, especially when directly applied to them, causing them to become rigid and white, apparently from coagulation of the myosin. It does not exert this action on the muscles of mammalia. The tetanus is removed by artificial respiration, and if this process is kept up for about a quarter of an hour, no recurrence of the tetanus takes place, even though the respiration is then discontinued, showing that the caffeine is quickly eliminated or destroyed in the organism. Occasionally it produces a paralysis of the hind legs in rabbits, but the author is uncertain to what cause this is to be attributed. It quickens the heart and at the same time reduces the blood pressure. This effect he believes to be due to stimulation of the cardiac ganglia, combined with diminution of what he regards as cardiac *tone*, due to paralysis of the nerves passing from these ganglia to the muscular substance.

The action of caffeine does not explain the stimulating and reviving action of coffee.—*Journ. Chem. Society.*

CLOSING OF THE DUBLIN EXHIBITION AND AWARDS OF THE JURIES.

The Dublin Exhibition was closed on the 30th of last month by the Lord Lieutenant and the Countess Spencer by a ceremonial of some hours' duration.

Mr. Lee, the manager, who some time since was connected with the Crystal Palace, London, received at the hands of his Excellency the order of knighthood. This exhibition, although more of a national one than international, has been attended with a considerable amount of success. The real promoters of the undertaking were Sir Arthur and Mr. Cecil Guinness, and it is generally supposed from the success that has attended it that their munificence will not be taxed to any great extent.

It was not originally intended to give medals, but a short time before the close, and at the request of some of the Executive, it was determined to change the original plan. The following will be found to be the awards of the jurors in Section A (natural products, food, raw materials). The awards were only publicly announced on the 1st of December, and in the official list of the awards, there is no intimation given of what the medal is given for. It merely gives the name of the firm to whom the award has been given, but the following list will be found to be correct. The exhibitors are divided into four sections or classes, but as the exhibitors in the three other sections would not interest the readers of the PHARMACEUTICAL JOURNAL, Section A alone is given.

The Jurors in Section A were—

John Adair, Esq.; John Bagot, Esq.; Prof. Barker, College of Surgeons; Prof. Cameron, City analyst; Charles R. C. Tichborne, F.C.S., etc., Apothecaries' Hall of Ireland; Alderman Purdon, etc.

Medals were awarded to—

Andrews and Co., Dublin, for a general collection of food products.

Berger, Spence and Co., Manchester, for alum.

Boileau and Boyd, Dublin, for a general collection of fine chemicals.

Bewley and Draper, Dublin, for mineral and medicinal waters.

Boyd and Alexander, Dublin, for chlorinated lime and manures.

Belfast Cement Company, Belfast, cement.

Colman, J. and J., Norwich, pure mustard and rice starch.

Croft, Thomas, and Co., Cheshire.

Cantrell and Cochrane, Dublin, mineral waters.

Crawford, Alexander, and Son, Belfast, for fine samples of wheat starch prepared as food for sundry purposes.

Cooney, Charles, Dublin, for ball blue and blacking.

Drogheda Manure Company, Drogheda.

Dublin and Wicklow Manure Company.

Eckford, A. L., Dublin, manures.

Fry, J. S., and Son, Bristol, chocolate.

Field, J. C. and J., London, for ozokerite and general collection.

Goulding, W. and H. M., Dublin, manures.

Hayes Brothers, Dublin.

Killaloe Slate Company, Nenagh.

Lewis, Fred., and Co., Dublin, perfumery and soaps.

Mining Company of Ireland, The, Dublin, for general collection, including the chief preparations of lead and silver.

M'Kenzie, T., and Son, Dublin.

Marine Salts Company of Ireland, Dublin, for iodine, and products from kelp.

McMaster, Hodgson and Co., Dublin, for general collection—linseed and rape oils, fluid annatto, Warren's sweet essence of rennet, etc.

Metcalf, Samuel, Dublin.

Ordnance Survey of Ireland, Dublin.

Price's Candle Company, London, glycerine and general collection.

Royal Dublin Society, The, for models of vegetable products.

Richardson Brothers and Co., Belfast, manures.

Rathborne, John C., Dublin, bleached wax, spermaceti and sperm products.

Rimmel, Eugene, per Mr. Griffin, London, perfumes.

Raynbird, Caldecott, and Co., Basingstoke.

Stanford, E. C. C., Dunlocker, iodine, and various patent processes.

Tallerman, London, for Australian preserved meats.

Victoria Slate Company, Dublin.

Certificates of Merit were awarded to—

Bolton, W., and Co, Dublin, whisky.

Burke, John, Dublin.

Green, John, London.

Holt, Norwich and Co., London, for oil soaps.

Hickisson, John, London.

Kelly, John, Graigue, for rice starch.

Moses, Mr. T., Dublin.

Pickering, D., Dublin.

Rumsey, W. S , London, polishing pastes, etc.

Wright, Freeman, Suffolk.

THE INCOME TAX.

On Friday, December 13th, a public meeting was held in the Guildhall of the City of London, under the presidency of the Lord Mayor, to consider the incidence of the Income Tax, and the justice of its final repeal. It was attended by many members of Parliament, and deputations from various parts of the United Kingdom.

Mr. W. M. Massey, M.P., moved the first resolution —"That the Income Tax is inquisitorial in its character, unjust in its operation, and demoralizing to the national character." He said that the tax was almost peculiar to this country, and here it was adopted formerly only in times of great pressure, such as during the latter period of the great revolutionary war, and again in 1842, upon the accession of Sir Robert Peel to office. At that time that minister had to deal with a chronic deficit in the revenue, a million and a half of which was due to the reduction of postage charge, besides having to provide for the great fiscal changes he intended. Even then it was vigorously opposed, and Lord Brougham submitted a series of resolutions to the House of Lords protesting against its adoption as a permanent source of revenue. Those propositions were even more applicable at the present time than they were then. Since that time no Chancellor of the Exchequer had ventured to suggest that this tax was ultimately to be adopted as a permanent part of our fiscal system. On the contrary, each one had pledged himself to the final repeal of the tax. That period of repeal, however, seemed still indefinite, and it was necessary that the tax-payers should express an opinion whether the present time of the prosperity of the revenue was suitable for such abolition. He was not there to advocate the exemption of any class from bearing its share of the burden. If it were necessary that the trading classes should pay two millions in the shape of direct taxation, let that contribution be made; but he maintained that no two millions of taxation was levied in a form more objectionable than that which was levied under Schedule D.

The motion was supported by Sir John Bennett and Mr. C. E. Lewis, M.P., and carried unanimously.

Mr. John Glover moved the second resolution, to the effect that the continued imposition of the Income Tax is contrary to the pledges of Governments of both parties; is a direct breach of faith with the tax-payer, and having been always relied on as an extraordinary tax, ought now to be repealed. This was seconded by Mr. John Jones, a liveryman, and carried unanimously.

A resolution, that with the view of giving effect to the forgoing propositions, the meeting should resolve itself into a National Anti-Income Tax League, was proposed by Mr. Alderman Sydney, supported by Mr. Seaton, of Hull, Sir Charles Dilke, M.P., and Mr. Alderman Hawkes, of Birmingham, and carried unanimously.

Mr. Samuel Morley, M.P., proposed a vote of thanks to the Lord Mayor for his conduct in the chair. The Lord Mayor, in replying, said he felt certain such a meeting would have great effect on the Government, and lead Mr. Lowe to the reconsideration of the question of the Income Tax. At all events, if it, or any portion of it, were to be continued, the course of proceeding adopted within the last few years towards those who paid it should be so amended as to give no offence.

Administration of Metals in Cod-Liver Oil.—According to the *Practitioner*, Herr Godin recommends, in place of the ordinary solutions of the metallic salts, their solution in cod-liver oil by means of benzoic acid. Cod-liver oil can thus be made to take up benzoate of iron and benzoate of mercury. Benzoate of iron is a beautiful orange-coloured salt of stable character, which increases the therapeutic activity of the oil, conceals its unpleasant taste, and renders it more digestible.

Laurel Leaves as a Febrifuge.—M. A. Doran has communicated a note to the French Academy recording the febrifuge and antiperiodic properties of the leaves of *Laurus nobilis*. The green leaves are prepared by drying them at a gentle heat in a closed coffee roaster, to avoid the loss of the volatile constituents, until they become brittle, but without undergoing any alteration. They are then reduced to a fine powder of which one gram, macerated in a glass of cold water for ten or twelve hours, is administered as a dose.

The Pharmaceutical Journal.

SATURDAY, DECEMBER 21, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

WOMEN AS PHARMACISTS.

THE admission of female students to the lectures of the Pharmaceutical Society, and their prospective admission to the laboratory practice, have called forth from the Press a considerable amount of favourable comment, and, as far as we can learn, no adverse criticism in that quarter.

The promoters of this new movement in the pharmaceutical world, and the ladies most directly concerned, may certainly be congratulated upon its cloudless inauguration. For notwithstanding the assertion of the *Pall Mall Gazette*, that "there are no objections worth naming against the sexes being instructed together," when "the subjects treated of are botany, chemistry, and the knowledge of drugs," the newness and singularity of the event, might well have occasioned some slight alarm in this country of grave traditions and precedents. Some are persuaded that such alarm would have been the result more of habit than of thought, and that women would be welcomed as pharmacists by all true devotees of the art; while any pharmaceutic lore they might add to the general stock, would be greeted with all the respect and acclamation it deserved, just as if it had sprung from the industrious brain of the most able masculine pharmacist.

Respecting the article in the *Pall Mall Gazette* upon this subject, above referred to, which has been reproduced in our columns, it may be remarked that it has given occasion for pungent criticism on the part of some of our correspondents. With the memory still green, however, as to former exploits of our contemporary when dealing with technicalities of pharmacy, it is hardly probable that too much importance will be attached by pharmacists to any fresh opinions expressed in the same quarter on analogous subjects. But as a reflex of public opinion upon the policy or justice of the recent decision of the Council, it cannot be denied that the article has considerable interest, especially to a body to whom the public has delegated considerable powers. For the rest, we quite agree that the time has scarcely come when the business can be correctly described as "at once scientific, privileged and profitable;" or as one in which the stock is not perishable, or the profits range from 400 to 600 per cent. Such rosy visions, it is to be feared, must at present remain *in nubibus*; together with a correspondent's dream that we are likely to introduce to his notice "a nice gushing young lady who is anxious to be initiated into the mysteries of our lucrative calling," in order that he might make arrangements for taking her as an apprentice.

By the force of circumstances, "the dispensing of medicines is an occupation in which many women are engaged." This fact justifies the provision of facilities for and incentives to study being made for women who purpose entering into the vocation of pharmacy; and in the interests of the public, as well as of pharmacy, it becomes a necessity that women should have the same opportunities that are enjoyed with so much advantage by men.

Whatever may be the ethical considerations for or against the suitableness of women for occupying the position of pharmacists, the public are the ultimate arbiters of this as of most other important questions. If it be found that educated women pharmacists are incompatible with the requirements of modern Society—a conclusion which we do not anticipate—they will soon withdraw from the scene.

In the meantime, let this interesting social experiment be fairly and equitably tried. Let the conditions as far as possible be the same, without favour and without prejudice, for the students of both sexes, and the result, whatever it may be, will be accepted as decisive and final.

DEPUTATION TO THE LOCAL GOVERNMENT BOARD.

IT is astonishing, and to those uninterested it might be amusing, to observe in the newspaper reports of what took place on this occasion how totally the objects of the deputation have been misrepresented.

The complaint that the Adulteration Act would prevent the appointment of properly qualified chemists was never urged by the deputation, nor were any hardships or grievances affecting chemists and druggists brought before Mr. STANSFELD. There was indeed no occasion for any such steps, inasmuch as the interpretation of the Act by the law officers of the Crown may well be taken as conclusive in upsetting the notion that the mere specification of *medical* knowledge being required of analysts meant that they could only be medical practitioners.

However, the mistaken reports published in the London papers have been sent on to the country, and, in some instances, have been made the opportunity for foolishly abusive comments. It is, therefore, desirable to mention that the object of the deputation from the Pharmaceutical Society was simply to obtain an official enunciation of the principle affirmed in the law-officers' opinion, viz., that the eligibility of any person for the office of analyst was to be determined as a question of fact, and that the possession of competent *medical* as well as chemical and microscopical knowledge was to be determined as a matter of fact without reference to any Registers of medical practitioners, pharmaceutical chemists, chemists and druggists, or the roll of membership of any body of microscopists.

THE TESTING OF MILK.

The question as to the most efficient and convenient method for testing the quality of milk is one that just now is of considerable interest, in consequence of the first operations of the public analyst appointed under the Adulteration Act having resulted in several prosecutions against vendors of that article; another result, by the way, being that the old proverb "tam similem quam lacte lacti est" has been completely upset. It has come under our notice that, notwithstanding the defects of the lactometer are now pretty generally recognized, there is an inclination in some quarters to use it for this purpose. We, therefore, take the opportunity of pointing out that the instrument in question represents exceptionally rich milk and watered milk as of the same quality; and further, that it enables a skilful dealer to pass off milk which has been partially skimmed as if it were unsophisticated. This feat is accomplished by adding to the partially skimmed milk a little water, whereby an article is produced which is of the same specific gravity as fresh milk, and which, at the same time, yields the normal proportion of cream. In fact, neither the lactometer (lactodensimeter, as it is sometimes termed), nor the combined use of that instrument and the creamometer is to be depended upon. The testing of milk has, however, been recently put on a more scientific basis, and we have great pleasure in directing attention to an article on the subject by Mr. Charles Ekin, which appears in another part of this Journal. A valuable suggestion has also been made by Mr. J. F. Brown, of Dover, who titrates the milk-sugar with standard solution of copper. All authorities agree in representing the proportion of lactose in milk as being very constant. We should, therefore, expect good results by this method.

THIRST FOR KNOWLEDGE.

Under the above title a correspondent has forwarded to us the following paragraph, taken from a circular issued by the Council of the Liverpool Chemists' Association:—

"The chemistry class has not been carried on "owing to a sufficient number not having joined. "If six members will join on Thursday, the 19th "inst., at 7 p.m., the class will be commenced."

At the time of going to press we have not been informed whether this modest *desideratum* has been satisfied, but we hope for the best, that there may be no precedent for the obliteration of Liverpool as a centre of pharmaceutical education.

In the meantime it may be remarked that the above quotation has a special interest in its bearing upon the opinions that have been lately expressed respecting the demand for pharmaceutical education, and we fear it is also generally characteristic of the actual case, together with the financial prospects of any attempts to supplement that supply.

THE NEW ADULTERATION ACT.

At the meeting of the City Commission of Sewers, on Tuesday last, the Court proceeded with, but did not complete, the consideration of the reports of the Sanitary Committee, as to the preparations for carrying out the Adulteration of Food Act of last session. With the consent of Dr. Letheby, who has been appointed analyst, it was decided not to fix at present any salary or scale of remuneration for the performance of the duties of that office until there has been better opportunity of estimating their extent. The three inspectors of streets are appointed inspectors under the Act, with an addition of £25 per annum each to their former salary. The following summary of the arrangements with respect to the appointment of public analysts in the metropolis is taken from the *Times* of Wednesday:—

"In St. George's, Hanover Square, and Chelsea, it has been resolved to include the office of analyst in the duties of officer of health. In St. Saviour's it was voluntarily undertaken by the medical officer of health. In Poplar the appointment was offered to the medical officer of health and accepted by him, payment being made for each analysis on a scale. Dr. Bernays, Professor of Chemistry at St. Thomas's Hospital, has been appointed analyst for Camberwell, and he is to be paid by fees the first year; and in Marylebone Dr. Whitmore, the medical officer of health, has been appointed, his salary having been some time since increased, to include a laboratory assistant. In St. James's, Clerkenwell, a salary of £100 has been decided upon; and in St. Luke's, Dr. Pavy, medical officer of health, has been appointed, at a salary of £150. In St. Martin's-in-the-Fields, Hampstead, Holborn, Mile End Old Town, St. Pancras, Bermondsey, and Woolwich, the subject is still under consideration. In Limehouse, Dr. Rogers, medical officer of health, has been appointed; and in St. George's-in-the-East, Dr. Rygate, medical officer; and a similar course has been adopted in Bethnal Green. In Whitechapel, Dr. Liddle, officer of health, has refused to accept the appointment on the ground that the medical officers of health, as a body, are not properly qualified to undertake the duties indicated by the general intentions of the Act. In Lambeth and in St. George's, Southwark, a chemist, Dr. Muter, has been appointed, with the fees only as his remuneration. In Hackney, Dr. Tripe, the medical officer, has declared himself to be not qualified within the meaning of the Act, and the local authorities appear to be disposed to allow the Local Governing Board to exercise the power which they have of themselves nominating an analyst."

In consequence of the occurrence of Christmas day in the forthcoming week, the next number of the Journal will be published on Saturday instead of Friday.

Provincial Transactions.

LEEDS CHEMISTS' ASSOCIATION.

The second meeting of the session was held in the Philosophical Hall, Park Row, Leeds, on Wednesday, December 11th, 1872; the President, Mr. E. Brown, in the chair. R. Parkinson, Esq., Ph.D., delivered a very interesting and instructive lecture on "The Chemistry of a Piece of Coal;" demonstrating by experiments the process of obtaining coal-gas, and likewise referred to the other products, *i.e.* ammonia, ammoniæ carbonas, nitro-benzol, aniline, picric acid, etc. There was a large attendance of members and invited friends, and at the close of the lecture Mr. Reynolds, F.C.S., proposed "That the cordial thanks of the meeting be given to Dr. Parkinson for his interesting lecture;" the resolution was seconded by Mr. E. Yewdall, and carried unanimously.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL ASSOCIATION.

The third general monthly meeting was held on December 11th; Mr. W. V. Radley, President, in the chair.

The meeting, which was well attended, proceeded to the election of three gentlemen as associates, after which a lecture was delivered by T. W. Hime, Esq., M.B., L.R.C.S., etc. etc. (President of the Natural Science Section of the Sheffield Philosophical Society), on the "Sources of Vital Activity."

The lecture, which was listened to with great attention, was of a highly interesting character, and during its delivery elicited frequent applause. At its close a cordial vote of thanks to Dr. Hime was proposed by the President, who, in the course of his remarks, regretted that only a limited number of members of the trade could have the advantage of being there to hear the lecture; he hoped, however, that it might be put into such a form as should enable members generally who had not that advantage to enjoy the next most desirable privilege, viz. that of reading it.

This met with the hearty approval of the meeting, the vote of thanks to Dr. Hime being carried by acclamation.

[We hope to be enabled to publish the lecture in a future number.]

The attention of the meeting was then called to a valuable collection of old engravings, being portraits of past medical celebrities, which had been kindly lent for the inspection of those present by Mr. E. Wilson, Local Secretary of the Pharmaceutical Society.

A vote of thanks to Mr. Wilson for his kindness brought the meeting to a close.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

This society has been devoting itself unremittingly to hard class-work, holding regularly three meetings for study every week. In order to vary the proceedings, a lecture was delivered before the members on Thursday evening, the 12th inst., at their rooms in Halford Street, by John Burton, Esq., entitled "Elementary Structural Botany." The subject was treated with considerable skill, and illustrated by a number of carefully prepared slides, shown under powerful microscopes, including the various forms of cells, their contents, combinations, etc.

At the conclusion of the lecture, on the motion of Mr. S. H. Cadoux, seconded by Mr. W. Thirlby (Hon. Sec.), a cordial vote of thanks was passed to the lecturer for his kindness, which was suitably replied to.

Proceedings of Scientific Societies.

THE MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS, DUBLIN.

Wednesday, April, 24th, 1872.

THE APPLICATION OF GASES AS A MEANS OF DESTROYING CONTAGION.

BY CHARLES A. CAMERON, PH.D., M.D., L.K., and Q.C.P.;
Professor of Hygiene in the Royal College, etc.

It is impossible to discuss in a scientific manner the subject of disinfection without at the same time considering that of the intimate nature of contagion. Enormous quantities of bleaching powder, carbolic acid, and other substances are annually used in these countries as sanitary agents. They are often solely employed for the purposes of preventing putrefaction; but no inconsiderable proportion of the quantities of "disinfectants" used is applied for the purpose of destroying the *materies morbi* of enteric and other fevers, small-pox, cholera, and other zymotic diseases.

During the decomposition of animal and vegetable substances, sulphuretted hydrogen, phosphoretted hydrogen, and other offensively odorous gases, as well as vapours, and probably solid particles, are evolved. The continuous inhalation of these aeriform products of the retrograde metamorphosis of organic bodies may, like intemperance and deficient nutrition, lower the vital powers, and thereby render the animal mechanism less able to resist the influence of small-pox, cholera, and similar maladies when they are epidemic. There is, however, no evidence of a satisfactory nature to prove that the ordinary emanations from decomposing animal or vegetable substances are the cause, *per se*, of any contagious disease.

If, during the decomposition of ordinary animal and vegetable substances, matters were evolved capable of producing fevers and other zymotics, it is difficult to conceive how the population of towns could escape complete extirpation from those diseases.

It is more reasonable to believe that zymotic diseases are each of them produced by the introduction of a specific *virus* or *germ* into the animal economy. It is probable that some zymotics are caused by germs which are incapable of multiplication in the body. Such diseases are not, therefore, contagious in the ordinary sense of that word; that is, they are not propagated by matters which are cast forth from the bodies of the sick. In the valuable Report on Yellow Fever, prepared by Dr. J. C. Nott, and published in the Annual Report of the Board of Health of the City of New York, for 1870–71, very strong evidence is adduced to prove that yellow fever is caused by germs, which are not bred within the body. It is, however, shown that those germs may be transported from place to place in the clothes and baggage of men. Dr. Nott brings forward the most convincing proof that decomposing organic matter does not, *per se*, produce yellow fever; and shows that the germs which cause the malady are devitalized by exposure to a temperature of 32° Fahr.

It is very easy to destroy the unpleasant matters that are given off during the decay of organic bodies. These matters obey the physical law of the diffusion of gases, and spread rapidly and equally throughout the atmosphere. When they are generated in, or enter, a room, they are readily rendered innocuous by admixture with a small proportion of chlorine or sulphurous acid gas. The use of disinfectants is, therefore, to be commended, because they preserve the atmosphere free from malodorous gases and vapours. Some kinds of so-called disinfectants* are also of great

* This term is used in its popular signification, and includes those substances which, like nitrous acid, destroy noxious matters, or which, like carbolic acid, act chiefly as antiseptics.

utility as a means of preventing the putrefactive decomposition of organic substances. These disinfectants are properly termed antiseptics. They do not altogether prevent animal and vegetable matters from decay; but they greatly retard that process, and then decomposition without sensible putrescence only takes place. It is well then to put into our sewers and other places containing effete organic matter such substances as bleaching powder, which destroy the fetid products of too rapid decay, or such compounds as carbolic or chromic acid, which prevent these hurtful products from being formed, except in almost infinitesimal quantities.

The application of disinfectants for the purpose of destroying the actual *contagion* of certain diseases is the most important use to which these substances are applied. And here the question arises—what is the physical nature of contagion? If we have not some clear conception relative to this point, it is evident that our use of disinfectants is merely empirical.

What is it that we try to destroy when we generate chlorine gas in a room which has been tenanted by a small-pox patient? Is it a gas, or a vapour, or an abnormal condition of one or more of the ordinary constituents of the atmosphere? If the cause of the disease lies in an abnormal condition of the atmosphere—in the occurrence of a "pandemic wave" in that fluid, the disinfection of the air of a particular room, would be useless, because, where ordinary ventilation is adopted, the purely gaseous contents of an apartment are wholly renewed many times in an hour. What, therefore, would be the use disinfecting a room if the atmosphere, on entering it, be already tainted! There are many physicians who believe that epidemic diseases are caused by an abnormal condition of the atmosphere; but even those, or at least the majority of them, admit that they may be propagated directly from the sick to the healthy. Who can deny that the matter taken from a small-pox pustule will produce small-pox, if introduced into the blood of a healthy man? It is clear that in this case a palpable agent produces the disease, and the observation of mankind during countless ages has incontrovertibly established the fact that some diseases are communicated from individual to individual. If cholera, small-pox, rinderpest, and other zymotic and epizöotic diseases are caused by abnormal atmospheric conditions, why is it that they speed along the highways of commerce, that they spread most rapidly as the density of population increases, and that they prevail most in those places where least attention is paid to the removal of organic filth? If the amount of carbonic acid in the atmosphere were increased from its normal proportion of 4 parts in 10,000 parts of atmospheric air to 4 parts in 100, serious disease would be the result; but it would afflict all classes alike, and would ravage the country regions equally with the urban districts.

A careful examination of acknowledged facts relative to nearly all the more important epidemic diseases fully justifies the belief that each is produced by the introduction of a *materies morbi*, or germ, or virus, or some palpable substance from the bodies of the sick into those of the healthy; and by that way alone. This view of the mode of propagation of zymotic diseases is, perhaps, most conclusively proved by admitted facts in relation to two contagious diseases—namely, *scabies*, or common itch, and syphilis. Is either of these diseases ever produced by atmospheric causes? Who would be believed if he stated that he caught syphilis from the air? True, we have not isolated the actual poison of syphilis; but we know that an extremely minute quantity of a liquid, containing solid particles, includes this poison; and it is further clearly established that sporadic cases of syphilis do not occur in our time. With respect to common itch, it was proved long ago that the disease was produced by a small insect, and that it was propagated from individual to individual. If all the *acari scabiei* and their *ova* now in existence were destroyed, there would be an end to the itch for ever. Huxley, who is by no means an ultra vitalist, admits that there is no evidence of spontaneous generation occurring in our time.

The itch is a good example for the purpose of illustrating the nature of contagion. The *materies morbi* is easily seen; it is an entity, it possesses reproductive powers, begetting its own kind, and it is never found except in the bodies of higher animals. The non-contagionists must admit that at least in the case of this disease the theory of the contagionists is proved to demonstration, and simply because the virus of the disease is so large as to be almost seen by the unassisted eye.

The weight of evidence and of opinion too, in the case, at least, of epidemiologists, is in favour of the germ theory of zymotic disease, but most important problems relative to the intimate nature of the different contagia and to their co-relation, are still to be determined. In general the contagious matter appears to be excessively minute. Chauveau ('Comptes Rendus,') October 19th, 1868, diluted the liquid taken from the pustules of sheep-pox with 10,000 parts of water, and found that it still retained its power of producing small-pox in the sheep. Vaccine matter from man may be diluted with ten times its weight of water without losing its contagious property to a sensible extent, but if diluted with 500 parts, it becomes perfectly inactive. Hence it is evident that the contagious liquid of sheep-pox is many times more powerful than vaccine, probably because it contains a larger number of the actual particles, or germs that produce disease. These germs have been carefully sought for by such eminent pathologists and microscopists as Béchamp, Estor, Cohn, Nägeli, Hallier, Chauveau, Sanderson, De Barry, Thomé, Klob, Hoppe-Seyler, and Lionel Beale. On the whole, the results of the investigations of these inquirers have not been barren. It is shown that vaccine contains, in suspension, minute quantities of two kinds of solid particles—*leucocytes* (which resemble pus corpuscles), and smaller particles not exceeding the $\frac{1}{20000}$ of an inch in diameter. The leucocytes may be easily separated from the other particles and the serum; and they are found to be perfectly inactive. The vaccine property must, therefore, reside either in the small particles or the clear serum. By means of the diffusion apparatus, Burdon-Sanderson and Chauveau have succeeded in obtaining the serum free from the small particles, but failed to produce vaccinia with it either in man or in the ox. These important and accurately conducted experiments prove that the actual cause of cow-pock, and inferentially of other kinds of small-pox, is a minute solid and insoluble body.

In liquids containing decomposing organic matter we usually find large numbers of minute living beings in a state of great activity. Some are spheroidal, others resemble knotted rods. The former are termed monads: *micrococci*, or *microspores;* the latter are called *bacteria*, *zooglœa*, *vibriones*, *etc.* The micrococci are each about $\frac{1}{20000}$ of an inch in diameter; they move about with great rapidity, and multiply by cell division. When they elongate into roots, they acquire a peculiar vibratory movement, which has led them to be termed vibriones. Béchamp and Sanderson include under the generic name, *mycrozyme*, both the spheroid particles and the rod-like bodies, into which they are developed. No doubt there are numerous varieties of microzymes, but the minuteness of these infusorial animals renders it extremely difficult to discriminate between the different species.

Hallier regards the bacterium, notwithstanding its activity, as a plant. He asserts that the micrococci or their germinal matter exist in all contagious liquids. It is remarkable that Sanderson did not detect either mycrozymes or their germinal matter in ordinary pus, whereas in pyæmic pus he found swarms of these objects.

It has been strongly urged as an argument against the germ theory of disease that it fails to account for epidemics. Why should small-pox die out in Ireland and then suddenly reappear and rage with great violence in many parts during the last twelve months? How is it that cholera periodically invades the west from the east? Why does an epidemic gradually increase in intensity, attain a maximum of virulence, and then gradually die out? It is difficult to answer these questions satisfactorily, because all the factors concerned in the propagation of zymotic disease are not known. The anti-contagionists contend that small-pox and similar diseases are propagated by other means than by emanations from the bodies of persons suffering from the diseases, and they believe that at particular times the condition of the atmosphere and of the constitution of the population are peculiarly favourable to the spread of these maladies.

If it be admitted that small-pox and certain other diseases are sometimes caused by matters thrown off from the sick making an entry into the bodies of healthy persons, then the phenomena of epidemics may be shown to be explicable without abandoning the theory that small-pox and some other diseases are only communicable from individual to individual. We can readily understand that the low forms of life which produce epidemic and epizöotic disease might, under favourable circumstances, multiply to a greater extent than usual. Under such circumstances the chances of their getting into the bodies of animals would be proportionally increased, and a local epidemic would be the result. Intercommunication between the place where the germs were first developed and other places would soon scatter them over areas more or less considerable. During the siege of Paris small-pox germs largely multiplied in that city, because, owing to privation and depressing influences of every kind, the population were rendered peculiarly susceptible to the influence of zymotic diseases. The stock of small-pox germs accumulated in Paris during the siege has since, there is little doubt, been distributed over a large part of Europe.

In some epiphytic diseases we find the analogues of epidemic and epizöotic maladies. The "blights" in the cereals and other plants are caused by the ravages of minute parasitical fungi. A common disease of wheat grain is occasioned by the presence of the fungus *Uredo caries*, the seeds or sporules of which are so minute that, according to Bauer, a single grain of wheat may contain 4,000,000 of them. The fungi which produce the diseases of plants do not originate sporadically, nor are they ever found except as parasites. For years a whole locality may be absolutely or comparatively free from them, when suddenly those pests will appear and destroy whole crops. It is the same with respect to the ravages of plants by insects; suddenly the caterpillars of moths will appear in vast numbers in localities where they had previously been very scarce. A few years ago the extensive plantations at Dunsany Castle, county of Meath, became suddenly the abode of myriads of caterpillars, which speedily stripped the barks and leaves of a large proportion of the trees. On investigating the nature of the caterpillars, it was found that they belonged to a rare species of moth, which had never been observed in the locality before, but which occasionally appeared in large numbers in certain districts in England. Amongst the numerous insects which ravage our gardens and fields, it is interesting to note that in the seeds of wheat there is occasionally found an infusorial animalcule, termed *vibrio tritici*. It is, however, very many times larger than the vibriones above referred to.

Phytologists acknowledge that they cannot account for the sudden appearance of vast numbers of epiphytical fungi and other pests of the higher members of the vegetable kingdom; but their ignorance in that respect in no way detracts from the positive knowledge which they possess relative to these fungi and insects being the actual cause of epiphytical diseases. Unsuitable soils, excessive damp, and other causes predispose certain plants to succumb to the attack of parasites, but the germs must be at hand, for there is absolutely not the slightest evidence to prove that any of these fungi originate spontaneously. No matter how sickly a wheat plant may be, it could not suffer from the blight unless there are fungi to prey upon it.

That which is true of what we may term epidemics amongst plants, also holds good with respect to epidemics amongst animals. We do not as yet certainly know, though we may venture on hypotheses, why the germs of disease long absent from a locality may reappear, and fructify to an extraordinary degree. But our want of information on this point is not the slightest obstacle in the way of our belief in the "germ theory" of zymotic diseases. On the contrary, to abandon this theory would be simply to reject the only reasonable explanation as yet advanced as to the means by which contagion is propagated and maintained. If we give up this theory we lay ourselves open to the charge of being believers in the doctrine of spontaneous generation.

If species of bacteria or similar objects are the contagia of certain diseases, then we can understand why it is that so many persons who are near small-pox and fever patients escape, whilst persons not in contact with the infected catch the disease. The bacteria thrown off from the bodies of the sick are not equally diffused throughout the air as a gas or vapour would be, but, for the most part, are scattered about on the clothes and on other solid surfaces, from which they may be conveyed to great distances without making their entry into the body of any one. Ordinary bacteria are not found floating about in the air: if proper precautions are taken an animal liquid may be exposed for months to the air and yet be found free from bacteria; whilst on the other hand, if the liquid be allowed to comci nto contact with a wine-glass, or a wall, or ordinary water (unless the latter has been heated to a point at which animal life is impossible), it will soon teem with bacteria. Contagion in general is conveyed by means of clothes or other solid substances, and is rarely directly propagated through the air. In the Report on Yellow Fever, by J. C. Nott, which appears in the Report of the Board of Health of the City of New York for the year 1870–71, page 388, that writer says,—

"No evidence, I think, could be more complete to establish the probability of a disease. All facts being opposed to its contagiousness, I can come to but one conclusion, viz., that the germ may be closed up in trunks or boxes, or be shut up in the baggage car of a railroad, transported from one point to another (as from Mobile to Grove Hill and Citronelle), and turned loose to propagate and do its work of destruction. The disease was equally fatal at Citronelle and Spring Hill. Contagionists will doubtless regard this as a case of communication by contagion, but from the facts that I have never seen anybody communicate the disease, where luggage was not taken with the patient, and that the disease generally goes everywhere that steamboats go from our infected ports in epidemic years, I see no other conclusion than the one I have before given, viz., that the germ is carried closed up with baggage, and not generated and communicated by personal contagion."

Dr. Nott believes that the germs of yellow fever are not bred within the bodies of men; but still men carry about these germs in their clothes just in the same way that the nurse from a fever hospital conveys contagion from the sick to the healthy, without herself becoming affected with the disease. My friend, Professor Moore, has favoured me with the following letter, the facts contained in which show how the first cases of zymotics in towns originate:—

"*Wexford Infirmary, March 5th*, 1871.

"My dear Sir,—A railway labourer, from Glasgow, came to Wexford on or about the 30th December, 1870; sickened on the 2nd January, and died of small-pox on the 12th. In the house he died, a case appeared early in February, and in the same locality we had over twenty cases, and in other parts of the town say ten or twelve. I have had two cases in private, modified and mild. We have had five deaths, and no new case repeated since the 24th of February.—Yours faithfully,

"H. H. Boxwell.

"Dr. Moore, King's Professor of Medicine."

There were no cases of small-pox in any of the southern counties of Ireland, in December, 1870; but the disease was epidemic in Glasgow at that time.

(*To be continued.*)

Parliamentary and Law Proceedings.

Charge of Arson against a Chemist and Druggist.

At the Winter Assizes at Lewes, William Henry Funnell, 45, described as a chemist, was indicted on Tuesday last before Mr. Justice Byles for wilfully and feloniously setting fire to his dwelling-house at Brighton, one Thomas Foat and other persons being therein at the time.

The charge was varied in different counts of the indictment, and by one of them he was charged with attempting to set fire to his house under such circumstances as that if the house had taken fire he would have been guilty of felony.

Mr. Merrifield conducted the prosecution; the prisoner was defended by Mr. Willoughby.

The circumstances of this case were of a very extraordinary nature. It appeared that the prisoner occupied a house, No. 13, Charles Street, Brighton, and he used the front room on the ground floor as a chemist's shop, and the back room as a consulting-room, and the upper floors of the house were occupied by a Mr. Foat and his family, who rented them of the prisoner. On the 11th of October the prisoner seemed to have insured his stock in trade as a chemist in the front shop, and his furniture in the back room, with the agent of the Scottish Union Fire Office at Brighton, for £100, and the fire that was the subject of inquiry took place on Monday, the 4th of November. On the previous day, Sunday, the prisoner appeared to have gone to his shop, which was unusual for him, and it was suggested by the prosecution that he was engaged in making preparations for the event which took place on the following day. On the Monday morning he was at his shop about ten o'clock, and he then appeared to have informed Mrs. Foat that he had received a telegram which required him to go away immediately, and he left in a hurried manner, having previously locked up his shop and the door that communicated from the shop with the back room. From this time no one could have had access to the prisoner's premises, and nothing seemed to have occurred until about three o'clock in the afternoon, when the person who lived in the house adjoining the prisoner's observed a peculiar blue flame burning in the partition between the two houses. An alarm was given, and it was at first thought that it was an escape of gas, and a gasfitter named Slatter was sent for, and he broke into the room at the back of the prisoner's shop. He was astonished to find that the flames were proceeding from a hole that had evidently been purposely made in the wooden partition of the room, and the combustion was of such a character that although he poured a considerable quantity of water into the hole, it did not seem to have any effect upon the flames, which appeared, on the contrary, to burn all the more fiercely, and it was evident that the fire was not at all of an ordinary character. He then scraped out the burning material, which appeared to consist of a quantity of lint, sawdust, and paper, and a portion of the lint which was not lighted when he pulled it out burst into a flames when it fell upon the floor, and it was evident that some chemical ingredient had been used to occasion the fire. A portion of the lint was subsequently submitted to Mr. Schweitzer, an analytical chemist at Brighton, for examination, and he ascertained beyond a doubt that it and the paper also had been impregnated with phosphorus, and he succeeded in extracting thirteen grains of pure phosphorus from a portion of the lint. He also explained that a person acquainted with chemistry, and the peculiar qualities of phosphorus, might have so arranged his preparation for the fire that the ignition would not take place for several hours, and that consequently all the arrangements for the fire might have been made by the prisoner at the time he was last seen at the house at ten o'clock, although no discovery took place until five or six hours afterwards. In consequence of the timely discovery it appeared that very little damage was done. In addition to these facts, which appeared to be almost conclusive to show the guilt of the prisoner, evidence was given that the furniture in the back room was not worth more than £5, and that the stock in the shop was also of very trifling value. When the prisoner was apprehended and the warrant charging him with the offence of arson was read to him he made no reply, and he never attempted to give any explanation of the extraordinary facts that were apparent when the discovery was made.

Mr. Willoughby, at the close of the case for the prosecution, submitted that there had not been a sufficient burning of the house to support the first counts of the indictment.

The learned judge, however, said that without deciding that question, it was certainly impossible for him to withdraw the last count, which alleged that the prisoner had set fire to the place under such circumstances as that if the house had taken fire he would have been guilty of felony, from the consideration of the jury.

Mr. Willoughby then addressed them for the defence, and he endeavoured to show that the evidence with regard to chemical matter having been used to occasion the fire was purely theoretical, and that the charge, which was one of a most serious character, rested entirely upon circumstantial evidence, which was not sufficiently cogent to justify them in convicting the prisoner.

Mr. Justice Byles having summed up, the jury, after a short deliberation, found the prisoner guilty of attempting to set fire to the house.

The learned judge said that the prisoner had been found guilty of a very serious offence. He must have known that persons were in the house when he made his arrangements for the fire, and although probably from the hour of the day at which the fire was likely to have broken out, they would not have incurred the same peril that they would have done if it had happened in the night, his crime was a very serious one, and he felt it his duty to sentence him to seven years' penal servitude.

It transpired in court that there had been three other fires in premises occupied by the prisoner, and that there was a suspicion in every case that they had been occasioned by some chemical agency.—*Standard.*

Charge of Fraud against a Herbalist.

At the Hull Police Court, on Saturday, December 14th, Henry Jackson was charged with obtaining money under false pretences. The warrant only charged the prisoner with obtaining £25, but it was stated that the sum really obtained was upwards of £250. The prosecutor was a farmer named John Richardson, residing at Easington, in Holderness. In the month of February, 1871, he was in Hull, and, in passing down Blanket Row, where defendant kept a herbalist's shop, his attention was attracted by a bill displayed in the window setting off the advantages of the "Famous Indian Remedy" as a restorer and establisher of life. At that time he was sickly and suffering from general debility, and, allured by the announcement in the window, he entered the shop and stated his case to the prisoner, who said he would give him a month's trial for two guineas. Any extras he required Richardson was to pay for, but he was to be supplied with medicine in the usual way. From that time Richardson appears to have paid a visit to the prisoner about once a week. The actual offence charged in the warrant was alleged to have been committed in July, when Richardson paid prisoner £25 for a box of medicines. He was shown a number of what were called testimonials from distinguished persons, and was by this means induced to pay £3 10*s*. for a box of medicine, which, it was stated there was evidence to prove, was worth only a few shillings. A bottle, produced, was in the £25 box. It was labelled "for the heart." Prisoner told Richardson he had the heart disease, and gave him the medicine for the disease. He also said his kidneys were diseased, and gave him medicine for them. It was stated that it would be proved that neither of these bottles contained anything that could effect such cures. The prisoner was remanded upon bail until Friday. On the previous day, when the warrant was applied for, it was stated that a great portion of the so-called medicines had been examined, and had been found to consist of water coloured with a magenta dye. In several instances Jackson had posted the arms of the Pharmaceutical Society upon his nostrums. Amongst the articles which he stated possessed such wondrous virtues, and for which he charged almost fabulous prices, were such things as aniseed balls, smokers' bonbons, chocolate creams, etc. In a peculiarly shaped bottle he had placed some diluted muriatic acid, which he represented as being the great restorer of life and for which he charged several guineas. He also sold to Richardson some bottles containing a liquid, which he alleged he had himself extracted from the Temple of God in South America.—*Eastern Morning News*.

Death from Opium.

On Monday morning, December 16, an inquest was held at Scarborough, before Mr. R. Collinson, Borough Coroner, respecting the death of Elizabeth Brown. She resided at the house of a labouring man, named Watson, and had been known to Mr. Meggit, surgeon, as being addicted to taking opium for the last twelve years. On Wednesday night last she complained of headache, when Watson accused her of having taken opium. She made no reply, and was helped upstairs to bed, where she became so ill that at about two o'clock in the morning Mr. Meggit was sent for. His assistant attended immediately, and found the woman suffering from the effects of opium. He administered the usual remedies, and at nine o'clock she was visited by Mr. Meggit, who considered the case hopeless. The remedies were continued, but she died on Friday evening. A small box containing about 25 or 30 grains of extract of opium was found in her bed, and was believed to have fallen from her pocket. Mr. Meggit said that four grains were sufficient to cause death, and he had no doubt that deceased had died from an overdose of the drug. The jury returned a verdict of "Died from the excessive use of opium." Deceased was 51 years of age. — *Sheffield Telegraph*.

The Attempt to Poison by Arsenic.

At the Central Criminal Court on Wednesday, before Mr. Justice Brett, Samuel Hoy, 12, was indicted for attempting to administer a dose of poison to Emily Hoy, with intent to commit murder.

The evidence as to the circumstances under which it was charged that the prisoner attempted to administer a quantity of arsenic to his stepmother, in a cup of tea, was described last week (p. 475).

The jury found the prisoner guilty, and he was sentenced to ten years' penal servitude.

Reviews.

Elementary Treatise on Natural Philosophy. By H. Privat Deschanel: translated and edited by J. D. Everett, M.A., etc., Professor of Natural Philosophy in Queen's College, Belfast. London: Blackie and Son.

Professor Everett has done good service to science by this excellent translation of Deschanel's well-known treatise on Physics. But the work is much more than a mere translation. It has the far higher merit of containing much original matter of considerable value. The amount of these additions may be roughly estimated from the fact that though there is rather more text in a page of the English edition than in a page of the French, yet the former volume contains fifty pages more than the latter. Both editions are before us; we know them each pretty well, and there cannot be a doubt that Professor Everett has very much enhanced, in every way, the value of the original work. Even the woodcuts, which we thought so splendid in the French edition, look far better on the toned paper of the English copy. One or two of the additions made by Professor Everett catch our eye at once. Regarding the cause of capillary phenomena, Deschanel gives an altogether poor and unsatisfactory account, occupying but one page; on the other hand, Everett has dealt with the subject in the light of recent investigation, and devotes eight pages to it. The chapter on the pendulum, too, has eleven pages added to it. An entire chapter is also added to the treatise on sound, and there are some useful additions to the parts on heat and optics.

The additions on the subject of electric potential and electric and magnetic units are extremely valuable, and supply a want long felt by students of physics. For at the present time these terms are constantly used, but are little understood by those who are not electricians, as none of the ordinary text-books explain their meaning. Our readers may therefore be glad to read the following useful remarks on electric potential and electric force, which Professor Everett gives in chap. 39 A:—

"When electrical potential is constant throughout a given space, there is no electrical force in that space; and conversely, if there be an absence of electrical force in a given space, the potential throughout that space must be uniform. These propositions apply to the space within a hollow conductor. They also apply to the whole substance of a solid conductor, and to the whole space enclosed within the outer surface of a hollow conductor. Whenever a conductor is in electrical equilibrium, it has the same potential throughout the whole of its substance, and also through any completely enclosed hollows which it may contain. When a conductor is not in electrical equilibrium, currents set in tending to restore equilibrium; and the direction of such currents is always from places of higher to places of lower potential. In like manner, when a small positively electrified body experiences electrical force tending to move it, the direction of this force is from higher to lower potential. When flow of electricity is compared with flow of heat, potential is the analogue of temperature. Heat flows from places of higher to places of lower temperature.

"The precise direction of the force exerted upon a positively electrified particle (or upon an element of positive electricity) when brought to a place where potential has not a constant value from point to point, is the direction in which potential diminishes most rapidly. A negative electrified particle (or an element of negative electricity) will be urged in the opposite direction, which is the direction in which potential increases most rapidly. We here use the words increase and decrease in the algebraical sense. . . . *Lines of electrical force* are the lines along which resultant electrical force acts. . . . . An analogy is thus suggested between different potentials and different levels. Positive electricity tends to run down from higher to lower potentials, and when it does so run down, there is a loss of potential energy equal to the product of the quantity which runs down, and the difference of potential through which it runs down. When the quantity which runs down is unity, the loss of potential energy is equal to the loss of potential. It is usual to assume, as the zero of potential, the potential of the earth at the place of observation; but this assumption is not rigorously consistent with itself, since the existence of earth currents demonstrates that different potentials may exist at different parts of the earth. Electrical potential is rigorously zero at places infinitely distant from all electricity. An *equipotential* surface is the surface over the whole of which there is the same value of potential." We refrain from quoting any more, as we are afraid that the recurrence of the word potential will by this time have nearly exhausted our reader's patience as well as our printer's type.

Whilst Professor Everett has thus raised the character of the work, we miss, to some extent, the clear and concise language of the French author. There are some parts, too, in which we fear the student is likely to be puzzled or misled. In sect. 97 we are told that capillary phenomena cannot be attributed to the action of the atmosphere, as they take place alike in air and in vacuo. But further on in sect. 97 D we read that two parallel vertical plates are urged together by capillary action, because "the portion of liquid elevated between them is at less than atmospheric pressure, and therefore, is insufficient to resist the atmospheric pressure which is exerted on the outer faces of the plates." The explanation of the charging of the prime conductor by an electric machine is also ambiguous; all that is said on the subject is that the rubbed glass "gives off its electricity through the points to the prime conductor, or, what amounts to the same thing, the conductors give off negative electricity, through the points to the positively electrified glass." We do not think these two statements *do* amount to the same thing; moreover, nothing is said about the inductive influence exerted by the rubbed glass on the points, and which, necessarily, precedes the discharge of the opposite electricity from their extremities. In current electricity there is no description of Grove's battery, and in the explanation given of of Bunsen's no notice is taken of the chemical changes going on in the cell. Surely, also, it is a mistake to say in England that Bunsen's form of voltaic battery is the one chiefly used for class experiments, though it may be true enough on the Continent.

The weakest part of the original work to us appears to be the article on magnetism; though Professor Everett has much improved it, more remains to be done. The whole of the large subject of diamagnetism and magnetocrystallic action are dismissed in a couple of short sections, and there is no mention whatever of diamagnetic polarity. We notice also one or two little inaccuracies and omissions that we are surprised to find have escaped Professor Everett's observation. For example, in sect. 308 an ingenious mode of determining the law of inverse squares as applied to radiant heat, is ascribed to Professor Tyndall, in both the French and English editions, when really it is due to Melloni. It will be found fully described in his famous work 'La Thermochrose.' A reference to Professor Tyndall's 'Heat as a Mode of Motion,' at once shows how the mistake has arisen. There is a very good account of Melloni's experiments in radiant heat, but an extremely poor record of what has been done since. In this respect Atkinson's edition of 'Ganot's Physics' is far superior. In the treatise on sound there are one or two noticeable omissions; we find no reference whatever to sensitive flames, nor to Wheatstone's Kaleidophone, nor to a recent and more perfect form of this same instrument known as the Tonophant, which might well have been described in the paragraph relating to the various modes of producing Lissajous' figures.

These are, however, but slight blemishes in a work of real excellence. Indeed, it is not too much to say that this work may be regarded as the best text-book in Experimental Physics that we possess in the English language. As we write this we cannot but feel that English physicists, and also English draughtsmen, ought to be ashamed of themselves. Why should we have to go to our continental neighbours for physical handbooks, and for cuts to illustrate them? Even in the two or three treatises on Physics written by Englishmen, the illustrations are in nearly every case almost unintelligible. Compare, for example the woodcuts in Balfour Stewart's 'Physics,' or Airy's 'Magnetism,' with the clichés of the exquisite French engravings to be found in the volume before us. How is it that with our South Kensington Schools of Art we cannot get a bit of apparatus decently engraved in England? Illustrations are by no means an unimportant adjunct to scientific text-books. Instrument-makers have to construct many pieces of apparatus solely from what they see figured in a new work. To them, therefore, much depends on this matter. And those who have not access to apparatus, are often misled in their conception of things by the rude unmeaning cuts which are the common offspring of the English wood-engraver.

Science and Commerce: their Influence on our Manufactures. A Series of Statistical Essays and Lectures, describing the Progressive Discoveries of Science, the Advance of British Commerce, and the Conditions of our Principal Manufactures in the Nineteenth Century. By P. L. Simmonds. London: Hardwicke. 1872.

Only a few persons comparatively have any idea of the mass of valuable, yet crude and undigested, information that is locked up in what are popularly known as "blue books." Not many tasks, however, are more repulsive than to have to hunt for it through page after page of consular reports or revenue returns, although many of them contain matter pregnant with interest to the public. Therefore when a book is published by so indefatigable a labourer in the field as Mr. Simmonds, the critic's favour is already bespoken on its behalf. But even a desire to speak well of the work bearing the rather ambitious title placed at the head of this notice, cannot blind us to the fact that, as a whole, it is but a sorry specimen of book-making, and that a considerable proportion of it has little other *raison d'être* than that it consists of lectures delivered by the author before various audiences during the last twenty years.

We say "as a whole," because taken apart there are several essays containing valuable information upon various subjects, which information is made more readily available by an index. That this measure of praise cannot be extended to the whole book is the more regrettable, since the evil that vitiates it was one that was foreseen. In the Preface the author says that his literary and professional engagements have prevented him from rewriting and condensing some of the treatises, but that he has supplemented them, and brought down the statistical and general information to the present time. The result is unfortunate, as, we think, will presently appear.

The book opens with two lectures upon the obligations of science to commerce, and on the vegetable, mineral and animal products entering into commerce, which formed the Travers' course of Lectures at the London Institution in November, 1871. These lectures are based upon information of comparatively a recent date. But the next is a lecture on almost the same subject delivered in 1859, or *twelve years previously*, and the effect of reading this one after the other is sufficiently perplexing. To give a typical instance, after being told on p. 32 that we import annually nearly 21,000,000 rattans, on

p. 101 we are told with a note of exclamation that in 1857 we imported of reeds, canes, and rattans together 12,000,000. The promise to bring down the statistical and general information to the present time is performed in a manner that adds to the confusion. The fresh matter is sometimes placed in the text without a mark, or between brackets, or sometimes as a foot-note. One consequence is, that after meeting with dates as late as 1869, preceding and following 1858, spoken of as "now," the reader is puzzled as to what time the "last eighteen years" "a quarter of a century ago," or "the present moment" represent. Another consequence is that aluminium is spoken of as a new metal which might do for plating purposes. The improvements which in manufacture have so reduced the price of sodium, are referred to as matter of hearsay; potash, we are told, is collected on a large scale *only* in those countries where wood is the principal fuel; in a lecture on the scientific discoveries of the nineteenth century, we are gravely told that England is within ten days of America, and can speak to Continental Europe across the Channel (not a hint of the Atlantic telegraph); and in an article on dyes and colouring stuffs, the aniline dyes and the artificially-prepared alizarin are not mentioned.

In treatises which owe their principal value to statistics, a little padding as a relief might be expected and allowed. It would not be fair, therefore, to criticize too severely such passages, although we had marked one or two specimens of "high falutin" for quotation. But when the padding of various treatises is pitched together without sufficient supervision, there is danger of a disagreement. Thus, although not prepared to concur altogether in the remark, that without colonies and commerce (if such a state of things could now be) England would sink to a petty fourth-rate state—for England made her mark in Europe before she had one or the other—we are disarmed when we find that England's greatness is afterwards attributed in different places to Christianity and the gold discoveries!! In one place the year 2000 is fixed as the probable era when manual labour will cease through the extension of machinery; although in another it is stated that machinery has not in any way diminished the demand for labour.

Again, on p. 89, we read, "There has been obtained from the earth in England in the last quarter of a century more rude stone than, when converted into railway bars, would form an iron girdle round the earth itself." Considering England's share in the iron trade, this statement remains pretty safe, but becomes rather obsolete in the presence of another on p. 137, that the railways in existence measure 642,000 miles (450,000 miles of which are in Europe) and are increasing at the rate of 100,000 miles a year.

To wind up our catalogue of criticisms, we may remark that it is scarcely correct science to say that "carbon exists more abundantly in charcoal than any other fusible substance, and the smoke that goes up from the charcoal forge is carbon in a fluid state;" this is a definition not likely to suffer from plagiarism.

Notwithstanding these serious blemishes, the book is in many respects a useful one, some of the essays containing a quantity of curious information which Mr. P. L. Simmonds is peculiarly well-fitted to deal with. Such are his lectures on "Shells and their Uses," the woollen, silk, iron, and other industries; also that on Nuts, which has already been printed in this Journal, and for which the silver medal of the Society of Arts has been awarded to the author. But had he waited until he had leisure to weed out all repetitions and obsolete matter, and to reduce antiquated statistics to their proper proportions, the book would not have numbered so many pages, but more readers beginning to read it would have persevered to the end, and these who did so would have been spared the vexation of seeing good materials ingeniously spoilt.

Notes and Queries.

*** *In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

[323.]—GLASS LABELLING.—One part of Nelson's gelatine, two parts of acetic acid, digest 24 hours, then boil ten minutes in an enamelled saucepan, kept stirred with a glass rod, answers admirably.—H. J. LUTWYCHE.

Mr. R. W. Watson, of Sheffield, states that glaziers' putty answers the purpose admirably.

[324.]—SYRUPUS CALCIS LACTO-PHOSPHATIS.—*S. W.* having made several unsuccessful attempts to obtain Syrupus Calcis Lacto-Phosphatis, wishes for a good formula and instructions for preparing the same.

[325.]—STEARINE IN BUTTER.—A correspondent wishes for information respecting the detection of stearine when present in butter.

[325]—LYCOPERDIUM GIGANTEUM. — Professor J. Léon Soubeiran has kindly forwarded the following answer to "*L.*," taken from Dr. de Beauvoys:—"The *Lycoperdon giganteum* and some other species are eaten while young. In order to prepare this fungus for use in stupifying bees, it should be compressed while it is yet spongy and before it has become brown and soft, in order that it may be better preserved, but it is not necessary to steep it in solution of nitre or of starch. A small piece is cut off and put into the fumigating vessel and burnt with some well dried chips. A piece the size of a five-franc piece is sufficient to stupify for nearly half an hour."

APPOINTMENT.

Mr. Frederick F. L. Robertson, pharmaceutical chemist has been appointed by the Camberwell Board of Guardians dispenser to the Infirmary in Havil Street, Camberwell.

The Universal Pharmacopœia.

Sir,—Let me express my intense satisfaction with the recent leading article on the Universal Pharmacopœia. I had hoped to have said something on the subject but was under the impression that the proposed work described at a late evening meeting was under the sanction of our authorities. Every Pharmacist of whatever nation would hail the appearance of any new good book of reference which might present in a clear and well-ordered manner the formulæ of the world—but I *do* object to the title Pharmaconomical. No one country can lay down the law of Pharmacy for another. We may endeavour by proper means to suggest, and by persevering labour, to effect assimilation of strengths and uniformity of names—but that is the limit of our power until we can arrange for our convenience the atmosphere in which we breathe and the soil on which we live—till we can arrange moreover hereditary habits and individual constitutions.

Secondly, an editor may print according to his own judgment, formulæ in assorted type, but I totally dispute the right of any one to dictate to me the importance of a particular formula. This is a pure matter of nationality and accidental circumstance. Our British Pharmacopœia is admirable for *us*, but it would be a vain idea to make it binding in the City of Paris. The Codex is excellent for France: in London its authoritative teaching would amount to foolishness—yet both compendiums are consulted with mutual benefit by Dumas and Professor Redwood; by the foreign médecin and the English physician.

A sensible plan for lessening national differences is described in a most lucid manner in your editorial notice—its accomplishment will necessitate time, infinite research and large accommodation amongst learned bodies. Let me add one remark. A splendid work of reference (Hager) is alluded to by yourself. I have no wish to depreciate other manuals, but I may be permitted to direct the attention of dispensing Pharmacists to an Universal Pharmacopœia which without exaggeration I have successfully consulted many hundred times—it is by Jourdan—I have never found it fail. By its employment most of the inquiries now weekly submitted to editorial consideration respecting international information would disappear. Its arrangement, as far as my lights go, is perfect. An English translation by Rennie (edition scarce) would prove an infinite convenience to those thrown in contact with formulæ which to us are foreign. Kindly observe this phrase—the word foreign has no actual, but a relative, meaning—and the word *important* follows the same rule. With these two Pharmacopœias in our possession we may await the publication of the Pharmaconomical Society with Christian placidity and calmness.

Joseph Ince.

Pharmacists as Analysts.

Sir,—I think the best thanks of all pharmacists who wish to see the gulf that exists between our present status and that of a profession bridged over will be given to the deputation that lately waited upon Mr. Stansfeld respecting the appointment of analysts under the Adulteration Act, for their able advocacy of our claims to recognition. It is the first door that has been opened to us, and we ought not, if possible, to allow it to be closed against us with the sentence, "Depart from me, for I know you not." Is it possible that the present shyness of Government is the shadow of that Nemesis which Mr. Giles foretold would come upon us, if we broke faith with it on the Poisons Bill? I think it not improbable that it is so; but be this as it may, it is evident from the tone of some of the observations that some higher standard of attainments in general science is necessary to be taught at our school in Bloomsbury Square before the certificate of that Institution will place the holders of it in a first position as regards public appointments. I am not going to advocate any additional subjects to the Major as compulsory; but I do think, and I hope many others will be of the same opinion, that some other honorary title of a higher standard (but quite voluntary) should be attempted, in which microscopy, some physiology and pathology, entomology, and natural science is included in the curriculum Is it not strange that the business from which has sprung so many of the greatest chemists should be ignored as not possessing any members competent to fill such an office? I believe it would be quite possible at the present time, to select a score of pharmacists from our body as competent or more so than out of the ranks of the medical profession for this special duty.

I care but little for the immediate appointment of any of our body to the office, for it is at present doubtful whether it will be worth holding, but the recognition of our eligibility is all important. It would be a solid reason for a higher standard of scientific teaching.

T. M. Rimmington.

Bradford, December 15th, 1872.

The Working of the Pharmacy Act.

Sir,—I think with your correspondent, Mr. Metcalfe, that the Pharmacy Act has fallen short of what it was intended to be. So far as protection goes, I think it is a perfect failure. For instance, take the small shops whose ignorant proprietors are called "quack doctors." What protection has the qualified chemist from them? Simply next to none at all. They are not allowed to sell any of the poisons mentioned in the schedule, but that does not prevent their selling soda carb., acid. tart., rad. gent., sarsaparilla, and such articles which really constitute the country chemists' business; neither does it prevent their prescribing for any deluded person who is foolish enough to go to them, and of the latter there are plenty. It does not prevent their opening shops and calling them "Botanical Dispensaries," and themselves professors or members of some society which never existed. Neither does it prevent the abominable insults which chemists and druggists are subjected to by quacks who hold forth in our country markets, and at the street corners in our country towns. It is against these ignorant men that protection is needed, not only by chemists but by the public needs.

As to the evasion mentioned by Mr. Metcalfe, I know of a similar case. This sad state of things might, I think, be very easily remedied. In place of allowing certain poisons only to be sold by registered men, I would restrict the sale of all the articles mentioned in the Pharmacopœia to those men who have shown themselves to be fit and proper persons to be entrusted with the sale of such articles. By so doing, the grocers would be prevented, not only from selling cream of tartar, etc., but patents also. To my mind, it is a question whether a grocer or stationer who now sells a bottle of Collis Browne's or Towle's chlorodyne does not commit a breach of the Pharmacy Act, and render himself liable to prosecution.

I hope the matter will receive thorough ventilation through the columns of your Journal.

J. N. M'Neil.

Crewe, December 3rd, 1872.

Sir,—Evasions of the Pharmacy Act are not at all unfrequent, and I quite fail to understand how your correspondent (W. Metcalfe) has in his power the remedy for such cases as are within his own cognizance. I am strongly of opinion, and it is the opinion of chemists generally, that the sale of all medicines intended for internal use shall be in the hands of qualified persons only.

Notwithstanding the fact that many patent medicines act as powerful narcotics, and in not very excessive doses as poisons, it is possible that through the present imperfect state of the law, any person may, by paying the licence fee, sell such articles indiscriminately.

Though we enjoy the very doubtful monopoly of the sale of acid. hydrocy., morphia, belladonna, etc., yet by mixing these drugs, and calling the mixture by some arbitrary name, any grocer or small shopkeeper may purvey the "nostrum" *ad libitum*. Indeed, there is nothing to prevent the sale of morphia itself, pure and simple, providing only that it is called by some mysterious name, and sent out as a "patent."

As regards this (not unimportant) branch of the business, raising the cost of the licence three or four fold might to some extent palliate the evil, but it can only be effectively suppressed by an amendment to the Pharmacy Act as suggested by Mr. Metcalfe.

I shall be glad to see this question taken up by those in "high places," as at present it is evident neither of the objects of the Pharmacy Act are attained, viz.—the protection of the trade and safety of the public.

J. Rymer Young.

Warrington, Dec. 5th, 1872.

The Duties of Local Secretaries.

Sir,—The question has sometimes occurred to me—what are the duties of the local secretaries? Is the title one that is conferred on certain individuals pointing them out as the representatives of the Pharmaceutical Society, but having no functions to perform? With some few exceptions, this does appear to be about the state of the case, judging from the lethargic indifference that reigns over the majority of those holding this important office. But it does occur to me that one of the duties that ought to attach to this office is to see that the integrity of the Register is not infringed by unregistered persons commencing and carrying on business without let or hindrance. If this be permitted without protest, it will not require the powers of a prophet to foretell what will be the consequences. The Pharmacy Act will become a dead letter, and the Council will be laughed at. I, therefore, in the name of right and justice commend this matter to the consideration of the Council.

Justitia.

November 29th, 1872.

Lady Students.

Sir,—The ladies now attending lectures seem by their manifesto to be rather aggrieved that the laboratory is not open to them, and suggest that to admit them would complete the generous initiative already taken by the Council.

I am tempted to ask in the interest of the ladies themselves (broadly), what possible good can arise by their admission; do they hope to obtain employment in first-class pharmacies? If so, I fear ancient usage would compel the proprietors to prefer their male competitors, and surely they have not the hardihood to venture into business on their own account without first gaining that practical knowledge which can only be obtained behind the counter.

This is not a question of gallantry but of expedience, and I maintain it to be inexpedient both to present members and future possible female students. With the new regulations looming in the not far-distant future, containing that most salutary clause requiring three years to be actually passed with a qualified man, I am afraid another difficulty would arise. What master with more than one assistant would care to introduce a fair young maiden of sweet seventeen behind his counter? and if she have to gain her experience where only one is kept, her lot will not be very enviable. In sober earnestness I would recommend her parents or guardians to choose some other sphere for her usefulness. A liberal education she must have had to enable her to pass the Preliminary, and I will assume she is of gentle birth; is such a one fitted to wield a pestle heavy enough to thoroughly incorporate a pill mass weighing 12 oz. or lb j? Would she more easily accommodate herself to a 12-inch drum sieve? And if she possess the strength, would her previous training be at all likely to make her feel happy in her new occupation?

The past shows plainly that the female chemist and druggist never attained any position worth notice in the trade. Would it be different now that examination is compulsory? And, if not, would it not be wiser to close the door of the lecture-room to her, for she who enters there will certainly not leave care behind her, and will, I much fear, be a victim to that hope deferred that maketh the heart sick.

A London Member of nearly 20 Years' Standing.

December 17th, 1872.

The Amended Regulations of the Board of Examiners.

Sir,—I see on looking over the Amended Regulations of the Board of Examiners in your issue of the 7th, that those who present themselves for examination on and after October, 1874, must present a certificate as to having been three years in the employment of a pharmaceutical chemist or a chemist and druggist.

Now, on the north side of the Tweed, I am sorry to say, there are a great number of young men who cannot comply with this regulation, there being so many surgeons keeping open shop for the dispensing of medicines, who, almost without exception, employ apprentices or young men who have not served their whole apprenticeship, or who I may say have forsaken their first love. I regret to think that young men will be drawn into the surgeon's net, I may say, unawares; with this one temptation, viz., that they will receive more remuneration for their services than if they entered a highly respectable chemist's. If it were not for this the surgeons would be unable to procure apprentices. Besides, the surgeons are indifferent as to whether their apprentices pass the necessary examinations or not.

Now, the subject developes itself into this, can a certificate granted by a surgeon be legally accepted by the Board of Examiners in conformity with the amended regulations? My impression is that it cannot be accepted, for section 23 of the Pharmacy Act, 1868, distinctly sets forth that persons registered under the Medical Act shall not be or continue to be registered under this Act. Hoping that some of my fellow-pharmacists with a more able hand may take the subject into consideration and cast more light upon it, I am, etc.,

A. Strachan.

Ellon, N.B., December 14th, 1872.

The Edinburgh Chemists' Assistants' Association.

Sir,—In the end of April last a few formed themselves into a committee for the purpose of having a social gathering of the chemists' assistants and apprentices of this city. Notices were sent out and between eighty and ninety responded to the call. When I mention that this was brought about in less than a week, I think you will agree with me in saying that it betokened a healthy sign on our part for forming a more mutual intimacy than has hitherto existed amongst us.

At this meeting the proceedings throughout the entire evening were marked by the most cordial unanimity of feeling, and when the chairman (who was one of the most active originators of the meeting) in speaking of pharmaceutical education, referred to the cord of friendship amongst us which he was sorry to say, was very "slack," and expressed the hope that this state of matters would soon be remedied by the formation of an association to be called the Edinburgh Chemists' Assistants' Literary or Mutual Improvement Association, an impression seemed to pervade the minds of all that a new era was about to dawn on our hitherto isolated existence.

The suggestion was received with hearty marks of approval, and the most sanguine hopes were entertained of its success.

A meeting was subsequently held for the purpose of framing a code of rules and making such other arrangements as might seem necessary, but, alas! the great block in the path seemed to be, who were to render the contributions in the way of essays, debates, etc. This stumbling-block could not be got over, and the meeting had to be dispersed, resting itself content with the election of a committee who were empowered to use such measures as they thought best towards the putting of the association in working order. The gentlemen forming this committee were the very persons who formed themselves into the committee for getting up the social gathering.

They held several meetings, but the spirit of their zeal seemed to wane, notably that of the worthy chairman who made the suggestion, and a final meeting was held, declaring the scheme an utter failure. Now, Sir, is it not sad to think that with our numbers there is not sufficient talent to carry on the work of a mutual improvement association? Every opportunity is offered to us; I believe, were we to memorialize the North British Branch of the Pharmaceutical Society, they would grant us the use of their new rooms gratis for the purpose of holding our meetings: and what more could we want?

A meeting of that Society was held here recently, and the subject of pharmaceutical education was discussed, but no light was thrown on that perplexed question. I am convinced that the cure lies in the assistants and apprentices setting themselves to with a right good will, and preparing themselves for the respective examinations; I am sure they could have no better assistance than what they would get by connecting themselves with an association, and I hope that this fact will be a new stimulus for our now defunct committee "to try again what they failed in before." *Nil desperandum!* Apologizing for occupying so much space.

AN EDINBURGH ASSISTANT.

Edinburgh, November 26th, 1872.

PHARMACEUTICAL EDUCATION.

Sir,—Having carefully read the various schemes published in our trade journals respecting pharmaceutical education, I think every one, like myself, must have come to the disheartening conclusion, that we are as far off any definite plan as we were at the commencement of the discussion.

It has been proposed that the Pharmaceutical Society should cease to be an educating body; but how will it be possible to get rid of so enormous a surplus as is now accumulating unless it be spent upon educational purposes?

In the discussion which followed Mr. Mackay's paper, read at Edinburgh, a remark fell from Mr. Mackenzie which I think worthy of attention, viz., "That the Society should pay competent men to edit a work of the nature of 'Cassel's Popular Educator.'" Now, having derived great benefit from that periodical myself, I am of the opinion that lessons on chemistry, botany, materia medica, etc., published in the same manner, would be much more beneficial to the country student than lectures in a few large towns, as it would place all on a more equal footing, in which object every system hitherto proposed seems signally to have failed.

I do not wish to enlarge further upon the efficiency of the plan, but simply to bring it forward, so that if thought worthy of discussion, it may be taken up by more competent and experienced persons.

CECIL.

December 3rd, 1872.

[*** We cannot give insertion to this letter without expressing our opinion that such a proceeding as that advocated by its writer would be constituting a high road to "cram."—ED. PHARM. JOURN.]

THE PATENT MEDICINE LICENCE.

Sir,—Will you allow me through the medium of the PHARMACEUTICAL JOURNAL to suggest what I think would be a satisfactory settlement of the patent-medicine licence. Let the wording of the Act be altered from medicines liable to stamp duty, to all medicines and medicinal compounds. I would not take off the stamp duty on patent medicines, but allow that to remain as at present, and let the licence be 20*s*. throughout the country. By adopting this plan, a great benefit would be derived by the trade, and those who have no right to deal in medicines would probably be excluded.

H. G.

DISINFECTANTS AND DISINFECTING.

Sir,—I have been preparing for some time "Disinfecting Sawdust," which, whilst it possesses all the advantages of carbolic acid (of which it contains 20 per cent.), is perfectly harmless and efficient. I cannot claim any credit for the ingenuity of the preparation, as the manipulation is exceedingly simple, but from experiments I find there is a great difference in the absorbent properties of the different woods; and I have taken care to avail myself of the best for the purpose, so that I am now able to produce a very even dust and one of a very absorbent character after it has had the required impregnation of the acid. It has been much used in this neighbourhood during the small-pox epidemic, being adopted by the sanitary committee of Helstone, where it was found that many of the poorer people especially, who objected to the wholesale sprinkling of liquids in their homes, did not object to the use of it.

It is self-evident that such a preparation cannot be swallowed by mistake, cannot corrode metals, furniture, cloth, etc., nor act so injuriously on the valves of water-closets, etc., as either liquid acid or any of the chloride powders or carbolate of lime will do, hence it must be valuable in public institutions, schools, asylums, and in the bed-room and nursery, and for general purposes, for using in stables, dog kennels, bird cages, and a variety of other places where many of the preparations in general use would be positively dangerous.

W. W. MILDREN.

Hayle, Cornwall.

"*Piper.*"—*Nepaul Pepper.*—Mr. G. B. Clarke, of Woburn, has kindly forwarded a specimen of "nepaul pepper," which he believes to be made from a small yellow *Capsicum* similar to one which was brought over by the gardener to the Prince of Wales, and used in this country for table decoration. The specimen sent is very pungent.

Proctor Jones.—The 'American Journal of Pharmacy' is supplied by Messrs. Trübner and Co., Paternoster Row.

W. Y.—The amended Regulations of the Board of Examiners do not come into operation until October, 1874. With respect to the regulations fixing the age of the candidate for the Minor at twenty-one years, we cannot agree either with your opinion or anticipation of its acting injuriously. With regard to your further remarks we remind you that the action of the Council is not regulated by the probability "that every youth of the age of sixteen or seventeen who had passed the Minor would immediately rush into business on his own account," but that it is the business of the executive of the Society to prevent such a possibility.

R. R.—Any person passing the Minor examination becomes thereby entitled to be placed on the Register of Chemists and Druggists, and to commence business as such.

Datura.—No other preparation is required than to roll it up in cigarette form, like an ordinary tobacco leaf. It should be used with great care. See Warin's 'Therapeutics.'

W. J.—Inquiry shall be made and the result communicated in a future number.

J. H. Pumphrey.—(1) It is published privately, and is not for sale. (2) The crystalline character is obtained by submitting the oxide to a high temperature, just under that sufficient to produce decomposition.

Dr. C. Kidd is thanked for his communication, but we think it treats rather too much of the medical aspect of the subject to be suited for our columns.

R. S. (*Gateshead*).—The eligibility of chemists and druggists who were in business before August 1st, 1868, to be members of the Pharmaceutical Society was prescribed by the terms of the Pharmacy Act, 1868. The same Act says (clause xv.) that a person who has passed the Modified examination "shall be eligible to be elected an Associate of the Pharmaceutical Society, and every such person so elected and continuing as such Associate, being in business on his own account, shall have the privilege of attending all meetings of the said Society and of voting thereat, and of otherwise taking part in the proceedings of such meetings, in the same manner as members of the Society.

"*Cuprum*" appears to have omitted putting the question that he wishes to have answered.

"*Juvenis.*"—Dissolve the borax in the elder-flower water, slightly warmed, and add the opium wine.

"*Nil Desperandum.*"—Equations are simply means of representing chemical facts, and without a thorough knowledge of the facts represented, it is impossible to understand the meaning of the corresponding equations. You are recommended to study carefully the introductory chapter in the work referred to.

W. T.—The examination for the Prize of Books is a written one, and is conducted under similar regulations to the Preliminary examination.

C. N.—The fluorescence is a physical character belonging to some substances in the same manner as sweetness is a character of sugar.

"*Incertus.*"—The words "Entered at Stationers' Hall" on the label would probably be held to indicate that you have or claim to have an exclusive right or title to the making or preparing of the article so labelled.

Philip Childs.—We agree with your remark, but think it probable that the article in question was intended to be highly coloured.

"*Linimentum.*"—The best way would be to well mix the liq. plumbi and oil, and gradually add the other ingredients previously mixed together. Even then it is doubtful if a perfect admixture could be maintained.

W. Litchfield.—Your letter and enclosure have been handed to the publishers.

"*Ranunculus.*"—Under the present regulations the Latin examination for the Junior Bell Scholarship is in Cæsar's 'De Bello Gallico;' but under the amended scheme, which comes into operation after the award in 1873, the subject will be the first three books of Virgil's Æneid.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Kay Bros., Atkins, Campbell, Rogers, Parsons, Stables, Simpson, Jenkinson, Wheeler, Mackay, "An Associate."

NOTE ON THE OCCURRENCE OF SILVER IN THE PHARMACOPŒIA PREPARATIONS OF BISMUTH.

BY CHARLES EKIN, F.C.S.

II.

Having found, as lately published in the Journal,* that silver is a frequent adulterant of commercial Bismuth. Subnit., it occurred to me to see if it is also to be found in the Liquor Bismuthi as met with in our Pharmacies. I again procured twelve samples from first-rate London and country houses, and, not to weary you with details, I found that two contained a large amount of silver, one sample a very appreciable trace, and that the remaining nine, so far as silver is concerned, were pure.

On communicating with the makers of the two first samples, I find that they were made strictly B.P., and the makers had not the least suspicion of the presence of silver.

I have also examined three samples of commercial metallic bismuth, two of which contained both silver and copper, and two samples sent out as Bismuthum Purificatum, B.P., both of which also contained silver and one copper as well. The sample of commercial bismuth which contained neither silver nor copper contained lead.

From my recent experience, I am inclined to wonder that only 25 per cent. of the samples examined contained silver. Mr. Umney's statement, in his paper published in the Journal of the 23rd ult., that "perhaps the officinal method is seldom resorted to for the production of the liquor," probably furnishes the explanation why this is so. Still, if we remember that these were all picked samples where we might fairly expect unexceptionable purity, it must be confessed that the bismuth preparations of the Pharmacopœia, as at present met with in commerce, are far from being satisfactory.

It is only just to Mr. Schacht, of Clifton, the inventor of the fluid preparation, to say that the liquor as prepared by him is invariably free not only from silver, but also from copper, antimony, and arsenic, and that in his, prescribers have at all events one preparation that they may at all times depend upon.

* See *ante*, p. 381

COWS' MILK AND THE BEST METHODS OF DETECTING ITS ADULTERATIONS.

BY GEORGE BROWNEN.

The article on milk by Mr. Ekin in the last issue was an able introduction to the subject of milk analysis. It is, however, incomplete, and I am, therefore, led to supplement it with a few remarks from my own experience with London milk. No trustworthy analysis of milk can be performed which leaves the albumenoid nitrogen unestimated. The process of Wanklyn has not only been adapted to the analysis of cows' milk, but an attempt was made only a short time since by the same test to connect certain forms of disease with the poorness of human milk. I have found very little difficulty in using the test myself in examining cows' milk. The estimation of the solid residue of milk is a more difficult operation. Casein and fat are not easily dried unless a known quantity of some inert substance be used to divide the mass; the heat also requires careful regulation to prevent decomposition.

A quick and reliable method of calculating the fat in milk is by means of Vogel's lactoscope—a glass cup the sides of which are parallel, and about ·5 of a centimetre apart—its action depends on the amount of milk required to be added to a known quantity of water to obscure a strong light. A little experience with the instrument soon decides a twofold question, viz., whether cream has been removed or the milk is rich in butter.

Mr. Brown's use of the copper test for glucose is a step in the right direction, as lactin is the most invariable constituent of genuine milk; but his test requires a little modification, as the results with milk are sometimes rather too high. I have adopted successfully the following modifications of Daubrawa's method:—Mix two volumes of alcohol sp. gr. ·833 with one volume of the milk; filter off the coagulated butter and casein; a spirituous solution of milk-sugar is thus obtained; every increase of ·004 above sp. gr. ·905, the sp. gr. of the alcohol and water of the milk indicates about 1 per cent. of milk-sugar. Evaporate the solution to a syrupy consistence, dilute with distilled water, and estimate the sugar by the copper test. An odorous or volatile reducing agent sometimes present in milk is thus got rid of.

The butter on the filter may be separated from the casein by any appropriate solvent and estimated.

Although the microscope cannot be relied on for the determination of fat globules, it is a valuable instrument in cases of diseased milk; misshapen globules, pus-like bodies and bacteria may thus be identified, which elude every other test. I had a sample of this kind of milk a short time since, and I afterwards obtained confirmatory proof that the cow was diseased.

[*** The difficulty referred to has probably in some cases originated in the taking of an unnecessarily large quantity of milk for determinations of solid residue, 30 to 100 grammes having been recommended by Goppelsröder for this determination. When so large a quantity is taken the operation of drying is very tedious and uncertain. If, however, a much smaller quantity of milk (five grammes, for instance) be employed the drying may be very readily accomplished, especially if a shallow platinum vessel be used to contain the milk during the evaporation. There is no necessity for the employment of sand or other porous material, which, indeed, is calculated to introduce error.—ED. PHARM. JOURN.]

THE CHINESE MATERIA MEDICA.

In a recent number* we mentioned the fact that a committee of the French Academy of Medicine had made a report upon a manuscript work by M. Dabry de Thiersant, French consul in China, and Dr. Léon Soubeiran upon this subject. The work is entitled 'Études sur la Matière Médicale des Chinois,' and from the report, which was read by M. Gubler, on November 19th, the following notes are extracted:—

In drawing up the present work, the authors have been able to take advantage of the labours of their predecessors in the same field, such as Tartarinov,

* See *ante*, p. 448.

F. Porter Smith, O. Debeaux, and especially Daniel Hanbury. But an inherent difficulty in the subject has existed in the fact that the medicaments used in China are nearly always in a state of mixture, altered by successive boilings in different liquids, and reduced, if not to powder, at least to such small fragments as to be almost unrecognizable. The investigations of one of the authors upon the spot have, therefore, been of great service.

The subtances of the materia medica are in this work divided into three classes, mineral, animal and vegetable. In looking over the list one is struck that it presents as a whole, and even in many of its details, many of the features of the European materia medica. The present work might almost be taken as one of the old treatises in which a nascent science, not yet confident in itself, has not disdained to adopt the errors of charlatanry and popular superstition.

The belief in the specific action of drugs seems to have strongly influenced medical practice in China, as it did but lately that of Europe. Besides, the Chinese believe, as Europeans did in the middle ages, that the appearance of a substance will give a clue to the services it may render to man, *i.e.*, the doctrine of signatures. Thus the luciole is recommended for affections of the visual organs; a madder (*Rubia mungista*), having a red root, is given for amenorrhœa; *Polygonum tinctorium*, which yields indigo, is reputed efficacious for eruptive fevers; the reniform fruit of the *Kadsura chinensis* is said to possess aphrodisiac properties; while ginseng, with its bifurcated root resembling the legs of a man, is looked upon as restoring virile powers to the sick and aged. Considerations of the same kind are, doubtless, the foundation of the reputation of the *Cordiceps sinensis* as exciting the genital organs; that of the *Bidens parviflora* as infallible in making the nails grow; of the *Vitex incisa* in making the beard grow; and of the *Apocynum juventus* as a rejuvenescent. These are strange illusions, but they merit indulgence from those whose ancestors administered the lungwort to cure phthisis, the gromwell to cure the gravel, and the carrot for the jaundice.

In other points the Chinese show more scientific tendencies. For instance, the astringent substances of the materia medica, whether vegetable (oak galls and Chinese galls, etc.) or mineral (alum, acetate and sulphate of iron, salts of lead, silver etc.), are used like the bitters as tonics and febrifuges (*Salix babylonica, Populus tremula, Dichroa febrifuga*), to arrest perspiration, for atonic diarrhœa and spermatorrhœa. The aromatics, essential oils, and balsams, obtained from the Labiatæ, Umbelliferæ, Compositæ, Myristicaceæ and Styracaceæ, garlic, santal, *Daphniduim cubeba*, etc., are used as diffusible stimulants, febrifuges, antispasmodics, and remedies for catarrhs; wormwood and saffron are considered emmenagogues, and the abortive power of the ergots of rice and maize is well known. Mercurial preparations have been employed from time immemorial in Chinese medicine for syphilis; arsenic for strumous and herpetic affections and certain intermittent fevers; iron as a blood restorer. Borax is prescibed for aphthæ; nitrate of soda as a diuretic; carbonate of lime as an absorbent, and an oleo-calcareous liniment for burns. Ancient writers recommended the ashes of sea-weed in cases of goitre. Other substances used by them as by Europeans are sulphur, acetate of copper, castor oil, gamboge, aloes, rhubarb, aconite, veratrum, colchicum, camphor, musk and opium. They have sternutatories, sialagogues and anthelmintics analogous to ours. Further, they pretend to possess a number of substances capable of preventing drunkenness (*Betonica officinalis, Hovenia dulcis, Chrysanthemum album*, nutmeg and borax), and others exercising an influence upon the lactic secretion, either by suspending it (sprouted barley) or increasing it (*Silene? Alisma plantago*).

One thing is very remarkable, that surgical anæsthesia, general and local, has long been used in China. The great surgeon, Houa-To, who advocated hydropathy, used a species of *Atropa* described in the 'Pun-Tsaou,' which produced an insensibility sufficient to permit him to perform important operations upon the abdomen. The *Datura alba* has similar properties. Besides these, the *Azalea procumbens*, which they often associate with andromeda and henbane as a narcotic, produces, when mixed with powdered aconite root, a local anæsthesia which is utilized for small operations.

Chinese medical men have recognized that there is an antagonism between certain substances; that they are incompatible in the same formula, and that they may be used reciprocally as antidotes. Thus, it is recommended to avoid the association of ta-ky (a species of *Carduus*) with *Glycyrrhiza, Chamædaphne* and *Helminthocorton*; wasp stings, and the bites of scorpions, and even of venomous serpents, are recommended to be treated by the *Bidens parviflora*; *Nelumbo* is to be administered to those poisoned by crabs, and the toxic effects of fungi averted by alum or the root of *Cichorium*, and those of aconite by *Libanotis*. An efficacious antidote to arsenic is said to exist in the *Phaseolus angulatus*, which would lead to the supposition that this species, belonging to a harmless genus, possesses exceptionally a pharmaco-dynamic activity comparable to that of the Calabar bean, and superior to that of another Leguminous plant, the *Cytisus Laburnum*, the toxic properties of which are perhaps analogous to those of the exotic *Phaseolus*.

Some of the observations of the Chinese show considerable sagacity, such as the favourable effects of sprouted barley in digestive disorders, the dispersive action exercised by nitre and sal ammoniac upon opacities of the cornea; the immunity from goitre enjoyed by persons drinking water preserved in leaden vessels, a circumstance which appears to point to the preparations of lead as preventitive of that disease. Moreover, some of the substances vaunted as remedies in the East probably deserve testing by experiment and clinical observation. Such are the *Anemarrhena asphodeloides* employed for the same purposes as squills; the *Pardanthus chinensis*, to which is attributed various and remarkable properties; the *Pupalia geniculata*, the acrid root of which is a sialogogue, and employed in cases of rheumatism, etc.; the *Passerina Chamædaphne*, a tincture of which is employed as a cordial, tonic and febrifuge; the *Rehmannia chinensis*, useful in general debility; the *Dimorephanthus edulis*, frequently prescribed for loss of blood, heart disease, etc.; the *Gynocardia odorata*, the seeds of which are extolled for skin disease and syphilis; and among the febrifuges, the *Tournefortia argusina*, the *Trichosanthes dioica*, and especially the *Dichroa febrifuga*, the reputation of which is great in Cochin China, and which doubtless has more claims than the others to be looked upon as a substitute for cinchona.

THE SULPHUROUS IMPURITY IN COAL GAS.*

BY A. VERNON HARCOURT, ESQ., F.R.S., SEC. CHEM. SOC.

The luminous flames we use to light our houses after sunset are all equally gas flames.

The gas which burns round the wick of a candle is formed by the action of heat on the grease of which the candle is made. The gas which burns over the wick of an oil lamp is formed by the action of heat on the oil. The gas which burns over a "gas-burner" is formed by the action of heat on coal.

By the heating of any of these substances many different kinds of gas are produced, some of which become liquids if they are allowed to cool, while others are permanently gaseous. In the case of candles and lamps, when the hot gas is burnt as fast as it is made, the uncondensable and the condensable are burnt alike, the latter contributing even more than the former to the luminosity of the flame. In the case of coal gas, which is kept for many hours, and has often to travel along many miles of iron piping before it is burnt, only very little condensable gas reaches the burner. In this respect "gas" illumination is at a great disadvantage as compared with candles or lamps. To counterbalance this disadvantage gas must be produced from some substance which is much cheaper than grease or oil, and such a substance we have in coal. But coal, like all minerals obtained on the large scale, is mixed with small quantities of other substances, and, in particular, masses of coal always contain a greater or less proportion of a mineral known, according to its form, as pyrites or marcasite, composed of eight parts of sulphur united with seven of iron. When coal is heated, a part of the sulphur from this mineral unites with the carbon and hydrogen of the coal, and thus the illuminating gas formed from coal is contaminated with at least two sulphur compounds—carbon bisulphide and hydrogen sulphide. Such gas yields when it is burnt, in addition to water and carbon dioxide, sulphur dioxide produced by the burning of the sulphur. This gas has a well-known pungent smell; it acts on various colouring matters, and it is gradually changed in presence of air and moisture into a far more destructive substance called hydrogen sulphate or oil of vitriol. Unlike sulphur dioxide, which is a gas and can be removed by ventilation, hydrogen sulphate is not volatile, and exercises a continued corrosive action upon organic materials or fabrics on which it is deposited. In a furnished room the leather bindings of books and coverings of furniture are especially liable to be injured thus; perhaps because this material, being a better conductor of heat than others which are used for the same purposes, is more bedewed after gas has been lighted in a room than they are, and also because it requires less often to be cleaned or renewed. Fortunately the conversion of sulphur dioxide into hydrogen sulphate takes place so slowly that in a room lighted with gas and well ventilated a very small part of the sulphur which gas is liable to contain remains in this destructive form. Fortunately, also, the quantity of sulphur which gas as at present manufactured is liable to contain is very small. In a room lighted with four gas-burners the volume of sulphur dioxide mixed with the atmosphere of the room in the course of an hour is about one-hundredth of a cubic foot. The amount actually present at any moment, if the room is fairly ventilated, is a small fraction of this volume. Nevertheless, it is possible, and even probable, that some injury, especially to the bindings of books, may in the course of years be caused under these circumstances; and it is desirable, with a view to avoiding any such injury, and also with a view to allaying the apprehension of it, that the proportion of sulphur compounds in coal gas should be reduced as far as possible.

A ton of coal may contain about 30 lb. of sulphur: it yields nearly 10,000 cubic feet of gas, and a considerable part of the sulphur contained in it is given off with the gas in combination with either carbon or hydrogen. Of these two elements, hydrogen claims by far the larger proportion, not less than ten parts for one that is united with carbon. For the purification of gas from hydrogen sulphide, excellent methods are everywhere in use. The gas is passed through layers of slaked lime or of iron oxide, by either of which substances all the hydrogen sulphide is capable of being completely absorbed. But the smaller quantity of sulphur existing in the form of carbon bisulphide is not arrested by these agents, nor is there at present any material or process known by which it can be effectually removed.

When coal gas which is pure from hydrogen sulphide is heated and tested again, it is found to contain this impurity, showing that some ingredients of the gas are capable of producing hydrogen sulphide by their mutual action. Hydrogen seems to have a much stronger affinity for sulphur than carbon has. One consequence of this difference is the unequal partition of the sulphur between the two elements in the gas retort. But this inequality does not reach its limit in the short time which elapses between the formation and cooling down of the gas; and accordingly, when foul gas (or gas which has not been purified from hydrogen sulphide) is further heated, the proportion of hydrogen sulphide in it is increased, and that of carbon bisulphide diminished. From a number of experiments in which foul gas was passed through an iron tube three inches in diameter, filled with iron turnings and heated for a length of about two feet to low redness, it appeared that the amount of carbon bisulphide could be so far reduced that the gas, after purification from hydrogen sulphide, contained five or six instead of thirty grains of sulphur in 100 cubic feet. The gas was driven through the heated tube at a rate of from one to two cubic feet a minute.

A somewhat greater reduction in the amount of sulphur is obtained by heating the gas after, instead of before, purification and purifying it a second time. If it is the case, as seems probable, that the sulphur present in coal gas distributes itself when the gas is heated between the carbon and hydrogen in a ratio dependent upon the relative affinity for sulphur of the two elements, the proportion of carbon bisulphide to the total sulphur in the gas will be always the same when the composition of the gas is the same, and when it has been heated long enough for the establishment of an equilibrium. Accordingly we should expect the removal of sulphur, by the conversion of carbon bisulphide into hydrogen sulphide and the absorption of the latter, to be accomplished more effectually with gas from which the chief part of the sulphur had already been extracted. And this, as has already been stated, is found to be the case.

The nature of the chemical change which takes place when coal gas is heated may be illustrated by passing hydrogen over the mouth of the tube containing carbon bisulphide, and thence through a piece of combustion tubing heated nearly to a red heat. The mixture of hydrogen and carbon bisulphide vapour has no action on a solution of lead acetate; but, after the application of heat, the gas which issues produces at once a black precipitate, proving that hydrogen sulphide has been formed. This change occurs readily with hydrogen which has been carefully dried; but the presence of moisture appears to promote it; and as coal gas contains a quantity of aqueous vapour, much more than sufficient to react with the maximum amount of carbon bisulphide, it is possible that the formation of hydrogen sulphide when coal gas is heated, may be partly due to the intervention of moisture.

If clean iron nails are heated to redness in a glass tube, and coal gas is passed slowly over them, a soft

* Paper read at the Royal Institution, Friday, April 19th, 1872.

black carbonaceous deposit is formed, and the gas is deprived of a part of its carbon. If, however, the gas be passed through more rapidly, no such deposition takes place, although the time of contact of the gas with the heated surface is still sufficient to effect the conversion of the carbon bisulphide into hydrogen sulphide. In the latter case it may be presumed that no change occurs in the illuminating power of the gas. But to establish a point which is of capital importance, some direct observations were made on the illuminating power of gas thus treated. It was found with gas passing at the rate of 5 cubic feet an hour through a half-inch iron tube, heated for a length of twelve inches, that, when the heat did not exceed low redness, no change was observable. When the heat was raised to bright redness, there was a perceptible increase in the illuminating power.

If the process of heating coal gas, in order to remove the sulphur contained in it, should be employed on the manufacturing scale, the rate of transmission of the gas through the heating apparatus would necessarily be such as to render any deposition of carbon very unlikely. But even where such deposition takes place, it is not necessarily accompanied by a diminution of the illuminating power.

An interesting experiment, from this point of view, is the decomposition of marsh gas by the electric spark. When a stream of sparks from a Ruhmkorff coil is transmitted between the ends of platinum wires through a small quantity of marsh gas enclosed in a glass tube over mercury, the gas gradually expands. In about ten minutes it is nearly doubled, and at the same time a black deposit appears on the tube, in the neighbourhood of the wires. Here the intense heat applied has effected an almost complete decomposition of the hydrocarbon into its elements. But at the same time there is found a small quantity of some more condensed hydrocarbon, probably acetylene. On expelling the gas through a jet attached to the upper end of the tube, and burning it, the flame is seen to be much more luminous than that of marsh gas itself. The fact of which this experiment gives a striking illustration is that the illuminating power of gas depends much more upon the nature of the hydrocarbons it contains, than upon the total amount of carbon. How great would be the gain to the manufacturers of coal gas, if such an operation as this were possible on the large scale, by which the volume of gas is doubled and its illuminating power, at the same time, greatly increased!

As far as chemistry is concerned, the simple operation of heating gas appears to offer the means of a sufficiently perfect purification. The construction of a suitable system of iron pipes for heating the gas, and the best mode of obtaining and applying heat, is a problem for the engineer. On the scale on which gas is manufactured, all the apparatus for dealing with it must be of a magnitude to which it is difficult to pass, even in imagination, from the small scale of laboratory experiments; but, otherwise, the problem does not appear to be one of any peculiar difficulty. It may perhaps be found possible to employ some of the waste heat of the retort-house for this purpose, and thus to effect the required purification without much increasing the consumption of fuel.

RESEARCHES UPON SANTONIN.*

BY M. L. DE SAINT-MARTIN.

Santonin is the active principle of *Semen contra*, and has been prepared for some years past, upon a large scale, for therapeutic use. The reactions of this principle have, however, as yet been little studied. It remained outside any methodic classification until Berthelot, in his *Traité Elémentaire de Chimie Organique*, included it in the grand class of organic compounds which in 1860 he instituted under the name of phenols. The author, therefore, undertook an investigation in order to ascertain its chemical relations. The investigation included its reactions with reducing, oxidizing and decomposing agents; but the present paper only deals with some reducing experiments.

If santonin be really a phenol, its formula $C_{15}H_{18}O_3$ indicates that it should be possible by its methodical reduction to obtain—

(1) A diatomic phenol ($C_{15}H_{18}O_2$);
(2) A monatomic phenol ($C_{15}H_{18}O$);
(3) A carbide of hydrogen ($C_{15}H_{18}$).

This last carbide would present the composition of a homologue of naphthalin, isomeric or identical with amylnaphthalin.

The author has succeeded in obtaining the monatomic phenol ($C_{15}H_{18}O$); and he hopes to obtain shortly the other terms of the series.

The monatomic phenol, to which compound the author has given the name of santonol, was obtained by introducing into a long green glass tube, between two plugs of asbestos, a mixture of one part of santonin and four parts of zinc in powder, and heating it over a gas stove, in a current of hydrogen. A thick yellowish-brown liquid condensed in the cool parts of the tube, which after a few days, was full of crystals. This crude product was neutral to litmus, insoluble in water, very soluble in alcohol and ether; treated with solution of potash in suitable proportions it dissolved completely. An excess of potash separated, under an oily form, potassic santonalate. This compound, or an analogous body very rich in potash, was also precipitated as an oily liquid when the original solution was diluted with pure water. Treated with an acid it reproduced santonol. These properties, and various others undescribed, show that the product was constituted by a body analogous to the phenols.

But the crude product of the reaction was not a pure substance. In fact, the crystals and the mother-liquor presented a different composition. The first answered nearly to the theoretical formula $C_{15}H_{18}O$, while the mother-liquor contained much less carbon, perhaps because of the presence of the compound $C_{15}H_{18}O_2$, intermediate between santonol and santonin. The crude product was therefore redistilled, which operation was effected without difficulty at about the boiling-point of mercury. The distilled liquid still separated into two portions, the one crystallized, and the other liquid; these were analysed separately, and found to be isomeric.

The crystallized santonol had the appearance of the stearin which separates in the fatty bodies. After being purified as much as possible by pressure, it acquires a tolerable degree of hardness. Its fusing-point was about 135° C. It was insoluble in water, very soluble in alcohol and ether. Sulphuric acid formed with it a compound sulpho-acid, of which the salt of baryta was soluble. Analysis gave—

	Found. I.	Found. II.	Calculated.
C	83·9	83·8	84·1
H.	8·8	8·9	8·4
O (difference) .	7·3	7·3	7·5
	100·0	100·0	100·0

The liquid santonol was a very unstable substance, which turned brown under the influence of the air. Like its solid isomer, it was insoluble in water and very soluble in alcohol and ether. Its properties are

* Memoir read before the Académie des Sciences, Nov. 11th, 1872 (Comptes Rendus, lxxv. 1190).

difficult to define individually, because it was evidently saturated with solid santonol. Analysis gave—

The author is continuing his investigation of this body, and of the other derivatives of santonin.

GALVANIC BATTERIES.*

BY THE REV. H. HIGHTON, M.A.

I shall not attempt to give any ultimate explanation of the phenomena of galvanism. It appears to me that it is true wisdom in science not to attempt to do more than to give an intelligent and comprehensive classification of the phenomena themselves. Deeper theories may sometimes be useful in suggesting experiments, if it be borne in mind that those theories must always be doubtful, and mere matters of guess, and, at best, simply provisionary. Thus Maxwell has shown that the laws of hydraulics may be applied to electrical currents, though he cautiously and wisely guards us against supposing that it follows from this that there is any real electric fluid similar to ordinary fluids. It would have been well if other well-known scientific men had been content to follow his example. In the same way I should object to the assumption of any ultimate theory of galvanism, beyond the mere intelligent and classified expression of the laws of the phenomena.

In the kindred subject of heat, I think great injury has been done by asserting that it is "a mode of motion," which has introduced many wild and visionary ideas. If the word "motion" be meant simply as a translation of the Greek word κίνησις, which includes nearly all kinds of change, and it also be meant that a change of temperature is a mode of motion in the ordinary English sense of the word, the assertion is, in a certain sense, true, but deceptive; if it be meant that simple heat, without change of temperature, is motion of any kind, this is not only extremely doubtful, but, I believe, absolutely untrue.† With regard to galvanism, then, I would merely say that it would appear that wherever there is a chemical there is also a galvanic action, which only requires proper arrangements to be made for exhibiting it.

Perhaps the simplest method of producing a galvanic current is by the formation or decomposition of water. Thus, if we have two plates of platinum, the surface of one of which is covered with a film of hydrogen, and the other with oxygen, on making a metallic connection between the two, a galvanic current passes, and the hydrogen and oxygen unite and form water. Conversely, if we take two metals, one of which has a greater affinity for oxygen than the other, and place them in water, then, on metallically connecting them, the water is separated into oxygen and hydrogen, the oxygen uniting with the more oxidizable metal, and the hydrogen being evolved on the surface of the other metal, and a galvanic current flows. I will show you both these actions by actual experiment. In both cases one pole of the battery is said to become positive and the other negative, and the action passing between the two is commonly called a galvanic current.

Take, again, the simplest of all forms of a galvanic battery—zinc and carbon, with a dialyte, as it is called, of dilute sulphuric acid between them; the oxygen of the water unites with the zinc, and forms oxide of zinc; the sulphuric acid unites with the oxide, and forms a sulphate of zinc, and the hydrogen is evolved on the surface of the carbon. This double chemical action gives rather more electricity than the single action, as you see.

Now, it is a well-known fact that chemical combinations frequently produce heat, and it is also a well-known fact that an electrical current in passing through a homogeneous conductor also produces heat; and it is an exceedingly interesting problem to ascertain what relation the heat of the chemical combination bears to the heat produced in the conductor of the current. An investigation of this kind requires the most delicate and expensive apparatus, much more delicate and expensive than I possess; but in searching into the records of the most trustworthy experimenters on this point, and comparing the results obtained by them, I have arrived at the following conclusions:—

1. That, in all cases of galvanic action, the heat evolved in the battery, plus that in the exterior circuit, is exactly equal to the heat produced by the chemical action.

2. That, in most cases, a certain portion of that heat is retained exclusively in the battery, besides what is due to the internal resistance of the battery, and is not transmitted through the circuit.

3. That the potential of the battery varies, not only with the total chemical heat produced, but also with the proportion which that part of the heat which is transmitted through the circuit bears to the total chemical heat produced by the action of the elements of the battery. Indeed, the potential of a battery is exactly proportional to the amount of heat transmitted through the circuit by each unit of the atomic weight of the metal or other substance consumed or chemically changed. Thus, if we take two batteries, one of zinc, sulphuric acid and carbon, and another of zinc, sulphuric acid and copper, the heat evolved by the sulphoxidation of the zinc is the same in both cases; but the potential of the former, and consequently the heat evolved in the circuit, is greater;—what becomes of the difference? Is the heat in some mysterious way lost? No; the surplus heat is not evolved in the circuit at all, but remains in the liquid of the battery, useless for the production of electricity. Now, it is an exceedingly remarkable circumstance that the only battery yet examined in which the whole of the heat produced is transmitted through the circuit, is that form of the Daniell's battery in which zinc, in a solution of sulphate of zinc, is used for the positive, and copper, in a solution of sulphate of copper, for the negative, and in which the sulphuric acid and oxygen are transferred from the copper to the zinc.

With zinc, strong sulphuric acid and platinum, about five-sixths of the heat produced is transmitted through the circuit, but this varies somewhat with the strength of the acid; with iron in sulphate of iron and copper in sulphate of copper, only about two-thirds are transmitted; with copper in nitrate of copper, and silver in nitrate of silver, about $\frac{39}{82}$. In this way we account for the circumstance that, with the same positive metal, the potential varies with the character of the negative metal, less of the heat of the oxidation of the positive metal being transmitted through the circuit, and more retained in the battery itself. I may as well say that I obtained these results by comparing some well-known experiments of M. A. Favre with some very important ones of M. Soret, which are scarcely known at all. I will illustrate this by showing you the amount

* Lecture delivered before the Society of Arts, Wednesday, December 11th, 1872.

† Aristotle, in his 'Physics,' suggests an important principle which might with advantage be studied by our modern theorists on the subject of heat. He says ('Physics,' v. 1, 5), 'Αλλ' ἴσως οὐχ ἡ λευκότης κίνησις ἀλλὰ ἡ λεύκανσις. That is, "But perhaps whiteness is not a mode of motion, but whitening is;" so by analogy heat and cold are not modes of motion, but heating and cooling are so—that is in the Aristotelian sense of the word.

of current derived from the oxidation of iron in conjunction with carbon, silver, and copper respectively.

But the whole subject of the relations between heat and electricity is one which requires deep and accurate investigation. M. Favre, in France, and Dr. Joule, in England, are the principal experimenters on this subject, and having spent very much time in carefully examining the published records of their experiments I have no hesitation in saying that the conclusions they deduce cannot be accepted till they are repeated and varied with the most careful precautions, either by themselves or by others. It is much to be regretted that the Committee of the British Association appointed three years since to investigate and report on the question in which these points are involved, and since reappointed from year to year, have not yet made public a single syllable by way of report as to their proceedings or conclusions.

I will only make one observation more before I leave this part of my subject, and that is, that chemical actions which produce cold create a galvanic current, and therefore produce heat, as much as those actions which primarily produce heat. Thus copper and carbon, acting on water, produce a current exactly the same in kind as zinc and carbon, although the heat produced by the oxidation of copper is less than the cold produced by the separation of the hydrogen and oxygen of the water. Again, you will see that while the combination of sulphuric acid with water, which produces heat, produces a galvanic current, the combination of acetic acid and water, which produces cold instead of heat, produces also a galvanic current of exactly the same kind as the combination of the sulphuric acid and water. Let me then show you these facts by actual experiment. And I may note, by the way, that it is a curious circumstance that the combination of many acids and other substances with water, while they produce a contraction of volume, at the same time produce cold, not heat. In the combination of an alkali with an acid, which also produces much heat, you will see that a strong galvanic current is produced, and in this case the alkali, like the water in the former case, acts as the positive, and the acid as the negative. These circumstances, with many others, illustrate the fact that the view of heat, as given in Tait's 'Thermodynamics' and other better-known treatises, namely, that there is a certain absolute zero of temperature, fixed at -272 C., where heat finally ceases to exist (just as there is a certain absence of motion when a body is at rest), and that all heat above this point is equivalent to a certain amount of mechanical force, is a view utterly erroneous; that, on the contrary, any variation of temperature, either upward or downward, involves mechanical force, and that the true zero of temperature is, when all contiguous bodies are of equal temperature, just as the true electrical zero is when all contiguous bodies, are of an equal medium of electrical tension.

But I now turn to the more practical view of the subject. And here let me begin by saying that, in order to understand practically the action of a battery, the most essential thing of all is thoroughly to comprehend what is called Ohm's law. I have no hesitation in saying that the discovery of Ohm's law was to electricity not a whit less important, indeed, I should say more important, than Newton's law of gravitation in astronomy and general physics; in fact, it has been like the rising of the sun to travellers groping their way in darkness. It is now, of course, universally acknowledged as the great law of electrical action, though I need hardly say that when first enounced it was received by the scientific men of the day with the utmost scorn, and actually denounced as the wild ravings of a madman. But Ohm was then an unknown man—now his name is a household word with all electricians. This great law then is, that the quantity of electricity passing through each part of a circuit in a given time is proportional directly to what is called the potential or electro-motive power of the elements, and inversely to the total resistance of the circuit. Thus, to express it algebraically,

$$Q = \frac{E}{R}.$$

Again, the resistance of the circuit consists of two parts—the internal resistance of the battery, and the resistance of the rest of the circuit. Calling these R' and R'', we have the equation,

$$Q = \frac{E}{R' + R''};$$

and in the practical comprehension of this equation under the different circumstances to which it is applicable consists the whole difference between a good and a bad electrician; everything as regards the relation between batteries, the work they have to do, and the cost of doing it, depends upon this equation. If we have many similar cells in a battery, say n cells, then the equation becomes

$$Q = \frac{n\,E}{n\,R' + R''}.$$

Q represents the amount of chemical action going on in a given time in each cell, and if R'' be small, it is plain that, though with many cells we get many times the waste of zinc and other elements of the battery, we get no addition to the current; on the other hand, if R'' be large, we want a good many cells to produce the same current, and, in fact, as I said before, in the practical application of this equation to every varying case lies the whole art of the proper or improper use of a battery, and the art of using such batteries as are properly suited to the object desired to be attained. It will be obvious, from what I have said, that the main points of merit in a battery are—

1st. A large potential, or electro-motive force.

2nd. A small internal resistance, for where there is much internal resistance a large part of the power of the battery is wasted in itself, in overcoming—if I may so speak—its own friction. To these two points I may add two more, viz.:—

3rd. Constancy, or a power of keeping up an action nearly uniform.

4th. Permanency, or the power of working for a long time without attention or fresh making up of the battery.

When I say that the heat produced in a given time—and in some cases the magnetic power—is as the square of the quantity, and not simply as the quantity, you will see at once the great importance of having a large potential.

The two instruments I have here will serve to show the first three points in different batteries, namely, the potential, the internal resistance, and the constancy for at least a short time. The permanency must, of course, be a matter of time to ascertain. The first instrument, a galvanometer with a large resistance, will, I think, show practically better than any other the potential of a battery. By either observing the degree of deflection with the same resistance, or the resistance through which the same degree of deflection is produced, we get a good practical idea of the potential of a battery. And this is really all we want; an exact theoretical determination is valueless, as it is always varying, more or less, from moment to moment.

I will now show you the practical potential of a large number of combinations. Let us take, as a convenient standard, zinc in sulphate of zinc, copper in sulphate of copper.

It is more convenient in practice, though a little larger than the British Association unit, which they call a "Volt," in which the negative is copper in nitrate of copper.

You see the degree to which it attains; now let us compare with this the following elements:—

Zinc, dilute sulphuric acid, platinum.
Do. do. carbon.
Do. do. silver.
Do. do. copper.
Do. dilute sulphuric (||)* nitric acid, platinum (or Grove's form).
Do. do. (||) nitric acid, carbon (or Bunsen's form).
Do. a mixture of dilute sulphuric and chromic acids, and carbon, without a porous cell, as recommended by Roscoe and Bunsen.
Do. dilute sulphuric acid (||) carbon and mixed sulphuric and chromic acids.

I add a little permanganate of potash to the negative, and you see the potential raised a little. Now I will show you some forms of my own.

Zinc, solution of potash (||) carbon packed in a mixture of carbon, precipitated sulphur, peroxide and of manganese with dilute sulphuric acid.
Zinc, common salt (||) . . . do. do.

Next what is in most respects, I think, the most convenient, and best and cheapest in action (for the power produced) of all batteries:—

Zinc, common salt (||) . . carbon packed in granulated carbon, peroxide of manganese, with a mixture of sulphuric, nitric, and chromic acids.

The potential of the first of these then is, as you see, very high, much higher than a Grove or a Bunsen, indeed, nearly 50 per cent. higher. The second and third also considerably higher; the third is very constant, very enduring, and, from the peculiar chemical action of the materials, emits none of those poisonous nitrous fumes which have so seriously and permanently injured the health of many who have used the Grove or Bunsen batteries. Now we will try the potential of iron instead of zinc; this, you will see, is about three-fourths that of zinc, so that four cells of iron will be about equivalent to three of zinc. But as iron is about one-third the price of zinc, and is much less liable to be affected by local action, it would seem as if there was great advantage in using iron. But as every pound of iron consumed will take a little more acid and manganese than the zinc (that is in the proportions of eight and seven), and the internal resistance of four cells will be more than that of three, there is, on the whole, probably not much economy in using iron. Here is another battery in which no acid is used, and in which the potential is as high, or nearly as high, as a Grove, and very constant in its action. It is zinc, solution of salt, (||) carbon, and the peroxide of manganese, with a mixed salt of sodium, tin, and mercury. For telegraphic purposes, where the use of acid is thought objectionable, I know no better form.

But instead of zinc or iron, or indeed any metal, we may use any oxidizable liquid, and collect the electricity derived from its oxidization by means of a carbon plate. The cheapest, probably, of all is common salt; you see this gives a very fair potential, in fact not very short of a Daniell. Again, take sulphate of protoxide of iron, a very cheap material, which may be kept in a state of protoxide by placing it in pyrites or other sulphide of iron, which is a material almost valueless. Cyanide of potassium, you will see, gives a good potential; also hyposulphite of soda, and sulphide of soda or potash. You will observe that the potential of this last is very much greater than a Daniell, and approaches that of a Grove. Sulphide of calcium—a waste material in many places—gives a very good potential. Again, brandy and water, sugar and water, milk, flour and water, all of which, being oxidized by the oxidizing materials of the negative side of the battery, produce a considerable galvanic current. Indeed, with these kind of materials the battery plays the same part as the stomach and lungs of the animal body, the negative part of the battery supplying oxygen to oxidize the food materials of the positive part, just as the lungs furnish oxygen for oxidizing the food supplied to the stomach and brought into circulation in the blood. You will observe that milk and tea are more easily acted on, and give a larger potential than brandy and water or flour and water. But before I conclude this part of my subject, I ought to show you the potential of some other of the common forms of battery, namely, the Wollaston, the Smee, and the Le Clanché. You will see they are much inferior to some of the forms I have shown you, besides having other disadvantages which I shall show you in due time.

* The mark (||) is intended to denote a porous diaphragm.

Well, let me next show you the internal resistance and constancy of some of the common forms of battery. In order to show this properly we must, of course, take elements of an equal size. This instrument is a galvanometer of very small internal resistance, so that, practically, it shows you what is the internal resistance of the battery, as that is the main element of resistance. Of course the potential also affects the result, so that the degrees in this instrument will practically show you the combined result of potential and small resistance, where a large amount of current with a small resistance is required; and the loss of power in a minute (I cannot afford time to show you the effect of a longer duration), will give you some idea of their constancy.

Let us just take that modification of the Daniell now used in the Post-office and generally for telegraphic use. You have seen that it stands low in the scale for potential; and you will now see that for small internal resistance it stands very low indeed, but that its constancy for one minute at least is perfect. But still the amount of electricity produced in a minute is so very small that it ought to remain constant, there being so little expenditure of force in the time. Now, compare with this two forms of battery introduced by myself for telegraphic purposes—zinc in salt or dilute acid for positive, and carbon placed in granulated carbon and peroxide of manganese with dilute acid for negative. You will see the comparatively enormously large quantity of electricity which this produces; though in the course of a minute, where there is no resistance, it of course partially exhausts itself, the peroxide not being able to furnish oxygen rapidly enough for the supply; but, after a short interval of rest, it recovers its full potential. On the London and North-Western Railway ten of these cells were found to work to Manchester equally well with 60 of the ordinary sulphate of copper batteries; not, of course, that the potential is six times as large—indeed, it is not more than double—but in damp and wet weather, where there is much leakage from the wires, the small internal resistance of these batteries enables them to supply enough electricity to make up for the leakage, whereas the larger internal resistance of the Daniell batteries prevents them from supplying in a given time more than a comparatively small given quantity, which will not bear much loss from leakage. I am glad to say that this form of battery is being fast adopted for railway use. Then we try the Wollaston—a small potential, a small resistance, and a very rapid fall of power; then the Smee—a small resistance, fair potential, and, in consequence of the rapid escape of hydrogen, considerable constancy. To this battery the hydrogen fumes are a great objection. Next try the Le Clanché, a fair original potential, moderate resistance, and rapid fall of potential. Next, the form I mentioned before as introduced by myself, with a higher potential than the Le Clanché, and much more constant, though, like the Le Clanché, used without an acid, and therefore quite as permanent. It is simply a solution of common salt with a combined salt of sodium, tin, and mercury in the negative. This combination has the peculiar property of being able to extract rapidly the oxygen from the peroxide of manganese. The tin causes in time a little local action, but if it be left out, the mercury by itself cannot so rapidly extract the oxygen, and the local action caused by the tin is very small indeed. Next the "Grove," a high potential, very little resistance, even an increase of potential as the liquid gets warm; Bunsen the same; but both, after a short time, producing intolerable poisonous fumes, which produce dangerous inflammation of the lungs, take away the voice, and when a man's system has once been injured by them, act upon the lungs on subsequent occasions with the utmost rapidity. For myself, I am now so sensitive to them that I cannot expose myself to them for even a few minutes without losing my voice, and my chest getting seriously affected; besides, they are far from permanent, as a few hours exhaust their power. Next, I try the bichromate battery, without porous cells; small resistance, high potential, but soon losing its power, and very expensive and wasteful in use, destroying itself by a single night's action. Next, the bichromate, with a porous cell, high potential, moderate resistance, moderate constancy, but very expensive in use. Next, let me take my own form, which, for general practical use—as for induction coils, for keeping up a powerful magnetic action when required, and other such purposes—I think is far superior to all others. Zinc in salt, carbon packed in granulated carbon and peroxide of manganese, filled in with dilute sulphuric acid, mixed with a little nitric and chromic acids. Here is very high potential, as I showed you before, moderate resistance and great constancy. I have had them standing for months, used occasionally, and using but little of their original potential.

For electro-plating, in power, convenience and long endurance, they exceed all others. Some electro-platers prefer iron as the positive, some zinc; for each has his own peculiar preferences and modes of working; but they are now becoming largely adopted, having more than the power of the Bunsen, without the inconveniences, and lasting, I may say, thirty times the length of time. Some electro-platers have had them in daily use for two months at a time. The chromic acid has the especially valuable property of absorbing all nitrous fumes.

To show you the power of the battery, here is an electro-magnet magnetized by a single cell. I will defy the strongest man in this room to separate the soft iron keeper from the magnet.

Where very great constancy and a very large current of electricity is not required, the nitric and chromic acids may be omitted, and then the local action becomes next to nothing; but with the latter a moderate-sized battery of a single cell has been used for plating six dozen forks at once.

I am afraid that I have occupied you too long, but, as it is, I have been obliged to compress my matter unduly, and to omit many points on which I should have wished to dilate.

APPEARANCE OF SWEET AND SKIM MILK UNDER THE MICROSCOPE,*

BY M. BOUSSINGAULT.

Butter-milk under the microscope appears very different from milk from which no butter has been made; it contains, however, a certain amount of the characteristic butter-globules.

The author's experiments show that the fourth part of the entire amount of butter remains in the butter-milk. In sweet milk the butter globules are numerous and crowded together; in butter-milk they are fewer, and widely separated from one another.

By the gathering together of these butter-globules, cream is formed on the surface of milk—milk which contained 3·62 per cent. butter, after standing 24 hours, still showed 1·4 per cent.—so that all the butter globules do not collect in the cream; a good cream contains 37–40 per cent. butter.

Skim milk contains less butter than butter-milk; the latter is therefore often adulterated with the former, but this admixture of skim milk may be detected by the the microscope.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

PUBLIC ANALYSTS.

For some years past it has been evident that there is a growing need for an organized system of dealing with certain questions of public interest, involving exercise of chemical knowledge and skill, especially of that technical nature which is requisite in conducting analysis. The various chemical questions affecting the Revenue have hitherto generally been dealt with in special laboratories attached to the Customs or the Excise departments under the direction of chemists who have gained experience in those departments, and in this way all requirements have been to that extent satisfied. But recent sanitary legislation has had the effect of raising, directly or indirectly, a multitude of other questions, for the solution of which chemical knowledge is required, and in many such cases the evidence of analytical data is indispensable. The want thus manifested has been to some extent met by the appointment of such officers as the inspectors under the Alkali Act, the inspectors of lime juice and the Rivers Pollution Commissioners, as well as by making the laboratories and chemical staff of the Excise or Customs departments available for any inquiry involving chemical or microscopical work. The Health Bill introduced by Mr. STANSFELD last Session contained clauses providing for the analysis of water supplied for domestic purposes, of matters polluting streams, and of samples of food supposed to be adulterated, etc.;* and although this part of the measure was deferred for the present, something of the same kind was carried in the Adulteration Act by the provision for appointment of analysts under that Act.

These various official recognitions of the necessity for chemical services may perhaps not unreasonably be regarded as foreshadowing the establishment of a department of State chemistry, much of the same general character as the department of State medicine which has done so much public service as a branch of the Privy Council, and has lately been merged in the newly constituted Local Government Board. When the Health Act of last session is supplemented by more detailed legislative enactments, it may be expected that the very general need for chemists' services will constitute an inducement for more general qualification in this respect on the part of those engaged in trade as druggists, and, at the same time, offer an opportunity of improvement in the character of the trade. The systematic testing of gas and water, as well as such other demands of the kind as may arise from time to time, must, we imagine, be provided for in future by some system more certain and convenient than the chance presence of a person competent to conduct such work, or the recourse to chemists in the metropolis. Very much of such work will be matter of daily routine, and must, therefore, be carried out by a person on the spot, though it is probably desirable that the plan on which it is done should be laid down and regulated by some central authority. The same may be said in regard to the analytical inquiries needed in cases of poisoning, or for other legal purposes.

To take for instance the working of the Adulteration Act, if such a thing be conceivable, there would be some five or six hundred appointments to be made throughout the kingdom, and we maintain that no class of persons would be more suitable for the purpose than pharmacists.

It has been objected that the fact of a pharmacist being a tradesman would render him unfit for the office of analyst, or, as a correspondent expresses it, for "sitting in judgment on the wares of his fellow-shopkeepers."

There is a narrow sort of plausibility about this objection, but even that is only apparent, and a moment's consideration will show that it has no better basis than ignorance of the provisions of the Act, and of the nature of the analytical work requisite in such cases.

There is no sitting in judgment at all,—but merely the production of evidence that is required of the analyst; it is not even necessary or perhaps desirable for him to know whose are the "wares" submitted to the scrutiny of his art. Even if it should turn out to be his neighbour's ware which fails to bear this test, we cannot see that any one could be blamed but the defaulter.

In reference to the functions of the analyst under the Adulteration Act, it may be well here to point out what seems to be a misinterpretation of the Act by Dr. LETHEBY, according to the report printed at p. 512, where he speaks of the analyst being clearly justified in directing the inspectors to purchase samples of articles suspected of adulteration. So far as we are able to read the Act, it confers no such dangerous power on the analyst, and although there is a strange absence of any indication who is to exercise the function of "suspecting," and thereupon to put the collecting inspectors in motion, there are many reasons for securing the entire independence of the analyst in this respect.

It is with much regret that we have seen such a precipitate attempt made by medical men, or at least

* See PHARM. JOURNAL [3] vol. II. p. 756.

by Medical Officers of Health, to monopolize the office of public analyst, and we think this course must have been taken without sufficient consideration.

The medical papers of last week appear to have taken especial umbrage at the representation of the claims urged by the Pharmaceutical Society on behalf of the eligibility of pharmacists for the appointment of analyst. Setting aside the element of abuse which is introduced into the remarks of one of our contemporaries, we will venture to point out in answer to the arguments of the *Medical Times and Gazette*, that in this case too much stress seems to be laid on the word "medical" when it is endeavoured to interpret it as properly signifying only the art of treating disease; for what kind of necessity is there for competence in that respect in order to make an analysis? Granting even that the pharmaceutical chemist "knows nothing practically of anatomy, physiology or pathology," what logic is there in the inference that he must, therefore, be incompetent to make a chemical analysis? It might even be added that in cases of poisoning or accident, knowledge of those subjects would not confer any fitness for the performance of the special work of deciding whether certain parts of an animal body or certain materials contained poison or not; and that is really the main point to be ascertained by the analyst. It is also conceivable that the important aid medical men can render in such cases would be more serviceable if it were not associated with the strictly chemical work, but merely brought to bear on the analytical results obtained by an experienced chemist.

In regard to the *Lancet's* remarks upon the misuse of the word "chemist," we object altogether to the insinuation that any "pretensions" have been founded upon that basis. All that is contended for by the Pharmaceutical Society is, that, considering the nature of the duties appertaining to the office of analyst under the Adulteration Act, they present no features which demand the skill of the qualified medical practitioner, and that in consequence eligibility for the office should not be restricted to that class. It is also contended that many persons in business as druggists—to use the least pretentious term—are fully competent both as chemists in the strict sense, and as microscopists, as well as by possessing a knowledge of medicines, to perform the duties of the office; this is, we believe, a modest contention and one which we venture to say cannot fairly be disallowed.

Lastly, we learn from the *British Medical Journal*, that in consequence of the Pharmaceutical Society having sent a deputation to the Local Government Board, a communication has been addressed to Mr. STANSFELD by the Chairman of the Parliamentary Bills Committee of the British Medical Association, for the purpose of pointing out to him the opinion of that body, that whereas an Act of Parliament exists, regulating the examinations which certify medical knowledge, subsequent Acts requiring medical knowledge should be interpreted by that light; and that, for any post which an Act of Parliament designates as requiring medical knowledge, those persons only should be considered eligible who have passed one of the recognized examinations. This suggestion is very reasonable within the limits of its applicability, but, since in regard to it Mr. STANSFELD's discrimination will no doubt enable him to appreciate the fact that the Act therein referred to is one appertaining solely to the practice of medicine, and having nothing to do with the chemical or microscopical qualifications essential for a public analyst, we may well leave this communication without further comment.

It is satisfactory to learn from Dr. LETHEBY's address that he has taken upon himself as representing the Association of Medical Officers of Health, to urge upon Mr. STANSFELD how important it is for the effective working of the Act that the appointment as analysts of persons having competent medical, microscopical and chemical knowledge, should be strictly carried out. We fully concur with him in this opinion, and we feel sure that all classes of tradesmen likely to be affected by the Act will, on consideration, perceive that it is of vital importance to them that these appointments should be efficiently filled up. It is still more satisfactory to learn from the same source that Mr. STANSFELD, in replying to the suggestions of the Association, has intimated that the Local Government Board will require satisfactory evidence of the qualifications of the appointed analysts.

As yet we believe the necessary approval of the Local Government Board has not been given to any of the appointments that have been made; and for the present we can only rely upon the assurance given by Mr. STANSFELD that proper attention will be given to the question of qualifications.

Our space does not permit us to deal with some other details of the Adulteration Act; but, as pointed out by a correspondent, there appears to be in some quarters a singular want of appreciation of the nature of the work that will be required from analysts, as evidenced by the proposition that it should be paid for by a fee of half-a-crown. It may be advisable in carrying out the Act that analyses should be obtainable by the public for very moderate sums; but if such analyses are to be of any value, it is obvious that under such a system the officer conducting them should, in matter of remuneration, be placed on a footing with other municipal officers, and adequately paid for his services out of the public funds, as part of the expense of carrying out this Act. It is idle to expect that trustworthy analyses, sometimes requiring two or three days, will be conducted by skilful analysts unless they have something more to look for than a trumpery half-a-crown fee.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

December 18th, 19th, and 20th, 1872.

Present—Messrs. Allchin, Barnes, Carteighe, Cracknell, Davenport, Edwards, Gale, Haselden, Ince, Linford, Martindale, and Southall.

Dr. Greenhow was present on the 19th on behalf of the Privy Council.

Major Examination.

Twelve candidates were examined. *Five* failed; the following *seven* passed and were declared duly qualified to be registered as Pharmaceutical Chemists:—

	*Hanbury, Frederick Janson	London.
	*Collishaw, John	Nottingham.
	*Edwards, David	London.
	Jones, David	Rhyl.
	Nuthall, Edwin	Norwich.
	Houghton, Robert William	Bermuda.
	Trist, Richard	Plymouth.

Minor Examination.

Fifty-one candidates were examined. *Twenty* failed; the following *thirty-one* passed, and were declared duly qualified to be registered as Chemists and Druggists:—

	*Richardson, Edward	Dresden, Staffs.
	*Samson, Ernest	Bristol.
	*Smith, Arthur Harry	Eccleshall.
	*Marson, William	Stafford.
	Price, Rees	Neath.
	Newhill, John William	Huddersfield.
Equal.	Almgill, John	Bedale.
Equal.	Scoley, Thomas Edward	Boston.
Equal.	Walton, Thomas	Bishopwearmouth.
	Smith, John Jacob	Yeovil.
Equal.	Ellis, Robert	Aberystwith.
Equal.	Roberts, William Henry	Bath.
	Deacon, Henry James	Norwood.
Equal.	Lansdale, John Anstey	High Wycombe.
Equal.	Lunn, Thomas	Worcester.
Equal.	Smith, Tenison	Cambridge.
	Jones, James Parry	Newcastle.
	Mellor, John Gilbert	Southport.
	Fletcher, Frederick William	Totton.
Equal.	Robinson, Richard Atkinson	London.
Equal.	Thomas, Llewellyn	Swansea.
	Smith, Nathan	King's Lynn.
	Hannah, Charles	Abergele.
	Hardcastle, Stephen Barnabas	Knaresborough.
	Sharrah, Richard	Hull.
	Nicholls, Theophilus	Lower Mitcham.
	Evans, Evan	Cardiff.
Equal.	Ashwell, Lawrence Thomas	London.
Equal.	Betts, Samuel	Oadby.
	Burder, Robert	Manchester.
	Sparshott, Harry	Birmingham.

The above names are arranged in order of merit.

Preliminary Examination.

Certificates were received from the following in lieu of this examination:—

Certificates of the University of Oxford.

Heywood, John Henry	Lincoln.
Walker, George	Liverpool.

EDINBURGH MEETING.—NORTH BRITISH BRANCH.

The second meeting of the present session took place in the Society's rooms, St. Giles Street, on the evening of Wednesday, 11th December, at 8.30. There was a large attendance, the room being crowded; Mr. Baildon, President, in the chair.

After a few remarks by the Chairman, Professor A. Crum Brown, of the Edinburgh University, was introduced to the meeting, who delivered a very interesting and eloquent address on "The Relation of Chemistry to Pharmacy." The Professor occupied fully an hour, but as he had no manuscript we are only enabled to give the following short abstract from one portion of the lecture:—

Pharmacy is an *art*, the art of preparing and dispensing drugs. The principles of this art, like the principles of other arts, are derived from various sciences, and as these sciences give help to Pharmacy by supplying it with principles, so they derive help from it in the form of facts and observations. Among the sciences thus related to pharmacy these may be mentioned:—botany, zoology, and chemistry. Pharmacy derives from botany the means of recognizing and identifying the various plants used in medicine. Botany has received compensation from pharmacy in the minute and careful study of plants and parts of plants which would otherwise have been left comparatively uninvestigated. The oldest lists and descriptions of plants are "herbals," and these were made with a purely pharmaceutical object. Similarly, though to a smaller extent, zoology and pharmacy are related. But chemistry has a much more intimate relation to pharmacy than either botany or zoology. The term 'chemist and druggist' shows that this relation is generally and popularly recognized. No one would call a pharmacist a "zoologist and druggist" and the term "botanist and druggist," or any similar phrase, is reserved for a class of persons with whom we do not wish to claim any relation.

The reason of this more intimate relation is obvious when we consider that, while pharmacy owes to zoology and botany some of its raw materials and the means of testing their genuineness, all pharmaceutical *processes* and *operations*, which are not purely mechanical, are chemical.

Thus nearly every fact or observation in pharmacy is of chemical interest, and a very large number of the discoveries of chemistry are of use to the pharmacist. Indeed, as every science originates in one or more arts, pharmacy may be said to be one of the roots of chemistry, the other being metallurgy. Chemists were for a long time the producers of metals and drugs, and their aim was to discover the philosopher's stone and the elixir of life. This relation may be very well seen if we consider what parts of chemistry have been most minutely studied, when we shall find that they are those of special pharmaceutical or metallurgical interest.

It is desirable that a druggist should have a good knowledge of the natural history sciences; it is essential that he should be a chemist.

As an instance of an eminent chemist and druggist, Dr. Crum Brown gave a short sketch of the life of Carl Wilhelm Scheele.

Born, 1742, the son of a merchant at Stralsund, he was apprenticed in his fifteenth year to a druggist at Gothenburg. He remained as apprentice and as assistant in Gothenburg till 1765. During these eight years he acquired a very complete acquaintance with chemical analysis, devoting all his leisure to the study of chemistry, reading such books as he could obtain, and experimenting for himself with such means as his master's shop afforded. From 1765 till 1775 (when he obtained the management of a pharmaceutical establishment in Köping, a small Swedish town) he acted as assistant in various places—Malmö, Stockholm and Upsala. He died at Köping in 1786 at the early age of forty-three.

Always a poor man, with limited means of study and of experiment, Scheele, in his short life, succeeded in making a larger number of important discoveries in chemistry than any other chemist before or after him. He discovered

* Passed with Honours.

tartaric acid, citric acid, malic acid, oxalic acid, gallic acid, mucic acid, lactic acid, uric acid, prussic acid, and glycerine. In the department of inorganic chemistry, he discovered molybdic acid, tungstic acid, arsenic acid, and baryta; he conducted series of valuable investigations upon fluorspar and black oxide of manganese, and discovered chlorine and (a short time after, but quite independently of, Priestley) oxygen.

This list is a marvellous monument of genius and industry, and we are sometimes tempted to speculate as to what Scheele might have done, with wealth, social influence, and long life. But the peculiarities of Scheele's work, its independence and directness, his confidence in Nature and distrust of authority, were no doubt greatly owing to the conditions of his life, which appear at first sight so unfavourable; and it is not impossible that with greater advantages he might have done less, as it is certain that scarcely any chemist had fewer advantages, and that none has done more.

Scheele's work was almost purely practical; towards the close of his life he published, in connection with his discovery of oxygen and of chlorine, important speculations on Air and Combustion, but it is with his discoveries of methods and facts that his name will always be associated.

There will always be pharmacists as poor and as unaided as Scheele, though we can scarcely hope that one of them will rival him as a discoverer; but all, whatever may be their circumstances, can imitate his industry and thoroughness, his quiet self-respect and devotion to the truth of nature, and by doing so each will make the most of whatever genius he may happen to possess.

At the close of the lecture a hearty vote of thanks was proposed by the chairman and seconded by Mr. Gilmore. Professor Crum Brown replied, and the meeting thereafter separated.

Provincial Transactions.

BRISTOL PHARMACEUTICAL ASSOCIATION.

The usual monthly evening meeting of the association was held on Friday, December 13th; the President, Mr. Townsend, briefly opened the proceedings.

Mr. Giles exhibited a modified form of copper siphon for the more convenient transference of spirits of wine or other liquids.

The suction tube was differently arranged (being placed at the top of the arch) so as to enable the operator to put the instrument into action with a less violent effort of the lungs than is necessitated by the usual vintners' siphon, and also to avoid the inspiration of strong spirit which almost necessarily attends the use of the old siphon for that liquid.

A lecture was then delivered "On the Processes employed in the work of Organic Chemistry" by Thos. Coomber, Esq., F.C.S., upon the following outline:—(1) Fractional distillation, with experimental illustrations of the process at work; (2) Pressure tube operations—illustration of the mode of conducting these operations. Collection and examination of ethyl; (3) Limited oxidation—working illustration of the process, and examination of the product; (4) Processes of Organic Analysis—Methods of Liebig, Will and Varrentrapp, and Dumas, in operation, with experimental illustrations of the principles on which these operations depend.

CARLISLE CHEMISTS' ASSOCIATION.

The monthly meeting of this association was held on Friday evening, the 20th inst., in the class-room, Barwise Court. Votes of thanks having been passed to Messrs. Maw, Son and Thompson, London, for their gift of several useful articles of chemical apparatus, and to Messrs. Barron, Harvey and Co. for their present of fifteen remarkably fine specimens of drugs, a very interesting paper on "Water and Water Analysis" was read by Joseph Pattinson, Esq., and illustrated by several experiments.

There was a moderate attendance of members and associates; Mr. A. Thompson, President in the chair.

On the conclusion of the reading of the paper, a vote of thanks was unanimously passed to Mr. Pattinson for his kindness.

Proceedings of Scientific Societies.

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.

On Saturday, Dec. 21, Dr. Letheby, the Medical Officer of Health and public analyst for the City of London, presided at a meeting of the Association of Medical Officers of Health, held at the hall of the Scottish Corporation in Crane Court. He opened an important discussion on the working of the new Adulteration Act, premising that he had transmitted to Mr. Stansfeld the suggestions of the association as to the effective working of the Act, and especially that in which they urged that the appointment as analysts of persons having competent medical, microscopical, and chemical knowledge should be strictly carried out. He had received a reply to the effect that the suggestions should receive the attention of the Local Governing Board, and that the Board would require satisfactory evidence of the qualifications of the appointed analysts. What that "satisfactory evidence" was to consist of he was not yet aware. He contended that it was advisable that the Act should be carried out with uniformity all over the metropolis, and he, therefore, proposed to suggest to his fellow-analysts what should be the mode of procedure. First, he said, it was necessary that the articles should be "suspected to be adulterated," and that suspicion might be either special or general. If special, and the suspicion was directed against one particular article or one particular man, he had ordered in his own district that forms should be kept in which any one could enter a complaint, and hand it for private retention to the inspector. They must not keep a book of complaints, because tradesmen and others in such a case could see who were the persons complaining and act accordingly. The suspicion ought to be a well-recognized and well-grounded one, and not mere idle gossip. If general, and the suspicion was directed against all the dealers in a certain article, say milk or coffee, in a particular district, the analyst would clearly be justified in directing the inspectors to purchase samples of such suspected article from each and all of them. There would be, in such a proceeding, no invidious selection made, and besides, the analysis, directed as it would be to one particular article, would be more conveniently made. The Act next provided that the purchaser or inspector must prove to the satisfaction of the justice that the article in question was delivered to the analyst in the same condition in every respect as it was when he received it from the seller. How was that to be accomplished? In the case of an ordinary purchaser, he must give notice at the time to the dealer of his intention to submit it for analysis, so that he might either put his seal to it, or at once accompany the purchaser to the inspector. But in the case of an inspector purchasing an article no such form need be gone through, for it was obvious that if once the officer declared himself he would never be able to purchase again. After a purchase, the purchaser wishing to have the article analysed would hand it to the inspector, and on payment of a sum to be fixed in each district, varying from 2*s.* 6*d.* to 10*s.* 6*d.*, an analysis would be made and a certificate given. The analyst had no business to receive any articles direct from the purchasers, for the Act provided that everything should be done through the inspector. In the case of an inspector buying and bringing an article to the analyst, he must designate the article by a number, enter in a memorandum-book all the circumstances relating to the purchase, and secure and seal samples of the articles, so that in case of dispute a further investigation might be made. The duties of the analyst were to witness the sealing of the articles, to conduct the analysis, and to give the certificate. As to the manner of conducting the analysis, he ought first to make a physical examination with reference to the appearance, colour, smell, or taste of the thing, then a microscopical examination to discover the structure of the substance, and, lastly, a chemical examination. Dr. Letheby strongly dwelt on the importance in all analyses of the incineration of the article, which, he said, was perhaps the greatest "tell-tale." He observed that the analyst was bound to give a certificate to an ordinary purchaser, but there was nothing to compel him to give one when the inspector himself bought the article. He advised his colleagues so to frame their certificates that they might not be used as trade "puffs," and he submitted a form of certificate which met his view on the subject. They must sign and write their certificates in the presence of the inspector, and those certificates would be then legal evidence, and there was no necessity for the analyst to appear in a court of law at all. By the Licensing Act, where the analysts were appointed by the Inland Revenue, it was provided that they should attend the Court for the purpose of cross-examination if need be, but there was no such provision in the Adulteration Act. The analyst, therefore, he contended, had finished his work when he had given the certificate on which the proceedings were founded. The difficulty in the Act was how to deal with articles which were debased, but not adulterated, such as skimmed milk, spices from which all the volatile oils had been extracted, tobacco and other things which by keeping had lost their active principles, and drugs produced in climates which did not bring out those principles, and he confessed he had not been able to solve it. He added that the Act should not be put into operation without due notice of all its provisions to the public, and he handed in a circular which was about to be issued in the City.

Dr. Liddle, in the name of the association, thanked the president for his interesting remarks, and for his very valuable advice and assistance.

Dr. Tripe disagreed with Dr. Letheby as to his opinion about general suspicion, and observed that the analysts were only required to give a qualitative and not a quantitative analysis.

Dr. Sarvis and Dr. Woodforde remarked that, to their great surprise, Mr. Bushby, a metropolitan magistrate, had held that any one was competent under the Act to give an analysis, that the inspector was not bound to receive the article from the purchaser and hand it to the analyst, and that all that was necessary was that the thing should be proved not to have been tampered with.

Dr. Hardwicke and Dr. Ross spoke strongly against the assertion made by members of their own body that, as a rule, medical officers of health were not qualified for appointment as analysts.

The meeting, after some further discussion, adjourned.

PHILADELPHIA COLLEGE OF PHARMACY.

At the pharmaceutical meeting held on Tuesday, November 19th, Mr. Remington made some remarks upon ceresin as a substitute for white wax. It is obtained by distilling ozokerite at between 250° and 300° C., to separate liquid oils, and treating the residue with Nordhausen sulphuric acid to separate impurities, and afterwards refining. It differs from paraffin by its greater opacity, its not being unctuous to the touch, and its behaviour with ether, boiling alcohol, turpentine and benzine. Chloroform dissolves both ceresin and paraffin to some extent, but upon the cooling of a warm solution, paraffin is deposited unchanged on the sides of the vessel, while ceresin forms a heavy flocculent precipitate. Mr. Remington also drew attention to a modified form of crystallized permanganate of potash, in which the ordinary needle-like character was entirely wanting, the crystals merely showing the pyramidal summit common to the usual salt. The modified form had led to suspicion of an adulteration; but it was thought to be probably due to the interference of salts of greater solubility present in the solution from which the specimen had been crystallized.

Professor Maisch exhibited some musk pods, obtained from Mr. Cramer, an importer. The following details from records kept by Messrs. Cramer and Co., were furnished to illustrate the yield of musk :—

No. of bags.	Weight of bags (troy). oz.	dr.	gr.	Weight of Musk (troy). oz.	dr.	gr.
2	1	3	0	0	5	0
3	2	3	15	1	2	0
6	4	3	10	2	2	10
4	4	1	0	1	1	30
12	10	0	0	3	2	40
1	0	5	40	0	3	0
1	0	6	23	0	3	23
29	23	6	28	9	3	43
Average for each bag—	0	6	34	0	2	36⅔

Professor Maisch also exhibited a sample of South Carolina opium. It is considered by persons engaged in producing opium in that State that the plants can be grown there with considerable profit. The sample sent had not been analysed; it was gathered when the plant was green and in its luxuriance of growth. In the discusion which followed, opinions were expressed that with care opium might be produced in the warmer States of the Union equal in quality to that obtained from the usual sources.

CHEMICAL SOCIETY.

Thursday, 19th December, 1872; Professor Williamson, F.R.S., Vice-President, in the chair.

After the ordinary business of the society had been transacted, several interesting communications were read. The first entitled "Analyses of Water of the River Mahanuddy," by Mr. G. Nicholson, gave the results of the author's examination, from which he finds that the water of this river contains less dissolved matter than that of any other river in India. The next paper, "Researches on the Polymerides of Morphine and their Derivatives," by Mr. G. Ludwig Mayer and Dr. C. R. A. Wright, gave an account of the various derivatives obtained from morphine by acting on it with zinc chloride, hydrochloric acid, and sulphuric acid respectively, and also of the physiological properties of the compounds produced. Three communications by Dr. H. E. Armstrong, from the laboratory of the London Institution were then read. No. VIII. "Derivatives of β-dinitrophenol." No. IX. "Note on the Action of Bromine in the Presence of Iodine on Trinitrophenol (picric acid)." No. X. "Preliminary notice on Iodonitrophenols." The last paper, by Mr. C. E. Groves was "On the Formation of Naphthaquinone by the direct Oxidation of Naphthalene," which the author effects by means of chromic anhydride.

The meeting was finally adjourned until Thursday, 16th January, when papers will be read "On Several Vanadates of Thallium," by T. Carnelly; "On the Heptanes from Petroleum," by C. Schorlemmer, and "On Ethylamyl," by Mr. Grimshaw.

THE MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS, DUBLIN.

Wednesday, April 24th, 1872.

The Application of Gases as a Means of Destroying Contagion.

BY CHARLES A. CAMERON, PH.D., M.D.,

Professor of Hygiene in the Royal College, etc.

(*Concluded from p.* 494.)

Before the question of bacteria as a cause of zymotics arose, Haygarth, Murchison, Ryan of Lyons, and others denied that small pox poison was directly transmitted through any considerable space in the open air. Murchison asserts that the poison was not contagious in the open air at a distance of half a yard. Chauveau states that the contagious matter of small pox is volatile—that the solid particles float into the air at a temperature of 40° centigrade, but in his experiments the matter was carried away by a current of vapour. The pent-up gases in a sewer when they find an outlet into a house undoubtedly often carry up mechanically the *materies morbi* whatever it may be, of enteric fever.

It would appear that whilst minute plants and spores float about abundantly in the atmosphere, minute animals and ova adhere to walls and other solids. Now, in ordinary disinfection the principal object is to act upon the atmosphere. A bad odour is observed in the sick-room wherein lies a small-pox patient, but that odour is not actually connected with the cause of the disease; the contagious matter which produces small-pox is odourless. We might destroy the bad odour in the room without diminishing the quantity of contagious matter present.

The following experimental results prove that the ordinary disinfection by gases does not kill the bacteria which are usually associated with putrefaction, nor does it perfectly destroy the contagious matter of at least one zymotic disease:—

Several watch- and microscopic object-glasses were dipped into filtered beef-tea, which contained enormous numbers of bacteria, and whilst still moist they were placed in different positions in a hood, or small chamber made of wood and glass, containing 16½ cubic feet of space. Half an ounce of chloride of lime was placed in a capsule and introduced into the hood, and an equivalent quantity of hydrochloric acid was poured on the powder in such a way as to prevent the chlorine evolved from passing out of the hood. After the lapse of 24 hours the door of the hood was opened and the glasses removed. They were found to be covered with extremely thin films of solidified beef extract. A few drops of pure water were used to render the film semi-liquid, and its contents were examined with a microscopic power of 800 diameter. In a few seconds the bacteria were detected moving about with great rapidity, and with apparently undiminished vigour. It was clear then that fumigation at the rate of a little more than three ounces of bleaching powder per 100 cubic feet of space had no effect in destroying bacteria. The hood was more air-tight than a room is when its doors, windows and fire-place are closed. On opening the door of the hood after 24 hours the odour of chlorine was distinctly perceived at a distance of several feet. If a room 15 feet long, 10 feet wide, and 10 feet high, and having, therefore, a capacity of 1500 cubic feet, were disinfected by chloride of lime in the relative proportions employed in the foregoing experiment, it would be necessary to use nearly three pounds of chloride of lime.

As the gases evolved from three ounces of bleaching powder per hundred cubic feet of space did not destroy bacteria, an experiment was made with one ounce per 16½ cubic feet, or at a rate of nearly six pounds per 1500 cubic feet—the size of a small room. The result was similar to that of the first experiment, the bacteria being almost as lively after as they were before the process.

The next quantity tried was one and half ounces of bleaching powder per 16½ cubic feet, or at the rate of about eight and a half pounds per room of 1500 cubic feet capacity. After 24 hours' exposure to the highly chlorinated atmosphere produced by this experiment, the greater number of bacteria were not only alive, but most of them exhibited the utmost vitality. Two ounces of bleaching powder per 16½ cubic feet were next tried, and after exposure to the gases evolved from this quantity by the action of an acid, the bacteria, though languid, were still mostly alive, and a few of them were very active. The last experiment was made with three ounces of bleaching powder per 16½ cubic feet, or at the rate of 16½ pounds of the disinfectant to 1500 cubic feet; but even the enormous amount of gas evolved from this quantity failed to kill the greater number of the bacteria subjected to its influence. Films of moist meat extract containing bacteria were next exposed to an atmosphere of equal parts of chlorine gas and ordinary air. This operation was conducted on an air-tight glass vessel. After 24 hours they were examined, and no life could be perceived. Dried films of meat extract containing bacteria were submitted to the influence of this gaseous mixture, but after being moistened many of the bacteria were found still alive though almost inactive.

Similar experiments were made to ascertain the action of sulphurous acid gas upon bacteria, but this gas was also found to produce but little effect on these animalcules.

Having proved that the bacteria which exist in liquids are not destroyed by exposure to atmospheres highly charged with chlorine or sulphurous acid gas, an experiment was next made with the view of ascertaining whether or not the germinal matter of bacteria could be destroyed by ordinary gaseous disinfection. Accordingly filtered beef-tea, which did not exhibit any forms of life under the microscope, was divided into three parts. One portion (*a*) was placed in an ordinary test-tube, and loosely plugged with cotton wool, another portion (*b*) was placed in a test-tube, which had shortly before been heated nearly to redness, and loosely plugged with cotton wool, which had been highly heated to 350°; the third portion (*c*) was poured upon microscopic object- and shallow watch-glasses, and these were placed in the hood and exposed for 48 hours to the gases evolved from two ounces of bleaching powder, treated with acid. In 24 hours the liquid (*d*) which had simply been deposited in a test-tube, was found to swarm with microzymes; the liquid which had been placed in the tube that had been heated to redness was, after a week, found to be free from animal life,* whilst a few hours after their removal from the hood, the films of beef-tea exhibited swarms of vibriones, although every precaution was taken to prevent contamination from solid surfaces subsequent to the removal of the glasses from the hood.

The following experiment was made in a room of 1600 cubic feet capacity. Animal liquids containing microzymes were placed upon the chimney-piece, upon the window panes and other smooth parts of the apartment. Seven pounds of chloride of lime were then decomposed by oil of vitriol, and the room carefully closed up. After 48 hours the room was opened, and the films containing the bacteria were, with every precaution washed upon object-glasses, and examined microscopically. In every case there were large numbers of living microzymes.

The next experiment was conducted as follows:—

Four ivory points, charged with vaccine lymph, were

* Dr. Sanderson has shown that animal liquids, deposited while fresh in tubes which had been highly heated, and loosely plugged with cotton wool, remained free from bacteria for a long time.

placed in the hood, and subjected, during 24 hours, to the influence of the gases evolved from one ounce of bleaching powder, decomposed by acid. With these points I successfully re-vaccinated two persons, but with the other points I failed. Six charged points were next exposed to the gases evolved from two ounces of chloride of lime per 16½ cubic feet; but attempts to vaccinate with these points proved unsuccessful.

The results of these experiments show that bacteria and the contagious particles of vaccine lymph resist, when protected by an extremely thin film of solid, or semi-solid matter, the action of chlorine and sulphurous acid gases applied to them in larger quantities than are usually employed in disinfection. The filtered meat-juice used in these experiments contained only five grains of solid matter, per ounce of 480 grains—rather more than one per cent. The object-glasses were dipped in this liquid, and many of them allowed to drain before being subjected to experiment. We may readily conceive then how extremely thin the film was that separated the bacteria from the gases set free in the hood. It is extremely improbable that the actual contagious particles of small-pox or cholera, or similar diseases, are ever detached from the serum and other matter with which they are associated when thrown off from the body. They are, no doubt, invested with some such film as that which protects the contagious granules in vaccine. If ordinary gaseous disinfection sometimes fails to destroy the vitality of vaccine, and has no effect on ordinary microzymes, we cannot rely upon it as a means of destroying the contagia of zymotic diseases which certainly are near akin, if not to bacteria, at least to the virus of vaccine. The recent experiments of Crace-Calvert show that bacteria sustain a very high temperature without being killed; and on the other hand, Melsens in the 'Journal de Pharmacie et de Chimie' for September, 1870, shows that vaccine lymph retains its activity when exposed to the intense cold of 80° Centigrade. The low forms of life are often capable of resisting influences which, in the case of the most highly organized animals, would produce fatal results.

No doubt, chlorine, sulphurous acid, and some other of the so-called disinfectants, destroy bacteria and contagia; but in order to do this, they must be employed in much larger quantities than they have hitherto been used. *Strong* solutions of disinfectants, when mixed with liquids containing microzymes, kill these animalcules, and the germinal matter from which they are evolved; but gases appear to have comparatively little effect in destroying bacterium life.

The following directions for disinfection, issued to the medical officers of the army, will serve to illustrate the absurdity of the present methods of disinfection :—

"To fumigate a room 60 feet long, 20 wide, and 12 high,

1. Take common salt	4	ounces.
,, oxide of manganese	1	,,
,, sulphuric acid	1	,,
,, water	2	,,

"The water and acid to be mixed together, and then poured over the ingredients, in a delf basin, which should be placed in a pipkin of hot sand.

"With nitrous acid gas,

2. Take copper shavings	½	ounce.
,, nitric acid	1½	,,
,, water	1½	,,

"Pour the acid and water upon the copper, in a small jar.

"With sulphurous acid gas,

Burn two ounces of sulphur in a pipkin."

The complete disinfection of a room tainted with the poison of contagious disease can only be accomplished by the most thorough cleansing. The paper should be removed from the walls, and the latter scraped. The ceiling should be washed and whitewashed, the woodwork and floors should be scoured; all these detergent processes remove—probably without utterly destroying them —the contagious particles. The old-fashioned plan of simply whitewashing the walls and ceiling of a room, and washing the woodwork has much to commend it, and it is infinitely more efficacious than gaseous disinfection without liquid applications. If the whitewash does not kill the bacteria, it certainly imprisons them securely. The disinfection of the air of the room is best accomplished by a solution of chloride of lime, carbolic acid, chromic acid, chloralum, etc., applied in the form of spray; but this process is not likely to be generally adopted. A little chlorine may be generated in the room, and if it do no more than remove a bad odour, it will prove useful. As people cannot comfortably breathe in a room which has just been disinfected by sulphurous acid, or chlorine, they are obliged to open doors and windows, in order to admit the fresh air. In this way the use of disinfectants is to be commended, because it obliges people to ventilate their apartments. If solutions of disinfectants be applied to the walls and woodwork, they should be strong ones—say half a pound of chloride of lime to an imperial gallon of water. With respect to clothing and furniture, unless they can be treated with strong disinfecting solutions, or exposed to a temperature of 320° Fahr. for eight hours, it were better to destroy them by fire.

In the discussion that followed the reading of this paper—

Dr. Malachi Burke said he thought Dr. Cameron's paper one of great importance. He wished to refer to what had been recently stated by a distinguished member of the Public Health Committee of the Corporation, that a house or a room could be disinfected in two or three hours. If the work of disinfection could be done so rapidly, what were they to say to Dr. Cameron's paper? He wished to ask Dr. Cameron what time he would consider necessary for the disinfection of a house?

Dr. Grimshaw said the gentleman referred to by Dr. Burke stated that the Corporation disinfected clothing by heat in two hours, but Dr. Cameron said it would take at least eight to do it effectually. The process of disinfection was carried out by the officers of the Public Health Committee after this fashion. A man comes with a pint of chloride of lime in an old battered tin; he dilutes it with sulphuric acid, places it in a vessel in the middle of the room, shuts it up and leaves it there until the next morning. The usual course when he turned his back was for the owner of the room to throw the disinfectant out of the window. There were but two men at present employed by the Public Health Committee disinfecting the whole of Dublin, so that chemical disinfection, or disinfection by gas, was not fairly tested in that city; and it appeared that only one in thirty-five of all the houses reported as being infected by small-pox had been disinfected. The whole question that Dr. Cameron had discussed depended on a point which was by no means sufficiently determined; he did not believe it was proved that bacteria were the essential accompaniments of contagious disease, so that the killing or non-killing of those organisms could not be taken as a proof that disinfection had been effectually accomplished or not. So far as they knew at present, the only effective disinfectant was a high heat, and even more important were detergent measures. It was only recently it had been announced in Dublin that gas was a disinfectant. Formerly such a thing was never attempted as trying to purify a house by fumigation. The houses in which there had been contagious disease were all cleaned, scraped, and swept out. This was the plan pursued until the matter was taken up by the city authorities, and they seemed to have assumed that a small quantity of chlorine spread in a room would effect its purification.

Dr. Darby said that in the process of disinfection now employed they were using chemical agents to destroy they did not know what. He believed that plenty of soap and water and pure air were the best disinfectants. When small-pox appeared in the hospital under his care, he placed over the doors of the ward a curtain steeped in a solution of chloride of lime. He did not know that it did any harm, and he doubted whether it did any good; but he had great faith in fresh air and in cleanliness. The fact that these epidemics come suddenly, rise gradually to a maximum, and then decline was an argument against the germ theory. If that theory were true would not the epidemic continue to spread more extensively the greater the number of people suffering from the disease, and, therefore, the greater the likelihood of its being communicated to others?

Dr. Lyons rose to say a few words, rather to avoid being taken as concurring with many of the statements that had fallen from Dr. Cameron than as thinking they could enter profitably on the present occasion into a discussion of the many points he had raised. The basis of his paper seemed to be an assumption that the germs for the introduction of disease were different for different diseases, and that in the next place, those germs or microzymes had some close affinity, or relation to, if they were not identical with bacteria, vibriones, etc. He (Dr. Lyons) could not be taken as concurring in the idea that minute microscopic animalcules or vegetations were the germs or origin of any but a few and well-defined forms of cutaneous disease. He thought they were travelling in an entirely wrong direction in looking for the origin of epidemic disease in that quarter. He had himself an idea that diseased processes, however variable in their superficial manifestations, were, when viewed from a profound pathological point of view, more nearly allied, and much more closely similar in their essential conditions, than would be supposed from a superficial view of them. He had in his own mind the elements of a theory of disease, of which he was not yet prepared to produce the proofs in all their details, the principle of which was the unity of all diseased action in the body: that whereas, for instance, in cases of cerebro-spinal meningitis there was an especial manifestation of nervous power of one kind, there were other forms of disease, in which the activity of the nervous system was brought into play in a different manner, causing one class of eruption on the skin in one epidemic, and another kind of eruption in another epidemic. But that was a subject of too wide a range to be followed upon that occasion. He did not think Dr. Cameron had undertaken to say that the use of gaseous disinfectants would not to some extent destroy the supposed germ of disease, admitting, for argument's sake, that such germs did exist. What his paper had shown, as far as it had shown anything, was that by the use of very large quantities, and especially by potent solutions, of certain powerful agents, we could destroy the vitality of bacteria, or prevent their development. He (Dr. Lyons) for one was not prepared to admit that all diseases were propagated by contagion, that like generated like in disease, or that contagion would explain the development of all epidemic diseases. He doubted if, in the present condition of knowledge, any two persons in that room would agree as to what was, and what was not contagion, or what was to be accepted as the element of contagion in any given case, or, if admitted, how its action was to be explained. He might observe that he thought they were all too hard on the corporation of Dublin. How could that body undertake for the disinfection of a large city, to employ the thousands of tons of disinfecting agents which would be necessary on the basis of Dr. Cameron's calculation? In his opinion they were a long way off yet from having ascertained the true origin of any of the principal forms of epidemic diseases. His view was that they followed a certain course of development in cycles, and were to be explained by the destruction of a certain portion of nervous energy in the individual and in the population, and not so much as was ordinarily supposed by any form of contagion, in the sense in which that word had been hitherto employed so vaguely and so unscientifically.

The Chairman (Dr. Aquila Smith) thought Dr. Cameron had, to a great extent, established the object he had in view with respect to the action of disinfectants. He had shown that it required a much higher degree of concentration to destroy animalcules than had been heretofore considered necessary. He thought until they had something more tangible than they had as yet, they were not able to say that disease was propagated by germs, and that the study of the natural history of epidemics would throw more light on the subject The Metropolitan Sanitary Board of London requested returns to be made from all the vestries who employed people in cleaning the sewers, of the number of persons employed in that way, the age of those persons, the duration of their employment, and the cases of fever amongst them. 234 individuals were included in the returns. A great many of them had been engaged 17 years in that occupation, and the whole sum of the cases of fever amongst them was six. That struck him as a very remarkable event.

Dr. Cameron, in reply, said that all he could find in Dr. Grimshaw's remarks was that there was a something in contagion which heat destroyed. If that something were any of those abnormal conditions of the air, or loss of nervous energy, of which they had heard, he did not see how an increase of temperature or whitewashing could destroy it. There was a something which was capable of communicating disease from one individual to another; for there could be no doubt there was contagious matter in small-pox pustules, in farcy in the horse, in pleuro-pneumonia in the ox, and in vaccine, and we could produce any of those diseases by introducing a certain kind of morbid matter into the blood of an animal. This palpable matter could be reduced in an almost infinitesimal degree, and yet be capable of conveying disease. Any one who read Chauveau's experiments would see he clearly proved there were living particles in vaccine, and in the matter from sheep and ox pustules; if they were taken out of the fluid, it became non-contagious; but if left in it, it remained contagious. What could be a greater proof of the germ theory? Dr. Darby stated that lice assumed an epidemic form. Did not that go far to prove the germ theory? Surely Dr. Darby did not mean to say that where lice and itch became epidemic diseases, there was an actual creation of lice and acari? If he did not go to that extent, he must admit that those diseases could only be propagated from individual to individual. With regard to these diseases, they might be spread in a great many ways which appeared to be extraordinary and unaccountable; but when they carefully inquired into the mode by which the contagion was communicated, they were often able to penetrate the mystery. For example, the recent report of the Board of Health, in Victoria, gave an extraordinary instance of the spread of small-pox contagion by myriads of flies in a place where there was little or no communication with the districts in which the disease first appeared. It was found that the disease spread in the direction of the flight of myriads of flies that had previously tormented small-pox patients, and which carried from them the contagious matter, whatever it might be. Dr. Lyons, he knew, was not a strong contagionist, but he misunderstood one or two of his (Dr. Cameron's) experiments. He did not mean to say chlorine would not do some service. All he wanted to say was that unless used in very large quantities it did not destroy the lowest forms of life, and then he asked why did they use chlorine at all? Every physician who used chlorine must have had some foregone conclusion as to its effect? Surely it was not to produce a change in nervous energy; it must be to do some specific thing—that is to destroy contagion—

and could anything be more reasonable if contagion was to be found in the floating objects in a room? The germs of disease, or, at all events, bacteria, did not float in the room, and they were not destroyed by the quantities of the disinfectants ordinarily used. To destroy them larger quantities must be employed, and they should be, in great part, used in solution. He had dipped a brush in a strong solution of chloride of lime, and passed it over a glass on which there were bacteria, He then passed over this water, which had been previously heated to a high degree, and he found the bacteria were destroyed. As to what Dr. Smith had said about sewers, it establishes the theory of contagion. There was no other theory that afforded a satisfactory solution to immunity from epidemic diseases in certain cases. The immunity of the persons employed in cleaning the sewers merely showed that decomposing ordinary animal and vegetable matter, *per se*, would not produce zymotic disease. He knew a family in the country who persistently drank water that contained 20 grains of organic matter per gallon; it had even a bad odour, and it came from a well so situated that the drainage from the stable-yard and out-offices flowed into the shaft of the well. The family, as he had said, drank it continuously, and yet no contagious disease had ever broken out amongst them. Why? The water was impure, it had a bad smell, but the germs of disease were not there. Time was a great factor in disinfection. He found that the quantity of disinfectant matter applied in gaseous form which would not kill bacteria in a short time, would do so after a prolonged contact. They could not properly disinfect a house in less than twenty-four hours. No house in which a small-pox patient had died could be considered free from contagion until the walls were scraped and white-washed, and the place thoroughly swept out.

Parliamentary and Law Proceedings.

Alleged Adulteration of Butter.

At the Liverpool Police Court, on Wednesday, Dec. 18th, before Mr. Raffles, Edward Kelly and Co., provision dealers, Dawson Street, were summoned for selling "as unadulterated an article of food, to wit, butter," which was adulterated, contrary to the recent Adulteration of Food Act. The information was supported by Mr. Atkinson, deputy borough solicitor, and Mr. Segar, barrister (instructed by Mr. Yates), appeared for the defendant.

G. H. Robinson, an inspector of nuisances, stated that he went to defendants' premises on the 28th ult., and asked an assistant who was behind the counter to let him have a pound of 7*d*. butter. The assistant supplied him with the article, and received the money for it, after which witness told him that he was going to take it to the public analyst. He also informed Mr. Kelly of his intention, telling him that he could send somebody with him if he liked, but he did not do so. Witness then took the butter to Dr. Brown, the public analyst.

Inspector Fitzpatrick produced a certificate that he had received from Dr. Brown, and which referred to the butter bought by Robinson, at the defendants' shop. The document was as follows:—"This (the sample of butter) contains a quantity of stearin and palmatin; it is, therefore, largely adulterated by the admixture of fats containing these substances, the most common of which are lard, tallow, dripping, palm oil, and the fat from certain seeds. This adulteration is not necessarily injurious to health."

Dr. Brown was then called, and justified, in scientific terms, the conclusions at which he had arrived and stated in the certificate. He was of opinion that the fats mentioned had never passed through the udder of the cow or other animal, and that they were not the constituent parts of milk or butter.

Cross-examined by Mr. Segar: He said he could not deny that there was not naturally a certain kind of palmatin in butter, but he was quite confident that in the pure article there should be no stearin.

Mr. Raffles said he did not think that he ought to be called upon to judge of the scientific evidence. The question for him to decide was, whether there was a foreign substance in it which was not butter. Could Dr. Brown say that there was?

Dr. Brown: Certainly.

Mr. Segar subjected Dr. Brown to a long cross-examination, and elicited from the witness that he had not the slightest doubt that there were other fats in the butter analysed than those which passed through the udder. There were fats apparent which were largely used in the adulteration of butter.

Mr. Raffles: Does the admixture increase the bulk or weight of the butter?

Witness: It increases the bulk and weight.

By Mr. Segar: Would not assert that there was lard in the butter, but there was fat from the melting of the flesh of animals—pigs, sheep, or cows. There was a substance similar to palmatin in butter. It was, however, different from that which he found by his analysis. A scientific man could find the difference between stearin and palmatin in fats from butter and fats from the flesh of animals.

Mr. Raffles said it was necessary for Mr. Atkinson to show that the seller had a knowledge that the butter had been adulterated with intent fraudulently to increase its weight or bulk. The third section of the Act said, "Any person who shall sell any article of food, or drink, or any drug, knowing the same to have been mixed with any other substance, with intent fraudulently to increase its weight or bulk, and who shall not declare such admixture to any purchaser thereof, before delivering the same, shall be deemed to have sold an adulterated article under this Act."

Mr. Segar submitted there was no evidence at all with regard to the bulk or weight.

Mr. Atkinson said he did not propose to show that. He had shown by the second section, under which the proceedings were taken, that the article sold was adulterated, and that therefore an offence had been committed. The second section provided that "any person who shall sell any article of food or drink with which, to the knowledge of such person, any ingredient or material injurious to the health of persons eating or drinking such article has been mixed, and every person who shall sell as unadulterated any article of food or drink, or any drug which is adulterated shall, etc., pay a penalty of £20." He contended that the present information could be sustained, though it was not proved that the person selling the butter knew it to be adulterated.

Mr. Raffles felt that before he could convict, it must be proved that the person selling knew of the adulteration. No penalty was attached to the third section. He was, therefore, of opinion that the third section was intended as an interpretation of the other sections.

Mr. Atkinson submitted that it would be most unfortunate if his Worship's ruling was a correct one, as it would have the effect of repealing an Act passed for the protection of the public.

Mr. Raffles repeated that it must be shown that the seller knew of the adulteration. In the milk cases lately decided the adulteration was so apparent that the fact of adulteration must have been known to the sellers.

Mr. Atkinson thought that the onus of proof that there was no adulteration should rest with the seller. When a person sold an article, such as butter, he ought to know of what it was composed.

Mr. Segar said that the butter was Canadian butter, and Mr. Kelly could not therefore know what it contained. Moreover, they had an eminent analyst in court who would be able to demonstrate that the butter was beyond question pure.

Mr. Raffles said he must hold it necessary to prove that the seller had a knowledge of the adulteration. As this had not been shown the summons would be dismissed.

Mr. Atkinson said that under the circumstances he should withdraw seven other summonses.

Mr. Raffles, on the application of Mr. Atkinson, granted a case.

Mr. Segar applied for costs, but they were refused.

It will be seen that the defendant's version of the case was not heard, in consequence of the summons having been dismissed from want of evidence that the defendant was aware of the presence of an adulterant. The *Liverpool Courier* states that it has been supplied with the following list of quotations as to the component parts of butter, by Mr. Martin Murphy, analytical chemist, who would have given evidence as to the purity of the butter had the case gone on:—

Fownes' 'Handbook of Chemistry,' new edition, 1872, page 733, says, speaking of stearin and stearic acid, "It is found in the softer fats, such as butter of cows' milk, etc." Gmelin's 'Chemistry,' published by the Cavendish Society, vol. x., page 387, organic section, says, "Summer butter contains relatively larger proportions of olein; winter butter of stearin." Miller's 'Elements of Chemistry,' 4th edition, 1869, vol. iii. page 294, says, "Butter consists of a mixture of olein with several fats, amongst which palmatin is the principal solid constituent."

And Watts's 'Dictionary of Chemistry,' vol. i. 1863, article "Butter," says, "Ordinary butter, from cows' milk, is composed, according to Chevreul, of stearin, margarin, and olein, with small quantities of butyrin caproin and caprin, to which its odour is due. According to Heintz, it contains olein, a large quantity of palmatin, and a small quantity of stearin, etc."

From these statements, he says, it would appear that the components of butter are also those of lards and tallows, but in variable proportions. He doubts if the learned analyst could extract stearin from seed oils.

Alleged Adulteration of Milk.

At Worship Street, on Monday last, Mr. Job Mansfield, a cowkeeper, of Bethnal Green, attended, in answer to a summons charging him, under the Act lately passed, with selling adulterated milk. Mr. Fenton represented the defendant.

Edward Hutton, a dairyman, carrying on business in Mostyn Road, Old Ford, said that he had been in the habit of dealing with the defendant for milk, which he subsequently retailed to his customers. They had complained of the quality of the milk, and witness, in consequence, sent a sample, in the condition in which he received it from the defendant, to Dr. Sarvis, and another to Dr. Woodford, of Bethnal Green. He also saw the defendant upon the matter and showed him the milk, which he admitted to be "not very good." He then threatened to proceed against the defendant, who replied that he could not be fined £50, as clean water was not anything bad. Corroborative evidence was given. The wife and the son of the complainant said that on one occasion when his father spoke to the defendant about the milk, his reply was that there was nothing but clean water in it.

Dr. Sarvis deposed to testing the milk brought to him, which he found to contain one-fifth of water.

In defence the foreman to Mr. Mansfield was called. He said that on the day in question he was with the milk from the time it came from the barn till delivered to the defendant, and up to that time not a drain of water was put to it. His master supplied wholesale dealers, who, he believed, watered it. That was called "Simpson." In cross-examination he said that the milk was delivered to Mrs. Johnson in the dairy. He could not, of course, say if she watered it or not. There were seventy-five cows on the premises and several pumps. This witness subsequently contradicted his previous statement as to having noticed the milk on the morning in question.

James Horsley, a dairyman, said that he dealt with the defendant for milk, and served his customers, who, so far from complaining, generally praised the milk. Witness "generally" milked the cows for himself, and then added "Simpson" at discretion.

Dr. William Woodford, called by direction of the magistrate, said that he was one of the inspectors appointed by the parish of Bethnal Green under the Adulteration Act. The milk in question as brought to him had only water added to it—15 to 20 per cent. The average specific gravity of milk was 1030.

The magistrate said that there was not, in his opinion, sufficiently independent corroboration of the complainant's evidence to support this case, and therefore he dismissed the summons.—*Times*.

Action against a Chemist.

Liverpool Winter Assizes, December 20th.

(Before Mr. Justice Lush and a Special Jury.)

POWELL *v.* HINGSTON.

The plaintiff is a perfumer and hairdresser, and the defendant a chemist and druggist in Bold Street, Liverpool, and this action was brought for injuries suffered by the plaintiff in consequence of the defendant supplying him, as was alleged, negligently, with a bottle of nitric instead of sulphurous acid. It appeared that in April last the plaintiff had been ill, and was using, by the orders of his medical attendant, for a relaxed throat, an application of sulphurous acid, which was administered by means of a "spray." He was in the habit of getting the acid for the purpose at the defendant's shop, the prescription having been first sent to the defendant some time previously, and the bottle, having the label upon it, containing the words "poison" in print and "sulphurous acid" in the defendant's handwriting, having subsequently been refilled on several occasions. The bottle was a 2-oz. bottle. The plaintiff had also been in the habit of obtaining other substances at the defendant's shop both as medicines and for the purposes of his business, and, among others, nitric acid, used either as an ingredient of the ladies' hair dye called "auricomous," or for bleaching the hair before applying the dye. The plaintiff and his witnesses stated, however, that this description of acid was always obtained in a larger and wider bottle than a 2-oz. bottle—viz., a 6-oz. bottle, having the same description of label printed "poison," as the other, but with "nitric acid" written in the defendant's handwriting instead of "sulphurous acid." The plaintiff's case was, that on the 4th of April, a little girl took the smaller bottle used for the sulphurous acid, and having that label upon it, to the defendant's shop, and asked for "Sixpennyworth of this stuff; the name is on the label." The bottle was filled by the defendant himself, but with nitric, and not sulphurous, acid. When the nurse uncorked the bottle she was struck with the fumes that came from the acid, but reading "sulphurous acid" on the label, she was re-assured, and used it on the plaintiff's throat. He immediately shut his mouth, but the acid had gone into the throat and also on to the chin and face. The consequence was that the plaintiff was very much burnt, and he bears now permanent scars upon the mouth and chin, and suffers still acute pains when in a hot room or temperature. It appears that he is an amateur musician, and plays upon most wind instruments, and these injuries have considerably interfered with his ability to do so. The day after the accident Miss Edwards, the plaintiff's assistant, went to the defendant's shop for some magnesia for her master, and the defendant went back to the plaintiff's shop with her, where she showed him the bottle. He carried it away with him, and it has never been seen since. A chemist had been sent for, however, immediately on the happening of the accident, and he said that he looked at the label on the bottle, and, reading there "sulph." on that part of it which the acid had left unburnt, exclaimed, "Why this is nitric, and not sulphurous acid!" The defendant afterwards stated that he was very sorry for what had happened, and gave the plaintiff a £5 note in consideration of the injury.

The defendant's case was, not only that there was negligence on the plaintiff's own part sufficient to disentitle him to recover, but also that there was no negligence at all on the part of the defendant. He and his assistant and porter brought from his shop stated that the little girl brought a bottle with a label almost obliterated, and asked for "three or four pennyworth of the acid," and that the defendant ordered the porter to wash out the bottle and the assistant to fill it with nitric acid. He then wrote out a new label with "Nitric acid" upon it, and put it on the bottle, and giving the girl a caution about taking care of the acid, which would burn her, sent her off with it. When the defendant got the bottle from Miss Edwards the next day it still had the "nitric acid" label upon it, and the defendant produced it in court as having been in his possession ever since. This case was further supported by the evidence of the plaintiff's own medical attendant, Mr. Taylor, who was called in in the confusion immediately after the accident, and he stated that he then saw the bottle, and that it was labelled "nitric acid." On this point his evidence was in direct contradiction of that of the chemist, who also saw the label, and spoke to its containing "sulph." and Mr. Taylor was closely cross-examined as to a part he was accused of taking in attempting to compromise the case, and also as to his complaining that his bill had not been paid by the plaintiff, and threatening that he would not be able to give the same evidence in the case as if it were. He entirely denied these suggestions, however. With reference to the nurse's declaring that she had read "sulphurous acid" on the label, it was said that she was unable to read, and she certainly appeared unable to read letters put into her hand in the witness-box.

In consequence of the contradictory evidence on the two sides in this case it became invested with more than an ordinary amount of interest, and the learned counsel on both sides made most able and forcible speeches. In the result the jury found their verdict for the defendant. —*Times.*

Charge of Fraud against a Herbalist.

At the Hull Police-court, on Friday, December 20th, Henry Jackson was charged on remand with obtaining money under false pretences from John Richardson. The particulars of the former hearing were reported last week at p. 494. In his evidence the prosecutor stated that on his first visit the prisoner gave him a glass containing a liquid, and told him to blow through a tube into it. The liquid turned white, which prisoner said was a sign of bad health. This was repeated on subsequent visits, when the mixture did not turn so white, and the prisoner said it was a sign his blood was clearer. Prosecutor then described various other articles for which he had paid money on the representations of the prisoner, such as a box made of cedar of Lebanon, containing "Indian balsam" (for which he paid £27), "bread of life," Indian myrrh, spikenard ointment, two "Indian pulse glasses" (eight guineas per pair), galvanic fluid, elixir of life (eight guineas a bottle), sediment of gums 30*s.* a box), and a box (£50), containing, among other things, gold and silver pills, "extracted from the roots of trees in gold and silver mines."

The prisoner was again remanded.

The Adulteration Act.

Sir,—It is only for the purpose of eliciting the sentiments of others interested in questions connected with the working of this Act that I venture to trespass on your kindness again, by giving insertion to this letter in your next issue.

I see in an article in Saturday's Journal you enumerate the appointments of analysts made under this Act in the different metropolitan districts, and that some of these have accepted the office with the fees for their sole remuneration. This fact, Sir, strikes me, as being so singular, that I am anxious to know what sort of an analysis is to be made for half-a-crown. As an example, take milk as one of the simplest that can come before an analyst. How far is the analysis to be carried? It cannot stop at the specific gravity. It must go to the proof of the adulteration or otherwise. And supposing a prosecution follows, who pays the attendance at Court of the poor recipient of a half-crown fee? Will he be expected to do that extra duty for the same exorbitant fee? Again, there is a strongly latent suspicion in the public mind that beer and wine are almost universally adulterated, therefore it is probable these may often be submitted for analysis. I shall be glad to know the chemist that could make such an analysis for half-a-guinea. Cheap labour cannot be good, more especially the highly skilled labour such as is required in making these examinations. The probability is, serious mistakes will be made, as was the case at Liverpool last week, and the office of analyst brought into contempt. It is one thing to know a subject by reading, and another to really know it by experience.

F. M. Rimmington.

Bradford, December 23rd, 1872.

Chemists as Analysts.

Sir,—Every one will agree with Mr. Rimmington that Mr. Haselden took a step in the right direction when he asserted the right of duly qualified chemists to be eligible candidates for the office of public analyst.

Up to the present time the chemist's efforts to raise his social position by means of a higher educational qualification has received no recognition; it ought not to be forgotten that the first steps taken were voluntary, and long before public opinion had made itself heard upon the subject. With regard to the office of analyst, I feel sure that there are few large towns but contain at least one man equal to the duties of the office; as to the future, let it once be known that the course is clear, and few students would neglect the requisite studies. I still adhere to my formerly expressed opinion, that the present state of the business does not justify the high standard of qualification now demanded unless those in authority have made up their minds to strain every nerve to render it more remunerative; that they can only do by securing dispensing for the legitimate dispenser, and in every way asserting the rights of those who have always shown themselves willing to meet the requirements of public opinion and make themselves worthy of the just reward they ask for.

Henry Lawrence.

Kensington, December 23rd, 1872.

Lady Students.

Sir,—I was much surprised to see by the report of the Council Meeting which appeared in your issue of December 7th, that Mr. Hampson's motion respecting the eligibility of lady students to compete for the sessional prizes was even made the subject of a discussion, and I do not at all understand on what grounds it can be contested after they have once been admitted to the lectures.

On page 169 of the Calendar for 1872, which, being published by the Council, I take to be a trustworthy authority on the regulations of the prizes, etc., we are informed that "At the expiration of the session a competitive examination of the students in each class is held, and the Council award medals and certificates of honour and merit to the successful candidates." Evidently all students attending the respective classes are equally eligible to compete for, and one would naturally suppose equally eligible to take, the prizes to which their answers may entitle them. The letter which appeared in the Journal of December 14th shows that the ladies now attending the lectures have their time quite as fully occupied as a large proportion of the other students; and (should the opposition of part of the Council continue) it would be only an act of courtesy on the part of the gentlemen to petition the Council to grant the ladies equal privileges with themselves—a step which would show that they are not afraid to meet them in competition, on what I believe to be all the ladies desire, viz., even terms. Hoping soon to see both sexes in possession of the same facilities for study in laboratory as well as lecture work.

SALE OF DRUGS, ETC., BY GROCERS.

Sir,—In reply to your correspondent 'W. Metcalfe,' I would suggest that when he is prepared to set up branch shops with duly qualified managers in every village, then will be soon enough for shopkeepers to give up selling the drugs usually kept by them; such a law as he proposes would inflict great inconvenience upon the poor of agricultural districts, who are not able to drive ten or twelve miles to the nearest town, or keep supplies in the house. In most villages it is looked upon as a public convenience if the shopkeeper will hold a stock of medicines in common use, so that the people can get when they need them such things as aperient pills, tinct. rhubarb, etc. With an extensive acquaintance amongst country shopkeepers, I am quite sure that I am right in saying that they are wishful to avoid the sale of dangerous medicines, and that serious accidents at their hands are as rare as amongst surgeons and chemists. It would be wise to advocate to shopkeepers the sale of drugs ready put up in packets and bottles, duly labelled by the chemist. Let us carry out the Pharmacy Act thoroughly, but at the same time not be too ready to find fault with those who are outside the trade, remembering that accidents do take place with us as with outsiders, *e.g.*, see the letter preceding Mr. M.'s., where particulars are given of the use of liq. morphia instead of aqua pura. Speaking of poisons, it seems very desirable that there should be more uniformity about registering vermin killers. Some of us have done it for years, but are sometimes told by customers that they can get it at other chemists "without any bother." It is a good deal of trouble to all parties, but if unfortunately an accident should occur, the seller who had observed the law would be in a much better position before the public and the jury.

J. F.

November 30th, 1872.

UNUSUAL DOSES.

Sir,—As an amendment to the suggestion at page 473 I would propose that whenever an unusual dose is intended, the prescriber shall show that he knows the Pharmacopœia maximum dose, by placing that first and the excess after, both included in brackets under the ingredient referred to.

All doubt would then be removed. For example, take the following well-known prescription to hand this day:—

℞. Potass. Iodid. . . ʒ iv.
Ammon. Carb. . . ʒ j.
T. Cinchon. . . ʒ xij.
Julep. Camph. ad ℥ vj.

M. ft. mist. A tablespoonful for a dose in water as before.

We know that this dose may be far exceeded, but many an inexperienced though examined man might hesitate to give the full quantity of potassii iodidum. Then for the future let the top line be written as below. It would look neater (though not necessary) to convert it into an equation by placing the number of doses before the brackets to balance the total ordered. Thus:—

Potass. Iodid. . . . ʒ iv.
12 (gr. x + gr. x)

Another example which is more interesting in its way (the prescriber having intended to give two grain doses but ordered ten) was thus written:—

℞. Pulv. Opii . . . gr. xxx
Sapo Cast. . . . q.s.
M. ft. pil. vj. Capt. ij. p. r. n.

Now, no accident in this case need happen if the dose were interlined as I have proposed.

I would further suggest that a committee of physicians and pharmacists be appointed to consider this subject, a subject which affects their reputation as well as their patients' welfare.

Their attention should also be directed to the following:—

That the dispenser shall be justified in reducing to the Pharmacopœia maximum dose when that ordered is excessive and not interlined.

If the above suggestions were laid down as rules emanating from a properly constituted commission, the prescriber would secure the accurate dispensing of his unusual doses, the patient would gain a great safeguard, and the dispenser would have removed a serious responsibility.

H. SIMPSON.

Regent's Park, December 17th, 1872.

REMUNERATION OF ASSISTANTS.

Sir,—The suggestion thrown out by Mr. Lindley in your Journal of November 23rd would, if adopted, receive the earnest support of the great mass of assistants. Something must be done, for an assistant's life, as at present constituted, is one continuous round of slavery.

A more badly paid, harder worked set of men do not exist. If employers be not wise in time, they will have difficulty in obtaining assistants at all. Everybody leaves the business who can, and they do not fail to give advice to would-be future apprentices. I do not condemn employers wholesale, for I believe the majority would be favourably disposed to ameliorate the present state of things, and I agree with Mr. Courtenay, that many who give high salaries can barely afford it.

The proper remedy would be for employers to take the initiative, by coming to some common agreement to close their establishments at a given time, and,—if not advancing the price of medicines,—to charge one uniform price, thereby gaining the respect, instead of, as at present, the distrust of the community.

There unfortunately exists such an utter want of "understanding" between man and man—each jealous of his neighbour—as does not exist in any other trade going. That being the case, the only course I see open is for assistants to combine, form some such a society as Mr. Lindley suggests; and I have no doubt that it would not only result in benefit to themselves, but to employers, who, having one line of action to pursue, would establish a better feeling, resulting in one uniform scale of prices (or an advance), and a much greater reduction in the hours of labour.

EXCELSIOR.

December 2nd, 1872.

THE PUNGENCY OF WATERCRESS.

Sir,—I shall be glad if some of your botanical readers will give me some information as to the difference in flavour between two specimens of *Nasturtium officinale* which I recently collected. The first was gathered in a mountain stream, and in this I observed that the peculiar pungent flavour was particularly strong; the other grew in stagnant water on a plain, and in this the pungency was extremely delicate, in fact, hardly perceptible. This plain is several miles in extent, and the cress grows in the ditches which separate the fields; it is in close proximity to the sea, and in former years the tides overflowed a considerable portion of it.

It is well known that the flavour of watercress is much stronger during the winter months, but how are we to account for the difference in degree of pungency between these two specimens collected at the same time?

AN ASSOCIATE.

"*Spes.*"—(1) The books mentioned should be of great assistance to a beginner. (2) The British Pharmacopœia. (3) The certificate required will be to the effect that the person has been employed in the trade three years, but not necessarily to one person.

F. Parsons.—Suppository moulds may be made of many less expensive substances than gun-metal. See an article in PHARM. JOURN., vol. II. [1871] p. 26.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Broad, Bell, Smith, A. H. Mason, Gurnell, Benger, Dunn and Co., Sturton, Southwell, Shaw, Hutchinson, Macintosh, Reade, T. W. P., D. V. S. "Studens," *Liverpool Courier*, from Messrs. Clay and Abraham; *Liverpool Daily Post.*

THE EFFECT OF MANURES ON THE ALKALOIDAL YIELD OF CINCHONAS.

At the suggestion of Mr. Broughton, the Government Quinologist at the Ootacamund Plantation, the Government of India sanctioned some experiments being made with certain artificial manures, to ascertain if their application to cinchona-trees would increase the alkaloidal yield, and the results have recently been made the subject of a letter from the Revenue Department of Madras.*

For this purpose 12 cwt. of ammonic sulphate and 9 cwt. of Peruvian guano, both of good quality, were ordered from England. These manures were applied to trees of *Cinchona succirubra* and *C. officinalis* in quantities of 4 oz. to 1 lb.

Some fine three-year-old plants of *C. succirubra* were treated in November, 1869, in plots of fifty each, with 1 lb. of ammonic sulphate and the same quantity of guano, but no perceptible increase in luxuriance or rapidity of growth was noticed up to the month of January, 1872. At that time bark from manured and non-manured *succirubra* plants was submitted o analysis with the following percentage results:—

	Manured.	Unmanured.
Total alkaloids	7·25	4·89
Quinine	2·45	1·78
Cinchonidine and Cinchonine	4·80	3·11

This showing a gain by manuring of 2·36 of alkaloids, 0·67 consisting of quinine.

Trunk bark of trees manured with 1 lb. of guano gave the following results as against trees not so treated:—

	Manured.	Unmanured.
Total alkaloids	5·29	4·76
Quinine	0·91	1·04
Cinchonidine	4·38	3·72

This showed but an increase of 0·53 of total alkaloids, and the manured bark contained 0·13 less of quinine, owing possibly to the exciting action of the guano hastening the change through which, as *C. succirubra* grows older, it loses its alkaloidal yield.

From the results of these experiments Mr. Broughton does not recommend that *C. succirubra* should be manured, as the cost of manure would outweigh the small increased richness in the bark.

The *C. officinalis* has always been noted for its extreme sensitiveness to situation, sun-light and character of soil, and therefore Mr. Broughton was the more anxious to test the effect of manures on this species. Trees were therefore placed under the same conditions with regard to time of manuring; and the bark of trees treated with 1 lb. of guano, though differing in no respect while growing, gave the following results compared with the bark of unmanured trees—

	Manured.	Unmanured.
Total alkaloids	6·51	3·98
Pure quinine	4·41	2·40
Cinchonidine and cinchonine	2·10	1·58

Thus by this treatment showing a gain of 2·53, of which increase 2·01 was quinine. With other trees of the same species, treated with ¾ lb. ammonic sulphate, the results were as follows—

	Manured.	Unmanured.
Total alkaloids	5·76	4·54
Pure quinine	3·11	2·54
Cinchonidine and cinchonine	2·65	2·00

Thus showing an increase of 1·22, of which 0·57 was quinine.

During the period between 1867 and 1872, trees of *C. officinalis* were treated with about four barrowloads of farmyard manure each. In February, 1872, bark from trees so manured was analysed—

	Manured.	Unmanured.
Total alkaloids	7·49	4·68
Pure quinine	7·15	2·40
Cinchonidine and cinchonine	0·34	2·28

This analysis gives in favour of manuring 2·81 of total alkaloids; but the most remarkable fact is that it has favoured the production of quinine over cinchonidine and cinchonine, the total increase of quinine being no less than 4·75.

On these results Mr. Broughton remarks that stable or farmyard manure has somewhat of an advantage over the more artificial manures. The effect of these manures is only seen in analysis, as, during growth, no greater luxuriance is noticed in manured trees than in trees not so treated. These results appear to bear out Mr. Broughton's hypothesis, "that the alkaloids in the bark of the trees are not specially active constituents in the processes connected with the life and growth of the plant; and this supposition is supported by the circumstance that the increased amount of alkaloid produced by the manure caused no change in the appearance and rate of growth of the tree."

Mr. Broughton thinks these experiments to be so important that he has made application for further supplies of manure, and proposes that, if stable manure cannot be obtained in sufficient quantity, guano should be the manure used.

* Proceedings of the Madras Government Revenue Department, April 10th, 1872, No. 93.

STRIATED IPECACUANHAS.*

BY M. PLANCHON.

It is known that writers on materia medica designate under the name of "striated ipecacuanha" emetic roots which are distinguished from other sorts of ipecacuanha by the longitudinal striæ that mark their surface. This kind appeared to be perfectly characterized and its history cleared up, when some years since there appeared a memoir by M. Vogl† upon the ipecacuanhas in the pharmacological collection at Vienna. While comparing the species described in that memoir with those in the collection of M. Guibourt, it appeared to me that the same name had been attributed to different species. A striated ipecacuanha which I met with about the same time at the Pharmacie Centrale of M. Dorvault confirmed me in the opinion that this question was worthy of investigation, and I engaged several of our students successively to deal with it in their inaugural theses. M. Georges Durand,‡ in examining the structure of various kinds of ipecacuanhas, pointed out that the striated ipecacuanha of Vogl did not correspond in its anatomical characters to those of the sort so named in the Guibourt collection. M.

* Translated from the Journ. de Pharm. et de Chimie [4] xvi. p. 404.

† Vogl, 'Zeitschrift des oesterr. Apothekervereins;' Wiggers and Hüsemann, 'Jahresb. d. Pharmacognosie,' 1867, p. 64.

‡ 'Etude des différentes racines d'Ipécacuanha du Commerce' (Thèses de l'Ecole de Pharmacie de Paris, 1870).

Thénot*, *préparateur* of natural history in the School of Pharmacy, went further, and showed that in the collection of the school there existed in reality two species of striated ipecacuanha differing considerably in their anatomical characters. This result was afterwards confirmed by M. Charles Menier†, who passing in review all the true and false species of ipecacuanhas submitted them to a microscopical examination.

It thus appeared from these researches that under the name of striated ipecacuanha, writers have generally confounded two very distinct roots. It is to these species I therefore would wish to refer, in order to indicate their characters, investigate their botanical origin, and establish exactly their synonymy.

The two sorts are so different in their dimensions that they may be designated respectively the major and the minor striated ipecacuanha.

1. *The Major Striated Ipecacuanha.*—This ipecacuanha is met with in moderately long fragments, sometimes attaining a length of nine or ten centimetres. The diameter varies between five and nine millimetres. The fragments are sometimes rectilinear, sometimes sinuous, more rarely tortuous. At rather distant intervals they are marked by contractions or simply circular interstices. The whole of the surface is rather coarsely striated longitudinally. On the upper side the roots often bear the base of several stems, distinguishable by their much smoother surface. The colour of this ipecacuanha is a tawny grey, tending sometimes towards a reddish brown.

As in the other species of ipecacuanha, a section of this root reveals a cortical portion and a ligneous meditullium. The cortical portion is soft enough to allow of its being marked by the finger nail. It has a horny appearance, and is rather variable in colour, being sometimes whitish, and passing by shades of rose and violet to a violet black. Its thickness is relatively considerable, at least two-thirds of the radius, and it becomes still more so when the root is placed in water, which causes it to swell freely. The meditullium is of a yellowish white colour. The odour of the root is not very marked. The taste is scarcely nauseous, being sometimes insipid and frequently sweetish.

A microscopical examination of the cortical portion shows beneath five or six layers of tubular cells, with brownish walls, a parenchyma formed of large polygonal cells. These cells become smaller as they approach the ligneous meditullium; they become pretty regularly hexagonal, and form series radiating almost rectilinearly. They are entirely free from starch; a certain number of them contain bundles of raphides, and all are filled with an amorphous substance soluble in water, and capable of reducing cupropotassic solution. The ligneous meditullium consists of fibres with incrusted sides arranged in radiating series, between which are interposed vessels with very narrow openings, not exceeding the diameter of the ligneous fibres. It contains no trace of starch.

The salient characters resulting from this examination, and which may be regarded as distinctive from those of the second species of striated ipecacuanha, are (1) the complete absence of starch; (2) the relatively small diameter of the vessels of the meditullium; (3) the presence of a principle capable of reducing the cupro-potassic reagent. This matter exists in very great quantity in the cortical portion; a simple digestion in water giving a liquid with strongly reducing power, but which does not exercise a deviating influence on a ray of polarized light. This substance merits a closer study.*

The major striated ipecacuanha comes from New Granada. It contains but very little emetine; at least so it would appear from the analyses made by M. Dorvault, which confirmed those made by Professor Attfield,† who attributed to it two and a half per cent. of active principle.

2. *Minor Striated Ipecacuanha.* — This sort is distinguished from the former by its much smaller dimensions. It is in very short fragments, two or three centimetres or more. Some nearly cylindrical, scarcely constricted, are only two or three millimetres in diameter; others are narrowly fusiform; others again are formed of cylindrical or pyriform segments placed end to end; these are generally thicker and attain a diameter of five or six millimetres. The general colour is a grey brown, darker than that of the first sort. The longitudinal striæ are fine and regular. In a transverse section the cortical portion is as horny and the consistence closer than in the major kind. The meditullium is yellowish, marked with a great number of pores, visible with a glass.

The microscope shows in the cortical portion—(1) a first zone, formed of from seven to nine layers of very narrow tubular cells; (2) a thick parenchyma formed of cells with irregularly sinuous walls, filled with starch, and containing here and there bundles of raphides; (3) a liber zone, in a transverse section of which are seen narrow polygonal fibres and cells ranged in radiating series. The ligneous meditullium is distinguished immediately by the dimensions of the vessels, which give a porous appearance to this part, and which stand out distinctly by their size from the woody cells surrounding them.

The salient microscopic characters of this species are (1) the presence of starch; (2) the relative development of the liber zone; (3) the size of the vessels in the middle of the woody layer.

This sort of striated ipecacuanha contains a much larger proportion of emetine than the preceding: nine per cent., according to the analysis of Pelletier;‡ six and a half per cent. of pure emetine according to Attfield.§

It will be seen that the two preceding species are perfectly distinct in some of their anatomical characters. Let us try and complete their history, profiting by the data above given.

First, what is their botanical origin? It is known that writers on materia medica have referred the striated ipecacuanha to a New Granada plant, sent by Mutis to Linnæus, and described by him under the name of *Psychotria emetica.* Which of the two commercial kinds of striated ipecacuanha are obtained from this species? An examination of the roots ought to clear up this question. M. Triana, on the one hand, and M. Posada, on the other, have kindly furnished me with specimens of these roots,

* 'De la Cellule Végétale; de son importance au point de vue de la matière médicale' (Ibid. 1870).

† 'Des Ipécacuanhas' (Ibid. 1871).

* Professor Attfield has noticed the presence in this root of 5·39 per cent. of grape sugar, and 34 per cent. cane sugar, or of substances soluble in water and capable of being converted into sugar by boiling with an acid (PHARM. JOURN., second series, vol. XI. p. 141).

† *Loc. cit.*

‡ Journ. de Pharm., vol. vi. p. 261.

§ PHARM. JOURN. [2] vol. XI. p. 141.

taking from the living plant. These specimens, coming from different sources, have both the outward appearance and anatomical structure of the major striated ipecacuanha. So that in this respect the question is completely settled.

As to the origin of the second sort, I am obliged to remain in doubt. Its structure appears to differ too much from that of the roots of *Psychotria* to allow of its being referred to a species of the same genus. It presents anatomical characters approaching to those of the white or undulated ipecacuanha, which is referred to *Richardsonia scabra*, St. Hil.; and I should not be surprised if it were to a plant of this genus, or at least of a very near genus, that this commercial sort owes its origin. I incline the more to this opinion, since some specimens appear, as it were, intermediate between the minor striated ipecacuanha and the undulated ipecacuanha. I have in my possession some fragments sent to me by Mr. Hanbury, labelled "Spurious Ipecacuanha.—*Richardsonia scabra*." Now, the smallest of these fragments recall the minor striated ipecacuanha, whilst the larger approach more nearly undulated ipecacuanha. But, I will not dwell further upon a point which at present can only be matter for conjecture.

INDIAN OPIUM.

The eight monthly sales of Bengal opium for the past year and the seven months' duty on Madras opium have given to the Indian Government an actual revenue of 762,374 rs. more than the estimate of the budget. 25,500 chests of Behar and 16,500 chests of Benares opium are to be brought forward for sale by public auction in 1873. The sales will take place in the first week of every month, commencing with 6th January, and terminating the 4th December, At each sale 2125 chests of Behar opium will be offered, and 1375 chests of Benares opium—altogether 3500 chests at each sale. The opium will be ordinarily offered at an upset price of 800 rupees (£80 per chest), and sold to the highest bidder above that price.

THE DECOMPOSITION OF HYDRATE OF CHLORAL.*

BY M. BYASSON.

Former investigations of the author have led him to the conclusion that the physiological action of hydrate of chloral is not the same as that of chloroform introduced slowly into the system, but that it is the joint result of the chloroform and the formic acid produced under the influence of the alkalinity of the blood.† He has also shown that sulphuretted hydrogen combines with anhydrous chloral to form a sulphydrate analogous to the hydrate, and like it having soporific properties.‡

In the decomposition of oxalic acid by glycerine M. Byasson, by replacing the water by alcohol, has etherified directly the formic acid, and thus obtained formic ether by a new process. He was also induced to experiment whether hydrate of chloral, which contains the elements of chloroform and formic acid,

$$C_2HCl_3O, H_2O = CHCl_3 + CH_2O_2$$

could be decomposed into those two bodies without the intervention of alkalies. The following experiment, repeated several times, always yielded concordant results:—If hydrate of chloral be dissolved in five times its weight of syrupy glycerine, and the mixture heated in a retort furnished with a receiver, at about 110° C., a regular action is established which continues up to about 230°; at this temperature the glycerine is strongly coloured, and becomes thick, and it is advisable to stop the operation so as not to complicate the results. The product condensed in the receiver is liquid, and separates into two layers; the underneath layer consists of chloroform, the upper one contains formic acid, hydrochloric acid, formate of allyl, and hydrate of chloral dissolved in water. The proportion of chloroform produced as the mean of three operations, was 31 per cent. of the hydrate of chloral. The formation of the formate of allyl is secondary, as also that of the hydrochloric acid. These two bodies are relatively in small quantity, and proceed, the first from the decomposition of glycerine under the influence of heat and nascent formic acid; the second from the decomposition of chloroform. In order to obtain the above results it is important to use syrupy glycerine; if water be added, the greater part of the hydrate of chloral distils over without being decomposed.

THE KOMBÉ ARROW POISON (STROPHANTHUS) OF AFRICA.*

BY DR. THOMAS R. FRASER.

In nearly every narrative of exploration in uncivilized tropical regions, accounts are given, often no doubt somewhat fanciful, of poisonous substances which are said to possess the most remarkable properties. Usually these poisons are of vegetable origin; and the great majority may be included in the two divisions of ordeal and of arrow poisons, according as they are applied to one or other of these purposes. Among the most remarkable of the ordeal-poisons are the *Tanghinia venifera* of Madagascar, the *Physostigma venenosum* of Old Calabar, and the Akazga poison of the Gaboon; and of the arrow-poisons, the famous Curara or Wourali of South America, and the *Antiaris toxicaria* of Java.

The examination of these substances has not only proved of great value to physiology, but practical medicine has likewise been benefited—one of them, at least, being now an important medicinal agent.

In bringing before the Royal Society of Edinburgh a few of the results of a recent examination of a new arrow-poison, the author expressed his gratitude to the President to whom he was indebted for the specimens with which the experiments had been made. These specimens, consisting of a number of ripe follicles, were sent to Dr. Christison by Mr. Walker, and were collected in the expedition of the late Bishop Mackenzie.

Several specimens of the poison have likewise been sent to Professor Sharpey by Dr. Kirk, her Majesty's consul at Zanzibar. Dr. Kirk states "that the plant is a woody climber, growing in the forest, both of the valley and hills, and found at various places between the coast and the centre of the continent, above the Victoria Falls of the Zambesi. The stem is several inches in diameter, and rough outside. The plant climbs up the highest trees, and hangs from one to the other like a bush-vine. The flowers are of a pale yellow, and last for but a short

* Abstracted from an article in the 'Journal of Anatomy and Physiology,' vol. vii.

time during the months preceding the first rains of the season (October and November). The fruit is ripe in June, and collected by the natives, who separate the rough outer coat before drying it, preserving the more leathery inner covering and the seeds."*

Dr. Livingstone gives some interesting information regarding the poison in his 'Narrative of an Expedition to the Zambesi and its Tributaries.' He mentions that arrows poisoned with it are used for killing wild animals only; arrows destined for the more noble object of killing men being poisoned with the entrails of a small caterpillar. Dr. Livingstone says that in hunting, the natives follow the game with great perseverance and cunning: "The arrow, making no noise, the herd is followed until the poison takes effect, and the wounded animal falls out; it is then patiently watched till it drops; a portion of meat round the wound is cut away, and all the rest eaten" (p. 465).

Dr. Livingstone also says that the poisoned arrows are made in two pieces. "An iron barb is firmly fastened to one end of a small wand of wood, ten inches or a foot long, the other end of which, fined down to a long point, is nicely fitted, though not otherwise secured, in the hollow of the reed which forms the arrow-shaft. The wood immediately below the iron head is smeared with the poison. When the arrow is shot into an animal, the reed either falls to the ground at once, or is very soon brushed off by the bushes; but the iron barb and poisoned upper part of the wood remain in the wound. If made in one piece, the arrow would often be torn out, head and all, by the long shaft catching in the underwood, and striking against trees" (p. 466).†

It would appear that this arrow-poison is widely distributed over Africa, for it has been found not only at Kombé, on the west coast near the equator, and in the Manganja country, near the Zambesi at the south-east of Africa, but also in the Gaboon district,‡ in Guinea,§ and in Senegambia.|| In the Gaboon district it seems to be called Inée, Onaye, or Onage.**

The follicles examined by the author vary in length from about nine and three-fourths to about twelve and one-fourth inches, and in greatest thickness from about one inch to three-fourths of an inch, and they vary in weight from about 130 to 330 grains. They contain from 100 to 200 seeds, each of which weighs about half-a-grain, and has attached to it a beautiful comose appendix, placed on an extremely brittle stalk. At first, Professor Oliver, of Kew, to whom the plant was submitted for identification, referred it to *Strophanthus hispidus*, DC., natural order *Apocynaceæ*, but he was led, by a further examination of the botanical characters of the Kombé-poison plant, to doubt its identity with *S. hispidus;* and, accordingly, he has described it in the 'Icones Plantarum,' No. 4. 1870, under the name of *S. Kombé*.

When the seeds contained in the follicles are bruised and treated in a percolator with rectified spirit, a greenish-yellow tincture is obtained. By distilling off the greater part of the spirit, and drying the residue on a water-bath and in the exhausted receiver of an air-pump, an extract is procured which weighs about 25 per cent. of the seeds employed, has an intensely bitter taste, and contains about one-half of its weight of an inert fixed oil.* From this extract Dr. Fraser succeeded in separating a very powerful active principle, which he proposes should be named strophanthin.

The physiological action of this active principle is of the same character as that of the extract.

When a small dose (one-twentieth of a grain) of this extract is mixed with a few minims of water, and injected under the skin of a frog, no distinct symptom is seen until about half an hour, when the animal's movements become somewhat sluggish. Soon afterwards the respirations cease, some stiffness occurs in the thoracic extremities, reflex sensibility diminishes, some stiffness appears in the pelvic extremities, and in about two hours after the administration voluntary movements entirely cease, and strong galvanic irritation produces no effect, even when applied to exposed muscles and nerves. An examination of the heart shows that it is completely paralysed, the ventricle being pale and contracted, while the auricles are dark and distended.

As the result of many experiments under varying conditions, Dr. Fraser is of opinion that (1) Strophanthus acts primarily upon the heart, and produces, as the final result of this action, paralysis of that organ with permanence of the ventricular systole; (2) Pulmonary respiration continues in cold-blooded animals for several minutes after the heart is paralysed; (3) The striped muscles of the body are acted upon: twitches occur in them; their tonicity is exaggerated; and, finally, their functional activity is destroyed, the muscles being then hard, and, soon afterwards, acid in reaction; (4) The reflex function of the spinal-cord is suspended soon after the heart is paralysed; but the motor conductivity of the spinal-cord and of the nerve-trunks continues after the striped muscles of the body are paralysed; (5) The lymph-hearts of the frog continue to contract for many minutes after the blood-heart has been paralysed.

THE HISTORY OF OZONE.†

BY PROFESSOR ODLING, F.R.S.

The most important points in the history of ozone are the following:—I. Its recognition as a distinct variety of matter or substance, by Schönbein in 1840. II. An inquiry into its nature, made by Marignac in 1845, whereby it was established that the action of ozone on various substances results simply in their oxidation. III. The evidence of different kinds, accumulated by many observers during a period extending from 1845 to 1863, that the matter of ozone is identical with the matter of oxygen. IV. The demonstration by Andrews and Tait in 1860, that ozone is a condensed form of oxygen. V. The recognition by Andrews and Tait in 1860, and interpretation by Odling in 1861, of the singular fact that, in certain cases, the removal of its constituent ozone from a mixture of ozone and oxygen is unattended by any alteration in the volume of the gas, notwithstanding the considerable oxidation effected by it. VI. The study of the quantitative reactions of ozone by Brodie in 1872; and his establishment of the relationship of ozone to ordinary oxygen, in corroboration of some less exact results obtained by Soret in 1865, as also of a suggestion made by the speaker in 1861.

I. Ozone was discovered by Schönbein, in 1840, when experimenting with the then newly-invented battery of Sir Wm. Grove,—an instrument still recognized as yielding a current superior, in respect of joint quantity and intensity, to the current yielded by any other electromotor available for general use. Ozone was recognized

† Paper read at the Royal Institution, Friday, June 7, 1872

by Schönbein successively, as a minute constituent of the oxygen gas resulting from the electrolysis of water effected by a current of high tension; as a minute constituent of air or oxygen through which electric discharges have taken place; and as a minute constituent of air in which moist phosphorus has been undergoing slow oxidation. To Schönbein then is due the great merit of recognizing ozone as a distinct form of matter, having an identity of its own by whatsoever means prepared—as also the merit of discovering the most important means for the production of ozone, and of establishing its principal properties and reactions.

The general properties of ozone are those of an active oxygenant. Thus, like chlorine and peroxide of nitrogen, it bleaches colouring matters, corrodes fabrics, tarnishes or otherwise attacks metals, and liberates iodine from iodide of potassium. Its special properties are its characteristic pungent odour, its destructibility by a moderate heat, and its non-manifestation of any aciduious reaction.

II. The nature of ozone was at first the subject of much speculation, Schönbein inclining to the view that it was a new elementary body, and a component of nitrogen. But in 1845, Marignac, in a series of most exact experiments, made partly in association with De la Rive, brought the question as to the nature of ozone within a very narrow compass. The experiments of these investigators, in which they established, among other points, that by exposure to the action of ozone, moist silver was converted simply into oxide of silver, and iodide of potassium into its oxidized form of iodate of potash, were susceptible only of one or other of two interpretations—either the interpretation which they themselves put on their results, that the matter of ozone is identical with the matter of oxygen—or, else the interpretation put on their results by Schönbein, that ozone is constituted of oxygen plus the elements of water, or in other words, that it is a peroxide of hydrogen. For a long time, experiment seemed quite incompetent to decide between these two views—opposite conclusions being arrived at almost alternately by the different investigators engaged on the inquiry. Corroboration, however, if any were needed, of the fact that ozone is really formed from oxygen itself with or without water, and not from any trace of nitrogen or other foreign matter that might possibly be present, was afforded by a remarkable experiment conducted by Fremy and Becquerel in 1853, being, indeed, the first recorded quantitative experiment made with ozone. By passing a long series of electric discharges through a given volume of oxygen standing over an aqueous solution of iodide of potassium, Messrs. Fremy and Becquerel succeeded in causing the whole of this oxygen to assume the form of ozone; as was shown by its ultimate complete absorption by the solution, with correlative liberation of iodine from the dissolved iodide of potassium.

The difficulty experienced in those early days of making out the real nature of ozone—of ascertaining whether it is a form of oxygen or a peroxide of hydrogen—depended mainly on the very small degree to which it was then possible to charge air or oxygen with the ozone to be examined, and on the necessity for the exclusive employment in the investigation of apparatus in which neither metal nor organic matter was present for the ozone to react with. The apparatus had consequently to be constructed entirely of glass, and all the junctions to be made before the blow-pipe or by grinding. Now-a-days, by improvements in the methods of conducting the processes of electrization and electrolysis, it is possible to charge oxygen with ozone in very considerable proportion; while by means of paraffin, a substance on which ozone is without recognizable action, junctions of the glass apparatus employed may be made and unmade with the greatest facility.

III. Assuming the ozone furnished by the three principal processes for its production to be one and the same substance, it was not until the year 1863 that the absolute freedom of ozone from any proportion of hydrogen was so definitely established as not to allow of any further question. In this year, Soret showed that although ozonized oxygen obtained by electrolysis, after having been desiccated as thoroughly as possible, frequently yielded some water as a product of its decomposition by heat, yet that when certain precautions were taken, and certain sources of error in the production and collection of the electrolytic oxygen were recognized and avoided, a uniformly negative result was obtained, and not a trace of moisture or other compound of hydrogen resulted from the decomposition by heat of the ozone present in the oxygen.

This conclusion of Soret's was confirmatory both of the previous result of Andrews with regard also to electrolytically obtained ozone, and of the yet earlier result of Schönbein himself with regard to the ozone obtained by the slow oxidation of moist phosphorus. For in opposition to the view enunciated first by himself, and in seeming discrepancy with the undoubted fact that for the production of ozone by means of phosphorus the presence of moisture is essential, Schönbein, in 1849, showed by repeated experiment, that when ordinary air in quantities of several hundred litres, ozonized as strongly as possible by its passage over moist phosphorus, was transmitted first through a desiccating tube, then through a tube heated to 400°, so as to effect the destruction of the ozone present, and finally through another desiccating tube to absorb any moisture that might result from the destruction of the ozone, this last desiccating tube did not show, by an increase of weight or other change, any absorption of moisture whatever, notwithstanding the largeness of the absolute quantity of ozone destroyed in the experiment. From this time forth, Schönbein abandoned the notion of hydrogen being a constituent of ozone; and while making a valid distinction between his own view and that of Marignac and De la Rive, admitted with them that the matter of ozone is identical with the matter of oxygen. These last-named investigators, in their research already referred to (1845), showed that perfectly dry oxygen, submitted to the influence of electric discharges, experienced an alteration of character, whereby it acquired the property of liberating iodine from moist iodide of potassium,—a result afterwards confirmed by Fremy and Becquerel. But they did not regard this alteration of character as due to the formation in small proportion of a new substance within the mass of oxygen, but rather to the assumption by the mass of oxygen of a peculiar electric condition. Moreover, the fact of dry oxygen being capable of some modification by the action of electric discharges, coupled with the fact of the inability of the so modified oxygen to act upon iodide of potassium save in the presence of water, was not inconsistent with the notion of this modified oxygen having to unite with water in order to produce a compound identical with the ozone obtained immediately from moist or watery reagents. That the effect of electrical discharges, and more particularly of the silent discharge, on perfectly dry oxygen, is really to convert a small proportion of this oxygen into ozone identical with that furnished by electrolysis, and capable of acting upon certain substances, as mercury and iodine, when in the dry state, and on certain other substances, as iodide of potassium and metallic silver, only when in the moist state, was first put beyond question by Andrews and Tait, in a research next to be considered.

IV. In the spring of 1860, Dr. Andrews and Prof. Tait made a joint communication to the Royal Society on the volumetric relations of ozone. The primary object of this research was to ascertain whether any, and if so what, alteration of volume took place in the conversion of a given quantity of oxygen into ozone. They thus attacked the problem from an entirely new point of view, and, with admirably direct pains and skill, succeeded in making probably the most important contribution hitherto made to an exact knowledge of the nature of the ozone. In their experiments, a quantity of perfectly pure and dry oxygen, contained in a straight glass tube with a pressure-gauge appendix, was ozonized by means of the silent electric discharge passed through the gas for some time. Coincidently with the passage of the silent discharge through it, the quantity of gas contained in the glass tube was observed to undergo a marked contraction in volume. This contraction proceeded at first rapidly, but afterwards more slowly, till it attained a limit which, in one of their experiments, was estimated at one-twelfth the original volume of the gas. And as whenever the gas, contracted in this manner, was examined, it was found to be proportionately ozonic, the general fact was established that the production of ozone from ordinary oxygen is attended with a contraction in volume. The converse result was also obtained. It was found that when oxygen, contracted by the passage of the electric discharge, was exposed for a short time to the temperature of 270°–300°, it was restored to its original volume. And as whenever the gas, re-expanded in this manner, was examined, it was found to be free from ozone, the general fact was established that the conversion of ozone into ordinary oxygen is attended with an expansion in volume. And this alternate contraction of a given quantity of oxygen by exposure to prolonged electrization, with production of ozone, and re-expansion of the gas to its original volume by exposure to a temporary heat, with destruction of ozone, could be repeated an indefinite number of times. Now the only possible conclusion to be drawn from these experiments would appear to be that, the matter of ozone being identical with the matter of oxygen, ozone is oxygen in a denser form,—that is to say, in the form of a more complex unit. Some years afterwards, this conclusion was confirmed in a very interesting manner by Professor Tyndall, in the case of ozone obtained electrolytically. He found that the absorptivity for radiant heat of electrolytically obtained oxygen, when rich in ozone, was upwards of a hundred times greater than that of ordinary oxygen—a result indicating ozone to have a more complex molecular constitution, and consequently a greater density, than ordinary oxygen. Moreover, after this same electrolytically obtained and richly ozonic oxygen had been subjected to the action of heat, so as to have its ozonic character destroyed, it then exhibited merely the absorptivity for heat of ordinary oxygen,—the observed absorptivity not going at all beyond that of ordinary oxygen, as would have been the case if the ozone originally present in the electrolytic gas had been decomposed into ordinary oxygen and aqueous vapour.

Referring to the statement already made, that in Messrs. Andrews and Tait's experiments, the oxygen gas, more or less contracted by the electric discharge, was found to be proportionately ozonic, this point was ascertained in the following way:—A small thin glass bulb, containing a solution of iodide of potassium, was introduced into the oxygen-holding tube, prior to its being filled with the gas, which, after having been more or less contracted by the process of electrization, was next submitted to the action of the solution, released on the breaking, effected by concussion, of the small bulb wherein it was contained. And on estimating the quantity of iodine set free from the iodide of potassium solution by its reaction with the contracted gas, it was found to be the exact chemical equivalent of a weight of oxygen equal in volume to the amount of contraction which the original gas had experienced during the process of electrization; so that if in the process of electrization, there had been one, two, or three cubic centimetres of contraction, the quantity of iodine liberated was chemically equivalent to the weight of one, two, or three cubic centimetres of oxygen; whence it results that to ascertain the iodine-titre of the ozonized gas is to learn the contraction of the original gas effected by its electrization, or the correlative expansion of the electrized gas effected by its exposure to heat. In the case also of electrolytically obtained ozonized oxygen, it was shown firstly by Andrews and Tait, and subsequently by Soret, that the iodine-titre of the gas is the measure of its expansion by heat, consequent on the conversion of its constituent ozone into ordinary oxygen.

V. It has just been remarked that in the action of the contracted gas on iodide of potassium solution, there is absorbed by the reagent, with equivalent liberation of iodine, a weight of oxygen corresponding to a volume equal to that of the original contraction; but very curiously, the absorption by the reagent of this weight of oxygen from the contracted gas was found by Messrs. Andrews and Tait not to produce any further contraction or alteration of its volume; or the weight of oxygen which acted on the iodide of potassium solution appeared to occupy no part of the volume of the contracted gas, its removal from the contracted gas by means of the reagent not affecting any alteration in that volume. Since this remarkable result was first announced by Messrs. Andrews and Tait in 1860, it has been abundantly confirmed by Von Babo and Claus, by Soret, and by Sir Benjamin Brodie—the modes of experimenting adopted in the original investigation of Andrews and Tait and in the three subsequent investigations, being all different from one another. And moreover, not only has the fact been established by the four several investigations with regard to iodide of potassium, but by one or other of the investigations with regard also to iodine, to mercurous salts, to ferrous salts, to arsenites, and to ferrocyanides. So that, when a given volume of ozonized oxygen is allowed to act upon these different oxidizable bodies, the oxidation effected by the ozone present in the gas is found to be unattended by any diminution in the volume of gas. An interpretation of this singular result was put forward by the speaker soon after the publication of Messrs. Andrews and Tait's experiments, to the following effect: Ozone being proved to be a condensed form of oxygen, it is clear that any volume of ozone will contain a greater weight of the matter of oxygen than is contained in the same volume of ordinary oxygen. And since in the action of ozone upon iodide of potassium, the volume of the reacting gas does not undergo any alteration, it is obvious that the oxidation effected must be effected by only so much of the matter of oxygen contained in the volume of ozone, as is in excess of the matter of oxygen contained in the same volume of ordinary oxygen. This interpretation, so far as it went, was considered to be demanded by Messrs. Andrews and Tait's experiments, as the only satisfactory explanation of them. With regard to the weight of the matter of oxygen contained in a given volume of ozone, in excess of the weight of the matter of oxygen contained in the same volume of ordinary oxygen, no data whatever existed to show what this weight really is. But relying upon the fact that the weight of oxygen contained in a standard volume of free oxygen is composed of two simple weights of the matter of oxygen, it was conjectured that the weight of oxygen contained in a standard volume of ozone might not improbably be constituted by an introduction into the standard volume of ordinary oxygen of another simple weight of oxygen—equal volumes of ozone, free oxygen, and nitric oxide, for example, being expressible by the comparable formulæ O_3, O_2, and NO respectively. In accordance with this supposition, the action of ozonized gas upon iodide of potassium, etc., is explicable as follows:—The ozone which acts is decomposed into a weight of free oxygen equal in volume to the volume of the ozone, and into another weight of absorbed oxygen, assumed to be one-half of the former weight. The suggestion as to the standard volume of ozone being constituted thus of three simple weights of the matter of oxygen, was admittedly not a necessary deduction from the then known facts, which were indeed equally consistent with its being constituted of four, five, or six such weights; it was only the suggestion of the simplest possible constitution for ozone that was consistent with the facts.

A few years afterwards, in 1865–66, the probability of this being the real constitution of ozone was much strengthened by the results of some experiments conducted by Soret. Operating by a process very simple and ingenious, but scarcely calculated to afford precise results, Soret found that when electrolytically-obtained ozonized oxygen was allowed to act upon oil of turpentine, the absorption of the ozone by the turpentine was attended by a diminution in the volume of the gas equal approximatively to twice the initial contraction,—as inferred, of course, from the iodine-titre of the ozonized gas, or from its permanent expansion after exposure to a temporary heat. Supposing the final diminution effected by the turpentine to have been exactly twice the initial contraction, inferred from the iodine-titre, it is clear that, while the original gas would have suffered altogether a diminution of three volumes, the ozonized gas would have suffered a diminution of only two volumes. Or there would have been ultimately abstracted from the original uncontracted gas three volumes of the matter of oxygen, occupying in the contracted or ozonized gas, submitted to the action of the turpentine, only the bulk of two volumes. But as a mean result of Soret's first set of five experiments, the final diminution effected by the turpentine was 2·40 times the original contraction; while, as a mean result of his second set of seven experiments, the final diminution was 1·81 times the original contraction. Assuming, however, ozone to have the constitution expressed by the symbol O_3, its specific gravity, and consequently its diffusion-velocity, would approximate closely to the specific gravity and diffusion-velocity of carbonic acid gas, CO_2; and in 1867, Soret, in corroboration of his previous absorption results, satisfied himself that the diffusion-velocity of ozone really does approximate very closely to that of carbonic acid.

VI. During the last few years, the quantitative reactions of ozone have been made the subject of an elaborate study by Sir Benjamin Brodie, whose results constitute indeed "a body of exact information as to the chemical properties of ozone, through which it may be hoped that this important question will be finally removed from the domain of arbitrary speculation and brought within the precincts of science." In Brodie's experiments, a quantity of pure perfectly dry oxygen, after having been submitted to electrization by its passage through a modified form of Siemens' induction tube, carefully maintained at a low temperature, was collected in an oil of vitriol gas-holder, to the amount of four or five thousand cubic centimetres. From the store of ozonized gas thus collected, which was found to maintain its proportion of ozone without appreciable deterioration for some hours, portion after portion was allowed to pass into a pipette of about 250 c. c. capacity, by displacement of the oil of vitriol originally filling it; and successive equal volumes of the store of ozonized gas so measured off, were submitted one after another to the action of the same or of different reagents, by the passage of each pipetteful of gas through a small bulb-tube containing the reagent in solution. The gas, freed from all ozone by its passage through the reagent, was next received into a mercurial measuring cylinder, in which it was expanded to a definite volume; and then, by reading off the pressure at which it occupied this volume, its proper volume was ascertained. Finally, the difference between the capacity of the pipette and the volume obtained in the mercurial cylinder showed the volume of the gas absorbed by the reagent,—the weight of this gas being determined directly or indirectly by titrations of the reagent. Of course, very many points of detail in the construction and use of the apparatus had to be attended to, in order to ensure trustworthy results; but, both in its principle and general working, the process is exceedingly simple. One essential novelty consists in the application of that very useful instrument, the pipette, to the purposes of gas analysis: and by its aid, results having a degree of accuracy far greater than those furnished by any previous method of ozone investigation, were found to be obtainable with both speed and facility.

Operating, then, with the apparatus just described, Brodie has succeeded in establishing three perfectly definite classes of ozone-reactions,—the first of them including the instances previously made known by Andrews and Tait. In this first class of reactions, of which there are several distinct varieties, the absorption or decomposition of the ozone present in a mixture of ozone and oxygen, is unattended by any diminution in the volume of the gas; or a volume of ozone O^2+x, is resolved into an equal volume of free oxygen, and an indefinite weight of other oxygen, either absorbed or set free. This class of reactions accordingly does not afford any information as to the value of x, or, in other words, as to the relationship of the formula O^2+x to the formula O^2.

$$\overbrace{O^2 + x = O^2}^{\text{Unit-Volumes.}} + x\,O \text{ absorbed.}$$

In a second class of reactions, the absorption or decomposition of the ozone present in a mixture of ozone and oxygen, is attended with a diminution in the volume of the gas, equal to half the volume that the weight of oxygen absorbed would occupy in the free state. In this class of reactions, then, one of but two occurrences must happen: either the ozone present in the mixture of gases, is absorbed wholly without decomposition, in which case the density of ozone must be twice that of ordinary oxygen, and the formula $O^2 + x$ become O^4; or the ozone present in the mixture is decomposed into half its volume of oxygen liberated, and into a quantity of oxygen, corresponding to its entire volume, absorbed; in which case the density of ozone must be one-and-a-half that of ordinary oxygen, and the formula $O^2 + x$ become O^3.

$$\overbrace{\begin{array}{r} O^2 + x = \text{nil} \\ 2\,(O^2 + x = O^2 \end{array}}^{\text{Unit-volumes}} \begin{array}{l} +\ 4\,O \\ +\ 4\,O \end{array}\Big\}\text{ absorbed.}$$

In a third class of reactions, the absorption or decomposition of the ozone present in a mixture of ozone and oxygen, is attended with a diminution in volume of the gas, equal to two-thirds the volume that the weight of oxygen absorbed would occupy in the free state; or the weight of the gas absorbed is to the weight of an equal volume of oxygen as 3 to 2. But consistently with this class of reactions, the density of ozone must necessarily be one-and-a-half times that of ordinary oxygen, and the formula $O^2 + x$ must become O^3.

$$\overbrace{(O^2 + x) = \text{nil}}^{\text{Unit-volumes.}} + 3\,O.$$

This last and most important class of reactions, by which the formula of ozone as O^3, is put beyond question, was established by a long series of experiments, made chiefly with a neutral or but slightly alkaline solution of hyposulphite of soda, and in a few cases with oil of turpentine. As a result, the ratio of the entire diminution in volume suffered by the original oxygen, to the diminution in volume of the electrized or contracted oxygen effected by the reagent, was found to be, as a mean of twenty-seven concordant experiments made with the hyposulphite, 3·02 to 2·02; and as a mean of eight concordant experiments made with the turpentine, also as 3·02 to 2·02. But neither with the hyposulphate nor with the turpentine, could the weight of oxygen absorbed by the reagent be determined, otherwise than by a calculation from the alteration in volume of the gas. A direct determination, however, was effected in the case of a few experiments made with protochloride of tin, under conditions carefully considered and regulated so as to ensure a trustworthy result. And it was found in these few experiments that the weight of the matter of oxygen absorbed from the ozonized gas by the tin-salt was almost exactly three times the weight of the matter of oxygen absorbed from the same gas by iodide of potassium,—the volume occupied by the weight of oxygen absorbed by the tin-salt being almost exactly twice the volume proper to the weight of oxygen absorbed by the iodide of potassium.

Independently of the importance attaching to the actual determination of the density of ozone, Sir B. Brodie's result has a further interest for chemists, which it would be difficult to exaggerate. The principal of the elementary bodies known to chemists in the gaseous or vaporous state, are hydrogen, chlorine and its congeners, oxygen, sulphur, nitrogen, phosphorus, arsenic, mercury, and cadmium. Now it is a fact that the weight of phosphorus or arsenic contained in any volume of phosphorus or arsenic vapour is four times the weight of phosphorus or arsenic contained in the same volume of phosphoretted or arsenetted hydrogen, and of a host of other phosphoretted or arsenetted gases or vapours. It is also a fact that the weight of hydrogen, chlorine, oxygen, or nitrogen contained in any volume of each of these elementary gases is twice the weight of hydrogen, chlorine, oxygen, or nitrogen contained in the same volume of a variety of hydrogenous, chlorinous, oxygenous, or nitrogenous compound gases. It is also a fact that the weight of mercury or cadmium contained in any volume of the vapour of either element, is identical with the weight of the element contained in the same volume of the vapour of all its hitherto examined volatile compounds. But now a variety of oxygen is shown to exist, the weight of any given volume of which is three times the weight of oxygen contained in the same volume of the simplest of oxygenous compounds respectively, thus:—

	Unit-volumes.		
P_4	O_3	O_2	Hg
PCl_3	CO	NO	$HgCl_2$.

The question, then, naturally arises, how long will it be before another variety of oxygen is recognized, the weight of any given volume of which, like that of a given volume of phosphorus vapour, shall furnish the weight of the element contained in four such volumes of its several simplest compounds? And again, how long will it be before yet another variety of oxygen is recognized, the weight of any given volume of which, like that of any given volume of mercury vapour, shall furnish but the weight of the element contained in the same volume of its several simplest compounds? There is the strongest indirect reason for believing in the existence of such a unitary oxygen. For in its reactions, oxygen behaves as a sort of more active electro-negative counterpart of electro-positive mercury Hg; and like mercury Hg, and unlike hydrogen H_2 and chlorine Cl_2, it enjoys the property of adding itself to a pre-formed unit of substance by an indivisible proportion.

THE ESTIMATION OF NITROGEN.*

BY L. KESSLER.

Experience has convinced the author that the soda-lime process for the estimation of nitrogen does not, with certain organic substances, give nearly the quantity which they contain, the error with cutaneous matters dissolved in sulphuric acid being sometimes more than fifty per cent. Even when operating volumetrically upon not more than one or two decigrams, carbides of hydrogen and volatile nitrogenous bodies are produced, which by their coloration, insolubility, and more or less feeble basicity, interfere with the ascertainment of the exact point of saturation. When calcination of the platinum salt, after washing with alcohol and ether, is adopted, the washings are nearly always turbid, and deposit incessantly platinum compounds which escape weighing. If it be considered, also, how easily gaseous ammonia is decomposed at a high temperature into its elements, it is surprising that in a process where the ammoniacal gases issuing from the reaction have to filter slowly through a long row of substances brought to a red heat, a greater loss does not take place. Such a want of exactness, the author considers, renders this method, nearly the only one at present adopted by commercial analysts, unsuited to be the basis upon which the manure trade should be carried on; since being founded upon the ultimate production of a compound (ammonia), itself decomposible under the conditions of the experiment, it does not present the characters of exactness usually found in elementary analysis.

With this conviction he has sought to simplify the processes for the measurement of nitrogen disengaged in a free state, employing by preference that of Dumas, by oxide of copper, except that instead of collecting the gases yielded by the combustion over mercury, he receives them in an india-rubber bag. This bag is formed of two disks of supple india-rubber, free from sulphur, one millimetre thick and from twelve to fifteen centimetres in diameter, joined together at the edges, and having issuing from one side an india-rubber tube of the same size as the delivery tube of the combustion apparatus, and from the other a glass tube graduated in cubic centimetres. The india-rubber tube is made to close with a small stop-cock or compresser.

For the examination of the carbonic acid gas used to sweep out the combustion tube, bags similarly made may be used, but without the graduated tube. The bag is filled with water, then emptied and closed under water. The delivery tube of the combustion apparatus is then introduced into the end of the india-rubber tube beyond the stop-cock, without lifting it out of the water. The stop-cock is opened quickly and the gas introduced. When the bag is full, the india-rubber tube is closed and the delivery tube removed; then, without bringing the opening of the tubing above the water, the end of a pipette filled with a solution of soda is thrust into it. The carbonic acid is absorbed, and by the volume of the residue it may be judged whether the air has been sufficiently removed from the combustion apparatus. In order to estimate this residue more conveniently, it may be transferred under water to a test tube.

When the air is considered to be sufficiently removed, the first-mentioned bag is attached in the same manner, first introducing into it fifteen to twenty grams of concentrated solution of caustic soda. If the bag be too much inflated, it should be agitated. M. Kessler prefers to keep the absorption apparatus under water to prevent the unnoticed escape of any gas. When no more gas is disengaged, the combustion tube is again swept out with carbonic acid gas, and the bag is removed, the india-rubber tubing being pinched progressively so as to drive into the bag any nitrogen present. After the removal the carbonic acid gas may be examined as before.

In measuring the nitrogen the bag should be shaken until the gas in the graduated tube no longer diminishes in volume. Then pinch the end of the flexible tube with the fingers, open the stop-cock, place the bag under water, keeping the graduated tube above the surface, and the caustic soda will run away. Lastly, bring the surfaces of the liquids, inside and outside, to the same level, and note the volume of nitrogen, the temperature of the water and pressure of the atmosphere.

If the quantity of nitrogen should exceed the capacity of the tube, or if it be desired to obtain a more exact measurement in a narrower tube, the gas should be transferred to another vessel before running off the soda. In this case the delivery tube should be carried to the top of the fresh graduated tube to prevent loss by absorption while passing through the water.

The Pharmaceutical Journal.

SATURDAY, JANUARY 4, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

1872.

THOUGH it is the business of a journal like this to have regard only to the more immediate present, it is allowable, in passing from one year to another, to deviate from ordinary routine by taking a review of the past, counting our gains and losses, and summarizing the events, the achievements, and the efforts that have marked the last page of our pharmaceutical history.

Another turn of the glass of time! Another convenient standpoint for a retrospect at the beaten paths, for taking stock of what has been accomplished, and determining whether it affords ground for congratulation, or gives reason for regret! Such a review of the pharmaceutical year just closed is here laid before our readers; and notwithstanding that outside "inversum contristat Aquarius annum," and inside there are still subjects of difficulty to be dealt with, we think that, on the whole, the body of pharmacists may take heart and go forward.

To speak first of matters concerning the Pharmaceutical Society. After the termination of the poison regulation contest, towards the end of 1871, attention was turned to the subject of education, and early in 1872 this became the principal topic of the year. Mr. SCHACHT having, in 1870, started a discussion as to the duty of the Pharmaceutical Society in relation to education, with a declaration that the scheme previously adopted by the Society for carrying out pharmaceutical education had "failed largely," and having afterwards followed up this subject in his address at the opening of the Session 1870–71, and at the Annual Meeting in 1871, it has since been dealt with by Messrs. REYNOLDS, BAYNES, RADLEY, PICKERING, and others, and the claims of the country members of the trade upon the Society's funds for the purpose of education have been fully as well as ably urged. But notwithstanding the statement that the country was fully roused upon the subject, Mr. MACKAY was able at the Annual Meeting of last year to illustrate the care requisite in dealing with this question, by pointing to numerous localities where means of education had been provided and where students were not forthcoming. Our pages have unfortunately afforded repeated evidences of this fact, and a signal instance of the kind was quoted only a fortnight since.

So long as this state of things prevails little reason can be shown for distributing the surplus funds of the Society among provincial associations to support the mere semblance of schools. The attention of pharmacists should rather be turned to that advancement *from within* which the President of the Pharmaceutical Conference did not hesitate to say might now be fairly expected of them. And—quoting from the same authority—lest the accumulation of surplus income might, contrary to the spirit of the Society's founder, represent "good left undone," there seems ample scope for its useful investment in science and intellectual wealth, by affording facilities for original investigation, or by establishing scholarships as suggested by Mr. EKIN.

As might have been expected, the general subject of pharmaceutical education in the provinces has been repeatedly under the consideration of the Council. In July, the Provincial Education Committee presented a Report recommending that the scheme drawn up by Mr. SCHACHT, and based upon the Government "Science and Art" system of "payment for results," should be, in principle, adopted. That scheme was referred back to the Committee for further consideration, and it was hoped that by its publication, suggestions from members throughout the country might be brought under the notice of the Committee. Though amongst the many who have responded to this appeal it might appear invidious to mention individuals, exception may be made concerning the paper of Professor REDWOOD—in justice to his experience—and the communication of Mr. RICHARD REYNOLDS as the exponent of a former scheme. We believe, however, the idea that it is the duty of the Pharmaceutical Society to originate or provide means for the Pharmaceutical education of the mass of the trade is now pretty well exploded; and the present outcome of the discussion may be summed up in the recent words of Mr. SCHACHT at Bristol, that "it would be unwise in the executive of the Pharmaceutical Society to adopt, at the present moment, any scheme whatever." From all that has been said and written on this subject there may, however, be gathered the recognition, more or less involuntary, of the fact that, although we are still destitute of any adequate educational system, the work of organizing such a system must be done by the pharmacists of the future rather than by the Society of the present day. The School of Pharmacy in Bloomsbury Square, though quite inadequate to meet the requirements even of those who are seeking education, may serve as a model and a guide in the attempt to carry out the idea of establishing centres of education throughout the country, and on that ground alone it should receive the most liberal support, rather than the almost envious appreciation we have lately seen conferred upon it.

Before it will be possible, however, to organize any thorough system of education, it will be necessary that there should be a more intimate connection between the Pharmaceutical Society and the trade generally. It is essential that the Society should become more strictly speaking representative than has been the case. This idea is embodied in the wish recently expressed at Glasgow by Mr. Betty, that the numbers of the Society would so increase that ere long at the Council election the last elected should receive more votes than those who stood highest at the late election.

But although this representative character of the Society is consistent with the spirit of the age, and eminently to be desired now that the Council is the executive in whom is vested the control of matters relating to all chemists and druggists, whether members or not, still the attainment of this character must be a work of time since the necessity for keeping in view the advancement of pharmacy must not be overlooked. We trust that the growth of the Society will never be merely in numbers, but that every accession to its ranks will be accompanied by a corresponding development of that earnest desire for improvement which led to the foundation of the Society when it was good for pharmacy that the few should rule rather than the many. We have indeed more than once expressed surprise that so many should still remain "outsiders;" but while we hear it seriously asked what a member of the Society can have for his subscription besides a Journal that might be borrowed, it is scarcely possible to avoid either the thought that representation might at present involve "levelling-down," or the hope that the selection of the Society's Executive may never be determined by a mob under the guidance of a few active demagogues.

As closely connected with the important subject of pharmaceutical education, we must also refer to the discussion on the examinations conducted by the Society for the purpose of ascertaining whether persons are qualified to perform the functions of a chemist and druggist, and fit to be registered as such. Early in the year, Mr. Siebold, in a lecture delivered before the Manchester Chemists and Druggists' Association, criticized somewhat severely the system adopted in carrying on these examinations, and his assertion that competent men were rejected attracted considerable notice. It seemed to be the general opinion that Mr. Siebold had been too sweeping in his statements, and likewise that some of the alterations suggested by him would not be improvements. The subsequent report of Dr. Greenhow, the Government visitor, did not bear out Mr. Siebold's views; and as regards the Minor examination, it was then stated that the failures—amounting to about one-third of the candidates—were obviously due either to defective early education, or to ignorance of the elements of chemistry, and inability to recognize the commonest drugs. Moreover it was suggested that, since three years had elapsed from the passing of the Pharmacy Act, it was time to commence a gradual raising of the standard of competence.

The large proportion of failures at the Preliminary examination in this, as in former years, still continues to furnish evidence of the low standard of education in the class from which apprentices have hitherto been drawn. At the commencement of the year we were able to illustrate the truth of this by showing that, in 1870, 220 out of 741 candidates failed; but that by the end of 1871, 120 out of the 220 had succeeded in passing upon presenting themselves a second time. It is satisfactory to note that there has been a great development of opinion in favour of the rule that a lad must pass this examination before he is received as an apprentice. This is a very promising feature, and we trust that ere long it may be generally recognized as indispensable. It is to be hoped, too, that with a superior class of apprentices, the kind of service to be required from them will be more generally consistent with the requirements of subsequent steps in their career than is sometimes the case, so that the disputes which we must refer to as certainly an unpleasant feature in our year's history will disappear from our legal reports, and that consistently with the suggestions of the President in his paper on "Pharmacy in the Laboratory," and of Professor Redwood in his speech at the Crystal Palace, there may be some gradual progress towards every druggist's shop being a fit school for apprentices to acquire a sound practical knowledge of the subjects essential for them.

At the Brighton meeting of the Pharmaceutical Conference attention was again directed to the examinations by Professor Attfield, who strongly urged the adoption of more stringent measures to meet the evils of "cram," and to prevent unqualified persons from passing the ordeal of examination, while Mr. Schweitzer advocated the plan of making the Minor examination compulsory for assistants, and the Major compulsory for all those in business for themselves or as managers.

Meanwhile, the Board of Examiners had not been unmindful of the necessity for progress, or of the propriety of gradually advancing the standard of competence originally adopted on the passing of the Pharmacy Act as barely sufficient to guarantee the safety of the public. As the result of its deliberations, a statement of amended regulations was submitted to the Council at the December meeting. These regulations were then discussed and adopted, October, 1874, being fixed as the time for their coming into force. The chief object they aim at is to ensure more thoroughly the practical skill of candidates in accordance with the opinion put forward in the reports of the Government

Pharmaceutical Society of Great Britain.

LIST OF ADDITIONS TO THE LIBRARY

FROM JANUARY 1ST, 1872, TO JANUARY 1ST, 1873.

(*P.*), Pamphlet.

Agriculture.
See CHURCH (A. H.), Chemistry.

visitor, that "inasmuch as the increase of pharmaceutical skill is what will most conduce to the service of the public," a profounder acquaintance with practical chemistry should be required not only for the Major but also for the Minor examinations.

The wholesome and very reasonable provisions that candidates must have attained the age of twenty-one, and have been, as suggested by Mr. Barnard Proctor, practically engaged in pharmacy for three years before they can present themselves for the Minor examination, obviously lead in the same direction. To those who think this is demanding too much before admitting a person to be placed on the Register, and giving him the right to conduct business as a chemist and druggist on his own account, we would remark that it is a requirement by no means singular; for in a Pharmacy Act for New York, passed at the commencement of the year, it was provided that even "practising assistants" should be over eighteen years of age, and have had two years' experience, while in the Philadelphia Act, passed a little later, it was provided that no person who has not been apprenticed two years and attended one full course of lectures on chemistry, materia medica and pharmacy, is to dispense prescriptions—except as an aid under the immediate supervision of his employer or of a qualified assistant,—and that no proprietor is to leave his store in charge of any but a qualified assistant. This change will doubtless be distasteful to some of our "young friends" who have not contemplated the possibility that the standard of the examinations will be raised; but we hope and believe that as they grow older they will grow wiser upon this as well as other points, and will then confess that it has resulted in their permanent good.

Another matter of interest with respect to examinations has been the alteration in the regulations under which the Bell Memorial Scholarships are to be competed for after the award in 1873. With a view to make these scholarships an assistance to young men desirous of improving themselves in knowledge of their business rather than a reward for superior attainments, the Senior Scholarship is to be abolished, and both scholarships are to be equal. They are to be open only to "registered students or apprentices" who have been engaged for not less than three years in the pharmacy of a registered pharmaceutical chemist or chemist and druggist.

The examination fees have also furnished subject matter for discussion. On the one hand Messrs. Vizer and Carteighe have discussed the influence they exercise upon the numbers of persons passing on to the Major examination, and of those who ally themselves with the Pharmaceutical Society; while, on the other hand, Mr. Frazer and others have urged that the present examination fees are too high, and are therefore causing many young men to leave the trade. Certainly, the prospect of all the efforts on behalf of pharmaceutical education culminating in master pharmacists having to take down their own shutters is sufficiently terrible!

But we entertain no apprehension of such a result being caused by the Board of Examiners increasing its requirements; and as regards those who abandon the business rather than face the examinations and pay the fees connected with them, it is reasonable to believe that in the main the effect thus produced will be for the general benefit eventually, although for a while there may be among the number some few good men.

The attractions of other forms of business will hardly be resisted by the followers of pharmacy, unless the conditions under which it is practised are rendered much better than they have been and kept abreast of improvement in other pursuits. There is, perhaps, no way in which the Pharmaceutical Society can more effectually aid in this direction than by making the "compulsory" need for thorough education more generally appreciated and felt. With those who comprehend the problem of Pharmaceutical progress, it is natural to find that this principle is acted upon in preparing their sons for the business, as in Mr. Frazer's case, and that he should thus in practice offer the most cogent argument against the policy he has advocated at the Council table and in the pages of this Journal.

It has also been asked, with some force, on the part of assistants, whether it is expected that they will incur the expense of qualifying themselves and undergoing examination, unless there be something more tangible to look forward to in the way of remuneration than the mere raising of their status? To this question we believe the best answer will be a satisfactory reply to another one put by ourselves last March—"Shall not every dispenser of a prescription, and every person entrusted with the sale of poisons used as medicinal agents, whether master or servant, be bound to pass some examination before being allowed to do either of these acts?" As bearing on this point we may refer to the question raised as to whether the practice of pharmacy is a trade or a profession, for the purpose of repeating Mr. Brady's remark that until the pharmacist—like the lawyer or the physician—spends money and time upon his technical education as so much capital invested in business he will not have established his title to professional status or remuneration.

Place aux dames! If an additional spur be required by the aspiring pharmacist of the sterner sex, it will be found in the necessity for straining every nerve to run a level race with these new competitors under the championship of Mr. Hampson, who are entering upon the practice of Pharmacy.

In compliance with a request expressed in this Journal, the Council decided in January last that the library and reading-room should be opened on

Tuesday and Friday evenings from eight to ten o'clock. We believe that this privilege has been freely taken advantage of.

In Scotland, the North British Branch of the Pharmaceutical Society has acquired a definite recognition of its position in respect to the Parent Society, and a grant of money was made towards providing premises and a museum for the more convenient carrying out of the examinations. This step has been satisfactory to members north of the Tweed, and it will doubtless stimulate them to increased activity, not only in educational work, but also in the cultivation of pharmacy and the general improvement of the business.

The periodical meetings in connection with the Society have been held as usual. The Annual Meeting in May, was occupied at great length mainly with the subject of education; the Conversazione at South Kensington presented the now customary features of attraction, and at the meeting in October, to inaugurate the session of the School of Pharmacy and distribute prizes to the students of the previous session, a very instructive address to the students was delivered by Mr. W. W. Stoddart, of Bristol. The Evening Meetings have been, in regard to attendance and interest, fairly up to the average, though there is still much room for improvement. The Chemists' Ball was as successful as ever; and there was also the novel feature—connected with the visit of provincial members to the metropolis in May—of the first Annual Dinner of the Society at the Crystal Palace, when upwards of two hundred gentlemen connected with pharmacy met together with a mutual satisfaction which we hope will characterize many similar gatherings in the future. The meeting of the British Pharmaceutical Conference at Brighton, in August, was one of great interest to the trade, by reason of the important discussion which took place upon the education question. Several valuable papers on pharmaceutical subjects were also read there.

In deference to the expressed wish of a majority of the Society's members, the present Council decided at one of its earliest meetings that in view of the representative character of its deliberations, full reports of the proceedings at their meetings should be published in this Journal, and at present there does not appear to be any reason to regret that decision. While on the subject of the Journal, we take the opportunity of thanking those who have been kind enough to furnish us from time to time with papers containing reports of local occurrences; and at the same time of urging upon our readers, especially local secretaries, that they should immediately forward to us information respecting anything happening in their localities which is likely to be of general interest. We would go further, and say that were each pharmacist to contribute an account of such fresh experiences in practical pharmacy as came under his notice, our columns would be enriched with much valuable information.

The contributions to the Benevolent Fund have increased during the year, the last week of the year having been marked by the receipt of a legacy of £500, clear of duty, from the executors of the late Mrs. Lyon. The disbursements in annuities and grants during the year have amounted to £525 10s.

In order to carry out efficiently that important provision of the Pharmacy Act relating to the publication of a Register of Pharmaceutical Chemists and Chemists and Druggists, the section providing for the sending out of registered letters was acted upon; the result being that in October the Registrar published a list of upwards of one thousand names of persons who had failed to reply and a notice that they would be struck off the Register unless they communicated their proper addresses before the 31st December. Of this number, we understand that 660 have failed to comply with the requirements of the Act, and that their names will consequently be omitted from the Register now in the press for this year.

In respect to infringments of the Act relating to the sale of poisons, some complaints have been made, apparently upon the assumption that only the Pharmaceutical Society could prosecute for the sale of poisons by unqualified persons, and that the Executive was in this particular indifferent to its duties. Both these assumptions are incorrect, for any person is competent to prosecute who can prove a breach in the provisions of the Act; moreover, we are informed that while every case which has been brought under the notice of the executive of the Society has been attended to, it has, in several instances, been found, after considerable trouble and expense, that they would not bear the test of a prosecution. The position of widows under the Act has also been discussed and illustrated by what was claimed to be a particularly hard case. It was felt, however, that as the law had to be dealt with as it stood, the best way to meet the difficulty was for chemists and druggists to consider and act upon the actual terms of the Act; and with the object of securing that end several articles in this Journal were devoted to the subject. It may be remarked that the duties of Local Secretaries in respect to carrying out the Pharmacy Act, as well as in other matters, appear in some places to be imperfectly understood, and it would be well if some clear definition of them could be promulgated.

In May last, statistics were published in this Journal of the cases of accidental poisoning that had occurred since the passing of the Pharmacy Act in 1868. These statistics afford the best answer to, and take away all excuse for, the sensationalism and vague generalities upon the subject previously indulged in to some extent by the newspapers, and more especially by the medical press, which ought to have been better informed as to the real facts of the case. Since the publication of the statement referred to, we have reported 41 cases of poisoning by accident, suicide, or with intent, and among these two only were referrible to mistakes made by druggists either in the sale or dispensing of poisons, one of these being in part due to the want of precision in the terms of a prescription. We may, perhaps, be permitted therefore to congratulate our readers that there is still no evidence to establish the necessity for hanging a Chemist and Druggist believed in by the *Pall Mall Gazette*, nor any justification for the flagrant accusations of some of our medical contemporaries.

The numerous cases of death, accidental and otherwise, from poisoning by vermin killers, have directed attention to the conditions under which these are to be sold, and many communications have been published, showing that great and wide-spread uncertainty exists upon this point. The matter has recently been under the consideration of the Council, and, on the recommendation of the Parliamentary Committee, it was decided to add some explanatory words to the regulations, and to issue a revised copy of them, defining more clearly the manner in which poisonous vermin killers are to be dealt with.

We took occasion, some time since, to point out the inconsistency of the present rates charged upon the patent medicine licence, and to suggest that the equalization of all the rates to the higher sum of £2, or some approximation thereto, would be conducive to the interests of chemists and druggists. In the correspondence that followed the balance of opinion seemed to incline towards some such alteration.

It is a matter for congratulation that the persistent and energetic efforts of the advocates for the adoption of fewer hours of business have met with considerable recognition, and that this year more has been accomplished towards earlier closing and the avoidance of Sunday business by chemists and druggists than in any previous year. Still much more remains to be done, and it is to be hoped that the custom will become each year less exceptional.

The relations between medical men and chemists and druggists are so intimate, that it is extremely desirable every cause of misunderstanding between them should be removed. The practice adopted by some prescribers of using a peculiar nomenclature in order to secure to a particular chemist and druggist the dispensing of their prescripions has again been referred to, and the conduct of both parties to such an agreement denounced. But still more serious grievances result, on the one hand, from the practice of medical men keeping "open surgeries," and on the other hand from the cultivation of "counter prescribing" by some chemists and druggists. It was therefore satisfactory to find the *Lancet* recently declaring that it would "gladly see the entire surrender of medical dispensing as a practice, and would like to abandon the ordinary supply of medicines to the druggist, at the same time restraining him from prescribing." The confusion to which the present custom leads is amusingly illustrated by our contemporary, who, in sarcastically defining a "chemist" as a person who sells Epsom salts and has a shop window containing blue and green bottles, unconsciously propounded a definition that would include many persons on the Medical Register. Evidently the popular idea of the "doctor's" shop was for the moment lost sight of.

Amongst other matters connected with the trade which have been brought forward during the year may be mentioned the desirability of some improvement in the method of supplying medicines to seagoing vessels, and the claims of various deodorizers and disinfectants. Serious evasions of the law in reference to the sale of spirit have occurred, and extensive seizures were made in consequence. It is matter for regret that the subscriptions to the Betts' Suits Defence Fund have not yet amounted to sufficient to clear off the balance due for legal expenses.

The good feeling existing between the pharmacists of England and the United States was illustrated by courtesies interchanged at the meeting of the American Pharmaceutical Association, at Cleveland, Ohio, and no doubt the bond will be strengthened by the hearty response which was made in this country to the appeal on behalf of the Chicago College.

The Parliamentary measures affecting pharmacists have been few. Among these the Juries Bill and the Petroleum Bill stand over. This is also the case with greater part of the Public Health Bill. The Adulteration Act presents at least so much interest that it has raised an important question as to the office of public analyst, the discussion of which is too recent to need recapitulation.

Although original communications of chemical researches or on subjects of pharmaceutical interest have not been so numerous as might have been wished, some of great value have appeared in this Journal during the year. Messrs. Stoddart and Tucker's paper on the Tinctures and Wines of the Pharmacopœia has been followed by Mr. Umney's on the Specific Gravities of the Liquids of the B.P. Mr. C. H. Wood has dealt with the subject of metric weights and measures. Mr. Daniel Hanbury has thrown light on the origin of Calabrian Manna. Mr. Morson has described a new test for Creasote, and Mr. Williams has investigated Guaiacol. Mr. Ekin has found silver in preparations of bismuth. Mr. Moss has contributed a valuable paper on Antimonium Sulphuratum. Dr. Tilden has continued his researches upon Aloes. Mr. Treves has contributed an original note on the Odour of Gases. Mr. Schweitzer has given some useful instructions respecting Percolation. And last, but not least, there has been a valuable series of papers by Mr. Pocklington, on the Microscope. From America we have had valuable papers by Professor Parrish on Pharmaceutical Processes; Mr. Rother, on Emulsions; and Mr. Scheffer, on Pepsin and some of its compound preparations. From France we have had the Memoirs of Messrs. Duquesnel and Nativelle on Crystallized Aconitine and Digitaline respectively; and M. Lefort's exhaustive investigation into the distribution of Atropine in the Belladonna Plant.

"New remedies" must always be a phrase of interest to the pharmacist. Cundurango has rapidly declined in favour, and a recent report is very unfavourable as to its value in cancerous affections. Eucalyptus, Samadera Bark and Kokoon Bark, Koegoed, Boldo, Vandellia diffusa, Guarana, and Japanese Wax; Dugong Oil and Bullock's Blood; Xylol, Sulphydrate of Chloral, Sulphovinate of Soda, Monobromide of Camphor, Picrate of Ammonia, and Aconitine and Digitaline in a crystalline form, may be all classed under this category. Antiseptic pharmacy has also had its place in our pages. Phosphorus has recently received an unusual share of attention. Combinations of Oleic Acid with metals have also been recommended. Interesting and favourable reports have been published of the Cultivation of Cinchona in India, Jamaica and Java, and of Ipecacuanha in India; while another Indian-grown drug, Opium, has now to compete with that grown in China, Persia, Australia and the United States.

The death-roll of 1872 contains the names of many who were held in honour by pharmacists. Amongst these may be mentioned:—Edward Arnold of Norwich, H. Argles of Maidstone, Professor Blyth of Cork, John Cargill Brough, Dr. Day, Ernest T. Chapman, F. R. Garden, Dr. Gray, W. Huskisson, Joseph Kernot of Naples, Professor Le Canu of Paris, Sir J. Murray, Professor Parrish of Philadelphia, Reuben Payne, Mrs. Somerville, Dr. Welwitsch, and Dr. Wight.

Having now referred to all the more important incidents of the past twelve months, we must conclude by wishing our readers a prosperous new year, and expressing our hope that it may be marked by many indications of pharmaceutical progress,

MUSEUM, LIBRARY AND READING ROOM REGULATIONS OF THE NORTH BRITISH BRANCH.

The following regulations, which have been issued by the Council of the North British Branch of the Pharmaceutical Society, for the museum, library and reading-room in St. Giles Street, Edinburgh, may be of assistance in drawing up rules for similar institutions, projected or established, in other localities:—

1. The rooms are to be open every lawful day from 10 till 4, and from 6 till 10, excepting on Saturdays when the hours will be from 10 till 3.
2. No smoking to be allowed under any pretence whatever.
3. Season tickets for the removal of books to be had on personal application to the Secretary, 119, George Street.
4. In the meantime, and until further arrangements now in contemplation are carried out, no specimens are to be removed from the cases.
5. No publication lying on the reading-room table to be removed at any time, until such periodical be four weeks old, and then under the same conditions as if it were a book.
6. All books damaged or lost while on loan must be made good at the expense of the party responsible therefor.
7. Every volume to be returned to the library within a month, and in the event of no inquiry having been made, the party returning the book may retain possession of the volume on again entering it in the library book.
8. Any parties desiring books not in the library, will require to make application by entering the same in the want-book, which will be found on the library table.
9. All entering the rooms are requested to write their names in the visitors' book, and those receiving books must show their library ticket; and on getting the volume or volumes they wish, enter their own name, as well as that of the publication in the library book, which will be found in charge of the keeper of the rooms.

WOMEN AS PHARMACISTS.

The following notice concerning the employment of women in pharmacy is in the *Gazette Médicale de Paris*, for December 28th, 1872:—"After female doctors we shall have female pharmacists; the one necessitates the other, though we should have thought that the mistress of pharmacy would have preceded the doctoress. However that may be, the School of Industry for Women, established in Amsterdam in 1869, by the Society of Public Usefulness (*Société d'Utilitie Publique*), has already qualified five young women for the pharmaceutical profession, and is now engaged in educating seven others for the same vocation. Doubtless others will not be slow to follow this example. Already German societies, instituted to obtain means of existence for women, think of uniting to present to the Federal Council of the Empire a petition, praying that women should be authorized to follow the profession of pharmacist, or, at least, that of a dispenser. It seems that there is a complete dearth of dispensers in the little German towns, especially in the country. The new measure which is demanded should have the effect of obviating this state of things."

Dr. Corner, Medical Officer of Health for Mile End, has been appointed analyst for the district. Dr. Thorpe has been appointed analyst to the city of Glasgow. There is also a vacancy for an analyst for the Wandsworth district announced.

NOTICE.

In consequence of the adjournment of the Meeting of Council until January 8, the publication of the next Number of this Journal will be deferred until Saturday.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

January 1st, 1873.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

Present—Messrs. Betty, Hampson, Hills, Owen, Sandford, Urwick and Williams.

The minutes of the previous meeting were read and confirmed.

ADULTERATION OF FOOD, ETC., ACT.

The PRESIDENT reported that the Deputation had waited on Mr. Stansfeld, as requested at the last meeting of the Council. It was promised that the matter should be fully considered by the Local Government Board, but no answer had yet been received. An account of the interview appeared in the Journal of the 14th December.

The following letter from the Privy Council Office was read:—

"Medical Department of the Privy Council Office,
"4th December, 1872.

"Sir,—

"In answer to your letter of the 9th ultimo., submitting, on the part of the Council of the Pharmaceutical Society of Great Britian, for the approval of the Lords of Her Majesty's Council, the name of Mr. William Martindale, a Pharmaceutical Chemist in London, proposed to be appointed Examiner for the Society in the room of Mr. Augustus Bird, resigned, my Lords direct me to inform you that they approve of the appointment submitted to them.

"I am, Sir, your obedient servant,
"JOHN SIMON.

"The Secretary,
"Pharmaceutical Society of Great Britain,
"17, Bloomsbury Square."

The names of former members, associates and an apprentice who had paid their arrears and subscriptions for the current year, together with the fines, were respectively restored to their former status.

The following Pharmaceutical Chemists were respectively granted a diploma stamped with the seal of the Society:—

Collishaw, John ....Nottingham.
Edwards, David ....London.
Hanbury, Frederick Janson ..London.
Houghton, Robert William ..Bermuda.
Jones, David ....Rhyl.
Nuthall, Edwin ....Norwich.
Trist, Richard ....Plymouth.

ELECTIONS.

MEMBERS.

The following Pharmaceutical Chemists were elected Members of the Society:—

Daniel, Silas ....Ramsgate.
Dunkley, Edward...........Tunbridge Wells.
Forbes, William Thomas ....Reigate.
Johnson, Robert Allen ......Bayswater.
Metcalfe, Wilson ....Chelmsford.
Whitfield, Henry ....Worcester.

The following "Associate of the Society, before July, 1842," was elected a Member:—

Lawrence, Henry Job ......London.

ASSOCIATES.

The following having passed their respective examinations, and being in business, were elected "Associates in Business" of the Society:—

Minor.

Baker, William Ritchie ......Sidcup.
Betts, Samuel ....Oadby.
Gorrie, John P. ....Perth.
Graham, Alexander ....Lochgelly.
Lester, Henry ....Nuneaton.
Richards, James Griffiths ....Hastings.

Modified.

Bogle, Robert ....Heywood.
Calvert, Edwin Archer........London.
Done, Henry Thomas ....Birmingham.
Donston, William............Tottenham.
Hilton, William ....Whitefield.
Kermath, William Ramsay....St. Andrew's.
Wilson, Clement Fisher ......Stoke-on-Trent.

The following, having passed their respective examinations, were elected "Associates" of the Society, not in business:—

Minor.

Allen, Charles Bowen.........Penzance.
Almgill, John.................Bedale.
Cooper, Frederick Richard....Manchester.
Gordon, John ....Aberdeen.
Markham, William Charles....Bristol.
Mathie, William ....Edinburgh.
Nicholls, Theophilus..........Lower Mitcham.
Norweb, Arthur..............Nottingham.
Pickard, William ....Yeovil.
Rees, Joseph Henry Williams..Clutton.
Richardson, Edward..........Dresden.
Robertson, George...........London.
Samson, Ernest..............Bristol.
Shirley, Stephen Shillito......London.
Smith, Tenison ....Cambridge.
Sumner, John Joshua.........London.
Taylor, John James..........London.
Tully, John..................Brighton.
Weaver, Edwin Thomas......London.

Modified.

Clarkson, Thomas............Hartlepool.
Hughes, John Henry.........Holywell.
Jones, Owen ....Litherland.
Markham, John, jun. ....Reigate.
Stubbs, Thomas Shaw.........Bristol.

APPRENTICES OR STUDENTS.

The following having passed the Preliminary Examination were admitted Apprentices or Students of the Society:—

Beringer, John Jacob ....Redruth.
Bond, Henry Greensill ......Portishead.
Cairns, John ....Kelso.
Clark, William Coltart ......Dalbeattie.
Daniel, John ....Ceibach.
Evans, John ....London.
Gardner, William............Barnard Castle.
Gibson James ....North Shields.
Graham, William Woodrow..Dalbeattie.
Hardwick, Stewart ....Sleaford.
Jeanes, George ....Alverthorpe
King, William ....Southend.
Knight, Alfred George ......Swansea.
Robertson, John ....Inverness.
Shepherd, John William......Settle.
Turner, William Spencer ....Hingham.
Umpleby, Samuel Sayer......Harrogate.
Weatherley, Richard John....Teignmouth.
White, Osmar Alfred ....Woolwich.
Whitwell, Ewen ....Peterborough.
Wilks, Maurice..............Leeds.
Williams, James Edward ....Louth.

Wills, George Sampson Valentine . . Hay.
Wolstenholme, John, jun. . . . . Bury.
Woodall, John Leigh . . . . Manchester.
Worringham, Edward . . . . Ipswich.

Benevolent Fund.

The Treasurer reported that he had received of the executors under the will of Mrs. Jane Lyon, late of 17A, Albert Terrace, Knightsbridge, the legacy of £500, bequeathed to the Benevolent Fund of the Society, free from duty.

Resolved—"That the Treasurer be requested to invest the said £500 in Consols to the account of the Benevolent Fund."

In reply to an inquiry the Secretary said that each of the executors of the testatrix would be entitled to five votes for life at each election of annuitants.

The Treasurer was also requested to pay the fourteen annuitants on the Benevolent Fund their quarter's annuities to Lady Day next.

Finance Committee.

The usual monthly report of the Finance Committee was read and received, and payments for rents, salaries, etc., ordered.

Adjournment of the Council.

It was moved by the President, seconded by the Treasurer, and resolved—

"That the Council do adjourn until Wednesday, January 8th, at 11 o'clock."

BENEVOLENT FUND.

Subscriptions, Donations, and Legacy Received During October, November and December, 1872.

Provincial Transactions.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION.

An ordinary meeting was held in the class-room, 37, Blackfriars Street, on Thursday evening, December 12th; Mr. W. S. Brown, President, in the chair.

The following gentlemen were elected associates:—Messrs. Halliwell, Unsworth, Orton, Crowther, Lupton, Clegg, Drew, Hudson, Pollett, Chatwood, Lister, Bennett, Baynor, Mason and Walters.

Mr. J. T. Slugg, F.R.A.S., delivered a most interesting lecture on "Our Planet, its size, shape, weight, past history, and present condition."

A cordial vote of thanks to the lecturer, proposed by Mr. Hampson, of London, and seconded by Mr. Mumbray, was passed.

The Chairman then briefly explained the amended regulations of the Board of Examiners, and considerable discussion followed, Mr. Hampson and some others expressing their disapproval of the alterations.

Mr. Siebold thought that an attempt had been made to render the examinations more practical; the slight extension of chemical knowledge required was most desirable. He believed that to be any use to the pharmaceutical student, chemistry should be carried far enough to enable him to apply ordinary tests, and he had met with many young men who had passed the Major utterly unable to perform such operations. He hoped that this increase of science would be balanced by a corresponding decrease of mere "cram" subjects. He had before expressed his strong disapproval of what appeared to him objectionable in the examinations, and his opinions remained unchanged as to the utter uselessness of such knowledge as could be only crammed up for the occasion. He did not believe there was a pharmacist present, even of forty years' experience, who could remember the exact composition of all the compound powders, etc. of the Pharmacopœia. If such knowledge was not found necessary by heads of large establishments, why should it be required of students? He had observed for some time past, however, a growing inclination on the part of the examiners to ask candidates more difficult questions than formerly, often with a view of testing the soundness of their knowledge, and he believed that every effort was now made to exclude the unqualified man.

The next meeting will be held on Friday evening, January 17th, at 7.30, when a lecture will be delivered by Mr. Louis Siebold.

Proceedings of Scientific Societies.

PARIS SOCIÉTÉ DE PHARMACIE.

A meeting of this society was held on Wednesday, November 6th, under the presidency of M. Stanislas Martin. After some preliminary business, M. Roucher brought forward his proposition as to the collection of the materials necessary for an universal pharmacopœia. M. Roucher has been promised the assistance of many competent persons, and he asked that he might be charged with the labour requisite for carrying out this important project. It was decided to remit the consideration of his request to the committee previously nominated upon this question.

M. Poggiale presented a note from M. Dubois, pharmacien militaire, upon two new processes for the preparation of sulphovinate of soda. After the sulphovinic acid has been prepared by the ordinary process and allowed to cool, it is diluted with strong alcohol and saturated directly with purified carbonate of soda in powder. When this method is adopted no special precautions are necessary, since if too much carbonate of soda be added that salt is insoluble in the alcohol, and remains upon the filter with the sulphate of soda. As there is no elevation of temperature, the chance of loss is avoided. The whole is thrown upon a filter and the sulphate of soda is washed with a little alcohol. The liquid is then distilled and evaporated in a water-bath to crystallization. Should the crystals retain any of the colour of the mother-liquor, it is only necessary to redissolve them in water and evaporate to a density of 36° to 38° to obtain perfectly white crystals.

In a footnote the editors of the *Journal de Pharmacie et de Chimie* state that when sulphovinate of soda is prepared by saturating sulphovinic acid with carbonate of baryta, and decomposing the sulphovinate of baryta thus formed either by sulphate or carbonate of soda, it might happen that the whole of the sulphovinate of baryta was not decomposed, and then that dangerous salt would remain mixed with the sulphovinate of soda. M. Duquesnel has recently recommended that sulphovinate of soda should be carefully tested with dilute sulphuric acid for baryta; and with chloride of barium for carbonate of soda.

At the introductory meeting of the session of the School of Pharmacy, M. Bussy delivered an address to the students. He illustrated his advice to them to make the best use of their opportunities by referring to two illustrious men, Vauquelin and Parmentier, whose busts have recently been placed in the entrance hall.

Vauquelin, starting from the lowest position, as a laboratory boy in a provincial pharmacy, became by persevering labour one of the most distinguished chemists of his time; to him we are indebted for many discoveries important to science and industry, among which may be mentioned those of chromium and glucina. As a colleague of Fourcroy, professor at the School of Mines, at the Museum of Natural History, and the Faculty of Medicine, he formed part of the glorious constellation who, under the impulse of Lavoisier, laid the foundation of modern scientific chemistry. Named director of the School of Pharmacy at the time of its institution, he then became connected with the establishment in which he had left such pleasant memories. Many of those present, amongst them the speaker, could remember the inexhaustible kindness which was the principal trait and particular charm of his character.

Parmentier, like Vauquelin, commenced his career under the most unfavourable conditions; like him, too, starting from the modest laboratory of a provincial pharmacy, he attained by labour the highest positions and considerable fame. He is honoured particularly for the benefits he conferred upon France by his successful efforts to introduce the potato as an article of diet; efforts which have been recognized by the public in conferring upon it the name of *parmentière*. Parmentier occupied for a long time the highest post in the corps of military pharmaciens; but neither personal abnegation nor devotion to his duties prevented him from the cultivation of science, and by his merits he placed himself in the front ranks among such men as Bayen, Laubert, Boudet, Serullas, and Millon.

M. Bussy concluded with a reference to the death of M. le Canu, who was long a professor in the school.

Parliamentary and Law Proceedings.

The Charge of Fraud against a Herbalist.

On Saturday, Dec. 21, the hearing of this case was resumed. Dr. Munroe, who, with Dr. Walton, had made an analysis of a great part of the articles supplied to the prosecutor, said the glass into which Richardson was to blow through a tube contained a solution of lime. One of the glasses called by the prisoner "pulse glasses" was merely an air thermometer toy. The other tubes were of a similar character, and were not of Indian manufacture. The box stated by prisoner to be of cedar wood was merely stained deal. The bottles labelled for the "heart," "appetite," "rheumatism," "kidneys," "lungs," and "blood," contained a simple saline solution. There were about eight grains of chlorate of potash in each bottle. The "spikenard ointment" was cocoa-nut oil mixed with lard.

Cross-examined: Chlorate of potash was not a stimulant. It was a refrigerant, and was formerly thought to be a diuretic. It was thought that it gave oxygen to the blood, but that was a fallacy. Chiretta, which some of the "medicines" contained, was a nice tonic for a person who had a weak stomach.

Dr. Walton said that the eight-guinea bottle called "restorer of life" contained water with a little sulphuric acid. The contents of the bottle would not be worth 6*d*. The bottle itself would be worth about 2*d*. It was a tonic and astringent. The "sediment of gums" was only bay salt, and would be worth about 2*d*.

Cross-examined: Thought the solution of sulphuric acid might excite the appetite and promote digestion, and would be a proper thing to give to a man in a similar condition to that in which prosecutor said he was. In his analysis he found no trace of any tincture of buchu. The bottle said to contain myrrh no doubt did contain it. Myrrh had the reputation of being a stimulant-tonic.

Examination resumed: The "bread of life" was granulated effervescent magnesia. A smaller bottle labelled "The Indian Remedy" also contained water acidulated with sulphuric acid. The guinea bottle said to contain chiretta did contain diluted tincture. It would be worth about 3*d*.

Prisoner, who said it was very hard that he should have to neglect his business through other people's false statements, was further remanded.—*Eastern Morning News*.

Accidental Poisoning by Arsenic.

On Thursday, December 12th, an inquest was held at Kilgananagh, in the neighbourhood of Antrim, on the body of a woman named Margaret Carlisle, thirty-five years of age, wife of a respectable farmer of that place, whose death was caused under the following circumstances:—On the previous Tuesday deceased's husband had gone to the market at Antrim, where he was to have been joined by his wife, who shortly afterwards left home for that purpose. Previous to leaving, however, feeling not very well, she went to a drawer to get a little cream of tartar, which she occasionally took when she felt unwell, but in mistake she took half a teaspoonful of arsenic (a small quantity of which was in a paper in the same drawer), instead of the cream of tartar, and on reaching Antrim she became so ill that Dr. Taggart was sent for, but death put an end to her sufferings next morning. The jury returned a verdict "That the deceased died from the effects of poisoning by arsenic, which she had taken in mistake for cream of tartar."—*Belfast News Letter*.

VACANCIES AND APPOINTMENTS IN CONNECTION WITH PHARMACY.

The Editor will be glad to receive early notice of any vacancies of pharmaceutical offices connected with public institutions, and likewise of appointments that are made,—in order that they may be published regularly in the Journal.

APPOINTMENT.

Mr. Oswald A. Reade, pharmaceutical chemist, of Belfast, has been appointed Dispenser to Her Majesty's Naval Hospital at Ascension, with charge of stores.

VACANCIES.

Dispensers possessing the Major qualification of the Pharmaceutical Society are required for service in Her Majesty's hospitals. Particulars may be obtained at the Medical Department of the Navy, Admiralty, Somerset House.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

Local Secretaries.

Sir,—No decision has yet been arrived at by the Council on the notice of motion proposed by me a few months ago, and in the slight correspondence which has taken place on the subject my meaning seems to have been misunderstood.

The Preliminary examination cannot be carried on without some out-of-pocket expenses for stamps, blotting-paper, pens, ink, etc., a detailed account of which many would not trouble themselves to keep; and it occurred to me that without considering it at all in the light of a professional fee, a small sum per head might be allowed by the Society to cover these miscellaneous expenses.

I have not the slightest wish to press this particular form of compensation upon the local secretaries, but I feel sure that Mr. Hills, who proposed another way of doing it, wishes with myself that we could arrive at something satisfactory to those whose interests are concerned. Trusting that these few words may lead to a more general expression of opinion on the matter, I am, Sir, yours, etc.,

Francis Sutton.

Chemists as Analysts.

Sir,—We are admonished in the book which is recommended to us for the guidance of our lives not to "Render evil for evil or railing for railing, but contrariwise blessing." The rule is, perhaps, a hard one to practise at all times, but if we cannot always bless them that despitefully use us, we may pity the ignorance which dictates such conduct. These thoughts were forced upon my mind on reading the unreasonable and unfair article in the *Lancet* of the 21st ult., on the subject at the head of this letter. I am only surprised the writer restrained himself from calling us some other ugly names. He exercised no virtue by refraining, as he contemplated what he only from policy left undone. His own profession, of course, he assumes to be immaculate. The line of argument adopted by the writer is as absurd as if it had been proposed to recognize the eligibility of tailors and shoemakers. No one has ever suggested that all druggists (as he disparagingly chooses to designate us) were either qualified for such duties, or deserved such an appointment; and although "the dense and hopeless ignorance of Gwydyr House" may be impenetrable to the discernment of the *Lancet*, let us hope the higher qualities of justice, impartiality and reason, still hold sway in the councils of the Local Government Board, and that Mr. Stansfeld will have the moral courage to despise the senseless railing and meditated insults of such articles as have disgraced that publication.

An Analytical Chemist and Pharmacist.

December 30th, 1872.

The Adulteration of Food Act.

Sir,—It is satisfactory to learn that in the choice of persons desirous of filling the office of public analyst, the appointors are not pledged to favour the ranks of any particular profession.

I am ignorant as to the value of the appointment, but unless it be of sufficient importance to form an independent source of income, I venture to anticipate a weighty objection to the fitness of a pharmacist, in his quality of tradesman, sitting in judgment on the wares of his fellow-shopkeepers.

The man who undertakes the delicate and responsible task of analyst under the new Adulteration Act ought to be far removed from the petty influences and prejudices of ordinary commercial life.

The argument is, I think, so evident that I need not follow the subject.

Walter A. Powell.

Castle Street, Swansea.

Sir,—The columns of the Journal have been for some time past pretty fully occupied in discussing the claims of rival parties—medical and pharmaceutical—for the appointment of public analysts under the recent Adulteration Act. I have no intention of entering upon the subject at any length, but I cannot, in passing, refrain from expressing my sympathy with the pharmaceutical body in this somewhat vexed question. There is, however, a difficulty in their way which I have never yet seen provided for. Drugs come as much under the Act as food. Let us suppose that any of my brethren in business succeeded in getting this *very lucrative* analytical appointment, and that it should so happen that the medicine which he himself dispensed or sold was suspected. What is to be done? I fear the community would hardly be content with his analysis—however accurate—in such a case.

If proper remuneration were held out, the appointment might become a valuable one; for besides food, drink and drugs, in many agricultural districts in Scotland and England vast quantities of mineral manures are now used every year. These, and others which might be named, would properly enough come within the province of the public analyst, and would, I believe, form the most lucrative source of revenue under the appointment. We have among us not a few men highly competent for the situation; but in order to secure thorough confidence, the party holding such an appointment should not, in my humble opinion, have connection with any branch of trade coming under the operation of the Act.

The same remarks, of course, would apply to medical men who hold a direct or indirect interest in drug shops.

Wm. Robertson.

Clydesdale Buildings, Elgin,
December 30th, 1872.

Sir,—In reference to the question that was raised in this Journal whether ph rmaceutical chemists are eligible as analysts under this Act, it seems to have been settled that, if otherwise qualified, they are thus eligible.

Some have thought that members of our body might probably become candidates for the appointment, but I think a very little consideration would show that such a course is by no means desirable for the following reasons:—

1st. The very wide qualification required under the Act, viz., competent medical, microscopical, and chemical knowledge would exclude with very rare exceptions the whole of our body from the field.

2nd. It seems most improper that any person engaged in trade should be empowered to set in motion a prosecution against his compeers, perhaps rivals in business; how impartial soever such an analyst might be, his reports would on this ground be always open to suspicion and dispute.

3rd. The Act, as I understand it, imposes an indefinite amount of work for a fixed annual remuneration, and it is quite possible that in large towns the whole time of the analyst might be required for his official duties, thus compelling him, if a pharmaceutical chemist, to give up his ordinary business. In the district where I reside, the authorities propose to remunerate the analyst by the munificent salary of £100 per annum. I need hardly say that not many pharmacists, competent or otherwise, will be taken with this bait.

Seeing that the Act requires medical, microscopical and chemical knowledge embodied in the same individual, I will venture to say that very few of the medical profession could fairly and conscientiously undertake the duties. It must be remembered that questions of a difficult character may frequently arise which cannot be conclusively solved by such a smattering of chemistry or medicine as may be picked up by a six months' attendance on lectures on the respective sciences, and herein lies a great danger to the public—really able and competent men will hold aloof, and pretentious sciolists get the appointments. Now, of all the impostors who have deceived the public, perhaps the worst are some of these pseudo-scientific men who have puffed themselves into a cheap notoriety by playing on the credulity and the fears of the ignorant with respect to the adulteration of food, etc., and some other sanitary questions.

The Act, although it imposes severe penalties for selling adulterated food or drugs, provides none for selling adulterated science; and as it is not to be expected that the local authorities can fairly estimate the qualifications of candidates for the office, I tremble to think of the danger to property and reputation to which the trading community will be liable in the hands of some "scientific" analysts who are sure to come to the surface. I would suggest that pharmacists might, with great advantage to the public, occupy a little time in testing the analysts who may be appointed. Every chemist knows that an accurate separation of vegetable and animal products as found in commerce into their proximate constituents is tedious, difficult, and in many cases impossible, but there are men who profess to be able to analyse anything and everything; let some organic substance, either known to be genuine, or mixed in known proportions, be submitted to some of the analysts for their examination and report, and they may thus be made to appear in their true colours.

Evidence internal and external might be adduced to show that the Act, if not originated, was yet greatly coloured by an interested and noisy clique operating on the credulity and practical ignorance of the legislature. I will venture to predict that it will become a dead letter, a fate which has already befallen the Arsenic Act, and will at no very distant period overtake Clause 17 of the Pharmacy Act.

A Pharmaceutical Chemist.

[*⁎* In publishing the foregoing letters, we must remark that some of the opinions expressed are based upon erroneous reading of the Act, and that some of the arguments they contain have already been dealt with in last week's Journal.—Ed. Pharm. Journ.]

Milk Testing.

In the article on "Cows' Milk and the Best Methods of Detecting its Adulteration," by Mr. Charles Ekin, in last week's issue of the Pharm. Journ., it is stated that cows' milk is a slightly alkaline liquid. I have examined several samples of cows' milk and have always found a slightly acid reaction. According to Dr. Parkes, an alkaline reaction indicates either that the cow is diseased, that there is much colostrum, or that carbonate of soda has been added.

The system of estimating the richness of genuine milk by the amount of solids may be of value, but in cases of adulteration with chalk, starch, etc., the result would be far from satisfactory.

The estimation of fat by ether is a very delicate process, and I think the lactoscope of Vogel is preferable, a description of which may be found in Parkes' 'Manual of Hygiene.'

The cream may be estimated by allowing the milk to stand 24 hours in a glass tube graduated into 100 parts; the percentage can at once be read off. Any deposit should be examined with the microscope for starch or epithelium; chalk, etc. should be tested for in the usual way.

With regard to the estimation of water by specific gravity: on Saturday last I obtained a sample of pure milk, sp. gr. 1031, at 60° Fah., and when this was mixed with water, I obtained the following results:—

10	per cent. of water gave a sp. gr. of			1027	at 60° Fah.
20	„	„	„	1024	„
30	„	„	„	1022	„
40	„	„	„	1020	„
50	„	„	„	1018	„

Charles H. Southwell.

The Edinburgh Chemists' Assistants' Association.

Sir,—In the number for December 21st, there appeared from some one subscribing himself 'An Edinburgh Assistant,' what must be considered as an impotent attempt to throw discredit, and a want of sincerity upon the committee entrusted in following up and carrying out the "suggestion" made at a meeting last April, viz., the necessity of the Edinburgh chemists' assistants forming themselves into a literary, etc. association. The following, I trust, will be sufficient to remove such imputation, that the committee has either been unfaithful, or wanting in zeal towards their commission, in having allowed matters to drift to such a termination as stated by your correspondent."

At a meeting of committee held on the evening of Dec. 6th, in the rooms kindly furnished by the Council of the North British Branch of the Pharmaceutical Society, the majority at once agreed to act as office-bearers for the present unavoidably short session. Rules were drawn up, duly passed into the printer's hands (a copy of which is herewith enclosed), and it is now the pleasing duty of the committee to announce that the President will deliver the introductory address to the Edinburgh Chemists' Assistants' Association, on the evening of Friday, 3d January, 1873, regarding which due intimation will be given.

Further, I would remark that at the close of the present session office-bearers will be elected, in accordance with the rules, from the members of the association, so that all will be on an equal footing, in being eligible for honours; indeed such should and would have been the case at present, but it being only two or three weeks since possession of the rooms was obtained, it was thought the sooner we got set to work the better. It will be gratifying to find that the result of the deliberations of the committee shall have merited and met with general approval; should there have been the slightest appearance of "tardiness" in the matter, it should be remembered that "Rome was not built in a day."

All are earnestly invited to come forward, even to the number of the eighty, or ninety, or more, who evinced such unmistakable satisfaction over the "material." The call being made, it is desired that they will not be dilatory in coming forward to partake of the more exalted,—the "intellectual."

John Hutchinson, *Vice-President*,
Chairman at the April meeting.

Edinburgh,
December 23*d*, 1872.

Co-operative Stores.

Sir,—Many members of the trade having expressed their conviction to us, that the sale of goods at the co-operative stores could be prevented by the proprietors of specialities like patent medicines, if they put a pressure upon the wholesale houses by refusing to supply them, we beg to call the attention of your readers and the trade in general to the few following facts. Ever since the origination of the co-operative system, we have publicly announced our intention to stand by the trade, and have resolutely refused all orders offered by the Civil Service Stores and every other co-operative association. Having even (not two months back) closed an account by refusing to supply goods, on the mere suspicion that they were intended for the Stores, we were, therefore, considerably surprised at receiving a letter from the proprietor of an article of very limited sale, to the effect that goods supplied to us had reached the Civil Service Stores in the Haymarket. We called on him, and were told the date and quantity of goods. We traced the goods as having been supplied to a customer who had dealt with us for years. We wrote to him on the subject, and received a reply to the effect that he felt at liberty to sell in any market and at any price. We closed the account with a remonstrance, and regret that he should support so iniquitous a system. We communicated the details to the proprietor by a first letter, asking him to call and see the order; by a second inviting him to read the correspondence. He acknowledged these and said he was satisfied. Possibly he is, but what advantage has been gained by the transaction? Our customer has opened with another house, and is, doubtless, selling to the Stores as before. If proprietors were in earnest in the matter and the retail trade were so too, doubtless the supply might be stopped; but as it rests in this case, the Stores will get their supplies with the same facilities as before. Suppose this proprietor traces his next lot of goods to another wholesale house. He will stop supplying them. Supposing they take no notice of his letter, but simply buy through another wholesale house. Why it would go on before it was stopped until we had all passed into another world, and had forgotten the difficulties of this. However, if this proprietor really is in earnest, he will, ere this, have advised all the wholesale trade who the man is. Then, after that even, some other retailer might yet be found to take the place of the one in question. We only write this letter in the feeling that it will throw a light on the way the Stores are supplied, and to show how impossible it is to prevent goods reaching the Stores, unless you can bind the retail trade to be unanimous in defending themselves.

John Sanger and Sons.

Chemists' Profits!

Sir,—A short time ago I received for preparation a prescription as follows:—

R.	Ext. Cinchon. Flav. Liq.	ʒ vj
	Potass. Iodidi	ʒ ij
	Potass. Bromid.	ʒ vj
	Aq. ad	ʒ xij
	M. etc.	

for which with bottle I considered 4s. a fair price.

My customer, a lady on whose word I can thoroughly rely, and who offered to show me the bills, states that at the first establishments in two large towns near she only paid 2s. 6d. and 2s. 8d. respectively. Now, ext. cinchon. flav. liq. costs 26s. per lb., and has (or ought to have) a specific gravity of 1·200 f ʒvj. would weigh ʒ vij. and would cost . 1s. 5d.

ʒ ij Potass. Iodid., over ¼ oz. at 2s. 3d. per oz.	0s. 7d.
ʒ vj Potass. Bromid. at 6s. per oz.	0s. 4d.
Bottle	0s. 1½d.
Aq. Dest.	0s. 0½d.
Total cost of materials	2s. 6d.

I am puzzled as to whether my worthy confrères of the larger towns keep shop for the fun of the thing, or to live by the losses, or whether (can it be possible) they forget that f ʒ vj of a liquid having a specific gravity of 1·200 will weigh much more than ¾ oz. Whatever may be the explanation, such practices cause great inconvenience and annoyance to those tradesmen (by all means let us sink the idea of profession) who look for a fair profit on each transaction.

I trust that calling attention to this occurrence will tend to prevent the repetition of such a scale of charge.

Pharmaceutical Chemist.

November 22nd, 1872.

Commercial Morality.

Sir,—Having just unpacked an "original" case of "Honeycomb Sponges" from a well-known London firm, I beg to send you another version of "Commercial Morality."

Although the sponge was large and forty-eight pieces in the case, after well beating, 2½ lb. of sand was all that could be got out; the sponge was all that could be desired, and in this instance will leave a wider margin for profit than, as hitherto, buying ready cleaned. Apologizing for troubling you on this subject again.

J. Colenutt.

Sandown, Isle of Wight,
December 12th, 1872.

[*** It may fairly be inferred that this case, as well as that mentioned by Messrs. Newham, were exceptional in opposite directions, but the two extremes indicate that there is always a considerable amount of uncertainty in purchasing original packages of sponge.—Ed. Pharm. Journ.]

Earlier Closing.

Sir,—Seeing that the examinations in 1874 will be somewhat more difficult than they are now, I think we, the present assistants and apprentices, would do well to make some endeavour to curtail the long hours that now exist. What studying can a youth do after a hard day's work and ten p.m. before that ceases? Perhaps existing masters may say "We have had to do it;" but that is no reason why circumstances which are bad should not be altered. Give the young student a chance to improve himself, and then it is his own fault if he does not make good use of that time. There is no profession or trade, as far as I am aware, that suffers so much from indoor confinement as a chemist, and I do not see any reason why such cannot be amended. There is no doubt many objections will be raised against the short-hours' movement; but let assistants and apprentices join in a body and go the right way to work. I think the task would be found comparatively easy. Drapers close at seven p.m., and so might pharmacists if they would. I think some one should always be in readiness to dispense urgent medicines, but I do not think it requisite to accommodate any person with a ha'porth of hair oil or a pen'orth of pills at ten p.m., when it is only for the customer's convenience to come for them at that hour; but they know they can get them just as well then as at 5 p.m. How can a young man's health be what it should be when he is confined in a shop or laboratory all day, and then four or five hours in the evening breathing certainly not pure oxygen and nitrogen, but an atmosphere vitiated with the noxious products of the combustion of London gas. Hoping some abler pen than mine may take further steps in the matter, I remain etc.

17, *Bloomsbury Square.* W. S. Stables.

Chloral Hydrate.

Sir,—Referring to "Dispensing Note on Chloral Hydrate," *vide* Pharmaceutical Journal, last issue, I forward the following prescriptions ordering chloral hydrate, etc., prescribed by a medical gentleman of extensive practice, for a gentleman of ample means (but unfortunately of most intemperate habits) and dispensed by myself and assistant:—

R.	Chloral Hydrat	ʒ ij.
	Syr. Simple.	ʒ iv.
	Aquæ ad	℥ iv.

Take one 3rd part every 2nd hour.
6. 12. 72. Signed.

R. Rept. Mist.
Chloral Hydrat.

Signat. One half to be taken for a dose.
6. 12. 72. Signed.

R.	Chloral Hydrat	ʒ iij.
	Tinct. Aurant.	ʒ iv.
	Aquæ ad	℥ iv.

Take one half for a dose.
7. 12. 72. Signed.

R. Rept. Mist.
Chloral Hydrat.

Had this morning.
7. 12. 72. Signed.

R.	Chloral Hydrat	ʒ iij.
	Morph. Muri.	gr. iv.
	Aquæ ad	℥ iv.

Take one fourth part every second hour.
8. 12. 72. Signed.

R.	Magn. Sulph.	ʒ j.
	Conf. Sennæ	ʒ ij.
	Liq. Sennæ Dulc.	
	Tinct. Jalapæ ana	ʒ iij.
	Inf. Sennæ ad	℥ iij.
	M. ft. Haust. statim sumend.	

9. 12. 72. Signed.

Last Monday evening the medical man called to tell me his patient was "all right with the exception of considerable depression, and debility generally." The above prescriptions are given as written.

Thos. C. Morris.

W. and L.—You will find an answer to a question on the same subject at p. 540 of the last volume. Should you require more definite information it would be advisable to apply to the Inland Revenue authorities.

F. W. P.—It cannot be made clear without adding more acid than is ordered.

Pungency of Watercress.—J. Tully (East Grinstead) is of opinion that the difference of flavour in our correspondent's two specimens of watercress was due to the relative absorption of substances from the water in which they grew. Possibly the pungency was due to excessive manuring.

R. M. Gurnell.—We have received your letters referring to the nuisances which you describe as existing at Bethnal Green, and would advise you to communicate the facts to some of the medical journals.

G. T.—We believe the work you name is out of print.

"*Query.*"—A solution may be made as follows:—

Bimeconate of Morphia .	10 grains.
Rectified Spirit. . . .	1 fluid drachm.
Distilled Water . . .	13 fluid drachms.

"*Studens.*"—(1) It is evident that there was something faulty in the manner in which the experiment was conducted. (2) For the Major examination a knowledge of the Linnæan and De Candolle's systems is required.

Communications, Letters, etc., have been received from Messrs. J. Tully, J. F. Brown, J. Wilson, J. David on, Willmott, Ekin, Benger, J. R. Marrack. T. B. Groves, G. Turner Robertson, T. Farnsworth, and R. G. Maunbray.

EXAMINATION OF THE LEAVES OF CINCHONA SUCCIRUBRA.

(ESPECIALLY IN REFERENCE TO THE PRODUCTION OF ALKALOID.)

BY JOHN ELIOT HOWARD.

In a communication to the Pharmaceutical Journal (Nov. 4, 1871) in which I described various products of cinchona trees received from India, I gave expectation of some further information respecting the leaves.

As I have now had the opportunity of following out the investigation of these, I think that it may be well to place on record the result, especially as I have enjoyed the assistance of the chemical skill of my nephew, Mr. David Howard, and having a sufficient quantity of dried leaves (about 20lb.) at our disposal, it is not very probable that we should have missed the main object of our researches—the elimination of any alkaloid that might be contained.

This result may be stated as virtually *negative;* for though a few grains of precipitated alkaloid were obtained which yielded by further treatment crystallized cinchonidine, the quantity was so exceedingly minute as to suggest the probable explanation that the source from whence this product originated was rather some fragments of bark of small branches accidentally mingled with the leaves than any portion of the leaves themselves. If even the footstalks yielded alkaloid, it seems probable that more would have been present. The leaves, carefully reduced to powder, were divided into different parcels, and subjected to various modes of inquiry, in order to investigate the different component parts. Of these the chlorophyll must be first mentioned, but I do not think that our researches added any new features to those brought into notice by M. Fremy and others (including perhaps the purpurophylle of M. Harsten*); then followed the vegetable wax—the kinovic acid,—the resin, for the origin of which I am inclined to look rather to the stalks of the leaves, as I doubt its being a primary product of vegetation.

Altogether the examination quite precluded the expectation of the leaves being ever made use of to advantage in the treatment of fevers. In this point I find that the observations made by medical men in India accord with my own opinion.† Also I must mention that it is highly important and equally gratifying to me to know that the researches of Mr. Broughton on the leaves are not in disaccord with those here recorded. I cannot at present find any published report of Mr. Broughton's analysis, but in 1869 Mr. B. wrote me as follows:—"From 20 lb. of leaves I have obtained crystallized cinchonidine, cinchonine and quinine, but in minute quantities, a few grains merely." Apart from the medical question of the utility of the leaves in pharmacy, it is to me a satisfaction to be able to decide that the alkaloids do not even begin to be formed in the leaves, and that their existence is not (except indirectly) connected with the chlorophyllian respiration. This view of the matter entirely accords with the conclusions which I have elsewhere expressed as seeming to result from consideration of the manner in which the fresh bark filled with alkaloid begins to form on the surface of the uninjured cambium. When the bark has been stripped off, the fresh material appears almost like an exudation,* and this takes place with great rapidity, two or three days marking a decided commencement of renewal. I suppose that this results from a rapid multiplication of the vessels of the cambium, and that the alkaloids are elaborated in those cells of the lax cellular tissue which are figured in my 'Quinology.' But the *material* must come from *somewhere*, and the source cannot be the leaves, as the circulation from thence must be impeded by the rough treatment of the tree. I conclude that the *whole* plant, in a certain sense, contributes its supplies to any wounded part, and, therefore, it would seem to follow that the *whole plant must be injured by so great a tax upon its resources*—as will probably be found to be the case. But why should the reproduced bark present us with alkaloids in a purer state than in the original condition of things in the plant? If the supply were drawn by any channel from the leaves, it would partake of the quality of the leaf products, which is not the case. But in the *heart-wood* the material is abundant, and also ready to hand.

It is instructive to compare this state of things with that which is observed in the formation of the gall-apple on the oak. Here we find that the puncture and irritation caused by the insect (*Cynips*) induces the tree to form an abundant cellular tissue of a somewhat similar construction; and this becomes filled with specially astringent juice, to the detriment doubtless of the tree itself.

I am indebted to the good offices of M. Adolphe De Candolle in sending me for comparison a work by M. Casimir, the son of this eminent botanist, 'On the Natural and Artificial Production of Cork in the Cork Tree.' It would lead me too far from my present subject to follow out the comparative physiological changes in the two trees—the *Cinchona succirubra* and the *Quercus suber*, when submitted thus to partial decortication.

I may possibly return to this interesting question. In the meantime I may remark that I have described (in my 'Quinology') the mother-substance, which seems most probably the one to be modified into alkaloid; and I agree with Mr. Broughton in the view he has expressed that the first modification is into uncrystallizable quinine, or into the quinicine of Pasteur, which my nephew has recently afresh described. From one of these it is probable that the molecule or compound atom of quinine is built up in a complex manner; and that the difference between the first-formed alkaloid and actual quinine consists in the addition or subtraction of an atom of water; and that not as an hydrate, but peculiarly allocated in the intimate structure of the molecule itself. Researches with polarized light seem to lead to this view of the matter; and it is, if correct, hostile to the expectation of our being able

* Poggendorf's 'Annalen,' t. cxlvi. p. 158.

† Decoction of cinchona leaves (with acid sulph. dil.) "was found to be a good tonic, but quite useless as a febrifuge."—'Return (E. I. Cinchona Plant.),' p. 126. Ordered by the House to be printed, June 18th, 1866.

* Mr. Broughton wrote, "I have long remarked that the bark, when carefully removed without injury to the cambium, quickly renews itself from below, not from edge." March 16th, 1868. Mr. M'Ivor writes me, June 3rd, 1868,—"The new bark rises direct from the sap-wood; if the old bark is carefully removed, in three days the new bark is formed entirely over the whole surface, *i.e.* rising directly from the sap, and not formed by a current of cambium from under the remaining bark, and so far it is certain that the new bark does rise off the sap-wood, and apparently without any special action on the part of the leaves."

to imitate this artificially, so as to produce real quinine by chemical methods.

I am confirmed in the opinion expressed in my 'Quinology' that the alkaloids must be regarded as highly complex and, so to speak, animalized products of the *general* (or nocturnal) as opposed to the chlorophyllian respiration, being in this way fitted to act powerfully on the animal economy, the blood having an alkaline reaction; as, conversely, acid gases of simple constitution (sulphurous, nitrous, etc.) are deadly poison to vegetables whose juice has an acid reaction.

THE MICROSCOPE IN PHARMACY.

BY HENRY POCKLINGTON.

(*Continued from p.* 383.)

My notes on the structure of the woods of the Pharmacopœia are not sufficiently complete to enable me to proceed to describe them at present with comfort to myself or justice to my readers. I have, therefore, deemed it preferable to take the barks first. The woods that are chiefly remarkable for their colouring matters will be taken last of all, and will be discussed with especial reference to the optical qualities of these colouring matters, some, at least, being more complex than I believe is generally supposed. The structure of bark differs sufficiently from that of wood to require slightly different treatment in preparing it for the microscope. The great point is to avoid too prolonged maceration, hich is apt to render the more delicate portions so soft as to yield under the pressure necessary to push the razor through the other portions. Usually a few minutes, or half an hour, in warm water will make the softer barks quite soft enough to permit good sections to be cut. The harder and more dense barks will of course require longer maceration; in practice it will be found to be best to make frequent examinations of the portions in soak, that the right moment for removing them may be seized. Sections should always be mounted either in fluid or in glycerine jelly, and a specimen of each should be carefully stained with magenta, and a third one with a purple solution of logwood and alum, as the position, size, and shape of the liber are rendered easily visible by the use of these reagents.

Those who are interested in vegetable structure, are working up for an examination in structural botany, or desire to make themselves thoroughly familiar with the structure of bark, will find it of great value to begin their work upon young shoots, and to work by progressive stages from shoots of one, two, three, and four years' growth to the bark of full-grown trees. This is a very good period of the year in which to begin this work; and to keep steadily at it through the winter, till the spring brought into notice a new formation, would be to occupy oneself with an interesting as well as an instructive recreative pursuit. The use of carmine and magenta staining fluids, and in some cases of the logwood* and alum solution now much used in some histological laboratories, will permit of much useful work being done with but moderate manipulative skill and low powers of the microscope, and one or other of them should always be employed. The following brief biography of bark will perhaps be of service to the student as giving him some notion as to what to look for. It is at first composed of precisely similar tissues (irregularly shaped, more or less globular parenchyma cells) to that of the stem from which it has begun to be differentiated. The next stage appears to be the formation of elongated cells between the stem and itself, and these are presently developed into the "bast layer" liber or *Endophlœum*. It is at this stage that the use of staining fluids is especially of value, as they bring into notice changes that might otherwise escape observation. Contemporaneously with the bast, or liber, the outer cells become hardened or otherwise changed into the Epiphlœum or corky layer, the middle portion or Mesophlœum retaining its active vital powers longest, as evidenced by the action of carmine fluid, and yet more decisively by the presence of chlorophyll and other cell contents. The Epiphlœum may strictly be regarded as dead tissue, and is often thrown off at intervals. The middle layer alone can be regarded as actively long. It only retains active vitality so far as regards power of growth for a somewhat limited period; and all increase of the diameter of the bark circle takes place within the region commonly known as the cambium region, between the now woody portion of the stem and the earlier liber layers of the bark; and finally various modifications of the component tissues of the bark and of the bark as a whole take place in consequence of successive secondary deposits within the liber cells, and of pressure from the expanding stem within, and atmospheric influences without. The record of most of these may be found in sections prepared for the microscope.

Mezerei Cortex.—The barks of *Daphne Mezereum* and *D. Laureola* do not differ sufficiently widely to render it needful to describe them at great length. The latter is easily obtainable in a fresh state, and on this account is the one most likely to be selected for examination. Neither of them present any great difficulties, unles it be desired to obtain transverse sections showing the structure of the long fibrous and very tough liber common to all the plants of this genus. The only differences between the two species named consist in the development of the parenchymatous cortical substance and in the size of its cells and those of the outer cuticle. Sections should be cut in two directions, across the stem (transverse), and towards the centre of the stem longitudinally (vertical). Sections may be also cut longitudinally in a direction across the medullary rays of the stem (radial), but will not be of much service in this case. Logwood stained sections are the most useful. In such a section, if it be a transverse one, we see, beginning at the exterior, first the cells of the epidermal layers deeply stained; beneath this are the cells of the cork layer unstained; and beneath this are well-stained, large-sized parenchymatous cells and a largely developed fibrous liber, which does not stain. The liber is best seen in vertical sections. Apart from the liber there are no special features that need detain us. Before passing to a more important bark I will mention that the wood structure of the stem of *D. Laureola* (the spurge-laurel of the hedgerows in some parts) is specially interesting, on account of the peculiar spiral and dotted markings and pits on

* A convenient way of applying this reagent is to immerse the section of bark in infusion of logwood for a few minutes, remove, it to a slide and add a drop of ammonia. Wash in alcohol in water, and mount.

the well developed vessels. These vessels may be regarded as types of one class of vessels, but must not be more fully referred to here.

Cinnamomi Cortex.—The chief adulteration of cinnamon either in the form of powder or otherwise is by admixture of cassia with, in the case of powdered cinnamon, the addition of some form of starch. It is not difficult, as every one who deals with the two articles knows, to distinguish between "whole" cassia and cinnamon, but the case is very much otherwise when we have to distinguish between unadulterated cinnamon powder and either powdered cassia or an admixture. It is perhaps impossible to detect a small amount of admixture of cassia with cinnamon in the powdered state, but it is perfectly easy to detect any considerable admixture or to distinguish between the two powders. But to be able to do so requires prolonged and careful study of the special features of each of these barks. Their preparation for microscopical examination is more easy than is the case with most barks. A short maceration in warm water will render either of them sufficiently soft to permit very thin sections to be cut both transversely and longitudinally, the latter in a direction perpendicular to the surface. The only precaution to be taken is to take care that the piece of bark, especially if cinnamon, is well wedged in the section cutter with pieces of good cork. The best plan being to select a fine textured cork, the size of the tube of the section instrument, to halve it, take a thin slice from each half, and then place the piece of cinnamon between the halves, and put the whole into the section instrument. Very fine and perfect sections may thus be cut with great ease, and will show the whole of the tissues without solution of continuity, such as will result from careless cutting. The razor should be well wetted and the sections floated into water, whence they may be at once mounted in fluid or glycerine jelly, or removed to alcohol, boiled therein for a second, transferred to oil of anise and heated therein for half a minute, and finally mounted in dammar or balsam. This last plan is particularly applicable to sections of cassia, stained with magenta and intended to be viewed by polarized light, but in this last event the sections should be cut either from a piece of dry bark or from a piece that has been soaked in cold water only, this being necessitated by the ease with which cinnamon and cassia starch undergoes transformation.

It will perhaps be more useful if I describe the structure of cinnamon in comparison with that of cassia, omitting all reference to such minor points as they have quite in common. Its general structure is characteristic enough. Beginning at the outside, we have first a layer of flattened cork cells, somewhat brown in colour, and not otherwise of special interest. In cassia these are slightly larger than in cinnamon, but are otherwise similar. There are sometimes two or three layers of cells of this class present in both cinnamon and cassia; more frequently in the case of the latter. Beneath these, in the case of cinnamon as a tolerably complete and continuous layer, and less complete and continuous in the case of cassia, are, what Hassall calls, "stellate cells," that is, cells whose interiors are almost wholly filled up with deposits of secondary matter (sclerogen); very distinct pores traversing the deposits. These cells have, in cinnamon, seldom any contents, and their central cavity is but small. In cassia the cavity is larger, and sometimes ("frequently"—Hassall) contains starch. They are larger, and in proportion to the other tissues, less numerous in cassia than in cinnamon, and are best seen in longitudinal sections, and can be easily isolated if desired. These cells, carefully mounted in thick balsam without preliminary soaking in essential oils, show the successive deposition of secondary matter and the arrangement of their pores remarkably well, and on this account are deserving the attention of beginners in structural botany. Unless care be taken they may be confused with a very different structure, especially if studied in cross sections of the bark, the much thickened liber cells, very numerous in cassia, and almost wholly filled with sclerogenous matter. The absence of pores in cross sections of these liber cells, of course, at once distinguishes them from the "stellate cells," and dissection of the whole tissues confirms the diagnosis. If a section be stained with magenta, and carefully boiled in alcohol for a few minutes afterwards, these several features are easily demonstrated, and such a section is furthermore a very pretty object.

The parenchymatous tissues of cassia and cinnamon are very dissimilar. One very prominent feature is the presence of great quantities of large starch granules, eminently doubly refractive, and giving a black cross with polarized light in the case of cassia, and of very much smaller quantities of smaller-sized starch corpuscles in the case of cinnamon; excepting in size and number the starches are very similar. The cells of this tissue are larger in cassia, and much more thickened than in cinnamon. These differences are best seen in stained sections.

Small quantities only of starch should be present in good and pure ground cinnamon. The presence of foreign starches is, of course, a matter of easy detection, but is not, so far as my experience goes, of common occurrence. A proportion of the oil may sometimes be extracted before grinding the bark; but the microscope would only enable us to guess at this by the transformation of the starch granules under the action of heat and water, and by the absence of or alteration of certain small masses of brownish-yellow colouring matter, common to both cassia and cinnamon. As before said, careful study of the minute structure of the two barks is needful to enable us to tell "which is which;" but, granting this careful study, the difficulties in the way of so doing are not very serious.

THE RATE AT WHICH AMMONIA DISTILS OVER FROM WEAK SOLUTIONS.

BY J. ALFRED WANKLYN.

In the first number of the new series of the *Mechanics' Magazine* I am publishing a mathematical theory of "Fractional Distillation." Some of the material, however, which is contained in the paper has other bearings, and, in particular, some experiments on the distillation of ammonia appear to me to be of interest to all chemists who are working the ammonia process of water-analysis.

The following experiments on dilute solutions of ammonia will possibly afford acceptable data for laboratory use:—

Into a litre of water 1000 milligrams of ammonia were placed, and the liquid distilled. The first 50 c. c.

of distillate was found to contain 480 milligrams of ammonia.

Similarly 1·00 milligram, 0·50 milligrams and 0·20 milligrams of ammonia were dissolved in a litre of water, and the solutions distilled. The first 50 c. c. of distillate contained 0·50; 0·235, and 0·095 milligram of ammonia respectively.

Collecting the results in a tabular form we have—

Ammonia in litre of water before distillation. Milligram.	Ammonia in first 50 c. c. of distillate. Milligram.
I. . . 1000· . . .	. . . . 480·
II. . . 1·00 . .	. . . . 0·50
III. . . 0·50 . .	. . . . 0·235
IV. . . 0·20 . .	. . . . 0·095

Showing that the strength of the distillate is proportional to the strength of the original liquid, and that when $\frac{1}{20}$ of a dilute solution of ammonia is distilled off, that distillate will contain $\frac{48}{100}$ of the original quantity of ammonia.

It will be obvious, on reflection, that the second 50 c.c. of distillate (or the second $\frac{1}{20}$ of distillate) must contain about $\frac{25}{100}$ of the original quantity of ammonia, and the third 50 c. c. of distillate $\frac{13}{100}$ of the original ammonia, etc.; and this is borne out by actual experiment. An important use may be made of these data. We are now in a position to tell whether ammonia is originally present in a solution, or whether it is formed during the distillation; furthermore, we can tell whether it is rapidly formed or slowly formed, and thus are provided with new analytical data which may be used in distinguishing organic nitrogenous compounds.

KOUMISS, BLANDA, SYRE, SIGRE, OR AIREN.*

BY JAMES T. GEORGE, M.R.C.S.E., *Keith, Banffshire.*

For upwards of twenty years I have used as a restorative medicine the vinous liquor procured by the fermentation of cows' milk; and although a liquor has been for some ages employed by several tribes of Tartars, as procured from the fermentation of mare's milk, it was with difficulty I could learn the particulars of the mode of preparing it. The books which I consulted, which were various, gave me little satisfaction concerning it. All writers say it is a vinous liquor obtained by the fermentation of milk, but none describe the mode of preparing it, or the purposes in medicine to which it is applicable. M. Paulus Venetus, in a work published in the thirteenth century, only mentions it to be a common beverage among the Tartars. Another writer on the Russian Empire gives a formula which, if followed, could not be attended with success; for he mentions that the Kalmucks take off the thick substance, which, when sour, rises to the top of the milk, and employ this in food, and the remaining liquor is drank. But should any part of the milk be taken away, no fermentation will or can take place; all the parts of the milk must be left in their natural proportion. The method which I have adopted in my own practice with success, and which was communicated to me by a Russian gentleman, is as follows:—

"Take of newly-drawn milk any quantity; add to it a little water, and pour the mixture into any vessel. Use as a ferment an eighth part of the sourest cows' milk that can be got—but at any future preparation a small portion of old koumiss will better answer the purpose. Cover the vessel with a thick cloth, and set it in a place of moderate warmth. Leave it at rest twenty-four hours, at the end of which time the milk will have become sour, and a thick substance will gather on the top; then with a stick, made at the lower end like a churn staff, beat it until the thick substance be thoroughly blended with the subjacent fluid. Leave it again at rest for some time; repeat the beating, after which pour it into a narrow vessel like a churn, agitate the liquor until it be perfectly homogeneous. In this state it is called *airen.*"

Its taste, if properly prepared, ought to be a pleasant mixture of sweet and sour (agitation must be employed every time before use). When it is necessary to have it quickly made, heat the milk before applying the sour milk, and agitate every hour or half hour. By doing this it is obtained in twelve hours. If well secured in close vessels, and in a cool place, it can be kept a long time without injury to its qualities. There appear to be three things necessary to the vinous fermentation of milk; heat, souring, and agitation, the chief being agitation. In fermenting vegetable juices nature is sufficient to keep the parts of the fluid in mutual action, while milk is no sooner soured than a separation of its parts takes place; the cream rises to the top, while the cheese either falls to the bottom, or is suspended in the whey. When these parts are brought into close contact with one another by agitation, frequently repeated, a vinous liquor is produced, which, in my practice, I have found highly beneficial as a dietetic, and of considerable virtue as a medicine.

In cases of general debility I have given it largely, with essential service, as a nutritive. W. G., aged twenty-six, was sent to this place from Edinburgh for change of air. He had been under a mercurial course for a venereal affection, which left him in a very weak state. He was much emaciated; his face of a leaden hue; his eyes sunken; he had slight cough, with expectoration of toughish phlegm; his appetite was impared, and he was feverish toward night. On using the wine for about two months he got perfectly well and fat. He drank daily two quarts with a relish, and without any intoxicating effect. During the time he was under the medicine he required no purgative, and it seemed to act as a diuretic. I have found it of great use in typhoid fever, the patients using it for meat and drink. In a few cases no other remedy was used, young and old taking it. In nervous, dyspeptic, and hypochondriac subjects, its use for some time has a powerful restorative effect, giving flesh and strength. Invalids, not only without disgust, but with a sort of pleasure, drink it in large quantities, and, even when they do so, without headache or other unpleasant feelings, which the abuse of other fermented liquors produces. As stated, I have used it in various complaints with success above my most sanguine expectations; and, in pulmonary consumption, when cod-liver oil cannot be taken, I have found it (but at the same time using whisked cream) equally, if not more efficacious, in relieving cough and giving plumpness to the body. From its mild acid, its vinous spirit, and its oily qualities, I consider it to be a cooling antiseptic, a mild stimulant and tonic, and a valuable nutrient. In acute diseases, with marks of weakness and putridity, in cases of excessive irritability, in dyspepsia, in phthisis, and in hectic, from ulceration or suppuration.

I again repeat, that all that is necessary for its preparation is, after it is sour, frequent agitation. No spirit can be produced from any one of the constituent parts of milk taken separately, nor any two of them unless mixed with the third. The closer it is kept the more spirit is obtained. If made in a glass vessel, that is to say if it undergo fermentation in it, it must not be more than two-thirds filled in case the bottles burst. When it is bottled for keeping any time, the bottles must not be full, and the corks must be fastened as in lemonade bottles.

A NEW ANÆSTHETIC DERIVED FROM CHLORIDE OF CARBON.*

BY MM. HARDY AND DUMONTPALIER.

Chloride of carbon combines in definite proportions with alcohol, forming a liquid which has a fixed boiling-point, and possesses very decided anæsthetic properties. In its preparation, a mixture of 30·8 parts of chloride of carbon and 4·6 of alcohol are submitted to distillation, and the portion collected which passes over at 66° C.

The liquid thus obtained is colourless, transparent, mobile; has an agreeable odour and a density of 1·44, at 17° C., and under a pressure of 0·755. It boils regularly at 66° C., a boiling-point below that of either of the two bodies from which it is formed (chloride of carbon boiling at 77° C., and alcohol at 78·5° C. It burns difficultly with a green-bordered flame; undergoes no alteration in the air, and volatilizes slowly. It is decomposed by water into alcohol, which is dissolved, and chloride of carbon which is deposited. Sulphuric and hydrochloric acids also decompose it with deposit of chloride of carbon. Nitric acid, under the influence of slight heat, attacks it briskly with disengagement of nitrous vapour and separation of chloride of carbon; on concentrating the supernatant liquor a deposit of oxalic acid is obtained.

An analysis of this compound points to the formula $2\,(CCl_4), C_2H_6O$. The vapour density in one experiment was 4·2, in another 4·1, figures which do not correspond with the theoretical density according to the above formula. The question therefore arises whether there is a combination in the proper sense of the word, or a simple union of two substances remaining distinct, although presenting a fixed boiling-point and all the physical appearances of a distinctly defined body. Similar facts have already been indicated, but their interpretation has yet to be found.

This substance acts as an anæsthetic; its ethereal odour and low boiling-point facilitating its employment. In experiments made upon a dog of average size, 15 grams sufficed to produce insensibility to pricking or pinching. Comparative experiments made upon the same dog, at intervals of several days, with chloride of carbon and with chloroform, also in doses of 15 grams, have led the authors to conclude that chloride of carbon, and particularly chloroform, act with more intensity than the new substance, which, on the other hand, appears to cause less restlessness, especially at the commencement of the experiment. In any case the new anæsthetic should only be administered to man with the greatest care.

[*⁎* The preparation herein referred to, whatever its value as an anæsthetic, cannot be regarded as an individual chemical substance. Evidently the case is one of mere physical mixture. It is not uncommon for mixtures of organic liquids to boil at temperatures below the boiling-point of either, and it is the rule *not* to boil at the mean between the boiling-points of its components. See an article in Pharm. Journ. [3] vol. ii. p. 528.—ED. PHARM. JOURN.]

* Bulletin Thérapeutique and Journ. de Pharm. et de Chimie [4] vol. xvi. p. 428.

SPIRITUALISM AND SCIENCE.

It would be useless to ignore the fact that what is commonly known as "Spiritualism" has been gradually taking up more and more of the public attention, and that for good or for evil—unfortunately it has proved for evil in many cases—the number of those who placed faith in the asserted communications from the spirit world is steadily increasing. Whether the desire of furnishing its readers with a "Christmas Number," in the approved style of a ghost story, has influenced the *Times* we are unable to say, but certainly on the 26th of December an article appeared in its columns, giving a brief *résumé* of the controversy arising out of the appointment of a committee by the Dialectical Society to investigate the subject, and it also recorded the writer's experiences at four *séances* which he attended. It is probable that many persons, after reading the article, would impatiently throw down the paper as answering to the definition of Christmas literature recently given by the *Athenæum*, as rubbish that would have no chance of publication at other seasons. But the discussion has probably gone too far to be thus extinguished, and in order to keep our readers *au courant* with a topic which promises to assume a position in the scientific world, it is proposed to give an abstract of the article and the correspondence it has provoked.

Those who remember the prominence to which "table-turning" attained in the attention of the public some twenty years since, will also remember the relief with which Professor Faraday's explanation of it as arising from unconscious muscular action was received. Notwithstanding, however, the weight of the great philosopher's name, there are probably more believers in the supernatural origin of the phenomena now than there were then. It is not surprising, therefore, that a desire should have arisen that the whole subject should be thoroughly investigated by scientific men, so as to expose any fraud that might be present, and to attribute the phenomena to their proper place in the domain of science or conjuring. A society called the "London Dialectical Society," took the matter in hand, and appointed a committee, which, after eighteen months, published a report 400 pages long, that has been stigmatized as nothing more than a farrago of impotent conclusions, garnished by a mass of most monstrous rubbish. It is unfortunately this style of denunciation which has contributed to the present state of affairs. As a rule scientific men hold carefully aloof from any attempt to solve or expose the mystery, and when the attempt is made by others—who may possess every other requisite—the cry is that the work is unscientifically done. Professor Huxley wrote a note stating that the only good of a demonstration of the truth of spiritualism would be to furnish an additional argument against suicide, "for it would be better to live a crossing-sweeper than die and be made to talk twaddle by a medium, hired at a guinea a *séance*;" a remark which although at once witty and true was completely beside the question. Professor Tyndall was willing to pay "due respect to the invitations of such men as Mr. Wallace and Mr. Crookes," and to witness whatever new phenomena they were in a position to show him. Mr. G. H. Lewes sent them good advice, and Dr. Carpenter sent them an abstract from an article in the *Quarterly Review*.

As illustrating the extent to which the belief is spreading, it is said that a volume, consisting of 150 pages of reports of private *séances*, was privately printed by a noble earl recently deceased, and that the attestation of fifty respectable witnesses is placed before the title-page, among whom are a dowager duchess and other ladies of rank, a captain in the guards, a nobleman, a baronet, a member of Parliament, several of our scientific and other corps, a barrister, a merchant, and a doctor. Upper and upper middle-class society is represented in all its grades, and by persons, who to judge by the positions they hold and the callings they follow, ought to be possessed of intelligence and ability. Under these circumstances it is not too much to say that it is time that a thorough and practical investigation cleared this cloud out of the intellectual sky; and this task need not be scouted by professors or other learned men, by Royal or other societies.

And now for the experience of the *Times*' correspondent, which we suppose may be taken as a fair specimen of what is met with by those who attend these *séances*.

The first was at a private house, where machinery in the furniture or any similar deception was out of the question. Mr. Home was the medium, and the party sat round the table for two hours without anything unusual occurring.

The next day he went with a friend to a second *séance*, held in a small drawing-room, where arrangements had been made for excluding the light. The floor and walls were scrutinized and sounded, the felt for darkening the windows, the chairs and the small round table examined, but nothing was found. There were two mediums present, and the two friends sat in the dark, clasping a hand and pressing a foot and knee of a medium on each side. Presently one of them felt something hard pressing against the back of his head. Saying nothing, he leaned his head backwards, when the substance seemed to yield and slide softly over the hair. Suddenly grasping at it with his left hand, he still held the medium with the right, while the other visitor struck a lucifer; there was a sound of something falling, and one of the chairs was seen lying on the table, but nothing else. They again sat down together for some time, without any further surprise, although in spite of a warning that the spirits would drop anything they were holding, wherever they might be, a match was unexpectedly ignited by one of the visitors. Daylight was then admitted and the room searched and researched, nothing abnormal being found. But the furniture now became quite lively, and this in broad daylight. A chair jumped three or four yards across the carpet, and there were other similar occurrences, but nothing so satisfactory as the fall of the chair on the table, as in that case they had fast hold of the mediums, who now were moving about the room, while everything seemed to happen just as the visitors were not looking, and one of the mediums was somewhere behind them.

The third *séance* was held in the evening at the house of a celebrated professional medium, in this case a lady, who, having been left some money, has retired from public practice. Scarcely had the medium's fingers touched the small table round which they sat, when it began to play all manner of antics under the influence of "John King, her well-known familiar." But the lady's fingers were strong, and there was a difficulty and delicacy in clearing away the folds of her dress, which left the experiment unsatisfactory. What was sought was decided raps and motion, absolutely without contact, and this was not obtained, although several attempts were made. An alphabet of printed letters was now produced and the visitor desired to think of a name and pass a pencil along the line of letters. The raps came at the right letters, but it was thought that possibly there might unconsciously have been something in the manner in which the pencil was passed along sufficient to give the clue. Another name was thought of and a paper and pencil put under the table; presently afterwards the paper was picked up with some markings upon it, the beginning and end of which consisted of the first and last letters of the name thought of, but the remainder was illegible. The performance was concluded by the "spirit" intimating that they were taking all the magnetism out of him, and wishing them good night in a series of raps, beginning loudly and gradually dying away into an apparent distance.

At the fourth *séance* Mr. Home was present, and as it appears to have been the most remarkable of the series, we quote the words of the visitor:—"There were nine persons present, including Mr. D. Home and Miss Fox, the well-known American medium. We formally searched the room and examined the furniture before we sat down at the table, which measured 4 ft. 5 in. by 6 ft. 4 in. The room was at first well-lighted from a gas-burner overhead. On the table was an accordion, which we took to pieces and tried, and found to be in every respect an ordinary instrument; a light lath about two feet long, a small brass hand-bell, matches, paper (which we marked), pencils, and two spirit lamps. We sat down, and almost immediately loud raps appeared to come from the table and floor. Miss Fox then got up and went to the door of the room, inviting us to stand by her and to hold her hands, which we did, when loud thumps seemed to come from the panels as if done with the fist. These were repeated at our request a desired number of times. To give a detailed account of everything which occurred would need more space than we can now spare. Suffice it to say, that the table was made light and heavy at our wish, that it moved in every direction, that there were vibrations of the floor and of our chairs, that on Mr. Home holding the accordion under the table in his right hand and by the end furthest from the keys, it played a distinct tune, Mr. Home's left hand being on the table and his feet so raised as to be visible. All other hands were on the table. At the same time, and under the same conditions, a small hand-bell was wrung in different parts of the space beneath the table. The gas was now turned out and the two spirit-lamps lit; these gave a fair light. The raps became louder, and, in the usual method, directed us to take a leaf out of the table. This was done, when the table appeared to float up about eight inches off the floor, settling down again in a gentle swaying manner. The thin wooden lath lying on the cloth was seen by the whole party to be in motion. It tilted up sideways and endways, and then seemed to float backwards and forwards. Holding our hand three inches, as near as we could guess, above the cloth, the lath rose three times; the last time it touched our hand, and directly afterwards the table jumped and shook violently, and loud raps seemed to come from all parts of it and of the floor. The spirit-lamps were now put out, and what light there was from a low fire only just enabled us to see white paper on the table and each other's positions. Presently, Mr. Home's and Miss Fox's hands and feet being in strict custody, we felt the accordion pressing against our knees. We put our hand under the table, when the instrument appeared to be moving round, till its wooden base was placed between our fingers. In that position we held it with its keys downwards; it seemed to be pushed up towards our hand and played a few bars. It then stopped, and presently we felt the bell thrust between the fingers of the same hand. Almost immediately a flower or sprig was put into our fingers, but as we were already holding in one hand the accordion and the bell, the sprig was dropped. It was picked up and again put into our fingers, and as we received it we felt distinctly the touch of a large thumb and finger. We did not let it drop this time, and there was immediately a succession of raps of a loud and jubilant nature. They seemed to come from the table in our immediate vicinity. A match was now struck, and we drew our tired hand from under the table, displaying the accordion, the bell, and the sprig. This was the end of the *séance*, for the 'spirit' would do no more. In the account of it we have omitted several experiments about which we cannot speak decidedly. We tried every test we could think of. A subdued light, darkened as the evening went on, was one of the conditions we were obliged to comply with, and while the accordion was in our hand we were desired to sit passive, though, as we stated, the hands and feet of the 'mediums' were in strict custody. Mr. Home seemed to wish to conceal nothing, and gave us every opportunity, consistent with the above conditions, for satisfying our scepticism. Yet we need hardly say that we were unable to satisfy it. By his request we got under the table with a lamp a great many times, insisted always on seeing his hands and feet, or on having them as well as those of Miss Fox held firmly. As to the hand with which Mr. Home held the accordion under the table, all we know is that on one of our sub-mahogany expeditions with the spirit-lamp, we saw that hand quite still, and saw the accordion moving up and down and playing music. We heard the key-notes, but the position of the instrument prevented our seeing the keys moving, if they did move. There was nothing during the whole evening except the phenomena themselves to suggest imposture. We tried our best to detect it, but could find no trace of it. We searched Mr. Home, and found nothing whatever upon him but his clothes.

"Yet, even with all this, we are not a Spiritualist, and do not even believe in 'Psychic Force.' We remember and lay to heart Mr. G. H. Lewes's admirable maxim, 'Distinguish between facts and inferences from facts.' We are certain that the table rose from the ground, that our hand received a sprig under the table from what felt like another hand; but how these things happened we do not know. The nature of the phenomena and of human nature are such as to force us to suspect imposture and legerdemain until we can satisfy ourselves of the true causes, whatever these may be."

This communication was followed by a letter from Mr. Henry Dircks, urging that the efforts of the "spirits" were not allowed to be tested openly as an ordinary experiment, but that certain conditions were always stipulated for; also that the results were unreliable and often incorrect. There was also an insinuation that the automaton chess-player at the Crystal Palace was worked by a small concealed boy, and that a similar artifice might account for the manifestations of spiritualism; but the truth of the insinuation was denied by the proprietor of the automaton figure. An assertion that "no really scientific man believes in spiritualism" was met by the counter-assertion that two Fellows of the Royal Society were believers in "spiritualistic" phenomena, namely, Mr. Crookes, who reserves his opinion as to their cause, and Mr. Cromwell Varley, electrician to the Atlantic Telegraph Company; to these names was added that of Mr. Alfred Wallace.

In concluding our notice of this subject it will be well perhaps to disclaim any sympathy with what is popularly known as "spiritualism;" our opinion is simply this, that the time has come for a thorough investigation of the subject, with the object of preventing unexplained and misunderstood facts being misinterpreted and used to take advantage of credulous people. On this point we cannot do better than quote the following words from a letter to the *Times* written by Dr. Fenton Cameron, of Derby:—

"I am a man accustomed to close and careful examination of intricate matters. I studied spiritualism for about two years with great care, and, I believe, with perfect coolness and impartiality of mind. I saw it in almost all its phases. I saw its manifestations in private and in public, in the light and in the dark; and though there is much that is childish, though many of the believers are most credulous and would accept almost anything coming in the name of the 'Dear Spirits,' and though in many of the dark *séances* there was abundant room for trick, if trick were necessary, I was yet compelled to believe that there was a power at work unknown to science, and which was not under the control of the so-called medium.

"I do not, for what seem to me good reasons, believe that the spirits of our departed fellow-creatures are the agents in all this, but I have no explanation of my own to offer. Faraday's unconscious muscular action theory was quite unworthy such a mind as his. Dr. Carpenter's unconscious cerebration may explain a few phenomena, as may also Serjeant Cox's Psychic force, but there is much, very much, in spiritualism that none of these explanations touch at all; and, as the new faith has now spread so widely and has done so much mischief to many, the time has, I agree with your reporter in thinking, fully come when even our greatest scientists may, without loss of dignity, consent to become as little children, that they may learn something of this strange thing before they pronounce upon it; for many think with me that men who have fairly won great names by scientific discovery rather detract from than add to their reputation by speaking dogmatically concerning that of which they are practically in utter ignorance."

EXPLOSIVE MIXTURE OF NITRATE OF POTASH AND ACETATE OF SODA.*

BY M. VIOLETTE.

An accident in the author's laboratory made known to him a singular reaction between nitrate of potash and acetate of soda, which, under the influence of heat, constitutes an explosive mixture equal in force to gunpowder. In some researches upon saltpetre he had heated moderately in a small phial a few grams each of nitrate of soda and acetate of soda, both previously fused and anhydrous. The two salts melted formed a colourless and transparent liquid, which gave off a few gaseous bubbles. At the same moment, a violent explosion occurred, accompanied by flame and smoke, which scattered the phial in fragments all over the laboratory; a fresh gaseous combination between the elements of the salts had taken place, leaving a slight residue of alkaline carbonates.

In repeating the experiment a gram of nitrate of potash was melted in a small platinum capsule at a gentle heat, and a gram of acetate of soda previously fused added to it. At a temperature of about 300° C. the mixture remained fluid, transparent and without alteration as long as the temperature remained constant; upon raising it to about 350° C. there was slight ebullition followed instantly by a loud explosion, with light and smoke, similar to that of gunpowder. As before, there was a slight residue of alkaline carbonates. The same result followed when a substance in ignition without flame was plunged into the liquid at 300° C.

If the melted mixture be poured upon a cold surface a white substance is obtained, which is hard, brittle, rather hygroscopic, more fusable than nitrate of potash, and being melted explodes violently. In the solid form it does not burn when placed in contact with an ignited body; but reduced to fine powder, it deflagrates violently upon the application of a flame.

The explosive properties of the mixture are only developed when the nitrate of potash and acetate of soda are present in certain proportions,—from 50 to 100 parts of the acetate to 100 parts of the nitrate,—the most explosible mixture being 100 parts of the fused nitrate to 60 parts the fused acetate. When the nitrate is in excess, the combustion is only partial and of short duration; when the acetate is in excess, the mixture burns slowly and similarly to a light wood.

A mixture of nitrate of soda and acetate of potash was found to have the same explosive properties, but to be more hygroscopic. Mixtures of nitrate of potash with the acetates of copper and baryta did not yield an explosive product.

BETEL NUT CHEWING.

The Eastern correspondent of the *New York Mail* writes to that paper:—"There is a fascination in betel nut more extraordinary than in a tobacco passion. The consumption of the latter in chewing alone, in the United States, is a modern phenomenon. An inveterate chewer may have moral resolution enough to break off the habit, though it rarely happens that an effort is made to do so, as an apology is found for continuing a practice that is positively destroying the foundations of health. Once addicted to chewing tobacco, to abandon it is an achievement few have the happiness to perform, notwithstanding the melancholy mortality of men in the meridian of life who are constantly being destroyed by the subtle influence of that strange plant on the nervous system. Thus, sudden palsy of the heart, palsy of a limb, palsy of one-half the tongue, and even instantaneous death, are traceable by physicians to excessive use of tobacco. But the vice of betel-nut chewing, however, is still more remarkable. When the habit is established, there seems no retreat. Each victim wears out his teeth, gums, digestion, and dies with an unsatisfied longing for another quid. The betel-nut-tree thrives in most parts of tropical India, the Indian Archipelago, and the Philippine Islands, growing up gracefully about thirty feet, rarely more than eight inches in diameter. It is the *Areca catechu*. Penang is the universal name of the nut in those places where it is produced: hence Pulo Penang means a betel-nut island. At six years of age, the tree commences bearing nuts of the size of a small pullet's egg, of a bright yellow colour, enclosed in a husk similar to the cocoa-nut; within is a spherical nut very much like a nutmeg. Broken, a bit of it is wrapped up with a piece of unslaked lime in a peculiar leaf, the siri betelpiper, extensively cultivated for that purpose. The gums and mucous membrane of the mouth are quickly stained a brick-red; the teeth crumble to a level with the gums; and in that condition an inveterate betel-chewer is wretched without a supply. There are large plantations of betel-nut-trees in Java to meet the demand for home consumption and distant provinces. To augment the pleasure, those who can afford it add tobacco to the lime.—*Brit. Med. Journ.*

THE SURREY MAGISTRATES AND THE ST. PANCRAS VESTRY ON THE NEW ADULTERATION ACT.

At the meeting of the Surrey magistrates on Tuesday, December 31st, a report was presented in which it was recommended that an analyst be appointed in that county, with the following allowance:—For the first hundred cases in any one year £1 for each case, for the second hundred 10*s*. each, and if the number should exceed 200 in the year, then 5*s*. each for cases above 200; and further that the inspectors of weights and measures be appointed to procure samples of food, etc., and be allowed £1 in each case of conviction.

Mr. Gassiott advised the appointment of a practical chemist, as carried out by the Home and Indian Governments.

Sir A. Baggallay pointed out that the Act stated that those competent as medical men and conversant with chemistry and microscopical knowledge should be chosen.

Dr. Webster thought they would not get first-class men to accept the position at such a rate of pay.

Dr. Carpenter said the appointment was a most important one. It was to act as a check to the great adulteration of food at present going on and doing so much harm.

Mr. Hardman said the figures were based upon the scale to be paid Dr. Letheby, who was appointed for the county of Essex.

Some discussion ensued as to the payment by private persons who wished to have an analysis made, and ultimately, after remarks from Sir Francis Hicks, Mr. Locke King, and others, the amount to be paid was fixed at 10*s*., and the remainder of the report and recommendations were agreed upon.—*Morning Advertiser.*

The Vestry of St. Pancras has issued a series of regulations for the conduct of the officers appointed under the Adulteration of Food Act, these rules being divided into two parts—viz., those relating to private purchasers who may wish articles analysed, and those for the inspector under the Act who should submit articles for analysis in his capacity as public officer only. As regards the regulations for purchasers generally, the Act provides for the payment of a fee for analysis of not less than 2*s*. 6*d*., nor more than 10*s*. 6*d*., and the General Purposes Committee, by whom the regulations have been drawn up, state that as the object of the Vestry should be to have the Act carried out efficiently rather than to receive large fees, and as it would be difficult for the ratepayers generally to understand a scale of fees, whether governed by the value of the analysis or otherwise, there should be an uniform fee of 2*s*. 6*d*. charged to all purchasers of articles not intended for re-sale, and a fee of 10*s*. 6*d*. to all purchasers of articles intended to be re-sold. The fee should be paid to the inspector, and accounted for by him to the vestry clerk, and the inspector should not, under penalty of dismissal, be allowed to receive any fee or reward other than that fixed by the Vestry. When a sample is brought to the inspector by a private purchaser, such purchaser shall make a declaration that the article presented has been purchased at a place within the parish. The sample should be divided into three, and each portion enclosed, sealed, and numbered in the presence of the purchaser; but no name or other distinguishing mark should be placed on the sample, except the name of the article and labels descriptive of any admixture; but the inspector should enter in a book provided for the purpose the date, the name, the address of the person bringing the sample, the number of the sample, and other particulars. One portion should be returned to the purchaser, another retained by the inspector, and the third should be divided into two, sealed and marked, in the presence of the analyst—one portion left with the analyst and the other retained by the inspector. The inspector should not, except as provided for in section 3 of the Act of 1860, give the name of the person bringing an article for analysis to the analyst. The analyst should in his certificate of the result of his analysis refer to the particular sample analysed by number and description, and the certificate should be so worded as that it cannot be applied to any other sample, or used in any other way for the purposes of advertisement. The inspector should not be allowed to alter or interfere in any way with the certificate so as to identify such certificate with the vendor of the article or with any other person, and should not be allowed to give any form of certificate himself. As to articles purchased by the inspector, there should be a systematic scheme of sampling. The inspector should be only partially under the control of the analyst—*i.e.*, he should at the request of the analyst obtain samples of any one article—say bread—from the tradesmen in any one ward or district of the parish; but in every other respect he should act only under the regulations of the Vestry, or a committee of the Vestry. When required by the analyst to obtain samples of bread, he must obtain samples as far as possible from all vendors of bread in the ward or district. He must, in the presence of the vendor, divide his purchase into three, and enclose, seal, and number each portion himself, under seal, and dividing the third portion into two, in the presence of the analyst, retaining one portion and leaving the other with the analyst, and upon this portion the certificate of the analyst should be given. The certificate to be given under the same conditions as above-mentioned in regard to a private purchaser. When the analyst shall be of opinion that the result of an analysis of any article is such as to warrant the Vestry instituting proceedings against the vendor, he shall make a report to that effect to the Vestry, using only the number of the sample, and the Vestry shall thereupon, and without the name of the vendor being made known, resolve whether proceedings should be taken against such vendor. The analyst should be required to provide a laboratory at his own expense, and all things necessary for the purposes of analysis. He should be paid by a fixed salary, and not be allowed to receive any fees whatever except fees for attendance in a court of justice on proceedings being taken by the Vestry. The book containing the names and other particulars with reference to the numbered samples should be kept in the custody of the inspector, and no officer or other person should have access to such book or to the sealed samples in the possession of the inspector, except as ordered by a court of law upon any proceedings against the vendor of adulterated articles or by the Vestry or a committee of the Vestry.—*Times.*

The Pharmaceutical Journal.

SATURDAY, JANUARY 11, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

DISPENSING CHARGES.

THE exigencies which have to be satisfied by the editors of our daily evening papers may often be accepted as an excuse for their dealing with subjects they know little or nothing of, or treating those subjects in a claptrap and sensational manner. The idlers and gossips of the clubs must be provided with material for chatter; and if the events of the day do not afford anything of sufficient novelty and interest, the contributors' ingenuity must be taxed to invent something. It is probably under the influence of some such conditions that the *Globe* has lately produced an article entitled "The Charge for Drugs," in which it is sought to maintain the opinion that the pharmacist's charge for medicine is very frequently so excessive, that not only are the general public made the victims of imposition, but at the same time the kindness of medical men in prescribing gratuitously for the poor is often rendered abortive.

With the object of demonstrating that this is the case, the writer of the article referred to carried out what he terms the experiment of presenting a very simple prescription to a number of unsuspecting (*sic*) dispensers and ascertaining the price to be charged for the medicine both in the ordinary course of business and likewise in the event of its being required by an invalid in very poor circumstances.

To judge from the localities mentioned in the article, several of the leading pharmacists of the metropolis were in this way put to the test. At the same time the experiment was extended to Whitechapel and Bethnal Green, while as a crucial demonstration, we suppose, recourse was also had to the stores of a Co-operative Society.

The result, as might naturally be expected according to the most ordinary common sense view of the case, was that, on comparing the prices charged for the medicine at different establishments, there proved to be a very considerable range of variation. This fact, however, the Editor of the *Globe* seems to regard in the light of a great discovery, forthwith proceeding to moralize upon it with the air of a public benefactor, and to declare that, judging by the simple comparison of one druggist with another, there is justification for asserting that, while there may be houses from which the best of drugs are dispensed at a fair profit, there is, at least, a lamentable proportion of those whose charges are altogether unreasonable.

The ostensible object of this inquiry had reference to the numerous applications to our hospitals by the "decent poor" for medicine, and it was taken in hand by the *Globe* to show that they could not do otherwise than thus avail themselves of opportunities of procuring medicine gratuitously so long as present charges prevail; in short, that it is simply impossible for them to obtain necessary medicine elsewhere than at the hospitals.

This conclusion is perhaps perfectly reasonable and well-founded; we may also add that there does not seem to be any impropriety in the practice to which it points; but the case is different as regards the assertion previously referred to, and the doubt raised by the writer in the *Globe* as to whether there are any druggists content with what ought to be regarded as a fair profit.

In considering this part of the writer's opinions we will, in the first place, point out the glaring fallacy there is in regarding the observed variation of charge as being either wonderful or indicative of unfair dealing. The range of variation is no doubt wide—from 8*d*. to 1*s*. 6*d*, 2*s*., 2*s*. 2*d*. 2*s*. 6*d*., and 3*s*., but it is absurd to argue from that, while the conditions of the business carried on at the various establishments are totally ignored. Some of those referred to in the *Globe* were evidently situated in the most fashionable localities, while others were presumably establishments where dispensing prescriptions constituted the chief business, and where consequently an expensive staff of skilled assistants is kept. Others again, to judge from some of the localities named, were not subject to the charges appertaining to either of these conditions, being adapted to the modest requirements of a ready-money trade in small quantities of drugs and preparations,—dispensing being a thing almost unknown. Upon what ground, therefore, a comparison is made between these different cases for the purpose of showing that the higher charges are unreasonable it is difficult to see, and it is still more difficult to perceive why the lowest charge of all, made at a shop of the character last mentioned, should be taken as the measure of reasonableness in the charges made at Bond Street or St. James's. Unless it be for the purpose of making the argument fit the foregone conclusion, we confess our inability to see any such ground.

Moreover, what kind of bearing have the charges of Bond Street and similar localities on the possibility of medicine being obtained by needy persons. If we desired to learn how far the price of pea-jackets was within the means of navvies, we should scarcely go to POOLE or BUCKMASTER for the information!

The remainder of the argument based upon the intrinsic value of the ingredients of the medicine, together with the cost of bottle, label, paper, string, sealing-wax and pill-box, as estimated for the *Globe* by "a competent authority" is equally fallacious with that already referred to, as our readers will readily understand. But the remarkable feature of this is, the almost incredible meanness of the idea it conveys, according to which it might be contended that the value of George Eliot's writings should be assessed at the same rate as that of the news paragraphs or, we might say, the articles of the *Globe*.

It is remarkable that the above-mentioned estimate contains no reference to the value of the skilled labour employed in dispensing, nor to the fact that, irrespective of the cost of materials and of allowances for establishment expenses, a dispenser is in some degree entitiled to an honorarium for his skill and experience, just as the medical man is entitled to his honorarium for prescribing. This view of the case was well put by a "Chemist and Druggist" who replied to the article in the *Globe*, urging it upon the ground that the pharmacist has, like the medical practitioner, to undergo an examination in chemistry, pharmacy, botany, materia medica and practical dispensing before he can open a shop and carry on business for himself. But what will be thought of the competence of the writer in the *Globe* for criticizing the charges for dispensing, or the value of the services rendered in various ways by the qualified pharmacist, when we find him in answer to the letter above-mentioned, confessing such utter ignorance of the subject as is indicated by the following editorial note appended to this letter? "It "was certainly quite unknown to us that before a chemist can open a shop he must have passed an examination. We have always understood that such "an examination was purely optional.—Ed. of Globe!!"

ADULTERATION OF BUTTER.

Recent prosecutions at Liverpool have illustrated some of the legal difficulties which it has been foreseen will arise whenever an attempt is made to enforce the provisions of the new Adulteration Act. They have also illustrated another difficulty, which might equally have been foretold, viz., the confusion in which the administrators of the law would be involved by the conflicting testimony of witnesses in reference to scientific and technical details. An instance of this is the case reported at p. 517 of this Journal. A provision dealer was summoned for selling adulterated butter, and Dr. Campbell Brown, D.Sc., the public analyst for Liverpool, stated in his evidence that a sample of the butter in question contained a quantity of stearin and palmitin, and that it was, therefore, largely adulterated by the admixture of fats containing those substances. Dr. Brown also added, in cross-examination, that he was quite confident that in the pure article there should be no stearin.

Now, it is well known to chemists, as pointed out by Mr. Murphy, that butter consists of a mixture of fats comprising the common kinds of fat, viz., olein, stearin and palmitin, together with certain uncommon kinds, such as butyrin and caproin. So that, in fact, the reverse of Dr. Brown's statement is true; and it might be contended that the *absence* of stearin from a sample of butter would be strong evidence that it was not what it professed to be.

The relative proportion of these different fats in butter is said, moreover, to be subject to variation. Hence there must be no little difficulty in pronouncing with certainty on the genuineness or otherwise of samples of fat alleged to be butter. We require to know to what extent real butter is liable to variation; and until this point shall have been determined, the chemical examination of butter cannot be placed on a scientific basis.

One of the criteria insisted upon as a sign of sophistication is the requiring of a very large proportion of ether in order to effect complete solution. When this is the case, the fat is held to be too rich in stearin, and to have been mixed with some fat which is not butter. It is a question whether a determination of the butyric acid obtainable from a specimen of fat would be a valuable datum; and we understand that Mr. Wanklyn is engaged in investigating this point. A common malpractice in the trade is to cause butter to take up much water; and, as will readily be understood, the selling of water at the price of butter is highly remunerative. Good butter contains some 85 per cent. of pure dry fat; whereas some specimens of the article supplied to workhouses under the name of butter do not contain much over 60 per cent. of fat.

Mr. John James Bancroft, of Ruthin, Pharmaceutical Chemist, and Local Secretary of the Pharmaceutical Society, has been appointed Public Analyst for the county of Denbigh, under the Adulteration of Food, Drugs, etc. Act. Mr. Bancroft was analyst under the old Adulteration Act.

In medical literature the new year has produced no less than three new competitors with the older journals. In England the *Medical Record* is to be issued weekly by Messrs. Smith, Elder and Co.; and the *Students' Journal and Hospital Gazette*, fortnightly, by Messrs. Baillière, Tindal and Cox. The *Irish Hospital Gazette* is also to be issued fortnightly.

Transactions of the Pharmaceutical Society.

ADJOURNED MEETING OF THE COUNCIL.

January 8th, 1873.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

MR. WILLIAM SCOTT BROWN, VICE-PRESIDENT.

Present—Messrs. Atherton, Baynes, Betty, Bottle, Greenish, Hampson, Hills, Owen, Radley, Schacht, Shaw, Stoddart, Sutton, Urwick and Williams.

Elections.

MEMBERS.

Pharmaceutical Chemists.

The following, being duly registered as Pharmaceutical Chemists, were elected Members of the Society:—

Squire, Alfred Rook..........London.
Young, John Rymer..........Warrington.

Chemists and Druggists.

The following Registered Chemists and Druggist were elected Members of the Society:—

Abington, Herbert Joseph .....Ringstead.
Fletcher, John........59, Southgate Road, London.
Garstang, John..............Blackburn.
Heppell, Henry Huggins......Shepherd's Bush.
Hodgkinson, George..........Coventry.
Hodgkinson, John Samuel.....Matlock Bridge.
Jones, John Harrison.........Denbigh.
Phillips, John................Brighton.
Plumley, James George.......Bristol.
Shaw, Ralph Hopwood........Seacombe.
Sissmore, Henry Tertian......Cranbrook.
Smith, Richard Edwin........Bridlington.
Wiggins, Henry ....Bermondsey.

ASSOCIATES.

The following, having passed their respective examinations, and being in business, were elected "Associates in business":—

Minor.

Beard, Thomas William ......Walmer.
Butcher, Henry ....Swinton.
Mortiboy, John ....Herne Hill.
Shakerley, Benjamin ....Penzance.

Modified.

Coke, Richard Sweet ....Devonport.
Gee, David Gillam ....Whitehaven.
Gee, Stacey Thomas..........Whitehaven.
Rayner, Hessey..............Hull.
Rees, Joseph ....Cardigan.

The following having passed their respective examinations were elected "Associates":—

Minor.

Anderson, James Laurie......Leith.
Anthony, David ....Cardiff.
Ashwell, Lawrence Thomas ..London.
Atkinson, Miles Christopher ..Manchester.
Ellis, Robert ....Aberystwith.
Fletcher, Frederick William ..Totton.
France, Joseph ....Rotherham.
Hannah, Charles ....Abergele.
Hardcastle, Stephen Barnabas. Knaresborough.
Manlove, Richard Joseph ....Slough.
Roberts, William Henry ......Bath.
Sadgrove, Arthur Augustus ..Faringdon.
Sharrah, Richard ....Hull.
Taylor, Stephen John ....Westbury.
Woolldridge, George ....Birmingham.

Modified.

Furniss, Thomas ....Halifax.
Lugar, Henry ....London.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary Examination, were elected "Apprentices or Students of the Society:—"

Billinge, Mark ....Hyde.
Carter, William Gibbon ......York.
Charles, Thomas ....Bacup.
Clegg, Joseph ....Manchester.
Cooper, Albert Henry ....Walmer.
Davies, George Edward ......Notting Hill.
Dobson, Fred ....Great Driffield.
Fawthrop, Thomas ....Ryde.
Goss, Walter Herbert ....Barnstaple.
Green, George ....Thetford.
Hawken, Alexander Menhinick. St. Austell.
Hine, Alfred Leonard ....Cheltenham.
Hobbs, Thomas Henry Hurle..Wells.
Holyoake, Francis ....Wandsworth Road.
James, Joseph ....Hanley.
Jeans, Thomas Robert ....Mansfield.
Jinks, John ....Tipton.
Jones, Charles ....Wellingborough.
Lewis, David ....Merthyr.
Matthews, George Francis ....Bristol.
Simpson, Robert George ......Stowmarket.
Treadgold, Frederic Cecil ....Ferneley.
Tritton, Charles Edmund......Bristol.
Walker, George ....Liverpool.
Wilson, Thomas Whiting......Harrogate.
Wingrove, Thomas............St. Albans.

Finance Committee.

The report of the Finance Committee was read.

Mr. Shaw asked if the Committee had ever made any report on the subject of varying the investment of the Society's funds, as they were desired to do by resolution in July last.

Mr. Betty said the Committee had obtained the opinion of the solicitor that their funds might legally be invested in freehold ground rents, and a letter from him to that effect had been laid before the Council, but the Committee had made no formal report on the matter. Mr. Urwick had given a notice of motion on the subject, which would be brought forward later.

The report was received and adopted.

Library, Museum and Laboratory Committee.

The report of this Committee was read. It recommended the purchase of the following:—

Attfield's 'Chemistry.' Fourth edition.
Bengal Pharmacopœia.
Fownes's 'Manual of Chemistry.' Eleventh edition.
Valentin's 'Introduction to Inorganic Chemistry.'
Philosophical Transactions.

Professor Attfield reported that there had been fifty-six entries in the Laboratory since the commencement of the session, and that fifty-four students were working very satisfactorily.

Parliamentary Committee.

The report of the Parliamentary Committee was read. The Committee had considered the question of the fees payable at the examinations, and suggested a re-arrangement making the fee for the Minor five guineas, and that for the Major three guineas, leaving the Preliminary examination fee two guineas as at present. The report also recommended the framing of a new bye-law, providing that no resolution be entertained or considered at any general meeting which would affect the legal status of the members, unless a fortnight's notice thereof be given.

The report was received.

New Bye Law.

It was then moved by the Vice-President,

"That the following be added to the Bye Laws, Sec. 20, as Clause No. 4: 'No resolution of the Society by which the legal position of the members of the Society or the legal position of chemists and druggists, whether members of the Society or not, may be altered, shall be passed at any meeting, unless fourteen days' previous notice of the intention to introduce such resolution has been given.'"

Mr. Hampson seconded the motion.
