Mr. Williams suggested that according to the wording of the resolution, such a resolution as was referred to might be introduced and discussed the whole day, though it could not be passed, and suggested a slight verbal alteration in it to meet this difficulty.

The Vice-President said the matter had been referred to the solicitor, who had prepared three alternative forms of bye-law, of which he had chosen the one which seemed on the whole most suitable. With regard to the objection made by Mr. Williams, he did not think any chairman would allow a matter to be discussed when it was not competent for the meeting to come to a decision upon it. A distinct pledge was given at the last annual meeting that such a bye-law should be passed before the next meeting; and in order to this being done, it was necessary to take action at once, as the new bye-law must be passed at two succeeding Council meetings, and a special meeting, as well as submitted to the Privy Council.

Mr. Bottle expressed his approval of the new bye-law.

Mr. Williams had much pleasure in supporting the resolution, and only regretted that some further alterations in the bye-laws were not made at the same time, since it would save trouble and be better in every way if they went to the Privy Council with several alterations at once. He might take credit to himself for having called attention in the first place to the fact that under the present bye-laws a resolution of a most obnoxious character might be brought forward and passed without any previous notice having been given.

The President having expressed his approval of the proposed bye-law, the motion was put and carried unanimously.

Provincial Education Committee.

The report of this Committee was read. It stated that the Committee had further considered the schemes which had been suggested for promoting provincial education; that the Committee were early impressed with the conviction that, for the successful carrying out of any scheme for promoting provincial pharmaceutical education the general co-operation of pharmacists throughout the country was necessary, and they accordingly suggested that the Council, in publishing a proposition advanced by one of their own members, should invite the fullest expression of opinion on the matter. This had resulted in a manifestation of so much variety of opinion, that the Committee did not feel able to recommend the adoption of any particular scheme; they, however, recorded their opinion, that any project of this nature should include not only a provision for aiding isolated local efforts, but also a plan by which these could be united in some common ground of mutual interest and mutual rivalry.

Mr. Schacht said he should be sorry if it were considered that the whole matter was at a standstill because the Committee did not feel able to move much further at present. The report truly stated that the variety of opinions elicited had been rather confusing; but for the successful carrying out of any plan something like a cordial co-operation throughout the whole country was necessary, which at the present moment was scarcely to be expected. He hoped, however, that one step had been gained, and that they had arrived at this stage, that any scheme pretending to satisfaction must include some plan for the display of its results upon a larger arena than could be obtained in isolated provincial schools. It was thought that the present method of aiding individual effort throughout the country had this great disadvantage, that both the students and their instructors had not much space in which to distinguish themselves; therefore any scheme, aiming to do good service and to promote really scientific education, should have as an essential feature of its operation, some method of gathering together all these results at the close of the year, so that those who had exerted themselves successfully might meet with recognition at the hands of the pharmaceutical world. He would add that he was by no means discouraged or disappointed at the present result, for he did not expect that any scheme would be universally adopted without a great deal of discussion and consideration, and he was quite satisfied that an important step was gained if the principle were fully recognized which was stated in the report of the Committee, and which he had endeavoured fully to illustrate.

The report and recommendations of the Committee were received and adopted.

Report of Examinations.

ENGLAND AND WALES.

Investments of the Society.

Mr. Urwick moved, in accordance with notice:—

"That £10,000 of the Funds of the Pharmaceutical Society be invested in Freehold Land or Freehold Ground Rents, and that the Secretary be instructed to look out for such investment, subject to the approval of the President and Treasurer of the Pharmaceutical Society."

He said it was unnecessary to speak at any length upon this topic; the Solicitor had advised that such a mode of investment would be perfectly legal, and as it would increase their income by at least 1 per cent., he hoped it would be agreed to. It had been said that the Council generally ought to attend to this matter, but he had such confidence in the President and Treasurer that he thought they would be quite competent to act as was suggested. He would only add that he did not mean that the whole £10,000 was to be invested in a lump sum on one security, because it might happen that it could be laid out to greater advantage in separate amounts. If the principle were adopted he had no doubt, at some future time, it would be extended to the Benevolent Fund as well as to the General Fund of the Society.

Mr. Baynes seconded the motion, and said he regretted that there was no report from the Finance Committee on this subject, referred to them some time ago. Large life assurance companies were in the habit of getting $4\frac{1}{4}$ to $4\frac{1}{2}$ per cent. for their money, and he thought the Council ought to do something of the same kind, and to endeavour to make the best use of the spare funds they had in hand. They had nearly £30,000 at command, and 1 per cent. increase on equally good security was an important matter.

Mr. Shaw supported the resolution, and hoped it would be extended to the Benevolent Fund, which certainly was in want of all the assistance which could be obtained for it; an increase of 1 per cent. in the interest on their investments would enable them to do considerably more for persons in need of assistance from the Benevolent Fund, perhaps to add three or four annuitants. The sole question was as to the security, and he must say that freehold land or ground rents were fully equal to the Funds.

The PRESIDENT read a letter from Mr. Sandford, who was not able to attend, in which he deprecated the adoption of the resolution on various grounds, but suggested that the funds of the Society might be invested in India Bonds to pay 4 or $4\frac{1}{2}$ per cent.

The VICE-PRESIDENT inquired what was the average rate of interest paid by the whole of their investments.

Mr. HILLS said he could not say exactly; it would be from $3\frac{1}{4}$ to $3\frac{3}{8}$; certainly under $3\frac{1}{2}$ per cent.

Mr. SUTTON said India Bonds were now becoming very prominent as an investment, and they were just as good as English Government securities; at any rate, this was the opinion given to him by a legal gentleman whom he had recently had occasion to consult.

Mr. HILLS said that might be so, but India Bonds did not come within the definition of Government securities to which they were limited by the Bye-laws.

Mr. GREENISH said investments in India Bonds were allowed by the Court of Chancery.

Mr. BAYNES said there were two classes of Indian securities, one guaranteed in India, and the other having the guarantee of the Imperial Government, but the latter, he believed, paid a much smaller rate of interest than the former.

The VICE-PRESIDENT said he did not think this latter class of Bonds could be brought to pay more than 4 per cent. The Treasurer had informed them that the average rate of interest was about $3\frac{3}{8}$, and he should like to know where they could invest their money upon freehold land without buildings upon it, which would pay a rate of interest exceeding that which their Government investments brought in at the present time. He did not think they could do so unless they went into speculative purchases on the contingency of the land increasing in value, and that was totally foreign to the objects of the Society, and ought not to be encouraged. It would open the doors to what might prove hereafter a very awkward state of things. Freehold ground rents were no doubt a very good security, but he did not think they could be purchased to pay more than 4 per cent., not such ground rents as they would have anything to do with. He had known such property sold repeatedly for from 26 up to 32 years' purchase, and 25 years' purchase, which would only give 4 per cent., was a low average value to give for ground rents of an unexceptionable character. Personally, he should be very sorry to confine himself to the Public Funds for any investments he had to make; but they were trustees for the Society, and were placed in a different position.

Mr. BOTTLE said the question of changing investments was an idea which he himself had proposed some fifteen years ago, when he felt extremely warm upon it, and urged the Council to do what was now proposed with all the force he was able to command; but fifteen years had made a change in circumstances relating to freehold ground rents, and at the present time he should feel bound to vote against the resolution. Had they made a purchase of freehold land fifteen years ago, probably £10,000 invested then would be worth £15,000 now, but he saw no prospect of a similiar increase in the value of land taking place in the next ten or fifteen years; on the contrary, he thought it had reached its maximum value, and taking into account the salaries and expenses which would be requried in managing this class of property, he thought they would be losers rather than gainers if they invested £10,000 in freehold ground rents rather than in Consols.

Mr. HILLS said he should prefer the matter being referred to the Finance Committee to report upon.

Mr. BAYNES said he made a similar motion some time ago, referring the matter to the Finance Committee, but it came to nothing.

Mr. URWICK, in reply, said he had confined himself to testing the opinion of the Council with regard to the investment of £10,000 from the General Fund before going into the question of the Benevolent Fund, though he should be glad to see all the funds invested more profitably. He thought Mr. Brown was in error, as he could speak from experience of 4 per cent. and even more being easily obtained in ground rents, though he did not believe more than $3\frac{1}{2}$ could be obtained from the purchase of freehold land. He differed, however, from Mr. Bottle in thinking that land had reached its ultimate value in England, for he did not think this was the case by any means. As a security he believed freehold ground rents were preferable even to the Funds, and with that class of security he should suggest there would be no difficulty in collecting. With regard to foreign funds, which had been suggested by Mr. Sandford's letter, the Council had no power to invest in them, and although India Bonds might pay better interest than Consols, still most of them now stood at from £108 to £110, and were liable to be paid off at £100, and if such a thing were to happen, the percentage would be considerably reduced. But the Council had no power to invest in Indian securities.

The motion was then put, with the following result:—

For—Messrs. Baynes, Shaw and Urwick.

Against—Messrs. Atherton, Betty, Bottle, Brown, Greenish, Haselden, Owen, Radley, Schacht, Stoddart, Sutton and Williams. The motion was therefore lost.

Mr. Hills and Mr. Hampson were present but did not vote.

GENERAL ARRANGEMENTS OF THE HOUSE.

Mr. BETTY, in accordance with notice, moved—

"That the house committee be instructed to inquire into and report upon the present duties of the clerks, and house servants, and generally as to the arrangements and accommodation of the establishment."

He said the present arrangements of the establishment were most inconvenient in many ways, not only for the Council, but also at the times of examinations. On a recent occasion there were upwards of forty young men crowded into two rooms which was most undesirable in a written examination. Great confusion consequently existed, and great annoyance, not only to those who were being examined, but to the whole establishment. It was certainly very clear that a young man could not pass an examination with satisfaction to himself in the midst of such bustle and confusion as took place under such circumstances, especially with the knowledge present to his mind that he was then in one of the most important crises of his career. Various suggestions had been made at former times for the purpose of remedying these evils, but he hoped now the whole matter would be relegated to a committee, and that they would devise some means of more satisfactorily carrying out the Society's business.

Mr. WILLIAMS had great pleasure in seconding the motion. He was very sorry the Society did not see its way some two years ago, to take advantage of an opportunity which then occurred of purchasing the Inns of Court Hotel, and converting the portion fronting Lincoln's Inn Fields into a proper edifice for the use of the Society. However that was past now, but the question which Mr. Betty now brought forward was of even greater importance. He did not think that proper accommodation could be obtained in the premises they occupied without very considerable alteration, involving the expenditure of a large sum of money; and he hoped one of the first steps would be to carry out the principle of Mr. Urwick's motion, and invest a sum of money in purchasing the freehold of their own establishment. He should quite agree that that would be a proper and a right investment of the Society's funds, and he hoped that would be borne in mind before any great expenditure were incurred; in fact that had been one reason which weighed upon his mind in voting against the last motion. He hoped the Council, in agreeing to send this matter to the Committee, would be prepared to act in a bolder spirit than they had hitherto done, and to take steps which would result in providing something like a proper home for the Pharmaceutical Society of Great Britain.

Mr. Hampson said he had noticed when the examinations were going on a great confusion in the building, the stairs and passages being crowded by the students.

The President before putting the motion said, he thought the inconvenience of the examinations had in some respect been exaggerated. With regard to the Modified examination, the numbers did not generally exceed forty, and the candidates were never all in the room at the same time; and with respect to the ordinary examinations, it was now arranged that the number seldom exceeded twenty-five, in fact the examiners would not take more than that number in one day, so that generally not more than fifteen were in the room at one time. The Library was large enough to hold all the students who came, and they all assembled there at the beginning of the day, and the lounging about the staircases which had been referred to, arose, he believed, from young men waiting after they had finished their examinations in the hope of getting some information as to the result, instead of going away.

The motion was then put and carried unanimously.

Lady Students.

Mr. Hampson, in accordance with notice, moved:—

"That all persons attending the Professors' morning lectures be eligible to compete for the prizes and certificates given at the end of the session."

He was sorry to trouble the Council again so soon, but he brought forward the subject again because of its urgency, and this being the season of the year when good resolutions were usually made he hoped to obtain a favourable vote. If the minds of members had been free from prejudice, it would not have been necessary to introduce the matter at all, because the published regulations provided that all students might compete for prizes and certificates, and lady students being now admitted to the lectures, it appeared to him to follow necessarily that they should have an opportunity for competing for the prizes. It was simply giving a full and legitimate effect to their admission. Their fees had been taken, and so long as the present regulations were in force, the Council ought, both legally and honourably, to give them an equal share of the privileges for which they had paid. During the last discussion Mr. Bottle had raised a very wide question as to making the competition perfectly equal, and no doubt as far as possible this should be done; but it had never been attempted for the male competitors, and it would be utterly impossible, in fact, to effect it. He repeated that it was very undesirable that any delay should take place in settling this question, and he hoped it would now be settled in a favourable sense.

The Vice-President seconded the motion, saying he did not see how, having admitted the ladies to the lectures, they could be precluded from competing for the prizes. At any rate, he should be glad to hear any objections stated.

Mr. Betty objected to the way in which these resolutions came forward. He thought it was rather a roundabout way of bringing forward the question. If the intention was to encourage ladies to enter the business, it ought to be plainly stated, and a vote taken upon it in an open and straightforward way. It must also be remembered that the sessional prizes were not a permanent institution, for in the course of a longer or a shorter time their whole educational arrangements might be modified, and there might not be even a laboratory or lectures connected with the institution. It therefore seemed to him uncalled for to bring forward such a resolution now.

Mr. Schacht said the last speaker had insinuated that there was an ulterior object in the minds of those who advocated that which he himself did not quite approve of, but he saw no ground for such an assertion. On the last occasion he (Mr. Schacht) stated that he had no other object in the matter than what was plainly and straightforwardly stated on the motion. Mr. Hampson could, no doubt, answer for himself; but he certainly did not think it was at all necessary to suppose that in this matter there was any other consideration than that which came plainly before them. There was a distinct application made to the authorities at the institution to know whether ladies could be admitted. That was brought before the Council by a direct proposition, and it was determined that they should be admitted to the lectures but not to the laboratory. Next came the question whether they were to be fully admitted or only half admitted; another application being made by the ladies to know if they were entitled to the full privilege of students. That also had to be answered by the Council, and a direct proposition was made for the purpose of obtaining a decision. As far as he could see, nothing could be more straightforward. He did not wish to introduce any more ladies into the business than those who wished to come, but if they wished to attend, and the Society was bound to admit them on the Register, they ought to have the same opportunities as others to qualify themselves for the duties. That position had never yet been answered, nor did he see how it could be.

Mr. Shaw endorsed the argument of Mr. Schacht. He said he had before deprecated the reintroduction of this question over and over again, as he thought it very undesirable that ladies should be admitted to the privileges of the Society, but with regard to the immediate resolution before them, inasmuch as lady students had been admitted, it appeared to him that the bye-laws were conclusive that they were entitled to compete for the prizes. He therefore scarcely saw the necessity for the resolution—unless, indeed, the Council had the power to veto the presentation of prizes to ladies simply because of their sex. He did not, however, think they would come to that conclusion.

Mr. Stoddart said he could not yield to any man in kindly feeling towards the ladies, but, at the same time, his opinion was that the school of pharmacy was not their proper place at all. He considered it quite an act of grace to admit them to the lectures. To take a case in point. If he sent his own daughter to that institution, and she were admitted to the classes, he should consider himself very much obliged for the favour, and should certainly never dream of her coming to compete for the prizes. He therefore could not vote for the resolution.

Mr. Baynes said he was bound to vote not exactly according to his own personal feelings, but taking a broad view of the whole question. He did not think there was any probability, in his day at least, of ladies being members of Council or filling the Presidential chair, but, nevertheless, if in accordance with the times such a thing were to happen, he for one should be prepared to accept it. The chief difficulty in his mind was this, not whether ladies should be put upon the same footing as all other students—and he thought they should, for having once admitted them he saw no other course open—but that although the institution was formed for the promotion of pharmacy, as he took it, amongst persons actually in the business, yet mere amateurs, medical students, or any one else might attend the lectures, and if they did they might compete for the prizes. The bye-laws appeared to him a little defective in this respect, but so long as they stood in their present shape he could not make any distinction between a male and female student.

Mr. Sutton said that there was a difference made with regard to those attending the lectures as to the fee which they paid according to whether they were connected with the Society or not. Now the lady students would naturally fall into the latter class, and the question was whether a regulation could be made that all persons competing for the prizes should be connected with the Society. As far as Mr. Hampson's proposition was concerned, he did not see how they could stop the ladies from competing under the existing regulations.

Mr. Radley thought it was quite a privilege given to the ladies in allowing them to attend the lectures, and he certainly should be averse to holding out any inducement to ladies becoming competitors in the trade. It was not the province of the Society to do anything of that kind, and rather than go on in that direction, he should prefer retracing the step they had already taken.

Mr. Atherton said there was some excuse for ladies seeking a medical education, but there was none for their desiring to become chemists and druggists. He should therefore vote against the resolution.

Mr. Urwick said he should support it. They had no right to look into the future and speculate as to what was to happen hereafter. He believed it would have a very beneficial effect if some of the ladies did take prizes.

Mr. Williams said when he voted in favour of ladies becoming students, he had no idea of their desiring to attend the lectures for anything except their own information, and he certainly was averse to their competing for the prizes.

Mr. Bottle said Mr. Schacht had asked whether ladies were to be fully admitted or half-admitted. As far as he understood, they were only half admitted, availing themselves of the privilege of attending the lectures; but if they desired to become students and obtain all the privileges of the Society, they must become students and pay their annual subscriptions accordingly, as provided by the bye-laws. They would then be in a fair position to compete.

Mr. Sutton said prizes were now given to those who were not registered students of the Society.

Mr. Bottle said if that were done it was a mistake, it was not intended when the prizes were instituted. He was most desirous not to place the ladies in any different position to those of the opposite sex, but on the other hand, if they were desirous of becoming pharmacists, they must do it on the same footing as the male students. He believed the prizes were intended for those connected with the Society, and if any one else had been allowed to compete it was plainly an error which ought not to be perpetuated. He would ask Mr. Hampson, therefore, to advise his lady friends, if they desired to compete for the prizes, to become registered students of the Society.

Mr. Shaw said he did not think the bye-law quoted by Mr. Bottle was binding at the present time.

Mr. Hampson, in reply, said Mr. Bottle professed himself anxious as far as he could to act justly in this matter, but he did not think that the lady students were entitled to compete for prizes, because they were really not genuine students in the same light as others. This was a mistake on his part, inasmuch as the three ladies now in attendance had already undergone the test of the Preliminary examination, and were going through the regular course which male students usually took. Consequently it was not any amateur attempt on their part, but a genuine desire to obtain a position in pharmacy. On these grounds, therefore, he claimed Mr. Bottle's support. These young ladies were not studying for a mere pastime, but with a view of earning their daily bread. With regard to there being some prospective changes to be made in the educational arrangements hereafter, it was mere nonsense to set that up as an obstacle on the present occasion, there being no positive connection whatever between the two things. The ladies in question were students of the Pharmaceutical Society; they were anxious to gain all the information they could, and they simply wanted the common privileges given to the other students.

The President said it was no doubt a mistake to allow those not connected with the Society to compete for the prizes, but because one mistake had been committed, that was no reason why they should go on and commit another.

On putting the question to the vote, the result was as follows:—

For: Messrs. Baynes, Brown, Hampson, Schacht, Shaw, Sutton and Urwick.

Against: Messrs. Atherton, Betty, Bottle, Greenish, Haselden, Owen, Radley, Stoddart and Williams.

The motion was therefore lost. Mr. Hills was present but did not vote.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The fifth general meeting of the session was held on the evening of December 19th, the President, Mr. E. Davies, F.C.S., in the chair.

A discussion took place on the decision of the magistrate the preceding day, in a prosecution under the Adulteration of Food Act, in which the President, Mr. Abraham, and Mr Shaw took part. Mr. Shaw stated that the magistrate's ruling was directly opposed to that in a previous case. The President repeated his conviction that the Act would prove powerless unless the vendor was made responsible for any adulteration whether he were aware of it or not.

The President called attention to a new quinimetric process by P. Carles, published in the December number of the 'Journal of the Chemical Society,' and mentioned some experiments he had made with a view to determine its success. He also stated that he had tried a process contained in the same number of the Journal for testing for nitro-benzol in essential oil of almonds, which was simple and had proved in his hands perfectly successful.

Mr. A. E. Tanner was glad that the President had tried the process mentioned for testing strength of barks; he had seen it described in the 'Year Book of Pharmacy,' and felt a wish that the method should be tried.

The President said that he had found the use of the air-pump of great advantage in his experiments in Carles's process, as the causing a vacuum in the receiver of the percolator had facilitated the extraction of the matter very much.

MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

A meeting of the Midland Counties Chemists' Association was held on Monday evening, December 30th, at the rooms of the Association, Quadrant Chambers, New Street. The chair was taken by Mr. J. Lucas, pharmaceutical chemist. A paper by Mr. H. W. Jones, on "Yellow Cinchona Bark," in which the subject was ably treated, was read by the author, who gave some interesting information about some new alkaloids, etc.

Proceedings of Scientific Societies.

MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS.

Disinfection in Connection with Small-pox.

BY CHARLES R. C. TICHBORNE, F.C.S., M.R.I.A.;

Hon. and Corresponding Member of the Chicago and Philadelphia Colleges of Pharmacy, etc.

In considering the contagious nature of small-pox and the value of antiseptics in connection therewith, I will ask you to bear with me for a short period, whilst I consider the germ theory of disease generally. It has been conclusively proved that all rooms are filled with a certain amount of dust moving about in variable quantities —at least, to all intents and purposes, it may be considered as never being absent. The greater proportion of this dust, as shown by Tyndall in the analysing tube, is organic, or, in other words, can be destroyed by heat. Some medical men of great celebrity are of opinion that most of the epidemic diseases are carried through the atmosphere in the form of germs peculiar to each disease—that certain diseases again may be instigated by the change or fermentation induced during the growth of germs (not peculiar to the disease), at the expense of their surroundings. As regards experiments performed upon the development of bacteria, they would properly only bear upon epidemic diseases from this point of view; but I myself do not see that there is anything particularly to connect them with small-pox or such like contagious diseases. They are always the forerunners of putrefactive change where atmospheric air has been in contact, but this simply proves that the germs of bacteria are always present in ordinary atmospheric air. Here is a substance that was once a solution of milk-sugar, now converted into solid lactate of lime by germs taken at as high an altitude as the top of Nelson's Pillar. But these results can be obtained equally well when there is no small-pox in the city. As regards the nature and actual appearance of most contagious germs connected with epidemics, I plead total ignorance, and think the biologist, physicist and chemist are all equally ignorant. We are not yet armed with instruments powerful enough to investigate or classify the "milky way" of minute organism, as Ehrenberg terms it.

There is, however, another view to take of the atmospheric propagation of disease, which, I think, has been too much lost sight of. This is the mechanical action of this dust, or the raft theory, as I will call it. I, however, lay no claim to the use of the word raft. It was used by Professor Tyndall in one of his lectures to explain how the particles of a *non-volatile* salt, chloride of sodium, were always found in the air. Now, as we know that the virus of small-pox may be dried without impairing its activity, we have all the requisites for dissemination by the atmospheric rafts. It is self-evident that we can inoculate contagious diseases directly or indirectly (I use the word contagious and other similar words in their strict sense). The Otomak anoints his thumb nail with the deadly curara, and scratches his enemy, but the Indian generally anoints his arrows with it to send his poison through the air, and yet these arrows are equally efficacious as engines of death. Is not this the raft theory of indirect contagion merely exaggerated? If we consider the immense amount of inoculable matter that is disseminated in a city like this, where 600 to 700 lie ill of the same contagious disease, we shall see no difficulty in arriving at this conclusion. I have no hesitation in saying that there is not a cubic inch of atmosphere in Dublin where the small-pox virus is not. But, like all poisons, there is, I suppose, a point of attenuation where it is inert, and to keep it below that point is the great use of volatile disinfectants. The dried virus floating upon those rafts cannot be affected by non-volatile disinfectants.

I listened a few nights ago with a great deal of pleasure to a paper read by Dr. Cameron upon this subject, it being filled with a number of observations of great originality. The tendency, however, as I understood it, was rather to undervalue disinfection as regards epidemics of this class. Now, I am of opinion that it would be dangerous in the extreme to cast away these now old and well recognized friends. In fact, to me it seems to be only within the last few years that we have been beginning to understand the principles of disinfection. We are frequently told by the medical men that there is nothing like "fresh air," which, translated chemically, means oxygen, plenty of it, and in an active state. Such remarks are the true harmonic chords of science, but how are we to get fresh air in a contaminated city, if my mechanical theory of atmospheric dust is correct, or has the slightest stability whatever? Does not the real difficulty of disinfection lie in our misapplication of each particular disinfectant which has its peculiar function, and our want of knowledge of its action on those germs at present unknown? If we use chlorinated lime to disinfect a room (chlorinated lime being simply an oxidizer), what do we do but facilitate the efforts of the atmospheric oxygen to purify by oxidation? We charge the air with nascent oxygen, or that element in its most active form. Thus this air that had been already artificially deprived of its activity outside by contact with contagious matter, is re-oxidized to its maximum capacity. Now, although this is quite consonant with our chemical knowledge, it might be said that, after all, it is but a theory; but let us see how it agrees with our experience.

On the first week in November, 1871, in an establishment, the name of which, from obvious reasons, it is not desirable to mention, a case of small-pox occurred. As there were about 200 beds upon this establishment, it is almost needless to remark that considerable alarm was felt by those with whom rested the responsibility of management. A consultation was held, and a well-known and well-advertised disinfectant was used with every precaution as regards cleanliness. Imagine the consternation when case after case was sent out of the house, until the eleventh was taken to the hospital on the 6th January, who died on the 11th of the same month—a case every fifth day. A consultation was again held, and with advice the following plan was adopted. The disinfectant was changed, and the use of carbolic acid and chlorinated lime was agreed upon. The carbolic acid (pure) was chiefly used in water-jugs, a few drops in each jug. A man was told off specially to disinfect the place, and to do nothing else. In the morning he made his solution of "chloride of lime," about ½ lb. or 1 lb. to the gallon of water, in a large tub. It was allowed to subside, so that it was quite bright and clear when he wanted it for use. At three o'clock P.M., he went through all the rooms, sprinkling the solution over every floor, and the windows were left open, so that the rooms were dry by the time they were required for use, equal attention being paid to the mechanical cleaning of the walls. The change in the system of disinfection was made on the morning of the 11th of January, the day when the last case was buried, and from that day to the present there has not been a single case of small-pox in this seething mass of humanity.* Can we believe, after such an instance as the above, that there is nothing in disinfection if systematically and judiciously applied? I may mention that other establishments in Dublin have had a very similar experience. Cresylic and carbolic acid are the most efficacious volatile antiseptics, and chlorinated lime one of the most efficacious as an atmospheric oxidizer. Permanganate of potash is invaluable for certain special applications. Here is a simple experiment which, I think, conclusively proves the value of chloride of lime as an oxidizer. I blow through a series of wash bottles and tubes. In the first bottle the air traverses a fermenting mass containing a weak solution of a ferrous salt. If the air contained any readily available oxygen (it matters not whether we consider it ozone, or condensed oxygen, or nascent oxygen, if it does its work), it will be deprived of it. This fact is demonstrated by being passed over ozone test-paper contained in the next tube. There is no evidence of decomposition. It is then passed in the next bottle through water containing a few drops of chlorinated lime, and then through a wash-bottle con-

* On the 24th of June, when this paper was going through the press, this house was still free from any case of small-pox.

taining a solution of ammonio-chloride of silver to remove any trace of chlorine. It lastly passes through a tube containing the ozone paper, which is now seen to be rapidly acted upon by the air. It is completely changed in its character, and is now a powerful oxidizer; and it is immaterial to our purpose how this has been brought about. It is now replenished, ready to do its duty and fight the battle with the rafts of contagion; and if it only succeeds in further attenuating the effects of this poison by burning up a fraction, the "disinfectant" has done some good.

As regards antiseptic treatment in the blood, it is a subject with which, I think, chemists are justified in dealing. Medicine may act simply by a certain portion of it getting into the circulation by diffusion, by some inherent virtue of its own upon other constituents of the body; or it may act by virtue of a partial decomposition or oxidation occurring in the blood, and producing effects not directly from the operation, but from an infinitesimal small amount of a new product being liberated in the nascent condition in the blood. Thus in the case of chloral hydrate it is probable that it is but a fraction of the dose given that finds its way by diffusion into the circulation as chloral hydrate, but there it is also converted into nascent chloroform, and produces its well-marked effects; no dose of chloroform will, when taken internally, produce similar results. Such reactions as these are the most potent and valuable in medicine.

Xylol's action is said to be due to the fact that it becomes an antiseptic in the blood. Now it is probable that if it does act as such, it is due to some product of oxidation. That it is really rapidly oxidized there can be no doubt from the fact that a peculiar odour, distinct from xylol, can be perceived in the urine. It is worthy of note that this hydro-carbon xylol, C_8H_{10}, may be viewed as either dimethylbenzene $C_6H_4(CH_3)_2$ or ethylbenzene $C_6H_5(C_2H_5)$. Now if either of these be its true composition, the residual molecule benzene is the hydride of phenyl, the radical of the so-called carbolic acid. Thus if we act upon benzene by bromine, which is merely a convenient mode of oxidizing, hydrogen is given off, and we get bromide of the radical phenyl.

$$\text{Phenyl}—\left.\begin{matrix}C_6H_5\\H\end{matrix}\right\} O = \text{Carbolic acid.}$$

From the reports of the medical men I should consider the efficacy of xylol as doubtful, but it is self-evident that it may not necessarily possess specific properties to be an active medicine. It would require a lengthened experience of its capabilities at the bedside to determine its actual value in the human laboratory. Although its action may be generally prognosticated, it can never be proved in the test-tube.

The ultimate oxidation products of carbolic acid would probably be oxalic acid and carbonic anhydride, and therefore the action of sulpho-carbolates of which some medical men speak very highly, is that the carbolic acid *per se* acts as an antiseptic being diffused into the circulation. I have tried experiments upon dilute solution of albumen and vibrios, from which it would appear to me that the dilute solutions of carbolic acid destroy the activity of the vibrios before they coagulate the albumen. The more diluted the solution of carbolic acid the more marked is this phenomenon. The sulpho-carbonates being crystalloids are more suitable for diffusion than the carbolates, whilst the residual carbolic molecule acts as if uncombined. In addition to the sulpho-carbolates of iron and sodium, I should suggest the use of the potash salt, which, from its action upon the skin and kidneys, would probably be useful. It is readily prepared. The real colour of the sulpho-carbolate of iron is green or nearly white, but it is always found of a dark violet colour in commerce, and it is stated to be that colour in works upon chemistry. This, however, is due to the fact that as soon as there is a trace of ferric salt formed, it reacts upon the carbolic acid molecule to produce a beautiful violet, which is characteristic of the molecule.

In seeking for a remedy for internal disinfectives of the blood, it is evident, from my point of view, that we should try to search into the substances which will produce in the blood the antiseptics slowly, but in a nascent condition. Carbolic acid is the most available antiseptic (for the production of sulphurous acid in the circulation would be out of the question), therefore on consideration, the first things that will present themselves are the methylsalicylates ($C_8H_7M'O_3$), or the salicylates. Methylsalicylates I find are slowly but perfectly decomposed in the cold, and in alkaline solutions, such as the blood. Therefore it is theoretically immaterial which is used. Salicylic acid, if heated, is converted into carbolic acid and carbonic anhydride, and there seems to be a wonderful chemical relation between these two substances, *i.e.*, carbolic acid and salicylic acid; thus either of them can with facility be formed from the other.

The salicylates only require one equivalent of oxide to convert them into carbonates and carbolate of the metal. Thus:—

$$\underset{\text{Salicylate.}}{C_7H_5M'O_3} + M_2O = \underset{\text{Phenate.}}{C_6H_5M'O} + \underset{\text{Carbonate.}}{M_2CO_3}$$

And if we use dilute solution, we get the same reaction with reagents. Thus ferric chloride gives the same beautiful violet reaction independently if we use a carbolate, sulphophenate, or salicylate; it acting in each case upon the carbolic, or phenol residue. I am sorry that this paper is not more matured, and that I cannot give you the results of some practical experiments that some of my medical friends are trying, but the situation would not allow of my doing so. In concluding these rather disjointed remarks, I have to apologize to so learned a body as this for bringing before them a lot of matter, which will probably appear stale and unprofitable, and I have no doubt occasionally not very pertinent; but I could not do myself any justice if I did not put my views on paper in some manner of sequence, even at the risk of appearing loquacious. As I have studied the subject of disinfection and atmospheric dust with some care for years, I thought that these observations might be of use from the very fact of being trammelled by the ideas of a chemist. Out of a great mixture often come good compounds. I almost feel that we are in a degree neglecting our duty in not constructing committees of investigation upon such occasions as the present visitation. To work with one object, and approach it with the best intention of seeking truth and shutting out emulation. Such a work should run in no grooves, but should emanate from the biologist, physician, and chemist; in fact, from science itself.

The reading of the paper gave rise to the following discussion:—

Dr. Cameron said, as he had recently read a paper on this subject he wished to make a few observations, more especially as he apprehended that the views Mr. Tichborne had put forward might appear to clash with those which he had submitted to the Society. He did not at all doubt the efficacy of gaseous disinfection to a certain extent, but what he said was this—and he spoke from the results of his own experience—that gaseous disinfection, as ordinarily carried out, was totally inefficacious as a means of wholly destroying germs in a room. He held that the recent experiments of Chauveau—who occupied the first position as an investigator in this department of medical science—and more recently the experiments of Dr. Burdon-Sanderson, one of the medical inspectors of the Privy Council and professor in the Brown Institution, rather indicated that as a rule the contagious matter of zymotic diseases was deposited on solid substances. The experiments of Burdon-Sanderson proved that while the sporules of vegetables float freely around us in the air, and are deposited in solutions with great rapidity, causing the development of vegetable life to take place in solutions in an hour or two, organic solutions might be kept for an almost indefinite period of time exposed to the air without producing the slightest appearance of animal life. It might be said that the infectious matter of small-pox or other contagious diseases might be cells of plants of different kinds of fungi, and that in that way germs of disease would float in the atmosphere; but the whole drift of scientific investigation pointed in a different way, and showed that animal infectious matter—the contagium of disease—was a non-soluble solid substance, and the experiences of mankind proved that these matters were extremely small. It was probable that they adhered to solid substances, and that they clung to our clothes. If they were floating about in the air, it was utterly impossible that the germs of typhus fever, of small-pox, or of scarlatina could linger for months in rooms, as they had been proved they do, for the air was renewed hundreds of times in a day. The great use of the disinfection at present employed was that it obliged people to open the windows and let in the fresh air. They all knew how well the Germans did everything in scientific and medical matters, and he would mention the results of their experience of disinfection during the visitation of cholera in Leipsic in 1866. The chemical professor, Carus, was appointed head disinfector of the town, which was divided into 100 districts, each of which had a separate inspector. Never was disinfection more thoroughly carried out. Every house in which cholera appeared was disinfected with chlorine gas. And what was the result? There had been thirteen outbreaks of cholera in Leipsic since the first appearance of the disease in Europe, and never was the attack so severe as in the year 1866, when disinfection was carried out in so careful a manner. It was the same in Stettin and Erfurth, where disinfection was carried out under the orders of the Government and by a staff such as we could not have in this country. The following observations, which appeared in the *Lancet*, expressed his opinions on the subject of disinfection much more clearly and tersely than anything he could say:—"Recent experience has proved the insufficiency of the ordinary process of disinfecting dwelling-rooms without at the same time stripping off the paper and washing the walls and painted surfaces with caustic soda. In Manchester nearly all the men engaged in this duty have had fever or infectious disease, although the houses previous to their visits had been disinfected by chlorine, carbolic acid, etc. It is believed that contagious matter is retained in the paper, particularly when a number of layers have accumulated on the walls. In some cases the men removed as many as fifteen coats of paper, and they describe a fusty odour, which of itself may probably give rise to fever. We would recall to our readers the case of the Knightsbridge Barracks, where the accumulation of successive layers of size and paper formed a nidus for thousands of maggots. We must not, therefore, be satisfied with mere cleaning, whitewashing, and re-painting, but insist also on the cleansing and scouring of the walls. It is satisfactory to find that the recurrence of fever in the same houses in Manchester has greatly diminished since the introduction of this thorough mode of cleansing." Dr. Cameron proceeded to say that his views had been adopted by the Public Health Committee of the Corporation. They had increased their staff, and now, instead of merely disinfecting a room with chlorine gas, they removed the paper, if there were any, from the walls; scraped off the old whitewash, and whitewashed the walls afresh. If the whitewash did not destroy the infectious matter, at all events it imprisoned it. By the use of common water and whitewashing more good would be effected than by the circulation of thousands of feet of chlorine gas.

Dr. Hayden said he was particularly pleased at hearing Mr. Tichborne's paper read so soon after the paper of Dr. Cameron, which, with all respect to him, he thought missed the point. Dr. Cameron, he thought, meant to convey that germs, bacteria in particular, were identical with the *materia morbi* of epidemic disease.

Dr. Cameron said that he did not mean to convey that.

Dr. Hayden: Dr. Cameron said that the gases used as disinfectants were unable to destroy bacteria; therefore, they were useless as disinfectants in epidemic diseases. He had alluded to the experiments of Dr. Burdon-Sanderson; but when that gentleman was questioned on the point in a recent debate he declined to say that bacteria were themselves the *materia morbi*. The opinion he expressed confirmed the view taken by Mr. Tichborne, for he used the words that they might be carriers of the disease. Dr. Cameron seemed to think the atmosphere could not be a medium for the conveyance of disease. That, however, he (Dr. Hayden) doubted. Dr. Cameron, that evening, said it would be sufficient to cleanse the walls, but if it be true that the air was impregnated with organic matters, every one of which might be the medium for conveying the *materia morbi* of disease, he could not see how that could be neutralized without acting on the whole body of air in the room. He was glad to hear this practical paper of Mr. Tichborne, because the opinions urged in it had fallen in with his own preconceived views.

Dr. Cameron: What I meant to say was that if gaseous disinfectants did not destroy those tiny creatures, the bacteria, or destroy the contagious character of vaccine lymph, it was not likely to destroy the contagious matter of other diseases. I, therefore, said that unless they are applied dissolved in liquids, they are inefficacious.

Dr. C. Moore said that disinfection, as at present carried out in Dublin, was of very little use. In many parts of the Liberty the houses were nothing but a mass of infection, and the mere whitewashing of the walls would be ineffectual to destroy it. As long as the old floors of these houses were left full of the dirt of ages, the *débris* of persons who had suffered from countless epidemics, they must expect disease to prevail in these localities. Nothing but the most thorough cleansing of these houses would do good, and, indeed, many of them ought to be thrown down altogether.

Mr. Tichborne, in reply, said that Dr. Cameron, who had not heard the whole of his paper, had mistaken the drift of it. His theory was that the contagious matter of small-pox was a substance which was carried on the atmospheric rafts, and deposited on the clothes. Before it could be deposited on the clothes or on walls, it must have passed through the air; and he proposed to act upon it by gaseous disinfectants. Dr. Cameron believed in the germ theory of disease generally. There was evidently something in it; but if he believed in it, one thing was self-evident—namely, that non-volatile disinfectants could do no good, for they could not touch it; but volatile disinfectants would be found effectual; and this was wonderfully borne out by the case he had stated that evening, which was only one of several cases that had occurred under his own observation.

Dr. Cameron: What do you think of the spray mode of applying disinfectants?

Mr. Tichborne replied that it might be very useful. Disinfection was generally applied once, twice, or thrice, sometimes at long intervals; and that method was quite ineffectual. It must be applied in a systematic manner, like that which he had adopted in the house referred to; and should be kept up as long as there was any renewal of the disease.

Parliamentary and Law Proceedings.

Death from an Overdose of Morphia.

On Saturday, January 4th, Mr. Coroner Maynard held an inquest at the Sunderland Infirmary, on the body of James Sharer, aged fifty-seven, who died on the previous day from an overdose of morphia, which he had been in the habit of taking. From the evidence, it appeared that the deceased had become addicted to intemperate habits, and had also contracted a habit of taking laudanum, morphia, and similar drugs, through which his life had been, on two previous occasions, nearly sacrificed. His friends had more than once warned the druggists in the town against supplying him with anything of the kind, but he still seemed able to procure laudanum by the plan, it is supposed, of sending boys into shops for small quantities. On Thursday night he went to the shop of Mr. Cockburn, druggist, and asked for three drachms of the solution of morphia, but Mr. Cockburn declined, saying that he never supplied it except on the order of a medical man. The next morning, about half-past ten, he went in and asked for a small phial containing fourpennyworth, or nearly an ounce, of laudanum, which Mr. Cockburn gave him, believing his representations that he wanted it for a lotion, as he suffered from rheumatism in his hip. But even this, Mr. Cockburn said to the jury, was not an excessive quantity for any person who habitually used the drug, as he had seen women drink off more than that in the shop. Between twelve and one on the day named he was met not far from his house, reeling very much, and was assisted home.

Dr. Welford was called in, who, seeing the danger, drove at once to the Infirmary and brought the house surgeon, Dr. Hopgood, with the stomach pump, which, when applied, brought off the laudanum mixed with alcoholic spirits. As deceased continued to get worse, however, he was removed to the infirmary, where every effort was made to keep him awake by shouting at, pinching, and walking him about the floor, but he gradually sank into the fatal slumber and about four o'clock expired.

The Coroner said that the constable had been round to the druggists, but Mr. Cockburn was the only one who would admit having sold deceased any drugs. It was possible he might have obtained a large quantity by getting other persons to procure it for him in small quantities.

Mr. Cockburn stated that deceased was never in his shop before, and he was not aware that he was addicted to the use of opiates.

The jury returned a verdict in accordance with the above facts, there being no one to blame in the matter.—*Newcastle Daily Chronicle.*

THE CHARGE OF FRAUD AGAINST A HERBALIST.

On Friday, January 3, Henry Jackson, thirty-five, described as imperfectly educated, was charged at the Hull Borough Sessions with fraudulently obtaining from John Richardson certain sums of money under false pretences. The evidence was similar to that given at the preliminary hearings of the case, an abstract of which has already been given.

The jury found the prisoner guilty, and the Recorder sentenced him to twelve months' hard labour.

Obituary.

ADOLPHE-GEORGES GUILLEMETTE.

The death of one of the most distinguished French pharmaciens, Adolphe-Georges Guillemette, at the age of 64 years, took place recently. On the 28th of October the last honours were paid to him in the presence of a numerous concourse of relations and friends, when an allocution was pronounced over his tomb by M. Gobley, in the name of the Paris Société de Pharmacie.

Born in 1808, at Magny, near Caen, M. Guillemette commenced his studies as a pharmacien with an uncle at Bretteville. He afterwards went to Paris, and had the good fortune to obtain an engagement with M. Boutron-Charlard, under whose superintendence he perfected himself in the art of pharmacy. Being about to make an attempt to better his position he received an offer from M. Boutron, his employer, to succeed him in his business, and he thus, in 1835, became head of one of the most important pharmacies in Paris. In this position he superintended with great ability the production of medicaments, and at one of the national exhibitions he showed numerous crystallized products of opium of surpassing beauty.

M. Guillemette also published several researches of great interest. In concert with M. Boutron he showed the identity with mannite of grenadine, a crystalline substance obtained from the pomegranate, which had previously been looked upon as a peculiar principle. The crystallizable substance to which the melilot owes its odour was looked upon as an acid substance until Guillemette showed that it was neutral, and identical in properties and composition with the coumarine of the Tonqua bean. After thirty-five years of incessant labour, M. Guillemette was looking forward to the enjoyment of the competency he had won, when the events of the late war caused him to leave Paris with his family, and the anxieties caused thereby probably sowed the seeds of the malady which carried him off after an illness of scarcely three weeks.

Notice has been received of the death of the following:—

On the 6th June, 1872, Mr. John Taylor, Pharmaceutical Chemist, of Preston. Mr. Taylor had been a member of the Pharmaceutical Society from its foundation. Aged 68.

On the 21st December, 1872, Mr. Joseph Templeton, Chemist and Druggist, of Liverpool. Aged 47.

Notes and Queries.

[326].—SOLUTION OF SULPHURETTED HYDROGEN IN GLYCERINE.—Can any correspondent inform me whether a solution of sulphuretted hydrogen in glycerine can be preserved for any length of time without change? I have tested the strength of a sample, recently obtained from a London wholesale house, by precipitating with nitrate of lead, washing, drying, and weighing the sulphide so obtained, and find that it contains 210 volumes of the gas in 100 measures —or little more than double the strength of an aqueous solution. Its merit, therefore, must arise from its keeping qualities, and regarding these I ask the favour of information.—J. F. BROWN, Dover.

[324.]—SYRUPUS CALCIS LACTO-PHOSPHATIS.—P. Vincent (Paris) forwards the following for the Syrupus Calcis Lacto-Phosphatis, and states that having made the syrup several times with the same formula, he can strongly recommend it, as it continues to keep its clear appearance for some time.

Os Ustum	10 grams.
Hydrochloric Acid	20 grams.
Liquid Ammonia	13 grams.
Concentrated Lactic Acid } Distilled water }	. . q. s.
Sugar	528 grams.

Leave together for some time the bone ash and hydrochloric acid, until effervescence ceases, then add distilled water 500 grs., precipitate with the ammonia, filter, and well wash the precipitate with distilled water, until washing cease to give a precipitate with solution of nitrate of silver. Leave to drain for twelve hours, after gently heat in a porcelain capsule, and add sufficient lactic acid to dissolve the precipitate, add sufficient distilled water to make the product weigh 272 grams., filter and add the sugar, make dissolve with a gentle heat.

Milk Testing.

Sir,—Mr. Southwell questions the accuracy of my statement, that cows' milk has a slightly alkaline reaction. It is a matter of very little practical moment, but if he will examine milk directly it is drawn from the cow, he will find I am correct.

Pereira (4th Edition 'Materia Medica,' p. 814, vol. ii. part ii.) says, "when recently drawn from the animal, milk is slightly alkaline."

Fownes ('Chemistry,' 9th Edition, p. 726) says, "milk is a slightly alkaline liquid;" and again (p. 728) "In a fresh state, and taken from a healthy animal, milk is always feebly alkaline."

All the other authorities I have referred to say the same; and, indeed, considering the composition of milk, I do not see how it can be otherwise.

Of course no one would attempt to estimate the total solids in milk, without first making sure of the absence of such substances as starch and chalk; however, as I have said before, they are really never to be met with.

Vogel's lactoscope affords a good rough-and-ready way of estimating the value of any given sample, but we have already too many of such rough methods, and I think no one would venture to rely upon the lactoscope alone to give a decided opinion in a Court of law as to whether milk was adulterated or not.

In the table at the end of his letter, does Mr. Southwell intend us to infer that milk, having a specific gravity of 1027, must necessarily be mixed with 10 per cent. of water? I need hardly point out that this is very far from being the case. A milk containing a large amount of cream, which is lighter than water, may have a sp. gr. even lower than 1027, and yet be a better and richer milk than one having a sp. gr. of 1031.

Next to obtaining the total solids, perhaps the estimation of the milk sugar in the whey, as recommended by Mr. J. F. Brown, is the most satisfactory way of detecting adulteration by water. I have not found though, that titration with a standard solution of copper gives such accurate results, as determining the milk sugar directly by weight.

We must remember, too, that although milk sugar varies perhaps less than any other constituent of milk taken by itself, still it varies considerably.

Messrs. Henry and Chevalier found that with cows fed on grass, the quantity of milk sugar per cent. was 4·77, when the same cows were fed on carrots the milk sugar rose to 5·30, and when fed on beet, to 5·95 per cent., a difference from first to last of about 20 per cent.

Charles Ekin.

Bath, Dec. 26th, 1872.

Payment of Local Secretaries.

Sir,—Mr. Sutton asks for some further expression of opinion on the subject of remuneration to local secretaries for their services in the Preliminary examinations.

In responding to his request, I think there is no remuneration needed or desired; it is quite competent for every local secretary to deduct payments out of pocket from the sum he remits annually to Bloomsbury Square. These deductions would be exceedingly small, and during the twenty-five years I have been secretary, I do not recollect having made a charge for these trifling payments, but, on the contrary, have considered the honour of the appointment more than an equivalent.

While I am writing these lines five candidates for honour in the Preliminary examination are in my presence working on their papers. Three hours spent in this superintendence may not be always convenient, but the time may always be profitably employed; and as the Council receive no remuneration for the time devoted to the interests of the Society (the country members receiving a railway pass), why should any be given to local secretaries?

Should anything be done in this matter the railway pass is in my opinion the best suggestion.

Nathaniel Smith.

Cheltenham, January 6th, 1873.

The Subscription for Mrs. Stockman.

Sir,—May I trespass once more on your kindness by asking you to announce on behalf of Mrs. Stockman and family:—

Allen Smith, Sale, 27*s*., and J. J., Aberdare, 10*s*. 6*d*. The total sum subscribed is £185. 4*s*. 8*d*. This has been the means of placing the widow in a hosiery and haberdashery business. She and her family return their best thanks to the subscribers for their generous kindness.

Allow me also to thank you most sincerely for your kindness in allowing the acknowledgments of subscriptions to appear gratuitously in the Pharm. Journal.

Charles Mumby

Gosport, January 2nd, 1873.

J. Smith, M.D.—(1) We are unable to give you the formula. (2) The formula for Pommade de la Comtesse, as given by Dorvault (L'Officine) is as follows:—

"Noix de galle	30·0
Noix de cyprès	30·0
Ecorce de grenade	30·0
Sumac	30·0
Mastic	30·0
Onguent rosat	590·0

La Pharmacopœia Hispanica remplace la pommade rosat par de la cire jaune et de l'huile de myrte." (3) We believe the article is a specialty of Messrs. Gosnell. (4) We have been unable to obtain the information.

"*Inquirer.*"—We believe that no separate returns have yet been made. See *ante*, p. 347.

"*Spes.*"—The subject has already been discussed and a remedy suggested (see *ante*, p. 419). We therefore refrain from printing your letter, which would be only adding to the amount of "talk" upon the subject deprecated by you.

"*Chemicus.*"—Blaine's 'Veterinary Art.'

"*Hyoscyamus.*"—Valentin's 'Inorganic Chemistry,' or Fresenius' Works on analysis.

J. J. M. (Manchester).—Bentham's 'Handbook of British Botany,' or Hooker's 'Students' Flora of the British Islands.'

J. Davidson.—For a description of the manufacture of oxalic acid on the large scale, see Ure's 'Dictionary of the Arts,' Richardson and Watts's 'Chemical Technology vol. i.; Watts's Dictionary, vol. iv.

W. J.—There is no such law in force as that described by you.

J. A. Clarke.—The report was received too late for insertion this week. The lecture shall be attended to.

The following journals have been received:—The 'British Medical Journal,' January 4; the 'Medical Times and Gazette,' January 4; the 'Lancet,' January 4; the 'Medical Press and Circular,' January 4; 'Nature,' January 4; the 'Chemical News,' January 4; 'English Mechanic,' January 4; 'Gardeners' Chronicle,' January 4: the 'Grocer,' January 4; the 'Journal of the Society of Arts,' January 4; 'Grocery News,' January 4; the 'Scientific American,' January 4; 'L'Union Pharmaceutique' for December; 'Journal de Pharmacie et de Chimie' for December; 'Répertoire de Pharmacie' for December; 'Moniteur Scientifique-Quesneville' for January'; the 'Doctor' for January; 'Food, Water, and Air' for January; 'British Journal of Dental Science' for January; 'Practitioner' for January; 'American Chemist' for December; 'Medical Record' January 8; 'Journal of Applied Science' for January; 'Irish Hospital Gazette' January 1; 'Students' Journal' January 4.

Communications, Letters, etc., have been received from Messrs. W. R. Jones, Pattison, T. M. Stone, F. Coles, C. Hall, W. Proctor, G. Brown, P. Vincent (Paris), E. Gallois (Paris), M. C. Cooke, R. Smith, "Plumule," "Hyoscyamus," "Spes," and J. J. M.

EXTRACT OF MEAT.

BY BARON LIEBIG,

President of the Royal Academy of Sciences at Munich.

In a letter by Dr. Edward Smith, which appeared in the *Times* of October 16th, he reproaches me with several quotations contained in my letter of October 1st, which require on my part some vindication.

Dr. Smith says that the passages I have quoted on "economy of nutrition," "the small morsel of meat," "fish," "tea," are not extracts from any published work of his, and he calls upon me to explain where I had obtained my (most unaccountable) "quotations." My vindication is not a difficult one, and I gladly take this opportunity to explain more fully the real value of extract of meat for the alimentation of the people; the only unpleasant part of the task is, that in doing so I am compelled to speak more of myself than I like.

In the first place it is quite correct that the above mentioned quotations have not appeared either in the article in the *Standard*, or in that of the *Times* of August 20th. They are taken word for word from an article entitled "The Butcher's Bill," which appeared in the *Saturday Review* of August 31st. This article is avowedly based on Dr. Edward Smith's views, so that any one who took the trouble to read it, must, like myself, have arrived at the conviction that its sentences contained the authentic opinions of Dr. Edward Smith.

Dr. Edward Smith says, "Let it be clearly understood that at length Baron Liebig is in accord with other scientific men, and that all may adopt the words of Liebig—'Neither tea nor extract of meat are nutriment in the ordinary sense,' and all I contend for is accomplished." This does not seem to say less than that I have now been converted to views which either I formerly had not, or which I even disputed, while the real truth is that all that has been ascertained within the last thirty years on these subjects is in perfect accord with my teachings. Thirty years ago I taught in my 'Animal Chemistry,' that for the preservation of life the food of men, as also that of animals, must contain one indispensable element for the formation of blood or of the albumen in the blood. I have further explained in my 'Researches on the Chemistry of Food,' (1847), that "beef-tea" or "extract of meat" contains none of the substances called albuminates, as these latter coagulate and separate when the meat is boiled in water. In my 'Familiar Letters on Chemistry,' xxix. p. 421 (edition of 1851), I said, "In the albumen of this fluid (juice of flesh) we have the substance serving as transition product to the fibrine of flesh, and in the other substances (contained in beef-tea) the matters required for the production of cellular tissue and nerves." From this it will be seen that I never asserted that "beef-tea" or "extract of meat" contained substances necessary for the formation of albumen in the blood or of muscular tissue. I have, on the contrary, designated them as "food for the nerves," in the same sense as common salt is also designated as food, although one cannot always define in which manner it acts usefully.

It cannot, therefore, be said that "I am at length in accord with other scientific men," but that these scientific men, including Dr. Edward Smith, have simply adopted what I have always, and from the very beginning, taught. Based on my own definitions, Dr. Edward Smith informs me that extract of meat is not "food," but a "nervous stimulant." But what is a nervous stimulant? everybody will ask who is not satisfied with a word, but wishes for a definition. We take the constituents of extract of meat in our daily food, just as we take tea and coffee in addition to our food, and nothing can be more undeniable than that these substances produce a certain beneficial effect on all the functions of the body, and also on the process of nutrition. It is clearly not the duty of a scientific man simply to deny these effects, but to find out how great is the share these substances have in the functions of the animal organization.

Some years ago two physiologists at Vienna attempted to prove by experiments on themselves, respecting the effect and value of common salt in the process of nutrition, that salt is a luxury and of no value for nutrition and the preservation of health. In matters affecting the alimentation of the people no importance can be attached to such trifling experiments if they are in contradiction to confirmed experiences, and this contradiction will grow in the same proportion the less the experimentalist is capable of observing and rightly interpreting facts.

In order to comprehend the difference between "common food" and "nervous food," as I will call it in order to avoid circumlocution, it must be considered that man has two kinds of work to perform, muscular or mechanical work and brain or nervous work. The one, the muscular work, is under the dominion of the nerves and the brain.

By "common food" must be understood those substances which serve for the preservation of the temperature and restoration of the machine. Coffee, tea and extract of meat are not suited to these purposes; by their effect, however, on the nerves they exercise a decided influence.

The experiments made with extract of meat in Russia, France and Sweden are what in the scientific world are termed "sham experiments." They are not undertaken to find out that which is not known, but as the result is known beforehand, appear really only to be made with a view to deceive others, and the conclusions drawn from them are simply absurd. It will suffice to describe one of these experiments in order to convince any one who bears in mind that it has been scientifically determined that extract of meat does not contain any substances necessary for the formation of albumen in the blood, and for the restoration of the waste of muscular tissue.

Two dogs of almost equal weight were fed, the one with meat, the other with extract of meat. The former was fed with 400–500 grm. fresh meat, the other with 12½–15 grm. extract of meat (the quantity contained in 400–500 grm. fresh meat). The dog fed on meat flourished, his weight rather increased, while the other fed on extract of meat only, became thin, was attacked with diarrhœa, and would have died if the experiment had been continued. The inference drawn from this experiment is:—Extract of meat is not nutritious, it rather has poisonous effects, causes diarrhœa, and would produce death. That the other dog had likewise consumed 12½–15 grm. extract of meat in the 400–500 grm. of meat without being seized with diarrhœa or feeling any injurious effects, this fact does not trouble the experimentalist, nor does it concern him that a dog weighing from 2 to 3 kilogrammes requires from 40 to 50 grm. of carbon in his food for the process of respiration and to keep up the weight of his body, while 12 to 15 grm. extract of meat only contains 3–4 grm. of carbon.

These experiments, made by Dr. Beljawski, in Moscow, and the conclusions drawn from them, are identical with the French, *vide* 'Moniteur Scientifique Quesneville' 1–15 Dec. 1871). That no experiments have been made in England similar to those in Russia and France proves that English physiologists possess more common sense.

Concerning the standing of Professor Almen, in Sweden, it will suffice to mention here his assertion that "a glass of warm water with a little pepper must produce the same effect as a cup of beef-tea." What sensible physician would venture to prescribe warm water with pepper instead of meat broth to a patient recovering from typhoid fever? Nor in spite of Professor Almen is this done in the Swedish hospitals. Beef-tea is used there in the same cases and for the same purpose as with us.

That in Göttingen extract of meat is generally used in family households and also in that of Professor Mussner, I may venture to affirm.

In order to understand correctly the significance of meat diet and extract of meat, it is necessary to turn one's attention to the difference of the component parts of meat and those of vegetable foods. Meat contains in its albuminates the chief requirements for the renovation of the muscular tissues and for the preservation of lasting muscular action. Those constituents of the meat which are soluble in boiling water take no part in the formation and renovation of the muscular tissues. But by their effect on the nerves they exercise a most decided influence on muscular work wherein meat differs from all other animal and vegetable food.

By the use of meat we consequently obtain two effects, the one (effect on the nerves) perfecting and strengthening, the other (muscular action). The prices of other articles of food, even of those containing a considerable amount of muscle-forming material, are much lower than that of meat, and are not in proportion to the contents of muscle-forming substance. According to calculations made in my own household, we obtain in 100 lb. of butchers' meat (67 lb. muscle, 12½ lb. bones, 8½ lb. fat, 3 lb. membrane) 13·9 lb. albuminates. In 100 lb. cheese there are from 26 lb to 30 lb. albuminates, and the liver and brain are likewise richer in albuminates than the same weight of butchers' meat. The blood of animals is richer still in albuminates in proportion to its price. Nevertheless, nobody thinks of placing blood, liver or cheese fully on a par with butchers' meat.

Vegetable albuminates are still lower in price, and from these is produced in the bodies of animals all the muscular food which man consumes. 100 parts of ordinary wheaten flour contain very nearly as much muscular food as 100 parts of fresh meat, but how small is the price of bread as compared to that of meat!

This clearly shows that the instinct of man discovered a difference in the effects of his various foods, and that he does not estimate and judge them in proportion to their contents of carbon and nitrogen, or of muscle-forming and heat-producing substances; but that he pays a higher price for meat because meat contains certain other substances which are totally wanting in other articles of food, and it is these very substances which form the component parts of beef-tea as well as of extract of meat.

These substances, as is well known, impart to meat its peculiar value for nutrition, and constitute the difference between vegetable and animal diet. The difference between the two, therefore, is not based on the dissimilar nature and facility of assimilation of the albuminates contained in the animal and vegetable food, but consists in the fact that meat contains certain elements which are not to be found in cheese, in blood or in vegetables.

I believe that the researches of Pettenkofer and Voit are calculated to throw some light on the effects of the component parts of extract of meat. In their experiment on the tissue waste of a man in normal condition while abstaining from food, the individual breathing in the apparatus of respiration was left in three instances without food with the exception of water, salt (15 grm.) and a little extract of meat (12½ grm., rather less than half an ounce), and with respect to the results obtained the two experimentalists say, "The state of health during the privation of food for thirty-six hours was a completely normal one, and according to the assurance of the fasting man, he could have borne it longer." This fact explains, I believe, the physiological importance of the soluble parts of meat or extract of meat; they do not serve for the renovation of the machine, but they maintain it by their effects on the nerves during temporary disturbances, even when deprived of food, in normal action, and it cannot be doubted that it is this effect which is paid for by the higher price of meat.

London navvies who were sent out during the Crimean war to construct the railway at Balaclava, and who, according to the report of Dr. Baudin, created the greatest astonishment among the English and French soldiers by the extraordinary amount of work they performed, consumed daily in their food from 150 to 159 grm. albuminate.

The agricultural labourer in Upper Bavaria consumes in his farinaceous food, according to the experience and calculations of Professor Dr. H. Ranke, 153 grm., therefore almost the same quantity of albuminates as the English navvy; but how extremely different are the working capabilities of the English and Bavarian labourer in reference to the energy of work, *i.e.*, the amount of work accomplished within a given time? and this difference is attained by the English navvy consuming more than one half of the albuminates in the shape of meat, whilst the Bavarian eats meat only on six days of the year. A few slices of bread and butter with milk at breakfast give nutriment enough for a child; an adult, however, has very different work to perform, and he therefore increases the effect of his food by a cup of tea or coffee. It is stated in Frankfort-on-Maine as a well-known fact that old Mayer Anselm Rothschild, the founder of the eminent firm, never despatched any important business at night without having previously taken a cup of strong black coffee; and it may be supposed that the celebrated financier derived some advantage from the effect of the coffee on his decisions, for he was not the man to spend a farthing for anything which would not have given him a return.

When the meat by boiling has been freed from its soluble parts, the remainder, or more correctly the albuminates in such residue, have no greater nutritive value than the gluten of wheaten flour, which remains after the manufacture of starch. Both the meat albuminates and the gluten are chemically and in their physiological effect identical things.

If to meat exhausted in this way, the extracted parts are again added in the shape of beef-tea or extract of meat, it is eagerly eaten by dogs who despise it without such addition; in fact, all the component parts of meat which are contained in roast meat are thereby reunited.

Now, as vegetable albuminates are identical with albuminates contained in the flesh of animals, it will be easily perceived that if we add to our vegetable food, rich in vegetable albuminates—for instance to bread, peas, beans, or even potatoes and rice,—the soluble parts of meat such as are combined in extract of meat, we thereby impart to it the peculiar nutritive value which distinguishes meat in our estimation from other food.

Dr. Gerhard Rohlfs, well known by his travels in Morocco, says, in reference to the effect of extract of meat in a letter addressed to me:—"As regards extract of meat it has proved, particularly to us travellers in Africa, one of the greatest blessings. On my travels through the great desert from Tripolis to the Ischad Lake, it was my daily food. Being without any meat I took it in the morning spread upon biscuits, and this was not only very palatable but it proved a complete substitute for meat diet. In the evening I made beef-tea, adding a good portion to rice, lentils, or kuskuss, or whatever I happened to possess in the shape of vegetables. I have become so accustomed to the extract of meat that I am still obliged to keep it constantly in my house."

It will be well understood, therefore, that by the addition of extract of meat to our food, we neither economize carbon for the maintenance of the temperature nor nitrogen for the sustenance of the organs of our body, and that therefore it cannot be called "food in the ordinary sense," but we thereby increase the working capabilities of the body and its capacity to resist exterior injurious disturbances, *i.e.*, to maintain health under unfavourable circumstances. Thus an addition of extract of meat to vegetable food forms the only means to make up for a want of meat.

All this taken together gives to these substances, to which also belong tea and coffee, a very high value in the alimentation of our populations, the last and true object of which is the production of working power for mental and bodily work; and it becomes perfectly intelligible why the great historian Macaulay, in his celebrated work, very properly devoted an entire chapter to the introduction of coffee into England as being to some extent connected with modern life.

For our object it is tolerably indifferent with what name the effect of the so-called "Nervous stimulants" is designated.

A few years since agriculturists still considered gypsum, lime, and bone meal to be stimulants for the growth of plants; now we know perfectly well that they are nutritive substances for plants. In modern life men on the whole perform more muscular and brain work than formerly; still the average duration of life of individuals has not decreased but increased, and nobody who takes a comprehensive survey of life can doubt that coffee and tea contribute largely to this end, and that extract of meat properly used is a really good and most useful thing.

In conclusion, it may be mentioned that I have given my ideas on this subject in two treatises, both of which appeared in English scientific journals; the one "On the Nutritive Value of Different Sorts of Food," in the *Lancet* (January, February, and March, 1869), the other in the London PHARMACEUTICAL JOURNAL ("The Source of Muscular Power"—September and October, 1870), and I think that no English physician wishing to criticize my opinions should be allowed to ignore these two treatises of mine.

One word more about Dr. Edward Smith. It is a pity that he thinks himself competent to give his opinion on questions of which he cannot be said to have a perfect knowledge. This becomes evident as soon as he touches on chemical subjects. For instance, in a letter to the *Standard* (October 24th, 1872) Dr. Edward Smith declares that beef-tea made of fresh soup meat would certainly contain albumen, etc., and he charges me with "hardihood" for comparing extract of meat with such beef-tea. Dr. E. Smith apparently forgets that the soluble albumen of meat is coagulated by boiling it with water, exactly in the same way as the albumen of eggs, and that, therefore, beef-tea cannot contain albumen any more than extract of meat. Both extract of meat and beef-tea are prepared from the same material exactly in the same manner, and the difference of the former from beef-tea consists simply in extract of meat being beef-tea condensed to the consistency of honey.

ORIENTAL ACONITE.

BY M. C. COOKE, M.A.

Dr. Hooker has expressed his opinion ('Flora Indica') that the "Bish" of the Himalayas is the produce of four species of *Aconitum* respectively.

ACONITUM LURIDUM, *Hook. and Thom.*, found in Alpine East Himalaya at an elevation of 14,000 feet.

ACONITUM PALMATUM, *Don.*, inhabiting the Temperate Himalaya from Sikkim to Garwhal, at an altitude from 8000 to 10,000 feet.

ACONITUM FEROX, *Wall.*, in the Temperate sub-Alpine Himalaya, from Sikkim to Garwhal, at an elevation of from 10,000 to 14,000 feet.

ACONITUM NAPELLUS, *Linn.*, in Temperate Alpine Himalaya, from 10,000 feet to the highest limit of vegetation in the North Western Provinces.

Such being the case, it would be satisfactory if the varieties of "Bish" could be traced to the plants producing them; but on this point the same author adds:—"We have not detected any characters by which the dried roots of these species can be specifically recognized, nor do we believe that any such exist." It is very clear that some samples of "Bish" are very distinct in appearance and texture from others. The question arises whether this is determined by the mode or period of collection, method of drying, or distinctive features of the species or variety of plant. The latter seems to be most probable. There is a confusion of species most probably, and of native names, in the drug as found in the Bazaars. Moodeen Sheriff, in the Supplement to the Pharmacopœia of India gives all the native names under the head of *Aconitum ferox*, of which the Arabic is *Bish*, and the Persian *Bishnag*, whilst in

Hindustani *Bis*, *Singya*, *Singya-bis*, *Mitha-zahar*, *Teliya-bis*, and *Bachhnag* are given to varieties of the same plant; *Navi* and *Vasha-navi* being the Tamul, and *Vasanabhi* and *Nabhi* the Telugu names. *Bish* is also the Bengali, *Vachhnag* the Gujerate, and *Vachanabhi* the Cinghalese names. The same work mentions four varieties of Bish, two of which are named *black* and *white* according to the colour of their substance internally.

1. *Kala-bachnag* (*Black Bish*). "The black variety is generally of a reddish-brown colour, and is considered by native practitioners and druggists to be more virulent than the other." This is the whole description which Moodeen Sheriff gives of this variety.

2. *Sufed-bachnag* (*White Bish*) is not described at all.

3. *Mitha-zahar* (sweet poison). This name is usually applied to "a root an inch or an inch and a half in length, and its circumference at the base about the same; it is tapering, slightly compressed, and very rough from wrinkles; brown externally, and pale brown internally; slightly but distinctly sweet in taste, and produces a kind of tingling or peculiar sensation on the tongue when chewed."

4. *Singya-bis* (*Horny Bish*) or *Teliya-bis*, "looks like a small horn of a deer or goat, being very hard, smooth and tapering; and of a dark brown colour. It is generally longer than the sweet variety, but seldom more in thickness; and the colour of its substance is dark brown, shining when recently broken. On chewing a very small bit of it, there is a feeling of great acridity on the tongue and lips, which is followed by a kind of numbness or altered sensation." Of these varieties the *Singya-bis* is considered the strongest of all, and *Mitha-zahar* the weakest.

Dr. Buchanan, in his 'Account of the Kingdom of Nepaul,' names four kinds of *Bish*, of which the *Singya-bikh* is one, and is referred by him to a species of *Smilax*. In the absence of specimens and detailed information, it would be fruitless attempting to determine the sources of the varied drugs bearing the name of *Nirbisi* or "*Buchnag*" in different parts of India.

The officinal drug is described in the Pharmacopœia of India as follows:—"It occurs in the form of tuberous roots of a more or less conical form, from two to three inches in length, and from half an inch to one inch in thickness at their upper end. They have usually a shrunken appearance, and are covered with a dark shrivelled bark; fracture shining and resinous, sometimes waxy, varying in colour from pale to deep brown. Some specimens are white and spongy, and these, it is asserted, are superior in activity to the more compact kinds. Inodorous; taste at first slightly bitter, leaving a peculiar sense of numbness on the tongue and fauces." In Baden Powell's 'Punjab Products' *Bish* is described as a dark brown wrinkled conical root, with either a black or white centre, very brittle, containing much starch, Taste, irritating and acrid, causing a persistent tingling sensation; a virulent acronarcotic poison, containing from 50 to 90 grains of aconitine in a pound. It produces tingling and numbness, debility and contraction of the pupil. Used by natives and Europeans in rheumatism and neuralgia, but seldom given internally; by the latter also employed in tetanus, rheumatism, gout, and heart disease, also leprosy, and cholera fever. Dr. O'Shaughnessy observes that the roots (which enter into several formulæ constantly employed by the native practitioners, and which are also doubtless too often used as convenient instruments of poisoning) are sold in every bazaar in India, and may be purchased in large quantities for about 10 annas the seer. A preparation of the root is much used in all the hilly districts in India to poison arrows for the destruction of wild beasts. "We seldom, however, obtain the root sufficiently fresh in the plains to produce such effects as would explain its alleged utility for this purpose. It has been used on several occasions to poison wells and tanks, and doubtless might be made a formidable means of defence against the invasion of the territories in which it abounds."

Captain Lowther, writing from Assam in 1859, with a specimen of the 'Bikh' or aconite poison, observes that "of twenty-five wounded Europeans only four died, one of these in half an hour. Fortunately for humanity the Digarroo tribes are the sole producers of this virulent drug, and they are chiefly peaceable traders. It is almost solely to the rascality of our subjects that the hostile tribes are now indebted for their comparatively small, and hence adulterated, supply of this root, which, under the present system of frontier trade, finds its way down into the shops of the covetous Hindostanee Bunneahs, and thence oozes out in the transactions for rice and boats with the Mori nomades of the Dihong, and these in their turn purvey all they can get to the Abors. Fortunately, our enemies have to pay for their poison, and even then cannot obtain the genuine article, or our force would all be dead men. The great alpine region of the Digarroo country is described as abounding with the plant furnishing the Bish. Last cold season I was out with a Digarroo hunting party; one of the men stalked a large female sambur deer feeding on the grass; he made a bad shot, merely ripping up the skin on her side, and off she bounded, followed by the active savage, who caught her up in her death struggles a few hundred yards. I am told that the method of preparing the drug is as follows:—Bruise the root on a flat stone, gradually grinding it into a mass with the fresh juice of the fruit of *Dillenia speciosa;* while in this moist state it is to be kneaded to the required size of the wood of the arrow to be poisoned, a few deep notches being first cut just below the junction of the metal that the weapon may break off into the wound. The 'Singpho' people slay their elephants and rhinoceroses after this fashion —the hunter patiently tracking them till they drop, and which sometimes occupies many hours.

"The Kamptees tell me they employ saltpetre both externally and internally in case of wounds so poisoned, with success; others profess to heal with seeds or barks of the jungles, and which I have seen administered to a wounded man without saving his life. However small and superficial the said arrow wounds, even those made with pointed bamboos, the pain is described as horrible, and the appearance is invariably highly inflamed and attended with suppuration. Dysentery too is a usual feature, and concomitant of these venomous applications, and which seem to affect the native less than the European system, to judge by the rapid recovery of the former under medical treatment. Dr. White of the Naval Brigade was eminently successful in his treatment of wounded soldiers. It ought to be known that he sucked all the wounds himself like a veritable leech of the olden time, and made the caste gentry of the native force stare in astonishment at this novel application of the sacred organ."*

In this instance of an important drug involved in mystery, we see the necessity for some official medium through which to prosecute inquiry. Individual effort is insufficient, and the only effectual mode would emanate from the Government of India, to ascertain the areas and statistics of production of the different aconite roots in the Himalayas, their value commercially on the spot, the native names applied to the different kinds, and the plants producing them properly and satisfactorily identified. Then, as a consequence, the different varieties will be analysed and the value of each determined according to the amount of alkaloid present. This is but one out of scores, perhaps hundreds, of instances, in which information is required, of a special character, on the products of our vast Indian empire, and which no private effort is capable of obtaining.

The Chinese species of aconite, allied to those of the Himalayas, are enumerated by Dr. Porter Smith as *Aconitum sinense, Aconitum variegatum*, and one or more other species known as *Ts'au-wu-t'u*, and *Tuh-peh-t'sau*. The first named (*A. sinense*) are top-shaped, conical, tuberous roots, tapering down to a point, from one inch and a quarter to one inch and a half in length, and rather more than half an inch in thickness, according to the size and number of the dried rootlets which project irregularly from the surface. The external cuticle is irregularly rough and hard, and of a brownish-black colour, whilst the interior mealy structure is firm and of a dirty-white colour. The taste is bitter, acrid, and benumbing. Highly poisonous and scarcely used.

The *Ts'au-wu-t'u* may be *Aconitum ferox*, but of this there is no certainty. They are probably the mixed roots of several species of *Aconitum*, of a very poisonous character from Kiangnan and Chekiang, and were formerly used to poison arrows for military and hunting purposes. "The specimens vary a good deal, being sometimes ovoid, oblong, and tapering to a point, or bifid, or even rounded at the extremities. They vary from three quarters of an inch to one inch and a half in length, are covered with a smoothish or wrinkled dark cuticle, and are very frequently worm-eaten. Internally they are whitish and starchy, have very little, if any, odour, but the taste is very acrid and benumbing. Liautung is said to yield the plant, from which a very powerful sun-dried extract is said to be prepared."†

Tuh-peh-t'sau is a species of aconite from a country west of China, where a kind of arrow-poison is said to be prepared therefrom.

ACTION OF BORAX ON FERMENTS OF THE DIASTASE GROUP.

BY M. DUMAS.‡

In a note recently presented to the French Academy, M. Dumas communicated the following interesting information relative to the action of borax upon the ferments of the diastase group:—

Solution of borax coagulates beer-yeast, and the supernatant liquor does not invert cane-sugar as yeast-water does. It dissolves albuminoid membranes; those, for example, which separate from white of egg when suspended in water.

Solution of borax neutralizes the action of yeast-water upon cane-sugar. If solutions of sugar and yeast be placed together in one tube, and solutions of sugar, yeast, and borax in another, the first will quickly give signs of inversion; the second will not.

Borax also neutralizes the action of synaptase. It is known that the bitter almond contains amygdalin, and the sweet almond the synaptase, which, mixed with the amygdalin, produces the essence of bitter almonds, accompanied by prussic acid. It suffices to suspend the meal of sweet almonds in the one instance in pure water, and in the other in a solution of borax, and to add amygdalin to both liquids, to demonstrate this influence. With pure water, the odour of essence of bitter almonds becomes increasingly manifest, and the presence of prussic acid becomes more and more evident by the formation of prussian blue. With the solution of borax, neither is the odour of essence of bitter almonds perceptible nor the formation of prussian blue.

Borax neutralizes the action of diastase. If four tubes containing water and potato starch be kept at 70° C., the first without addition, the second with the addition of borax, the third with the addition of diastase, the fourth with the addition of both diastase and borax, it will be found that after several hours there will be no glucose present in the first and second; after the first quarter of an hour there will be a considerable and increasing quantity in the third; in the fourth, where the borax and diastase are both present, the conversion of the starch into glucose does not take place.

Malt suspended in water quickly yields an abundance of glucose if heated to 70° C., but the addition of borax arrests this action. With malt, water and borax, traces only of glucose are observed, which are probably due to its pre-existence in the malt.

Borax interferes also with the action of myrosin. Flour of black mustard suspended in water, exhales almost immediately the odour of essence of mustard, which increases in strength. Suspended in solution of borax, the odour characteristic of mustard meal is perceptible, which is due to the presence of a trace of the essence already formed; but this does not augment, and there is nothing that recalls the known effects of water upon mustard, and the plentiful production of irritating vapours to which it gives rise.

So that borax, by a property as remarkable as unsuspected, neutralizes the action of yeast, synaptase, diastase and myrosin. M. Dumas promises to make known its effects upon pepsin, and the bearings these curious reactions have upon the theory of ferments.

THE MORE IMPORTANT SUBSTITUTES FOR GUNPOWDER.

BY F. A. ABEL, F.R.S.*

No progress has been made since 1868 in the application of explosive agents, other than gunpowder, to artillery purposes. Somewhat limited experiments with gun-cotton in small field guns led the Austrians, about ten years ago, to the erroneous conclusion that they had conquered the difficulties attending the safe employment of gun-cotton, applied according to Van Lenk's system, in guns of small calibre at least. Considerable progress was made in England during 1867–68 towards the production of a thoroughly safe cartridge of compressed gun-cotton for field guns, but much evidently still remained to be done when the experiments were suspended before a sufficiently uniform action of such a cartridge

* Journal Agri. Hort. Society of India (1860), vol. xi. part 2, p. i.

† Dr. Porter Smith's 'Chinese Materia Medica.' 1871.

‡ 'Comptes Rendus,' vol. lxxiv.

* Read at the Royal Institution of Great Britain, on Friday, May 17th, 1872.

would be secured. The difficulties which have since been encountered in moderating and regulating the explosive force of gunpowder when employed in the large charges which have now to be used in heavy guns show how remote is the prospect of successfully applying explosive agents more rapid and violent in their action than gunpowder to artillery, with the exception perhaps of the smallest calibres.

The numerous attempts to apply substitutes for gunpowder in small arms have in some instances been attended with partial success. Many of these have differed greatly from each other, but all of them have been more rapidly explosive and therefore more violent and destructive in their action than powder. Gun-cotton in one form or another has been repeatedly made the subject of patient experiment as a material for use in small arms. The first attempts at its employment, made soon after its discovery in 1846, were disastrous in their results, and the success which long afterwards was believed to have been achieved, by Von Lenk's indefatigable labours, in the production of a safe and uniform cartridge, ingeniously constructed of layers of braided gun-cotton threads, was not confirmed by experience. Several methods of reducing the rapidity and increasing the uniformity of action of gun-cotton in small arms have since been made the subject of experiment in England. Some of these, which consisted in the uniform dilution of gun-cotton either with ordinary cotton or with less explosive varieties of the material, have furnished fairly-efficient cartridges for sporting purposes, which, though wanting much in uniformity, have established for themselves a superiority over gunpowder in regard to freedom from smoke and fouling, and one or two other qualities. But the only direction in which substantial prospect of success has hitherto attended the use of gun-cotton cartridges in arms of precision has been the conversion of gun-cotton pulp by moderate compression into very uniform masses, the rapidity and violence of explosion of which were retarded by impregnating these throughout with some perfectly inert material, thus enveloping each particle of gun-cotton in a film of non-explosive substance. The experiments upon this system of preparing cartridges have not been pursued for the last four years, but some very good targets at 500 yards were made with the service Enfield and Snider arms in 1867 and 1868, with cartridges of gun-cotton impregnated with small quantities of paraffin or stearin. India-rubber has also been employed in a similar manner as a retarding, and, at the same time, water-repelling agent. Considerable success has recently attended repeated trials with a species of gunpowder devised by Mr. Punshon, in which the principle of dilution of gun-cotton is also adopted, this explosive being incorporated with sugar and saltpetre. A preparation of somewhat similar nature, containing as one component an imperfect kind of gun-cotton made from sawdust, and known as Schultze's powder, has also acquired some reputation, though scarcely bidding fair to compete in uniformity of action with the excellent gunpowder now manufactured for breech-loading rifles.

The application of powerful explosive agents in shells would appear at first sight to present little difficulty, beyond that involved in the selection of a material which presents a decided advantage in point of disruptive power over gunpowder, without exerting an excessive disintegrating action upon the mass of the shell, and thereby effecting its comparatively harmless dispersion. An important obstacle to the employment of many of the more powerful explosive agents as charges for shells exists in their liability to premature explosion by the concussion which the shell has to sustain upon the discharge of the gun. Attempts to employ gun-cotton in shells have several times been attended by such premature explosions, more or less disastrous to the guns used. In comparing the relative sensitiveness to explosion by a blow or concussion of different compounds and mixtures, their submission, under precisely similar conditions, to the blow of a weight falling from measured heights has furnished satisfactory results, and by pursuing this line of experiment, very useful data have been obtained. The conditions which are variable in such experiments require, however, very careful regulation, as the results attained may be modified to almost any extent by variations of such elements as the area of the surface of material struck, the thickness of the mass, its mechanical condition (whether in coarse or fine powder, or in a rigid or plastic mass), the nature of the materials composing the weight and the anvil or support. Thus, a layer of mealed powder 0·05 inch thick placed between two flat brass plates one inch square is exploded by the blow of a 50-lb. weight falling from a minimum height of 36 feet, while a layer of the same thickness placed between brass plates like the preceding, but 0·5 inch square, is exploded by a fall of the 50 lb. from a height of about 9 feet. Small flat charges of fine-grain powder weighing five grains, enclosed in tin-foil and placed upon a steel support, were always exploded, in ten successive experiments, by the fall of a steel 25-lb. weight from a height of 2 feet; when a brass support was substituted for that of steel, only four charges out of ten were exploded; when both weight and support were of brass, only two out of ten were fired, and when the support and weight were of lead or wood, no explosion was obtained even when the weight fell from a height of 40 feet. Again, a nitro-glycerine preparation, of which a layer of a particular thickness, placed between brass plates resting on a solid block of iron, was exploded by a fall of a 50-lb weight from a height of 2 feet, was not exploded by a fall of 40 feet, when the lower brass plate was fixed upon a wooden block, the upper plate being attached to the weight by means of a small block of wood.

Of the many explosive preparations more violent than gunpowder which have been submitted to comparative experiments of the above nature, a mixture of ammonium picrate with saltpetre proved the least sensitive to explosion by blow, thus contrasting remarkably with the violently explosive mixtures of potassium picrate, which have been made the subject of experiment in France. Picric acid, which is now manufactured extensively for tinctorial purposes by the action of nitric acid upon phenol or carbolic acid, has been known since the end of last century as capable of furnishing explosive mixtures. Some of its salts, such as those of potassium and barium, are of themselves explosive, and furnish violently detonating mixtures with saltpetre and potassium chlorate. The mixtures of ammonium picrate with these salts, though less powerful in their action, are considerably more so than gunpowder, and the saltpetre mixture which has been called *picric powder*, has been shown by extensive experiments to be as safe as powder in manufacture and use, and as permanent in character; shells charged with it have been repeatedly fired from guns of large calibre, with heavy powder-charges, and there appears strong reason for placing confidence in this material as fulfilling the conditions, in regard to safety and power, of a very efficient powder for shells.

Most important progress has been made, during the last few years, in the application of explosive agents, more violent than powder, to mining and quarrying, and to various civil and military engineering purposes. The hope of realizing the advantages which would be secured, especially in point of economy in time and labour, by an explosive agent combining increased power with other essential qualities of a practically useful material, has led to the production of a great variety of preparations designed to serve as powder-substitutes in its industrial applications. The powerful oxidizing agent potassium chlorate has thus been applied in numerous ways; and some of its preparations, of comparatively safe nature, such as Horsley's and Ehrhardt's powders, have afforded prospect of advantageous employment, though at present it appears doubtful whether they can enter into competition with the more violent explosive agents which have within the last six years become formidable rivals of powder.

Gun-cotton was gradually growing into extensive use, as a mining agent in England, within a year of its discovery by Schönbein; but its application was arrested for many years by the explosion which occurred at Messrs. Hall's works in 1847. Between that period and 1863, when its manufacture was resumed in England, the material was made the subject of elaborate experiment in Austria. Important improvements were eventually introduced in its production and purification by Baron von Lenk, and it was converted by him into a form decidedly better adapted for mining purposes than the gun-cotton wool, namely, that of a compact rope, having a central perforation, and cut into suitable lengths for mining charges. An extensive series of experiments, instituted in Austria with gun-cotton in this form, appeared satisfactorily to establish its superiority over gunpowder, bulk for bulk, as regards rending and shattering effects, when used in hard rock or when confined in strong cases. The absence of smoke, and the considerable reduction in weight of the charge required to produce a particular result were also important advantages, substantiated by the experiments of Sir Edward Sabine's Committee on Gun-cotton, and by the results of practical trials in this country. The benefits, in point of economy and efficiency, derived from the employment of the rope-charges, were very greatly increased when the system was devised of reducing the gun-cotton fibre to pulp, and converting it by powerful compression into compact homogeneous masses, having about double the density of the rope. Important consequences of the large reduction in the space occupied by gun-cotton, when used in this form, were the very considerable increase in the amount of tamping which could be used in blast-holes, and the greater concentration of the force applied; the destructive effects in hard rock were consequently much augmented, and the blast-holes could be placed further apart, and reduced in dimensions. Large charges of compressed gun-cotton occupied so much less space than the rope-charges, and were so considerably lighter than powder-charges, that the material became specially valuable for submarine operations. Other peculiar advantages were presented by the compressed material; thus, its cost of production was greatly reduced, because cotton-waste could be employed in its manufacture, and because its conversion into the required forms required comparatively little time; its purification was more complete, as the finely-divided fibre was much more readily washed than the long fibre required for furnishing rope-charges; and its uniformity was much greater, because the products of a large number of successive small operations were intimately blended together in the pulping and washing processes.

One point of inferiority, exhibited by gun-cotton in the form of wool or rope, was not at first remedied, but rather increased by its conversion into compressed masses. This consisted in the necessity for very strong confinement of the material, for the proper development of its explosive force. If used just like gunpowder, in rock which was soft or contained fissures, its destructive effects were very imperfect, and under these circumstances very irritating and unwholesome vapours were produced by its ignition. Large charges used in military operations or for the removal of great masses of rock required to be confined in very strong receptacles. Hence, although the use of compressed gun-cotton in ordinary blasting and quarrying operations in hard rock soon began steadily to increase, and though its value for submarine operations was undoubted, it continued for some time to be uncertain in its effects when employed in a particular class of mining operations and when used for military engineering purposes. After it was found, however, that compressed gun-cotton could be exploded through the agency of detonation, the metamorphosis being thereby so rapidly transmitted throughout a mass as to render any confinement unnecessary, its application became extended to new and important purposes, and it became closely allied, in regard to the results which it furnished, to the companion explosive agent, nitro-glycerine, which has been raised within the last nine years from the obscure position of a useless chemical product to an exalted rank among practically useful explosive agents entirely through the labours of Mr. Alfred Nobel.

In 1863 Mr. Nobel first attempted to apply nitro-glycerine by impregnating the grains of gunpowder with it, and igniting the mixture in the usual way. But this mode of proceeding being uncertain in its results, he concluded that the certainty of exploding nitro-glycerine would be increased if a small portion of the mass were raised by some special contrivance to the heat at which it would violently explode, the explosion being thereby transmitted through the entire mass. He suggested several devices for producing what he termed the initiative explosion of a portion of the charge, but the most simple and successful one consisted in the employment of a large percussion cap, by the explosion of which the adjacent particles of nitro-glycerine were suddenly exposed to a high temperature and to a sharp concussion. This was the first instance in which the violent explosion or detonation of compounds of this class, known not to explode violently unless strongly confined, was accomplished through the agency of initiative detonation. Compressed gun-cotton was soon afterwards observed by Mr. Brown to behave similarly, and in the course of an investigation instituted by Mr. Abel into these and other phenomena exhibited by explosive agents, this susceptibility to violent explosion, without the aid of confinement, through the agency of a detonation, was found to be shared by all explosive compounds and mixtures, even including gunpowder, though the force and nature of the detonation required to develope the explosive metamorphosis differed very considerably with different substances. Numerous interesting results were obtained which showed that the development of detonation was at any rate not simply due to the exposure of particles of the substance to a very high temperature or to the suddenness and violence of the concussion to which they were submitted.

Mr. Nobel's discovery of a simple method of exploding nitro-glycerine placed this substance at once at the head of practically useful explosive agents in point of power; and the success with which he developed the manufacture of nitro-glycerine soon rendered this remarkable liquid available for extensive technical uses. Its value as an explosive agent for mines, especially where very hard rock had to be operated upon, was speedily established in Sweden, Germany, and some other countries; but its extensive manufacture and employment was very soon followed by numerous fearful accidents, which appear mainly ascribable to the physical peculiarities of the substance. Its liquid nature, though valuable in special instances of its employment, constituted a serious obstacle to its safe transport, storage, and use; its liability to leak from receptacles in which it was stored and the great susceptibility to explosion, by friction or blow, of portions which escaped confinement, were unquestionably fruitful sources of accident. The precaution of storing and transporting nitro-glycerine in the form of a non-explosive solution in wood-spirit did not prove to be a trustworthy safeguard against accident, as the spirit was liable to evaporate or become weaker, and thus allow the nitro-glycerine to separate from it to a sufficient extent to re-establish danger.

A very simple expedient, which Nobel devised in 1867, soon enabled him to provide the miner with nitro-glycerine in a very convenient and comparatively safe form. The observation that this substance could be exploded by detonation as readily (and even with greater certainty) if mixed with solid substances, which might be perfectly inert in character, as when used in the liquid form, led him to the production of solid but plastic preparations of this substance, to which he gave the name of *dynamite*. The earliest of these supplied to the public, and the one which, in its present improved form, is superior to any other known nitro-glycerine preparation in point of safety in storage, consists of 75 parts of nitro-glycerine held absorbed by 25 parts of a porous infusorial silicious earth, existing abundantly in Germany, and known as "Kieselguhr." This mixture was first supplied as a loose unctuous powder, from which the nitroglycerine appeared to have a tendency to separate; it is now converted by pressure into small cylindrical rolls or charges wrapped in parchment paper, from which, as far as the lecturer's observation goes, the liquid does not appear liable to exude, even upon prolonged exposure to elevated temperatures, though immersion in water will cause a separation of nitro-glycerine after some time. Many experiments were made in Paris during the siege, by MM. Girard, Millon, and Vogt, to ascertain what absorbent materials could be best applied to the manufacture of dynamite, in the absence of Kieselguhr; precipitated silica or aluminia, sugar, and several other substances were found to be suitable media, but the material originally selected by Nobel was undoubtedly superior to all in its power of absorbing and retaining a very large amount of nitro-glycerine.

The preparation of dynamite by Nobel was speedily followed by the production of other nitro-glycerine preparations, in some of which, such as Dualine, Horsley's mining powder, and Glyoxiline, explosive substances are used as the media for absorbing nitro-glycerine. Nobel himself prepares a less violent form of dynamite by mixing nitro-glycerine in smaller proportions with powder, saltpetre, and resin or coal. A preparation which is perhaps intermediate in value between this and the "Kieselguhr" dynamite is manufactured by Messrs. Krebs, of Cologne, who have called it *Lithofracteur*. As far as its composition has been made public, it is known to contain less nitro-glycerine than Nobel's ordinary dynamite; the absorbent material includes silicious earth and sand, saltpetre, coal, and sulphur. Some good practical experiments, made with this preparation at the Nantmawr and Breidden quarries, near Shrewsbury, satisfactorily demonstrated its safety in transport and use, when in its normal condition. In this, as in all other nitro-glycerine preparations containing solid materials of inferior absorbent power to Kieselguhr, freedom from liability to a partial separation of the liquid can obviously be only secured at the sacrifice of explosive power, by reducing the proportion of the nitro-glycerine, and it is difficult to conceive that the consequent loss in power can be compensated for by introducing solid explosive materials less violent in their action than nitro-glycerine as components of the preparation.

Nobel's dynamite, though obviously inferior to the pure nitro-glycerine in explosive power, weight for weight, is still one of the most violent explosive agents now in practical use. In regard to power, it seems to be on an equality with compressed gun-cotton, and the results of experience in mines and quarries appear to warrant the conclusion that in the class of work where these agents can be applied to the greatest advantage, their power is about six times that of blasting powder.

The advantages in point of saving of time and labour attained by the use of these violent explosive agents in tunnelling and other operations in hard rock are very important; they are also specially valuable in submarine operations, in the breaking up of large masses of rock or of large castings and forgings, in the rapid destruction of military works, bridges, and other structures, the clearing of forests, the removal of ice obstructions, etc. Their special value is partly due to the comparatively small weight and bulk of the charges of gun-cotton or nitro-glycerine preparations required to perform the work (which in many instances could scarcely be accomplished, even by extremely large quantities of gunpowder), and partly from the facility and expedition with which these explosives can be brought into operation through the agency of detonation. Hard tamping or strong confinement is superfluous, and in many instances operations of demolition and disintegration may be effectually carried out, though with some waste of power, without any confinement whatever of the explosive agent.

Dynamite and similar nitro-glycerine preparations possess two defects in common. One arises out of the poisonous nature of the liquid, which is readily absorbed into the system, producing severe headaches and other unpleasant effects, which, however, are said to diminish in severity and even to disappear by continued use of the material. Experience has scarcely been yet acquired regarding the ultimate influence upon the life of those constantly engaged in manufacturing nitro-glycerine or using its preparations. The form in which dynamite is now furnished appears to reduce to a minimum the liability of those employing it to be injuriously affected. The other defect arises out of the readiness with which nitro-glycerine freezes at a comparatively high temperature, especially when mixed with solid substances. The occurrence of several very serious accidents during manipulations with frozen nitro-glycerine, and the fact that the sensitiveness of a substance to explosion by a blow is in direct proportion to the rigidity of its particles, favoured the conclusion that nitro-glycerine was specially dangerous when frozen; there is, however, no doubt that the substance is very much less sensitive to explosion by blow or concussion in that state—a fact which must be due to the greater expenditure of heat requisite for conversion of the solid than of the liquid into gas. The accidents with frozen nitro-glycerine and its preparations appear to have arisen from reckless handling in consequence of over-confidence in the safety of the material, and also from want of care or ignorance in carrying out the necessary operation of thawing the explosive agent before applying it in the usual manner. The necessity for thawing dynamite and similar preparations, which remain frozen even at 50° Fah., is a serious inconvenience, which further experiment in the use and properties of these materials may perhaps set aside.

Plastic preparations of nitro-glycerine possess some advantages over compressed gun-cotton in several ordinary blasting operations. The application of a little pressure after the charge has been inserted will cause it to spread out and fill up any inequalities in the hole, and thus a larger charge may in some instances be employed than if the rigid cylinders of compressed gun-cotton were used; the latter are also liable to become jammed or fixed when they are being pushed down a rugged or irregularly-shaped hole; if the miner then proceeds to force the charge home by powerful blows, which, with reckless confidence engendered by the general safety of the material, he not unfrequently will, it may become ignited and must explode violently if force is being applied at the instant of its ignition, as it is then in the position of a strongly-confined charge. Accidents in the charging of holes are obviously less likely to occur with plastic materials. Dynamite has the additional advantage of being readily applicable in blast-holes from which water cannot be excluded, as the material resists penetration by water for a considerable period. To counterbalance these advantages, gun-cotton is perfectly innocuous, and its ready explosibility by detonation is not in any way affected by cold. When carried into the field for military purposes, compressed gun-cotton is very decidedly safer than nitro-glycerine preparations; because if carts or packages containing the latter are fired into from accident or design with ordinary small-arm bullets, their contents will be violently exploded as by detonation, while the gun-cotton under the same circumstances would be simply inflamed.

(*To be continued.*)

THE MANIOC, OR TAPIOCA PLANT.*

BY M. PAUL SAGOT.

Tapioca is obtained from the Manioc, or Cassava, a suffrutescent plant belonging to the Order Euphorbiaceæ, which has long been cultivated by the indigenous Indians of Guiana and intertropical America. It is the *Jatropha Manihot* of Linnæus, and the *Manihot utilissima* and *Manihot Aipi* of Pohl. By the Indians it is known under various names; the Caribs call it *Kière* and *canhim*; the Galibi, *Kie ray;* the Arrouagoue, *calôli.* In the Antilles, the Spanish colonies, New Granada, Peru, and Pará it is called *yuca;* in Brazil *mandiocca* and *maniba* and *aïpi* (sweet manioc); in Mexico it is called *tziim.* A great number of varieties have been observed under cultivation, each of them permanent, although sometimes closely resembling another variety, and each distinguished by some particular quality. Botanists have not yet met with any form of the cultivated manioc in a wild state; but in Brazil, Guiana and Venezuela many undoubtedly spontaneous species of the genus *Manihot* exist, and some of them resemble the cultivated varieties very closely. The province of Goyaz in Brazil produces the largest number of species, and amongst those offering the closest points of resemblance are *M. pusilla*, *M. flabellifolia*, *M. digitiformis* and *M. triphylla.* Pohl describes the sweet (non-poisonous) manihot (called *Aïpi* in Brazil, *M. Aïpi*, Pohl) as a distinct species from the poisonous manihot (*Yuca brava* or *Mandioca brava* of the Spanish and Portuguese colonies); but the author agrees with Goudot in thinking that they are only varieties of the same species.

The manioc or cassava plant is propagated by cuttings which grow with extreme facility. The plant appears at first as a straight stem, furnished with large digitate leaves, with about seven lobes. At the age of from six to ten months, and when from one to two metres high, it throws off from its summit lateral branches, with smaller leaves, and shortly afterwards bears flowers. The root then commences to develope several elongated amylaceous tubers, which continue to grow underground as long as the branches yield leaves and flowers. At the end of a year and a half or two years the roots are ready for collection; but if not wanted may be left in the ground for some time, provided they be watched that they do not rot. On the other hand, they may, if required, be gathered earlier, but the yield is not so good. The stalks, which are planted about a metre apart, usually produce two or three tubers, varying in size and weighing together from one to three kilograms. The plant is not very choice as to soil, but flourishes most in freshly cleared ground, and prefers well-drained spots, an excess of moisture causing it to rot. Although living for two or three years, the plant is not strictly a perennial, since it becomes gradually exhausted as the tubers attain their full size. The sweet manihot is usually gathered earlier, since the root becomes hard and bad if left to develope too much.

The yield of the manioc root, considering the time it occupies the ground, when compared with other farinaceous roots is not great; but on the other hand, it contains less water than any other starchy root;—when mature, less than sixty per cent. Its texture is very dense and compact. It contains much starch, and its richness in albumen and other nitrogenized matters is estimated at two per cent. In converting the roots into an edible flour, they are scraped, peeled, and then washed; next they are rasped upon a wooden plank armed with small iron teeth, and the pulp is left twenty-four hours, by which time a slight fermentation is set up. It is then placed in a long, flexible basket, called a *couleuvre*, usually made of plaited rushes. The *couleuvre* is suspended by a handle at its open end, and a heavy weight is attached to the other end, by which means the sides are compressed together, and a slightly opaline aqueous juice, which is highly poisonous, is caused to ooze through the plaits. The pressed meal is then taken out and exposed for some time over a fire; afterwards pounded, coarsely sifted and roasted on a brass plate over a fire to upwards of 100° C., care being taken by constant renewals to prevent scorching. Sometimes during the roasting it is stirred to and fro with a small rake of wood or metal; it is thus formed into small hard grains, having the appearance of semolina, which are called *couac.* When *cassava* is to be prepared, the meal is more carefully pounded and better sifted. It is then spread circularly upon the plate, pressed slightly with a pallet knife to cause it to aggregate and turned two or three times during the roasting. In both operations there is complete cooking and desiccation effected, which enables it to be kept an almost indefinite time. The aggregation of the meal is caused, not by the addition of water, but by the action of heat, softening and agglutinating some of the particles of starch.

M. Sagot considers the manioc to be healthy food, although of small nutritive value. Dr. Schier estimates it to contains 0·18 per cent. of nitrogen, but little phosphorus, and a very small quantity of fatty matter. The indigenous tribes, who make it the basis of their food, supplement it with a good quantity of fish and meat.

In the preparation of tapioca, the root is rasped and diluted with water, in which it is well worked up; the grosser parts are removed and the finer allowed to be deposited by subsidence in the water. In this form it is imported into this country in considerable quantities as Brazilian arrow-root. The tapioca is produced by roasting this starch on metal plates, stirring it the while with an iron rod; the starch grains burst, some of the starch is converted into dextrin, and the whole agglomerates into small irregular masses.

In Demerara, the manioc juice, deprived by boiling of its injurious properties, is used under the name of *cassareep*, as a sauce for the table. Besides this, the Indians use the root of the manioc to prepare fermented drinks, which, however, would hardly suit European tastes.

It is probable, M. Sagot thinks, that the poison present in the manioc is an instable organic compound, hurtful in itself, but especially dangerous from the fact that, under certain conditions, it will engender hydrocyanic acid. The leaves when bruised exhale a smell of bitter almonds, and the presence of prussic acid in the roots has been established. This he considers to explain the fact that while the manioc water, especially when distilled, is very poisonous, in Guiana and Brazil the Indians, after boiling it and removing the scum, use it as a beverage. Although wild animals, too, are sometimes poisoned through eating the leaves, sometimes they are not; this, he thinks, occurs when, a small quantity being eaten, the gastric juice exercises an energetic action before hydrocyanic acid can be developed.

The sweet cassava, or Camanioc, contains so small a quantity of acrid principles that the roots are cooked at a fire and eaten like potatoes. It is a rapid-growing variety, becoming ripe in five or six months, and in two or three months more the roots become hard and unfit to eat. The bark of the stalk is white, the petioles of the leaves are of a fine purple-red colour, and the luxuriant leaves at the foot of the stalk are 7-partite. The tubercles are long and of small diameter; when cooked in the ashes of a fire they are agreeable to the taste, sweet and of a fine consistence.

* Abstracted from a paper read before the Société Botanique de France, Dec. 18th, 1871 (Bull. de Soc. Bot. Fr. xviii. 341).

LACTO-PHOSPHATES.*

BY R. ROTHER.

Lactic acid abundantly dissolves many of the insoluble orthophosphates when freshly precipitated; among the most prominent of the resulting combinations are the so-called lacto-phosphates of calcium and iron.

When lactic acid is treated with an excess of either of these phosphates in the cold, a solution is obtained which still retains the acidulous taste of diluted lactic acid. If this solution is boiled, a copious granular precipitate occurs. However, if it be not heated and simply converted into a syrup by the addition of sugar, the saccharine solution, after the lapse of a few days, will deposit a voluminous white precipitate, or even completely gelatinize. The precipitates produced by heat or time are again readily and completely soluble in hydrochloric acid, producing then a permanent solution. The precipitation is also perfectly prevented if the saturated phosphate mixture is treated with an additional portion of lactic or hydrochloric acid before precipitation has begun. The supernatant liquid from which the phosphate precipitate has spontaneously separated apparently loses much of its acidity.

It is highly probable that the act of solution in the first instance is merely mechanical, and that the application of heat or a certain amount of time is required to determine a combination.

Nevertheless, the freshly precipitated phosphate is always taken up in a certain fixed proportion, and when the solution is thoroughly saturated with the phosphate, the resulting mixture invariably corresponds to one molecule of tricalcic-orthophosphate and four molecules of lactic acid, equal to one molecule of acid calcium phosphate and two molecules of normal calcium lactate, thus:—

$$(PO_4)_2Ca_3'' + 4\,(C_3H_6O_3) = (PO_4)_2Ca''\,H_4 + 2\,(C_3H_5O_3)_2Ca''.$$

On standing, actual combination, however, does take place, yet differing from the result indicated in the above equation. The phosphoric acid is then almost totally precipitated as the normal dicalcic orthophosphate ($(PO_4)Ca''H$) and the generation of acid calcium lactate, in solution, thus:—

$$(PO_4)_2Ca_3'' + 4\,(C_3H_6O_3) = 2\,(PO_4)Ca''\,H + (C_3H_5O_3)_2Ca''\,2\,C_3H_6O_3.$$

But, as above stated, an additional quantity of lactic acid ensures a stable product. This is effected by adding half as much more lactic acid as at first consumed, which then indicates a mixture of two molecules of free orthophosphoric acid, and three molecules of normal calcium lactate, thus:—

$$(PO_4)_2Ca_3'' + 6\,(C_3H_6O_3) = 2\,(PO_3H) + 3\,(C_3H_5O_3)_2Ca'' + 2\,OH_2.$$

The general process for permanent solutions of the so-called lacto-phosphates is then as follows:—Take any convenient quantity of concentrated lactic acid, and saturate two-thirds of it with any desirable orthophosphate, freshly precipitated, then add the remaining one-third of the acid, and if the preparation is to be a syrup, dissolve the sugar in the solution without heat, and strain.

In the preparation of syrup of calcium lactophosphate, the writer finds the officinal U.S. process the best method of obtaining the calcium phosphate, but the direction to wash the precipitate with boiling water must be faithfully ignored, as this produces the crystalline phosphate, which is insoluble in lactic acid. To obtain the gelatinous phosphate heat is not admissible.

The following is the process for permanent syrup of calcium lacto-phosphate:—

Take of either the precipitated calcium phosphate or calcined bones, about . . . . 6 drachms.
Lactic acid (concentrated) . . . $1\frac{1}{2}$ Troy ounces.
Sugar . . . . $10\frac{1}{2}$ Troy ounces.
Orange flower water . . . . . 2 fluid-ounces.
Hydrochloric acid, sp. gr. 1·16, one Troy ounce, or sufficient.
Ammonia water.
Water of each sufficient.

Mix the hydrochloric acid with one fluid-ounce of water, and add it to the powdered calcium phosphate previously mixed with four fluid-ounces of water; when the phosphate has dissolved, dilute the solution to twelve fluid-ounces, and precipitate it with an excess of ammonia, pour the magma upon a filter and wash it with cold water, add this washed magma to the lactic acid, and when dissolved dilute the solution after the addition of the orange flower water to $10\frac{1}{2}$ fluid-ounces, add the sugar to 9 fluid-ounces of this liquid, stir frequently, and after most of it has dissolved, pour the syrup through a muslin strainer, mix the undissolved sugar with the remaining liquid, and after solution add it to the rest of the syrup, through the strainer, and mix.

ADMINISTRATION OF ACETATE OF BARYTA IN THE PLACE OF SULPHOVINATE OF SODA.

A medical man at Verdun having last July prescribed a purgative consisting of 30 grams of sulphovinate of soda in q.s. of water, to be taken in three doses at half-hour intervals, a mixture was made up by a pharmacien, of which a third part was taken by the patient. Immediately afterwards the patient was seized with severe vomiting and other symptoms of poisoning. The medical man and the pharmacien were both summoned, and in order to reassure the patient as to the innocuousness of sulphovinate of soda, each drank a portion of the remaining mixture. The pharmacien, who had just eaten his dinner, was at once seized with vomiting, which caused the expulsion of the greater part of the liquid, but the medical man, although he had taken but 8 or 10 grams of the liquid, suffered from its effects for some months. The patient died twelve hours after taking the dose. At first it was thought the poisoning was due to a defective sample of the sulphovinate of soda, in the preparation of which it is known that great care is required to obtain it in a state of purity, and M. Duquesnel published a note on the subject. But M. Limousin reports that the mixture and the bottle containing the substance from which the mixture was prepared, having been sent for examination to the professors of the Paris School of Pharmacy, they discovered that the salt that had been employed was acetate of baryta, and not sulphovinate of soda. Upon further inquiry it was found that the wholesale druggist in labelling the bottles had labelled a bottle of sulphovinate of soda as acetate of baryta, and one of acetate of baryta as sulphovinate of soda.

M. Limousin considers this case instructive as showing that acetate of baryta, and possibly other salts of the same base, are more poisonous than is generally supposed. Referring to a method of preparing sulphovinate of soda, described at the last meeting of the Paris Société de Pharmacie, and printed at p. 536 of this Journal, in which the use of a baryta compound is avoided, M. Limousin states that in conjunction with M. Adrian he has tested it and that it appears to yield satisfactory results.

The Pharmaceutical Journal.

SATURDAY, JANUARY 18, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

VERMIN KILLERS.

WE have frequently had occasion, in replying to correspondents and otherwise, to point out how desirable it is that chemists and druggists, when dealing with "vermin killers" containing strychnine, arsenic and other poisonous ingredients, should comply with the conditions prescribed for regulating the sale of those poisons in the Pharmacy Act, 1868. This week we have to report two instances where these precautions have been neglected, and the result has been that in one the vendor has been prosecuted by the police authorities and fined, and in the other he has been sharply reprimanded by a coroner and threatened with further proceedings.

It appears useless to ignore the fact that the public is still desirous that the restriction attending the sale of poisons should in no way be relaxed so as to facilitate their purchase. We have on former occasions stated our opinion that in this desire there is nothing that should be looked upon as objectionable by the registered chemist and druggist, who is the only lawful seller of such poisons. For the work which is involved in providing the requisite safeguard is a need recognized by the public, and should not be performed without sufficient remuneration to prevent it becoming irksome. This seems to be the most fair and reasonable mode of dealing with the question.

But each of the cases mentioned illustrates an error, and these errors are prevalent amongst those in the trade who are too ready to look upon vermin killers and drugs generally as commodities to be dealt with after the same fashion as groceries or hardware. In the case at Cambridge the defendant pleaded that he had sold the vermin killer under the old law, and that vermin killers had been included for the first time in a new regulation which he had received the previous day. It is true that "Vermin Killers" were not included in the original Schedule A to the Pharmacy Act, 1868; but they were among the additions sanctioned by the Privy Council in December, 1869. In consequence of some doubt that existed as to which part of the schedule they were to be classed under, the Council of the Pharmaceutical Society, upon the report of a committee recommending the addition of some explanatory words, recently resolved that a copy of the revised regulations should be issued to every registered chemist and druggist, and it appears to have been one of these copies which the defendant looked upon as a new regulation, and to which he attributed his first knowledge that a vermin killer was a "poison!"

In the case at Wolverhampton, the druggist urged, in reply to the coroner's censure, that he did not know that "BATTLE'S Vermin Killer" contained strychnine. But, irrespective of this being a matter of common repute, surely in dealing with a substance prepared for the express purpose of destroying life, it is advisable that a man should have some idea as to what he is selling: and it is to the belief that the chemist and druggist is a man capable of acquiring and acting upon this knowledge that the willingness of the public to entrust the sale of such articles as vermin killers to registered chemists and druggists alone is to be attributed. We hope and believe that nothing will be wanting on their part to strengthen that confidence.

MEDICAL ELEGANCE.

DOES the *Lancet* represent the medical profession? This is a question which might be supposed to interest principally its subscribers; but in the light of recent circumstances it is one that may well be asked by those who have hitherto believed in the propriety of the phrase "gentlemen of the medical profession." For although the *Lancet* was never famed for being delicate in its choice of weapons when dealing with those who might fall under its displeasure, what gentleman can sympathize with the following paragraph, which is the summing up of a diatribe against dispensing chemists for their assumed exorbitant charges?

"The fact is, that retail trade has gone mad. There are far more shopkeepers than the wants of the public require, and they think themselves entitled to all the luxuries and enjoyments of life. Their wives, glorious in sealskin jackets and redundant jewellery, are to be seen everywhere; and the pretensions of the class are becoming a nuisance that it is high time to put down."

Is this another "sign of the times?" A short time since the *Lancet* favoured its readers with a singular argument that because the College of Physicians and the Apothecaries' Company had failed in their duty to regulate medical practice, the Pharmaceutical Society became responsible for the consequences of that failure. In a subsequent number it followed up this specimen of feminine logic by devoutly quoting, as if it were gospel, a rather foolish remark of an old lady of its acquaintance, with the object of proving that members of the Pharmaceutical Society were misled in claiming to be eligible as analysts. And now we have another instance of these feminine proclivities, but in a repulsive form that is seldom found far apart from the garrulity of dotage and the neighbourhood of Lower Thames Street.

THE CHEMISTS' BALL.

Those who in former years have been privileged to join the pleasant gathering known as the Chemists' Ball, will scarcely need reminding that Wednesday next is the day fixed for that of 1873. To them there can be offered no inducement stronger to accept the invitation of the stewards, than an assurance that—

"This festive fête, in fact, will be
The former fêtes' *fac-simile*."

Nor can it be doubted that the Ball at Willis's Rooms, on the 22nd, will be attended by many for the first time. For occasions like these will never lack patrons, affording, as they do, to gentlemen who pursue the same avocation, opportunities for friendly greeting and social enjoyment.

A few tickets still remain for disposal, and to prevent disappointment immediate application should be made for them, either to Mr. T. D. Watson, the Hon. Sec., 46, Halton Road, Canonbury Square, N., or to Mr. Richard Bremridge, 17, Bloomsbury Square, W.C.

"So prithee, come! our fête will be
But half a fête if wanting thee!"

THE PRIESTLEY MEMORIAL.

The discoverer of oxygen, the inventor of the pneumatic trough and of the artificial preparation of mineral waters is about to be honoured with a memorial. Birmingham, the city of his chief scientific triumphs, while Leeds was that of his birth, has taken the initiative, and Mr. Williams, the sculptor, has been commissioned to prepare a statue of the philosopher. Subscriptions are in course of collection for carrying out the movement, and already a considerable sum has been contributed. We trust that pharmacists will respond handsomely to the appeal of the promoters. Priestley has laid not only chemistry proper but pharmacy itself under deep obligations, while the example of his life—so rich in noble traits of character, not only as a *savant* and teacher, but as a vindicator of the catholicity of science and of the great principle of toleration—is a bequest which every votary of inductive research, in whatever field, ought to cherish with gratitude and pride. Science in general and chemistry in particular are not, in these days, so very rich in first-rate men that they can afford to seem indifferent to the life and labours of Joseph Priestley.

DANGERS OF GLUTTONY IN A PHARMACY.

According to the *Répertoire de Pharmacie*, a curious occurrence took place a short time since in a Paris pharmacy. An assistant, having to prepare some granules of arsenious acid according to the formula of the Codex, had made the mass a little soft, and in order not to augment the weight by an addition of inert powder, it was divided into little masses of about 100 granules each and spread out upon a raised place, behind some other articles, to dry. In the course of the day a tall young American lady, while waiting the dispensing of a prescription, made the round of the pharmacy, touching each article she fancied, as is too often the custom with foreigners. The pharmacien, accustomed to this sort of behaviour paid little attention to her proceedings, until happening to raise his eyes he saw her putting into her mouth one of the masses in question. Calling out to her sharply to spit out what she had in her mouth,—forty granules at least,—he gave her to understand that a pharmacy was not a confectioner's shop. The lady, somewhat surprised, obeyed, and excused herself by saying that she had mistaken the substance for *guimauve* paste, and that American pharmacists provided such things as pastes, bonbons, etc., for their customers. She treated the affair very lightly, was evidently not at all frightened by the words "arsenious acid," and left the shop soon afterwards evidently under the impression that the pharmacien had sought by frightening her to punish her for her free and easy behaviour.

MICHELIA CHAMPACA.

At the recent meeting of the North British Branch of the Pharmaceutical Society (see *ante*, p. 431) the President, Mr. Baildon, read an extract from a letter received from Mr. Jamie, of Singapore, referring among other things to the *Michelia Champaca*. The following additional information respecting this plant has been communicated by Mr. P. L. Simmonds, and has been placed at our disposal by Mr. Baildon:—

"The *Michelia Champaca*, Lin., is a native of the Indian islands, although cultivated in Bengal and in gardens in the Peninsula of India for its large yellow fragrant flowers. The tree is highly venerated by the Hindoos, and is dedicated to Vishnoo. It is celebrated for the exquisite perfume of its flowers. Sir W. Jones states that their fragrance is so strong that bees will seldom if ever alight upon them. The natives adorn their heads with them; the rich orange colour of the flowers contrasting strongly with their dark black hair. There are several Indian species of *Michelia*, but they have been somewhat confusedly arranged by botanists. The flowers of another species, *M. Rheedii*, growing in Malabar and Travancore, boiled up in oil, are applied in headaches and affections of the eyes. Oil in which the flowers have been steeped for forty days is also used occasionally in anointing the head.

"It is strange how little attention has yet been given to the distillation of new essential oils for perfumes, etc., from the odoriferous flowers of the East. The large white fragrant flowers of *Mesua ferrea* when dry are mixed in India with other aromatics, such as the sandal-wood, and used for perfuming ointment. The blossoms are found in a dried state in the bazaars, and are called Naghusur; they are used medicinally and much esteemed for their fragrance, on which account the Burmese grandees stuff their pillows with the dried anthers. The white flowers of *Mimusops Elengi*, Lin., are somewhat fragrant and powerfully aromatic. The natives distil an odoriferous water from them. Many other flowers might be cited."

THE DISPENSING OF ERGOT IN FRANCE.

A question having been raised whether ergot, which occurs in the schedule of substances that only medical men and veterinarians have the right to prescribe, should be supplied by the French pharmacien on the order of a midwife, it was referred by the Government to the Academy of Medicine to consider and report upon. After much discussion the Academy has agreed that although such a proceeding is contrary to the law as it at present stands, yet, in view of the fact that midwives are examined in the theory and practice of midwifery and that it would be inhuman to deprive them of the advantages offered by ergot in accouchements, it will recommend the Minister of Agriculture and Commerce to take the necessary measures for authorizing pharmaciens, pending an alteration of the law, to supply ergot upon the presentation of a prescription signed and dated by a certificated midwife.

By a decree dated November 29th, 1872. M. Quatrefages, pharmacien-major of the first class, Chevalier of the Legion of Honour since June, 1863, has been promoted to the rank of officer. M. Hebert, head pharmacien of the Hôpital des Cliniques, has just been named Chevalier of the Legion of Honour.

The members of the British Pharmaceutical Conference will be pleased to learn that the 'Year Book for 1872' is now ready, and will be issued immediately to every member who has paid the subscription for the current year. We have been favoured with an early copy, and our first impression is that in merit it ranks at least as high as either of those which have preceded it.

On p. 561 of the present number will be found an original contribution to the history of Extract of Meat with which we have been favoured by Baron Liebig. As the subject is one in which the learned author is *facile princeps*, and one not without its bearings upon pharmacy, we commend it to the attention of our readers.

Mr. A. Pedler, formerly a student at Bloomsbury Square, has just been appointed Professor of Chemistry in the University of Calcutta.

NOTICE.

We are requested by the Secretary and Registrar to state that the list of successful candidates in the Preliminary examination of the 6th inst. will be published in the next number of the Journal.

Provincial Transactions.

BRIGHTON ASSOCIATION OF PHARMACY.

The usual monthly meeting was held in the Hanover Lecture Hall, on Friday evening, January 3rd, Mr. W. D. Savage, Chairman, being unavoidably absent through indisposition.

The subject for discussion was, "The Adulteration Act in relation to Pharmacy," introduced by Mr. Cornish. Several points of importance were discussed, the principal, "What is an adulteration?"

This, in the opinion of the members present, was not clearly or satisfactorily defined by the Act, nor have the decisions in cases recently brought before Mr. Raffles at Liverpool, where attempts have been made to enforce the Act, proved more successful in elucidating the question.

The feeling generally expressed was, that different degrees of quality did not constitute adulteration.

Official articles of the B.P. should answer to the tests provided for them, and as *pure* and *impure*, or *commercial* were relative terms of degrees of quality, adulteration can only apply to those cases where goods are supplied with a guilty knowledge of being reduced in quality *fraudulently*, and represented as being what they really are not.

The value of pharmaceutical education was urged as a more important safeguard against sophistication than defective Acts of Parliament.

The appointment of analysts was also considered, and it was thought properly qualified pharmaceutical chemists were more eligible for the office than medical officers of health, possessing very little knowledge of practical chemistry.

Messrs. Schweitzer, Armitage, Ettles, Garrett, Smith, and others, took part in the discussion, which was carried on with animation.

After a vote of thanks to Mr. Cornish for his paper, the meeting, a small one, separated.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The third general meeting of the Association was held in Anderson's University on Wednesday, January 8th, 1873, at 9 p.m.; Mr. Davison, President, in the chair. There was a good attendance of members.

The minutes of last meeting having been approved of, the Secretary read a communication that he had received from the Midland Counties Chemists' Association regarding a magazine connected with chemists' associations, which that association purposes issuing, provided the circulation of a given number can be guaranteed.

After some discussion, the Secretary was instructed to write to the secretary of the Midland County Chemists' Association, intimating that the Glasgow Chemists' Association are willing to subscribe to the number of fifty copies of the proposed Journal monthly.

The question as to whether the annual festival should take the form of a supper or of a soirée and ball was next considered. On the vote being taken it was found that the members were nearly unanimous in the desire that it should take the latter form.

The necessary committee having been appointed, the Chairman then introduced Mr. James Stitt, assistant to Professor Thorpe, Anderson's University, who delivered a lecture on "Phosphorus," in which he gave a history of its discovery, and described its chemical and physical characteristics.

At the close of the lecture, Mr. Stitt was awarded a cordial vote of thanks, as was also Mr. D. Clark, who acted as Mr. Stitt's demonstrator.

Mr. Fairlie then moved—"That the secretary call a meeting of assistants to consider the granting to them the use of the hall fortnightly, alternately with meetings of the Association."

This was seconded by Mr. Alexander Kinninmont, and agreed to.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL ASSOCIATION.

The annual general meeting was held on January 10th. The report as read showed a slightly unfavourable aspect, considering the position an association such as this should hold in the midst of such a large business centre. The expenditure also has been in excess of the income, and an appeal was made to the members to give their personal support to the society, and by so doing restore it to something like its former condition of usefulness.

Much anxiety is caused by the seeming indifference with which it is regarded by the bulk of the trade in this district: and it is felt to be most important that every exertion be used that may possibly increase its influence.

The establishment of a Pharmaceutical Students' Association is a source of gratification, and it is hoped that as it has hitherto gone on most successfully, it may be a means of considerably increasing, which is felt in the doings of the society.

The election of officers for the ensuing year placed Mr. W. Ward, F.C.S., in the presidential chair, with Mr. W. V. Radley as treasurer, and Mr. E. R. Learoyd, secretary. The meeting, which was not so well attended as it might have been, was most sincere in its appreciation of the necessity for further exertion if its operations are not to be considerably curtailed in the future.

SHEFFIELD PHARMACEUTICAL STUDENTS' ASSOCIATION.

The annual meeting of this association was held in the Music Hall (Tudor Place) on Thursday, January 9th. After a preliminary speech by the President, Mr. E. R. Learoyd, in which he congratulated the association on the success which had attended its efforts, a report of past proceedings was given, which was considered very satisfactory, bearing in mind the short time the society has been in existence.

A latin class, a materia medica class, and a chemistry class are conducted weekly under the supervision of able gentlemen, and it is hoped they will be appreciated by the chemists' assistants and apprentices of Sheffield more than they are, although the attendance hitherto had been nothing to complain of.

A list of officers and rules were then presented, and received confirmation, after which a very interesting and exhaustive paper was read by Mr. J. S. Wilson, on "Nux Vomica and its Alkaloids," much amusement being caused by the fact that Mr. Wilson (to better illustrate the therapeutical effects of strychnia) had been experimenting upon himself, and when reading his paper was still under the influence of that poison.

A short discussion after the paper, and a vote of thanks to Mr. Wilson, proposed by the President and seconded by Mr. Dunnill, concluded the business of the evening.

Parliamentary and Law Proceedings.

The Sale of Vermin Killers containing Strychnine.

Mr. Crabb Gillett, a chemist, of Peas Hill, Cambridge, has been charged with unlawfully selling a quantity of strychnine to Walter Kirbyshire, on January 2nd, without entering the sale of the same in a book, against the provisions of the Pharmacy Act, 1868.

Walter Kirbyshire, aged thirteen, said that he went on January 2nd to Mr. Gillett's shop for a threepenny packet of "Battle's Vermin Powder," with which Mr. Gillett served him, and whilst he was in the shop Mr. Gillett did not enter anything in a book. The packet had on defendant's name and address, and the name, "Vermin Killer."

Detective Kirbyshire received the packet from his son and gave it to Mr. Deck, of King's Parade.

Mr. A. Deck, pharmaceutical chemist, said he received a packet marked "Battle's Vermin Powder" from Kirbyshire. He had subjected it to an analysis, and found it to contain strychnine in the proportion of a grain and a half to the packet. To take one-sixth of the packet would be very dangerous. The packet contained about forty grains.

Defendant said that he had sold the powder under what was then law, vermin killers not being mentioned in the Act of 1868, but the day before there had been a fresh regulation, in which vermin killers were added.

The Clerk said that that was only an explanation of the Act, and not a fresh regulation.

Chief Superintendent Turrall said that the summons was not laid against defendant individually; but in summoning him he considered himself proceeding against all chemists in Cambridge who failed to comply with the Pharmacy Act.

The magistrates mentioned that in August last a child had died from this same poison, and that in Cambridge nearly 100 dogs had been poisoned.

Fined in the mitigated penalty of *5s.*, with costs.

The Alleged Negligence of a Chemist and Druggist.—Powell *v.* Hingston.

This case came before the Court of Queen's Bench on Wednesday last. The particulars, which were recently reported in this Journal, were as follows:—

The plaintiff, a hairdresser at Liverpool, sent a child of 10 or 11 years old to the shop of the defendant, a chemist and druggist, for some acid. The truth was that the hairdresser used nitric acid in his business, but, at the same time, he wanted sulphurous acid for his throat. It was admitted, however, that the chemist did not know this, and he had sold the man nitric acid before, so he gave the child nitric acid, and labelled it so. The man, however, unfortunately did not observe the label, and applied the acid to his throat, the result of which was that he was very severely burnt. He sued the chemist for damages, and the case was tried at the last assizes at Liverpool before Mr. Justice Lush, who, upon the evidence thought that there was no negligence, and expressed that opinion to the jury, who found for the chemist.

Mr. C. Russell, Q.C., moved on the part of the plaintiff for a new trial on the ground of evidence of negligence, but

The Court thought there was no ground for disturbing the verdict, as there was no negligence on the part of the chemist. They thought, indeed, that it was foolish to send such a mere child on such an errand. The phial was duly labelled, and the mistake was the plaintiff's.—*Times.*

Suicide in Wolverhampton.—A Caution to Chemists.

On Friday evening an inquest was held at the New Market Inn, Cleveland Road, by W. H. Phillips, Esq., Borough Coroner, on the body of Thomas Woodward, 22, driller, employed at the Great Western Railway Works, Stafford Road, whose death had, it was supposed, been caused by poison. John Argyle, "boots" at the Coach and Horses, Snow Hill, was the first witness called. He said he had known deceased very well for some time. He was a single man and lived on the Stafford Road. About twelve o'clock on the previous day the deceased came to the Coach and Horses Inn, as he was in the habit of doing, to give any assistance he could. He remained on the premises until about nine o'clock. He went out, but returned some time afterwards, and about twenty minutes past ten he fell down in the kitchen; he went black in the face, and very stiff. Witness thought he was in a fit, and bathed his temples with vinegar. He sent four times for Mr. Pope, surgeon, but he did not attend, and then witness sent for Mr. Bunch, who came shortly after eleven o'clock. By his advice, deceased was then taken to the Hospital. In reply to further inquiries, witness said the deceased had been in very low spirits of late, owing chiefly he (deceased) had said to the manner in which his father (from whom he lived apart) had treated him. He had been very much down-hearted because his father had not taken so much notice of him, he said, as he did of his housekeeper, and he had told witness that he should kill either that person or himself. He had recently been in a "bother" at Tettenhall, and had been discharged from his work. This, also, had preyed on his mind. On two occasions, several weeks ago, deceased said he should poison himself, but witness persuaded him not to do so.—Susan Evans, waitress at the Coach and Horses, said she saw the deceased several times on the previous day, and noticed that he was more dull than usual; he would scarcely speak to any one. At about twenty minutes to eleven o'clock at night witness found him in a fit on the floor of the kitchen. She had not previously seen him since three o'clock, when she had given him some port wine at his own request. When Mr. Bunch arrived, he said (in reply to that gentleman's inquiries) that he had taken six pennyworth of vermin killer, which he had purchased from Mr. Moses, the chemist, and had taken it at ten o'clock.

Mr. H. Moses, chemist, Dudley Street, said that on the previous evening, about ten minutes to nine o'clock, he sold six pennyworth of Battle's Vermin Killer to a young man, whom he did not know, and whom he could not recognise in the person of the deceased. He had no recollection of the man. Witness did not make any entry of the sale, neither did he explain to the purchaser the nature of the purchase. It was labelled "Poison."

Alfred Henry Carter, house physician at the South Staffordshire Hospital, stated that he was called to attend the deceased at twenty minutes past eleven on the previous night, and found him insensible. He was then slightly convulsed. Witness administered an emetic within two minutes of the man's admittance, having heard that deceased had taken poison, and at once went for the stomach pump. Witness used other means to retain life, but the patient died within twelve minutes of admittance. The symptoms displayed were the same as those he might have expected from a person who had taken poison, but they were not definite. At this stage of the proceedings the inquest was adjourned till Monday, for the purpose of a *post-mortem* examination.

The adjourned inquest was held on Monday morning, at the New Market Inn, before W. H. Phillips, Esq., Borough Coroner. Dr. Carter stated that he made a *post-mortem* examination of deceased's body on Saturday afternoon. The heart was healthy, but gorged with red blood, lungs congested, the lining membrane of the stomach highly congested and covered with unusual viscid mucus and spotted with adherent particles of varying sizes with what appeared to be a white powder. It also contained a considerable quantity of grumous-looking matter, amongst which were small particles of what seemed to be Prussian blue. Mr. F. J. Barrett (the hospital pharmaceutist) made under his superintendence an analysis of about one-third of the contents of the stomach, and separated nearly one grain of strychnine, showing that the stomach contained about three grains, besides absorbing a sufficient quantity to cause death. There was no arsenic present. The witness was satisfied that the deceased died from poisoning by strychnine. He did not find any curvature of the spine or lockjaw.

After a short consultation the jury returned a verdict to the effect that "the deceased destroyed his life by taking some of Battle's Vermin Killer whilst in a state of temporary insanity."

The Coroner (addressing Mr. Moses, the chemist who sold the powder to the deceased) said it became his duty to call his attention to one or two matters. It appeared that he (Mr. Moses) sold a packet of Battle's Vermin Killer to a person whom he did not know, and after seeing the body of the deceased was unable to identify him as the same person. It became his (the Coroner's) duty to call his attention to section 17 of the Pharmacy Act, 1868, which required every chemist to endorse every packet of poison which he sold with the word "poison," and to enter the name of the person to whom he sold it in a book. Also the person to whom the poison was sold must be either known or introduced to the chemist. The Pharmacy Act contained a schedule of poisons for which caution was required to be taken, and "vermin killer" was amongst them. The chemist who did not comply with the regulations was liable to a penalty, on the first offence to £5, and on the second offence to £10. Mr. Moses had omitted to comply with these regulations by selling the "vermin killer" to the deceased without first being introduced to him; and secondly, not entering the name of the purchaser in a book. He (the Coroner) was therefore bound to bring the matter to the notice of the police authorities of the Borough.

Mr. Moses: I did not know that it contained strychnine.

The Coroner said he should have made himself acquainted with the matter. He had sold the packet of "vermin killer" without entering the name of the deceased in a book. Although he labelled it poison, he sold it to a person whom he did not know, and to whom he had not been introduced. The Coroner then thanked the jury for their attendance.

Alleged Attempt to Poison a Schoolmaster.

At the Thames Police Court on Tuesday, January 14th, James Thomas Langton, aged 15 years, a compositor, of No. 40, White Hart Place, Newgate Street, William Finchcliffe, aged 11 years, and James Grant, aged 11, were brought before Mr. Lushington charged with attempting to poison John Sonden, assistant-master at the industrial school, No. 96, Mansell Street, Whitechapel.

A police-constable said that the complainant came to the station, and from what he told him he took the prisoners in charge. At the station, Langton said that Finchcliffe gave him a penny to purchase a precipitate powder, and he went to a Dr. Squares and bought it of the assistant. He gave the powder to Finchcliffe, and asked him what he was going to do with it. Finchcliffe said he was going to give it to the master as a medicine, because he had flogged him. He (Langton) told him if he had known it was going to be used for that he would not have fetched it, and asked Finchcliffe for it back again. The latter refused to give it up. When the prisoners were told the charge Finchcliffe said he put the powder in the medicine, but was told to do so by the prisoner Langton.

Mr. Segueria, a surgeon, said that Mr. Pitt, the superintendent of the school, brought him the bottle of physic produced on Saturday last. It was half full. There was a sediment in the bottle, which he found to be precipitate powder, which was poison. There was about half a drachm of powder, which would be sufficient to destroy life.

Mr. Lushington remanded the prisoners for a week, and told the constable to bring the person from whom the powder was bought, on the next hearing of the case.—*Echo.*

REPORTED ARSENICAL POISONING OF SEVENTEEN PERSONS.

A singular case of wholesale poisoning is reported from Hampton-in-Arden, near Birmingham. A provision dealer in the village had a quantity of "collared" pork in his shop, and portions of it were purchased by a number of the poorer inhabitants on Saturday. After partaking of the pork seventeen persons were attacked with symptoms of arsenical poisoning. Medical men were called in, and all the sufferers recovered. The remainder of the meat has been seized by the police.—*Echo.*

DISGRACEFUL, IF TRUE.

At the Westminster Police Court on Saturday, Jan. 11, a young man was among the applicants to the magistrate for advice and assistance. He wanted to know whether the keeper of a chemist and druggist's shop could not be punished for being in a state of drunkenness while carrying on his business and serving customers. He said he went into a chemist's shop on Saturday morning in the neighbourhood of the court, and, after waiting twenty minutes to be served, was surprised to find the keeper of the shop crawl up from off the floor fearfully drunk, and wishing to know what the applicant required, but he would not allow such a dangerous person to serve him. Mr. Arnold could not see how he could interfere; people had better not deal with such a man, that was about the best remedy he could suggest. Applicant observed that a woman came in with a child and complained that he had given her a powder for her baby which had greatly injured it. The neighbours said he was eccentric, and the police reported that frequent complaints were made of the wrong drugs being served by the chemist. Mr. Arnold said he could not prevent a man getting drunk in his own house. He could not offer better advice than he had already given. If, however, the man sold drugs to persons which injured them, or to young persons, then he could be made amenable to the law. Applicant said the people who complained were poor, and could not lose their time.—*Times.*

Obituary.

GEORGE WAUGH.

Our readers will learn with unfeigned regret that one who held a prominent position among the early supporters and promoters of the Pharmaceutical Society, one who long filled the office of Councillor, who was Vice-president in 1850, and was often urged but persistently declined to fill the Presidential chair, has passed from amongst us, and that the familiar voice and genial countenance of George Waugh will no longer exercise the influence they have so often exerted in smoothing the ruffled waters of debate, or adding dignity to the deliberations of the council chamber. Mr. Waugh was one of those who took an active part in the formation of the Society, and a deep interest in the cause of pharmaceutical education. The character and position he had acquired, both morally and intellectually, together with his reputation as a high class pharmacist, gave to him an influence which was beneficially exercised in moderating and controlling occasional tendencies to extreme measures on the part of those who took an interest in pharmaceutical politics. His opinion and advice were frequently sought by his friend and neighbour Jacob Bell, to whose measures he generally, although by no means uniformly, gave his support. After Mr. Bell's death, Mr. Waugh may be said to have been the originator and one of the most active promoters of the Jacob Bell Testimonial Fund.

During the many years that he occupied a seat at the Council Board of the Pharmaceutical Society, he was regular in his attendance at councils and committees, and took part in the discussion of most subjects of importance. He was more given, however, to pass judgment on the measures of others than to originate any himself. In common with what is frequently observed in those who exercise a controlling influence upon the decisions of others, his own opinions were not hastily formed, and he may sometimes have subjected himself to the charge of inconsistency by the way in which his own decisions were arrived at. During the early history of the Pharmaceutical Society, Mr. Waugh was one of those well-known London chemists whose names appeared from year to year on the list of its Council, and who were at last thought to partake too much of the character of hereditary councillors. Mr. Waugh indeed was himself one of the first to contribute to the breaking up of the metropolitan character of the Council by withdrawing from it to make room for a greater infusion of new blood. He died on Sunday, the 12th inst., at his residence, Queensborough Terrace, Kensington Gardens, aged seventy-one, and was buried at Kensal Green Cemetery on Friday, the 17th. By the death of Mr. Waugh another link is broken in the chain which connected the pharmacy of a past generation with that of the present day.

Notice has also been received of the death of the following:—

On the 10th January, 1873, Mr. Edward Fowler, Pharmaceutical Chemist, of Bedale, Yorkshire, aged forty-two. Mr. Fowler had been a member of the Pharmaceutical Society since 1853.

Suddenly, on January 9th, 1872, at 40, Aldersgate Street, E.C., James Davies Parker, upwards of twenty years the confidential clerk of Messrs. Herrings and Co., wholesale druggists, London.

Reviews.

INTRODUCTION TO INORGANIC CHEMISTRY. By WM. GEO. VALENTIN, F.C.S. London: J. and A. Churchill. 1872.

This is a new edition of the first part of the 'Laboratory Text-Book of Practical Chemistry,' published by the author about two years ago. It has been slightly enlarged by the addition of a number of experiments, and by the further development of some of the explanatory and theoretical matter. The author hopes "that this first volume may now take rank as a suitable text-book for elementary classes preparing for the chemical examinations which are held annually under the Science and Art Department." Our conviction is that this hope will not be disappointed, and that Mr. Valentin's new volume will certainly find a very wide circulation, and meet with a very cordial reception both from students and teachers. We say this because we feel bound to reiterate the commendation which we took occasion to express in a former volume with regard to the original work. Both are very excellent books, and will satisfactorily supply an undoubted demand. The experienced author will, however, we trust, forgive us if we point out one or two considerations which in the compilation of a work of this kind deserve to be kept in view. In the first place with regard to the experiments.

Inasmuch as detailed directions are given for the performance of each experiment, it may be assumed, we suppose, that they are to be followed pretty closely. Does the author really mean to say that all, or even any large proportion of the students under his charge do absolutely perform the experiments as indicated? If so, each student would require at the outset to provide himself with a far larger and more expensive stock of apparatus than is usual. Gas-jars, gas-holders, complicated drying tubes for gases, fragile eudiometric apparatus and things of that sort are freely employed in the course of the experiments, and there seems in most cases to be no instructions for demonstrating the same facts by the use of instruments less elegant but more easily managed by inexperienced hands. It is true that the author says in his preface that some of the experiments he describes are more suited to the lecture-room; but this may be said of so many of them that he would probably render the book more acceptable to mere beginners, and especially to students working alone, if in the next edition he would add considerably to the number of *simple* and easy experiments such as might be carried out without the aid of special apparatus. According to our own experience nothing is more troublesome to beginners than being called upon at an early stage to employ apparatus which is not only strange in appearance, but is called by an unfamiliar name, and at the commencement it taxes sufficiently the patience and memory of most young students to recollect the uncouth titles of all the strange substances which form the indispensable material for work, and which are unavoidably introduced so rapidly one after the other.

In the treatment of some theoretical matters, we regard it as decidedly preferable to face difficulties boldly, and say to the student without rigmarole, "Here are the facts stated as plainly and in as few words as possible, and there is the explanation which has been generally accepted." In the majority of cases a more distinct impression is at once made upon the mind than can be produced by adopting any modification of the inductive process. In the book before us, as in so many other manuals, this latter is made use of in discoursing of the laws of combination and the atomic theory. In the early editions of 'Fownes,' which was the text-book of our own student days, a chapter was headed 'Chemical Philosophy,' in which the laws of combination were first distinctly enunciated in three or four short and impressive paragraphs, and *afterwards* illustrations and examples were supplied, all the unintelligible jargon about little particles being left till last of all. We should be disposed to maintain that, especially in the present stage of the progress of chemistry, this dogmatic kind of way of stating well-established laws is distinctly preferable to the possibly more logical but infinitely more difficult process of working from primary facts up to generalizations. But these things are after all a matter of opinion, and we by no means wish to find fault on this score with Mr. Valentin's book more than with others of the same class. It is astonishing, though, to what difficulties and inconsistencies even experienced teachers like Mr. Valentin are led in treating of this part of chemical theory, and we think the following definition on p. 44 a fair instance of this:—

"An atom is the smallest *particle of matter* capable of entering into or existing in a state of chemical combination." In the paragraph immediately preceding this we are told that "the smallest *proportion** by weight in which an element enters into or is expelled from a chemical compound constitutes its atomic weight, the weight of hydrogen being taken as unity," so that the smallest particle of matter weighs a *ratio!* If the author and not a few other chemists would be content to leave the "small particles" to whomsoever they may concern and be satisfied with proportions, no such absurdity could arise.

We observe that the author continues to make use of the hideous hybrids, monovalentic, divalentic, etc. Will no remonstrances induce him to change them, and are there no ears at the college?

In conclusion, there are one or two statements in the book which will probably be modified by the author in a future edition. We may select one as an example' "the *evolution* of *heat* which accompanied the combination of the white powder (anhydrous sulphate of copper) with water points to an actual *chemical* combination between the water of crystallization and the salt."

We think this conclusion admits of dispute.

* The italics are ours.

A MANUAL OF CHEMISTRY, THEORETICAL AND PRACTICAL. By GEORGE FOWNES, F.R.S. Eleventh Edition, revised and corrected by HENRY WATTS, B.A., F.R.S. London: J. and A. Churchill, New Burlington Street. 1873.

We cannot commence an examination of this well-known work without protesting in the loudest tone we can utter against the inordinate dimensions which all the old-fashioned books, familiar to by-gone generations of students, are gradually assuming under the hands of their modern editors. We entertain the highest possible respect for the learning of Mr. Watts, and for his experience in the literature of chemistry, but in the present instance we feel that although, as might be expected of him, he has produced a text-book that may be relied upon for accuracy, he has certainly made the volume unwieldy. We fully admit the difficulty of dealing with the daily increasing mass of organic compounds, but in mercy both to students and teachers we do hope Mr. Watts will not allow the book to grow any larger, and will, if possible, reduce the present number of pages. This can be done, we think, without difficulty and without detracting from its usefulness, by simply omitting the details of preparation and properties of all but really important and representative compounds.

As in the original editions of the work, the first part is devoted to a short treatise on physics, good enough in itself, though, we think, better omitted altogether in the present day.

Following this we have the usual account of the non-metallic elements and their chief compounds, but here, as throughout the whole book, is interspersed much new matter. It is, however, in the chapters devoted to "Chemical Philosophy," the history of the metals, and especially in the organic division, that the most important changes and additions are noticeable.

The chapter on the general principles of chemical philosophy is entirely re-written, and now includes not only the enunciation of the so-called "Laws of Chemical Combination," but also a discussion of the theory of atomicity and other subjects of comparatively recent growth.

In the classification of the elements we observe that Mr. Watts still uses the term "metalloïds" to designate that class of elements which are not metals. We should have expected almost that his ingenuity would have discovered or devised a new name, seeing that the title "metall*oïd*" is most inappropriately applied to these elements which in no respect bear any likeness to metals, and also because it ought to be reserved for that small class of bodies which *do* to some extent imitate metals in physical characteristics and chemical relations. Now we venture to make a suggestion, and crude as it is, leave it to the consideration of writers of text-books.

The elements may fairly be arranged in three classes. For the first of these the name "metal" must obviously be adopted. To the second, under which tin and titanium, antimony, arsenic, bismuth, and vanadium; tantalum and niobium; tungsten and molybdenum range themselves, the name "metalloïd" as obviously belongs. These elements resemble metals in possessing as a rule metallic lustre, rather high specific gravity, and in forming at least in some cases oxides in which the basic character is more or less developed. On the other hand, they differ from metals in being (except tin) so brittle as to be easily reducible to powder, in being comparatively feeble conductors, and in the fact that among the most stable and definite of their compounds are the higher oxides which invariably function as acid anhydrides. For the third class of elements those hitherto clumsily styled "non-metallic" we think there should be a name expressive of the opposition of their characters to those of the metals. With this view we suggest that the name "chloroid" might be used; it would serve, at least, to indicate the functions of the elements grouped under that title. The adjectives, "chlorous" and "basylous," have already been introduced and are sufficiently expressive and intelligible.

Mr. Watts gives much greater prominence to the rare elements than is usual in text-books of this sort. This, we think, is quite as it should be. One element is certainly as important as another from a theoretical point of view. At the same time, we think the description of their compounds is in some cases detailed at unnecessary length. It could not surely be necessary in a work which professes to be elementary to give, for example, to the ammoniacal compounds of platinum more than four pages.

The third part of the book, which constitutes very nearly one-half of the entire volume, is devoted to organic chemistry. It commences with a short but instructive section on the transformations of organic bodies under the action of reagents. In the following section, in which an account is given of the ordinary processes of organic analysis, less care seems to have been exercised than in the rest of the book. For purposes of organic analysis we should hardly consider that the copper oxide is best prepared from the nitrate;—the method of mixing in the tube itself is by many operators preferred to the use of the mortar;—the straight chloride of calcium tube (Fig. 150) is not by any means the best form, nor is calcium chloride the best desiccating agent for absorbing aqueous vapour from the gases generated in a combustion. In the analysis of chlorinated compounds the very convenient method of Carius, by heating with nitric acid and silver nitrate, would always be used, except in a very few cases in which the older method would be preferred.

The reader who has used one of the older editions of Fownes will find a great many changes introduced into the organic part. Organic compounds belonging to the several classes of alcohols, aldehyds, acids, hydrocarbons, etc., are now arranged in series, and the whole divided into two great groups—fatty and aromatic. The natural-history sort of arrangement served well enough in the early days of chemistry, but can now no longer be retained with advantage.

We observe that for the principal hydrocarbons Mr. Watts employs the names proposed for them by Dr. Hofmann. On looking in the index for "marsh gas," we are referred to page 164 among the compounds of carbon in the early part of the book; but to the name methane we find three references, two of them to pages in the organic part. Olefiant gas is indexed among inorganic compounds, and ethylene is nowhere to be found; but ethene, the new name, has two references. This is a little unfortunate, because nine people out of ten would certainly look for the older word. Moreover, it seems as though the new nomenclature for these bodies had not been adopted—at least, in the index—very consistently; thus, whilst we fail to find ethylene glycol, its homologue butylene glycol does occur.

In the aromatic group the theory of the isomeric derivatives of benzene is pretty fully explained, and the editor has of course introduced a notice of nearly all the recent researches of sufficient importance in the organic as well as the inorganic division. On the whole we can confidently recommend this new edition to students as being thoroughly trustworthy, though, as we have already explained, we think from its increased size it will scarcely meet with the universal favour enjoyed for so many years by the older editions.

Notes and Queries.

[325.]—DETECTION OF STEARIN IN BUTTER.—The micro-polariscope affords the only means of detecting the presence of stearine in butter without very refined chemical analysis. The procedure is briefly this. Take a clean glass slip and place on it a small portion of the suspected butter (about the size of a small pillule of homœopathic medicine). On the butter place a ¾-inch circle of thin glass, and slowly press it as close to the slide as possible so as to obtain a very thin and therefore transparent layer of butter between the cover and the slip. If it be now examined by polarized light, the crystals of stearin will easily be seen and recognized by their feathery arrangement. Their action upon a thin plate of selenite is also characteristic. It is obvious that other adulterants, as starch, may be detected by this means. It is well to bear in mind that stearin is not the only doubly refractive substance to be found in butter. Oil and fat globules under certain conditions are as doubly refractive as starch corpuscles, and have to my knowledge been mistaken for starch. The shape and arrangement of the stearic "crystals" are, however, sufficiently distinct. I believe there is no other means by which stearin can be detected as an adulterant, and even this only shows that it is present and not necessarily that it is not present, for very small quantities appear to be acted upon by the other components of the butter, and escape detection.—H. P.

[327.]—ILIAC PILL OF RHASIS.—Can any correspondent furnish me with the formula for the Iliac Pill of Rhasis?—J. S.

[328.]—HAIR RESTORER.—"*Alpha*" asks to be furnished with the formula for a good Hair Restorer.

[*⁎* Dr. B. Godfrey, speaking of general baldness in his little treatise on 'Diseases of the Hair,' says, "The tincture of cantharides should be applied with a sponge daily to the sterile surface on going to bed, and a diurnal wash be given with soap and cold water every morning; the head should then be dried with a rough towel, until the skin glows and blushes like a bashful maiden. Three months of such treatment ought to restore the lost hair. The expressed oil of mace and benzoated lard, in equal parts, vigorously applied daily will produce a like result."—Ed. Pharm. Journ.]

"Dispensing Charges."

Sir,—Your article on the *Globe* deserves the best thanks of the trade at large. It completely disposes of such clap-trap, and shows the ignorance of non-professional journalists in such matters. The *Lancet* of this week, however, among its "medical annotations," recites the "inquiry" of the *Globe*, and sums up the case in the following paragraph:—

"The fact is, that retail trade is gone mad. There are far more shopkeepers than the wants of the public require, and they think themselves entitled to all the luxuries and enjoyments of life. Their wives, glorious in sealskin jackets and redundant jewellery, are to be seen everywhere; and the pretensions of the class are becoming a nuisance that it is high time to put down."

Can the force of scientific and gentlemanly journalism further go? Need any comment be made when a wretched scribbler stoops to conquer in this style? I have been a subscriber and reader of the *Lancet* for twenty years and more, and am aware of its frequent assaults on pharmacists, but this is, I believe, the first funding which has touched our wives, and I for one desire to protest against such indecencies. I do not object much to be called mad myself, but I do assert that it is simply idiotic and to the last degree contemptible to vilify the whole retail trade and their wives upon the strength of such a ridiculous inquiry as that instituted by the *Globe*.

Wm. Matthews.

12, *Wigmore Street, January* 15*th*, 1873.

Lancet Amenities.

A correspondent, writing under the signature "Translator," suggests the following amended reading of the "elegant" paragraph to which we have referred in another column:—

"The fact is that the medical profession is gone mad, there are far more medical men than the wants of the public require; and they think themselves entitled to all the luxuries and enjoyments of life. Their wives, glorious in sealskin jackets and redundant jewellery, are to be seen everywhere, and the pretensions of this class are becoming a nuisance that it is high time to put down."

[We do not, however, quite agree with our correspondent, inasmuch as we believe the alteration to be admissible only in so far as medical men are content to endorse such representation as the *Lancet* seems to think suitable for the profession.—Ed. Pharm. Journ.]

Sir,—It has often been to me a subject of annoyance that my long-continued exertions in the cause of pharmacy have not been recognised by a public testimonial. Let it not assume the form either of a teapot or of a silver inkstand, as I have the former and never use the latter. My wife is not clothed in a manner I should desire, nor can she realize the description in the *Lancet*—a sealskin jacket would be most acceptable; and if the body of Pharmacists would kindly add a brougham my services would be amply rewarded.

Joseph Ince.

Sir,—Truly we are the best abused race of people in existence. It is only a short time since the leading medical journal very kindly and very considerately called us, without rhyme or reason, "malefactors." The *Pall Mall Gazette*, that aristocratic journal, written essentially "by gentlemen for gentlemen," "improved the occasion" by adding "it was high time a chemist was hanged" (*pour encourager les autres*, I suppose). The *Globe* being in want of something approaching a Christmas sensational article, and probably taking its cue from the *Times* article on "Spiritualism and Science," suddenly finds out that our charges are "excessive;" that we "impose" on our "victims," the general public, and "render abortive the gratuitous prescribing of medical men." The writer, in common with many of his class, will persist in confounding the "druggist" *pur et simple*, who is merely a retail tradesman, who buys goods for so much and sells them for so much more, with the "dispensing chemist" who passes a classical examination, pays a large premium, subjects himself to a studentship of four or five years, and subsequently passes two successive examinations before he receives his diploma. He will then, let us suppose, look out for a shop already established, and will give, say, £500, for one where the returns amount probably to £400. May I ask our friend if he would put a son to the business if the profits were only, say, 30 per cent., equalling £120 per annum, for an outlay of at least £1000, and out of which profits he must pay rent and taxes, and keep himself and family in a respectable manner? The profits of a business must be in a direct ratio to the turn over; a butcher or a grocer will turn over £500 a week, many of our brethren do not take that sum in a year. The butcher's profits at 5 per cent., more than double the chemist's whole receipts, and yet the butcher may not be able to sign his name, while the chemist must have had a thoroughly good education. The lawyer does not charge merely for the skin of parchment or sheet of foolscap; nor the penny-a-liner for just the pens, ink and paper he may consume, consequently the professional dispenser is entitled, *cæteris paribus*, to professional profits, which are totally different and entirely distinct from the ordinary profits of a retail druggist.

In applying the test, how is it that the open surgery and the apothecary's shop were not visited, so that the charges of properly qualified medical men might be compared with ours, and how many physicians actually do give their advice? Might they not be almost counted on the fingers? Many profess to do so, but it is rather singular, to say the least about it, that they compel their free patients to go to one particular chemist for their medicines.

If the *Globe and Traveller* wishes to organize a new crusade, let it commence at the top of the tree—the medical profession. Let it attack the physician who believes in "an equal division of labour," and also "an equal division of profits;" let it attack the surgeon who keeps an "open surgery," and sells hair oil and toilet soap; let it attack that anomalous animal the apothecary, who is chemist, druggist, midwife and bleeding-barber rolled into one; let it attempt to put down the nest of herbalists, Coffinites, hucksters, etc., who sap our very vitals. And let it also endeavour to teach the masses the different qualifications of the medical profession, so that if a person wishes medical advice he may go to a physician; if he requires his leg or arm amputating, he will go to a surgeon; if his wife be in labour, he will fetch the apothecary; and if he require medicine, he will go to a dispensing chemist. There is surely scope enough here for even such a "Traveller" as the "Globe," though he may travel in such a limited circle as not to know that dispensing chemists require to be examined; and then what a pleasure it is to possess a friend who is such a "competent authority" as to estimate articles at twice their actual cost!

In conclusion, I can assure the writer of the article that notwithstanding the "excessive profits," the chemist does not spend his life on a bed of rosæ fol.; many of us have great difficulty, and have to exercise great self-denial to enable us to pull through. The gratuitous insults which the *Globe* thinks fit to throw in are perhaps the result of New Year festivities—the toughness of the turkey, the plum-pudding being just a little "sticky," or the presence of mother-in-law may have deranged his digestive organs, and caused him to be splenetic. May I with all due deference prescribe a few doses of pepsin, and then hint that in a few years I hope to see the dispensing of medicines entirely in the hands of the chemist, and the present prices considerably augmented.

T. C.

Sheffield, January 10*th*, 1873.

Payment of Local Secretaries.

Sir,—I quite agree with the remarks of your correspondent Mr. Nathaniel Smith relative to the remuneration of local secretaries, and am also firmly persuaded he is expressing the views and feelings of the majority of those gentlemen who have hitherto acted, or are at present acting, in that capacity. If not positively insulting, it is, at any rate, paying but a poor compliment to their generosity and disinterestedness, to seek to rob the office of its honorary character by attaching to it either a meagre stipend or a paltry honorarium. We are becoming utilitarian with a vengeance, and all our better impulses will soon be utterly degraded, if every act of generosity and self-abnegation are to be made objects of pecuniary gain. To the major part, "the honour of the appointment," and the consciousness of doing good, will fully reimburse them for both time and any little pecuniary loss in the shape of stamps and paper, etc.

GENEROSITATE.

January 14th, 1873.

FELLOWS OF THE PHARMACEUTICAL SOCIETY.

Sir,—I beg to make a suggestion in reference to the above, as chemists in active business have but little leisure to devote to the scientific advancement of pharmaceutical chemistry, and still less to give much attention to analysis, other than their own business requirements, though, of course, all are not alike situated.

I cannot help feeling the force in the remarks of Dr. Attfield in respect to the great difficulty he experiences in inducing talented young men to remain in the ranks of pharmacy, owing probably to the unattractive prospects behind a retail counter that present themselves to the studious mind of a man who has attained a high standard at Bloomsbury; thus many are drifted away into other channels, and discoveries that might otherwise brighten the pharmaceutical horizon, and elevate its status, are lost.

In order to remedy this state of affairs, would it not be advisable to appropriate the surplus (or a portion of the) funds of the Society towards the foundation and endowment of "Fellowships," tenable for a certain period, or for life in some instances, as may be thought expedient, and under certain conditions?

Thus men obtaining these distinctions would be free to pursue their investigations, and in their own way become real helpmates to their less favoured brethren, and would be the men of all others to select as public analysts, and also as teachers and demonstrators to the various provincial associations.

Of course these fellowships would be open to men already in business, and would not prevent young men, who may obtain one, entering business if they choose.

Trusting the suggestion may not prove entirely useless, I am, Sir, yours respectfully,

CHEMIST.

Rhyl, January 9th, 1873.

ASSOCIATION OF ASSISTANTS.

Sir,—I believe that not a few of the chemists' assistants in London have of late been considering how much their interests might be furthered, and their educational requirements advanced, by the formation of an association amongst them.

We hear of several being already instituted by assistants in some of the leading provincial towns, and surely there is no reason why we, so numerous a body, in London, should not be able to raise an association, and one, too, of considerable importance.

Our examinations, we have been informed, are to become more stringent than they now are, so that there is need of some exertion on our part if we would meet successfully the well-meaning advances of education, as well as the worthy Board of Examiners.

We know that the numbers are comparatively few who have the privilege or means of attending lectures, laboratories, or schools of medicine, but we may feel sure that the numbers would be very considerable who could attend evening classes, and practical instruction, if an association were founded where we might, at a moderate expense, have teachers for the different subjects. Much could be said on the advantages that would be derived by our having such a means of coming together, but this may suffice to introduce the subject.

What we require, then, is the kind assistance and suggestions of some of the leading gentlemen connected with the trade in town, who know how to set about the matter, and where to select a central place for the institution; and there are not a few who, I am sure, will consider it a pleasure to contribute their energies towards such a praiseworthy cause. I have no doubt, many intelligent and active assistants will also gladly give their services, as far as they can, in whatever way may be required, towards seeing established, ere long, an influential "Chemists' Assistants' Association" in London.

ROBERT THOMSON.

300, *Holborn, W.C., January 14th*, 1873.

A WORD OF CAUTION.

Sir,—We think it desirable to put chemists throughout the country on their guard, with respect to various wine and other agencies which are being hawked about.

The following case has just come under our notice:—A man called upon one of our customers, soliciting him to become an agent for one of these companies; he objected for some time, but was ultimately persuaded to undertake it. A paper was then produced for his signature, which he incautiously signed. Thinking next day he had not been sufficiently careful, he looked at the paper, a copy of which was left with him, and found he had agreed to take about £100 worth of wine and give a bill on receipt of the goods at four months. He wrote at once to the parties cancelling the order, but they would not consent, and after some correspondence, served a writ upon him. He placed the matter in the hands of some respectable solicitor, who eventually compromised it for £20.

As this is not the first instance of the kind which has come to our knowledge, one case involving the man in ruin, we think a word of caution to chemists and others is not out of place, urging them not to sign any paper until they thoroughly understand the purport of it, and to what it renders them liable.

PRESTON AND SONS.

88, *Leadenhall Street, January 15th*, 1873.

CURIOSITIES IN DISPENSING.

Sir,—I, in common with many of your correspondents who have written on the above subject, occasionally meet with remarkable formulæ brought to be dispensed.

The following, I think, may fairly claim a place in the first rank of "Curiosities in Dispensing":—

R.	Nitrous acid	2	drams.
	Dilute Phos. Acid	6	,,
	Chloroform	$\frac{1}{2}$	,,
	Paregoric Elixir	$1\frac{1}{2}$	,,
	Tinct. Cardam.	$1\frac{1}{2}$	,,
	Simple Syrup	1	,,
Mix.			

The verbal message given was to make it up with the strong acid and no water. The chloroform, of course, remained at the bottom, and there were no directions to shake the bottle, or, still worse, what dose was to be taken.

J. H. BALDOCK.

South Norwood, Jan. 14th, 1873.

ANALYSIS OF MILK.

Sir,—Allow me to call the attention of milk analysts to an adulterant which I have not yet seen mentioned,—anatto; it disguises the *sky-blue* tint, and enables skimmed or partially skimmed milk to be sold as new, and possibly might interfere with the use of the lactoscope.

J. SLADE.

Messrs. White and Chignell, J. Lofthouse and *Brothwood.*—The advertisements and post-office orders have been handed to the publisher. They should have been sent to Messrs. J. and A. Churchill, New Burlington Street. See the Notice to Advertisers, published every week on the second page of the advertising sheet.

Sydney Taylor.—We do not think the charges were high, considering that stoppered bottles were used; but may suggest that it would have been preferable to have used ordinary corked bottles, in which case a lower charge would have been sufficient.

An Associate.—The words quoted refer to the practical part of the examination.

M. Graham.—We thank you for your suggestion, but the plan is adopted more frequently than you appear to suspect.

"*Certus.*"—(1) An Associate becomes such by election by the Council, not by examination. (2) It would depend upon the terms of the agreement. Consult a solicitor.

"*Junior.*"—The limitation as to age does not come into operation until 1874.

"*Plumule.*"—McNicoll's Dictionary of Terms and Walker's Pronouncing Dictionary.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. E. Charlwood, T. Garside, Goldsworthy, J. Slade, J. R. Jackson, F. J. Barrett, H. B. H., T. C.

THE MICROSCOPE IN PHARMACY.

BY HENRY POCKLINGTON.

(*Continued from p.* 543.)

NECTANDRÆ CORTEX.—This most intractable of barks is so nearly related to those last named that it must come in here. It is an exceedingly interesting bark and complex in structure, and it is by no means easy to deal with; in fact, I do not know anything in the way of wood sectionising that is more difficult to manage. There is this to be said, that no ordinary amount of maceration will be too much for it, and I much question whether any amount, short of a destructive amount, would be sufficient to render it soft enough for the production of a perfect section. Grinding down may be resorted to, but is tedious and unsatisfactory. For the benefit of those who may be disposed to try the grinding-down plan I will give a short account of the process. As thin a slice as possible should be cut, and rubbed smooth on one side, by grinding first on a rough stone and then on a hone. This surface must be cemented on a glass slide by Canada balsam that has been hardened by exposure to the air. Great care must be taken that no air bubbles are included between the surface of the section and the glass slip, or the section will inevitably tear away in those places and spoil the section. The cementing balsam should be kept warm until the adhesion of bark to the slide is thoroughly secured, experience only will give the means of judging when this is, and then allow to cool. If it be in a proper condition the balsam will, when cold, be found hard enough to permit of indentation by the thumb nail; if less hard the section will slip, if harder it may chip off. Of the two faults that of too much hardness is the least objectionable. The section is now to be rubbed upon a piece of millstone grit until as thin as possible without risk of breach of continuity, and finished upon a Canada oil-stone and Turkey hone successively, and finally mounted in balsam. This plan, be it noted, will, with slight modifications, apply to all hard substances as bone, teeth, coal, nut-shells and the like; the harder the substance the better it answers. With nectandra bark it answers fairly well, as well as any plan—which, however, is not saying much—but the difference of hardness, shape and arrangements of the various constituents of the complicated tissue render its application difficult, and the results, excepting by rare good fortune, anything but satisfactory. Grinding down, however, will be the young microscopist's only chance. The other plan is prolonged maceration in warm water—several weeks will not be too long a period; so far as my experience goes, not long enough. A very strong, moderately sharp, and not too highly tempered razor (I find Mappin's shilling razor answer admirably) and plenty of patience may enable one to get one good section out of a hundred attempts, but hardly a complete one, that is one right through the bark. The most hopeful direction, and fortunately also the most useful one, in which to cut the wood is longitudinally and vertically, that is from the bark towards the tree, but downwards. When cut the sections will require special treatment, and this is another reason why grinding down is objectionable. One section should be boiled in alcohol for a few seconds. The only way of doing this is to place the section in a shallow excavated cell with a little alcohol, cover it with the usual thin glass, and boil it over a spirit lamp, adding another drop of alcohol when needed. The alcohol is then to be removed by blotting paper, and glycerine added. The slide is next to be heated to nearly the boiling-point of the glycerine, and retained at this temperature for a few minutes. It is then fit for mounting.

A second section is to be treated with spirit, with water, and finally with nitric acid for half a minute. The acid is to be removed, the section washed with water (on the slide), and mounted in glycerine. A third section is to be treated with spirit and liquor potassæ, and well washed from all traces of both; then thoroughly dried at a low temperature, and finally mounted in thick balsam, inclusion of air bubbles being entirely disregarded. Magenta and sulpho-chromic acid are the other most useful reagents, but I do not know that the results gained by their use will compensate for the trouble in preparing additional sections.

The structure of Nectandra bark, as I have said, is exceeding complex. It somewhat resembles that of cassia, but is even more complicated, and each point of structure, whilst of the same type as in cassia, is dissimilar from the cassia tissues, so that whilst there is an unmistakable family likeness, there is a strong dissimilarity. The first thing that strikes one is the extent to which consolidation by deposition of secondary matters has gone. Nearly the whole tissues are thickened, the only exceptions, excepting the exterior cells, being resin receptacula and a few liber or semi-liber cells. The whole of the cortical structure, in fact, being an aggregation of Hassall's stellate cells; very much thickened, and altogether abnormal liber cells; thickened, variously shaped parenchyma; and special receptacula for resin or colouring matter; these last also presenting novel features.

The so-called stellate cells may be grouped as follows, including herein all the ordinary cortical cells other than liber. There are, first, the oval, much thickened cells of the rays of the bark. These have a much larger cortical cavity than the other cells, are porous, and the successive layers of thickening substance are not easily distinguishable without the use of reagents. These cells are best seen in the balsam-mounted slide, as also are those next to be mentioned, and the resin receptacula. Secondly, there are cells of too varied a shape to be very well described; all forms except oval are represented amongst them. Some few have a very large central cavity, porous of course, and are very angular. The majority, however, are nearly filled with the sclerogenous deposits, of which the successive layers are usually very evident. The pores of these cells are very numerous; and sometimes so fine as to give rise to false appearance, unless carefully illuminated. Certain liber wood cells have been very peculiarly modified by the pressure of the hardened stellate cells, and when isolated are not unlike the longer spiculæ of some species of *Gorgonia*. They are thin-walled and not visibly porous. Other wood cells are very little thickened, are more or less fusiform, and minutely porous. The receptacula are usually oval, sub-cylindrical or sub-globose cells, thin-walled, the walls being little affected by the coloured contents of the cells, and are somewhat irregularly distributed.

In conclusion, the structure of Nectandra bark is so exceedingly characteristic that any ordinary adulterant could at once be detected by the use of the microscope. The botanical student will find it worthy of special study, and, save for the difficulty of preparation, even the ornamental microscopist, who only cares for pretty things, will find it an interesting object; so much indeed is this so, that it is rather surprising that sections are not currently sold by the professional mounter.

MILK TESTING.

BY THOMAS GARSIDE.

I wish to point out a fact, in connection with the estimation of cream in milk by means of the lactometer, which I have not hitherto seen noticed, namely, the great difference in the results which a slight variation in the temperature produces. In Dr. Hassall's article on the estimation of the cream, given in his work 'Adulteration Detected,' I do not observe that any account is taken of this; the only reference to temperature which I find being in the following terms:—"Cream forms more quickly in warm than cold weather; and in making comparative observations on a number of samples, it is proper that each should be set aside in lactometers at the same time, and for the same period" (p. 225). Provided that the lactometers were all maintained at the same temperature, this method would give accurate results for the samples operated upon; but, as the following experiments will show, no dependence could be placed upon them unless the latter condition were complied with, nor could any set of observations be of use for comparison with another set unless the temperature were maintained at the same point.

In each of the following cases two graduated tubes were filled with milk from the same pail, as supplied in the usual way by the dealer, and a uniform temperature was maintained during the time mentioned. I may also state that in several other experiments of which I kept no record, no increase in the quantity of cream was perceived after three or four hours:—

No.	Hours.	Temperature Fahr.	Apparent percentage of cream.
1.	4	43°	14.
		55°	$8\frac{1}{2}$.
2.	4.	45°	12.
		60°	8.
3.	2.	45°	14.
		60°	12.

EMULSIONS.*

BY P. W. BEDFORD.

Although much has been written on the subject of emulsions, and various methods recommended for the more perfect emulsifying of oils and balsams, the old method of making a solution of gum arabic (sometimes using with it a portion of sugar) of about the same consistence as the article to be emulsified, and gradually adding the remaining portion of water, is that usually adopted. The objection to this method is that frequently the oil or balsam separates almost in its original bulk and does not readily become admixed. To my assistant, Mr. A. W. Peck, I am indebted for the suggestions, and for a series of experiments in which glycerine was used in connection with gum arabic, and the result is very gratifying. The general rule adopted has been to employ for each ounce of the oil or balsam one-half ounce of gum arabic, in powder, and one-half ounce of glycerine. The glycerine is mixed with an equal bulk of water, the gum arabic is incorporated with this in the mortar, then the oil or balsam is added, with constant trituration, and finally the remainder of the water gradually added. The oil or balsam should not be over one-fourth of the whole mixture.

Emulsions made in this way, while presenting no novelty in method of admixture, certainly keep more miscible, with but scanty separation of the oil or balsam, which separation does not apparently increase by standing, and, as compared with emulsions made by the ordinary method (without glycerine), are much superior. A series of parallel experiments with cod-liver oil, castor oil, balsam copaiva and turpentine show the superiority of glycerine in making the emulsion. Even balsam of tolu can be readily incorporated and emulsified to the extent of one part in eight.

The antiseptic properties of glycerine are noticeable, from the fact that the emulsions are more stable, and, so far as the experiments have hitherto extended, the emulsions show no disposition to become sour by keeping.

OLEATE OF MERCURY AND MORPHIA.

BY CHARLES RICE.*

This combination, suggested by Professor John Marshall, F.R.S., and first prepared by Mr. Frank Clowes, has been in considerable demand in New York,† but its preparation offers some difficulties, which do not seem to have occurred to Mr. Clowes, owing to a difference either in the character or quality of the solvent, or in the manipulation.

In using pure oleic acid as a solvent for oxide of mercury no difficulty is encountered, the oxide—both the red and the yellow varieties—being completely soluble in it, without any, or with only a very slight reduction to the metallic state.‡ This is not the case, however, with the commercial oleic acid, at least that which I have been able to procure in New York. It is, like the English, a residuary product in the manufacture of stearin candles, commercially termed "Red Oil," has a deep sherry-wine colour and a peculiar greasy odour; exposure to moderate cold causes the separation of a considerable amount of solid acid, consisting chiefly of palmitic acid. Its sp. gr. is 0·895 at 62° F. This substance cer-

* From the 'American Journal of Pharmacy.'

† Nearly ten years ago, Professor Attfield, in a paper published in the PHARMACEUTICAL JOURNAL, 2nd Ser. vol. IV. page 389, on a method of dissolving alkaloids in oils, directed attention to the fact that oleic acid readily combines, not only with morphia, quinia and ten or twelve other alkaloids, but also with the oxides of lead, mercury, zinc and iron. The following sentence from his paper may prove suggestive to some of our readers:—"Doubtless all bases form oleates, thus affording means whereby such preparations may be administered internally or externally in a true state of solution in oils, ointments or liniments." The Professor states that one firm recently told him they annually sent out between one and two thousand bottles of cod-liver oil and quinine prepared by this process. A few years since he found a combination of this kind alluded to in an old volume of the 'Journal de Pharmacie.'—ED. PHARM. JOURN.

‡ The only objection to the employment of the pure acid is its high price.

tainly dissolves the oxide of mercury, but it requires a greater degree of heat than the pure acid to affect the solution, while at the same time some of the oxide is invariably reduced to the metallic state, owing to the presence of some readily oxidizable impurities in the acid, or perhaps due to the oxidation of the acid itself. The amount of reduction is in direct proportion to the degree of temperature employed, as might have been anticipated, and was proved by a number of experiments:

192 grains of oxide of mercury, corresponding to 177·7 grains of metallic mercury, heated with ten times the weight of oleic acid, gave the following reductions:—

At 300° F. amount of reduced Hg	.	175 grains.
At 280° F. ,, ,,	.	152 ,,
At 212° F. ,, ,,	.	69 ,,
At 200° F. ,, ,,	.	35 ,,

Between 200° and 180° F. the amount of reduction varied between 20 and 40 grains, according to shorter or longer exposure to heat; but I have been unsuccessful in effecting a solution unaccompanied by reduction. This makes it necessary to estimate the strength of each fresh lot of solution.

The strength of the preparation as prescribed by different physicians has varied from twenty per cent. to two per cent. of oxide of mercury, with variable quantities of morphia; but of late a uniform strength of six per cent. of oxide of mercury and two per cent. of morphia is deemed sufficient for most purposes, and the following is the process which I employ for its preparation:—

Expose the commercial oleic acid to a temperature of 40–50° F., and express the liquid portion, which is oleic acid, deprived of the greater portion of the accompanying solid acids. Take of oleic acid, prepared as above, 1536 grains; oxide of mercury, perfectly dry, 192 grains. Rub the oxide in a mortar with some of the oleic acid to a smooth paste; add the remainder of the acid; place the mortar on a water bath, and promote solution by frequently stirring, taking care not to allow the temperature to exceed 200° F.

As soon as all the oxide has disappeared, or rather as soon as the undissolved residue is of a pure grey colour, remove the mortar from the water bath and allow it to stand for twenty-four hours. Then pour off the clear solution into a tared capsule; wash the residue thoroughly with ether, and add the washing to the liquid in the capsule. Expose the latter to a very gentle heat, until all the ether has evaporated, and weigh. The residue, after being properly washed and carefully dried (without heat), may be weighed as metallic mercury, which is in practice sufficiently correct.

Supposing the weight of the obtained solution to be 1698 grains and the weight of the reduced mercury to be thirty grains (assuming therefore that there has been no loss incurred during heating and during the subsequent washing of the residue, whilst in practice a small loss always occurs), we first calculate the amount of HgO_2, to which the thirty grains Hg correspond:—

$$\begin{array}{cc} Hg & HgO_2 \\ 200 : 30 = & 216 : 32{\cdot}4 \end{array}$$

The solution, therefore, weighing 1698 grains, only contains 159·6 grains of HgO_2 or 9·4 per cent.

This solution is now to be reduced to the strength of six per cent. by the addition of more oleic acid, until it weighs 2660 grains, but we also want two per cent. of morphia. The balance wanting (2660 — 1698 = 962 grains) is obtained by dissolving fifty-three grains of morphia in 909 grains of oleic acid and adding it to the first obtained solution of 1698 grains, making a dark brownish-red liquid, of sp. gr. 0·975 at 60° F, and containing six per cent. (159·6 grains) of HgO_2, and two per cent. (53 grains) of morphia.

It is scarcely ever used for the purpose of producing the constitutional effects of mercury, but rather as a resolvent for articular anchylosis, and it has produced excellent effects in cases of chronic articular rheumatism and in gout, by removing the stiffness and producing flexibility of the joint.

After writing the above the author succeeded in obtaining a sample of oleic acid, which dissolved the oxide completely, and, if previously separated by cooling from the solid acids, did not produce the least reduction. He also found that a much lower degree of heat was sufficient to effect solution (160°–180° F.). A lot of oxide of mercury mixed with half its weight of carbonate was employed in a few instances, and gave even better results than the oxide alone. The resulting product, made with this kind of oleic acid, was of the consistence of thin cream and of a light brownish-yellow colour.

A sample of the English oleic acid, expressly imported by a friend, gave invariably a greater or lesser reduction, and so did all the other varieties tried, with the exception of the last.

THE MORE IMPORTANT SUBSTITUTES FOR GUNPOWDER.

BY F. A. ABEL, F.R.S.*

(*Continued from page* 569.)

Although gun-cotton and nitro-glycerine mixtures possess very important advantages over gunpowder in all applications where suddenness and violence of action are desirable, there are some directions in which they do not possess superiority over powder, and others in which they cannot replace it, irrespectively of its applications to projectile purposes. In soft rock, in earth mines, and in some blasting operations, when it is desired to *displace* large masses of earth, rock, or stone, the gradual action of gunpowder gives it decided superiority. The more violent explosive agents produce great local effects; the rock, if hard, is much shattered near the charge, and is also rent and fissured to considerable distances, but the *displacing* effect is generally inferior to that produced by the equivalent of powder, and always very much so in earth or soft rock. Decided advantages have arisen from a judiciously-combined application of gunpowder and gun-cotton or dynamite, the more violent explosive agent being used to prepare the way for gunpowder, which is afterwards applied to the removal of the material shattered by the first sudden explosion.

The degree of safety with which explosive agents may be manufactured is an important question connected with their extensive application. The fact that the manufacture of gun-cotton as now carried on involves not the slightest risk of explosion up to the final stage, when the material has to be dried, distinguishes it from most other explosive agents. In gunpowder-manufacture liability to explosion exists throughout all operations from the point when the ingredients are mixed, and with regard to nitro-glycerine it appears that up to the present time occasional severe accidents during manufacture

* Read at the Royal Institution of Great Britain, on Friday, May 17th, 1872.

have been inevitable. The immunity enjoyed by gun-cotton is due to its being wet, and therefore absolutely uninflammable, throughout all stages, even after it has been compressed into cakes or disks. At this point it contains 15 per cent. of water, the expulsion of which by desiccation is unattended by any liability to explosion, or even to ignition if very simple precautions are adopted. For storing large quantities with absolute safety it is very convenient to preserve the compressed gun-cotton damp, as it is delivered from the presses. It has been thus stored for very long periods without the slightest detriment, and its non-inflammability in this condition is aptly illustrated by the fact that the perforations required in some of the charges are produced by drilling the damp gun-cotton, the drill revolving at the rate of about 600 revolutions per minute. The gun-cotton employed in some extensive experiments recently made on the South Coast had been stored damp for nearly nine months, and was dried partly in the open air and partly in a hot-air chamber, when required for use. On that occasion 6 cwt. of damp gun-cotton, packed in twenty-four strong wooden boxes, were stacked in a wooden shed and surrounded by inflammable material. The building was then fired, and soon burned fiercely, which it continued to do for about half-an hour, when the fire gradually subsided, and the building and its contents were entirely consumed. The gun-cotton must have slowly burned away as the surfaces of the masses became sufficiently dry, but at no period of the experiment was there even any burst of flame, due to rapid ignition, perceptible.

Another very important consideration connected with the extensive employment of an explosive compound or mixture as a substitute for gunpowder is the question of its stability. Mixtures of saltpetre or potassium chlorate, with oxidizable substances of stable character, may be generally relied upon to equal gunpowder in their unalterable nature, under all conditions of storage and use in different climates; deterioration in explosive power by the absorption of moisture is the only prejudicial result which generally attends long-continued keeping of such mixtures. There are a few instances, however, in which absorption of moisture may in time establish slight chemical action between the components, and thus become, not only cause of more serious deterioriation, but also a source of danger; as chemical activity, once started in preparations of this kind, may gradually increase, being promoted by the heat developed, until it attains a violence resulting in the spontaneous ignition or explosion of the mass. Instances are on record of the spontaneous explosion from this cause of damp mixtures, well known to be perfectly stable when dry. Substances of organic origin, of uncertain stability, require application with much greater caution to the production of explosive mixtures, as it is possible that changes may occur spontaneously in them, or may be established by natural atmospheric fluctuations of temperature, eventually giving rise to chemical action between them and the oxidizing agent with which they are mixed. Although the stability of *compounds*, which are themselves endowed with explosive properties, may appear perfectly reliable when the substance is in a chemically pure condition, it is susceptible of being seriously affected by comparatively minute causes; hence the most scrupulous care in the production and purification of such substances is imperatively necessary; and in this respect they compare disadvantageously with gunpowder, as a want of care in its production, though it may lead to accident during manufacture, or to an inferiority of the product, will not affect the stability of the material.

Both nitro-glycerine and gun-cotton, when prepared in small quantities and carefully purified, have been long known by chemists to be subject to very gradual chemical change when exposed frequently to sunlight, and also to be liable to slow or rapid decomposition if exposed to temperatures very considerably higher than occur as extremes under natural conditions in any climate. Both substances are also well known to have exhibited great stability under normal conditions of preservation, and even when continually exposed to light; but though many specimens exist, which have remained unaltered almost since the first discovery of these bodies a quarter of a century ago, the instances are numerous in which laboratory specimens have undergone spontaneous change, with more or less rapidity.

The apparently variable nature of these substances, as regards stability, is due to the retention by them, in some instances, of small quantities of comparatively unstable impurities, derived from foreign matters contained in the cellulose or glycerine; exposure to heat or to sunlight developes changes in these, resulting in the production of acid substances; hence, if they exist in gun-cotton or nitro-glycerine, they may constitute the starting-point of decomposition when these are exposed to high temperatures or to the influence of sunlight. If they exist in gun-cotton, they will be, to some extent, enclosed in the hollow fibres, and are then only removed effectually by breaking up the latter, and long-continued washing. In nitro-glycerine, they are held obstinately dissolved by the liquid, and their removal can also only be effectually accomplished by a long-protracted washing of the very finely-divided substance. Alkaline agents are in both cases useful in accelerating purification.

For many years nitro-glycerine was universally regarded as specially liable to spontaneous change; even samples of different quantities of several pounds each, which, within the last four years, were produced at Woolwich in immediately successive operations, all apparently under the same conditions and with the special object in view of obtaining a thoroughly purified and stable material, have exhibited great differences in their keeping qualities. They have all been preserved in the dark, side by side; some are now in their originally pure condition, others have become more or less strongly acid, and two or three have undergone complete metamorphosis into oxalic acid and other products. The manufacturing and purifying processes, as perfected by Mr. Nobel, appear to furnish more reliably uniform products than those usually obtained on a small scale, and such specimens of these products as the lecturer has had an opportunity to examine have exhibited great stability. Yet, if it were possible to trace explosions to their cause more frequently than is the case, an accidental want of stability might perhaps have been found, in some instances at any rate, auxiliary in bringing about the violent nitro-glycerine explosions which have occurred. It has, however, been already established by very extensive experience during the last three years that nitro-glycerine is a far more reliable material than was formerly believed, and that if the most scrupulous attention is paid to its purification, and is combined with vigilance during storage and use of its preparations, and the adoption of certain precautions, which have already been proved important safeguards against chemical change in materials of this class, the risk of accident is so greatly reduced as to warrant the extensive manufacture and employment of nitro-glycerine preparations under restrictions similar to such as may be deemed sufficient in the case of other explosive agents.

The causes which led to the great uncertainty with regard to stability exhibited by gun-cotton, as manufactured in the earlier days of its history, have been discussed in former discourses. The very extensive experiments and observations which were set on foot nine years ago by the Government Committee, and have been continued to this day, on the keeping qualities of gun-cotton prepared by the Austrian process. have furnished most satisfactory results. Very considerable quantities of gun-cotton, in a great variety of forms, have been stored at Woolwich for several years, and their periodical examination has failed to afford any reason whatever for doubting the stability of gun-cotton under all conditions of storage which are likely to occur. The experience thus gained applies even more favourably to gun-cotton reduced to pulp according to the system lately in use, whereby the uniform purification of the gun-cotton is more effectually secured. Compressed gun-cotton has not only been stored extensively in different parts of Great Britain; it has also been exported in considerable quantities to Australia, India, the West Indies, South America, and other distant countries, and has been used under circumstances specially trying to any material of uncertain stability.

The explosions which occurred at Stowmarket nine months ago had the natural effect of dispelling from the public mind the great confidence which was becoming very generally entertained in the stability of gun-cotton. Fortunately the facts which were elicited in the course of the inquiry constituted so complete a chain of evidence as to place the first cause of the explosion beyond any reasonable doubt, and to demonstrate that it was quite independent of any want of stability of the properly-manufactured material. A supply of gun-cotton delivered from the works at Stowmarket, forming part of a quantity of which there remained a store in the magazines that exploded, was found to contain a proportion of disks in a highly impure condition. The proportion of free (sulphuric) acid existing in some of these was so considerable that it could not possibly have been left in the gun-cotton after the first rough washing which it receives immediately on removal from the acid, and *before* conversion into pulp in the rag-engines, where it is beaten up for several hours with a very large volume of water. Supposing, therefore, that the gun-cotton pulp composing these disks had been submitted to the compressing process without passing through the intermediate and principal purifying operation, it could not possibly have contained even a small proportion of the sulphuric acid discovered in the impure disks, and the same would have been the case even if the *un*-pulped gun-cotton, after the preliminary washing and ringing, could have been converted into compressed disks. It was indisputably established, therefore, that the sulphuric acid discovered in the impure gun-cotton, and which could not have been generated by any decomposition of the substance, must have found its way into the finished material in some manner totally unconnected with the process of manufacture, and that no amount of carelessness in manufacture, even to the extent of partial omission of the purifying processes, could have led to the existence of the acid found in the impure gun-cotton. That this impurity was sufficient to establish rapid change was sufficiently proved by the condition of some of the disks; and that this chemical change, accelerated as it was by the great heat of the weather at the time, gave rise to a development and accumulation of heat inevitably culminating in the ignition of some portion of the stored gun-cotton, was readily demonstrated by simple experiments with some of the impure disks themselves. But although the *ignition* of the store of gun-cotton in the lightly-built magazines at Stowmarket was completely accounted for, the very violent character of the explosions, and especially that of the second explosion of a small store, which was burning for a considerable time before its contents detonated, were results quite unexpected to those well acquainted with the properties of gun-cotton in the compressed form. Many practical experiments had demonstrated that it might be submitted to extremely rough treatment without any risk of explosion, and single packages of the closely-confined material had been repeatedly ignited, from within and without, no other result than an inflammation and a rapid burning of the gun-cotton having ever occurred. These demonstrations of the apparent immunity from explosive properties of compressed gun-cotton, unless very strongly confined or fired by detonation, appeared fully confirmed by the results of a somewhat extensive experiment made at Woolwich a year ago with gun-cotton packed in firmly-closed wooden boxes, of the kind which Government proposed to use for storing the material. Eight such packages, each containing 28 lb. of gun-cotton, were enclosed in a pile of similar boxes loaded to the same weight, and the contents of the centre box were ignited: no explosion resulted, and the contents of some of the boxes even escaped ignition A second experiment, in which the centre box was surrounded by inflammable matter, so that a fierce fire burned within the heap for many minutes before the gun-cotton ignited, was also unattended by any approach to an explosion. The apparently conclusive nature of these experiments undoubtedly encouraged a false confidence in the non-liability to explosion of stores of gun-cotton in the event of accidental ignition, and the Stowmarket catastrophe demonstrated the imperative necessity for a more extensive investigation of the subject. The results of some experiments recently instituted near Hastings by the Government Committee on gun-cotton have served to throw great light upon the manner in which the explosions at Stowmarket were brought about. In the first instance, twenty-four boxes (containing 6 cwt. of gun-cotton) of the kind used in the Woolwich experiment were stored upon tables in a small wooden shed of light structure, and a heap of shavings and light wood was kindled immediately beneath the boxes, two of which were left partly opened. After the fire had been burning for about seven minutes the gun-cotton inflamed and continued to burn with very rapidly-increasing violence for nine seconds, when a sharp explosion occurred; a very similar result was furnished by a second experiment, in which the same number of boxes of gun-cotton was stored in a small magazine of stout brickwork. By subsequent comparative experiments it was judged that a considerable proportion of the gun-cotton had been burned in both instances before the explosion occurred, but these were nevertheless of such violence as to produce large craters in the shingle on the site of the buildings and to project the *débris* with much force to considerable distances. Two repetitions were afterwards made of the first experiment, in wooden sheds of similar structure, and with corresponding quantities of gun-cotton similarly arranged in boxes of the same size, and fastened down just as securely as those in the former experiment, but the boxes were made of somewhat thinner wood and were constructed less strongly. In neither of these experiments did an explosion occur. In the one instance the fire was burning in the building for more than half an hour before the gun-cotton became ignited, and three minutes after the first great blaze had subsided there was a second blaze of gun-cotton. Although the latter must have been exposed to intense heat, no explosion was produced. In the second experiment the gun-cotton burned in three successive portions, the last having been exposed for many minutes to very fierce heat, yet burning non-explosively. The first two of these experiments demonstrated that if, in a store containing packages of gun-cotton in somewhat considerable number, the material became accidentally inflamed, the intense heat developed by the burning gun-cotton in the first instance might raise some portion, still confined in boxes, to the inflaming point, and that then, the mass of the confined gun-cotton being in a heated condition, the ignition would proceed with such rapidity as to develope the pressure essential to explosion while the gun-cotton was still confined, the resulting explosion being instantaneously transmitted to other boxes. When the magazines at Stowmarket exploded, a large volume of flame was observed to precede the explosion by a very distinct interval. The two other experiments described appear to demonstrate that *with such quantities* of gun-cotton as were stored in the experimental sheds, the fact of the material being confined in boxes of comparatively light structure constitutes a safeguard against explosion, the reason being that the weaker packages are opened up by comparatively feeble pressure from within, hence when the contents of a box become raised to the inflaming temperature, or become ignited by the penetration of flame to the interior, the pressure developed by the first ignition is not sustained by the box to a sufficient extent or for a sufficient time to bring about explosion.

On the occasion of the Stowmarket accident there were two storesheds containing gun-cotton packed in boxes of light construction, which were ignited by the first explosion and burned out without exploding, while a third, which contained gun-cotton packed in the strong Government boxes, exploded with great violence after having been in flames for some time.

Simple experiments demonstrate that if any explosive compound or mixture be ignited when in a heated condition, it will burn with a violence proportionate to the temperature to which it has been previously heated; if this be near the exploding point, explosion must ensue, which will be violent in proportion to the strength of confinement of the material. A practical demonstration of this was furnished by an explosion which occurred at Woolwich in 1866. Several very strong packages (metal lined-cases) filled with Von Lenk's gun-cotton, some of which had been purposely left impure, had been exposed for seven months to artificial heat in a strong brickwork chamber, heated by steam. The impure gun-cotton in some of the packages was then known to be in a decomposing state, but the experiment was continued, and eventually spontaneous ignition occurred and at a time when the boxes were heated to the maximum temperature. The result was a violent explosion of all the packages; the very strong confinement and the heated condition of the gun-cotton which ignited, added to its being at the time in a state of chemical activity, determined its explosion, and the explosion of the other packages was a necessary consequence of the violent concussion to which they were exposed.

There can be no doubt that the results of the recent experiments and of those made last year, as also the results of the Stowmarket accident, have to be considered in relation to the *quantities* of gun-cotton operated upon, as well as to its confinement. The confinement of the *eight* strong packages by the layers of boxes which surrounded them on all sides in the Woolwich experiment, was probably quite as great as that afforded by the light and roomy shed in which the twenty-four boxes of the same kind were placed in double layers, in the South Coast experiments; yet in the latter case an explosion was developed, and not in the former with the smaller quantity. In the South Coast experiments, with 6 cwt. of gun-cotton, the explosions occurred eight seconds and ten seconds after the ignition of the gun-cotton; in the Stowmarket magazine, where several tons of gun-cotton were stored, the explosion appears to have *almost* immediately followed ignition; it must be borne in mind, however, that in this case much of the gun-cotton was very closely confined by the large number of surrounding packages, and that the temperature of the gun-cotton was already raised considerably throughout by long-continued very hot weather. Both of these circumstances must have greatly favoured the very rapid development of explosion, independently of the much more intense heat generated by the rapid spreading of fire through a large proportion of the gun-cotton.

The satisfactory results obtained in the South Coast experiments with the lightly-constructed boxes, with employment of 6 cwt. of material, appear to have received confirmation from the result of an accident which occurred in 1869 at Penryn, when a magazine of brickwork containing 20 cwt. of compressed gun-cotton, packed in boxes of light structure, was burned down without any explosion. But it is nevertheless very possible that a similar result would not be furnished by several tons of gun-cotton similarly packed; the much higher temperature which would be developed in that case by the first spreading of the fire, and the additional confinement, due to the larger number of packages, might combine to develope conditions favourable to the violent explosion of some portion of the mass, though no doubt a much larger proportion would burn non-explosively than if strong boxes were used. While, therefore, in storing *dry* gun-cotton, the probability of violent explosions resulting from the accidental ignition of a magazine may be considerably diminished, or at any rate the violence of a possible explosion much reduced, by storing the material in packages of which some portions will yield readily to pressure from within, or by adopting any other storage arrangement whereby the rapid penetration of flame or heat between the compressed masses is promoted, it must be considered as conclusively established by the last twelve months' experience that such regulations as experience and prudence have rendered essential in connection with the storage of gunpowder and other explosive agents, must also apply to the storage of compressed gun-cotton when in the dry state.

The rapid development which has taken place within the last few years in the industrial applications of powerful explosive agents bids fair to continue. In illustration of this a brief reference may be made to some recent interesting results arrived at by Dr. Sprengel, who has observed that mixtures of liquid oxidizing agents (such as nitric acid) with liquid or solid oxidizable substances, may be made to detonate, as also mixtures of readily oxidizable liquids with solid oxidizing agents. Thus, mixtures of picric acid or of nitrobenzol with nitric acid, or of chlorate of potash with bisulphide of carbon, may be readily detonated, and are more or less violently destructive in their action.

Important advantages, in point of power in the one instance and of economy in the other, appear to be promised by the production, in compressed masses, of mixtures of gun-cotton pulp with *considerable* proportions of chlorate of potash or saltpetre. Even the efficiency of gunpowder itself as a mining agent has been decidedly augmented in some directions by the lecturer's observation that it is susceptible of violent explosion by detonation, like all other explosive preparations, and that strong confinement is consequently not essential to the development of its full explosive force. This observation has proved to be especially valuable in connection with submarine operations, for which the charges of gunpowder need no longer, as formerly, be confined in cases of great strength. There are several other directions in which the study of the behaviour of explosive agents, under conditions compatible with their practical application, promises to be fruitful of important results.

RETAIL TRADERS, BEWARE!

Mr. Punch begs to apprise the Retail Trade that its time has come. Up with all the Shutters! Announce Sale by Auction at any Sacrifice. Listen to the *Lancet*:—

"The fact is, that retail trade is gone mad. There are far more shopkeepers than the wants of the public require, and they think themselves entitled to all the luxuries and enjoyments of life. Their wives, glorious in sealskin-jackets and redundant jewellery, are to be seen everywhere; and the pretensions of the class are becoming a nuisance that it is high time to put down."

Put it down, then—pretensions, class, sealskin-jackets, and all! *Surge, carnifex!* The *Lancet* and the Profession have the matter in their own hands. If every Medical Man will undertake to exterminate—of course in a regular way—a single streetful of retailers and their families, the business may be done in the twinkling of a pestle and mortar.

"Charge for the golden guineas. Upon them with the—
Lancet."

The Pharmaceutical Journal.

THE "CHARGE FOR DRUGS."

It is not surprising that the sensational lucubrations of the *Globe* on the Price of Drugs should exercise a sort of infectious influence on the general press, but we must confess our astonishment at finding this the case with a journal so generally well informed and judicial as the *Medical Times and Gazette*, which, in the number for last week, not only adopted and reiterated the unfounded assertion as to extortionate charges by druggists, but also accused us of affirming it to be "only just and right" that decent poor people should be driven to hospitals for medicine as well as advice. This is so contrary to what was said on the subject, that if we were mischievously disposed it might be called misrepresentation. And if the druggists' charges for dispensing were proved to be exorbitant, it might, perhaps, be worth while for a medical journal to inquire how far the prescriber is *particeps criminis* in the manner pointed to in the evidence of a physician in a case reported at page 595. The other comments of our contemporary are, to say the least, illiberal, and we trust it is not a general idea of those who write prescriptions, that so little skill as the amount now required by law is sufficient for performing the onerous work of dispensing them. If that were the case in practice, the extermination "in a regular way" suggested by *Punch* might be more general, and not always confined to surplus retailers and their families.

As regards the *Globe*, we did hope that the appearrance last Friday week of a quotation from the Pharmacy Act for the purpose of showing that it did not involve annihilation of all those who had been in the business before the Act passed, might be regarded as an indication that the labours of that "mountain" were at an end. But the estimation of chemists and druggists by the relics of the past was not enough for the *Globe* inquirer, and last Tuesday we were favoured with a scolding for meeting "criticism" with virulent abuse, etc., etc. However we need not follow this writer further, since he has become bewildered, no doubt inextricably, by the notion that the use of brains in dispensing is worth more than the material operated with. We dare not hope to help him and can only deplore his sad disability.

We have received from a correspondent a printed slip with the heading, "Measure for Measure," and we think that the reproduction of its contents may at least serve the purpose of illustrating the mischief that may be done by a bad example. The source of inspiration will, no doubt, be sufficiently apparent

"A contemporary of ours has lately been taking a practical method of determining the scale of doctors' fees, and has arrived at the conclusion that no Medicos are satisfied with a fair professional profit, and that the charges of most are so exorbitant as to render it useless for any moderately poor person to think of getting advice outside of a hospital.

"The course pursued in the inquiry was to seek advice in the treatment of simple catarrh, or cold in the head, requiring neither great attention nor elaborate surgical skill. The estimated value of such advice according to competent authority is, including pen, paper, and time, *five pence*—an estimate that probably errs on the side of excess.

"The case was taken and laid before a number of medical men from Billingsgate to Brook Street, and a reduction of fees was asked for, and in almost every instance obtained, on the score of the poverty of the sick person. Nevertheless, the fees actually varied from 2*s*. 6*d*. to 23*s*. 6*d*. (including 2*s*. 6*d*. for medicine).

"The medicine prescribed would, according to the directions, last only one-third of a week, and as one other consultation only would be given for the original fee, it would thus entail on the patient a weekly charge ranging from 7*s*. 6*d*. to 49*s*. 6*d*. Our contemporary justly remarks that even the first would, in many cases, be prohibitory, and the patient driven to a druggist or hospital.

"We regret that the test was not carried a step further, and that means were not taken to test the charges of the *élite* of the profession.

"It is possible under the circumstances no advance might have been made, and that a sort of average might have been struck by charging the rich extra, to pay for the poor. We, however, know of long illnesses which have been almost ruinous to patients in respectable but not affluent circumstances.

"Zealous for the interests of 'Enlightenment and Popkins,' we pushed our investigations somewhat beyond the limits observed by our contemporary and peeped through the surgery window and into the drawing-rooms. There the mystery was solved.

"The fact is medical men are gone mad, and there are far more of them than the wants of the public require, and they think themselves entitled to all the luxuries and enjoyments of life. Their wives, glorious in satins and real sables, and resplendent in jewellery, ride and drive the best horses, give the best dinners, have the best opera boxes, and take the best physic, while their children have nightly juvenile parties, with Conjurors, Punch and Judy, and the Magic Lantern, and other extravagant amusements; they eat the choicest bonbons, and jingle the most costly rattles.

"The pretensions of the class are becoming a nuisance that it is high time to put down."

This is all very well as a "squib," but the relations between medical prescribers and pharmacists deserve and require to be treated in a more serious mood, though it is evident that if disparagement is to be the rule, it is as applicable in one case as in the other.

The contemptuous tone in which the *Lancet* speaks of chemists indicates a jealousy of their rising importance unworthy a journal claiming to represent a class generally characterized by gentlemanly feeling. The vulgar abuse, which has been noticed by several of our correspondents, would, we are sure, be disavowed by the best members of the profession. Not so wise as its contemporary, the *Times*, which can mould itself to public opinion so as to do no violence to common sense, the *Lancet*, adhering to old views and manners, ignores the changes of time. The chemist of to-day, qualified by years of study, not less severe than that of the medical practitioner, and tested by as severe an examination,—the exact and careful dispenser, who understands the nature of the potent agencies he handles, now kept by law out of less skilful hands,—will not be deprived of the growing estimation of his services by unreasoning depreciation or contempt. We confidently believe also that the time is fast approaching, although the *Lancet* sees it not yet, when medical men themselves will abandon their slovenly methods of preparing medicines, and gladly avail themselves of the services of the best chemists, regardless of the furs and jewellery which their skilled labour may provide for their wives and daughters.

The public know perfectly well that chemists, entrusted with duties in which life and death are involved, are not to be remunerated by the mere profits of retail trade, any more than medical practitioners; and the writer in the *Globe* should, if he desired really to make his inquiry of any use, have gone further, and ascertained what would have been charged for his test pills and mixture by medical men who dispense and furnish their own medicine. We may safely affirm that the price would have gone still higher, and that the minimum instead of eightpence would have become, at least, four shillings and six pence in a doctor's bill.

The best hope for medical men and chemists lies in maintaining mutual good understanding. And it is to cultivate this more generally that the efforts of both classes should be directed. They can assist each other materially in many ways. It is, therefore, to be regretted that so important a journal as the *Lancet*, instead of endeavouring to promote good feeling between prescribers and dispensers, should use language which can only tend to engender animosity, and neutralize the good each could do the other. The mission of the *Lancet* is not to foster arrogance in medical men, nor to provoke chemists to imitate its own vulgarity, and say, "the pretensions of the class are becoming a nuisance that it is high time to put down."

PHARMACEUTICAL WOMEN.

When some months ago a correspondent inquired whether women were admissible to the examinations of the Pharmaceutical Society we felt constrained to state what seemed the natural consequence of legislative recognition of Mr. Stuart Mill's definition of the word "person." Since then the lecture classes of the Society's school have comprised several female students, and by the report of the examinations published in this Journal it appears that two of them have already passed through the first grade of probation for being registered as duly qualified chemists and druggists, one of them heading a list of 166 successful candidates. We are informed that both of these ladies are regularly engaged in dispensing medicine as the avocation by which they gain their living, and that they contemplate following out this career thoroughly may be anticipated from the fact that, in addition to seeking the bare legal qualification, they have indicated their desire to be associated with the Pharmaceutical Society by becoming registered as "Apprentices or Students of the Society. This step will have the effect of placing these ladies beyond the influence of the objection raised at the last Council meeting to the admission of women students to compete for the prizes and certificates given at the end of each Session.

Last week the *British Medical Journal*, in commenting on the decision not to allow the industry of female students the chance of reward offered to male students by the session prizes, said, somewhat irreverently, that it seemed "as though the old women of the Council had determined to keep the young ones back" by doing "their utmost to handicap and discourage them."

We may expect, therefore, that the subject will again come forward at the Council table, and those who voted against Mr. Hampson's motion will either withdraw their opposition or take such steps as will show that they are not open to the reproach of our contemporary.

Meanwhile, it may not be superfluous in regard to this subject, as well as others, to embrace any opportunity of the advantage so earnestly desired by Robert Burns of seeing ourselves as others see us, and for this reason we quote here the following article from the *Pall Mall Gazette*:—

"There has been something like precipitancy if not error in the good words which have been spoken of the Pharmaceutical Society of London for the liberality which appeared to mark the recent resolution of the Council not to exclude women from the lectures on chemistry and botany delivered at their house in Bloomsbury Square. It appears from their late proceedings that what they did was only from a sense of legal necessity, and that they are preparing by side-winds to prevent the concession which they could not easily withhold from affording any real facilities for women to enter upon a career which has been fully open to them until the last few years, and of which some hundreds have availed themselves. The means by which an apparent liberality is made really exclusive, and by which the half-opened doors have been chained so as to deny ingress to women, are in more than one way worthy of attention.

"Until recent legislation converted the business of selling and dispensing drugs into a close guild governed by the Pharmaceutical Society, it was open to all the world. There were many sufficient considerations for that measure. Free trade in poisons afforded facilities to the prisoner and the suicide; the hazards to life incidental to the manipulation and sale of drugs with or without medical prescription were increased by the want of education of the vendor and dispenser, which went sometimes to the extent of complete ignorance of the art of reading ordinary labels and directions involving technical terms, and by carelessness, which permitted the employment of mere children as assistants at the counter. It was not possible to apply educational tests to ordinary traders, nor to impose regulations on an unregistered and motley body of shopkeepers. The Pharmaceutical Society, a voluntary educational body called into existence chiefly by the exertions of the late Mr. Jacob Bell, was therefore erected into a State institution, acting under the authority of the Privy Council. It was invested with very extensive and unique privileges. It combines three functions. Its Council has the power of a guild, regulating the conduct and mode of business in some important particulars of the members of the trade; it is the proprietary owner of a large school, through which candidates for introduction to the pharmaceutical business are passed; and it is the sole examining body which possesses the privilege of examining such candidates and of giving them the right to enter upon the business of chemists and druggists.

"Thus the trade is hemmed in on all sides by a far-reaching monopoly. In granting these powers, certain duties were imposed of which some have been well observed while others have not. The existing rights of persons in business were reserved, and it was provided that no other than educational restrictions should be imposed upon those who were desirous of entering the business. That women, already largely engaged in it, might not be disqualified, the Act throughout employs the word "person" as including both men and women. The course which the Council recently took of admitting women to the lectures of the School of Pharmacy was therefore in accordance with the law. That which they have since taken, of excluding them from the practical teaching of the laboratory attached to it, through which the other students pass, is not in accordance with the law. The law contemplated that in this business men and women should have equal opportunities, and that as some hundred women were before enabled to earn their living in dispensing drugs they should not now be disqualified, provided they equally with men submitted to the required educational tests. The still more recent resolution of the Council to prohibit the women attending the laboratory classes from submitting themselves to the usual examinations or competing for the scholarships and prizes is not less unfair. Is was at first alleged that they had more time at their disposal, and would have a greater chance of acquiring a high degree of knowledge, and of surpassing the male students in examination. If that were so, they would not prove the less valuable dispensers or assistants because they were better informed than the average students; and students possessing greater facilities for reaching a high standard of instruction should in the interests of the public and in the best interests of the trade—precisely those which the Pharmaceutical Society was instituted to promote—be encouraged rather than rejected. But on investigation the statement was found to involve an entirely erroneous view of the facts. Of the three ladies attending the classes during the session two were engaged in extremely laborious work as dispensers holding engagements by which they were occupied from early morning till late at night; and the third, it was stated, was also largely occupied in other pursuits. Moreover, it was known that many of the male students were able to devote their whole time to their studies: and it had never been and is not proposed to exclude them on that ground from competition. Nor is such a course customary on grounds of this kind in any educational institution. The majority which carried the restrictive resolution was narrow, and it may be supposed that the whole consequences and character of the proceeding were not apparent to them.

"The Council of the Pharmaceutical Society consists wholly of tradesmen of a superior class, but not yet accustomed to the kind of responsibilities weighing upon a body entrusted with State powers. A private and voluntary association, such as it formerly was, is free to indulge its fantasies and its tastes. It may be liberal or illiberal within the range of its conceptions; equitable or inequitable according to its standard of judgment or the elasticity of its corporate conscience. They might reasonably resent criticism from without, and propose to do as they please with their own. But in directing public interests and fulfilling public functions they must rise above the considerations of the counter, and consent to consider justly the claims of the most inferior being who can muster knowledge enough to decipher the medical caeograms which pass as prescriptions, distinguish between aconite and horse-radish, sugar the powders and gild the pill for which suffering mortals credulously but impatiently wait. As shrewd tradesmen they may consider the advisability of narrowing the competition among chemists, but as the interpreters of an Act of Parliament they must exclude personal considerations in framing the regulations which guard the entrance to the chemist's shop."

THE CHEMISTS' BALL.

That the Chemists' Ball is now permanently established as an annual gathering, must have been evident to those who were present at the very pleasant reunion at WILLIS's Rooms on Wednesday evening last. We understand that about 340 persons were present, amongst whom were many whose names are familiar to pharmacists as household words.

At the supper, which was good and well served, Mr. Frederick BARRON took the chair, and in giving the customary toast of the evening, "Success to the Chemists' Ball," coupled with it "The Health of the Ladies," and expressed a hope that although he had now been connected with the drug trade five-and-forty years, he might nevertheless live long enough to see the time when a lady would take the chair at the Chemists' Ball. This was received so enthusiastically as to leave no doubt, on the one hand, of the satisfaction the arrangements had given to those assembled, and on the other of the sympathy of the company with the views expressed by the chairman as well as in other quarters. It was mentioned by the Chairman with regret, that two gentlemen, Messrs. BILLING and WARWICK, who had done so much to contribute to the success of the Ball, not only on this, but on previous occasions, were prevented by domestic circumstances from being present.

THE NEW AMERICAN PHARMACOPŒIA.

AMONGST the matters which just now interest the pharmacists of America, the issue of the new edition of the United States' Pharmacopœia will be of paramount importance. It will be seen by a notice on p. 596, which, through the kindness of Professor ATTFIELD, who had received an advance copy, we are enabled thus early to put before our readers, that it has its points of interest for the English pharmacist also. First, in the fact that it is the fifth that has been issued at intervals of ten years, a definite time being thus recognized at which the Pharmacopœia should be modified in accordance with the progress of medical and pharmaceutical science; to this has now been added a resolution authorizing the issue of a fresh edition at a shorter interval if necessary. Secondly, that it is the work of a convention in which delegates from pharmaceutical as well as medical colleges take part. Both these points are worthy of consideration in this country, where, on the one hand, as was recently pointed out by a contemporary, no satisfactory provision has been made for the addition of a new remedy, even when so well established as hydrate of chloral; and, on the other, the responsibility of producing a pharmacopœia is, by the terms of the Medical Act, confined to the General Medical Council. Another matter, which probably will not be without its influence upon a future British Pharmacopœia, is the adoption of the system of nomenclature advocated by Professor ATTFIELD. While on the subject of pharmacopœias it may be mentioned that, in referring to the statement respecting a Universal Pharmacopœia made by Dr. THUDICHUM at a recent evening meeting, the New York *Druggists' Circular* expresses a regret that America is not yet taking part in the discussion.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN EDINBURGH.

January 14th, 1873.

Present—Messrs. Aitken, Buchanan, Gilmour, Kemp, Kinninmont and Young.

Major Examination.

Two candidates were examined. *One* failed. The following passed, and was declared duly qualified to be registered as a "Pharmaceutical Chemist":—

*Heppell, James..............Forest Hill.

Minor Examination.

Five candidates were examined. *Three* failed. The following *two* passed, and were declared duly qualified to be registered as "Chemists and Druggists":—

*Field, Alfred William........Edinburgh.
Beverley, George............Aberdeen.

Modified Examination.

Three candidates were examined, and failed.

Preliminary Examination.

The certificate of the University of Edinburgh was received from the undermentioned in lieu of this examination:—

Donaldson, James............Edinburgh.

EXAMINATIONS IN LONDON.

January 15th and 16th, 1873.

Present—Messrs. Allchin, Barnes, Carteighe, Cracknell, Davenport, Edwards, Gale, Haselden, Ince, Linford, Martindale. and Southall.

Dr. Greenhow was present on the 15th on behalf of of the Privy Council.

Major Examination.

Three candidates were examined, of whom *two* failed. The following passed, and was declared duly qualified to be registered as a "Pharmaceutical Chemist":—

Elliman, Samuel Francis......London.

Minor Examination.

Forty-two candidates were examined, of whom *twenty-five* failed. The following *seventeen* passed, and were declared duly qualified to be registered as "Chemists and Druggists":—

	*Andrews, William Leatham	Scarborough.
	*Bascombe, Frederick	Weymouth.
	*Dodds, William	Hull.
	*Bracher, Walter Phipps	Bath.
	Cooke, William Kendle	Brighton.
Equal.	Pidd, Arthur Joseph	Hulme.
	Rayson, Arthur John	Diss.
	Scott, Ebenezer	Chesterfield.
Equal.	Kirton, Christopher Henry	Hull.
	McKnight, John	Dalston.
Equal.	Adams, Andrew Henry	Montacute.
	Carlton, Thomas Wokes	Hull.
	Green, Edwin	Billinghay.
	Sargent, John Charles	Leamington.
	Harrold, Charles Jesser	Frome.
	Worthington, William	Preston.
	Francis, Charles Ernest	Wigan.

The above names are arranged in order of merit.

Preliminary Examination.

The Certificates of the University of Cambridge were received from the undermentioned in lieu of this examination:—

Smith, Charles Albert........Leeds.
Spence, John................North Shields.

* Passed with Honours.

PRELIMINARY EXAMINATION.

The following is the result of the Preliminary examination, held on the 6th instant:—

England and Wales.

Three hundred and thirteen candidates presented themselves for this examination, of whom *one hundred and forty-seven* failed. The following *one hundred and sixty-six* passed, and have been duly registered as Apprentices or Students:—

	Minshull, Rose Coombes	London.
	Newman, Frederic William	Falmouth.
Equal.	Smith, Peter	Runcorn.
	Wood, George Alfred	Bridgnorth.
	Tottle, Henry John	Bath.
	Pritchard, Samuel Evan	Bangor.
	Legat, William Henry	York.
	Fowler, Charles Henry	Boston.
Equal.	Parker, William Marris	Walcot.
	Trible, Edward	Launceston.
Equal.	Plumbe, Charles Marshall	Mansfield.
	Walton, Edward Bridges	London.
	French, Herbert Walter	Sydenham.
Equal.	Jones, George	Bedford.
	Servant, James	Thorne.
	Wing, William	Sheffield.
	Broadbent, Edwin Constantine	Douglas.
	Brown, Thomas	Birmingham.
	Locke, George	Aylesbury.
	Thomas, Frank	Boston.
Equal.	Jepson, Alfred	Swansea.
	Palmer, Tom Clifford	Grimsby.
Equal.	Green, James	Cheltenham.
	James, Richard	Camborne.
	Street, Walter Charles	Lincoln.
	Thompson, Leonard	Richmond, Yorks.
	Kemp, George	Birmingham.
	Duffus, Alexander	London.
	Stephens, Jonathan	Devonport.
Equal.	Jackson, Henry John	Bawtry.
	Ward, John	Derby.
Equal.	Francis, Frederick Tanton	Tavistock.
	Rees, Llewellyn Vosper	Swansea.
Equal.	Laurie, John	Ipswich.
	Williams, William	Saint Clears.
	Jenkins, Thomas	Swansea.
Equal.	Barrett, Josephus	Devonport.
	Harris, George Herbert	Woolwich.
	Park, Charles James	Devonport.
	Edwards, Frank Dunn	Usk.
	Baker, Matthias	Hanley.
Equal.	Balcombe, Charles	Hawkhurst.
	Beach, William Henry	Penkridge.
	Cleugh, Benjamin Sweeten	York.
	Herington, Joseph Henry	Leighton Buzzard.
	Watt, George Adam	Hartlepool.
	Weston, Matthew Frank	Bury.
Equal.	Nichols, Arthur F.	Leicester.
	Porter, Thomas	Fleetwood.
Equal.	Esam, Richard	Stamford.
	Parminter, Urban	Exeter.
	Wills, Andover Vincent	Blaenavon.
Equal.	Brown, Alfred Duncombe	Halstead.
	Evans, John Thomas Richard	Rhyl.
	Maxwell, James Ashworth	Altrincham.
Equal.	Catton, Frederic William	Knaresborough.
	Davies, Ivor Henry	Dowlais.
	Royse, John Frederick	Stockport.
Equal.	Brearey, Arthur William	Douglas.
	Greenwell, Alexander John	Newark.
	Kemp, Harry	Salford.
	Ellis, John William	Liverpool
Equal.	Peirson, Henry	Banbury.
	Roberts, William	London.
	Swindells, John Adam	Northwich.

Equal.
Churs, Robert ... Northwich.
Izod, William Henry ... Upper Norwood.

Equal.
Biddles, William Byron ... Reading.
Lucas, Joseph Michael Mark .. Gravesend.

Equal.

The questions for the examination were as follows:—

Latin.

1. Translate into English two at least of the following sentences:—

a. Dum hæc in colloquio geruntur, Cæsari nunciatum est, equites Ariovisti propriùs tumulum accedere, et ad nostros adequitare, lapides telaque in nostros conjicere. Cæsar loquendi finem fecit, seque ad suos recepit, suisque imperavit, ne quod omnino telum in hostes rejicerent.

b. Cæsar singulis legionibus singulos legatos et quæstorem præfecit, uti eos testes suæ quisque virtutis haberet. Ipse a dextro cornu, quòd eam partem minimè firmam hostium esse animum adverterat, prælium commisit.

c. Macera per quatriduum dein cola et sepone ut fæces subsidant. Liquorem effunde cumque defæcatum ad idoneam crassitudinem consume.

d. Fiat haustus, cui, tempore capiendi, adde Succi Limonis recentis cochleare magnum unum et in effervescentiæ sumatur.

2. Give the degrees of comparison of the following words:—*Audax*, *vetus*, *pulcher*, *dignè*, *graviter*, and *diu*.

3. Decline *Tu*.

4. When the genders differ in a sentence, with which does the adjective agree? Give two examples.

5. Parse "Regibus exactis consules creati sunt."

6. Give the endings of the Present Tense, Conjunctive or Potential Mood of the four Conjugations, Active Voice.

Arithmetic.

1. A man had a journey of 298 miles to walk; the first day he walked 42 miles, the second 36 miles, the third 31 miles, the fourth 27 miles; how much farther had he to go?

2. Multiply £874. 12*s.* $10\frac{3}{4}$*d.* by $10\frac{3}{4}$.

3. If 12 horses in 5 days draw 44 tons of stone from a quarry, how many horses would it require to draw 132 tons in 18 days.

4. Reduce $\frac{3}{7}$ of $\frac{9}{17}$ of $\frac{29}{78}$ of 32 to a simple fraction.

5. Reduce ·375 to a vulgar fraction.

English.

1. Give several examples of compound pronouns, and state how such arise.

2. Into how many classes may adjectives be divided? and give examples.

3. What does a preposition show? Furnish two examples.

4. Explain the meaning of a noun sentence, and furnish an example.

5. Correct the following: Either I or thou am mistaken, neither poverty or riches was injurious.

6. Write from fifteen to twenty-five lines upon *one* only of the following subjects:—

a. Real pleasure.
b. Letter writing.
c. Saving money.

Provincial Transactions.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION.

An ordinary monthly meeting was held in the class room on Friday evening, January 17th; Mr. W. S. Brown, President, occupied the chair. There was an unusually large attendance of associates to hear Mr. Louis Siebold, who explained, at considerable length, his views on pharmaceutical education. Discussion of the subject was prevented by the lateness of the hour. We hope to publish an abstract of Mr. Siebold's address.

NORTHAMPTON PHARMACEUTICAL ASSOCIATION.

A special meeting was held in the room in College Street, on January 20th, 1873; Mr. Hester, President, in the chair. He first alluded to the loss the association had sustained through the conductor of the chemistry class (Mr. Branson), and the materia medica class (Mr. Lester), leaving the town, both of whom had been indefatigable in the service of the association, and he was sure carried with them the best wishes of all the members. He then called attention to the new fume cupboard which had been filled up, and a Siebold's herbaria which had been purchased. He congratulated Messrs. Osborne and Gudgeon upon passing the Preliminary examination. Mr. Osborne had been chosen to conduct the materia medica class; the vacancy in the chemistry class had as yet been unfilled. He was very happy to say that the much talked of examinations would be held about the end of February, and he trusted that a spirited competition would ensue for the prizes.

The Secretary (Mr. Druce) having read a list of donations of prescriptions, etc., and called attention to a lifelike portrait of Professor Attfield, then said that their President, Mr. Hester, had offered a prize for chemistry and pharmacy in the coming examination, and their Vice-President, Mr. Sutton, another for botany and materia medica, and himself another in which the competition would be limited to apprentices.

Messrs. Osborne and Druce then exhibited two binocular microscopes; Mr. Osborne showing, among a large number of interesting objects, some good spiral vessels from rhubarb, and the glandular tissue of *Wellingtonia gigantea*, and various hairs, parasites, starches, which proved extremely interesting to the members. Mr. Druce confined himself to polariscope objects, the principal being the alkaloids strychnia, quinia, morphia, cinchonia, quinidia, santonine, atropia and salicine, and various salts of picric and chrysammic acid.

After the usual vote of thanks the meeting adjourned.

Proceedings of Scientific Societies.

SOCIÉTÉ DE PHARMACIE DE PARIS.

THE UNIVERSAL PHARMACOPŒIA.

This society met on Wednesday, December 4th, under the presidency of M. Stanislas Martin.

After some preliminary business, M. Adrian called attention to the project canvassed in other countries to draw up a universal pharmacopœia. He read a translation of the note of Professor Redwood upon this subject, taken from the report of the evening meeting of the Pharmaceutical Society of Great Britain in August last.

M. Boudet said that the idea of a Universal Codex originated in Paris at the meeting of the delegates to the Pharmaceutical Congress of 1866. Unforeseen circumstances had prevented the Paris Society from pursuing this question, but it ought, however, to be dealt with very shortly by the committee named for that purpose. The idea was entirely a French one, and it was important that it should be reclaimed and put into execution with as little delay as possible.

M. Planchon gave some explanations respecting the Pharmacopœia Europæa. In 1867, M. Phoebus had asked him to assist in compiling this pharmacopœia. He had thought such a work in which the articles prepared by each of the contributors would be revised by his colleagues belonging to other countries could not but be of great service to science; and, therefore, acting upon the advice of his friends he had accepted the proposition of M. Phoebus. But he did not think that the committee of the European Pharmacopœia could pretend to assume in any way a commission as the delegates of the various pharmaceutical societies to prepare a Universal Codex. The work in question was a private one performed by private individuals, which had no official character, and which, far from hindering the drawing up of a universal codex, would furnish for it some good materials.

M. Bussy said that a work compiled under the conditions indicated would not accomplish precisely the object proposed by the different pharmaceutical congresses, and particularly that of Paris in 1866, in promoting the publication of an international pharmacopœia. There were two ways which might be considered of carrying out the compilation of such a work. The first would be to unite all the official and general formulæ used in various countries; a work would be so produced analogous to the Pharmacopée Universelle of Jourdan. Such a work would, doubtless, be more complete, and more abreast of modern practice, but it would have no greater authority among pharmaceutists than any other work compiled by a single individual or association of pharmaceutists not specially commissioned for that purpose. The second plan, which seemed to him to be more in harmony with the wishes of the congress and the progress of medicine, would be to bring the composition of the most used and most active medicaments to a single type for each medicament, after discussion and examination of the various formulæ employed at the present time. Such a work would present fewer difficulties than is commonly supposed. All the pharmacopœias published during the past forty years have had a tendency to simplify the composition, and consequently to lessen the differences between the various medicaments contained in them. Another circumstance that would assist powerfully in the unification of the formulæ was the extended use at the present day of the alkaloids, or, more generally, the tendency which exists to substitute the active and well-defined principles of vegetables for the whole pharmaceutical prepreparations. A pharmacopœia drawn up under such conditions would be presented for acceptation to European and other States, and would become legal and obligatory within such limits as should be determined by those adopting it. The result would be that in all the States taking part in such a union all the compounds designated under the same name would have exactly the same composition, and a medical prescription dispensed at Paris or Berlin would be made up in exactly the same manner at London or St. Petersburg. But it must not be forgotten such a project presupposes an accord between competent and sufficiently authorized men, such as a body of delegates from the different countries of Europe would be.

M. Limousin did not think they could hope to obtain a Universal Pharmacopœia; there would be too many difficulties to overcome in securing its adoption by all the States of Europe.

M. Adrian having proposed that the number of members of the commission should be increased to nine, it was decided that M. Planchon should fill the place of M. Robinet so as to bring the number to five as originally decided, and the further increase was left to the consideration of the committee.

M. Grassi thought it would be useful now for the Society to put itself into communication with the English pharmaceutists upon the subject. This point also was remitted to the committee.

The society then elected officers for 1873 as follows:—M. Regnauld as vice-president, M. Vigier as secretary, M. Desnoix as treasurer.

CHEMICAL SOCIETY.

Thursday, 19th December, 1872, Professor Frankland, D.C.L., F.R.S., President, in the chair.

After the ordinary business of the society had been transacted several papers were read.

The first entitled "Notes on various Chemical Reactions," by Mr. Davies, contained observations on the formation of the sulphides of copper and barium, also some notes on the separation of cobalt and nickel.

Mr. H. Grimshaw communicated the results of his researches on ethyl-amyl and its derivatives.

After the President had made some remarks on the thoroughness with which this research had been carried out, a communication from Dr. Schorlemmer "On the Heptanes from Petroleum" was read. This paper contained among other matter an interesting account of the separation of isomeric heptylenes by means of hydrochloric acid.

A paper by Mr. T. Carnelley on the "Vanadates of Thallium" was then read. It contained descriptions of several new and complex vanadates of thallium.

Mr. Kingsett communicated to the society the results of his experiments on the conversion of sodium chloride into sodium sulphide by the action of hydrosulphuric acid; and finally Mr. P. Braham exhibited some ingenious arrangements which he had made for the prosecution of physical investigations under the microscope.

The meeting was then adjourned until Thursday, February 6th, when the following papers will be read:— "On Anthrapurpurin," by W. H. Perkin; "On the Solidification of Nitrous Oxide," by T. Wills, and on "Isomerism in the Terpene Family," by Dr. C. A. Wright.

PHILADELPHIA COLLEGE OF PHARMACY.

A meeting of this society was held December 17th, 1872; Professor Procter in the chair.

Professor Maisch read a paper on "Impurities in Ladies' Slipper-root," and exhibited preserved specimens of roots and flowering plants of *Cypripedium pubescens*, *C. parviflorum* and *C. acaule;* also commercial samples of pure cypripedium, and some admixed with hydrastis, senega and other dicotyledonous roots.

In answer to a question by Mr. Shinn, Professor Procter stated that there was considerable demand for cypripedium by eclectic physicians, who use it in such cases in which valerian is indicated.

Mr. Remington read a paper on "Ceresin," and exhibited a sample of simple cerate prepared from it. Nothing can be said as yet about its keeping qualities, the time being too short. It was remarked that cerate prepared from paraffin quickly spoils, while yellow wax and benzoinated lard preserve it for a long time.

Mr. Shinn remarked that emulsions of cod-liver oil containing phosphate of lime were being prescribed by physicians, and asked the experience of those present in making emulsions containing large quantities of fixed oils. He had samples from two makers, both of which separate and became rancid after some time; the quantity of lime salt in both is stated in ambiguous terms. The fair method would be to state the quantity of phosphate of lime, lactic acid and cod-liver oil in a certain measure.

Professor Procter had used a mixture of tragacanth and acacia in proportion of 1 to 6, and the product is rather thick.

Professor Maisch said one maker of this emulsion had lately obtained a patent, which, however, is probably of no value. As early as 1855 he prepared emulsions containing 50 per cent. of cod-liver oil, with alkalies and alkaline earths,* which may be sweetened and flavoured to taste. This is not a true emulsion, but a partial saponification.

Mr. Shinn had used lime water, 2 ounces to a pint, in conjunction with gum arabic; also sucrate of lime, by means of which a 75 per cent. emulsion can be prepared and mixed with syrup of phosphate of lime and lactic acid.

Mr. Remington remarked that he had seen a communication from an attorney threatening certain parties with prosecution for infringement of patent if they did not desist in the manufacture of this preparation; but apparently the threat would not be carried out.

Professor Maisch said a method is much needed whereby fixed oils can be emulsionized as readily as volatile oils, ether and chloroform are by the method of Mr. J. W. Forbes.*

Mr. Shinn had seen a patent churn in use as a labour-saving agent in making large quantities of emulsions.

Professor Maisch presented a well-made sample of benzoated oxide of zinc ointment, prepared by A. H. Bolton in a paint mill.

Mr. Boring exhibited cucumber ointment in good condition, made in 1868, by the method as modified from the French formula by Professor Procter,† who, having tried various methods, stated that with this one success depends upon time and patience properly expended upon it.

Professor Markoe, of Boston, who was present, at the suggestion of Mr. Shinn, addressed the meeting and spoke about his recent visit to England, describing several of what may be termed representative pharmaceutical establishments of Great Britain which he visited in Liverpool, Harrogate, Leeds, Newcastle, Edinburgh, London, etc. The proprietors, he said, rarely reside in the same building in which the business is carried on, but if the number of employés is sufficiently large a housekeeper is usually employed, the clerks residing and taking their meals on the premises. The current literature, especially scientific, and a well-selected library is not unfrequently met with, the clerks having access to it in the evening. In some stores apprentices are never employed, only qualified assistants, those acting as dispensers having their separate counters, each with complete apparatus and appurtenances, as for instance in Mr. Abraham's store, in Liverpool, where there are four dispensing counters. The precautions against mistakes with poisons, adopted by several British pharmacists, were mentioned, and a description was given of the alkali works at Newcastle-on-Tyne. The speaker then spoke about the Brighton Meeting of the British Pharmaceutical Conference, at which he was present, and said that the attendance was not as large as that at the meetings of the American Pharmaceutical Association, if the membership and the short distances which the British pharmacists have to travel is taken into consideration. Percolation, which is well understood and so indispensable in the United States, is little known and practised in England. The speaker's impression is that the British pharmacists, as a class, at least in the larger cities, are chemists and men of education, but that galenical pharmacy is better understood in America.

Parliamentary and Law Proceedings.

Sheriff Court of Lanarkshire, Glasgow.

Friday, 10*th January*, 1873.

(Before Mr. Sheriff Substitute Murray.)

THE PHARMACEUTICAL SOCIETY *v.* WILSON.

This was a complaint, under the Summary Procedure Act, 1864, at the instance of the Pharmaceutical Society of Great Britain, incorporated by Royal Charter, and Elias Bremridge, residing at 17, Bloomsbury Square, London, their Registrar, by authority of the Council of the said Society, Complainers, and Burns, Alison and Aiken, Writers, Glasgow, their Mandatories, against William L. Wilson, tenant of and carrying on business

* See 'American Journal of Pharmacy,' 1856, p. 1.

* See Pharm. Journ. [3] vol. ii. p. 747.

† See 'American Journal of Pharmacy,' 1853, 409.

as a retailer of drugs in the premises known as the Garscube Old Apothecaries' Hall, 142, Garscube Road, Glasgow. The complaint set forth that the respondent had contravened the Pharmacy Act, 1868, and particularly Section 15 thereof, in so far as, not being a duly registered Pharmaceutical Chemist or Chemist and Druggist under the said Act, he did, in the month of November last, keep open shop for the retailing, dispensing, or compounding poisons within the meaning of the said Act; and make two sales, which were specified, the one of laudanum and the other of oxalic acid, whereby he incurred a penalty of £5 for each of these contraventions. The penalties incurred were restricted in the complaint to a sum of £5 with expenses.

At the first diet of compearance Mr. Lucas appeared for the respondent, and stated, as preliminary objections, (1) that the complainers had not set forth any sufficient title to sue; and (2) that the Act of 1868 did not apply to Scotland.

Mr. Gill, who appeared for the complainers, referred the Sheriff to the 15th Section of the Act, which provides that the penalties thereby imposed may be sued for in the manner provided by the Pharmacy Act of 1852, and he read Section 12 of that Act, which lays the duty of recovering penalties on the Pharmaceutical Society, and provides for the mode to be followed in Scotland for the recovery of penalties, and he maintained that the complaint was entirely in conformity with the provisions of the Act. The Sheriff held that the Act undoubtedly applied to Scotland, and that the complaint was in proper form, and he accordingly repelled the objections. The respondent was then called upon to plead, when he recorded a plea of "not guilty," and the diet was adjourned to this date for the purpose of leading proof.

To-day, as at the former diet, the Society was represented by Mr. Gill, and the respondent by Mr. Lucas. The respondent having stated that he adhered to his former plea of not guilty, the following proof was adduced:—

William Logan, house-factor, Glasgow, gave evidence to the effect that the respondent had been tenant of the shop, No. 142, Garscube Road, since Whitsunday, 1870. It was the duty of the witness, as factor for the property, to fill up the returns required by the assessor for the valuation roll, and in the return for the current year he had inserted the respondent's name as tenant. Dr. Lawrie was the tenant of the shop prior to Whitsunday, 1870, and some time previous to that term he stated to witness that he had transferred the business to the respondent, and requested the witness to enter in his books the name of the respondent as tenant, and witness did so, on the condition that Dr. Lawrie should remain bound for payment of the rent, as the respondent's surety, which was agreed to by Dr. Lawrie. The witness understood that Dr. Lawrie was in the practice of attending daily at the shop for the purpose of meeting with patients. He could not say whether the name of any person was exhibited in the shop or over the door. There was on the signboard "Old Apothecaries' Hall."

Peter Scott said that on 12th November last he entered the shop, No. 142, Garscube Road, and asked for oxalic acid. He received and paid for a packet which he had sealed on the same day, and had retained in his possession ever since. He handed it to the judge. The label on the packet bore the name of the respondent as the seller.

James Angus said that on the 12th of November last he entered the respondent's shop and asked for twopence worth of laudanum. He received and paid for a bottle with its contents, which he now produced. He had sealed the bottle, and it had not been out of his possession since. The label on the bottle bore the name of the respondent as the seller.

Mr. Lucas admitted that the articles sold to the two preceding witnesses were truly oxalic acid and laudanum, which were poisons within the meaning of the Act, and that the respondent's name did not appear in the Register of pharmaceutical chemists and chemists and druggists. This concluded the complainers' proof, and the following evidence was led for the respondent:—

William L. Wilson, the respondent, stated that he had been in business as a chemist and druggist for more than eight years. Previous to the passing of the Pharmacy Act of 1868, he was as much in business as in November last. Some years ago he had entered into an agreement with Dr. Lawrie, whereby he was to receive a share of the profits of the business carried on at 142, Garscube Road. Dr. Lawrie was the former tenant of the shop. All goods purchased for the shop were bought and invoiced in Dr. Lawrie's name, and he produced a number of invoices, all of which were made out in the name of Dr. Lawrie.

In cross-examination the witness admitted that he had been tenant of the shop since 1870, and that one year he had put his name in the Glasgow Post Office Directory as chemist and druggist at the shop in question. The labels used in the shop all bore his name. The only name above the door was "Garscube Old Apothecaries' Hall." The arrangement with Dr. Lawrie was that Dr. Lawrie should get the whole profits derived from the sale of poisons, and that witness should have a share of the profits on prescriptions and the whole profits on perfumery. The arrangement was verbal; it was not in writing. Dr. Lawrie was in use to call at the shop twice a day, when he prepared prescriptions and sold articles if witness was busy.

Dr. James Lawrie, 191, St. George's Road, stated that he was a qualified medical practitioner and had been thirteen years in practice. For eight years he had been tenant of the Old Drug Hall in Garscube Road. In the year 1870 witness wished to give up the sale of drugs, and arranged with respondent that he should become a partner with him, taking the sale of the general drugs and chemicals, while witness should take all responsibility in point of law. There was no written agreement. Witness got the whole profits derived from the poisons sold in the shop and a share of profits on prescriptions. The respondent received the whole profits on the sale of other drugs and perfumery, which formed the main part of the business. Witness regarded himself as the seller of all poisons sold in the shop, and held himself responsible under the Pharmacy Act.

In cross-examination witness stated that he had asked the factor of the premises to accept the respondent as his tenant, and that the respondent's name was on the labels used in the shop. He repeated the terms of his arrangement with the respondent, and said that in making that arrangement he had in view the requirements of the Pharmacy Act. He recommended such patients as he visited and prescribed for at their own homes to take their prescriptions to the respondent's shop; and he said it was not uncommon for medical men to get a percentage of the profit on their prescriptions.

This concluded the proof.

Mr. Gill, in addressing the Sheriff, pointed out that the sales of articles in question had been proved, and that these articles were admitted to be poisons. It had also been proved that the respondent was tenant of the shop, and was not on the Register, and, therefore, could not sell poisons without contravening the Act of Parliament. That the respondent and not Dr. Lawrie was the seller of the poisons libelled was proved by the fact that the labels bore the name of the respondent as the seller. That the arrangement said to have been made between Dr. Lawrie and the respondent was only an attempt to evade the provisions of the Act, as there could be no doubt that the shop belonged to the respondent, and was kept open by him for the sale of poisons.

Mr. Lucas, on behalf of the respondent, maintained that his client was entitled to a judgment of absolvitor on the grounds (1) that under the Act persons who had been in business as chemists and druggists before it became law did not require to be registered, and he founded on the 3rd Section of the Act as providing that such persons were chemists and druggists within the meaning of the Act; and (2) that Dr. Lawrie was the seller of the poisons, the respondent being only his partner or assistant in business.

Mr. Gill read Sections 1, 5 and 15 of the Act to show that registration was necessary as a qualification to sell poisons.

The Sheriff held that registration under the Act was a requisite even in the case of a person who had been in business as chemist and druggist before it came into operation, the only advantage which such a person had, being that he was entitled to have his name placed on the Register on application, as provided in the 5th section of the Act. He found that the respondent had been proved to be the seller, and referred to his name appearing on the labels affixed to the articles sold as establishing that fact conclusively, and he accordingly convicted him of the contravention charged, and adjudged him to pay the penalty sued for, with expenses.

A Wrong Medicine Supplied at a Dispensary.

On Thursday, Jan. 16, Mr. Coroner Browne held an inquest at Nottingham on the body of a child named Elizabeth Ann Brown, aged eight years. It appeared from the evidence that the child had been for some weeks attended as an out-door patient by Mr. Richard Johnston, one of the surgeons at the Dispensary. On Sunday, the 22nd ult., the father went to the Dispensary for some medicine, when he received by mistake some opium and bismuth from Mr. Johnston, who mistook the child's father for another person, and gave him a liquid containing the above ingredients, which were intended for another patient. Mr. Johnston did not discover the mistake until after the medicine had been administered, when he at once sent on a request to have the medicine returned. The child, which had by this time taken two tablespoonfuls of the medicine, according to the directions given on the bottle, was brought to the Dispensary the same night, where an emetic was prescribed in addition to the application of the stomach pump. It had complained of not being well in about three quarters of an hour after the medicine had been administered. On the following Monday the child was somewhat recovered, but it thereafter became gradually worse up till its death last Sunday morning. Mr. Johnston had continued his attendance for rather more than a week after the mistake, but ceased to visit it on learning that Mr. Thompson, another surgeon, had been called in. On Monday, Jan. 13, the mother of the deceased had gone to the Dispensary, and there charged Mr. Johnston with having murdered her child, and requested him to give her some pecuniary consideration. Mr. Johnston, however, declined to do anything in the matter beyond providing medicine and attendance. Mrs. Brown thereafter went before the committee of the Dispensary, and stated her case to them. The committee gave her 10*s*., and asked her to come back next Monday, accompanying the request with an expression of sorrow that the mistake should have occurred. They had also remarked that it was a matter which ought to be looked into. The bottle had contained two and a half drachms of a liquid preparation of opium, and the quantity partaken of by the child had contained from twenty-five to twenty-eight drops.

In reply to a question it was stated that the names of patients were not put on the bottles issued from the Dispensary, but merely the directions.

Mr. Thompson, surgeon, said he had made a *post-mortem* examination on the body of the deceased, and expressed himself of opinion that the mistaken application of the medicine had had nothing to do with the child's death. There was nothing which he could at all connect with that beyond a slight inflammation of a part of the stomach. In his opinion death had been caused by inflammation of the membranes of the brain.

The Coroner in summing up said it was quite plain that there had been a mistake on the part of Mr. Johnston, but they had heard Mr. Thompson's evidence to the effect that death had resulted from the inflammation of the membranes covering the brain. They would have no difficulty, therefore, in arriving at a verdict. He could not let the case pass, however, without strongly expressing his opinions with regard to all the parties concerned. The mother had charged Mr. Johnston with murdering her child, and yet she was willing to receive money to hush the matter up. Then the conduct of the gentlemen of the Dispensary committee in giving the woman 10*s*. and sending her away without instituting further investigation at once, was disgraceful. For their own sakes, and for the sake of the institution, it was clearly their duty to have instituted a most rigid inquiry into the matter. Had it not been by a mere chance the child would have been buried on the previous day without his (the Coroner's) knowledge, and without the present inquiry, which he thought was a duty that plainly required to be done in the circumstances. A verdict of "Death from inflammation of the membranes covering the brain" was accordingly returned by the jury, and both the mother of the child and Mr. Johnston were reprimanded for the part they had taken.—*Nottingham Daily Journal.*

Obituary.

FRANCIS FLETCHER.

It is with deep regret we note the death of Mr. Francis Fletcher, who died at Cheltenham on the 6th of January, instant, in his sixty-first year.

His name is enrolled on the records of the Pharmaceutical Society from the year 1842 down to 1867, when, from continued pain and suffering, he relinquished business and thus severed his connection with the Society; but continued until his death a subscriber to the Benevolent Fund.

His career in Cheltenham dates from 1841, when he succeeded to the business previously started by Messrs. Knight and Wakeman, and in conjunction with his surviving partner he successfully carried on this business for a period of twenty-six years, under the title of "Fletcher and Palmer."

Francis Fletcher, though of a quiet and unobtrusive manner, was in his day and generation superior to most men of his class. With a cultivated mind, a genial manner, and an easy disposition, he has passed from this world, leaving an unsullied reputation and a large circle of loving and sorrowing friends.

Notice has also been received of the death of the following:—

On the 31st December, 1872, Mr. Henry Wake Allen, Chemist and Druggist, of King's Lynn, Norfolk.

Review.

The Pharmacopœia of the United States of America. Fifth decennial revision. By the authority of the National Convention for Revising the Pharmacopœia, held at Washington, A.D. 1870. Philadelphia: J. B. Lippincott and Co. 1873.*

The fifth of the decennial editions of the United States Pharmacopœia is now being published in Philadelphia. It is a handsome foolscap octavo of 383 pages, beautifully printed in sharp clear type on faintly-toned paper. In general style it is superior to the British

* The writer is indebted to the unexpected kindness of Dr. Carson, President of the National Convention, for an early complimentary copy.

Pharmacopœia of 1867, as that was to the fourth American Pharmacopœia.

As our readers already know, the task of producing a pharmacopœia in the United States is committed to delegates appointed by the incorporated colleges of pharmacy as well as medicine. In the present case eighteen medical colleges, associations or universities each sent one, two or three delegates, while eight colleges of pharmacy contributed representatives, as seen in the following list:—From the Maryland College of Pharmacy, Messrs. Thompson, Faris Moore and Dohme; from the St. Louis College of Pharmacy, Drs. Potter and Pruin, and Mr. Massott; from the Chicago College of Pharmacy, Messrs. Ebert, Biroth and Diehl; from the Massachusetts College of Pharmacy, Messrs. Markoe and Colcord; from the New York College of Pharmacy, Messrs. Hegeman, Neergaard and Bedford, Drs. Squibb and Manlius Smith representing the medical interests; from the Philadelphia College of Pharmacy, Messrs. William Proctor, jun., J. M. Maisch and A. B. Taylor, Drs. G. B. Wood, Bridges, and Horatio C. Wood being medical delegates; from the College of Pharmacy of Baldwin University, Drs. Clarke and Murray; and from the Pharmaceutical College of Harvard University, Drs. Loomis and Purves. The Convention first met in May, 1870, under the Presidency of Dr. Joseph Carson; manuscript contributions in furtherance of revision were presented from four pharmaceutical and two medical colleges, the plan of revision discussed, and a Committee of Revision appointed, consisting of fifteen gentlemen, including such well-known names in pharmacy as Alfred B. Taylor, John M. Maisch, Robert Bridges, Manlius Smith, Albert E. Ebert, J. Faris Moore, and G. F. H. Markoe. In June, 1870, the Committee commenced its labours, and, we are assured in the preface, continuously worked until the recent completion of the volume. Besides attending the meetings, individual members of the Committee seem to have given much time to personal experiment and research, and a recommendation is appended that reports contributed by pharmaceutical and medical bodies to the Convention should in future be made full and explicit in details, and to the Committee be left the task of verifying and testing rather than that of original investigation. Some such course is, no doubt, desirable, for although the expenses of the Committee are paid from the income of the copyright, much delay must occur when the necessary experimental work has to be done after instead of before the meeting of the Convention. Would not a permanent paid small sub-committee best do such work during the intervals of issue of the pharmacopœia?

Among the resolutions adopted by the Convention for the guidance of the Revising Committee was one of quite a new character, and such as is likely to influence considerably the character of future pharmacopœias: "*Resolved*, that if, in the judgment of the Committee of Revision, it should become necessary before the meeting of the Convention of 1880 to revise its labours, it is hereby authorized to publish a new edition." This course has, obviously, advantages and disadvantages. Hitherto the medical men and pharmacists of America have associated a new pharmacopœia with a new decade. Having accomplished the not always pleasant, but inevitable, task of mastering the novelties and changes of a new pharmacopœia, their minds have been at rest in respect of such matters for at least ten years, but under the present arrangement, omissions, additions or alterations of more or less importance are liable to be made at any time, resulting in the possible production of undesirable variations in the practice of medicine and pharmacy. On the other hand, it is advantageous that additions to the materia medica of a country should receive official recognition as soon as they have become generally accepted, and that in other ways a pharmacopœia should follow not closely, but not too remotely, in the path of pharmaceutical progress.

Another capital resolution of the Convention was to the effect that, in the revision of the official list and formulæ, the wants of the medical profession in all parts of the United States should be considered in reference to local peculiarities in climate and population, and that for these reasons the scope of the work should be extended rather than abridged. Accordingly, twenty-seven articles have been added to the materia medica, while only five have been omitted. Again, eighty-two new preparations have been included, and only seven dismissed. The action of the Committee in this matter foreshadows difficulties that would attend the production of a true Universal Pharmacopœia—one that should meet the requirements of medical practitioners in all countries. "Local peculiarities in climate and population" would probably prevent the exclusion of more than a very few official articles, or the alteration in strength of compounds to any useful extent. Hence the volume would become little more than a mere reprint of pharmacopœias of all ages of their brief existence, and would probably not be worth translation from the Latin or other original into the vernacular.

Among the additions to the materia medica are carbolic acid, nitrate of ammonium, hypophosphites of calcium, of iron, of potassium and of sodium, Indian hemp, oxalate of cerium, chloral, iodoform and Calabar bean. Also "*Cinchona.* The bark of all species of the genus Cinchona, containing at least two per cent. of the proper cinchona alkaloids, which yield crystallizable salts:" this is in addition to *Cinchona flava*, *Cinchona pallida*, and *Cinchona rubra.* The five articles dismissed are neatsfoot oil, star grass, angelica, Indian turnip and cotton-root. The new preparations include the benzoate, bromide, and iodide of ammonium, digitalin, citrate of iron and strychnia, oxalate of iron; cantharides paper and mustard paper (*chartæ*); glycerites (*glycerita*) of carbolic acid, gallic acid, tannic acid, tar, and borax; various suppositories and juices; and twenty-two new fluid extracts, in the manufacture of the majority of which glycerine is employed as well as alcohol, and the latter thus economized.

Respecting weights and measures, the Convention resolved that measures of capacity be abandoned in the Pharmacopœia, and that quantities be expressed both in weights and in parts by weight. The Committee, however, objected that the execution of such directions entailed the use of a metrical system not employed in the United States or England, and that therefore, especially as the plan was not anticipated in the revisions handed to the Committee, such an expenditure of time, labour and cost would be involved in applying the system to the whole ground covered by the Pharmacopœia as to render the plan impracticable.

Both measures and weights are therefore retained. The measures are derived, as heretofore, from the *wine* gallon of eight pints, each pint containing sixteen fluid ounces, each fluid ounce eight fluid drachms, or nearly 456 grains, and each fluid drachm sixty minims.

The weights are derived from the troy pound of twelve ounces, each ounce containing eight drachms, each drachm three scruples, each scruple twenty grains. It is greatly to be regretted that the unity of character of the Pharmacopœias of the United States and Great Britain, elsewhere strongly apparent in this elegant addition to the pharmaceutical literature of these two English-speaking countries, could not be extended in some way by mutual concessions to the weights and measures. When will these great peoples face the difficulties of application and accept the enormous advantages of the metric decimal system? At present the relation of weights to measures and of these to coins and numbers are, if possible, more complicated in America than in this country. Thus the pound contains 5760 grains or 6067 minims; the ounce weight is equal to 1·053 fluid ounces or 505 minims, or 480 grains. (Mercifully the grain, and only the grain, is the same weight on either side of the Atlantic, thus rendering comparisons not absolutely hopeless.) The drachm weight is heavier than the fluid drachm, for it contains 63·2 minims; the scruple of 20 grains weight contains 21 minims, and one grain has the volume of 1·0533 minims. On the other hand, the gallon of eight wine pints weighs a trifle over ten troy pounds, or 58,329 grains; the pint is rather more than one troy pound and a quarter or 7291 grains; the fluid ounce is nearly ·95 of an ounce weight, or 455·6944 grain; the fluid drachm weighs not quite 57 grains; the weight-equivalent of 1 minim being 0·9493 grain. "It is highly important that persons engaged in preparing medicines should be provided with troy weights. But those who are not so provided can make their avoirdupois weights available as substitutes for troy weights, by bearing in mind that 42·5 grains, added to the avoirdupois ounce, will make it equal to the troy ounce; and that 1240 grains, deducted from the avoirdupois pound, will reduce it to the troy pound."

Following, indeed heading, the lead of the British Pharmacopœia the weights and measures of the metric decimal system are set forth in appended tables, their relation to the weights of the U. S. Pharmacopœia and the relation of the latter to the former being very fully given. Also the relation of measures of the U. S. Pharmacopœia to cubic measure.

The galenical nomenclature of this fifth edition of the Pharmacopœia has scarcely been altered. The term *alcoholicum* has been dismissed in all cases where there is but a single extract of a medicinal substance, and this is specified by the term *extractum*, as "*extractum nucis vomicæ*" instead of "*extractum nucis vomicæ alcoholicum.*"

The chemical nomenclature has been altered considerably "to place the work in accord with the progress of chemical science." The particular variety of modern nomenclature adopted is that which, five years ago, was strongly advocated for use in pharmacy, by the writer of this notice, in a paper which had the support of all the leading chemical, medical, and pharmaceutical authorities in this country. He may, perhaps, be pardoned for regarding with much satisfaction the very practical support his advocacy has now received at the hands of the compilers of the important Pharmacopœia under review. It is unnecessary to recapitulate the many advantages of the system, its simplicity, or the ease with which it may be understood and employed; but inasmuch, to use the words of the preface of the new U. S. P., "the modifications thus made will probably soon be the language of pharmacy," it may be desirable to give a list of the old and new names now first officially sanctioned.

OLD NAMES.	OLD NAMES.	NEW NAMES.	NEW NAMES.
Latin.	*English.*	*Latin.*	*English.*
Ammoniæ carbonas	Carbonate of ammonia.	Ammonii carbonas	Carbonate of ammonium.
Ammoniæ murias	Muriate of ammonia.	Ammonii chloridum	Chloride of ammonium.
Ammoniæ sulphas	Sulphate of ammonia.	Ammonii sulphas	Sulphate of ammonium.
Ammoniæ valerianas	Valerianate of ammonia.	Ammonii valerianas	Valerianate of ammonium.
Barytæ carbonas	Carbonate of baryta.	Barii carbonas	Carbonate of barium.
Calcis carbonas ppt.	Ppt. carbonate of lime.	Calcii carbonas ppt.	Ppt. carbonate of calcium.
Calcis phosphas ppt.	Ppt. phosphate of lime.	Calcii phosphas ppt.	Ppt. phosphate of calcium.
Ferri et ammoniæ citras	Citrate of iron and ammonia.	Ferri et ammonii citras	Citrate of iron and ammonium.
Ferri et ammoniæ sulphas	Sulphate of iron and ammonia.	Ferri et ammonii sulphas	Sulphate of iron and ammonium.
Ferri et ammoniæ tartras	Tartrate of iron and ammonia.	Ferri et ammonii tartras	Tartrate of iron and ammonium.
Ferri et potassæ tartras	Tartrate of iron and potassa.	Ferri et potassii tartras	Tartrate of iron and potassium.
Liquor ammoniæ acetatis	Solution of acetate of ammonia.	Liquor ammonii acetatis	Solution of acetate of ammonium.
Liquor magnesiæ citratis	Solution of citrate of magnesia.	Liquor magnesii citratis	Solution of citrate of magnesium.
Liquor potassæ arsenitis	Solution of arsenite of potassa.	Liquor potassii arsenitis	Solution of arsenite of potassium.
Lithiæ carbonas	Carbonate of lithia.	Lithii carbonas	Carbonate of lithium.
Magnesiæ carbonas	Carbonate of magnesia.	Magnesii carbonas	Carbonate of magnesium.
Magnesiæ sulphas	Sulphate of magnesia.	Magnesii sulphas	Sulphate of magnesium.
Potassæ acetas	Acetate of potassa.	Potassii acetas	Acetate of potassium.
Potassæ bicarbonas	Bicarbonate of potassa.	Potassii bicarbonas	Bicarbonate of potassium.
Potassæ bichromas	Bichromate of potassa.	Potassii bichromas	Bichromate of potassium.
Potassæ bitartras	Bitartrate of potassa.	Potassii bitartras	Bitartrate of potassium.
Potassæ carbonas	Carbonate of potassa.	Potassii carbonas	Carbonate of potassium.
Potassæ chloras	Chlorate of potassa.	Potassii chloras	Chlorate of potassium.
Potassæ citras	Citrate of potassa.	Potassii citras	Citrate of potassium.
Potassæ et sodæ tartras	Tartrate of potassa and soda.	Potassii et sodii tartras	Tartrate of potassium and sodium.
Potassæ nitras	Nitrate of potassa.	Potassii nitras	Nitrate of potassium.
Potassæ permanganas	Permanganate of potassa	Potassii permanganas	Permanganate of potassium.
Potassæ sulphas	Sulphate of potassa.	Potassii sulphas	Sulphate of potassium.
Potassæ tartras	Tartrate of potassa.	Potassii tartras	Tartrate of potassium.
Sodæ acetas	Acetate of soda.	Sodii acetas	Acetate of sodium.
Sodæ bicarbonas	Bicarbonate of soda.	Sodii bicarbonas	Bicarbonate of sodium.
Sodæ boras	Borate of soda.	Sodii boras	Borate of sodium.
Sodæ carbonas	Carbonate of soda	Sodii carbonas	Carbonate of sodium.
Sodæ phosphas	Phosphate of soda	Sodii phosphas	Phosphate of sodium.
Sodæ sulphas	Sulphate of soda.	Sodii sulphas	Sulphate of sodium.
Sodæ sulphis	Sulphite of soda.	Sodii sulphis	Sulphite of sodium.

Vermin Killers.

Sir,—It has been my intention for some time to write a few words in reference to the sale of poisons, especially vermin killers, but I have deferred in hopes that some abler person would take the subject in hand. To every chemist throughout the kingdom it is a subject of the highest consideration. That it is not thoroughly understood is, I think, evident from the cases that are constantly appearing in the Journal. The question, then, naturally arises, "Who is to blame that it is not better understood?" With all due deference to the Pharmaceutical Society, I think a little more might be done by them to render the law rather more intelligible than it is at present.

I will take my own case as a sample. In August of last year I sold a woman two packets of Battle's Vermin Killer labelled with my name and address and the word "Poison." She took one herself and gave the other to her child. The child died, but she recovered, and was committed for wilful murder. Of course, I had to attend the inquest (two days), and the Assizes (three days), and employed a solicitor to show that I had done what I deemed necessary. To the best of my knowledge I had done everything that the 17th Section of the Pharmacy Act, 1868, required of me. I took a list of the poisons to the inquest to point out that the last name on the list in part II. was "Vermin killers, and all poisons sold for the destruction of vermin." But I was told by the coroner that it contained strychnine, and, doing so, I should have had a witness to the sale. I came away with the idea that I was in the right, and, at some little trouble to myself, inquired of a many chemists, and found that they were all of the same opinion. Imagine my astonishment when the case appeared in the Journal, with a note appended (August 3rd, 1872), stating that I was in the wrong, and that a list appeared in the *London Gazette*, December 21st, 1869, of articles that ought to be deemed poisons, in the first part of schedule A to the said Pharmacy Act, 1868, which list contained, among other articles, "Vermin Killers, etc." Now, I simply ask, "Would it not have been better to have sent a notice to the trade, instead of publishing it in the *London Gazette*?" for what percentage of chemists would see it in such a paper? but had a notice been sent to the trade, much trouble and uncertainty might have been saved. In your leading article on Saturday last you say, "that it was recently resolved that a copy of the revised regulations should be issued to every chemist and druggist, and that it appears to be one of those copies which the defendant had received that morning?" May I ask how it is that I have not received any such notice? You also say how desirable it is that chemists should comply with the conditions prescribed for regulating the sale of poisons in the Pharmacy Act, 1868. But I contend that, if we are kept in ignorance of alterations, we certainly are not blameable; for how can we comply with the law if we do not know what the law is? and who are more likely to tell us than the Pharmaceutical Society, who have the framing of them? I consider it an injustice to us all that it is not made known when any alterations take place in those Acts which so materially affect us. Had notice been sent out earlier, in all probability Messrs. Gillett and Moses would have been on the safe side, and registered the articles. There cannot be two opinions upon the point that the greatest confusion exists upon the question, which is a disgrace to those who have to administer the law, and an injustice to those who fall under its lash. Why, then, cannot we have something decisive done in the matter? Month after month passes away, case after case appears, the Journal has teemed with letters, but still there remains an uncertainty as to what is right to do in the matter. Something appears to have been done as far as the two cases are concerned mentioned last week, for the defendants say they had received notice that morning, but it has not extended as far as Leeds I think, for I have not heard of any one receiving such circular, and certainly I have not received one. In a letter, about twelve months ago, I proposed that a copy of the amended regulations and conditions be forwarded to every chemist in the kingdom, and the Society, at the same time, said that they had suggested it a few months before; but I think now that it really should be done, not only to chemists, but to every coroner and magistrate in the kingdom. If any abler person would propose some plan whereby to throw a light on the matter, I am sure he would receive the thanks of the greater part of the chemists throughout the country. If the law was better understood I feel convinced it would be better carried out, for, in the case of vermin killers, there can be no inducement to break it, and in the majority of cases it is broken in ignorance.

John Wm. Longley.

Leeds.

Lancet Amenities.

Sir,—I think it is quite time that not only protestation against such statements as have lately appeared in sundry journals should be made, but also a correct representation of the actual condition of the pharmacist compared with that of the medical profession, a representative journal of the latter having deemed it policy, sound or otherwise, to take up the hue and cry, originating from a source of lamentable ignorance. However, it must not be assumed, from the fact of a certain member of the medical profession having made an assault on pharmacists, and been ungallant enough to attack the ladies, and having ignominiously incited the public "to put down the pretensions of this class," that such conduct is endorsed by the medical profession generally.

It is an old adage that chemists make enormous profits, and that their chief article of commerce is the indispensable (though dispensed with every day) aqua pura, but, as your correspondent T. C. avers, such a state of affairs is not rampant in the present day; and if it were, it would not be unfair, considering the qualifications demanded by the public and enforced by law, and the expenses to be incurred in their attainment before a person can enter the business. But I am quite prepared to refute the statements made respecting the voluptuousness of the pharmacist, and I may safely state that where one man can afford a sealskin jacket for his wife, ninety-nine scarcely know how to get their bread and cheese. The following style of prescribing is too fashionable to admit of any very large margin for profit, and the patients having got their advice cheap, think when they have to pay more for their medicine that there is something wrong:—

℞. Tinct. Cinchonæ Co.
Sp. Ammoniæ Aromat. a a ℥j.
Potassii Iodidi ʒj.
Sig. coch. min. j. bis in die ex aquâ.

This is a very fair specimen, and hundreds of a more expensive nature and less profitable could be exhibited. The public also have acquired a habit of inquiring the cost of dispensing a certain prescription at various shops, and when they find a man—perhaps one of those surgeons with an open retail—who will do it exceedingly cheap, or possibly one who is glad to take the bare cost of the drugs in return for the sake of a customer, they are satisfied with their bargain; but, at the same time, think the man a swindler who demanded a reasonable profit for skilled labour and guaranteed drugs, and vow never to go near his shop again.

With regard to enormous profits, what does the note paper, ink, etc., used by the physician to write his prescription cost? or what does the actual operation of the surgeon cost? literally nothing; then what is it they charge so excessively for? They have no capital which they are obliged to invest in stock and to keep renewed to supply the wants of the public, nor does it cost them more when they are called out than it does when the patients go to them, and yet they charge more, if it is only across the way. If this question can be answered satisfactorily, our case is stronger, for besides incurring the previous outlay for qualification, we have to find capital afterwards, to invest in and keep the business floating.

One of the "Hornets" from the Nest Attacked.

Prices: A Problem for the 'Globe.'

Sir,—Having occasion to doubt the value, as charged, of two picture frames sent to me from a distance, I was reduced to the unpleasant alternative, much against my inclination, of inquiring the price of similar frames at various establishments from St. Paul's Churchyard to the Marble Arch. The following is the result, stating the localities near which the inquiries were made:—

Fleet Street	30s. each frame.
Drury Lane	32s. „
Temple Bar	36s. „
Charing Cross	42s. „
Holborn	50s. „
Pall Mall	55s. „
Oxford Street West	62s. „

Will the *Globe* solve the problem, and enlighten me as to the real value of my frames? If this range of prices is common to other trades, I ask, shall not the charm and logic of variety be conceded to ours?

W. W.

London, January 22nd, 1873.

Co-operative Stores.

Sir,—The letter in the Journal of 4th inst. from Messrs. Sanger and Son, shows how we as a body neglect one of the most powerful means of checking the Co-operative Stores. We do not as we ought resolutely refuse to do business with these houses supplying them (directly or indirectly.)

Of course if they prefer the support of the Stores to that of the trade, let them have it by all means; but let it be thoroughly understood that as a matter of policy we decline to have any business transactions with such firms, and let us make it our business to find out who they are, and close our accounts with them without delay. If the wholesale houses and manufacturers were on the alert, they could in almost every case discover if their goods were being bought for the Stores; but the fact is they don't want to, and will not so long as the retailers show such indifference.

It is well known that many of them sell to the managers of the different Stores in their own private names, and thus think to escape the charge of supplying the Stores. Let all those who wish for the welfare of the trade, act as Messrs. Sanger and Son have done, and they will be doing us a good turn.

E.

Milk Testing.

Sir,—On referring to Pereira's 'Materia Medica' and Fownes's 'Chemistry,' as quoted by Mr. Ekin, I find it stated that cows' milk when recently drawn from the cow is slightly alkaline; Mr. Ekin also says that if I examine milk directly it is drawn from the cow, I shall find that he is correct.

In opposition to Mr. Ekin and the above authorities I beg to subjoin the following facts:—

On Wednesday, January 15th, I went to a dairy in this town and tested the milk from six cows, in every case I obtained an acid reaction; from four cows the milk was drawn direct from the cow on to the test-paper, with the other two I dipped the paper into the milk contained in a tin pail.

On Thursday, January 16th, at another dairy in Boston, I took the reaction of the milk of six cows (one an Alderney); again, in every case, I obtained an acid reaction.

Mr. Ekin also states that chalk is really never met with in milk: I do not suppose that either Mr. Ekin or I shall find milk in our districts adulterated with chalk, but the case may be very different in London. I should like to know Mr. Ekin's authority for saying that "it really *never* is met with in milk."*

With regard to Vogel's lactoscope, I think Mr. Ekin is mistaken as to the use of it; in his letter he says, "I think no one would venture to rely upon the lactoscope alone to give a decided opinion in a court of law as to whether milk is adulterated or not." Vogel's lactoscope is not to detect adulteration, but to estimate the amount of fat in milk.

The system of estimating the percentage of water in milk by specific gravity is certainly open to many objections, the variable amount of cream and fat, still for want of a better method may be of use.

Chas. H. Southwell.

Boston, January 16th, 1873.

* The authority for this statement is Mr. Wanklyn, who has sought for chalk in hundreds of cases, and proved its entire absence in every one of those instances. Official investigation in the United States has also led to a like result. We think that recourse should be had to the taking of milk residues, and that the lactometer should be abandoned.—Ed. Pharm. Journ.

Erratum.—By a printer's error the name of the sculptor of the Priestley memorial was last week given as "Williams" instead of "Williamson."

Messrs. A. Payne, G. W. Thomas, J. Winn.—The advertisements and post-office orders have been handed over to the publisher. They should have been sent to Messrs. J. and A. Churchill, New Burlington Street. See the Notice to Advertisers, published every week on the second page of the advertising sheet.

Renovator.—We do not imagine that filtration through animal charcoal would injure the properties of either of the compounds mentioned, unless perhaps it removed some of the alkaloids.

J. W. B.—Recipes for making Cherry Tooth Paste will be found in the first volume of the present series of the Pharmaceutical Journal, pp. 557 and 577.

"Ph. C."—We do not know of the existence of any proprietary right in the name mentioned.

"Perseverando Vinces."—(1) Candidates who fail to pass either of the examinations cannot present themselves again for three months. (2) Yes.

"Inquisitive."—(1) The questions are put *vivâ voce*, and a knowledge of what they are can only be obtained by presenting yourself for examination. (2) The prescriptions in the book mentioned are only intended as examples. (3) Apply to the Secretary, 17, Bloomsbury Square.

"One who will Suffer."—Your letter appears to have been written under some misapprehension. The suggested increase in the Minor examination fee would not necessarily affect the assistant commencing at "£30 a year," since that examination is at present only compulsory before commencing business as a registered chemist and druggist, although assistants would probably find it to their own interest to pass it as soon as possible. As to the preliminary expense incurred in a course of instruction at Bloomsbury Square, it has been repeatedly stated that the Minor examination only requires an intelligent knowledge of the things daily met with in a pharmacy, which you yourself suggest could be obtained more economically elsewhere. At any rate, after the expenditure of the large sum specified by you, it would not be unreasonable to expect a man to go on for the "Major" qualification, in which case the gross total of the fees would remain the same.

A. W. Postans.—It would be quite justifiable to use an equivalent quantity of the strong acid, *i.e.*, ♏ v. to the thirty pills, adding it direct to the quinine, then mixing in the extract and a little absorbent powder if necessary. It has probably been an oversight of the prescriber, but not such a one as the dispenser might get over without troubling the writer.

W. W. Lindley.—We quite agree with the opinions contained in your letter, but we think the form in which they are expressed is rather too much like the article complained of.

"Scientific."—(1) Brough's 'Fairy Tales of Science' is published by Griffith and Farran, St. Paul's Churchyard, price 5s. (2) A lecture was delivered under the title mentioned at Exeter, by Professor Huxley, we believe, but we do not know whether it has been published.

Communications, Letters, etc., have been received from Messrs. R. Shepperley, J. L. Holmes, Shaply, W. Gunn, M. C. Cooke, N. Smith, W. Lindley, F. R. Bell, Stathers, R. O. Fitch., T. M., E. A. G., A Major before the Passing of the Pharmacy Act.

The following journals have been received:—The 'British Medical Journal,' January 18; the 'Medical Times and Gazette,' January 18; the 'Lancet,' January 18; the 'Medical Press and Circular,' January 18; 'Nature,' January 18; the 'Chemical News,' January 18; 'English Mechanic,' January 18; 'Gardeners' Chronicle,' January 18; the 'Grocer,' January 18; the 'Journal of the Society of Arts,' January 18; 'Grocery News,' January 18; 'Medical Record,' January 15 & 22; 'L'Union Pharmaceutique' for January; 'Journal de Pharmacie et de Chimie' for January; 'Anti-Adulteration Review' for January; 'Michigan University Medical Journal' for December; 'Western Lancet' for November; 'Photographic Journal,' January 16; 'Dublin Journal of Medical Science' for January.

PERCOLATION.

BY ERNEST C. SAUNDERS, A.P.S.

My attention has recently been drawn to several papers appearing in the Journal on percolation, and different processes of maceration. The subject may seem almost overdone, but I think that a process of such importance is worth all the attention that can be paid to it, especially as I think that it is hardly used as much among druggists, in preparing their tinctures, infusions, etc., as the great advantages it offers demands.

In Mr. Schweitzer's article, which appeared in the number of December 21st, there are several statements which seem to me hardly calculated to increase the efficiency of the process in inexperienced hands, and I should like to mention a few points which, in my own experience, appear to me most important. I must premise that I have rarely operated on larger quantities than fifty pounds at a time, but I have had to do with almost every drug in general use; and those who operate with larger quantities are comparatively few.

With regard to the form of percolator, I think it is too much to make the sweeping assertion that the cylindrical form is the best. For resinous substances and for anything percolated with strong alcohol it undoubtedly is, but for such articles as orange-peel, gentian root, and cinchona bark the conical form is preferable. It is said that the conical percolator does not exhaust the species at the junction with the sides, in consequence of the loose attachment to them, and of the slight pressure of the liquid at the top. I think that any one who has had much experience in percolating with glass apparatus must have noticed the gradual saturation of the menstruum equally as much in passing down the sides of a conical percolator as in a cylindrical one; while, after carefully watching and several experiments, I have come to the conclusion that pressure has nothing to do with the solvent power of the liquid, and that in some instances it acts injuriously by causing the operation to go on more rapidly than is advisable. In percolating with either form of percolator, I never allow of more than one to two inches of menstruum on the surface of the drug, arranging that it shall be supplied so as to be of a uniform depth throughout the operation.

Drugs ought in all cases to be of a uniform degree of fineness, according to their quality, and should be thoroughly moistened before being packed in the percolator. This is one of the most important points in the whole operation, as on it depends the possibility of successful packing in the case of all roots and dried herbs that will absorb much water. The amount of moisture should be only sufficient to form a slightly coherent powder, capable of being pressed into a mass, but not, under any circumstances, of forming a paste. The directions of the U.S. Pharmacopœia are distinct and of great practical value in this respect. Such drugs as gentian, calumba, etc., should be left in a covered vessel from six to twelve hours after being moistened, to allow them to thoroughly absorb the liquid and expand to their full amount.

In packing, it is always best to use the hand, and the occasions are very few where this cannot be done. I am surprised to see Mr. Schweitzer advocate the use of whole chaff and straw mixed with the drug to increase the bulk. Such articles are among those most likely to cause a failure in the attempt to exhaust any drug, forming channels down which the menstruum will run, instead of being gradually drawn through the whole body of the mass, and equably penetrating every part. Also, when the drug is properly moistened and packed, it will never rise to the top of the liquid, and such clumsy expedients as weighting down the top with glass stoppers are entirely unnecessary. After properly packing (an operation that nothing but actual experience can teach), all that is necessary is to cover the surface with filter-paper, not to keep the drug from rising, but to prevent the menstruum, as it is added, from stirring up the surface. If any of the drug should rise to the top, the operator may be certain that it is owing to its having been insufficiently or improperly moistened.

In conclusion, I must enter my protest against such preparations as Mr. Schweitzer recommends. There are many objections, but I will only mention the three principal ones. I will leave altogether out of the question the use of water as a menstruum, both on account of its inability to preserve the delicate active principles from decomposition, and of the impossibility of exhausting such drugs as orange-peel, cinchona bark, etc., with it. The objections to such concentrated solutions, made with ordinary menstruum, are these:—First. The difficulty of preserving such strong solutions without change, owing to the gradual deposition of a sediment, carrying with it frequently a large share of the active principles. This is not a hypothetical objection, but one which actually arises frequently, as in this country many fluid extracts are in use made practically in the manner suggested by Mr. Schweitzer, in which this change has often been noticed. Second. The impossibility, in many cases, of exhausting the species with so small a quantity of menstruum. It is needless for me to give any instances, as any one can see this at once on looking at the B.P. forms, and calculating to what bulk they would have to be reduced. Third. The increased facilities for adulteration and purposed diminution of strength; for were such extracts in general use, their manufacture would speedily fall into the hands of large makers, and competition would produce the inevitable results of lower prices and inferior qualities. Such preparations are largely in use in this country, and the above are the chief objections to be urged against their use.

I think the difficulties of percolation have been very much overrated. In large quantities the difficulties are great, and only to be surmounted by much care and some skill; but in working with small quantities the difficulties are very slight, while the results are so superior to those produced by the old process of maceration in general use, that I am sure any pharmacist having once tried it will never return to the old way.

Detroit, Michigan.

MILD ACONITES.

BY M. C. COOKE, M.A.

Supplementary to the observations already made on the Acrid Aconites of the East, some remarks may not be out of place on the milder forms, of which the "Atis" is the type. Before doing this, one cannot help remarking that up to the present this drug has not been fairly tested, in fact not tested at all in this country, although it promises enough value to repay amply a careful investigation.

The root of *Aconitum heterophyllum* has long been known in India as a valuable febrifuge and tonic, and may be obtained in all the bazaars, although it is not uncommon for the inert and insipid *Asparagus sarmentosus* to be substituted for it. Moodeen Sheriff gives the following as the synonyms for this root in the languages of India, '*Atis*' (often written *Atees*) in Hindustani; *Atvika* and *Vajje-turki*, Dukhanee; *Ati-vadayam*, Tamul; and *Ati-vasa*, Telugu. This drug is classed as officinal in the Pharmacopœia of India, and is thus described:—Ovoid tuberous roots, tapering downwards to a point, from one to one and a half inches or more in length, and from three-eighths to half an inch in thickness. The surface, which is covered with a thin greyish epidermis, is slightly wrinkled longitudinally, and marked here and there with rootlet scars. A transverse section shows it to consist of a pure white friable amylaceous substance, marked by five or six concentrically arranged dots, the terminations of threads of woody fibre traversing the root longitudinally, It is inodorous, and of a bitter taste, devoid of acridity. Does not contain aconitia. It may be readily distinguished from other roots sold in the bazaars under the same vernacular name by its characteristic bitterness. Tonic and antiperiodic. The plant is found in western temperate Himalaya, at 8000 to 13,000 feet elevation, from the Indus to Kumaon. In all examinations of this root, to ascertain whether genuine or not, the presence of starch, the five or six concentrically arranged dots towards the centre, as shown in a transverse fracture, and the bitter taste, devoid of all acridity, should be regarded.

Dr. Balfour, in the Indian 'Annals of Medical Science' for 1858, states that for two years he had this drug in constant use, and found it a most useful febrifuge, given in doses of half a drachm mixed with a little water every four or six hours during the intermissions, commencing its use during or towards the termination of the sweating stage. Of 66 cases of intermittent fever treated by it, of which notes were kept, it proved fully successful in 37, and comparatively so in 18; in 11 it failed. He directs that every root should be broken across, and all which are not pure white, with a short starchy fracture, should be discarded.

Of the value of "Atis" in India there can be little doubt. Subassistant-Surgeon Henning states that so steady and certain is it in its operation, that he never thinks of using quinine by any chance, and he adds, "Surely if I can do without quinine in a district where fever of a severe character is very prevalent, other medical men could easily do without it also." Similar testimony is given by Dr. Balfour, then civil surgeon at Delhi. "I think my prisoners more healthy than usual this year, partly from the season, partly from the effect of the *Atis*."*

The testimony as to the efficacy of this drug as a febrifuge is so contradictory that some systematic trials should be made. Some have asserted that it is quite valueless. The probabilities are greatly in favour of the assumption that the genuine drug has not always been used, but some almost inert substitute. Two kinds are mentioned in the Taleef Shereef, a white and a black variety, but both are said to partake of the same qualities, bitter, astringent, pungent, heating, aiding digestion, and useful in dysentery, vomiting and piles. O'Shaughnessy also mentions two varieties, one of which he considers wholly inert, and refers to the tubers of *Asparagus sarmentosus*. It is probable that of these two kinds, one only is the genuine *Atis*, and the other some substitute, or other substance passing under the same name. The Pharmacopœia of India gives no note of a second kind, or variety, differing at all from the officinal article therein described; but in the 'Supplement' Mr. Moodeen Sheriff has called attention to a root found in the bazaars of Southern India, under the name of *Ati-vasa*, which he considers a variety of *Aconitum heterophyllum*. "It is a small tuberous root, from one to two inches in length and circumference, conical or ovoid, with a tapering point towards one end; grey externally, and white internally, with more or less white scars of rootlets on the surface; inodorous, and bitter in taste without any acridity or astringency."* He compared this root with specimens of *Atis* from Calcutta and other places, and found it to correspond with them exactly in the appearance of their substance internally, and in taste, but it differed from some of them in shape and external colour. "In one of the specimens, the epidermis was of a brown colour, the roots were smaller and almost oblong, and in some of these the tendency to be divided into two tubers, as described in some books, was more distinctly marked than in the roots of any other specimen. In another specimen most of the roots were thin and cylindrical, with longitudinal wrinkles and with little or no point at either end. All these specimens agreed in three characters which were invariable, viz., the whiteness of the substance internally, the pure bitter taste, and the farinaceous nature."

Another root found in the bazaars of Southern India by Moodeen Sheriff is called *Nat-ki-vajje-turki* in Dukhanee; *Nattu-ati-vadayam* in Tamul; *Nattu-ati-vasa* in Telugu. This he describes as "a very small root, and bears more resemblance externally to the root of ipecacuanha than any other. It is generally about the thickness of a small quill, from half to one and a half inches long, annulated, of grey or dark grey colour externally and white internally, inodorous, and acrid in taste. It is clear from this description that it is not a variety of *Aconitum heterophyllum*, but probably another species of *Aconitum*."†

The roots of one or more species of Aconite of a similar character to *A. heterophyllum* are met with in the Bazaars of India under the Arabic name of *Jadvar*, and the Hindustani *Nirbisi*. Three or four well marked varieties may be distinguished, and these are enumerated in the Supplement to the Indian Pharmacopœia. Of these are the *Jadvar-hindi*, the *Jadvar-Khatai*, and the Round Jadvar. All these resemble each other in being either bitter or sweet without the least acridity, irritation, tingling, or any other unnatural sensation; and in being more or less brown, both externally and internally. The present communication is already

* Proceedings Agri. Hort. Society of India (1857) vol. ix. part iii. p. 271.

* Supplement to Pharmacopœia of India, p. 28.

† Supplement to Pharmacopœia of India, p. 28.

of sufficient length so that any further details that might be given of the different varieties of *Jadvar* or *Nirbisi* must be reserved for another occasion.

In China the prepared roots of *Aconitum variegatum* would appear to be employed in a similar manner, and for a like purpose to the *Atis* in India, under the names of *Fu-tsze* and *Heh-fu-tsze*. Dr. Porter Smith writes of this species of Aconite as cultivated on a large scale at Chang-ming-hien, etc. The roots are prepared by steeping in vinegar and salting them. The *Tien-hiung* is considered by the same authority to be a variety of the same species of *Aconitum* which is cultivated in Sechuen, etc. The prepared tubers are top shaped, ovoid, measuring one inch and three-quarters long by one inch and a half in breadth, of a black colour externally, and often encrusted with a saline efflorescence. Several tubercles emboss the outer surface, more especially at the upper part. The interior is of a a blackish-brown colour, moist and greasy. The *Fu-pien* is said to be merely the tubers of the same species, stripped of the cuticle after soaking in vinegar, dried thoroughly, and cut into thin slices, which are brittle, curled, translucent, white, and exhibit the concentric arrangement of the vascular bundles which traverse the root lengthwise. It is but very slightly acrid.

Tseh-tsze is another drug supposed to be derived from the small side tubers of the same *Aconitum variegatum*. All these forms are more or less employed in fevers, ague, apoplexy, rheumatism, leprosy, neuralgia, headache, dysuria, dropsy, cholera, and dysmenorrhœa. The preparation by salt and vinegar in order to correct the natural acrid properties of the plant is one of the disadvantages which the Chinese possesses in comparison with the Indian *Atis*.

BLUE MOUNTAIN TEA.

BY JOHN R. JACKSON, A.L.S.

Curator of the Kew Museums.

In a recent number of the 'Garden' we read that thirteen bales of Blue Mountain tea, weighing 1920 lb., lately arrived in Chicago from Lower Hill Schuylkill county. This so-called tea has some interest attached to it in a pharmaceutical point of view, inasmuch as the plant yielding it is an officinal plant in the United States, its use simply as a tea being hitherto considered of a secondary nature. The account in the 'Garden' proceeds as follows:—"This tea is composed of the leaves of a variety of the golden rod family, botanically known as *Solidago*. It is gathered in large quantities on the Blue Mountains, and the mountains to the north of that range. The tea matures in the latter part of September, and is gathered until late in October. It is then cured and put up in packages, selling on the mountains at from twenty cents to thirty cents per pound, but retailing in villages and towns at one dollar per pound. The tea has a very pleasant aromatic flavour, and is held by many persons in great esteem."

The plant referred to here is evidently *Solidago odora*, Ait., called the Sweet-scented Golden-rod. It grows in woods and fields, more or less abundantly, in all parts of the United States, and is described as having a slender erect pubescent stem, growing two or three feet in height, linear-lanceolate leaves, entire, acute, rough at the margin, and covered with pellucid dots, deep golden-yellow flowers, arranged in a terminal, compound, panicled raceme, the branches of which spread almost horizontally; the ray florets are ligulate, oblong and obtuse, the disk florets, funnel-shaped, with acute segments; the leaves have an agreeable, warm, aromatic taste, and a fragrant odour; when subjected to distillation an aromatic, volatile oil is produced, and by dissolving this in proof spirits an essence may be made. This, it is said, will stop vomiting, and correct the taste of medicines, even laudanum and castor oil. Applied externally it is a valuable remedy for allaying pain arising from headache. The oil is of a pale, greenish-yellow colour.

Wood and Bache thus speak of the medical properties and uses of this species of *Solidago*:—"Aromatic, moderately stimulant and carminative, and like other substances of the same class, diaphoretic when given in warm infusion. It may be used to relieve pain arising from flatulence, to allay nausea and to cover the taste or correct the operation of unpleasant or irritating medicines. For these purposes it may be given in infusion. The volatile oil dissolved in alcohol is employed in the Eastern States. According to Pursh, the dried flowers are used as of a pleasant and wholesome substitute for common tea." From this it will be gathered that though the plant has been long known in America for its medicinal properties, the application of its leaves as of substitute for tea has some novelty in it.

Another species of *Solidago* (*S. sempervirens*, L.), called the narrow-leaved golden-rod, which grows in moist situations in North America, is by some considered very valuable for the cure of wounds.

The common golden-rod of our woods and thickets (*S. virgaurea*, L.), which also grows in the United States, was at one time used with us as a diuretic and vulnerary.

THE EUCALYPTUS GLOBULUS IN CALIFORNIA.*

The annual report of the Board of Directors of the California Pharmaceutical Society, in referring to the *Eucalyptus globulus*, quotes a letter from Dr. A. B. Stout, contained in a paper read by Mr. R. E. C. Stearns before the California Academy of Sciences in July last, from which we abstract the following:—

"I am happy to contribute to your important article on the culture and uses of the Eucalyptus in California, my experience of the medical properties of that valuable plant. The Eucalyptus is not less precious for its medicinal virtues than it is ornamental in arboriculture and useful in the arts. Several months ago, incited by information derived from the 'Practitioner' and other sources of knowledge, I collected and dried the leaves. The agreeable empyreumatic oil of the leaves in evaporating, diffused a balmy odour through the house. I therefore considered that as this oil, as well as the catechu gum and kino, and the cajeput oil, are all similar hydrocarbons, their qualities must resemble the creasote, pyroligneous and carbolic acids in their disinfectant and hygienic properties. I have no doubt that Eucalyptus has these properties in a milder or weaker degree, only differing in being accompanied with an agreeable perfume, wanting to creasote and carbolic acid. As a purifier, therefore, of the musty atmosphere and unpleasant emanations in basements and cellars, I have recommended the scattering of the dried leaves in

* 'The Western Lancet,' vol. i. p. 696.

such places. The powder of the dried leaves scattered in trunks and among clothes will no doubt be as useful and more agreeable than tobacco or camphor to prevent the growth of moths or other insects. Its chief value is, however, as a sedative and antiseptic in asthma, and throat diseases, nasal catarrhs, and affections of the mucous membranes. To utilize these properties I had a concentrated tincture with alcohol at 95° prepared, and also contrived an inhaler with which to introduce the vapour of the essential oil to the throat and lungs. I can testify to the excellent effect of this mode of medication. The paroxysms of chronic asthma are relieved and shortened, and acute attacks are quickly allayed. The inhaler is a simple instrument made of tin. It is a cup of a capacity of 4 fluid ounces; the lid, attached by a hinge, has a tube from the centre about three inches high, bent near the end at a right angle, and terminated with a mouth-piece like that of a speaking trumpet. The cup is on legs so that a spirit lamp may be placed underneath, and has a wooden handle to move it about when heated. Put two ounces of boiling water (4 tablespoonfuls) in the cup; add one tablespoonful of the tincture; and inhale the vapour while the fluid is kept gently boiling with the spirit lamp. Again, I had prepared cigarettes with the coarsely powdered leaves. These produce a decidedly anodyne and antispasmodic effect. An agreeable syrup may also be prepared, useful in infantile maladies.

"There can be little doubt but that the oil of Eucalyptus, and Eucalyptine, when it can be procured, will be available remedies against malarious diseases of all types, and that the presence of the trees, cultivated in gardens, contribute to sanify the atmosphere from those emanations which give origin to epidemic diseases. That the parasitic insects which infest other plants do not relish the Eucalyptus, is evident from the general cleanness of the leaves and the fact that the hydrocarbon oils are fatal to animal life. The balmy perfume, therefore, that exhales from them must have an influence in destroying the parasites which frequent shrubs growing in their vicinity, tending to diminish if not suppress them.

"However obnoxious to parasites in general this tree may be, it appears it nevertheless has its own species in the *Psylla Eucalypti*. This insect is an Hemipteron, and appears on the Eu. dumosa. It deposits a species of manna, called in Australia *Lerp* or *Laap*. It is a white substance, 53·1 per cent. of sugar-syrup and 46·9 per cent. of a special modification of starch. This is prized by the inhabitants as a manna; and is greatly sought for by the bees, who convert it into honey. Dobson (entomology) describes it as the cup-like coverings of the Psyllidæ, but Wittstein mentions six varieties of *Psylla*, and that one species produces a coloured Lerp handsomer than the white, but as a deposit beneath the cup-like shields of the insect.

"If this insect derives its lerp from the aromatic and balmy oil of the Eucalyptus, and furnishes an agreeable aliment for the inhabitants, and a Mt. Hymettus-like honey stuff for the bees, certainly the busy little insect manufacturer, parasite as he is, may be freely pardoned."

Mr. Stearns says, "From experiments recently made upon myself, I find that small doses, ʒij to ʒiij, of the infusion of the leaves (of young trees) drank when cold, quiet the nerves and induce sleep; quite likely, in ordinary cases of wakefulness, a pillow stuffed with the leaves would produce the same result. My friend, Dr. Kellogg, has prescribed the infusion in dyspepsia, and reports favourably. In addition to the many valuable properties of the blue gum herein recited, I have no doubt but camphor in considerable quantity can be obtained from it."

The powers of the Eucalyptus in the treatment of intermittents, we sincerely hope, are rather under- than over-rated, as the discovery of an efficient substitute for cinchona would be an inestimable boon, in view of the high price and scarcity of that agent; to which hope may be attributed this extended notice of this new remedy.

HYDRASTIS CANADENSIS, OR GOLDEN SEAL, AND ITS ALKALOIDS.*

Dr. Van der Espt has recently presented to the Royal Society of Medical and Natural Sciences at Brussels an interesting memoir upon the *Hydrastis canadensis*. This plant, known also under the name of Golden Seal, is as its name indicates, a native of Canada, and belongs to the order Ranunculaceæ. It is the rhizome, which is yellow, lactescent when freshly fractured, tortuous, and composed of nodose, fleshy tubercles, furnished with numerous long fibres, that is employed in medicine. Two alkaloids have been found in it: one yellow, berberine; the other white, hydrastine.

Berberine, which is also found in the barberry, calumba root and elsewhere, appears in the form of small concentrically grouped prisms, or clear yellow silky needles. It is inodorous, but possesses a persistent bitter taste; it is slightly soluble in cold alcohol or distilled water, and perfectly insoluble in ether. With hydrochloric acid it forms a salt which crystallizes in slender yellow needles.

Hydrastine crystallizes in white shining four-sided prisms, which lose their transparence upon desiccation. It is very bitter and pungent, and provokes in the mouth a feeling of numbness which causes it to be employed in America as a local anæsthetic. Nearly insoluble in water, it is freely soluble in alcohol, ether, chloroform and benzine. As the last three do not dissolve berberine, the hydrastine may be easily extracted by treating the powdered root in a displacement apparatus with either of those solvents. The proportion so obtained is about 1½ per cent.

In America neither berberine nor hydrastine is prescribed, but a crystalline substance known under the name of hydrastin, which is said to be a mixture of hydrochlorate of berberine and hydrastine. The purity of this product depends upon its mode of extraction. Among the processes indicated, that of Professor Wayne is the most simple. It consists in the maceration of the powdered root of the golden seal and displacement by cold water. The product is treated with hydrochloric acid, the precipitate separated by filtration, and washed, treated with alcohol and left to crystallize.

The hydrastin appears under the form of yellow acicular crystals, without acid or alkaline reaction, and yielding upon trituration a clear yellow powder. It is soluble in boiling alcohol, insoluble in cold alcohol, ether, chloroform, spirit of turpentine and distilled water; but these various liquids acquire a yellow tint and contain hydrastine.

The rhizome of the golden seal is a bitter tonic analogous to calumba. It is administered in the form of powder, in doses from half a gram to a gram and a half. The hydrastin is prescribed in doses of from five to fifty centigrams. In larger doses these substances act as laxatives, similarly to rhubarb. This latter effect, in the absence of any cathartic or irritant principle, M. Van der Corput thinks would be due to a kind of indigestion, or the stimulation of the mechanical action of the digestive organs under the influence of large doses of the drug. The affections for which it is stated hydrastin may be beneficially employed are those connected closely with atony and increased secretion of the mucous surfaces. A decoction for external use is prepared by boiling thirty parts of the bruised root in five hundred parts of water.

* 'L'Union Pharmaceutique,' vol. xiii., p. 321, from 'L'Union Médicale.'

THE CHEMISTRY OF THE GREAT FIRE.*

A conflagration so extensive and destructive as that which laid waste a considerable portion of the city of Boston in November must be interesting and instructive in its chemical aspects, and we design to briefly direct attention to some of these. The process of combustion, whether it involves immense structures, or is confined to the narrow limits of a candle or common friction match, is strictly a chemical process. The burning of Boston was a chemical experiment on a vast scale, and withal so costly that the spectators hardly wish to see it repeated. To burn a substance is simply to change its condition; the matter involved is not destroyed, but from chemical action it is forced into new relationships, or into new forms of matter. There was nothing whatever actually *destroyed* by fire in this city on the night of November 9th, but an immense amount of material was changed from a valuable or marketable condition into one having no value. The sugar, coffee, tea and spices of the grocer; the prints, flannels, laces and silks of the dry goods dealer; the opium, gums, oils, and extracts of the druggist; the salts, acids, alkaloids and reagents of the chemist, consumed on that night, were but common and valueless elements thrown into complex combinations by nature or art, so as to meet or supply human wants. In the condition in which the hydrogen, carbon, oxygen, nitrogen, the metals, etc., existed, of which these diversified substances were composed, they were needful to feed us, keep us warm, or relieve us when ill; they, therefore, as related to our wants, had value; we were willing to exchange gold for them, a metal of such noble characteristics and so sparsely disseminated upon our planet that we find it to be a convenient representative of value. We had toiled for months or years to form these chemical substances and fabrics, or we had sent our ships to every point of the globe to gather them up, and we had stored them safely, as we supposed, in our warehouses. But the fire came, and in sixteen hours the whole was resolved into carbonic oxide, carbonic acid, water and a few tons of ash; products which we can neither eat, wear, nor utilize in any way to advantage. We do not need the forms of matter which the fire left for us, but we did need the same elements in the other forms, as we had them before the conflagration.

Combustion is a wonderful process. It may go on rapidly, as it did in November, and lay waste a city in a single night, or it may proceed slowly, and require centuries to effect the same changes. Our immense stores of merchandise, which were resolved so rapidly into invisible forms, would have passed through the same changes—in short, would have been burned—if no fire had come nigh them. This result would have been inevitable, if we had consumed them as food, worn them as clothing, or allowed them to waste from neglect. The burning would have been as actual as that of which we were eye-witnesses. The same amount of heat would have been developed, and the resultant products the same. All organized bodies are constantly undergoing a process of decay, which is slow combustion, and although we do not see the light or feel the heat, it is accompanied by them. The world of organized matter is certainly destined to be burned, but we prefer the slow form to the rapid, as we have had a notable example of the latter which will suffice for a lifetime.

It is quite easy to understand that wood and other organized bodies can burn; but the combustion of buildings constructed of brick, stone, and iron presents a problem not a little puzzling to many. A fire, sweeping through the streets of a city, lays low whole blocks of buildings, into which nothing combustible enters, save the wooden partitions, floors, and stair-cases, and these while burning afford combustible material enough to expand and topple over our thin walls, and render the ruin complete. Buildings considered fire-proof, that is, those constructed without wood, can be destroyed by fire, if any ignitible material is burned within them. The Palace of the Tuileries and the Hotel de Ville, in Paris, burned by the wretched Commune, were fire-proof buildings, and without the aid of our American kerosene oil or some similar inflammable material, they could not have been ruined as they were. It required nearly three hundred barrels of kerosene oil to destroy the Tuileries. The miscreants hoisted a barrel or more into each room, and knocking out the heads, allowed it to flow over the building, and when it was thoroughly saturated, they set it on fire. The metal and stone used in the structure were rapidly expanded by the intense heat, the walls were pushed outwards, the roof fell in, and the destruction was complete.

Our Boston fire has demonstrated the influence which extreme heat has upon granite structures. They do not withstand its influence so well as those built of brick, and therefore are not as safe buildings in time of large conflagrations. Pearl Street was lined with granite buildings, and after the fire the work of disintegration was so thoroughly accomplished that fine granitic sand covered the pavement several inches deep. Water we recognize as the antagonist of fire, and it was most liberally supplied in our great conflagration. It seems a little paradoxical at first view, the act of pouring an agent on to a fire with the design of arresting it, when we remember that the fluid itself is composed of two elements, one of which is highly combustible, and the other the grand supporter of combustion. It has been stated in several journals, that water thrown upon the fire in the form of spray was decomposed into its gaseous condition, and therefore actually fed the flames. Now this is not correct. We doubt if a single one of the millions of gallons employed was thus decomposed. It requires a most intense heat, equal to that of a blast-furnace, to decompose water, and it must also be accomplished under peculiar conditions. Water thrown upon buildings is often dissipated in steam by contact with flame before it reaches the burning body. Most of that used in this city was thus rendered ineffective, as the buildings were high, and the water was sub-divided into mist before reaching the point upon which it was directed. Water quenches fire by physical contact with the burning body, covering it, and thereby excluding the contact with atmospheric oxygen; also, it instantly reduces the temperature of ignited substances, by vaporization. By the sudden change from a liquid to vapour, it robs the substance of the heat necessary to keep up combustion, which is thus extinguished.

It is certain that we must seek new devices for subduing fires in large cities, and we will describe a plan which we think would prove practicable and effective. The plan is based upon the idea that every building must depend upon its own apparatus, and not upon that belonging to any municipality. Twenty years ago we employed carbonic acid water for quenching fires, long before any of the so-called fire-annihilators were used, and it is an agent so effective, and so easily and cheaply produced, that it must come into general use. Our plan is to place in the basement of every warehouse or store an iron vessel resembling a steam boiler, the capacity to depend upon the size of the building. This is to be kept two-thirds full of water, the chamber above the water to hold two glass vessels, one of which is filled with acid, the other with bicarbonate of soda. By a very simple device these glass vessels may be broken at any moment, so that the substances will instantly develope carbonic acid, which being absorbed by the water changes it into aerated, or carbonic acid water. The gas over the water affords immense pressure, and by pipes leading from the strong iron fountain, the gas-impregnated water may be directed at once upon the fire in its incipient stages, in any portion of the building. One gallon of this water is as effective as ten of common water, and therefore can be used to extinguish a fire without the great water damage to goods which often

* From the 'Boston Journal of Chemistry.'

results. The time is not far distant when apparatus of this kind will be regarded as much of an essential appendage to buildings which contain large quantities of valuable merchandise, as are gas pipes, or water closets.

The burning of our warehouse, at the time of the great fire, filled with chemical products, was in one sense an interesting exhibition. We cannot say that it was calculated to awaken much enthusiasm so far as we were personally concerned, as the spectacle was a little too costly for that. It was paying too high for the pyrotechny, no matter how grand the display. The nature of the substances burned was peculiar, affording intense heat and flames of divers and gorgeous colours. Numerous packages of the salts of strontium, calcium, magnesium, potassium, copper, barium, etc., were consumed, which produced a variety of brilliant illuminations, and these, with alcoholic preparations, carbolic acid, nitrate of ammonia, and hundreds of other highly combustible bodies, gave to the flames a fierceness and colouring not observed elsewhere. The brick vault in which were deposited our account-books and valuable papers, was in the midst of the fiery furnace, and subjected to the full fury of the flames. Owing to the great heat, it could not be reached until five days afer the fire, and when opened, the contents were found to be in a most perfect condition. The safe was a brick structure, carried up from the ground through the basement, having two iron doors, the space between the outer and inner being fourteen inches. The doors were about three-eighths of an inch in thickness, and without transverse bars or bolts, or other fastening, save one common lock. Apprehensive that these frail iron doors would not withstand intense heat in case of fire, we directed the American Steam Safe Company, two years ago, to put upon the inside of both twelve copper reservoirs of water, each holding about a gallon. These were constructed after their pattern, being sealed with a fusible plug. On the night of the fire, just before the store was burned, several of the young men employed in the counting-room gained access to the vault, opened it, and placed three wooden pails, filled with water, upon the floor; they then closed the inner door, and before locking the outer, placed two more pails full of water in the space betwen the two. This was indeed a thoughtful act in a time of so much excitement. We expected not only that the wooden pails behind the first door would be burned, but those in the interior of the vault; and therefore great was our surprise to find upon examination that they were entirely unharmed, and each contained a little water. Those in the interior contained nearly the same amount as when placed there. The copper reservoirs attached to the interior surface of the first door were entirely empty; those upon the second held about one-third of their contents. It is clear that we are indebted to the agency of *steam* for the preservation of the valuable contents of our safe. The reservoirs upon the first door held water sufficient to maintain an atmosphere of steam in the space, during the time the fire was most intense; afterwards, the heat was conducted through to the second, when the boiling water filled the vault itself with steam, and prevented the papers from igniting. Without the reservoirs upon the outer door, the two water pails would have been burned before their contents could have been evaporated, and the flames would have found access to the vault through the inner door, had it not been protected. We used an iron safe of an approved pattern, in the counting-room, as a matter of convenience, not trusting, however, any papers of value in it. This safe was taken from the ruins burned through and through. It afforded no more protection than would a wooden box. The plan adopted by the American Steam Safe Company of this city, of using water reservoirs as a lining, is an excellent one. So long as the water lasts, steam is present in the cavity, and the temperature cannot rise high enough to ignite or char paper. Every bank vault in the country, and every brick or stone chamber, in which valuables are kept, should have the doors covered on the inside with water reservoirs.

There are so many interesting points connected with the chemistry of the great fire, that we have not room to allude to them. At a future time we may present another article upon the subject.

SUPPOSITORY MOULDS OF PLASTER OF PARIS.*

BY CHARLES E. DWIGHT.

Pharmacists who have had many suppositories to make with the old moulds have undoubtedly often hurt their fingers by pounding in trying to remove the suppositories. I have been for some time using a mould which parts through the centre and is made of plaster of paris, which gives so much satisfaction that I can but wish for others to try it; it may have been used by others, but is entirely original with myself.

The expense of buying moulds of metal which part through the centre has probably been detrimental to their universal use, while they are undoubtedly superior to those old finger smashers in being easily cleaned and oiled, and also facilitating the extraction of the suppositories when cold. For the benefit of those unused to the manipulation with plaster, I will give a general plan for preparing the moulds.

Into a vessel of about six inches long by two wide and one deep (a pasteboard box will do), pour in plaster mixed to the consistency of thick cream, until half full; have ready six suppositories, moulded of wax, from other moulds of good shape, and while the plaster is yet soft immerse them to half their diameter, with their large end close to the edge of the box, all in a row and a uniform distance apart. When the plaster has set, gently remove the wax, and with a knife smooth off the surface and trim the edges of each mould sharp, and between each depression made by the wax suppository dig a small cavity about the size and shape of a small pea cut through the centre. Now we have half of our mould. When the face has become hard, oil or grease with linseed oil or lard, replace the wax suppositories and raise the edges of the box by wrapping heavy paper around, which will extend about another inch above the surface of the face; mix another portion of the plaster equal to the first, and in the same way, and gently pour over the greased surface until it will be about one inch deep above the other or lower half. When hard, the two parts can be easily pulled apart, the edges trimmed off and each part boiled for about an hour in linseed oil, which will prevent the adhesion of the substance to be moulded. The plaster must be mixed thin *and well stirred* to be substantial.

By following the above plan almost any number of sizes can be made at small expense, and will, I think, be found to answer admirably. If this will in any way alleviate the frown which comes over the face of the pharmacist when he finds he has to make suppositories, the object of the writer will be fully attained.

SOLANIA IN SOLANUM LYCOPERSICUM.*

BY GEORGE W. KENNEDY.

Having had a strong desire to know whether or not the common tomato plant (*Solanum lycopersicum*) contained any solania, and never having seen any analysis of the plant, I was induced to make a series of experiments. The fruit of the plant has been examined by several pharmacists, but I believe there was no solania discovered. The amount of citric acid obtained by the experimenters has varied very considerably, thus suggesting that the fruit of different varieties has been examined, or that the fruit was collected at different periods of the year.

* From the 'American Journal of Pharmacy.'

In giving the result of my examination I hope it may throw a little more light on a plant of some importance, which I have found to contain the alkaloid solania. The process for extracting the alkaloid was similar to that of Wackenroder, except a slight change in the maceration and in using ammonia instead of hydrated lime for precipitation.

I took a quantity of the living plant, leaves and stems, and bruised them with water into a pulp in a mortar. This pulpy mass was next macerated for forty-eight hours with water enough to cover it, previously acidulated with sulphuric acid so as to have a strong acid reaction. The liquid was then expressed, and the residue treated again with sulphuric acid and water, as in the first maceration. It was now expressed as before, the two liquids were mixed, and after standing for some days, filtered and treated with water of ammonia, sp. gr. 0·960, in excess. The precipitate that formed was separated by straining dried in heated air at 120° Fah., and then boiled several times with alcohol. The alcoholic solution, having been filtered while hot, upon cooling, deposited the solania in small feathery-like crystals, resembling quinine in appearance, having a smell like that of potatoes, and a taste rather nauseous, bitter, and somewhat sweetish. With sulphuric acid, it gave a bright red colour, passing into reddish brown. With iodine a characteristic yellowish brown colour was produced. Besides solania, I also found in the herb some fixed oil, gum, chlorophyll and inorganic salts.

OLIVE CULTIVATION IN SYRIA.

In a recent report on some of the chief products of Syria, Mr. Vice-Consul Jago remarks that olive oil is produced throughout Syria, but chiefly in the plains of Safet, Nazareth, and Nablous. The average produce is estimated at 6,000,000 of okes under favourable circumstances. That of 1871 amounted to between 5,500,000 to 6,000,000, of which about 1800 tons were exported. Prices ranged from 8 to 5½ piastres per oke.* The production of this article has increased of late years, and it promises to become, with the growing demand for exportation, one of the most important articles of Syrian produce.

The olive tree, like the mulberry, requires but little care, which is limited to ploughing the land two or three times a year. The crop takes place in September and October, according to situation. The fruit is knocked off with sticks, and the injury thus caused to the branches is probably the reason of the short yield of every second year.

The plantations are being extended principally on the coast line, between Lattakia and Jaffa, the climate of which seems to be peculiarly adapted. Nearly half a million of new trees are said to be annually planted throughout the country. This is perhaps an exaggeration, but the increase is very large.

The quality of the finer sorts of oil is equal to that of Italian, while that produced near Sidon is said to rival the finest qualities that Europe can produce.

About one-half of the crop is consumed in soap-making, one quarter in eating and burning, and the remaining quarter is exported, chiefly to France. The now extensive use of American petroleum oil for burning, of which 101,800 gallons were imported into Syria in 1871, has made a larger quantity of olive oil available for export.

The oil press used is the rude native one of bye-gone ages, and Mr. Jago believes there is but one European press in the country.

* Oke = 1200 grams. £1 = 110 piastres.

THE AGUE-PLANT.*

Dr. Bartlett, of Chicago, has forwarded to the editor of *Grevillea* (No. 6, 1872) specimens of the palmelloid plant, in which Dr. Salisbury believed himself to have discovered the germs of the ague. He says, "Desiring to investigate the subject, I sought for the plants described by Dr. Salisbury in the ague bottom of the Mississippi river, opposite Keokuk, Iowa, lat. 10° 25′. Not being provided with a suitable microscope, I was unable to discover the microscopic algæ described by the doctor. I was pleased, however, to find the fungi, samples of which I send you. Generally, it answers Salisbury's description." He adds, "By placing the cake of earth sent you in a plate, and adding water enough to make it of about the consistence of potter's clay, and keeping it at a temperature of above 60 deg., you will find a fresh crop of the plant to develope, and you will thus have an opportunity of studying them. Should you allow them to flourish and remain uncovered in your room, you might have the satisfaction of demonstrating the 'cause of ague.' This fungus was first found, so far as I know, by Dr. J. P. Safford, of Keokuk, who was kind enough to search for me while I visited an ague patient. In the locality of their growth they are to be seen in myriads, and near them, even on elevations of over one hundred feet, everybody had the ague. The course of this disease seemed *pari passu* with that of the plant."

CEMENTS.†

A good rubber cement may be prepared by dissolving one part india-rubber in two parts linseed oil, and adding to the solution a sufficient quantity of bole, say about three parts.

For amber and tortoiseshell, a cement is made by mixing together equal parts of mastic and linseed oil, and warming gently. This cement should be used warm.

To unite wood to wood, a thick solution of shellac in alcohol may be used. It is well to put a piece of fine gauze or crape between the broken surfaces of wood, and then press them tightly together until the cement becomes perfectly firm. Another good, durable cement for woodwork is made by fusing together shellac, mastic and common turpentine, and adding some broken isinglass.

For attaching small objects to anything turned, a mixture of colophonium, turpentine and yellow wax, with the addition of a little pulverized sealing wax, answers nicely. The cement sets quickly and holds well.

To fasten knives and forks in silver handles, a mixture of 2 parts of melted black pitch and 1 part of fine brick dust may be used. It must be used warm.

A varnish or cement to protect wood from the action of mineral acids, alkalies and corrosive gases like chlorine, is made from 6 parts of colophonium and 3 parts of wood tar by heating together in an iron kettle on a furnace in the open air, and then stirring in 4 parts of fine brick dust. The varnish is applied with a brush while warm.

An excellent cement for glass is made by dissolving 1 part india-rubber in 60 parts of choloroform, then adding 34 of mastic, and letting it digest for a week at a gentle heat. This cement is also applied with a brush, and is especially distinguished by its transparency.

Another cement for glass and porcelain is made by digesting small pieces of isinglass in 16 times their weight of water for 24 hours. The solution is evaporated to one-half, strained, and, while still hot, 8 parts of alcohol added, and at the same time a solution of 1 part mastic in 6 parts warm alcohol. One-half part of finely-powdered gum ammoniac is triturated in the warm solution until the whole mass is homogeneous. When used, both the cement and the object to be mended are warmed.

* From the 'British Medical Journal.'

† From the 'Journal of Applied Chemistry.'

This cement is highly recommended for its adhesive qualities.

GLUE AND GUM CEMENTS.

These are very tender and well adapted to mending ornaments. They resist the action of water and atmosphere. There are various kinds of these cements for bone, ivory, whalebone, mother-of-pearl and precious stones.

One of these is made by dissolving 2 parts isinglass and 4 parts colourless glue in 60 parts water, evaporating to half its volume, then adding 1–15 part mastic dissolved in 1 part alcohol, and stirring in 2 parts zinc white. The surfaces are warmed when the cement is applied to them. This cement holds well, dries easily, and may be kept a long time in tightly-corked bottles.

For bone, ivory, whalebone, mother-of-pearl, etc., a cement with a beautiful gloss may be prepared as follows:—Soak common cabinetmakers' glue in hot water, warm the jelly formed, add enough pulverulent slaked lime to give it consistency. Warm the object to be cemented, clean the surfaces carefully, apply the cement and tie the parts firmly together. In a few days it gets very hard. Even common glue, with pulverized chalk stirred in, makes an excellent cement for wood and metals.

For fastening leather to metal, the metal should be coated with a hot solution of glue, and the leather with a hot extract of nut-galls. Allow them to dry quietly, and they adhere well.

For porcelain, the well-known white-of-egg cement is best. To prepare this it is only necessary to stir the white of eggs into quite a stiff solution of glue, and then apply to the fracture.

A cement of gum for porcelain is made by pulverizing 4 parts of oyster shells and mixing intimately with 2 parts pulverized gum arabic. The powder is kept in a well-stoppered bottle, and when needed for use is rubbed up with white of egg, or warm water, to a thick dough, applied to the object and dried by a gentle heat. Another cement for glass and porcelain is made from 8 parts well-burnt pulverized alabaster gypsum and 2 parts fine gum arabic, mixed with water to a thick paste, and 40 to 50 drops of oil of turpentine added to an ounce of the cement.

CEMENTS FROM CASEIN.

For glass, porcelain, stone and wood, the very best cement is made of a suitable quantity of old cheese rubbed fine and mixed with water to a thick magma, and a fourth part of pulverized lime added.

A still stronger cement for the same purpose is made by slaking 1 pound of quicklime in water, and mixing with $\frac{3}{4}$ pound pulverized lime or sandstone and 1 pound pulverized cheese. Before using, it is well to moisten the fracture or edges with warm water.

A so-called casein waterglass is made as follows:—The casein of skimmed milk is separated from it by the addition of acetic acid, filtered, and the acid washed out with water. The pure caseine thus obtained is mixed with six times its volume of concentrated waterglass. This cement is thoroughly commendable, and well repays the trouble taken to make it.

An excellent cement for artificial meerschaum, and one that may be used to give consistency to silk goods or to coat artificial flowers and court plaster, to give more adhesiveness and firmness, is made by rubbing two to four parts of the above casein with cold borax solution till a thick liquid is obtained that becomes clear on standing. This also renders goods waterproof.

WATERGLASS CEMENTS.

For glass, earthenware, porcelain, and all kinds of stoneware, these cements are excellent. A cement for glass and marble is prepared by rubbing together one part of fine pulverized glass and two parts of pulverized fluorspar, and then adding enough waterglass solution to give it the consistency necessary in a cement.

Waterglass mixed with hydraulic cement to a thick dough makes a good cement for the edges and joints of stone and marble slabs. It is well to mix but little at a time, as it hardens very quickly.

LIME, GYPSUM, CLAY AND CEMENT, MIXED WITH WATER, OIL OR BLOOD.

For cementing stone and for filling crevices in buildings, before they are painted, the masons use a cement made of fresh blood, slaked lime, brick dust, broken up coal ashes, hammerslag and sand in all proportions. This excellent cement hardens quickly, and offers great resistance to the action of the weather.

A lime cement for connecting water pipes, bathing tubs, etc.; a mixture of two-thirds fine brick dust, two-thirds unslaked lime, and two-thirds hammerslag, is made and stirred up with lye or hot oil to a stiff dough.

Another cement, intended to render Hessian clay retorts impenetrable, is obtained by rubbing freshly slaked lime into a concentrated solution of borax. The solution is applied with a stiff brush and allowed to dry, after which it is heated until the glazing begins to fuse.

Clay mixed with water and fresh warm blood, containing some unslaked lime, is used in Germany to close joints in stoves. The cement is applied while the stove is hot. Wood ashes, fire clay and salt mixed with water is used for the same purpose. Fat and burnt clay, in equal proportions, moulded with water into a dough, is also used.

Plaster of paris mixed with water and a cold solution of alum is an excellent cement for stoneware. It sets slowly, but becomes as hard as stone.

IRON CEMENTS.

Their essential constituents are iron filings or borings. By the addition of some common salt or sal-ammoniac they are rapidly oxidized, and the cement being thereby increased in volume completely fills the crevices where it is put. An excellent luting or cement for the joints and crevices in iron surfaces, and for rendering tight cast-iron steam and water pipes and water tanks is made of filings of cast iron. The filings are sifted to obtain those of the size of a grain of rice, and then rubbed with horse urine and one-half part salt ammoniac, well worked together, and an equal quantity of flowers of sulphur added. The mass is hammered until it gets warm, and then cold, and, finally, it begins to be brittle. In this condition it is put in the joints, and soon hardens. The surfaces where it is applied must be free from rust. Greasy and oily substances are most readily removed by rubbing with cotton dipped in benzine. The cement keeps best under water.

Another good iron cement is made by stirring 5 parts clay, 1 part salt, and 15 parts iron filings together with vinegar to a magma. It will stand heat, and is used for bellows and air pipes.

OIL CEMENTS.

An excellent oil cement for porcelain and for luting of retorts, flasks and porcelain evaporating dishes is obtained when ordinary brick dust is powdered, sifted and mixed with an equal quantity of red lead, and then rubbed, under great pressure, into old boiled linseed oil to a thick paste, which is mixed with coarse sand to the stiffness of cement. When a dish is to be covered with it, paste is applied before the sand is put in, and the sand then strewn upon it. The dish is afterward exposed to a steady heat for a long time.

For larger vessels take 6 parts litharge, 4 parts fresh-burnt pulverized lime and 2 parts white bole, and mix with cold linseed oil.

To fasten metallic letters to a smooth surface a cement is made as follows:—30 parts copal varnish, 10 parts linseed oil varnish, 6 parts crude oil of turpentine, 10 parts glue dissolved in a little warm water, and 20 parts pulverulent slaked lime. It is very pliant and soon hardens.

To unite copper and sandstone, take $3\frac{1}{2}$ parts white lead, 3 parts litharge, 3 parts bole, 2 parts broken glass, and rub up with two parts linseed oil varnish.

As a polish for gravestones, basins, etc., a paint is made of 9 parts of finely sifted and burnt brick clay and 1 part litharge, mixed with a sufficient quantity of linseed oil.

For connecting cast-iron water pipes, 12 parts Roman cement, 4 parts white lead, 1 part litharge, and $\frac{1}{2}$ part colophonium are pulverized and mixed; from $2\frac{1}{2}$ to 3 pounds of it is triturated with old linseed oil, in which is boiled 2 ounces of colophonium.

Another for the same purpose is made of equal parts of burnt lime, Roman cement, potters' clay and clay, separately well dried, finely ground, sifted, well mixed and triturated with linseed oil. Common lead lute for stopping openings in apparatus is best made from litharge and red lead mixed with old boiled oil. In all cases the surfaces must be clean. They stand well under water.

As lead lutings are somewhat expensive, the following is recommended:—Take 2 parts red lead, 5 parts white lead, and 5 parts of the finest clay, and mix with boiled linseed oil.

A good oil cement for wood, especially for antique carvings, is made of 1 part pulverized slaked lime and 2 parts rye flour, mixed with linseed oil varnish. It takes any desired color and polish.

To make water holders tight we may use pulverized slaked lime and cod-liver oil.

A cement to make chemical apparatus tight can be prepared from oil cake or pressed almond cake rubbed with water.

MISCELLANEOUS CEMENTS, ETC.

Furniture polish:—Moisten 120 parts beeswax with oil of turpentine, and add 7·5 parts finely pulverized resin, and enough aniline red to give the desired mahogany colour.

Oil cement:—100 parts red lead, 250 parts white lead, 200 parts pipe clay: mixed with boiled oil.

Water cement:—100 parts slaked lime, 190 parts brick dust, 160 parts sand, 50 parts blacksmiths' dross, 50 parts powdered lime; mix with water.

Another:—600 parts iron filings, 100 parts ignited sand, 100 parts powdered slaked lime; mix with water.

Iron and blood cement:—100 parts pulverized lime, triturated with bullock's blood, 290 parts cement, and from 5 to 10 parts iron filings.

FORMULAS FOR POULTICES.*

The article "Cataplasm" in the new *Dictionnaire des Sciences Médicales* has been worked up by M. Brochin as completely as possible to the actual state of our knowledge of this ancient method of treatment. Amongst the opinions of authors and the modern modes of compounding cataplasms, M. Brochin cites those of Cayol, Broussais, Réveillé-Parise, and especially Velpeau and Trousseau. The editor of the *Journal de Médecine*, from whom we quote this article, observes that he has had the opportunity of following the last-named illustrious physician for some years, and never heard him order either a bath or a cataplasm; occasionally, however, and with a certain air of solemnity, he would order the poultice. This was made nearly as follows:—

Extract of Stramonium, or
Extract of Belladonna;
Extract of Opium;
Camphor in Powder;
Water. Of each 10 parts. Mix.

A bread poultice having been made, some camphorated alcohol is to be boiled with it; the paste should then be enclosed in a little muslin or tarletan, and the surface watered with the above mixture. It is then to be applied, and covered with some impervious cloth and a large piece of flannel. M. Brochin leaves out the camphor in powder, and replaces it with ten parts of ether. This topical application, which is rather expensive, can be retained in place several days. Trousseau only employed it in grave cases, such as mono-articular arthritis with acute osteitis and puerperal arthritis. He prescribed calomel simultaneously, and insisted on perfect immobility of the limb. The following is a narcotic poultice prescribed by MM. Bouchat and Desprès:—

Powdered Hyoscyamus Leaves;
" Conium Leaves;
" Belladonna Leaves;
" Solanum Tuberosum Leaves;
Linseed Meal. Of each 20 parts.
Decoction of Poppyheads, q. s.

Conium is also used in poultices specially intended for the relief of superficial cancers:—

Bruised Carrots, 500 grains;
Powdered Conium Leaves, 30 grains;
Powdered Opium, $\frac{1}{20}$ grain.

The following is intended to act as a diuretic poultice:—

Bruised Squill, 100 parts;
Nitrate of Potash, 10 parts.

And this to render the emission of urine less painful:—

Bruised White Onions, 6 in number;
Leaves of Parietaria, 50 parts;
Decoction of Marshmallow, q. s.

Both may be applied over the pubis.

* Practitioner, from the 'Journal de Médecine.'

THE ADULTERATION OF FOOD ACT.

The Local Government Board has officially announced its approval of the appointment of Dr. Whitmore, the medical officer of health, as public analyst of food, drink, and drugs, for the parish of St. Marylebone. The Bethnal Green Vestry have elected Dr. Sarvis as analyst for the district under the provisions of the Adulteration of Food Act; and at the last meeting of the Board that officer submitted a list of apparatus required for the duties of his office, and suggested that the room occupied as his office should be fitted up as a laboratory, and that a vote should be passed empowering him to spend a sum not exceeding £100. He estimated that the fittings and apparatus would cost about £50, the chief requisite being a microscope, which would cost £22. The mention of the cost of the last-named item was received with much laughter, and Mr. Jackson, a vestryman, intimated that he possessed a laboratory wherewith he could do almost anything, and which only cost 20*s*. Mr. Paterson, another vestryman, remarked that the microscope of Dr. Quekett, a man who attained the highest eminence for his analytical researches, cost only £2. The Vestry then appointed a committee of seven to ascertain Dr. Sarvis's requirements.—*Times, Jan.* 28.

The Local Boards and Vestries of the parishes and districts within the metropolis, have now with two exceptions, complied with the provisions of the Adulteration of Food Act, by the appointment of official analysts. The Act gives the local authorities the option of making the appointment by fixed salaries, by allowances for each analysis, or partly by salary and partly by allowance; and all these alternatives have been adopted by the various boards. In Mile-end Old Town, Dr. Corner, the medical officer of health, has been appointed analyst, the question of salary being left in abeyance. In St. Pancras, Dr. Stevens has been nominated. In Hackney, Dr. Tripe, the medical officer, has been elected, the point of salary being left open for future consideration. In St.

George's, Hanover Square, and Chelsea, it has also been resolved to include the office of analyst in the duties of officer of health. The Whitechapel Board have appointed Dr. Meymott Tidy, professor of chemistry at the London Hospital, at a fee of one guinea for the first hundred analyses, and a decreasing scale for cases beyond that number. Dr. Hardwicke has been elected for Paddington, Dr. Vinen for St. Olave, Dr. Muter for Wandsworth, and in St. Saviour's the office was voluntarily undertaken by the medical officer of health. In Poplar the appointment has been given to Dr. Woodforde, one of the medical officers of health, payment being made for each analysis on a fixed scale. Dr. Letheby has been appointed analyst for the City; Dr. Bernays, professor of chemistry at St. Thomas's Hospital, has been appointed for Camberwell, Dr. Whitmore for Marylebone, Dr. Pavey for St. Luke's, Dr. Rogers for Limehouse, Dr. Muter for Lambeth and St. George's, Southwark. With three exceptions the local authorities of each district have elected their own medical officers of health as analysts, and in Whitechapel the office was refused by Dr. Liddle, the medical officer, on the ground that medical officers were generally not competent to undertake the duties contemplated by the Act.—*Times*, Jan. 29.

CONVERSAZIONE OF THE MELBOURNE PHARMACEUTICAL SOCIETY.

The second annual conversazione of the above Society was held on Thursday, November 28th, at the residence of the president, Mr. Johnson, at St. Kilda. About 150 persons were present, including many of the leading medical practitioners of Melbourne and suburbs, together with a number of ladies. The rooms and garden were very tastefully decorated and illuminated. The President, in a few remarks, opened the proceedings, and announced the programme of the evening, which consisted of short lectures, of some ten minutes' duration (interspersed with music), from Baron Von Mueller and Messrs. Sydney Gibbons, R. L. J. Ellery, Government astronomer, and J. Bosisto, hon. secretary. Dr. Ralph and others exhibited microscopes, and during the evening the company had the opportunity of inspecting a number of valuable instruments, medical and chemical, and some rare preparations. In one of the rooms which forms part of the suite Mr. Pritchard highly delighted the visitors by the exhibition of the kaleidograph, an instrument invented by himself, intended to fix permanently pictures for patterns, being an adaptation of Sir David Brewster's discovery. During his remarks, Baron von Mueller showed that pharmacy had in different parts of the world, and in all ages, produced some of the most eminent philosophers the world has seen. A great number were mentioned who had passed away, and a goodly few of those living, such as Liebig, Rose, Wittstein, etc. Baron von Mueller also dwelt upon the aid pharmacy had rendered to medical science generally. Mr. Sydney Gibbons lectured upon the character of the water supply, illustrating his subject with some beautiful drawings. Mr. Ellery followed upon "Light, and the Nature of the Different Varieties and Effects upon Colours," and illustrated the subject with some marked experiments. Mr. Bosisto followed upon "The Sources of Perfume," showing that all plants had a perfume *sui generis*. The processes adopted for extracting these were explained very lucidly, and a number were exhibited obtained from Victorian plants, some of remarkable fragrance. Other gentlemen, including Messrs. Newberry, Blackett, Glover, Hill, Grimwade, Kennedy, Johnson, Wragge, etc., assisted greatly by contributions and explanations in filling up the time till supper, which was substantially and abundantly provided. During the interval the hall was cleared, and the entertainment terminated with a ball, which was kept up with great spirit and heartiness till three o'clock.

ANNUAL SOIREE OF THE MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

This event took place on the evening of Thursday week, the 23rd of January. As on the similar occasion last year, it was held in the spacious Assembly Room of the Royal Hotel, Birmingham, and it proved a most successful and enjoyable evening. About 250 guests assembled, composed of chemists and a few leading medical and scientific men, with a large number of ladies. An attractive display of objects of scientific, chemical and pharmaceutical interest, occupied several tables in the room during the earlier hours of the evening. Amongst these Messrs. Southall, Son and Dymond, exhibited several new and rare pharmaceutical products; Messrs. P. Harris and Co., a number of chemicals and a variety of Giessler's vacuum tubes in operation; Messrs. Hopkins and Williams some interesting and rare chemicals: Messrs. John Wright and Co., a series of models of Wallace's patent gas burners, heat regulators of novel construction, a small laboratory boiler heated by gas, a portable Turkish bath, etc. Mr. O. Sargent, experiments with yellow flame on a variety of colours. A number of microscopes, stereographs, photographs, pictures, with a variety of other objects, were also supplied by several gentlemen, forming altogether a display of much interest. Mr. Alfred Bird exhibited a fine cabinet of harmonized glass bowls, on which he played several tunes. At half-past nine o'clock, Mr. C. J. Woodward, B.Sc. of the Midland Institute, delivered a short and brilliant lecture on "Flame," which was highly appreciated. Dancing commenced about ten o'clock, and was kept up with great spirit and zest until after two o'clock, when the company separated after a most hearty re-union, which will class as one of the best of those which have distinguished the growing interests of chemistry and pharmacy in the Midland Counties.

THE BROUGH FUND.

For the Maintenance and Education of the Five Children who have been left unprovided for, by the untimely death,—at the age of thirty-eight—of

VERMIN KILLERS.

THE recent prosecutions of chemists and druggists for the sale of vermin killers will, of course, attract considerable attention from the trade, and consequently it seems desirable to revert to the subject here, for the purpose of reiterating the suggestions we have previously offered in the interests of the trade respecting the sale of these preparations.

In the first instance, however, we may point out that the chief practical difficulty in this matter arises from a supposed ambiguity in the terms of the additions made in December, 1869, to Schedule A of the Pharmacy Act, by which vermin killers were comprised among the poisons within the meaning of the Act. Perhaps it should rather be said that this difficulty is due to differences of opinion as to the meaning of the provisions respecting "vermin killers." Thus it has been argued that inasmuch as only four out of the ten additions to the schedule are specifically directed "to be deemed a poison in the first part of the Schedule A," and since "vermin killers" are not among these four, the sale of vermin killers does not involve the precautions required with poisons in the first part of Schedule A.

This argument has been met on the other hand by reference to the fact that, among the four additions which are to be deemed poisons in the first part of the schedule, "preparations of strychnine" are comprised, while preparations of arsenic were originally included in the first part of the schedule, and since certain vermin killers are notoriously preparations of arsenic or of strychnine, it has consequently been urged that they should be dealt with as such in the selling of them.

Then again it is argued that those additions were made without a knowledge that "vermin killers" contained or were preparations of arsenic or strychnine, but this contention has never been much insisted upon, and rightly so, for it would not be complimentary to the framers of the additions. The same perhaps may be said of the idea that the term "preparations" refers only to articles intended for medicinal use, for it must be borne in mind that the regulations apply only to the "sale" of poisons, and not to dispensing, or even to storage.

But individual members of the trade have at times endeavoured to maintain that they were under no obligation to know that a "vermin killer" contained arsenic or strychnine; that there was no reason why they should know this; that they sold these preparations as "proprietary articles," and that for these reasons the precautions directed for poisons in the first part of the schedule should not be required in the sale of "vermin killers." Some have even gone so far as to urge that in a shop full of customers, the time requisite for registering the sale of "vermin killers" could only be given to the detriment of the vendor.

We must confess that we cannot sympathize with those who hold these views, nor is it easy to understand the negation of the universal instinct of self-protection which they seem to involve. Looking at the matter merely from this point of view it appears inconceivable that the possibility of being charged with the infringement of the law should not induce greater caution. If the chemist and druggist is not under an obligation to know that "vermin killers" contain strychnine or arsenic, surely it would be to his interest to ascertain. Even the sale of such articles as "proprietary" does not in any degree lessen the need for this, for they are sold without the stamp which entitles them to be regarded (as "patent medicines") exempt from the provisions of the Pharmacy Act. As regards Battle's Vermin Killer the suggestion of our Warrington correspondent, that the proprietors should, when sending it out, mark on the wrapper of each packet the quantity of the potent poison it contains, is one which in the light of recent fatal cases of poisoning by means of this article seems desirable for every one dealing in it to adopt, in order to avoid the risk of being placed in the same unenviable position as Mr. MOSES and Mr. GILLETT.

We heartily endorse also the proposal that chemists should agree to sell these articles only in such a manner as would remunerate them for the trouble of registration, and we may add that this course was recommended in this Journal last September. The public claim to be protected against accidental poisoning and from the consequences of the too easy obtaining of poison, but they are not so unreasonable as to require that protection at the cost of chemists and druggists. In regard to this point, Mr. SLIPPER well remarks in his letter that it behoves chemists and druggists to show by their careful manner of dealing with poisons that it is a gain to the community to have an educated, well regulated body to store and distribute poisonous articles when they are required. This is an object much more worth securing than exemption from the necessity of registering sales, which after all, by Mr. SLIPPER'S account, does not seem to be a very troublesome matter.

To judge from some of the statements made at the recent trials relating to this subject there seems to be a great deal of misapprehension as to the position of chemists and druggists in regard to it, and from numerous letters lately received it seems that while there is a general disposition to comply with the law there are many who, to use the words of one correspondent, "are ignorant of the present list of poisons which require registering."

The subject, however, has been so frequently referred to in this Journal that it is not easy to understand why that should be, especially since it was last August brought forward as matter for discussion at the Council, and the proceedings then and on several subsequent occasions were fully reported.

"MAJOR ASSOCIATES."

One of the existing bye-laws of the Society, made immediately after the passing of the Pharmacy Act, sec. xi., clause 4, provides that "the names of persons registered as Associates or Assistants shall, upon their registration as Pharmaceutical Chemists, be removed from the Register of Associates or the Register of Assistants, as the case may be." The effect of this is that when an Associate of the Society passes the Major examination, and thus becomes eligible as a Member of the Society, he ceases to be an Associate; in fact, his connection with the Society is thereby terminated unless he presents himself for election as a Member.

By some unaccountable oversight, however, the bye-law has hitherto been disregarded, and by reason of this oversight some of those who passed the Major examination have been from time to time registered as Associates forming the class of Major Associates. Of course, when the true state of the case became apparent it also became imperative for the Registrar to discontinue the illegal practice that had crept in. According to the Act his duty is clear and cannot be avoided, and, consequently, he has given notice to those already registered as Major Associates that by reason of the bye-law above referred to their names must be removed from the Register of Associates, and that they must either take up the Membership for which they are eligible or cease to be connected with the Society.

To this course there was indeed no alternative, for there is really no such grade as that of Major Associate, and it is not even in the power of the Council effectively to alter the bye-law. Consequently some 149 persons have been removed from the Society's Register. We are glad to learn, however, that nearly one-half of the number have already sent in applications for Membership, but there seems to be on the part of some an idea that an injustice has been inflicted on them; and in our correspondence columns will be found two letters on this subject, to which, as they are mainly interrogative, it is desirable to refer here in order to point out the erroneous impressions under which the writers labour.

In addition to what has already been said as to the imperative necessity of the step that has been taken, it must be noted that so far from there being any hardship as regards those affected, the fact is, that for such time as they have been improperly registered they have enjoyed the advantages of connection with the Society for only half the amount of subscription that should have been paid. They have been, in this respect, actual gainers by the oversight of the bye-law in question. It is, therefore, unjustifiable that they should entertain any feeling of being "done;" and as regards the suggestion that they should have received fair warning, it must be remembered that they have still less ground for dissatisfaction, and are really in as good a position as if they had been warned five years ago.

It is equally unreasonable to speak of the Society having any motive for the course taken; and the view that it was prompted by the idea of a probable increase in the annual revenue is, at least, inconsistent with the history and policy of the Society as an educational body.

As regards the possible effect of the recent action we cannot share our correspondents' anticipation of consequences disadvantageous to the Society or to the higher qualification of those entering the business. In the first place the large proportion of applications to be placed in the grade of Members is sufficient to prove that connection with the Society is estimated more highly than to be prevented by a necessity for the payment of an additional half-guinea a year, and we venture to believe that this view will yet prevail with the majority, if not with all those who have been perhaps somewhat startled at receiving the Registrar's notice as to their position.

Again, there is no ground for supposing that the operation of the bye-law will in any degree depreciate or interfere with the desire to obtain the "Major" qualification, for this eminently desirable step does not by any means involve "an extra half-guinea yearly," and does not even require connection with the Society as an indispensable thing this being entirely optional.

It may here be remarked incidentally with regard to the Major qualification, conferring a right to the title of Pharmaceutical Chemist, that although it may not, at the present time be valued so highly as it should, yet we do not hesitate to say that it has even now a very appreciable value to those seeking engagements, especially in the position of managers, and there is every reason to believe that this will augment. It has always been the aim of the Society to promote the idea that the Major qualification was the proper standard of competence, and it is only by the support of those who acquire that qualification, whether they become Members or not, that we can hope for the attainment of the Society's original purpose of raising the status and condition of the trade.

We would suggest, therefore, that immediate advantages should not be dwelt upon so much as the measure by which the value of the Major qualification is to be gauged, but that its possession should be regarded as affording evidence that the holder is engaged in carrying out the good work of pharmaceutical improvement inaugurated by the founders of the Society, and is thereby entitled to the goodwill and esteem of his brother pharmacists, as well as to the respect of the medical profession and the public.

LANCET CHEMISTRY.

In the *Lancet* of last week we read of a wonderful chemical discovery. Another new ether! "Light ether"—*par excellence*, as the *Lancet* says—"consists of four atoms of carbon, ten of hydrogen, and one of oxygen." Our learned contemporary adds, "as compared with hydrogen, its vapour-density is 36."

Persons who are familiar with the *Lancet* will not be very much surprised to note that the ether consisting of "four atoms of carbon, ten of hydrogen, and one of oxygen," is our very old acquaintance the common sulphuric ether $(C_2H_5)_2O$ (ethylic ether). Nor need they be much astonished to learn that the vapour-density as compared with hydrogen is 36, inasmuch as the correct number is only 37. Respecting the wonderful compound in question, our worthy contemporary further remarks, "the temperature of the human body suffices to make it boil violently, as may easily be tested by putting a small quantity of it on the head." Our contemporary had evidently done so.

THE CALENDAR FOR 1873.

An advertisement in another part of this Journal announces that the new Calendar of the Pharmaceutical Society is now ready. Many of our readers are acquainted with the nature of the matter contained in editions of former years, and to them it will be sufficient to say that the Calendar for 1873 has been carefully corrected and modified so as to supply information of the most recent date. To those who are not familiar with the Calendar, we may say that, besides the lists of persons connected with the Society, it contains the Amended Regulations of the Board of Examiners, which are to come into force in 1874; the new regulations for the Jacob Bell Memorial Scholarships after the next competition; and extracts from all Acts of Parliament and other regulations in which chemists and druggists are specially and practically interested. An investment of the small sum annually charged for this publication would often save much anxiety and doubt, and frequently avoid the more lengthy process of appealing to our correspondence column.

THE CHARGE FOR DRUGS.

In pursuance of the principle on which we have before published quotations from the daily newspapers, we have much pleasure in directing the attention of our readers to the following extract from a recent number of the *Echo*, as affording evidence that although the dictates of common sense and British love of fairness are, in some exceptional instances, disregarded and sacrificed to the desire for producing sensation at any cost, those qualities still prevail among the conductors of the public press:—

"A great deal has been made lately of the very simple fact that you can buy a simple bottle of physic at a lower price in one part of the town than in another, and the chemists and druggists have been held up almost as rogues because of this well-known circumstance. A correspondent reproaches us for taking no part in the outcry. We will state generally our reasons for not doing so. In the first place, we think, as a rule that tradesmen have a right to make what charges they find for their own advantage. The proper and sufficient check against a system of over-charge is free trade and unrestricted competition. If we found the chemists adulterating drugs, our anger against them would be far more severe than any that has been exhibited. But to treat the members of this highly-skilled and intellectual trade as mere dealers in drugs is very absurd. A chemist who lives in a neighbourhood where the poor get all or nearly all their medicines from public hospitals and dispensaries, who is not called upon to keep the most costly drugs, nor those of the best quality, or in the best condition, where the resident doctors dispense their own medicines, of course, does a business very different in character, and requiring far less skill, than one whose whole time, as is the case with most of the leading chemists in the West End, is in great part occupied in acting, we may say, as the physician's assistant in the nicest possible operations with drugs, when life or death is but the matter of a half grain. To regard men who have such duties continually in hand as mere retail dealers in rhubarb and castor oil is only less ridiculous than to complain of Sir W. Gull for charging fifty guineas for a visit when the parish doctor can be had for as many pence."

We have also especial pleasure in coupling with the foregoing another extract, from the *British Medical Journal*, inasmuch as it realizes our anticipation that the representatives of the medical profession would not fail to repudiate and condemn the abusive, inconsiderate and unfounded charges in which the *Lancet* has recently indulged, and against which we regret having had occasion to protest:—

"It is not surprising that persons who have no technical knowledge of the subject should fall into absurd errors in discussing such a question as the charges of druggists for dispensing medicines; but it is unfortunate that those who have better information, and should be able to frame a more trustworthy judgment, should follow them in their errors. A writer in a daily paper has discovered that he can get a prescription dispensed far more cheaply in Mile End than in Mayfair; and a medical paper follows the popular lead in exclaiming that this is very sad and a proof of extortion. In the first place, the same may be said of herrings or potatoes, or of boots or trousers. The expenditure of a West End druggist to meet the requirements of a more wealthy and fastidious *clientèle*, is on a very different scale from that of the small druggist of the back streets. Even on the ground of ordinary trade-differences of price depending on the differences between the East and West, the poor and rich, a considerable difference in price is to be expected for articles much more delicately chosen, more carefully prepared and issued. But the fact which medical writers may be expected to bear in mind is, that there is the best reason for desiring to remove the position of a pharmacist from that of a person bound to merely trade considerations. Patients and physicians have a common interest in encouraging the higher education of pharmacists—in offering the rewards of higher remuneration and higher social standing for better education, professional trustworthiness, the cultivation of nice skill, and a professional standard of decorum. These are things which are to be encouraged by being paid for. The skill of the chemist, and his professional self-respect and knowledge, are appreciable elements in his value and in the value of his drugs. The extra sixpence or so on the bottle of medicine or the box of pills represents not only the return for the larger capital needed for a high-class business, but the tax which we are willing, within reasonable limits, to pay for greater neatness and elegance, promptitude, security, freshness of drugs, a large and well drilled staff, and a known reputation, won slowly, and scrupulously preserved. We are willing to pay for these immaterial elements in our dispensing, even more than for the material. It is absurd and mischievous for medical writers to ignore these considerations. A dead level of low prices is incompatible with the constant progress of pharmaceutical education and practice, which it is an important object to promote."

WOMEN AS PHARMACISTS.

The *Répertoire de Pharmacie* for the present month refers to the recent decision of the Council to admit female students to the lectures at the London School of Pharmacy, and also to the two other questions raised before the Council, viz., the admission of women as members of the Pharmaceutical Society, and their admission to compete for prizes at the end of the session, remarking that when these questions came before the Council they were rejected by the less gallant members, who would not admit the possibility of a woman taking part in the Council, or perhaps one day presiding over its deliberations. England, however, is not the only country where this question is being agitated. According to the *Gazette d'Augsbourg*, the President of a Society established at Bremen for providing women with a means of subsistence has proposed that all similar societies in Germany should join in a petition to the Federal Council of the Empire, asking that the calling of pharmacist, —or at least, that of assistant-pharmacist,—should be opened to women. The Prussian regulations are opposed to the adoption of this measure, since they require compliance with certain conditions before entering a pharmacy; but these conditions might be replaced by a certificate of a course in a superior female school recognized by the State, and proof of a knowledge of Latin sufficient to understand the pharmacopœia and medical prescriptions. The question has also been considered in Pomerania, especially at Koeslin, and it has been determined in Holland. In fact, the industrial school for women, established at Amsterdam in 1869, has already trained five young women for the profession of pharmacy, and it is training at the present time seven others for the same destination.

A CHEMIST AND DRUGGISTS' SOCIETY IN IRELAND.

The first meeting of the Chemists and Druggists' Society of Ireland, established "with a view to obtain a status similar to that secured by Act of Parliament to the Pharmaceutical Society of England," was held in Grafton Street, Dublin, on Monday, January 6th. Amongst the objects set forth in the prospectus are the regulation of prices, the raising the standard of the trade by making it compulsory that youths should pass examinations before being received as apprentices, and the promotion of friendly intercourse between chemists and druggists.

The next Evening Meeting of the Pharmaceutical Society will be held on Wednesday, February 5th, when a paper will be read by Dr. Arthur Leared upon "Some Drugs from Morocco." The chair will be taken at half-past eight o'clock.

We learn from the *Brighton Gazette* that a vacancy on the bench of magistrates for the Borough of Brighton has recently been filled by the appointment to that honourable office of Mr. William Dawson Savage.

According to a recent consular report from Guayaquil, so great has been the falling off in the demand for cundurango that, instead of that drug fetching 100 dollars per quintal, as it did for a time, several commercial firms in New York have declined to receive consignments of it unless the freight is prepaid, since they cannot sell it for enough to cover the cost of its carriage from Guayaquil to New York.

Two important cases relative to the sale of drugs in France have recently been decided. On the 11th of June, 1872, the Ninth Chamber condemned a wine merchant to a fine of 500 francs and 50 francs costs for having sold quinine wine, he not being a pharmacien. The wine merchant having appealed against this judgment, it came before the tribunal on the 5th of December, when not only was the judgment confirmed, but a second penalty of 500 francs with 100 francs costs was imposed upon him for having sold quinine wine at the Exposition of Domestic Economy.

On the 29th of November, also, the Ninth Chamber condemned a female herbalist to a penalty of 500 francs for having sold cod-liver oil; and to 50 francs penalty and 300 francs costs for a sale of extract of cod-liver oil capsules. Upon appeal this judgment was confirmed a few days since.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The sixth general meeting of the session was held at the Royal Institution on January 16th; the President, Mr. Edward Davies, F.C.S., in the chair.

Mr. Mason exhibited several interesting specimens of Indian drugs, etc., and explained their characteristics and uses.

Mr. Shaw called attention to the alteration of the schedule of poisons.* Vermin killers known to contain any of the poisons classed in Part 1 of Schedule A required to be registered accordingly; those which did not contain any of the poisons classed in Part 1 remained as hitherto in Part 2.

A paper "On Lead and its Preparation" was read by Mr. Thomas Williams, F.C.S. The author, after describing the different varieties of lead ores, their sources, geological characteristics, mines, etc., exhibited fine specimens of galena (sulphide of lead), anglesite (sulphate of lead), etc, and fully explained what is known as "the Flintshire process" for melting galena in its various stages. He also described Pattison's process for desilverization of lead. Mr. Williams stated that in the United Kingdom alone the production of lead ore is on the average 96,000 tons per annum, which yields about 72,700 tons of metallic lead and 792,700 ounces of silver. The author then described the manufacture of white lead, red lead, litharge, and mentioned some of its applications in pharmacy. The paper was illustrated throughout with some fine specimens of the products alluded to, and after a short discussion, in which the President, Messrs. Parnell, Rigby and others took part, a unanimous vote of thanks was voted to Mr. Williams for his paper, and the meeting adjourned.

BRADFORD CHEMISTS' ASSOCIATION.

The annual meeting of this society was held on the evening of the 28th January. The President, in reviewing the past year, regretted that it had passed with such slight evidence of progress. The only class that had been formed, for a course of Botanical lectures, was poorly attended by the young men in the trade, and gave little ground for hope in the future. After the routine business of the meeting, and the election of the new council, it was proposed by Mr. Rogerson, and seconded by Mr. Harrison, that Mr. Hicks be the President for the ensuing year. Dr. Parkinson moved, and Mr. Rogerson seconded, that Mr. Bell be the vice-president.

The best thanks of the meeting were then given to Mr. Harrison, the treasurer, and to Mr. Newsholme, the honorary secretary, for the valuable services they had rendered the society, accompanied with a request that they would continue their offices for another year. After a few complimentary remarks from Mr. Rogerson to the retiring president, the meeting terminated.

Parliamentary and Law Proceedings.

Prosecution under the Pharmacy Act with reference to the Sale of Vermin Killers.

A case of great importance to chemists and druggists has been brought before the Wolverhampton Police Court, in consequence of the death from poisoning by vermin killer, which was reported at p. 574; Mr. Henson Moses, chemist and druggist, Snow Hill, having been summoned for unlawfully selling certain poisons, to wit, Battle's Vermin Killer, containing strychnine, to Thomas Woodward, deceased, he not having been personally introduced to Mr. Moses, as required by Act of Parliament. Mr. J. E. Underhill appeared to prosecute, and Mr. Thorne defended. Mr. Thorne, on behalf of the defendant, pleaded guilty.

Mr. Underhill said he had little to say respecting the case, but he wished to state that it was one in which they were bound by law to take proceedings against the defendant. A compound, known as Battle's Vermin Killer, had been sold to a person, but he (Mr. Underhill) believed that the defendant, when he sold the article, had no intention of infringing the Act. The defence was that Mr. Moses acted in ignorance of the law, and the prosecution were simply desirous of showing to the defendant and others engaged in the same business that they were obliged to comply with the provisions of the Act of Parliament.

Mr. Walker (magistrate): Is it within the view of the Act that any person being ignorant of the fact that a substance contains poison, they shall be obliged to follow the provisions of the Act?

Mr. Underhill said he would show the Bench why it should be so; the vermin killer was sold as a poison.

Mr. Thorne said the proceedings were instituted at the request of the Borough Coroner, who inquired into the death of the man Woodward, and there seemed to have been some misapprehension about the state of the law on the matter. He (Mr. Thorne) found from the report of the proceedings at the inquest that the Coroner stated that all poisons were within the meaning of the Act, and that Battle's Vermin Killer was included in the schedule. All poisons were not included in the Act, nor was Battle's Vermin Killer mentioned in the schedule; therefore, as far as the Act itself was concerned, his client pleaded not guilty; but in the second section of the Act power had been given to the Pharmaceutical Society of Great Britain to add to the schedule in the Act any poisons which they might think fit, and, in accordance with the power given, a resolution was passed, and submitted to the Privy Council, containing a schedule of poisons, amongst which was Battle's Vermin Killer, which contained a proportion of strychnine. That fact was unknown to his client at the time of the inquest, and was not discovered until the matter had been further investigated. He might state that it was not generally known amongst the chemists and druggists of the district that they were required by the recent regulation to treat that poison in the same way as pure strychnine. He had seen several chemists and druggists with reference to the matter, but he was not at liberty to state their names, they having disregarded the new regulation, being unaware of the poisons which were added to the schedule by the Pharmaceutical Society. His client was in no way accountable for the death of the man Woodward, which was occasioned by poison. No doubt, if his client had asked the question of either the man who bought the compound, or any person who might have introduced him, "What do you want with this vermin killer?" they would have answered that it was required for the ordinary purpose of destroying vermin. That would not in any way have prevented the disastrous effects which followed.

Mr. Walker: Do you plead guilty or not? If not, it will be necessary to prove that the Pharmaceutical Society have included this poison in the schedule.

Mr. Underhill said his friend sent word to say that his client would plead guilty, otherwise he (Mr. Underhill) would have quoted a case bearing upon the point.

Mr. Thorne said his client did not dispute being guilty, but there was nothing in the case to which Mr. Underhill had referred.

Mr. Underhill replied that the case was one which had been tried at the Court of Queen's Bench.

Mr. Thorne: There is nothing in it.

Mr. Walker said if the defendant pleaded guilty it

* The alteration consists merely in the addition of explanatory words.

was sufficient, otherwise the case must be proved in the ordinary way.

Mr. Thorne said his client pleaded guilty, but, having regard to the whole of the circumstances, he hoped that a nominal fine of 1*s*. and the costs would meet the case. He believed the only desire of the prosecution was to give the case publicity, in order that it might be known that Battle's Vermin Killer was included in the poisons mentioned in the schedule.

Mr. Walker asked if the package was labelled poison?

Mr. Thorne replied that it was.

Mr. Walker remarked that he had been under the impression that the chemist himself was ignorant that the packet contained poison. The case seemed to be worse when it was patent by the label on the packet that the compound contained poison.

Mr. Thorne said all poisons were not included in the Act.

Mr. Walker asked if there were any poisons which could be sold without taking the address of the buyer?

Mr. Thorne replied in the affirmative, stating that it was quite sufficient, as far as some poisons were concerned, simply to put down the name and address of the seller; his client supposed that the packet contained one of those poisons. It was a patent medicine containing a compound. There were other things containing poisons in connection with which chemists were not obliged to follow the instructions of the Act, such as chlorodyne, for instance.

Mr. Walker said it was evident that Battle's Vermin Killer was added to the schedule.

Mr. Thorne replied yes, but at the same time chemists and druggists were in perfect ignorance of the fact.

Mr. John Ford (magistrate) observed that the person who sold poisons ought to know the state of the law under which he sold them.

Mr. Thorne said, as far as the Act of Parliament was concerned, there could be no doubt that he had adhered to the same, but the schedule referred to had only been sent round to chemists and druggists since the case had occurred.

Mr. Walker remarked that a chemist was a licensed person, and he ought to know the provisions of his license.

Mr. Thorne contended that his client could not tell what patent medicines were composed of, he not being an analytical chemist. With reference to all poisons which he sold, he was very careful indeed, as might be seen by his books if the Bench thought proper to examine the same.

Mr. Walker said the defendant was entirely guiltless of the death of the man Woodward, but no doubt he sold the vermin killer in ignorance of the law. It was plain that the Act must be obeyed, and that persons who sold the vermin killer ought to take the usual precautions required by the Act. The defendant would be fined 5*s*. and the costs, that being the first offence; for a second offence he would be much more severely dealt with.

Tartar Emetic administered in a Joke.

At the Bradford Borough Court on Tuesday, January 21st, John Wright was charged with administering a poisonous drug to Annie Slater and another in a dramshop in Iregate. It was proved in evidence that the prisoner was seen to take a packet out of his pocket and put part of the contents into two glasses of beer that were standing on the counter. A policeman was called in, and the prisoner given into custody, the beer and the powder remaining in the pocket being sent to an analytical chemist for examination. The prisoner said it was jalap, and that he only did it for a "lark."

Mr. Rimmington, analytical chemist, said he had examined the glasses of ale and the powder. It was tartar emetic, which would poison a person if taken in a large quantity. The powder would not make any difference either in the taste or appearance of the beer. It would depend upon the amount administered whether it would prove fatal or not. The powder was often used as an emetic for the purpose of making persons vomit.

Annie Slater, a young woman residing in Great Cross Street, said she went in with a friend to have a glass in the dramshop on Monday night, and the prisoner, who was there, asked her to have a glass with him. She declined to do so, and he then asked her to drink with him. She had no objection to that, and drank out of a glass which he handed to her. She remarked that it was "very funny beer," and the prisoner said it was old beer. Witness went out directly afterwards, and when she got outside she turned quite dizzy and felt a burning in her stomach. She had never seen the prisoner previously. Her companion also drank of the ale.

Mr. Rimmington, recalled, said that he could not account for the powder producing a burning sensation. It might nauseate the woman and make her feel sick and poorly for many hours.

The witness Slater said that after she had drank the prisoner did so, but only put the glass to his lips and tasted.

Mr. Rimmington, in answer to the Bench, said that half an ounce of the powder would poison a person, and possibly a drachm would. The label on the packet bore the name of a chemist at Eccleshill who was registered. The powder ought not to be sold without a witness being taken to the shop by the purchaser who knew the purchaser and the purpose for which it was required. The book of the chemist ought to show under what circumstances it was sold.

Mr. Berry, for the defence, urged that the prisoner might have felt unwell and got the powder for himself. He had been foolish enough to ask somebody else to drink, which was a very improper thing to do; but as to putting it into two or three glasses, that was not done. He did not think that the prisoner intended to hurt anybody, and the fact that the prisoner had not known the woman before was sufficient to warrant the conclusion that there could not have been any animus on his part in administering the powder. It was a stupid practical joke, and that was all.

Alderman Law said the prisoner would be remanded until Saturday for the attendance of the chemist from Eccleshill.

Mr. Berry: Will you take bail?

Alderman Law: No, certainly not.

Mr. Berry said perhaps they would hear his grounds for asking the question. The prisoner was a respectable man—

Alderman Law: We shall not take bail.

The prisoner was remanded until Saturday, and Mr. Rimmington was requested to analyse the contents of the two glasses.

On Saturday the prisoner was brought up on remand, when James Scott said the portion of powder put by the prisoner into the two glasses of ale was about as much as would cover a shilling.

Dr. Rabagliati deposed that two grains of emetic tartar had been known to prove fatal, although there had been recoveries from much larger amounts, probably half an ounce. A drachm would be considered a very dangerous dose indeed, and in medicine, in order to produce emetic action, they gave one grain. There was, in his opinion, about six grains in the paper produced. In answer to Mr. Mossman, Dr. Rabagliati said that if seven-tenths of a grain were divided into two parts and put into a glass, he should expect emetic action from any person drinking the beer; but should not apprehend dangerous consequences from such a dose.

Mr. Rimmington, analytical chemist, said he had examined the contents of the two glasses produced, and found that one of them contained tartar emetic; but he was of opinion that there was not a quarter of a grain in it. Supposing that three or four grains had been sold, there was still two grains and two-tenths left in the paper.

Mr. Edmund Taylor, chemist, Eccleshill, said on the 28th of December the prisoner called at his shop and asked to be supplied with six grains of tartar emetic for a vomit. Witness said he should not like to sell six grains, and that from one to two grains was considered an ordinary dose. In some cases the doses taken were as much as four grains. Ultimately he agreed to sell the prisoner three grains, and told him that the Act of Parliament required that he should sign for it. He got the prisoner's signature.

Alderman Law: We are very glad that you complied with the Act of Parliament. In addressing the prisoner, Alderman Law said he would be discharged, but the Bench never recollected such a shameful case coming before them in all their experience. He (the prisoner) ought to feel ashamed of himself, and he could not tell how he could manage to face anybody after doing such a dastardly act. The prisoner knew and intended that the emetic should make the girl painfully and distressingly ill. He had never known her before, and had had no provocation whatever. The prisoner ought to be heartily ashamed of himself, and he hoped that would be a caution to him in the future.

Mr. Berry said that was the feeling of the prisoner's friends, who were exceedingly respectable people.

Mr. Gurney said the magistrates thought that they would not have done their duty unless they had thoroughly investigated the whole of the case, and he thought that any one who read the evidence would agree with them. Although it might seem a long time for the prisoner to have been remanded, still under all circumstances it was necessary. If the emetic had been dangerous to life, it would have been the duty of the magistrates to commit the prisoner for trial, but as it was they discharged him, believing that he had committed only an idle disgusting freak.—*The Bradford Observer.*

Death while under the Influence of Nitrous Oxide.

An inquiry has been held at Exeter touching the death of Miss Ida Windham. It appeared from the evidence that the deceased lady had attended at the residence of Mr. Mason, dentist, for the purpose of having a tooth extracted. At her own request nitrous oxide was administered. The medical man who was present noticed the lowering of the pulse before the deceased was completely under the influence of the gas, and an unsuccessful attempt was made to extract the tooth. More gas was administered and the operation completed, when the patient's face suddenly grew livid, respiration ceased, and she shortly afterwards expired.

The jury, after a brief consultation, returned a verdict of "Homicide by misadventure," entirely exculpating the operators.

Obituary.

PROFESSOR SEDGWICK.

On Monday last, the University of Cambridge lost its senior Fellow and oldest Professor. On that day the Rev. Adam Sedgwick, LL.D., F.R.S., F.G.S., Professor of Geology in the university since the year 1818, died at his rooms in Trinity College. For some weeks previously the Professor had been in a very precarious state, and from his advanced age little hope was entertained of his recovery. Born at Dent, in Yorkshire, in 1794, he took his Bachelor's degree at Cambridge in 1808, being fifth Wrangler of that year. In 1810 he obtained a Fellowship; eight years afterwards he succeeded Professor Hailstone in the chair of geology, and continued to lecture for more than fifty years, Professor John Morris being appointed to act as his deputy in 1871. He was elected F.R.S. in 1818, and was President of the Geological Society in the years 1869–71. He was also one of the earliest Presidents of the British Association, he having been elected to the post forty years since, upon the occasion of the meeting of the Association at Cambridge in 1833. He has also filled the office of Vice-President and President of the Geological section on several other occasions.

Professor Sedgwick's studies were chiefly confined to geology, but in that field he was an acknowledged chief. He held a canonry of Norwich Cathedral, and also for many years acted as Secretary to the Prince Consort in his capacity as Chancellor of the University of Cambridge.

Notice has been received of the death of the following:—

On the 11th January, 1873, Mr. William Reynolds, Chemist and Druggist, of Hyson Green, Notts, aged 49.

Review.

Aide-Mémoire de Pharmacie: Vade-mecum du Pharmacien à l'Officine et au Laboratoire. Par Eusèbe Ferrand, Pharmacien, à Paris, etc. Paris: J. B. Baillière et fils. 1873. 8vo, pp. 587.

The object of the author in compiling this work has been to unite in a single compact volume the largest possible amount of information relating to Materia Medica, using the term in the widest sense. Each article furnishes the origin, composition, physiological action, and therapeutic applications of the substance to which it refers. With regard to the introduction of so much matter relating to the medicinal action of drugs, we quote the explanation given by the author himself in the preface:—

"L'action des médicaments sur l'économie devait tout particulièrement fixer notre attention, et dans notre opinion exigeait quelques développements; c'est un des côtés les plus importants de leur histoire. Si nous nous étions renfermés dans le cadre restreint de nos études légales, nous aurions pu limiter davantage cette partie de l'ouvrage; mais la pratique, qui est un guide sûr quand on veut écrire un livre pratique, nous poussait en sens contraire. . . . . .

"Nous sommes responsables, sinon d'après le texte de la loi, au moins d'après les traditions de la jurisprudence, de toutes les préparations que nous livrons au public. Le médecin lui-même, s'il vient à formuler une prescription dangereuse, peut abriter sa responsabilité derrière l'ignorance coupable du pharmacien qui n'a pas su reconnaître les lapsus d'une plume distraite."

The chemical portion of each article is treated from a practical point of view, the object being to furnish directions for establishing the identity of the substance and its freedom from impurity or sophistication.

Space is devoted to the analysis of many of the ordinary articles of commerce, with regard to which information is often required of the practical chemist. Antidotes to poisons and "incompatibles" are also noticed in their proper places, and appended to each article are the formulæ for most of the pharmaceutical preparations in use in French pharmacy, as well as, in a few cases, recipes from the British and other European pharmacopœias.

The chemical notation employed is exclusively that which is founded on the binary theory of the constitution of salts, and which we, in England, are in the habit of calling the "old notation," though it has been by no means completely abandoned by French chemists. Synonyms are supplied pretty freely, and a style of Latin nomenclature introduced which, if we mistake not, has already been suggested and discussed in connection with the nomenclature of our own Pharmacopœia. It results from an attempt to render into Latin the names which are in common use among chemists for distinguishing from such other salts corresponding to lower and higher degrees of oxidation. Thus we find carbonas ferrosus; chloruretum ferricum; chloruretum hydrargyrosum: chloruretum hydrargyricum. As will be seen, these are, in some cases, a little cumbersome, and there seems to be no well-founded reason for preferring them to the older names, with which, moreover, we are already familiar.

The whole is arranged in the form of a dictionary, the articles following one another in alphabetical order: and, in addition, there is a copious index. The book is not well printed, and is, of course, clothed in the usual paper cover, but the price is only six francs, and the addition of a strong binding would not very seriously increase the cost.

We have carefully examined the work, and can conscientiously recommend it to our readers as not only remarkably free from all but trifling inaccuracies, and as containing in a cheap and portable form much that will be useful both to pharmacists and students.

Notes and Queries.

[327.]—PILULÆ ILIACÆ RHASIS.—

Sagapeni aa . . . . ℥vj.
Diagrydii . . . . . ℥ij.
Cum succo porri fiat massa.

Schroder *Pharmacopœia Medico-Chymica*, Ed. 4., 1656. —D.H.

POMADE FOR FRECKLES.—The following formula is from the *New York Druggists' Circular*:—Take of

Citrine Ointment and Oil of Almonds, each	1 drachm.
Spermaceti Ointment	6 „
Oil of Roses	3 drops.

Mix well in a wedgwood mortar, using a wooden or bone knife.

PREPARATIONS OF EUCALYPTUS.—The following formulæ for preparations of *Eucalyptus globulus* are given by M. Dorvault in *L'Union Pharmaceutique*, vol. xiii. p. 259:—

Syrup of Eucalyptus.

Distilled Eucalyptus Water	500 parts.
White Sugar	950 „

Dissolve without heat and filter through paper.

Tincture of Eucalyptus.

Eucalyptus Leaves (dry and cut)	1 part.
Rectified Spirit	5 „

Macerate ten days and filter.

Wine of Eucalyptus.

Eucalyptus Leaves (dry and cut)	30 parts.
Proof Spirit	60 „
White Wine	1000 „

Macerate with the alcohol during twenty-four hours; then add the wine and leave together for ten days, and afterwards filter.

Extract of Eucalyptus.

Eucalyptus Leaves (dry and cut)	1000 parts.
Water	3000 „

Distil to obtain the essence. Make an aqueous extract with the residue in the apparatus and to this add—

Proof Spirit	1000 parts.

Filter; concentrate this alcoholic solution to the consistence of an extract, and when cool add the volatile oil, mixing thoroughly.

"MAJOR ASSOCIATES."

Sir,—Circulars are being sent by the Registrar of the Pharmaceutical Society to those Major Associates who are not in business on their own account, informing them that, "in accordance with the bye-law," they have been removed from the Register of Associates, and must either take up their membership—forms of application for which are enclosed—or cease to be connected with the Society.

As one of those to whom the alternative is presented, I would ask, which bye-law is referred to? The only one bearing on the point which I can find is clause 4 in Section XI., bearing date 1852. But this has been in abeyance twenty years, and no notice has been given of any intention to revive it. Naturally, therefore, considerable surprise and indignation are felt by those who are thus cavalierly told to increase their subscription or leave the Society. The salaries of chemists' assistants are not generally so large that half a guinea more or less is of no consequence to them; and on the other hand, an associate who has been connected with the Society for some years is unwilling to leave it.

What is the Society's motive in thus swooping down on us? In the Calendar for 1872, I see mentioned 149 Major associates who are not in business. Supposing that all these take up their membership, the Society will be an annual gainer of about £80. But is this likely? Is it not probable that the larger number of them will leave the Society? In that case we shall have the paradox that, while the Society laments that so few candidates present themselves for the "Major," it actually turns out a number who possess that qualification. And all for the sake of a potential eighty pounds!

Again, the bye-law directs that, on an Associate passing the Major examination, he shall be removed from the ranks of the Associates to those of the members. But in my own case I have been allowed to continue an associate for more than five years, and am now suddenly called upon to pay double subscription, or go. I cannot think this course a dignified one for the Society to pursue. Had they given us fair warning, there might have been dissatisfaction, but there would not have been the feeling of being "done," which now exists.

A MAJOR BEFORE THE PASSING OF THE PHARMACY ACT.

Sir,—Imagine my surprise when, on presenting the half-guinea subscription for the current year at the "Square," I was informed that it had just been discovered that a bye-law existed proving that there was no such grade as Major Associate, but that in future all Pharmaceutical chemists connected with the Society, whether in business or not, must pay the full subscription of one guinea.

Now, in the name of common sense, I ask, Where has this bye-law been all this time that it is only just discovered? and if brought into force, what will be its immediate effect? The secession of the greater number of those to whom the Society in the future must most look for support, and who have hitherto been known as "Major Associates."

Even as it is, I hardly know of one single immediate advantage to an assistant from holding the Major qualification. Painful experience shows that employers do not recognize it, for if the aspirant to the diploma dreams that he will get one penny more salary for his pains, he will, most probably, find himself painfully disappointed; and now if it is to mean an extra half-guinea yearly, I may safely predict that fewer will go to the expense and pains of qualifying, and fewer still will continue their connection afterwards.

If this hitherto dormant bye-law does exist, it should certainly be either amended at once, or allowed to die a natural death; to bring it into force would be ruinous policy to the Society, and a great injustice to those who have already qualified. I, for one, protest against it, and, in opposition, beg strongly to commend to the consideration of the Council a proposition of a late correspondent to the effect, "That Pharmaceutical Chemists not in business be admitted to membership on payment of the Major Associate subscription of half a guinea."

H. B. H.

P.S.—Provisionally that this bye-law does come into operation I have sent in my resignation, and I do not doubt that the example will be followed by many others.

Lancet Amenities.

Sir,—That the writer in the *Globe* should, through ignorance of the questions he was attempting to solve, have fallen into grievous error and committed himself to absurd "*non sequiturs*" is not surprising. Still less need one be astonished that the body of pharmaceutists having been attacked, the *Lancet* should have joined in the fray, and with its usual disregard of fairness and gentlemanly feeling done its little utmost to aggravate and exasperate the misunderstanding.

But the fact of the *Medical Times and Gazette* having also entered the lists, and, wonderful to observe, shown no greater degree of fairness or of good will than its contemporary, seems to point to a state of feeling in the medical mind that pharmaceutists are bound to take cognizance of. Do doctors, as a rule, regard the educated pharmacist as differing from an ordinary retailer only by his greater unscrupulousness and rapacity? Is that the sole result of the sustained efforts for thirty years of a host of men whom the public have regarded as at least respectable? What are we to think of the position we hold in the *public* estimation when a leader of medical opinion ridicules "the great skill required to dispense drugs" and propounds the question, "surely there is not such extraordinary skill required in obeying definite directions put down on a piece of paper?"

It is difficult to suppose that the writer could really have any other motives in inditing such remarks than to prejudice the pharmacist in the eyes of the public and injure his pecuniary position. He must be indeed ignorant of the kind and degree of knowledge required for the intelligent exercise of pharmacy to suppose that it is all summed up in the ability to mix certain substances "according to definite directions put down upon a piece of paper."

The less said about the "definiteness" of the directions, and the manner of "putting them down on paper," the better, I should have thought. Nor does it seem wise to disparage those who, being fairly behind the scences, and specially qualified to "reckon up" the pretensions of medical men, could so readily return a Rowland for their Oliver. But it is not worth while "to render railing for railing," for after all there is some look of hopefulness about the matter. Does not the crusade spring from an impression on the part of certain envious and probably impecunious individuals, that the status of the pharmaceutist is improving, and that he actually dares to approach the sacred dignity of a profession? And why should he not? Where is the great difference in the *personnel* of the trade and profession? Excluding from comparison the few doctors who have passed through a University course, the difference is very slight. Of course one ignores quacks on one side, and hucksters on the other. Yet, however true this may be, the public will not acknowledge it until the chemist makes up his mind to assert his position, and decline to be otherwise regarded than as equal to his medical brother. The relative position of the militia officer to the linesman is, I believe, defined as "with but after," and that, in his intercourse with the medical profession, every *pharmacist* should insist on. It is perfectly absurd to suppose that when a father having two sons, makes one a doctor and the other a pharmacist—the one should be treated as a gentleman, the other regarded as a social pariah. Such a state of things has existed and does exist. It depends on the rising generation of pharmacists to say how long it shall continue.

Rusty Cuss.

Sir,—The *Lancet* seems to be down on the trade and wishes to put the quietus on the seal-skin jackets of the chemists' better halves in this town. I do not know any chemist's wife who is the happy possessor of one, but I do know several wives of medical men who rejoice in them. If the editor of the *Lancet* will look down the list of businesses for disposal, returns in many cases from £250 to £400 a year, I think he will not be jealous of seal-skin jackets proceeding from the profits of such trading. The unlucky proprietors do not require putting down—down they are with their nose to the grindstone; and if they escape the list of bankrupts, eke out their wretched living either with Gilbey's wines, bottled ale, petroleum oil, mineral naphtha, Thorley's food, or a little bit of quacking. Therefore I hope more leniency will be shown to the poor chemist, who in small manufacturing and agricultural districts manages to keep the wolf from the door by little extras which may be *infra dig.*, but which very seldom produce that *rara avis*, a rich chemist and druggist.

Warrington, Jan. 27th, 1873. Pil Garlic.

Vermin Killers.

Sir,—I have read with a considerable amount of interest, and have derived a large amount of information from, the very able and comprehensive letter of Mr. Longley, of Leeds, on the subject of the Sale of Vermin Killers. I venture to assert that the majority of the trade (I ask the pardon of those members who take their stand on the lofty pinnacle and fondly imagine it ought to be designated a profession) have interpreted the meaning of the Act as he did, viz., that vermin killers were included in the second part of the Sale of Poisons Act. On reference to a card or paper issued to chemists and druggists by the local pharmaceutical secretaries, I find, in part two, the last article named is "Vermin Killers: every compound containing a poison and sold for the destruction of vermin." Now as far as my memory serves me, I think that paper was distributed since December, 1869; in that I may be right or wrong; but be that as it may, I think the Society, having the interest of the trade confided to their care, might have sent some time at all events during this last three years, a notification that vermin killers were classed in the first part of the list. Might I suggest to the proprietors of Battle's Vermin Killer—I merely take that preparation as I think it is the one most generally sold, and the one that after what it has done may with certainty be recommended as poison warranted to kill—that they should when sending it out mark the quantity of the potent poison on the wrapper, or say with each dozen, then the chemist may enter the quantity in his book, before serving his customer. Again, the question may be asked, Have these persons who put up the vermin killers any right to send it out without its being labelled with the name of the poison, the word poison, and their name and address? I fancy legally they have no right. I find it is the custom of the wholesale people to label all their poison with name and address—how then is vermin killer passed over? If chemists would agree to sell nothing less than say sixpenny packets, the profit on which would repay them for the time and trouble of registering the sale, I think it would be well. A beneficent legislature cries aloud, "Salus populi suprema est lex," but all the care of our paternal Government will not stop poisoning; but for the life of me I cannot see why the would-be-suicide should take so affectionately to vermin killers—how much pleasanter of the two would it not be to glide imperceptibly from the world under the influence of opium! the obtaining of which presents no difficulty, no signing in a book, no introduction required; sixpence and the excuse that the person suffer from neuralgic pains, or has been ordered to put laudanum in a poultice, is sufficient in pretty nearly every case.

Warrington, Jan. 27th, 1873. Pil Garlic.

Sir,—I must confess that I think the Council have arrived at a wise decision in adding "Vermin Killers" to Part 1 of the List of Poisons when they contain any such ingredients as strychnia or arsenic, and a chemist who sells them cannot plead ignorance as his reason for not entering the sale. There is no parallel case, as some have attempted to argue, between patent medicines that contain prussic acid, morphia, or tartar emetic, and the "Vermin Killers." The former are medicines prepared from private formulæ, and sent forth as remedies for certain complaints and diseases to which "mortal flesh is heir to," with full directions as to the dose, and generally accompanied with a promise to cure, but the latter are put forth as "Killers," not "Curers," and not to be taken at any time by our mutual friends the public. While on this subject I am obliged to acknowledge that entering poisons in a book is nothing like so troublesome a job as I expected it would be. Of course, on supplying a customer the first time there is rather more trouble than occurs afterwards, but any purchaser, having once been initiated into the course required, signs his name while I am getting his parcel ready, and very little time is wasted. On looking over about 200 entries during the three last months of 1872, I find not more than twelve are made for sales to fresh customers, so that more than ninety per cent. can be entered as "Known;" this, of course, very much diminishes both trouble and risk. It is quite evident that coroners are very desirous of keeping us up to the mark in observance of the necessary regulations of the Poisons Act, and in some instances have attempted to go beyond what the law allows; the public also back them up in censuring any laxity on the part of a privileged part of the community like ourselves, consequently it behoves us to show by our careful manner of dealing with poisons that it is a gain to the community to have an educated, well-regulated body of chemists to store and distribute such articles when required.

James Slipper.

London, January 28th, 1873.

Sir,—I am sure many will agree with your correspondent, Mr. J. W. Longley, in the Journal of January 25th, respecting the registering of the sale of vermin killers in the poison book. I for one do, being quite ignorant of the obligation so to do, until reading the correspondence in the last issue of the Journal and your editorial note in that of the 18th ultimo. In the latter you say, the Council of the Pharmaceutical Society resolved that a copy of the revised regulations should be issued to every registered chemist and druggist, but the copies have not reached this neighbourhood yet, and any detective might have pounced down upon us innocent, loyal creatures, by sending his son into the shop to purchase vermin poison, and while I was ignorant of the new interpretations of the law, might have brought me under the censure and reprimand of the coroner, though undeservedly. The plea of ignorance in this respect would surely have met with justice at the hands of the magistrates, but as to any intelligent member of the trade supposing that Battle's or other "killers" do not contain strychnine, or some poison, to me seems incredible.

Wm. T. Martin.

Lewes, January 28th, 1873.

Total Abolition of the Medicine Licence to Druggists.

Sir,—I read with much interest your minute and able *résumé* of the last page and year of our pharmaceutical history; it necessarily took notice of many points of a debatable character, which, though not yet settled, have given rise to discussions well calculated to ventilate matters of the first importance as regards our future welfare and progress as a body. At present I have no intention to take note of many subjects of major importance, which I doubt not will again be taken up by the stimulus which your own article has given to them. In the meantime, just allow me to refer to a comparatively small matter, but which, small as it is, I humbly think has not yet received that amount of consideration from you or from your correspondents which it properly deserves. I refer to the proposed change in the charge for licence duty for the retailing of patent medicines. On that point I cannot agree with you, that "the balance of opinion is inclined to a uniform rate of £2." In the metropolis and in large provincial towns such an alteration might be of advantage to the properly qualified chemist, but in country towns, properly so-called, and in villages which can boast of a professional pharmacist, the case would be quite different, as in such places the sale of "patents" is not at all confined to *our* fraternity, but is largely shared in by grocers and ironmongers, and booksellers and the like, who, indulging in the maxim of "small profits and quick returns," do not hesitate to act upon it, by selling "quack medicines" of all sorts and conditions—poisonous or non-poisonous—at a reduction of three-halfpence upon every shilling, that is, selling Cockle's Pills, etc., at 1*s*. instead of 1*s*. 1½*d*. Now, I believe, as a rule, that the increase in the price of licence duty might put a stop to this "cutting" business, but I verily believe that it would never tend to the aggrandisement of the druggist, as if the advanced licence duty would pay the one, I see no reason why it should not pay the other, to continue the competition.

But putting aside altogether the competitive part of the question, which alone has received consideration by your correspondents, I would just ask, firstly, why any but properly qualified chemists are allowed to vend the various, and in some cases the dangerous and poisonous, "nostrums of the day?" and, secondly, why *one* should be called upon to *pay any licence at all?* We have spent no end of time and money in receiving an extra liberal education; we have attended and paid for classes at the University or at Bloomsbury Square; we have passed the Preliminary, the Minor, and the Major examinations of the Society at great expense, and we annually put a guinea into the pharmaceutical coffers,—and for what, I would like to know, have we done all this? We have done it, I fear, just to be on an *equal footing* with our drug-selling neighbours, the grocers, who might and do sell nearly all the most profitable articles in the pharmacopœia, to say nothing of the "nostrums" referred to, or vermin killers, or "sheep-dipping compositions," whether poisonous or not. In fact, in such matters, more especially in the country, the Pharmacy Act, or Sale of Poisons Bill, is to all intents and purposes a dead letter.

But, referring again to the "patent medicine" duty, do you, Mr. Editor, not consider that we have already, by our education, and our examinations, and our fellowship with the Pharmaceutical Society, paid sufficient, and qualified ourselves sufficiently for the sale of Holloway's Pills and Ointment, without paying any more in the shape of a licence? I hold that the diploma of the Pharmaceutical Society of *itself* and *in perpetuity*, ought to be a sufficient warrant without a compulsory payment of two pounds, or even twopence per annum. On the other hand, as we have been promised so much increase of *status* (and *status* I consider of precious little value commercially, unless backed up by something more substantial), I venture to suggest that the privilege of selling drugs should no longer continue to be a marketable commodity, purchasable by grocers, booksellers, or anybody that can afford to pay the money, but should be the *exclusive right* of druggists and *druggists only;* or if this sweeping measure might be found to endanger our national resources in the matter of revenue, then let there be a licence of five guineas, to be paid by the cheesemonger aspirants to the drug business; thus would we gain at least one of the advantages so liberally promised to us; and so, the public, for the first time, would be made to see and to learn and to acknowledge, that our education gave us a privileged right and qualification above our worthy neighbours in the cheese and bookselling line of business.

January 8th, 1873. Scrutator, M. P. S.

J. Morris.—(1) We have seen it stated that an extract made from the watery matter which oozes from the livers, has sometimes been used in the preparation of pills. It has also been proposed to use a cod-liver oil and lime soap for the purpose (Vol. II. p. 830). See a report of an action for the price of a box of "Sir James Murray's Concentrated Cod Liver Oil Pills," printed in the first series of the Pharm. Journ., vol. XI. p. 478. (2) A formula for Tincture of Eucalyptus is given at p. 618.

K. T. F.—See Ure's 'Dictionary of the Arts,' *s. v.* "Bread," vol. i. p. 405.

W. H. W.—You will find an article on the subject in Ure's 'Dictionary of the Arts,' vol. i. p. 573.

"*Labiatæ*."—(1) You are recommended to forward the certificate to the Secretary in order that he may lay it before the Board. (2) No.

C. E. D.—The passages for the next examination may be selected from any part of the *De Bello Gallico* of Cæsar. In succeeding examinations they will be taken from either of the first three books of the Æneid.

G. J. C.—The only enclosure in your letter was the newspaper cutting.

C. Fryer.—We regret that we are unable to comply with your request.

J. Hamp.—Your letter has been handed to the Secretary who will forward you the information asked for.

A. Stathers.—According to the interpretation of the Regulations adopted by the Council in regard to "Vermin Killers," it is necessary to register the sale of "Battle's Vermin Killer," and otherwise to comply with the regulations relating to poisons comprised in the first part of Schedule A, as specified in Schedule F, the details of which are to be found in the Register or the Calendar of the Society. As to the quantity to be registered we are unable to give any information.

The report of the Leeds Chemists' Association reached the office after the Journal was made up.

We have to thank correspondents for supplying copies of the Brighton Examiner, Sussex Daily News, Melbourne Daily Telegraph, Northern Whig, Bradford Observer, Queen, Echo

Communications, Letters, etc., have been received from Messrs. J. H. H. Howard, F. H. Ellwood, Johnson, Barrett Whitwell, W. V. Churchill J. Young, Heaton M. M. B. "Tolu."

NOTES ON SOME DRUGS COLLECTED IN MOROCCO.*

BY ARTHUR LEARED, M.D., F.R.C.P., M.R.I.A.,

Senior Physician to the Great Northern Hospital.

In the latter part of the past year while travelling in the empire of Morocco, I had a good opportunity of making myself acquainted with the products of that extensive and little-explored country. My attention turned to the drugs and remedies employed by the people, and I set myself the task of collecting specimens and procuring as much information about them as possible. But the difficulties which at every step beset the inquirer in Morocco, from ignorance and fanaticism, almost exceed belief. That strange mediæval jumble of astrology and pharmacy may be daily witnessed in the Moorish towns. The turbaned and cross-legged medicine-man, before he prescribes, displays mysterious diagrams and consults your stars. Such information as a man of this kind possesses he will not impart. He would, if possible and convenient, destroy instead of benefiting the infidel. And although the Arab race is numerous in Morocco—the race which produced an Avicenna and a Rhazes—the state of barbarism into which this fine country has fallen is such that it possesses no native physician or pharmaceutist worthy of the name.

A few preliminary remarks on the climate, soil, and general productions of the country will not be out of place.

The vegetable productions of Morocco are those of a sub-tropical country, in which there is great variety as regards the nature of the soil, elevation above the sea-level, and irrigation. My own travels extended from about 36° to 31½° of north latitude. In the neighbourhood of Tangier in the north, the country consists, to a great extent, of a succession of low hills closely succeeding each other. They are in general sandy, and the succulent plants which belong to this kind of soil thrive luxuriantly. The aloe, and the prickly-pear (which is said to have been introduced from the Canary Islands) both attain large dimensions. Thousands of acres in the open country are clothed with the palmetto, which forms one of its main features. Junipers and various prickly shrubs cling to the stony hillsides, and, in some places, constitute extensive thickets, which afford shelter to boars and other wild animals. But anything worthy of the name of a tree is seldom seen. As one proceeds south, fine level plains having a deep loamy soil are met, and in the rainy season they are covered with rich herbage, dotted with a variety of bulbous-rooted flowers.

In a journey of about 130 miles, from Mogador to the city of Morocco, and from thence to the coast again to the town of Saffi, I had a good opportunity of judging of the interior of the country. From Mogador to the city the route is almost due east, and the elevation of the ground, I found by an aneroid barometer, at about 50 miles from the sea, to be 1250 feet. At this point the plain of Morocco begins, and the elevation in the next 80 miles is only 250 feet more, attaining its highest point at the city itself. A day's journey further east takes one to the foot of the great Atlas range, which, by forming a barrier towards the east, protects Western Morocco in a great measure against the scorching desert winds which are so hurtful in many countries.

But the point which at present deserves attention, as bearing on the productions of the country, is the great diversity of climate and soil experienced within short limits. When leaving Mogador on September 29th, the weather was, as usual, pleasantly warm; when inland, four days afterwards, the thermometer stood at 94° F. in the shade. Rain, which is usual between September and March, had not yet commenced to fall. The country, except where a rare irrigation afforded the grateful sight of patches of green maize, was, in general, parched and arid.

In this journey one thing arising out of the circumstances mentioned struck me forcibly, namely, the peculiar distribution of the vegetable products. It almost seemed as if the trees and plants of the soil, like the people who inhabit it, are possessed with those exclusive tendencies which prevent one race or one sect from mixing with another. Thus, on leaving Mogador the path lies through miles of deep sand, covered with nothing but the waving branches of the "artim" or white broom; then a tract is entered where the "argan"-tree prevails, at times to the degree which constitutes a forest. Gradually this tree drops out of the landscape. A zone of palmettoes is now passed through. Then broom reappears, and next on the plain of Morocco the whole country is covered with a thorny ill-conditioned shrub of moderate size, the name of which I am not acquainted with. After this, at Seshowia, about 80 miles from Mogador, where there is a river, the "sidra"-tree commences, and prevails to Monzoudia, a distance of about 17 miles. This is now replaced by a shrub about 3 feet high, called "shey," which gives the road a monotonous and dreary aspect. Finally, this is succeeded by the date-palm plantations, which, for many miles, surround the city of Morocco. As nothing of the kind is to be seen in the previous journey, and their limits are sharply defined, these trees present a magnificent appearance to the eye, and their pleasant shade is hailed with delight. The city of Morocco is well supplied with water, and the numerous gardens in and about it are stocked with fine fruit- and shade-trees, amongst which the orange, the olive, and the banana are conspicuous.

I have been somewhat minute in describing the vegetation of a portion of the country traversed, on account of its bearing on the diversity of the drugs to be described. Thus caraway seed, which is the product of a cold climate, is an article of export; and while many of the articles are produced in our own country, others belong exclusively to hot climates, and some, as argan nuts, ammoniacum and euphorbium gums, are peculiar to Morocco. In a few cases, the drugs are not products of Morocco, but have been added to the list to show the medicines in common use amongst the Moors.

Almost all the information about drugs which I possess, has been obtained from the Jews of Morocco. These people, degraded, oppressed, and consequently ignorant and superstitious, are observant and communicative. But there are some exceptions of educated and enlightened gentlemen amongst them. To one of these, Signor Yusef de Elmaleh, High Priest at Mogador, I am much indebted for many additions to my collection, and for information that may be relied upon. This collection, made at most of the coast towns from Tangier to Mogador, but principally at the latter place, and also

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, February 5, 1873.

in the city of Morocco, although somewhat extensive, cannot be said to have yielded rich results. As might be expected, many of the herbs proved to be old friends with new names. At the same time, a certain interest attaches to the identification of our own remedies amongst the Moors; and I am yet in hopes, that some additions to our remedies may result from the present inquiry. On the whole, it seemed to me that the matter possessed enough of interest to bring it under the notice of the Pharmaceutical Society. It will be easily understood that the difficulty of identifying roots and some other parts of plants has been very great, and that many specimens have consequently been as yet undetermined. In this place it is proper to add, that I have derived much assistance from Mr. Collins, who compared the specimens with those in recognized collections. I have taken much pains to render the vernacular names as closely as possible in English. These names appear to be, in almost every instance, peculiar to Morocco. Very few of them bear any resemblance to the Arabic names for the same drugs given in books.

Leaves, Flowers, and Plants.

Labiatæ.

Zater.—*Thymus species?*—Flowers. The infusion is used to promote digestion. It was formerly exported to Holland in large quantities.* It is also much used by the Moors for flavouring tea.

Aflau.—*Thymus species?*—Flowers, etc. They have a peppermint-like odour. The infusion is used for flatulence and colicky pains.

Taserkina.—*Thymus species?*—The infusion is used in diarrhœa.

Elhalhal.—*Micromeria species?*—Tops, etc. Stomachic, etc.

Azeer.—*Lavandula stœchas*, L.—Leaves. Used for fumigation in small-pox, gonorrhœa, etc.

S'dia.—*Lavandula stœchas.*—Tops. Used in colic, etc. The two last appear to be different names for different parts of the same plant.

M'roy.—*Marrubium undulatum*, Benth.—Tops. Used in stomach affections.

Timza.—*Mentha sylvestris*, L.?—Tops. Used in diarrhœa.

Maroui or Marout.—*Ballota lanata*, L. Used for removing the scabs of small-pox, and as an application to hæmorrhoids, etc.

Rutaceæ.

Ruta.—*Ruta angustifolia*, Pers.—Rue. Carried about the person as a safeguard against infection, etc. Given for "nervousness," etc.

Compositæ.

Sech.—*Artemisia Aragonensis*, Lam.?—Tops. Barbary worm-seed. Used in infusions for colds and also in fumigation for small-pox, etc. It is exported to Holland to make "bitters." Barbary worm-seed was considered by Guibourt to be the produce of *Artemisia glomerata*, Sieber.†

Shiba (trans. Old man's beard).—*Artemisia absinthium*, L.—Wormwood. Used in dyspepsia and also for giving flavour to green tea.

* 'Account of the Empire of Morocco,' by James G. Jackson. London: 1814. p. 243.

† Pereira's Mat. Med., art. Artemisia.

Babinouse.—*Matricaria chamomilla*, L. Used as stomachic.

Sadear —? Leafy tops. Used as a stomachic.

Leguminosæ.

Senaherram.—*Cassia elongata*, Lémaire Lisancourt.—Senna. Stated to be brought to Morocco by the pilgrims returning from Mecca. This is confirmed by the fact that the specimen is identical with Mecca senna imported *viâ* India into this country. Used as a purgative.

Artim.—*Spartium junceum.*—Spanish broom. This shrub forms a feature of the landscape. In many places it covers thousands of acres of sandy soil, to the exclusion of almost every other plant. Its white flowers in spring diffuse a strong and agreeable odour. It appears to be used by women as a remedy for barrenness, and although one would hardly regard it as poisonous, an instance was related to me in which death was caused by an overdose.

Myrtaceæ.

Rahan.—*Myrtus communis*, L.—Myrtle leaves. The infusion is used for diarrhœa. The leaves are also employed by the Jews in their ceremonies.

Oleaceæ.

Agzas.—*Phillyrea angustifolia*, L.—The infusion is thought to make the hair grow.

Paronychiaceæ.

Haydorley. — *Paronychia argentea.* — Flowers. Used as a diaphoretic, and also for colicky pains.

Dioscoreaceæ.

Eriffi.—*Tamus communis*, L.—Black bryony. Leaves. This plant, which is common to most parts of Europe, is employed, when pounded, by the Moors as a topical application to wounds and bruises as the root of white bryony, commonly known as mandrake-root, occasionally is in this country. The tincture of *Tamus communis* forms one of the so-called homœopathic remedies.

Gentianaceæ.

Castelheyea, or Noar Muley Ali (trans. Muli Ali's flower).—*Erythræa ramosissima*, Pers.—Closely allied to gentian. Used in dyspepsia.

Cannabinaceæ.

Kief.— *Cannabis sativa*, W. — Hemp. Whole plant. It is grown largely in the provinces of Haha and Shedma. The right of dealing in it and in tobacco is monopolized by the Emperor. These monopolies are farmed to Jews, who buy at a price fixed by law, and sell at an enormously advanced price. The plants are pulled up when the seed is ripe or nearly so; and the leaves, when dried and coarsely powdered, constitute kief. This is smoked in very small pipes. As may be supposed, a few inhalations exhaust the contents of the bowl. The smoke is taken into the lungs, and produces a powerfully narcotizing effect. But, unlike the preparations of the plant, which are swallowed, the effect soon passes away. Some smokers indulge their propensity frequently during the day; yet I have been assured by them that, after twenty or thirty years, they have not suffered from the practice.

Hashish, the preparation which is eaten, is too well known, from recent descriptions, to require much to be said about it. It is made by mixing the powdered leaves with butter, and also as a conserve with honey, to which opium is added.

?

MAROUT ZARBE.—Used as an application to wounds.

FRUITS AND SEEDS.

Umbelliferæ.

CARWIA.—*Carum Carui*, L.—Caraway seed. It is grown largely in the neighbourhood of Larache, and is shipped at Tangier in sugar casks and serons, but chiefly in bags, to England and America, It is also produced round Morocco city. At Mogador, where it is rarely shipped, it is called Fez caraway seed. One cannot help being surprised at finding this cold climate plant a product of Morocco,

CUMIN.—*Cuminum cyminum*, L.—Cumin seed. This is produced in quantity in the interior provinces of Hamer and Rahamna. The Jews mix it in their bread. It is exported to America, and also to the Canary Islands, where it is used in preserving tunny fish.

NAFFA.—*Fœniculum dulce*, C. Bauh, jun.—Fennel seed. This is used as a substitute for aniseed for flavouring mahaya, a spirit extensively used, which is made chiefly from the water in which the combs are boiled in preparing beeswax. This water being impregnated with honey is allowed to ferment, and is then distilled.

Euphorbiaceæ.

ELGASTO (trans. Castor oil).—*Ricinus communis*, L.—Castor oil seeds. Castor oil is not made in Morocco, although the soil and climate seem well suited to the plant. About Saffi, I saw it of the dimensions of a small tree, and abundant. It was introduced there only some years ago.

HABTMILK.—*Croton tiglium*, W.—Croton oil seeds. The Moors use the seeds as a strong purgative, and I found that they are well known in the interior of the country. But I was not able to satisfy myself that *Croton tiglium* grows in Morocco. The seeds were stated by the Moor who gave them to me to be *Romi*, *i.e.*, European.

Sapotaceæ.

ARGAN.—*Argania Sideroxylon*, Rœm. et. Sch.—Seeds. The oil expressed from the nuts is in general use for cooking. Fowls and other articles of diet are served up soaked in this oil, which is preferred by some Europeans to olive oil. But such greasy food is very distasteful to most stomachs. It is customary to allow it to simmer over a fire with a piece of bread in it to remove its pungent taste, and this process is also believed to obviate a supposed tendency to cause leprosy.

Goats, sheep and cows eat the fleshy part of the argan fruit freely, and the nuts are then laboriously broken with stones in order to extract the kernels. These are first partially roasted and then ground in a handmill. The oil is extracted from the meal by working it with the hands, and water is added to the mass as seems necessary. The argan, like many other trees in Morocco, has a local distribution. It is only found to the south of the River Tensift, and at no very great distance farther south again disappears. In the Province of Haha there are large forests of it, and a tree exists a few miles south of Mogador, which is the largest known. It is of great age and has a circumference of 72 yards. The trunk, which is very rugged and unequal, measures 26 feet close to the ground, and soon branches out. The branches extend more or less horizontally, and then droop so as to rest on the ground, while at the same time other branches are sent upwards. This gives the appearance of several trees in a group (as seen in the photograph I took) instead of being merely branches. The highest part of this venerable tree does not exceed twenty feet.*

Rhamnaceæ.

NABU.—*Zizyphus orthocanthus*, DC.—Jujube berries. The fruit of the sidra-tree. This tree varies in size from that of a small tree to a small shrub, depending upon the soil in which it is found. It is widely diffused. The berries are eaten and are commonly sold in the markets of Morocco. The oil of the kernel is used as a perfume.

Cucurbitaceæ.

ELHEDJA.—*Cucumis Colocynthis*, L.—Fruit. I obtained this pepo the size of a large orange in the city of Morocco. It differs from the ordinary Mogador kind in being, instead of a yellow colour, of a bright green with numerous yellow streaks, made up of more or less broken and irregular patches, which mark it into segments. It is probably only a variety. The Moors introduce colocynth pulp into the rectum as a purgative.

Zingiberaceæ.

GOOZA SEHRAWEEA.—*Amomum Melagueta*, Roscoe.—Grains of Paradise. This drug appears to be an importation from Europe. It is mixed in bread and is used as a sexual stimulant.

Rutaceæ.

HARMEL.—*Peganum Harmala*, L.—Seed. Used in fumigation as a disinfectant, and also against the effects of the "evil eye."

?

SANOUS.—?—Seed. Used as a diaphoretic. This seed resembles the preceding (harmel) in size and appearance, except in colour, which is perfectly black, whereas harmel is brown.

Plantaginaceæ.

ZERKTOUNA.—*Plantago Psyllium*, L.—Seeds. Used as a demulcent in fevers and in colds.

Ranunculaceæ.

HABRAS.—*Delphinium Staphisagria*, L.—Seeds. Used to destroy vermin.

Leguminosæ.

ELHELBA.—*Trigonella Fœnum-Græcum*, L.—Fenugreek. Employed by women to induce fatness, and it is also given with barley to horses. When first taken it purges.

BARKS.

Juglandaceæ.

SUMAC (trans. a stain).—*Juglans regia*, L.—Used by the Moorish women for staining the lips black.

?

EDRO.—Bark used in fumigation and also for tanning.

ROOTS.

Leguminosæ.

ARKSUS.—*Glycyrrhiza glabra*, L.?—Licorice. Given for coughs and chest affections. Produced in the southern province of Suse.

* The best account of the argan tree is contained in Hooker's 'Journal of Botany,' vol. 6, p. 97.

Thymelaceæ.

ADAD.—*Daphne Mezereum*, W.—Purgative; and used for fumigation in dropsy.

Zingiberaceæ.

KEDILSHAM.—*Alpinia galanga*, Swartz.—Infusion of root used in gonorrhœa and urethral discharges.

Asclepiadaceæ or Apocynæ?

WASKIZA.—Used as an emetic for children combined with *Taserkina.*

Cruciferæ.

L'FUELY.—*Raphanus sativus*, L.—Radish. The root, when pounded, is applied to wounds. I saw radishes in Morocco city of enormous size, quite as large as ordinary mangold wurzel roots.

Liliaceæ.

B'SELT DIB (trans. Jackal's onion).—*Scilla maritima*, L., or more probably *S. indica.*—This, when boiled in oil, is highly esteemed as a sexual stimuant.

Iridaceæ.

HAMBER ELHOR.—*Iris Germanica*, L.—Orris root. —It comes in large quantities from the city of Morocco to Mogador, from whence it is shipped to England and France. It is not yet two years since this trade sprang up, and at the present time many tons of the root are exported monthly.

ELFOA, Madder.—Long thin, almost tasteless root. Infusion used for diarrhœa, also as an application to sore eyes; taken by women as an emmenagogue, and to improve the complexion.

?

ODEN ELHALOF (trans. Boar's ears.) — Taken by women in decoction to induce fatness.

?

TOWSERGENT.—The grated root is mixed in bread to induce fatness.

?

TASERKA.—This root is emetic.

?

BERESIMIS. — Infused in water when given in fever, with the view of preventing the water from being injurious.

Araceæ.

IRENE.—*Arum Arisarum?*—The interest which belongs to this plant lies in the circumstance that it yields a useful starch. In times of famine, which occasionally happen from drought or from a visitation of locusts, the tubers are dug up, washed, dried in the sun, and ground between hand-millstones. Without further preparation the meal is then cooked by steam, like kuskusso, the national dish, made of granulated wheaten flour. As happens in the case of the allied plant, *Arum maculatum*, which yields Portland arrowroot, Irene tubers contain an acrid poisonous principle which should be removed by repeated washings. As this is neglected by the Moors, it is not surprising that people who live entirely upon this food suffer severely from abdominal pain, and that many of them die. When travelling between Saffi and Mazagan in the early part of November, the ground was in many places studded all over with the single leaf of this plant, which had then just appeared above ground. I may add that I succeeded in bringing home some growing plants, which are now flourishing in Kew Gardens.

EXUDATIONS.

Euphorbiaceæ.

PHORBIUM. — *Euphorbium resinifera*, Berg.—Euphorbium gum. I have little to add about this substance to what is already known. It is produced in the inland provinces of Deminet and Antife, but the plant is found in other places. A plant which grows freely in the neighbourhood of Mogador was pointed out to me as that yielding the gum, but it proved to be *Kleinia pteroneura.* A kind of honey from the province of Haha is sold in the Mogador market. This when eaten causes a burning sensation in the mouth and throat. It is on this account regarded as of a heating nature, and like the squill is valued as an aphrodisiac. I was assured that these properties are due to the euphorbium flowers, from whence bees obtain the honey. It calls to mind the intoxicating effects of honey, as experienced by some of the ten thousand Greeks in their retreat under Xenophon, effects attributed to the *Azalea Pontica.* But poisonous honey is found in various countries, and the poison seems due to many different plants. The people who pack euphorbium at Mogador wear veils to protect themselves from the dust which is so irritating to the eyes and nostrils. Pliny tell us (b. xxv. c. 28) that persons engaged in collecting the juice of the euphorbium plant were on account of its acrid nature obliged to stand at a distance and pierce it with a pole shod with iron, and that the juice flowed into kid-leather receivers placed beneath. Serapion makes the same statement, except that the stomachs of animals were employed as receivers.* Avicenna says that Euphorbium loses its virtues after three or four years. But he adds, some think these may be restored by placing the gum for some time in a vessel containing decorticated beans.†

Umbelliferæ.

FESHOOK.—*Ferula species?*—Gum ammoniac. It is called fasoy by the Barbary merchants. The plant is called kelth, and is abundant in Woled Busebbah, two days' journey from Mogador on the road to the city of Morocco. It grows very quickly after the first autumnal rain. The stalk exhibited is one inch and a quarter in diameter, and was obtained at Mogador. Before parting with it the Moor broke off a portion, intending it, as he said, to fumigate his sore eyes. By virtue of its adhesiveness, the gum is also used by the Moors as a depilatory. Very little ammoniacum is sent to Europe. But a great deal is carried by pilgrims to Egypt and Arabia, where it is used for incense. It is chiefly shipped from Mazagan to Gibraltar for reshipment to Alexandria; a little is sent from Mogador, and none from the other ports. Pereira was of opinion that the Greeks and Romans were unacquainted with Persian ammoniacum (the produce of *Dorema ammoniacum*, Don.). The name ammoniacum is stated by Pliny (b. xii. Chap. 49) to be derived, like that of the oracle of Jupiter Ammon, near which the gum was produced, from ἄμμος (sand), in reference to the surrounding sandy country. This would indicate that it was brought from Lybia, the modern Tripoli. The Arabian physician, Serapion, writing at the com-

* "Serapionis, Medici Arabis celeberrimi Practica" Venetiis, apud juntas 1500, p. 179.

† Avicenna, Venetiis, apud juntas, 1595, B. 2, p. 313.

mencement of the ninth century, mentions two kinds of ammoniacum, the best sort of which was produced from the root of a plant found in Crete; and an inferior kind of which he says, " Sed illud quod continet terram et lapides, nominat chironia et defertur a terrâ quæ dicitur Monacon et est succus plantæ, similis plantæ galbani in similitudine suâ et nascit ibi." This description agrees with the present Morocco product, and Monacon may be an early name for that country. It is observable that Serapion calls ammoniacum, 'raxach'; and that 'assach,' 'ushak,' and 'oshac' are severally employed by Arabian and Persian writers to designate the gum. These approach 'fasogh' and 'feshook,' the modern Moorish names.

?

Alkeptum.—This terebinthinate gum-resin I have failed to identity, nor do I know the uses to which it is put. It is probably the product of *Pistacia atlantica*.

Miscellanea.

Papaveraceæ.

Benaman.—*Papaver dubium*, L.—Capsules, etc. Used as a diaphoretic.

Tamaricaceæ.

Tacout. — *Tamarix articulata*, Vahl. — Galls. Used for tanning, and shipped for this purpose to Algiers.

Terebinthaceæ.

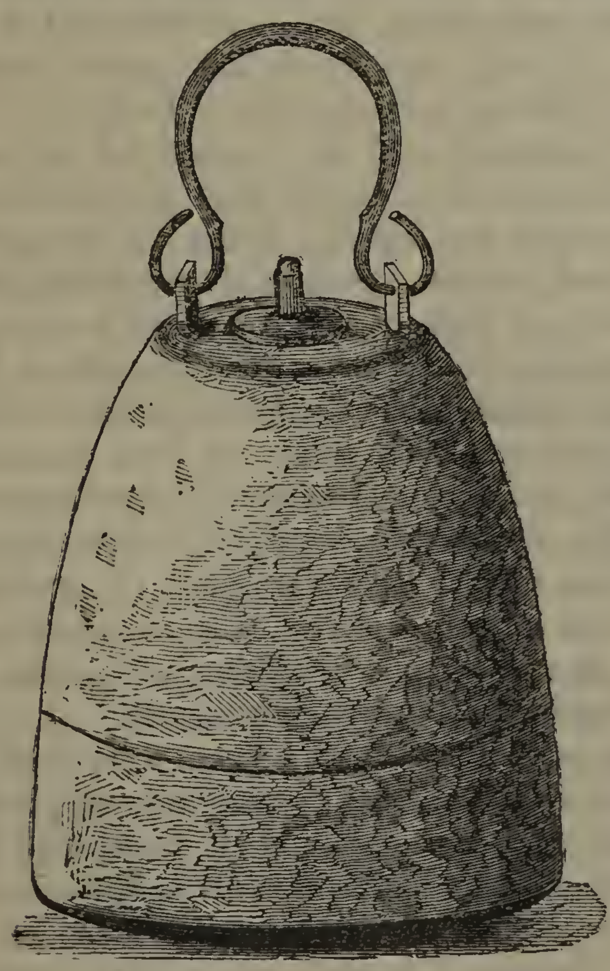
Elleg.—*Pistachia atlantica*, L.?—Pistachia galls. Produced in Showia. Used for diarrhœa, and also as a cosmetic.

?

Rassoul.—Is a mixture of stalks, buds, etc. Used for cleaning woollen clothes. I obtained it in the city of Morocco.

Aurantiaceæ.

Elma delichien.—*Citrus Species*|?—Orange-flower water. This, the quality of which is good, was



brought from Terodant, a town three days journey south of Mogador, which is unvisited by Europeans on account of the fanatic nature of its inhabitants. Rosewater is brought from the same place, and both articles are largely used by the Moorish ladies. Vessels like that represented in the engraving are used to contain these waters. They are made of hammered copper tinned over, and are of the shape of half an egg, having the top part depressed, to which part a handle is attached. These vessels are $8\frac{1}{2}$ inches in height by $7\frac{1}{2}$ inches diameter at the base, and contain about a gallon. It is curious to find such peculiarly shaped and well-made vessels, probably formed of native copper, employed in this way in this rude country.

Animal Substance.

Hamber.—*Amberbris.* — Strangely enough, this substance is brought to Mogador in considerable quantities by the Timbuctoo caravans from the interior of Africa. It probably finds its way there from the west coast. It is also obtained from sperm whales, which drift in dead on the Morocco coast. One of these whales has been thus procured at Casa Blanca in each of the three years just past. All contained ambergris, and the last an unusually large quantity. It was purchased by a Jew, who, it is said, sold it for £3000. Much of it was exported to London. At Mogador it sells for about £20 per pound. Most of the well-off Moors have ambergris in their houses. They use it in green tea as a flavour, and one of the greatest compliments paid to a guest is to present him with a cup of this curious mixture.

This somewhat extensive list does not pretend to be exhaustive, and yet it certainly contains a large proportion of the drugs commonly employed by the Moors. It will be observed that while a great many natural orders of plants are represented, there is a great preponderance of the Labiate order. I remember when travelling in Asia Minor, in a somewhat similar climate and country to Morocco, having been frequently struck with the number and diversity of this group, by whose fragrance the air was charged with odours.

Out of the foregoing list consisting of sixty-one articles, each having a distinctive Moorish name, more than half are well known and commonly used substances amongst ourselves, or else are obviously derived from plants so closely allied to those in common use as to be practically the same. About a fourth are on the same principle from plants known to us, but not in common use, and about the remaining fourth are derived from plants either not at all in use, or else as yet unidentified. The practical results are not at present important, but the members of a society engaged in such patient investigations as the Pharmaceutical Society will admit that knowledge is in itself important. To place the alleged virtues of a new drug on a secure basis, is a work of time and labour. It is not improbable that Morocco may contribute out of its undeveloped resources some agents of great value to our more enlightened materia medica. It is my intention to continue these investigations by trials of the drugs at present in my possession, and also by obtaining new ones, on a second visit to the country or through my correspondents in Morocco. On a future occasion I may again ask the privilege of laying the results before this Society.

[*The discussion upon this paper is printed at p.* 638.

The Pharmaceutical Journal.

SATURDAY, FEBRUARY 8, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

COUNTER PRESCRIBING.

THE following advertisement bears upon a question which occasionally threatens misunderstanding between the medical profession and ourselves :—

"WANTED.—Immediately, a young man, as dispenser to a surgeon with retail, capable of prescribing in simple cases, and able to extract teeth. Time for study allowed. Apply, by letter, stating salary, etc., or personally, before eleven or after six p.m., to Dr. Hutton, 240, City Road, or 87, Lever Street."

Being inserted in the PHARMACEUTICAL JOURNAL, it must be taken to be addressed to pharmaceutists. Nor is it a chance evidence of an unusual state of things, for we all know that it is not uncommon for dispensing surgeons in London and elsewhere to devolve a portion of their medical practice upon their non-qualified dispensers. The custom is no doubt convenient, and, if it is not abused, advantageous to the master and to the patients. But it follows that the same experience in the pharmaceutist's possession must be available to be exercised in his own shop for the public accommodation, as well as to be hired out to the use of the surgeon. In both cases the same conditions must be observed, viz., that the "prescribing" should not exceed proper limits or go beyond "simple cases."

If within such limits the practice is reprehensible, consistency demands that the profession should put a stop to it at home before they denounce it abroad. They altogether lose sight of the practicable when they call upon chemists to confine themselves *rigidly* to "the work of preparing drugs prescribed by others," and prohibit the public from taking any medicines except under medical prescription.*

We may here note for the information of our readers that another medical journal, the *Doctor*, has followed the *British Medical Journal* in denouncing as unjust the *Globe's* "rather silly assertion about the extortionate charges of druggists," expressing surprise that it should have been adopted by the *Medical Times* apparently under a misunderstanding of the question, and without giving pharmacists, as a body, credit for the advances they have made. The *Doctor* points out that, although the public is accustomed to amuse itself with good-natured smiles about the profits on medicines, it is generally known that the returns of chemists are so small that it would be impossible to exist on the profits that would be, in other trades, handsome.

* *Vide Lancet*, Oct. 22nd, 1870.

COMMENTARY ON THE PHARMACOPŒIA GERMANICA.

WE have just received the first number of a new work by an author whose name is well known to pharmacists in this country as an eminent pharmaceutical writer and commentator. A commentary on the German Pharmacopœia by one so well qualified for the task as Dr. MOHR is known to be cannot fail to prove a valuable addition to pharmaceutical literature, which many of our readers will appreciate. The part of the work before us, consisting of 96 pages, treats of the vinegars, acids, and other articles up to "*æther*," taken in the alphabetical order in which they are described in the German Pharmacopœia. The commentaries appended to each of the pharmacopœia processes and descriptions resemble, in their general scope, those given by the late Mr. RICHARD PHILLIPS in his 'Translation of the London Pharmacopœia.' They contain the critical remarks and observations resulting from long practical experience of one of the most accomplished of modern pharmacists. The work is remarkably well printed and illustrated with numerous excellent wood-cuts.

THE RISE AND FALL OF PHARMACEUTICAL PRODUCTS.

THE development and extended usefulness of some pharmaceutical products and the failure and loss of others are matters of interest for various reasons, especially as showing the real value for man's benefit of the earth's products, the more perfect test of their usefulness in the progress of science, and also sometimes of their failure through want of proper supplies consequent on the extinction of the plant in the country from which the sources have been drawn or from the fluctuations of trade.

No better notion of the rise and fall of medicinal products can be obtained than by reference to the old Herbals and similar works on the subject of drugs, and by comparison of them with the pharmacopœias and Materia Medicas which have connected those times with our own. The Herbals of PARKINSON and GERARD, the 'Compleat History of Druggs' by POMET and other works of that character, are valuable as showing the state of knowledge in those days, but, on the other hand, we fear that when these books have fallen into the hands of unscrupulous traders on human credulity, they have been a ready means of supplying a vocabulary of quaint phraseology used to puff up quack nostrums.

This subject has been indirectly touched upon in a recent article in a daily contemporary, wherein the value of modern science and its union with the progress of the noble profession of medicine in our own times is compared with medical science in the old days. Certain it is that many more nasty drugs were used in those days than at the present time, and we are not one whit the worse off for their loss, but then the fault usually lay with the patients themselves, for we are reminded that "nasty draughts" were preferred by the sufferers before "such mild and dulcet applications as the refinement of modern science has introduced."

As in other branches of science so in pharmacy, everything now works as by steam power compared with preceding generations. It does not now, as a rule, take us years to discover the true value of a new remedy; witness the rapid fall of cundurango, the efficacy of which from the very outset was doubted; *Eucalyptus*, again, seems to be now upon its trial, and by the end of the present year the verdict will in all probability be pronounced.

Setting aside the consideration of articles which, one hundred or two hundred years ago, were of medicinal value, but which are now obsolete, it is interesting to note the growth and development from those times of some pharmaceutical products which are now of known value; or again the accuracy with which many of them were often described, and to the knowledge of which we in modern days have been able to add little or nothing. These thoughts have been brought out after looking through an unpretending little book, published in London in 1690, entitled 'The Treasury of Drugs Unlock'd.' It was published at one shilling, and as the title-page tells us, it treats of "all sorts of drugs, and chymical preparations sold by drugists." Cowitch we find described as the "down of a large cod, like a pease-cod, of a brown colour, like dark cinnamon, the said cowitch being nothing else but a down covering the said cods, called cowitch, because of its provoking itching and scratching, is of no other use but to play tricks and waggery with; it cometh from Jamaica." Here then is a brief, popular and tolerably accurate description of the pods of *Mucuna pruriens* which could readily be "understanded of the people." The cuticle itself which, as every one knows, is composed of the short stinging hairs from the outside of the pods, and which is well known as a vermifuge, though not official, seem to have been of no medicinal value in those days. Perhaps before another two hundred years have passed the *Mucuna* will be entirely forgotten in the praise bestowed upon another remedy; who knows but that the short rigid hairs from the involucres of *Corylus rostrata*, Ait., which have been used as a substitute for *Mucuna* in North America, may not be sent over to us as an article of trade?

As an example of accuracy, we will quote a paragraph referring to white pepper, which we are correctly told "is made from the largest black pepper, by art, being very full, round, large and white;" we also learn that "some has been made here in England, but not so good." This knowledge contrasts favourably with that possessed by the directors of a Bencoolen pepper plantation, who, on account of the higher price of white pepper, gave orders to the superintendent of their plantation to cultivate the white pepper plants in preference to the black. With regard to the adulteration of drugs and other articles of trade, perhaps there is some consolation to be derived from the fact that our forefathers practised a system of cheating certainly equal to any system practised now, for we are told that musk is frequently adulterated, and are consequently warned that "those musk cods which have been opened and sowed again, are very suspicious of adulteration; for there is often found lead, stones, leather, etc., stuffed in the cods amongst the musk. and that so cunningly, that it can hardly be perceived." We hope now that we hear so much of public analysts, the dawn of a better time has arrived, a time when we shall get pure food and pure medicine, articles of approved value and acknowledged purity.

AMERICAN NOTES.

In New York a new monthly publication, to be called *The Druggist*, is announced, the earlier numbers of which are to be illustrated by coloured plates of poisonous plants.

It is satisfactory to find that the colleges of pharmacy in the United States are reported to have larger classes during the present session than ever before; that Philadelphia has within the last seven years doubled the number of its students, and has just issued a catalogue of the class for the fifty-first session (1872-73) numbering 293 names. At Cincinati the class numbers 50 students; at Louisville, in its second session, the class numbers 15, and an effort is being made to endow the college. At Chicago the college has 75 students, and the gift of books, etc., from English pharmacists is at last safely housed and being utilized. We regret, however, to hear that Professor Ebert has been seriously ill since the beginning of October. In explanation of the above figures, it may be mentioned that in some of the States the certificate of a legal incorporated college of pharmacy is allowed in lieu of an examination. In New York there appear to be several persons who have failed to comply with the new law regulating pharmacy in that city, against whom proceedings are to be at once commenced.

We learn from a letter placed at our disposal by Professor Attfield that one of the buildings which escaped destruction in the recent great conflagration at Boston was the College of Pharmacy. Among those destroyed was the office of the 'Boston Journal of Chemistry,' together with a drug warehouse, and two laboratories, which were in connection.

We are sorry to learn that, owing to the death of a relative, Mr. Daniel Frazer was prevented from attending the meeting of the Council on Wednesday last.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

February 5th, 1873.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

Present—Messrs. Atherton, Baynes, Betty, Bottle, Greenish, Hampson, Hills, Mackay, Owen, Radley, Sandford, Savage, Schacht, Shaw, Stoddart, Sutton, Urwick, and Williams.

The minutes of the meeting on January 1st and of the adjourned meeting on January 8th were read and confirmed.

BALLOT FOR RETIRING MEMBERS OF COUNCIL.

The lot for the next Council having been taken in the usual manner, the following were declared to go out of office, but are eligible for re-election:—

BAYNES, JAMES, 24, Waterworks Street, Hull.
BETTY, SAMUEL CHAPMAN, 6, Park Street, Camden Town, London, N.W.
BOTTLE, ALEXANDER, 37, Townwall Street, Dover.
HAMPSON, ROBERT, 205, St. John Street Road, London, E.C.
HILLS, THOMAS HYDE, 338, Oxford Street, London, W.
RADLEY, WILLIAM VALENTINE, 74, Market Place, Sheffield.
SAVAGE, WILLIAM DAWSON, 30, Upper Bedford Street, Brighton.

The following seven go out by rotation, but are eligible for re-election:—

ATHERTON, JOHN HENRY, Long Row, Nottingham.
BROWN, WILLIAM SCOTT, 113, Market Street, Manchester.
GREENISH, THOMAS, 20, New Street, Dorset Square, London, N.W.
HASELDEN, ADOLPHUS FREDERICK, 18, Conduit Street, London, W.
MACKAY, JOHN, 119, George Street, Edinburgh.
SANDFORD, GEORGE WEBB, 47, Piccadilly, London, W.
WILLIAMS, JOHN, 16, Cross Street, Hatton Garden, London, E.C.

The following gentlemen remain as members of the Council for the ensuing year:—

FRAZER, DANIEL, 113, Buchanan Street, Glasgow.
OWEN, JOHN, 51, Holloway Road, London, N.
SCHACHT, GEORGE FREDERICK, 7, Regent's Place, Clifton.
SHAW, JOHN, 24, Great George Place, Liverpool.
STODDART, WILLIAM WALTER, 9, North Street, Bristol.
SUTTON, FRANCIS, Bank Plain, Norwich.
URWICK, WILLIAM WALKER, 60, St. George's Road, London, S.W.

The following, being duly registered as Pharmaceutical Chemists, were respectively granted a diploma stamped with the seal of the Society:—

Elliman, Samuel Francis...... Slough.
Heppell, James.............. Durham.

Several persons having paid arrears of subscriptions, together with the subscription for the current year, were restored to their original status in the Society.

ELECTIONS.

MEMBERS.

Pharmaceutical Chemists.

The following Pharmaceutical Chemists were elected Members:—

Adams, Frank .... Stoke-on-Trent.
Ashworth, Amos .... Liverpool.
Badcock, Daniel .... Barnard Castle.
Borchert, Heinrich Theodor Gustav.. Netley.
Bridges, Charles William .... London.
Brown, Frederic Peter........ Bath.
Brown, James .... Rugby.
Butterworth, John .... Walworth.
Chater, Edward Mitchell .... Watford.
Clarke, George Ernest........ Lydney.
Collishaw, John .... Hickling Wharf.
Cope, John Ambrose .... Derby.
Davies, Peter Hughes, jun..... March.
Edwards, John Jones .... Douglas.
Elliman, Samuel Francis .... Slough.
Forster, Henry.............. Durham.
Griffiths, Waldron .... London.
Hackett, John Henry .... Pickering.
Hanbury, Frederick Janson .. London.
Henry, James Hay .... Macduff, N. B.
Heppell, James.............. Willington.
Hibbert, Walter Griffiths .... Neath.
Hick, George .... Bradford.
Holmes, Nathaniel Wheatcroft. Manchester.
Hooper, Frank.............. London.
Houghton, Robert William .. Bermuda.
Howie, William Lamond...... Edinburgh.
Iliffe, George .... Nuneaton.
Iliffe, Thomas Perkins ...... Nuneaton.
Jameson, William Edward.... London.
Johnson, Edward Eli .... Manchester.
Kitchin, William Henry...... Whitehaven.
Maitland, John Edward ...... London.
Mills, Robert................ Northampton.
Monkhouse, Joshua .... Liverpool.
Morgan, William............ London.
Moss, Albert .... Ilkeston.
Mumford, Alfred .... Southampton.
Palmer, Alfred Neobard ...... Bury St. Edmund's.
Parson, Henry James .... Hull.
Pasmore, Frederic Rich. ...... London.
Peel, James .... London.
Peters, David .... London.
Powell, Thomas Henry ...... Benson.
Preston, Joseph Classon ...... London.
Richardson, Robert .... Cheadle Hulme.
Shenstone, William Ashwell .. Colchester.
Sidley, Thomas Insall........ Lichfield.
Smith, John Francis .... Scarborough.
Stoakes, Benjamin Maidens.... Burgh-le-Marsh.
Swire, Jabez .... Halifax.
Thomas, John Darby Dermott Bristol.
Thompson, Henry .... London.
Thompson, William Milner .. York.
Thurston, Frederick .... Long Melford.
Townley, Thomas William.... Keswick.
Trist, Richard .... London.
Videon, Charles .... Paris.
Wallis, John Thomas Ward .. London.
Wilford, Josiah.............. Newport Pagnell.
Williams, James .... Dorking.
Wing, Lewis................ Yeovil.
Yates, Robert .... Southwark.

Chemists and Druggists.

Abbey, Joseph .... Nottingham.
Duncan, Alexander .... Bournemouth.
Jenkinson, John Henry Dixon. Sheffield.
Lemmon, George Francis .... King's Lynn.
Lewinton, Alexander Bellamy. London.

ASSOCIATES.

The following, having passed their respective examinations and being in business, were elected "Associates in Business of the Society":—

Minor.

Beard, James Collins .... Ealing.
Bowker, William .... Bolton.
Colley, John .... Ripon.
Cooling, William John ...... Newark-on-Trent.
Marshall, Alfred .... Upper Holloway.

Rieveley, Charles .... Birkenhead.
Smith, Arthur Harry .... Hanley.
Wenham, George Daniel...... Stamford.

Modified.

Arkle, William .... Lancaster.
Ault, Reuben................ Chesterfield.
Black, James................ Leslie, N.B.
Cock, John.................. Penzance.
Dobinson, Thomas .... Bishop Auckland.
Downing, James Henry ...... Southwell.
Houseman, Alfred Hodgson.... Southborough.
Kitchen, George Seaton ...... Nottingham.
Leithead, John Henry........ Chester.
Lugar, Henry .... Notting Hill.
Perkins, John Jaquest........ Denny, N. B.
Robinson, Jonathan Scott .... St. Leonards-on-Sea.
Robinson, John Threlkeld .... Compstall.
Scholefield, Herbert.......... Ravensthorpe.
Stewart, James .... Portishead.

The following, having passed their respective examinations, were elected "Associates":—

Minor.

Bascombe, Frederick .... Weymouth.
Beaton, William .... Fraserburgh.
Hearne, John .... Liverpool.
Jones, James Parry.......... Newcastle.
Lansdale, John Anstey ...... High Wycombe.
Marson, William .... Stafford.
Mumby, Charles John Everitt Bury St. Edmund's.
Pidd, Arthur Joseph .... Hulme.
Robinson, Richard Atkinson .. London.
Sargent, John Charles........ Leamington.
Scoley, Thomas Edward ...... Boston.
Smith, John Jacob .... Yeovil.
Williams, David Henry ...... Aberaman.
Worthington, William ...... Preston.

Modified.

Brooks, Owen .... Wellington.
Cavell, John .... Long Sutton.
Coates, Joseph .... Newcastle.
Johnson, Edward .... Southport.
Jones, Enoch Henry.... ..... Bristol.
Kay, John .... Crewe.
Lambert, George Pitt .... Brompton Road.
Pettinger, Elmer .... London.
Sharpley, Samuel Latham .... Sheffield.
Smith, James Malcolm ...... Doncaster.

APPRENTICES OR STUDENTS.

The following, having passed their Preliminary examination, were elected "Apprentices or Students of the Society":—

Ashley, Henry .... Gravesend.
Bailey, John Harvey .... Winchester.
Baker, Thomas.............. Ryde.
Barker, Charles Dexter ...... Birmingham.
Barlow, Frederick .... Birmingham.
Barnes, Nathaniel Morris .... Bolton.
Barton, Thomas James ...... Coventry.
Bray, Ernest Edward .... London.
Bray, William John .... Saffron Walden.
Brearey, Arthur William .... Douglas.
Brown, Alfred Duncombe .... Halstead.
Brumwell, Herbert .... Fleetwood.
Brunt, Edwin .... Great Grimsby.
Campbell, Henry .... Hammersmith.
Case, William .... Norwich.
Challinor, Cedric .... Bolton.
Clare, Thomas .... Cheltenham.
Davenport, Charles Aldersey.. Chapel Ash.
Davies, William .... Llandilo.
Donaldson, James .... Edinburgh.
Edwards, Frank Dunn ...... Usk.
Ellis, Henry .... Rochdale.
Evans, Evan Thomas .... Carmarthen.
Evans, Thomas.............. Cwmbach.
Fowler, George William .. Hackford next Reepham.
Garth, John .... Preston.
Geldart, William .... Seacombe.
Gibson, Frederick .... Blackpool.
Glasbrooke, Thomas Guttery.. Kidderminster.
Hammond, Henry .... Bradford.
Hanson, George Huskinson .. Boston.
Harriman, Edwin............ Liverpool.
Heywood, John Henry ...... Lincoln.
Higgs, Alfred Henry .... Bristol.
Hodgkinson, Peter James .... Congleton.
Hoyles, George.............. Lincoln.
Illingworth, William Henry .. Halifax.
Irving, Peter................ Dumfries.
Jacob, Henry Garrard........ Portsmouth.
Johnson, Edward .... Stockport.
Jones, Samuel .... Flint.
Jones, Thomas .... Rhuddlan.
Kemp, Harry .... Salford.
Kidd, William Champley .... Malton.
Laing, Joseph Lythall Leigh.. Ipswich.
Lawton, John Dyson .... Louth.
Legat, William Henry ...... York.
Leslie, George .... York.
Lewis, Edward Prosser ...... Tenby.
Littlewood, John Oscroft .... Sutton-in-Ashfield.
Lucas, Joseph Michael Mark .. Gravesend.
McCallum, Hugh............ Berwick.
Matthews, Thomas Averill.... Worcester.
Mill, George .... Edinburgh.
Millhouse, Harry How ...... Sleaford.
Mills, William Hamer ...... Heywood.
Moore, Henry .... Brighton.
Murdoch, John McGill ...... Glasgow.
Osborne, George Cooch ...... Northampton.
Oxley, Frederic Augustus .... Epsom.
Park, Charles James .... Devonport.
Parker, William Marris ...... Walcot.
Parminter, Urban .... Exeter.
Peché, John .... Chertsey.
Plumbe, Charles Marshall .... Mansfield.
Ponçon, Alfred Augustus .... Wallington.
Porter, Thomas .... Fleetwood.
Powell, Cuthbert .... Bristol.
Princep, Philip.............. Uppingham.
Richards, William .... Nottingham.
Roberts, William............ London.
Roberts, David Prosser ...... Hereford.
Robertson, Andrew .... Markinch.
Robinson, Edward .... Birmingham.
Royse, John Frederick ...... Stockport.
Servant, James.............. Thorne.
Shemmonds, Adrian .... Uttoxeter.
Slinger, Robert Thomas ...... Manchester.
Starling, William Egerton.... Tunbridge Wells.
Steele, Samuel .... Plymouth.
Stephenson, Robert .... Bradford.
Strickland, Augustus James .. London.
Sutton, William .... Chatteris.
Symons, William Henry .... Barnstaple.
Thomas, Frank.............. Boston.
Thompson, Lawrence Joseph.. Thirsk.
Topliss, Walter George ...... Wainfleet.
Trible, Edward.............. Launceston.
Ward, Matthew .... Leeds.
Wardley, Frederick Samuel .. Lowestoft.
Watt, George Adam.......... Hartlepool.
Webb, Robert William ...... Clifton.
Weston, Matthew Frank .... Bury.
Wing, William.............. Sheffield.
Wood, Henry .... Bury.
Wylde, James .... Reading.

The above list originally contained the names of three females, but on the fact being mentioned, it was decided that they should be put separately, in order that the question of admitting females to connection with the Society might be voted upon separately.

Mr. Schacht inquired if any ladies had ever been admitted to the Society heretofore.

The Secretary replied in the negative.

Mr. Hampson moved and Mr. Mackay seconded the election of the following as apprentices or students of the Society:—

Hart, Alice Marion .... London.
Minshull, Rose Coombes...... London.
Stammwitz, Louisa .... Wandsworth.

Mr. Sandford moved the following amendment:—

"That Alice Marion Hart, Louisa Stammwitz, and Rose Coombes Minshull be not elected apprentices or students of the Society."

He said the step now proposed was a very important one, and in refusing the privilege, the Council would not be in any way shutting ladies out from the business of a chemist and druggist. He should be sorry to prevent any lady devoting herself to any trade or calling which she desired to follow, but the Society was founded by men and for men, and this was altogether an innovation. There had always been an objection to receiving ladies as members, but if they were once admitted as apprentices, they would naturally go on to full membership. He had as much respect for the ladies as any one, and should not have voted with the majority had he been present at the last Council, when it was decided not to allow them to compete for the Sessional prizes. Having admitted them to the lectures, he thought they should be allowed to compete for any prizes which were offered to the students of the class, though not those offered to associates.

Mr. Betty seconded the amendment. He would not detain the Council by repeating the arguments he had formerly used, though he thought they all applied with redoubled force on the present occasion. The question was whether they should continue to be a society of men, or whether the female element should be introduced. It would not be competent to them to pass this amendment if it went in any way contrary to the intention of the Act of Parliament, but he did not believe this was the case. The 16th clause of the Act, which provided for executors carrying on the business of a deceased chemist and druggist for the benefit of his widow, to his mind showed clearly that Parliament never contemplated the case of such a business being carried on for the benefit of a widower, on the demise of a female pharmacist. There were many little matters which he need not advert to more particularly, which seemed to render it undesirable that ladies should be encouraged to enter the business, and as the admission of ladies as apprentices would lead to their attending the evening meetings, and ultimately perhaps to their appearance at the Council-table, he thought it best to interpose and check at the very outset what he considered a move in the wrong direction.

Mr. Savage could not conceive the object of the opposition to the admission of the ladies who now applied for election. It was quite a mistake to suppose that they would be inundated with ladies; the few who would come amongst them were exceptional, and might well receive exceptional privileges. The clause in the Act which Mr. Betty had referred to would justify him in supporting the admission of ladies, because it was one of the most anomalous clauses in the statute; and it was evidently a great mistake, as it was there enacted that ladies should be precluded from carrying on the business, if they were capable of doing so, after the death of their husbands. If ladies had the moral courage to undergo an examination and to obtain the qualification which was granted, irrespective of sex, they ought to be allowed to go through the whole curriculum, and be encouraged in so doing.

Mr. Williams said Mr. Betty's argument, founded on the Act of Parliament, had really nothing to do with the question. It was not whether these ladies would become pharmaceutical chemists, which they might do already, but whether they should become connected with the Society. There was no doubt this was the first step to admitting ladies to membership, because they would naturally proceed from studentship to associateship, and then to full membership. The question was so serious and important that he should like it deferred for further consideration.

Mr Urwick thought the matter had better be settled at once. If it really were the will of the majority of the Society that ladies should be members of the Council, he should be quite willing to see them elected. But it should also be remembered that it would appear by the Report of the last Preliminary examination that, in refusing to elect these ladies, they would be rejecting the very flower of the intellect which attended, for it appeared that one of these ladies was at the top of the list.

Mr. Betty explained that he quoted the 16th clause of the Act of 1868 simply to show that in not admitting ladies the Council would be in accord with the intention of the Legislature at the passing of the Act, as there was no provision made for them in it.

Mr. Hampson said when this subject was brought forward at the last Council, he was told that these ladies were in a measure out of order in applying to compete for the prizes, because they had not passed the examination which would make them eligible. Now he was told that that was of no effect at all. He did not see the necessity for considering the matter any further; he simply wanted the matter treated from a common-sense point of view. The Act permitted ladies to become pharmaceutical chemists, and therefore Mr. Betty's argument on that head, as far as he could see, came to nothing. If they were permitted to become chemists and druggists, surely they should be encouraged to become students in every sense of the word.

Mr. Sutton said when this question first came up, he was rather opposed to the admission of ladies in any way to the business, but his views had undergone a change, and he thought it really was a question for serious consideration whether the occupation of dispensing was not one which they ought to be encouraged to follow. For his own part, he believed that many young men were not nearly so careful, cleanly, and methodical in their habits as properly trained young women; and for his own part, he should feel no objection on principle to the introduction of them into the trade. It was admitted they might attend the lectures, and having done that, he thought this further step should not be denied to them.

Mr. Schacht remarked that a distinction had been drawn by Mr. Sandford between excluding ladies from the legal qualification to earn their livelihood as chemists and any claim they might have to become members of the Society, thereby contending that the Society was of a private nature, and had a perfect right to regulate its own affairs according to the wishes or even whims of its members. He could hardly take that view of the case at present, for they were not now simply a private society; since the passing of the last Act they were a society which had imperial powers, and if it were of advantage, as it was generally considered, to any member of the trade to become a member of the Society, it was certainly putting such persons under a disability if they were refused the privilege. The Council, in his view, had a certain trust imposed upon them which they had no right to exercise selfishly, but were bound to do so with the largest liberality possible. Anything which excluded a lady from the same advantages which the Society offered to men was a disability placed upon them on account of a natural accident which might as well be applied to men having hair of a particular colour. No one had shown that the occupation of pharmacy was unsuited for ladies, and that being taken for granted, it seemed to him an act of tyranny to exclude any one from the advantage of that Society. He therefore hoped the resolution would be carried by a large majority.

Mr. Bottle asked under what section of the bye-laws it was proposed to admit the ladies. He did not think section 10 met the case, because that applied to persons who were assistants or apprentices, which he did not understand these ladies to be. He suggested a compromise, that the ladies should be made honorary associates, and ventured to hope that the matter might stand over for another month, in order that this idea might be considered.

Mr. Betty also advocated an adjournment of the question.

Mr. Urwick said the ladies did not wish to be admitted on any but equal terms with the opposite sex.

The President said he did not see why ladies should be admitted to the Society simply because they had passed the Preliminary examination; many gentlemen passed that examination who never went any further. He should vote for the amendment.

The amendment was then put with the following result:—

For—Messrs. Atherton, Betty, Bottle, Greenish, Haselden, Radley, Sandford, Stoddart and Williams.

Against—Messrs. Baynes, Hampson, Hills, Mackay, Owen, Savage, Schacht, Shaw, Sutton and Urwick.

The amendment was therefore lost.

The original motion having again been put,—

Mr. Williams moved the following amendment, which was seconded by Mr. Greenish:—

"That the question of the election of Alice Marion Hart, Louisa Stammwitz, and Rose Coombes Minshull, be deferred until the meeting of Council in June next."

Mr. Baynes said he did not see the use of deferring a decision unless it stood over to a new Council.

Mr. Bottle suggested that it should stand over till the meeting of the Council in June; seeing that it was an extremely important subject, and as they were approaching the eve of a general election, the question would then go to the country and members would be returned to the Council after having expressed their opinions upon it. He therefore suggested that Mr. Williams should alter his amendment to that effect.

Mr. Shaw said the election of members of Council was not to hinge on that single question.

Mr. Williams said the course now proposed would give an opportunity for discussing it at the general meeting.

Mr. Owen said if it were deferred at all, it should be deferred to a new Council.

Mr. Urwick thought it a great mistake to defer a matter of this sort which might very well be dealt with at the present time.

Mr. Betty supported the adjournment of the question.

Mr. Hills said although he had voted against Mr. Sandford's amendment, he thought it might be better to delay a final settlement until after the annual meeting.

Mr. Mackay said that what had been said did not alter his opinion one iota that the Society would be stultifying itself to a certain extent if it refused admission to these ladies. Under the Act of 1868 no one denied that ladies were to be admitted to the Modified examination, or that several ladies came up for that examination, passed it, and were at this moment on the Register as chemists and druggists. And so far as he knew no one was able to show that they were not in all respects as fully qualified to conduct the business as any one else. He could not follow the argument advanced as to the propriety of deferring this question until the annual meeting; for he thought if they were not competent to settle such a simple question, they were not worthy of their position as councillors of the Society. He was not beset by the terrible fear which some seemed to feel, that if ladies were admitted to the educational department of the Society, and to the position of apprentices, associates, and members, they would come forward in such numbers as to swamp the male element. But even if a dozen, 100 or 500 ladies entered the Society, it did not follow that they would be elected on the Council. They could not be so elected unless it were the general wish of the whole body, and if it should happen that that was the case, he should certainly have no objection to seeing ladies sitting there. Still he looked upon that as not at all probable, though barely possible. He thought deferring this question for four months was quite unnecessary.

The amendment being put, the following gentlemen voted:—

For—Messrs. Atherton, Betty, Bottle, Greenish, Haselden, Radley, Sandford, Stoddart and Williams.

Against—Messrs. Baynes, Hampson, Mackay, Owen, Savage, Schacht, Shaw, Sutton and Urwick.

Mr. Hills did not vote on this division, consequently the numbers were equal, whereupon the Chairman gave his casting vote in favour of the amendment.

Finance.

The report of the Finance Committee was received and adopted, and sundry payments ordered to be made.

North British Branch.

Mr. Mackay presented the account of the North British Branch, audited by three gentlemen whom he named; and he stated he should be happy to give any further particulars which might be required. There was a balance of £67. 19*s.* 5*d.* in favour of the Society, which would go to carry on the current expenses of the present year. With regard to the payments in connection with furnishing the new rooms, it would be in the recollection of the members that £100 had been voted for that purpose, and the committee in Edinburgh had gone to work as economically as possible, still they had spent that amount and £32. 9*s.* 4*d.* in excess; but he believed very full value was obtained for the money, as might be seen by looking at the particulars. He also stated they were much in want of a set of specimens for the purpose of the Examiners. The reading-room and library, and especially the museum, were being taken advantage of by young men to a very gratifying extent; several students coming up, spending a fortnight or three weeks in close reading, etc., and examination of the specimens in the museum. They still looked forward to the President, or a deputation from the Council, coming down and seeing what was being done, and what their requirements still were. The President was *ex officio* a member of the Examining Board, and two former Presidents had done them the honour of visiting them; namely, Mr. Jacob Bell and Mr. Evans. He hoped, therefore, that at the approaching examination in April, the President, perhaps accompanied by some other members of the Council, would come down and see what they were doing.

Mr. Shaw said he had looked over the particulars and thought the money had been expended very economically. He had no doubt that when it was known to wholesale druggists and others throughout the country that specimens were required, they would be very soon forthcoming.

Mr. Schacht remarked that he hoped the Council would at once order the supply of everything which was necessary for the proper conducting of the examinations in Edinburgh; and if that was the proper time, he should be happy to move a resolution to that effect.

Mr. Hampson suggested that the North British Branch should prepare a statement of what they required, when he had no doubt the Council would supply it.

Mr. Williams was surprised to hear that the specimens were not in good order, because two years ago following the visit of Mr. Deane to Edinburgh, the Council authorized the expenditure of a sum of money for the purpose of making good these defects. He was rather astonished now to find it had not been done; it was certainly very false economy not to provide for the proper conduct of the examinations.

Mr. Mackay said the matter had been standing over in consequence of the getting into the new premises. In fact, even the old specimens had had to be stored until the new rooms were ready, and they had been rather hoping that the President would come down and see them, when it might be decided what additions and improvements should be made.

The President said it would be much more satisfactory to him if the necessary articles were provided first under the direction of the Edinburgh Board, so that when he visited them, as he hoped to do in April, he should see them in thorough working order.

Benevolent Fund.

The Report of this Committee was read, giving the particulars of an application for assistance by Elizabeth Parker, widow of Mr. James Davies Parker, upwards of twenty years confidential clerk to Messrs. Herrings, who died suddenly a short time since.

The Secretary said he was sorry to find, notwithstanding the distressing circumstances and deserving character of the applicant, that, though her late husband had made the necessary application and was eligible for the Modified examination, he had not presented himself for examination, and, therefore, was not registered as a chemist and druggist. As the Benevolent Fund was only applicable to registered persons, the Council were unable to make a grant to Mrs. Parker.

The report was received and adopted.

Library, Museum, and Laboratory.

The Report of this Committee was read. It recommended the purchase of a new edition of Beasley's 'Druggists' Receipt Book' for the library.

The report was received and adopted.

Provincial Education.

The Report of this Committee, recommending a grant of £10 to the Leicester Chemists' Association for the purchase of glass cases for the museum, was received and adopted.

Parliamentary.

The Report of this Committee was read, giving particulars of two cases in which proceedings had been taken against offenders under the Pharmacy Act.

The report was received.

One of these cases, that against William L. Wilson, of 142, Garscube Road, Glasgow, was fully reported in the Society's Journal, of January 25th. In the other case, against James Mathieson, of 109, South Portland Street, Glasgow, the defendant pleaded "guilty," and the penalty of £5 and costs had been recovered.

Proposed Alterations in the Bye-laws.

Several alterations in the bye-laws were proposed for the consideration of the Council. They were read by the President and discussed *seriatim*.

Present.	Proposed.
Section 1, *clause* 10.	*Section* 1, *clause* 10.
It shall be competent to the Council to restore any defaulter to his former status in the Society on payment of his arrears and any fine which it may be thought fit by the Council to impose, not exceeding half-a-guinea.	It shall be competent to the Council to restore any defaulter to his former status in the Society on payment of a fine, not exceeding five guineas.

This was agreed to without discussion.

Present.	Proposed.
Section 1, *clause* 12.	*Section* 1, *clause* 12.
All persons becoming Members of the Society, in exercise of the privileges conferred and defined by Sections 18 and 19 of the Act, 1868, shall on election pay an entrance-fee or sum of two guineas, exclusive of an annual subscription.	All persons becoming Members of the Society, in exercise of the privileges conferred and defined by Sections 18 and 19 of the Act, 1868, shall on election pay an entrance-fee or sum of one guinea, exclusive of an annual subscription.

The only alteration in this, as will be seen, was the substitution of one guinea entrance fee instead of two guineas.

Mr. Mackay thought this was a great mistake, and if a vote were taken upon it, it would be settled without further question.

Mr. Owen believed, on the contrary, that a vast number were kept away from the Society owing to the payment of an entrance fee of two guineas.

Mr. Urwick said he had given notice of a resolution to admit all chemists without an entrance fee, and therefore, of course, he should support the alteration. He did not know whether they would have many more or less, but he thought they should be liberal and ready to admit into the Society everybody, provided their character and position were respectable. It should not be a question of money whether a man should join the Society or not. For his own part he should like to see the entrance fee abolished altogether.

Mr. Atherton said there had been no general demand made for such an alteration, and he saw no necessity for it. It would be doing injustice to those who had paid the higher entrance fee.

Mr. Shaw thought the Council were unanimous on a former occasion, and declined to make any alteration such as was now proposed. He should object most strenuously to the proposed innovation. If a member discontinued his subscription and fell into arrear, by the section they had just adopted, they reserved to themselves the right to make him pay five guineas before re-admitting him, and what justice was there in admitting another man who had never paid anything towards the fund of the Society, on payment of one guinea only?

Mr. Stoddart said he should oppose the alteration.

Mr. Schacht said it was absurd to reduce the entrance fee in the first instance, and at the same time to charge an old member five guineas for restoration.

Mr. Betty said the entrance fee of two guineas was imposed in 1868 on all gentlemen who wished to enjoy the benefits of the Society in order to defray the great expense occasioned by the passing of the Pharmacy Act and by other matters connected with the conduct of the Society. They then undertook to register, free of cost, all those who chose to apply, and that was done at a very considerable expense, and he doubted whether the entrance fee of two guineas already received had recouped the Society the outlay then incurred. He saw no reason now to reduce that fee to one guinea. If the argument was, that more would be induced to join, he did not think that was worth consideration. Prior to the passing of the Act careful estimates were made as to the number of "outsiders," as they were then called, who might be expected to come in, and he believed that estimate had been pretty nearly justified. He did not think that the reduction of the entrance fee would cause any appreciable increase.

Mr. Savage mentioned a case which had recently come under his own notice in which a gentleman told him that he should have joined the Society a year ago if it had not been for the two guineas entrance fee, which he strenuously objected to.

Mr. Greenish believed that the reduction in the entrance fee would be the means of bringing in many new members, and the loss from this source would be very trifling; but he did not look at it altogether from a pecuniary point of view. He considered that if the alteration were adopted, it would be an additional element of strength in the Society.

Mr. Baynes said he should support the one guinea entrance fee, because he did not think the little difference to the Society was worth mentioning. He thought they were now making a fresh start, and should induce every one they possibly could to join.

Mr. Bottle opposed any alteration, saying the bye-laws were carefully settled after the passing of the recent Act, all these matters being taken into consideration; and the same individuals composed the class affected by this bye-law at that time as now. He did not think it was consistent with their own dignity that they should vary the fees in this way, and, like a Dutch auction, getting as many as they could at two guineas, then reduce it to one guinea; get as many as they could at that price, then, afterwards, reduce it to half-a-guinea, and then, finally, to five shillings. He did not believe that any great number would be attracted by the lowering of the fees, because any cautious man would say to himself that as the fees were being lowered, he would wait until they reached the minimum.

The President did not think it would be just to those who had paid two guineas to reduce the entrance fee to new-comers, nor did he think any large additional number would be induced to enter. The guinea subscriptions barely paid the expenses of membership.

On being put to the vote the proposed alteration was lost.

Present.	Proposed.
Section 3, *clause* 3. The Common Seal shall not be set or affixed to any deed, instrument, or writing whatsoever, unless in the presence of the Council of the Society, and in pursuance of an order or minute entered in their books.	*Section* 3, *clause* 3. The Common Seal shall not be set or affixed to any deed, instrument, or writing whatsoever, except by order of the Council of the Society, and in pursuance of an order or minute entered in their books, and in the presence of the President, or Vice-President, and two Members of the Council.

This alteration was agreed to without discussion.

Section 9, *clause* 1. This Committee shall consist of not less than four Members, two of whom shall constitute a quorum. The Committee shall meet once in every month, and report from time to time to the Council.	*Section* 9, *clause* 1. This Committee shall consist of not less than five Members, three of whom shall constitute a quorum. The Committee shall meet once, or oftener, in every month, and report from time to time to the Council.

This also was agreed to.

Section 10, *clause* 1. The Board of Examiners heretofore appointed shall continue in office until the first monthly meeting of the Council after the general meeting in the year 1869.	*Section* 10, *clause* 1. The Board of Examiners heretofore appointed shall continue in office until the end of the month of December, 1873.

The President said the object of this amendment was that the new Council should not have to appoint a Board of Examiners of whom they knew hardly anything. Being appointed in December, all the members of the Board would be known to the Council before they would be re-elected.

This was immediately agreed to, as also were the five following:—

Present.	Proposed.
Section 10, *clause* 2. The Council shall, at the first monthly meeting of the Council after the general meeting in 1869, and in every subsequent year, appoint such competent persons as they shall think fit, to be examiners to conduct all such examinations as are provided for or contemplated by the Charter or by the Statute, 1852, and the persons so appointed shall constitute and be called the Board of Examiners for England and Wales.	*Section* 10, *clause* 2. The Council shall, at their monthly meeting in December, 1873, and in every subsequent year appoint such competent persons as they shall think fit, to be examiners to conduct all such examinations as are provided for or contemplated by the Charter or by the Statute, 1852, and the persons so appointed shall constitute and be called the Board of Examiners for England and Wales.
Section 10, *clause* 3. The Council shall, at the first monthly meeting of the Council after the general meeting in 1869, and in every subsequent year, appoint fit and proper persons in Scotland to be examiners, and to meet in Edinburgh or Glasgow, or such other place or places as the Council may think desirable, and to conduct there all such examinations as are provided for or contemplated by the Statute, 1852, and the persons so appointed shall constitute and be called the Board of Examiners for Scotland.	*Section* 10, *clause* 3. The Council shall, at their monthly meeting in December, 1873, and in every subsequent year, appoint fit and proper persons in Scotland to be examiners, and to meet in Edinburgh or Glasgow, or such other place or places as the Council may think desirable, and to conduct there all such examinations as are provided for or contemplated by the Statute, 1852, and the persons so appointed shall constitute and be called the Board of Examiners for Scotland.
Section 10, *clause* 4. The President and Vice-President of the Society shall, *ex officio*, be members of the Boards of Examiners, and shall preside at all meetings of such Boards at which they shall be present.	*Section* 10, *clause* 4. The President and Vice-President of the Society shall, *ex officio*, be members of the Boards of Examiners, and one or other of them shall preside at all meetings of such Boards at which they shall be present.
Section 10, *clause* 5. After the first day of January, 1871, the Council shall not appoint any person who has attained the age of sixty-five years at the time of the appointment to be an examiner, unless such person shall be the President or Vice-President of the Society.	*Section* 10, *clause* 5. The Council shall not appoint any person who has attained the age of sixty-five years at the time of the appointment to be an examiner, unless such person shall be the President or Vice-President of the Society.
Section 10, *clause* 6. After the first day of January, 1871, no person shall be appointed an examiner who at the time of appointment is, or who during one year prior to the time of appointment has been, a Member of the Council, other than the President or Vice-President; and the election of any examiner to be a Member of the Council shall vacate his appointment as an examiner.	*Section* 10, *clause* 6. No person shall be appointed an examiner who at the time of appointment is, or who during one year prior to the time of appointment has been, a Member of the Council, other than the President or Vice-President; and the election of any examiner to be a Member of the Council shall vacate his appointment as an examiner.

The following proposed alteration was then read:—

PRESENT.	PROPOSED.
Section 10, *clause* 12.	*Section* 10, *clause* 12.
Such of the said persons as shall desire Certificates of competent skill and qualification to be engaged or employed as Assistants shall be examined in the First Examination, and also in the translation and dispensing of Prescriptions, in Botany, in Materia Medica, in Pharmaceutical and General Chemistry, the Chemistry of Poisons and Posology, which examination shall be called the Minor Examination; and such of the said persons as shall desire certificates of competent skill and qualification to exercise the business or calling of Pharmaceutical Chemists shall be examined in the Minor Examination, and in more extended knowledge of Botany, Materia Medica, the translation and dispensing of Prescriptions, Pharmacy, General Chemistry, the Chemistry of Poisons and Posology, which examination shall be called the Major Examination.	Such of the said persons as shall desire Certificates of competent knowledge and qualification to be registered as apprentices or students shall be examined or shall have been examined in Latin, English Grammar and Arithmetic. This shall be called the First or Preliminary Examination. Such persons as shall desire to obtain the Certificate of qualification of Chemist and Druggist under the Pharmacy Act, 1868 shall be examined in the translation and dispensing of Prescriptions, in Botany, in Materia Medica, in Pharmaceutical and General Chemistry, the Chemistry of Poisons, and Posology, which examination shall be called the Minor Examination. Such of the said persons as shall desire Certificates of competent skill and qualification to exercise the business or calling of Pharmaceutical Chemists shall be examined or shall have been examined in the Preliminary and Minor Examinations and in a more extended, and scientific knowledge of Botany, Materia Medica, Pharmacy, General Chemistry, the Chemistry of Poisons, and Posology, which examination shall be called the Major Examination.

Mr. HAMPSON thought there could be no objection to this, as it rendered the bye-law more clear and definite, and was in strict accordance with the Act of Parliament.

Mr. SANDFORD objected to the removal of the word "assistants," as the Act of 1852 contemplated the existence of such a class.

Mr. WILLIAMS said the Council might agree to the principle of the alteration, leaving any verbal alterations to the Parliamentary Committee, with the assistance of the Solicitor.

Mr. SANDFORD said he could not agree to the principle of omitting the word "assistant."

Mr. WILLIAMS said he did not think that was at all a point of contention.

The clause was thereupon agreed to, subject to the retention of the word "assistant."

PRESENT.	PROPOSED.
Section 10, *clause* 16.	*Section* 10, *clause* 16.
All persons before registration as Apprentices or Students shall pass the First examination, and shall pay a fee of Two Guineas, whereupon they shall be registered as Apprentices or Students.	All persons before registration as Apprentices or Students shall pass the First or Preliminary examination, and shall pay a fee of Two Guineas, whereupon they shall be registered as Apprentices or Students.
	After the 31st day of December, 1874, no person shall be admitted to the Minor Examination who shall not have attained the full age of twenty-one years. After the 31st day of December, 1876, no person shall be admitted to the Minor examination who has not been engaged or employed as an Assistant, Apprentice or Student at least three years previously.
	After the 31st day of December, 1876, the Board of Examiners shall cease to hold the First or Preliminary examinations, except in London and Edinburgh, and persons desiring to be registered as Apprentices or Students shall pass the Society's examinations in London or Edinburgh, or produce certificates of having passed either the Oxford or Cambridge local examinations, the examinations of the College of Preceptors, or of some other examining body, previously approved by the Council of the Pharmaceutical Society, provided such examination includes the Latin language and arithmetic.

Mr. WILLIAMS said he thought it would be convenient to omit the consideration of the first paragraph of the amended clause, because the whole question of fees could be considered afterwards.

Mr. HAMPSON said he was sorry to say he did not agree with the majority of the Parliamentary Committee in recommending this amended bye-law, because he thought it was introducing a great change, and one contrary to the spirit of the Act. The charter of 1843 gave power to the Society to examine candidates in such manner as the Council thought proper. The Act of 1852, which gave them further powers for the safety of the public, authorized the registration of such as passed the examination. Authority was also given by this Act to frame bye-laws proper and necessary for the purpose contemplated by the charter and the Act, and a detailed definition was given as to the nature of the examination intended, but there was no mention or allusion to any condition with which the candidates were to comply, other than the ability to comply with the tests imposed by the examiners, and thus showing that they possessed a competent and practical knowledge. The Act was framed with a view to the safety of the public, and not from any exaggerated notions of pharmaceutical attainment. In the preamble to the Act of 1868, the same plea on behalf of the public was set forth, and by this Act the Society was entrusted with large powers, including the power of compulsory examination of all persons intending to follow the business of chemist and druggist. But that Act gave no power to prescribe either the age at which the examination should take place or that any time of service should be previously passed. Now the proposed new bye-laws and regulations agreed neither with the letter nor spirit of the charter or Acts of Parliament in this respect, but constituted an unwarrantable innovation, and as the Council no longer represented a small voluntary association, he would urge upon them not to be too hasty in making new regulations which had not been proved to be either necessary or expedient. He was well aware that the Board of Examiners had recommended these changes, and that those recommendations were adopted, but he contended that they were not properly discussed, but were passed with unusual precipitation. Therefore he considered he was quite justified in discussing the matter on this occasion. He had more faith in the examiners than they had in themselves, and thought they were fully competent to test the qualifications of the candidate without arbitrarily fixing the age and intervals between the examinations, or prescribing that he should have passed any specified time in the business. He had not a word to say against the propriety and usefulness of the ordinary mode of entering the business, if it were done voluntarily, but he had the strongest possible objection to tying down the hands of the candidates in this way, and was sure that no good results would accrue from this source. He might be excused for remarking that if these regulations had been in existence some years ago, he should not have been a member of the Council or in the trade at all. He felt positive that this was a retrogressive step, and as other bodies, such as the Apothecaries' Company, no longer required a term of apprenticeship, he thought it was a great pity to introduce these limitations. He moved an amendment that the second paragraph be rejected.

Mr. Savage seconded the amendment.

Mr. Bottle submitted that the proposed alteration was strictly in accordance with the terms of the Act of 1868, referring especially to clause 4. If the Legislature contemplated that a man, in order to pass the Modified examination, should have been three years in business, it could not be inconsistent to ask that a young man who came forward subsequently should serve three years before passing the Minor examination. There were other clauses giving the Council power to make such bye-laws as they thought fit, and therefore he contended it was fully within their power to make the proposed alteration.

Mr. Mackay, on the whole, agreed with the proposed amendment, though he should have preferred the age being fixed at twenty instead of twenty-one. At the same time he would not take a vote upon that subject, especially as it would not come into operation until after 1874. His own idea, however, would be to make twenty the age for the Minor, and twenty-one for the Major. With regard to the objection to the term of apprenticeship, he thought that matter would right itself before the new bye-law came into operation, because there was a great feeling in Scotland, and he believed it would be so in England, that no apprentices should be taken who had not passed the Preliminary examination. Now, after he had passed that examination, it was quite right he should spend three years in practical acquaintance with the business before passing the Minor. In some branches of the legal profession it mattered not what was the age of the person applying, whether it was twenty, thirty, forty, or even sixty, he must serve a certain number of years and give evidence of having been so engaged before he could obtain the qualification he desired.

Mr. Shaw said this matter was fully discussed three months ago, and he did not think it ought to be reopened. He believed the proposed alteration was in strict accordance with the spirit of the Act, and it was impossible that a person could have a practical knowledge of the business without serving three years in it. With regard to the age, that had been fully discussed, and it had been almost unanimously decided that twenty-one should be the limit. He must say, however, he took exception to the last paragraph.

Mr. Urwick said it was true this matter had been previously discussed at the Council when he was in a minority, and he supposed he should be so still, for he had a strong objection to seeing industry and intellect weighted. By this clause they put a weight on young men who were persevering and intelligent, confining them to three years' experience and the age of twenty-one, when they might be fully qualified at an earlier period. He did not think in all cases three years were necessary to learn the business. It depended somewhat on the age at which a young man entered, and also on the education the lad received beforehand. It was very different now when youths were educated up to the age of sixteen or seventeen to what it was years ago, when boys were apprenticed at thirteen or fourteen. If a young man were apprenticed at sixteen or seventeen, and applied himself diligently to his business, so that he could pass the Minor at nineteen or twenty, he was worth to himself at least £10 a year more, and it was not fair to prevent him getting that. He thought the examiners themselves ought to be able to test the competency of a young man without reference to his age.

Mr. Williams was astonished at the discussion on this clause, since it was simply for the purpose of giving legal force to the regulations adopted by the Board of Examiners which the Council had already adopted.

Mr. Sandford said he thought the matter had been already settled. As to the age of twenty-one years, he might say that at the time the Act of Parliament of 1868 was under consideration the Government were very anxious, in the interest of the public safety, to introduce that requirement for passing the examination, but it was then waived in obedience to the wishes of the Council. However, he believed the Corncil were now pretty well convinced that the introduction of such a limit would be beneficial. The great point was to ensure the proper education of youths coming into the business, and therefore it was proposed to require an interval of three years between passing the Preliminary and the Minor, which would ensure not only sufficient education to begin with, but in effect a certain amount of practice in the business. It had been proposed to substitute the words "engaged and employed" for the word "registered," but he thought registered was the proper word, as a man would not register himself as an apprentice unless he intended to follow up the business. Registration was the legal thing, and he should prefer that word being retained. They did not require apprenticeship to any particular men, they only insisted that the candidates should have been occupied a certain time in the business. He had no doubt about their power to make the bye-law.

Mr. Greenish would have preferred fixing the limit of age at twenty.

Mr. Shaw said it was stated that it was illegal to admit persons under age to the qualification of chemists and druggists.

Mr. Baynes said the great point was that directly a man had passed the Minor examination he could immediately commence business, and he thought twenty-one was quite soon enough.

Mr. Hampson having briefly replied,

The President then proposed to put the amendment, but

Mr. Savage stated that he had only seconded it because he objected to the age of twenty-one years as the limit, and not with the intention of defeating it altogether.

The amendment, therefore, fell to the ground, and the paragraph was adopted.

With regard to the third paragraph, the President said he should recommend the rejection of it altogether. He thought that if youths were either obliged to pass the Oxford or Cambridge examinations, or to go to Edinburgh or London to be examined, it would put them to a great deal of inconvenience.

Mr. Greenish said there was a general impression that these examinations in the country were not satisfactory, and the desire was to abolish them altogether.

The President said they were as well superintended in the country as they were in London. He thought all the dissatisfaction arose in consequence of an unfortunate circumstance which took place on one occasion, but which could not take place again.

Mr. Betty said the Committee recommended this change, he believed, not as a matter of efficiency or otherwise in the Preliminary examination, but in order to separate the technical examination of the business which strictly belonged to the Society, from a matter which was already recognized as being one which could be equally well discharged by other bodies whose certificates were even now received. A change was proposed for the purpose of convenience and carrying on the Society's business, and with a view to draw a broad line between examining a man's knowledge of his business and that preliminary knowledge which would enable him to learn it. It had been originally proposed to abolish the Preliminary examination altogether in connection with the Society, but a compromise had afterwards been arrived at by which it was proposed to retain these examinations in London and in Edinburgh, and he thought that would meet all the difficulties of the case.

Mr. Savage expressed himself in favour of retaining the Preliminary examinations as at present, on the ground that their abolition would greatly inconvenience students.

Mr. Urwick was of the same opinion.

Mr. Sandford hoped the paragraph as amended would be passed, or else that the Council would go back to the old system under which the students either had to come to London to pass the examination or produce certificates from some competent authority. He thought these examinations in the country were often most unsatisfactory, and hoped they would not be continued.

Mr. Mackay did not think the present system was unsatisfactory, and saw no reason to effect a change. He had had from 24 to 30 students under examination at Edinburgh, and never discovered the slightest irregularity.

Mr. Betty hardly thought Edinburgh was a fair criterion.

On being put to the vote the paragraph was rejected by a considerable majority.

The following new clause, to follow number 19, section 10, was agreed to:—

To follow clause 19, *section* 10.

No person shall be admitted to the Major examination who has not passed the Minor examination at least three months previously, except in special cases, approved and allowed by the President of the Council for the time being.

The new bye-law of which notice was given last month was then considered. It runs as follows:—

Section 20, *clause* 4.

No resolution of the Society, by which the legal position of the members of the Society, or the legal position of chemists and druggists (whether members of the Society or not), may be altered, shall be passed at any meeting unless fourteen days' previous notice of the intention to introduce such resolution has been given, and ten days' notice thereof given to each person entitled to vote at such meeting.

The President read a letter from Mr. Vizer on the subject commenting on the above, which had already appeared, and suggesting as an improvement the following form:—

"That no resolution of the Society, by which the legal position of the members of the Society, or the legal position of chemists and druggists (whether members of the Society or not), may be altered, shall be received or adopted at any meeting of the Society unless 14 days' previous notice of the intention to introduce such resolution has been given by the secretary to the members."

Mr. Sandford remarked that the Parliamentary Committee had agreed to the addition of the words, "and ten days' notice being given to each person entitled to vote at such meeting." He did not like the phrase, "legal position," which was very vague. There was scarcely a resolution passed at an annual meeting which did not alter their legal position in some way. He therefore suggested the following:—

"That no resolution of the Society which would impose on Pharmaceutical Chemists and Chemists and Druggists any legal penalties or obligations shall be passed at any general meeting, unless fourteen days' previous notice of the intention to introduce such resolution has been given to the President of the Pharmaceutical Society, and notice thereof has also been given in the Pharmaceutical Journal by the Secretary, together with the notice convening the general meeting at which it is to be proposed."

Mr. Williams thought the Secretary was the person to whom the notice should be given.

Mr. Urwick thought the words "legal position" were better than those suggested by Mr. Sandford, especially as they had been settled by the Solicitor.

After some further discussion the clause was agreed to as first read, with the omission of the words "of the Society" in the first line, and the addition of the following words:—

"And notice thereof has also been given in the Pharmaceutical Journal by the Secretary, together with the notice convening the general meeting at which it is to be proposed."

Examination Fees.

Mr. Williams then moved,

"That the fee for registration upon passing the Preliminary examination be £2 2*s.*; for registration as a Chemist and Druggist upon passing the Minor examination, £5 5*s.*; and for registration as a Pharmaceutical Chemist upon passing the Major examination, £3 3*s.*"

Although several members of Council had left, he hoped this would be assented to on the understanding that it might be reconsidered at the next Council meeting.

Mr. Savage seconded the motion.

Mr. Betty thought they could not do it in that formal way.

The President thought it was a mistake to make a man pay two guineas more before he took up the status of Chemist and Druggist, and let off the man who passed as a Pharmaceutical Chemist to the same extent.

Mr. Williams said the man who passed the Minor examination got the full benefit of the Act of Parliament. It gave him power to keep open shop, and he held that was the one which he ought to pay the heaviest fee for. At the present time he stepped in for three guineas, and he believed this stood in the way of many coming forward to pass the Major examination. There was a great outcry made as to there being so few pharmaceutical chemists coming forward, and it was said there might be a difficulty hereafter in recruiting their members. It was with a view to remedy this that the change was proposed. The Minor examination was previously intended for assistants; and as it now gave a man a full qualification to enter a business, it was only fair the fee should be raised.

Mr. Mackay differed altogether from Mr. Williams on this point, seeing that this examination was now compulsory by Act of Parliament, and that the man who passed it must have already paid a two-guinea fee for the Preliminary. He considered three guineas quite enough, especially as compared with the fees paid in other higher professions. In Edinburgh a man could pass the examination of the College of Surgeons for a fee of ten guineas, and get a diploma, and even if he became a physician he had only five guineas more to pay. If he went on to the further degree of Master in Surgery, there was only a further five-guinea fee. In Glasgow the diploma of the Faculty of Physicians and Surgeons might be obtained for a ten-guinea fee; and if Chemists and Druggists were going to be weighted in this way with additional fees, it would simply have the effect of driving many men to scrape together a few guineas more to qualify themselves for the higher examination of the College of Surgeons, and pay the ten guineas, when they would open shop and do as they pleased. It must not be forgotten either that there were many young men to whom an extra two guineas at the expiration of their apprenticeship appeared a very large sum of money.

Mr. Betty said the fees payable in London on taking up a medical degree were much higher than in Scotland, amounting to about thirty guineas on the average.

Mr. Urwick was in favour of the proposed alteration, and did not think it would tell so much against the Society as some thought. He believed that the number of Pharmaceutical Chemists would continue to fall off, and that the expenses must be paid by those passing the Minor. The whole course of instruction was kept up for their benefit, and in the course of time they must expect that the Examiners' fees and other expenses would increase, and therefore he saw nothing unfair in increasing the examination fee.

Mr. Greenish deprecated any alteration. He considered it would be specially hard on those who passed the Minor and still continued assistants. It must not be taken for granted that every one who passed immediately went into business on his own account. Nor would lowering the fee for the Major induce men to present themselves for that examination. No doubt if the payment of the fee was a qualification for the ordeal, there would soon be a large addition to the number; but it was the examination, not the fee, which was the obstacle.

Mr. Hampson said, looking at the matter broadly, if three guineas paid the expenses, seeing that the examination was compulsory, he thought they ought to be satisfied.

Mr. Betty said he doubted whether the annual meeting would sanction a bye-law raising the examination fee, unless a clear necessity for it could be shown, which was not the case.

On the question being put, the proposed alteration was lost by a large majority.

It was then arranged that the alterations in the Bye-laws, as now agreed upon, be submitted to the Society's solicitor to be put into legal form.

The Report of the Board of Examiners was received and adopted.

PHARMACEUTICAL MEETING.

Wednesday, February 5th, 1873.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

The following donations to the Library and Museum were announced, and the thanks of the Society were voted to the donors:—

'Calendar of the Royal College of Surgeons of England, 1872,' from the College; 'Catalogue of Scientific Papers (1800–1863), Vol. vi.,' from the Royal Society of London; Signal Service Weather Maps and Meteorological Records of November 22nd, 1872, three issues, from the U.S. War Department; 'De la Rage en Algérie,' par Dr. C. Roucher, 'Essai sur un Arbre du genre Pinus,' par P. Dive, and 'Les Champignons de la Charente-Inférieure,' par J. Mousnier, from Dr. Soubeiran; 'Year-Book of Pharmacy and Transactions of the British Pharmaceutical Conference, 1872,' from Mr. R. Bremridge; 'Sur la situation actuelle du Bureau des Longitudes,' par M. Faye; A report of Microscopical and Physiological Researches into the nature of the agent or agents producing Cholera,' by T. R. Lewis, M.B., and D. D. Cunningham, M.B.; 'On a Hæmatozoon inhabiting Human Blood: its relation to Chyluria and other Diseases,' by T. R. Lewis, M.B.; 'The Telegraphic Journal for November, No. i.;' 'Sessional Proceedings of the National Association for the Promotion of Social Science,' Vol. vi., Nos. 1–2; 'The Ancient Physician's Legacy to his Country,' by Thomas Dover, M.B., second edition, 1732, from Mr. Daniel Hanbury; 'Specimens of Egyptian Tamarinds, of the rind of the Bergamot Fruit, and of the roots of the Jalap Plant, showing the formation of the tubercules,' from Mr. Daniel Hanbury; specimen of 'Guaiacol, and specimen of Theine obtained from Guarana,' from Messrs. Hopkins and Williams; 'Sulphocarbolate of Calcium, in very perfect Crystals,' from Mr. De Witte; 'Arsenious Acid with Crystals formed upon its Surface,' from Bissoc Arsenic Works, Cornwall, from Mr. R. H. Martin; 'Eucalyptus Oil,' from Messrs. Felton, Grimwade and Co.; 'Native Borate of Lime from Singapore,' from Mr. J. Collins.

The PRESIDENT, in announcing the contributions to the Library, called attention to a very old book which had been presented by Mr. Hanbury, and which was by Thomas Dover, the originator of "Dover's Powder." The book contained a curious recipe for the preparation of that powder.

Professor ATTFIELD exhibited some syrup of iodide of iron containing iodide of lead. The specimen had been sent by Mr. Rimington, of Bradford, who believed it to be quite unique. Specimens of syrup of iodide of iron had, probably, been brought before the Society as often as any preparation, but they had never had one like that then shown, which was truly a "golden syrup," full of spangles of golden lustre. These spangles were iodide of lead. Mr. Rimington stated in a letter that the iodine he had been supplied with contained lead, the iodine probably having been sublimed on to a leaden surface. Professor Attfield had sometimes found lead mechanically mixed with iron filings. If Mr. Rimington had made his syrup from iron filings, that fact might account for the presence of lead; being made from iron wire, however, the lead was clearly traceable to the iodine, added to which, Mr. Rimmington had detected lead in the iodine.

Mr. WILLIAMS said that on more than one occasion he had found his syrup contaminated with iodide of lead, and he once had more than 150 pounds weight thus spoiled. He separated it by sulphuretted hydrogen after dilution. In each of the cases he had met with, the lead was entirely derived from the iron filings, and not from the iodine. He had used portions of the same iodine with pure filings, and found his syrup free from lead.

Mr. UMNEY said that he had seen the same impurity in syrup of iodide of iron, but it occurred only when the syrup was prepared from rough iodine. He had checked this observation by the use of different qualities of iron, and had found the lead in the syrup even when iron wire had been used. When resublimed iodine was used, iodide of lead did not occur.

MOROCCO DRUGS.

A paper on "Some Drugs collected in Morocco" which is printed at p. 621, was read by Dr. Arthur Leared, and gave rise to the following discussion:—

The PRESIDENT, after expressing the thanks of the Society to the author for his interesting, instructive, and, he might say, amusing paper, remarked that orange-flower water was generally imported in copper vessels containing nine or ten gallons each, but not made in the costly style of the vessel which Dr. Leared had just exhibited.

Mr. HANBURY said that Dr. Leared had referred to a seed extremely like that of *Peganum Harmala*, but black instead of brown. *Peganum Harmala* was a plant well known in the East, and its seeds possessed a remarkable property of affording, when digested in spirit, a green fluorescent solution. With regard to orris root, which, they were told, had lately come into the market from Morocco, he had the other day observed the curious fact that at the beginning of the present century price currents always used to contain both Florentine orris root and Barbary orris root. The Barbary orris root was entirely derived from *Iris germanica*, the common blue flag of our gardens. With regard to cumin we were told that it was used by the Jews in their bread, and also for flavouring pickled tunny fish. In the middle ages it was much used in Europe as a spice and a condiment. Dr. Leared had drawn attention to the remarkable fact of caraways being brought from Morocco. He (Mr. Hanbury) confessed that when he was shown Morocco caraway seeds in London some time ago, he hardly knew how to believe his eyes, for the caraway was essentially a northern plant, dwelling in Scandinavia and the colder parts of Europe. On looking, however, at Jackson's 'Morocco,' a work published at the beginning of the present century, he found that the author distinctly mentioned caraway seeds as an export of Morocco, and upon his (Mr. Hanbury's) sowing some of the Morocco caraway seeds last spring, he obtained a plant exceedingly like that of Europe. As to grains of paradise, it might be true, as stated by the people of Morocco, that their drug came from Europe, but it was a very curious fact that at Tripoli and the towns on the northern coast of Africa grains of paradise were still brought by caravans coming from Soudan and Timbuctoo, and from the tropical parts of Africa east of Sierra Leone. They were so brought in the middle ages, and shipped to the ports of Italy; and as they came from an unknown and remote region, and were much esteemed, they acquired their present name, the people supposing that no place but Paradise could produce anything so delightful. In subsequent times, when there was direct trade between Western Africa and Europe, grains of paradise were an article of very large import, being brought direct even to England and France. They were once in common use as a condiment for human food.

Professor BENTLEY said that Mr. Hanbury had anticipated some of the remarks he had intended to make. He must say that, although he had come to the meeting fearing that the paper, being technical, would be uninteresting, he had found it quite the contrary, and had listened to it with great gain. Researches such as those of Dr. Leared were the only means by which they could get any historical knowledge of old remedies, or form an acquaintance with new ones. As to orris root, it was very interesting to find that it came in such large quantities from Mogador, in Morocco. Dr. Leared had referred to only one species of *zizyphus* though there were several species known by the common name of jujube;

but as to the so-called jujubes manufactured in London, it was quite understood that the juice or the fruit of the jujube plant did not enter into their composition. He was very sorry that the great fascination of partridge shooting had prevented Dr. Leared from seeing the ammoniacum plant, as he should have liked to be informed of the mode in which it was obtained. Perhaps Dr. Leared might have heard from the natives whether the drug ammoniacum was obtained from the root, from the stem, or from both. In the museum there was a very interesting specimen of the stem of the Persian ammoniacum plant, with the ammoniacum *in situ*. That result had been produced, not by incisions, but by the attacks of beetles or some creatures of the kind, in consequence of which the gum had exuded and covered the stem. The poisonous nature of *Spartium junceum* had been referred to in the paper. The Spanish broom had been examined by Dr. Stenhouse, who had found a new principle in it, and therefore, anything in connection with that subject was of interest. Of course, the drug was a strong diuretic. With regard to starch, no doubt it was present in plants allied to the arum, and could probably be obtained in large quantities from the large corms and underground stems without much difficulty. He apprehended that the poisonous quality was got rid of not so much by washing as by a certain amount of temperature that was employed in the preparation of the substance.

Mr. COLLINS said that there seemed to be two kinds of 'harmala' seed, and both seemed to have had that name at first. Those of *Peganum harmala* he had compared with a herbarium specimen. The other was certainly those of a rutaceous plant, but whether it was a variety of *Peganum harmala*, he (Mr. Collins) could not say. He did not see in the Herbarium of the British Museum any specimen which showed a variation in the seed between those two. With regard to argan, he could not help wondering why the oil had not been introduced into this country. Sir William Hooker, in the 'Journal of Botany,' gave a very good account of it, and it had been very highly spoken of. As to Tacout galls, they were very small, and they did not seem to be equal to the Morea galls. The latter were introduced to commerce some time ago, but from inquiry which he had made, he found that they were not considered good enough to be sent. The dealers said that when the galls were very small they did not like them, because they were very often mixed with foreign substances. With regard to *euphorbium*, it would have been very interesting if the plant from Kew had been sent to the meeting, because it had now, through the researches of Dr. Cosson,* some historical interest. It would be remembered that Dr. Berg sometime ago made an examination of certain parts of the stems found in the specimens, and he gave it the name of *Euphorbium resinifera*. Dr. Cosson having examined specimens which he received from Mr. Hanbury and others, said that he believed that Dr. Berg was correct. Dr. Hooker in the meantime had obtained a plant from Mr. Cartensen, and this was now growing. The only matter to be cleared, and to make one sure that it was this species which yielded the gum euphorbium, was the flowering of the specimen. That event would prove whether Dr. Berg and Dr. Cosson were correct. As to the wormwood, if he remembered rightly, Mr. Wilkomm and Dr. Berg gave it the new specific name of *Cina*. There was an article in the Journal on the subject.† Mr. Wilkomm had proved what Dr. Berg had said to be correct. They had given that new specific name to the Barbary worm seed.

At the request of the PRESIDENT, Dr. Leared consented to leave his specimens on the premises of the Society for two or three days, that other members might have an opportunity of examining them.

PROPOSED ADDITIONS TO THE BRITISH PHARMACOPŒIA.

The PRESIDENT informed the meeting that Professor Redwood was anxious to make an important statement with regard to the Pharmacopœia.

Professor REDWOOD said he should occupy but a very few minutes, as the usual time for adjournment was already passed. He might resume the subject at another meeting, probably; but there was an object in its being brought before the members of the Society before the next meeting was held. He referred to proposed alterations and additions to be made in the British Pharmacopœia. The work had now been published about six years, and it had, during that time, been reprinted, and would require to be reprinted again very shortly. In introducing a reprint of it on the next occasion, it was proposed to add to it a supplement or appendix which should contain certain new remedies which had been established in medical practice since the work was published. The question arose as to whether, on this occasion, a new edition should be brought out, or an alteration or addition made simply in the existing one. It had been considered that there were very serious difficulties and objections that would attach to issuing a new edition at the present time. The difficulty of inducing the medical profession generally to take up a new pharmacopœia was very great, and there were many other difficulties that would stand in the way. It was generally considered and recognized that ten years was about the time that a pharmacopœia should be allowed to remain in circulation before it was materially and generally altered; and therefore it was proposed merely to issue now a supplement or appendix with the reprint. This would be attached to the end of the reprint, and would be issued separately besides; so that those who had the work already could possess themselves of it in addition to the original work. The next question was, as to what this appendix should contain. There were several medicines and preparations that he had himself suggested, and other persons (members of the Pharmacopœia Committee of the Medical Council) had suggested others. It was desirable to induce pharmacists and others in this country, and in Scotland and Ireland, to make suggestions of what they thought should be introduced into the appendix of the Pharmacopœia at the present time. Now there were certain things that were quite obvious, as, for instance, hydrate of chloral and nitrate of amyl. Acetic æther he proposed more especially with a view to its use subsequently, when the Pharmacopœia was more generally altered. Then there were chloroform water (aqua chloroformi) and mustard paper (charta sinapis). There was a preparation of elaterium, which it was suggested to introduce in the form of a diluted powder (pulvis elaterii compositus), which would consist of elaterium with nine times or seven times (he should say nine times) its weight of sugar of milk. In that diluted form its administration would be facilitated and rendered more safe. Tincture of orange peel was a question which had been before them, and it was suggested that, leaving the present tincture in the Pharmacopœia, they, nevertheless, might add a tincture of the fresh peel; but that, however, was a question to be considered, and in reference to which they were anxious to receive the opinions of practical pharmacists. Then it was proposed to introduce a syrup of liquorice (syrupus glycyrrhizæ). Some of the medical members of the Committee had suggested that that would be a convenient preparation to order frequently in prescriptions. Then they had such things as the hypophosphites, hypophosphite of lime and hypophosphite of soda, and the sulphites, as, for instance, sulphite of soda, although he should himself consider that the hyposulphite, which was now in the Pharmacopœia among the tests, would answer every purpose, and be quite as effective as the sulphite. Then there was oxide of bismuth, and there were two preparations which were suggested and brought under the notice of the Society some time ago, by Dr.

Dyce Duckworth, assisted by Mr. Carteighe, namely the acetum and the oxymel ipecacuanbœ. And then it had been suggested that it would be very desirable to have a pill mass in the Pharmacopœia of a purgative nature, and not containing aloes. There was none such at present, and therefore they had proposed pilula jalapæ composita, which should be free from aloes, and should owe its purgative quality to some other ingredient. Then there was nitrate of ammonia, which they thought of introducing because it was now used in the preparation of nitrous oxide. Next there was precipitated oxide of mercury, which, for certain purposes, was found to be more active and efficacious than the red precipitate obtained by the application of heat. Then there was pepsine, some form of which it would be proposed to introduce into the supplement. It had been suggested, moreover, that they might probably introduce a new form of suppositories. Some medical men took exception to the present suppositories on account of their greasy basis, and it had been proposed that either gelatine, softened with glycerine, or starch and glycerine, might be used in certain cases as a more suitable because a more cleanly basis. The greasiness occasioned by the use of the present suppositories was a source of discomfort and annoyance. These were some of the propositions which had hitherto been made, and the Pharmacopœia Committee were anxious to obtain as extensively as possible the opinions of pharmacists with reference to these and other additions which it might be thought desirable to make to the Pharmacopœia.

The President said that this communication was a very important one, and he hoped that the members would work at the subject, and state the result at some future meeting.

Professor Bentley asked whether Dr. Redwood proposed to bring the subject forward again.

Dr. Redwood said that perhaps he should have explained that his reason for bringing the subject forward provisionally that evening was that the Medical Council expected to meet in the early part of April, and the Pharmacopœia Committee proposed to have the draft of an appendix prepared and submitted to the Council next month. He should have to draw up that appendix and submit it to the Committee by the 1st of March, so that it might be circulated before the Council itself met. Of course, it would be quite open to make any further alterations afterwards, but, in some form or other, the appendix would have to be before the members of the Medical Council soon after the first of next month. That would happen before the next meeting, but, probably, throughout the whole of this year the subject could be discussed, for he was not quite clear that the reprint would take place until the commencement of next year.

The President announced that the next meeting would be held on the 5th of March.

Provincial Transactions.

CARLISLE CHEMISTS' ASSOCIATION.

The usual monthly meeting of this association was held in the class-room on Thursday evening, the 23rd January. There was but a moderate attendance of members, but a tolerably good muster of associates.

Upon the table was displayed a collection of specimens of materia medica, comprising about forty articles, the gift of Messrs. Clarke, Bleasdale, Bell and Tollinton, of York; also a copy of Pereira's 'Materia Medica,' presented by W. Martindale, Esq., of London.

Votes of thanks were unanimously passed to the donors, after which, Mr. J. Robson proceeded to read a paper upon "Glycerine as a Means of Preserving Infusions," etc., which was very well received, and gave occasion for an animated discussion, diverging into the question of the propriety or otherwise of using concentrated infusions generally.

A cordial vote of thanks was given to Mr. Robson, and a similar vote to the president closed the proceedings.

Correspondence.

Milk Testing.

Sir,—Before closing your pages to the discussion on milk adulteration, I desire to express my dissent from the conclusion of Mr. Ekin, "that water is really the only adulterant ever met with in milk." That it is more extensively and frequently used than any other I freely admit; but when purveyors of milk become purchasers of lactometers, and milk, as an article of commerce, manufactured to a standard within the range, something more than aqueous attenuation must be sought for, and is, by diligent research, too frequently discovered.

I have found commixture with eggs adopted to conceal other adulteration of both milk and cream. Very recently a sample of the latter which had undergone spontaneous coagulation was sent to me for examination, and I believe that yolk of egg is the golden accompaniment which more frequently than any other colouring matter assists in passing off attenuated sky-blue as new milk. The suggested method of a correspondent for determining the amount of milk-sugar in whey by cupric reduction possesses no novelty. It is familiar as Barreswil's process. Many of your older readers will doubtless remember to have seen it as a portion of a very good article by M. Poggiale "On the Estimation of Sugar of Milk, and the Determination of the Richness of Milk," which was copied from the 'Journal de Pharmacie' into Vol. IX. of your Journal, 1849–50. This article also appears, with additions, in the 'Chemist,' vol. iv. N. S., 1857.

I remember to have read years ago of the discovery in Paris of the use of dextrine as a milk adulterant to some considerable extent, and then drew the inference that the comparatively easy transformation of this substance into glucose would materially detract from the value of Barreswil's process as a facile mode of approximately determining the amount of water adulteration in milk. To my mind it is open to question whether a useful cupric solution can be made, as stated by your correspondent, so that 100 grains should correspond to 5 whole grains of lactose, and I have still graver doubts as to whether the use of such a concentrated solution affords the best or even a reliable method of estimating lactose in whey. It is certain that lactose cannot in its reducing effect on cupric salt be considered equivalent to glucose, although the somewhat vague quotation from a correspondent's letter (page 482) would seem to imply that Dr. Attfield, in this respect, so treated them. I have read the several editions of Attfield's 'Chemistry' with both pleasure and profit, and venture to affirm that in all of them our worthy Professor has been too careful to commit himself to such a blunder, or even suggest the application of any such cupric solution as a mode of determining lactose. The divergent results of the observations of Messrs. Ekin and Southwell as to the acid or alkaline reaction of new cows' milk may be easily reconciled, and possibly were contingent upon the state of health and condition of the animals yielding it, but are far more likely to be dietary results arising from and attributable to variation in the mode of feeding. It will be found, as a rule, subject to some exception, that the recent milk of pastured cows indicates alkaline, whilst that of stall-fed cows gives acid reaction.

I need scarcely add that in other respects the quality of the milk yielded depends very much upon the quality and kind of food given. The observations and experiments of Mr. Thos. Garside, printed in your last number, commend themselves to the careful consideration and remembrance of all those who are engaged in milk investigation, or are ever required to offer opinion upon the dietetic value of milk of commerce.

Alexr. Bottle.

Joseph Young (Leicester).—Spirit of ·888 sp. gr. = 63 per cent. alcohol, is 24·3 o. p. Spirit of ·830 contains 87 per cent. of absolute alcohol by weight. The other equivalents you quote are correct.

☞ In consequence of the length to which the report of the Society's proceedings has extended, we are compelled to defer the publication of several communications and answers to correspondents.

Communications, Letters, etc., have been received from Messrs. C. Patrouillard (Gisors), J. Leay, Crew, McKnight, Bennett, White, Masson (Paris), J. Cyriax, Schweitzer, Haffenden, Pitman, A. H. Mason, R. E. Charles, Dawes, Widdowson, Yewdall, Biss. Kay Bros., Dr. Kidd, Cecil, Major Associate, Pix Liquida.

ARSENICAL WALL PAINTS.

BY FREDERICK JOHN BARRETT, F.C.S.,

Pharmaceutist to the Wolverhampton and South Staffordshire General Hospital.

A short time ago I was requested to make a qualitative analysis of three samples of a suspiciously brilliant green paint, which had been used for colouring the children's ward of a large provincial hospital. A preliminary examination gave abundant proofs of arsenic in all three of the samples, and the colours upon the walls were immediately ordered to be removed. In a subsequent quantitative analysis I discovered that all contained Scheele's green (arsenite of copper) in considerable proportions. The following are the results of my examination:—

Sample No. 1.—A light green powder, containing about 90 per cent. of pure arsenite of copper, $CuHAsO_3$ (corresponding to 47·52 per cent. of arsenious acid), with a small quantity of carbonate of lime as an admixture.

Sample No. 2.—A soft watery green paint, containing 9·73 per cent. of $CuHAsO_3$ (corresponding to 4·44 per cent. of As_2O_3).

Sample No. 3.—A darker green powder, supposed to be a mixture of Scheele's green with a non-arsenical green. This contained 36·5 per cent. of $CuHAsO_3$ (corresponding to 19·27 per cent. of As_2O_3).

I found on inquiry that the powder green, No. 1, had been converted into the paint No. 2 by the admixture of whitening, size, and water, and that the darker green had been used for painting the borders of the wall. About seven pounds of No. 1 powder (containing arsenicum equivalent to 53·224 ounces of arsenious acid) had been used for painting a ward the walls of which measured 910 square feet, so that upon each square foot there was Scheele's green equivalent to about 26 grains of arsenious acid. The paint, moreover, was readily removed by rubbing and by moisture.

Since making the above examinations I have been induced to extend my inquiries to various paints, wall-papers, and painted articles which, from their brilliant verdancy, attracted my attention, and which were readily obtained from the artists' colourmen and others. With very few exceptions, the more attractive green papers were laden with arsenical pigments, and only those colours which were dark and heavy looking were free from that poison. Scheele's green, emerald green, Brunswick green, Schweinfürth green, and mineral green are all arsenical compounds, and are extensively used in painting theatres, ball-rooms, and other public places. Large quantities of arsenical papers are exported to India and the Colonies. And it has been asserted by a correspondent of the *British Medical Journal* that severe attacks of throat disease, closely resembling diphtheria, at Melbourne, Victoria, and elsewhere have been caused by their use. He also states that "arsenic is largely used in oil paints, which are, consequently, exceedingly dangerous, owing to the escape of the poison in a gaseous form, a fact apparently unrecognized by the chemists and physicians of Great Britain and Ireland, though well known to their brethren in Germany." The greatest ignorance of the poisonous character of these paints appears to prevail amongst the vendors of them. Although they are preparations of arsenic, no questions are asked of the buyers, no poison label is used, no entry is made in the poison-book, and the sellers are not registered under the Pharmacy Act. In Germany the sale and use of arsenical pigments are prohibited by law, except under special circumstances.

In addition to the above uses arsenical pigments are also employed to paint children's toys, artificial flowers, confectionery, fancy boxes, wafers, etc., and (it has been stated) for painting the shelves upon which articles for domestic consumption are stored in the shops of bakers, greengrocers, and others.

I examined a quantity of children's toys and some confectionery, and was pleased to find they were not coloured with these paints. The box, however, which held the sweetmeats was ornamented with gaily coloured flowers, containing a large quantity of arsenic. A lady kindly furnished me with some artificial flowers from her head-dress, which, when tested, were found to contain a portion of this pigment. One berry alone containing equivalent to nearly one-sixth of a grain of arsenic. The lady, not being a qualified pharmaceutist, expressed much astonishment at the result.

I quote from Watts's 'Dictionary of Chemistry' the following remarks in reference to arsenical colours:—"A great deal of needless alarm has lately been excited about the supposed deleterious effects of this pigment. It is extensively employed in staining wall-papers, and persons inhabiting rooms thus papered are said to have had their health seriously injured by the arsenical fumes evolved from it. Now it is utterly impossible that arsenic should volatilize from such a compound at ordinary temperatures. It does not decompose at any temperature below redness. The only way in which danger could arise from the use of paper stained with an arsenical colour is that particles of the compound might be brushed off in dusting the paper, and thus become mixed with the air of the apartment; but it is not in this way the supposed accidents are said to have occurred; the panic has arisen from a mistaken notion as to the volatility of the arsenic. That the use of this pigment is not really dangerous may be safely inferred from the fact that no bad effects are experienced by the workmen engaged in its manufacture."

There can be little doubt that great danger does arise, not so much from the volatility of the arsenicum, or the decomposition of the arsenites, as from the fact that the colour is so easily removable from the walls. Danger there certainly is; and it is to be regretted that this is very insufficiently pointed out by the above remarks, for it is certain that many cases of poisoning, much injury to health, and even death have been clearly traced to the use of arsenical colours. In 'Taylor on Poisons,' cases are given in which the dust which had gathered upon the furniture in rooms painted with Scheele's green was carefully analysed, and arsenic found to be present in very considerable quantity. He says, "It is therefore obvious that the atmosphere of rooms papered with arsenical paper hangings must be more or less contaminated with the fine particles of the green pigments removed from the walls by mechanical causes. Changes of a hygrometric and thermometric nature may affect this porous pigment, and render it more easily detached by currents of air, vibration, etc.; the poisonous particles may thus be received into the lungs; and although the quantity breathed at any one time may be small, it is certainly not advisable that merely for the sake of a green colour, persons should be exposed to breathe, day by day, arsenic in any proportion." I must apologise for the want of originality in this communication, but as it is a subject of some importance I have been induced to forward it for publication.

STRIATED IPECACUANHAS.*

BY M. PLANCHON.

(*Concluded from page* 523.)

The synonymy of the two kinds of striated ipecacuanha described in the former part of this paper is difficult to clear up, in consequence of the manner in which authors have confused the two species. But a consideration of the characters previously indicated has enabled me to do so pretty clearly.

The first author whom I have found clearly referring to a striated ipecacuanha is Lemery, who describes the third of his four species of ipecacuanha as "espèce grise cendrée glycyrrhizée."† Now this sort, according to the characters attributed to it (larger dimensions than those of the official species, and a sweetish taste recalling that of liquorice) can only answer to my "major" striated ipecacuanha. It is the same sort as Mutis had sent to Europe as identical with "Brazilian" ipecacuanha, and of which he had sent the mother plant to Linnæus. At the end of the eighteenth century and the beginning of the nineteenth this sort was to be met with rather frequently in collections of drugs if not in pharmacies. It is clearly the root of the *Psychotria emetica* which Richard describes in his inaugural thesis‡ under the name of striated ipecacuanha; whilst Mérat and De Lens,§ and more lately Guibourt,|| confound it under the same name with the minor striated ipecacuanha.

This kind has occurred in commerce from time to time, but in the present day it has little chance of entering a pharmacy. Mr. Hanbury has sent me a specimen that was offered to the Pharmacie Centrale in Paris in 1858 under the name of Ipecacuanha of St. Martha. M. Vogl has described it in a memoir under the name of *Ipecacuanha glycyphlœa*,** and states that it was sent into the market of Bremen as Carthagena Ipecacuanha. Some fragments, which I owe to the kindness of Mr. Hanbury, came from some packages sent from Bogota in 1870 and offered in the London market. It was from these packages the specimens were taken that were analysed by Professor Attfield,* and which he called "elastic striated ipecacuanha." Lastly it was a short time previously that M. Dorvault received at the Pharmacie Centrale the "violet" ipecacuanha which attracted my attention and which agrees as nearly as possible with the roots of *Psychotria emetica*.

It appears difficult to say when the "minor" striated ipecacuanha first appeared in commerce. But it is clear that this was the kind analysed by Pelletier in 1820,† since that chemist noticed 79 per cent. of woody fibre, gum and starch, and we know that only the "minor" contains starch. Now this species existed in the drug cabinet of the father of Pelletier under the name of "Ipecacuanha des Côtes d'Or (Minas de Oro)," and Pelletier adds that he also recognized it in a mercantile house which had received it from Peru, *viâ* Cadiz. Moreover, it must have been present at that time in most collections. It was this sort that M. Guibourt used principally for illustration at the School of Pharmacy, and it is the only sort which I have found named as striated ipecacuanha at the Pharmacie Centrale des Hôpitaux. M. Vogl‡ saw it in the collection at Vienna described as *Ipecacuanha striata seu nigra*. Professor Attfield found it in the Museum of the Pharmaceutical Society of Great Britain, and analysed it under the name of "brittle striated ipecacuanha."§ Finally, it has recently been described in detail by Mr. Pocklington in a paper on the use of the microscope in pharmacy.||

It is remarkable that this latter sort has hitherto been considered by most authors to be the produce of the *Psychotria emetica*, to the exclusion of the former. Pelletier first, then successively Vogl, Thénot, C. Ménier and Pocklington have referred it to that origin. Professor Balfour,** also, after describing the *Psychotria emetica*, attributed to the root of that species the chemical composition given by Pelletier, which we have seen could only have agreed with that of the "minor" striated ipecacuanha. The more active properties of the "minor" sort, its greater richness in emetine, and also the fact of its having been analysed by Pelletier, have brought it into greater prominence and caused it to be looked upon as the true type of striated ipecacuanha, and consequently the botanical origin generally attributed to striated ipecacuanha has been specially applied to it. In no other way can the general error into which authors have hitherto fallen be explained.

To sum up, there exist two sorts of striated ipecacuanha, of which the following appears to be the synonymy:—

1. "Major" Striated Ipecacuanha. — Roots of *Psychotria emetica*, L.—*Ipécacuanha gris cendré glycyrrhizé*, Lemery (Dict. Drog. Simp. p. 459). *Ipécacuanha strié*, Richard (Thèse Inaug.). *Ipécacuanha strié* (*partim*), Mérat and De Lens (Dict. Mat. Méd. vol. iii. p. 643); Guibourt (Drog. Simp. 6th edit. vol. iii. p. 94). *Ipecacuanha glycyphlœa*, Vogl (Zeits. d. Œstr. Apot.). *Ipécacuanha strié*, G. Durand (Thèse, 19). *Elastic Striated Ipecacuanha*, Attfield (Pharm. Journ. [2] vol. XI. p. 141).

* 'Journal de Pharmacie et de Chimie,' vol. xvii. p. 19.

† 'Dictionnaire des Drogues Simples' (1759), p. 459.

‡ 'Histoire Naturelle des Diverses Espèces d'Ipécacuanha du Commerce' (Thèses de la Faculté de Médecine de Paris, 1820).

§ Dict. de Matière Médicale (1831), vol. iii. p. 643.

|| Guibourt's figures (Hist. Nat. des Drogues Simples, 6th edit. vol. iii. p. 94) agree in part (the two larger specimens) with the "major" striated ipecacuanha, and in part (the specimen placed between the other two) with the "minor."

** Vogl, *loc. cit.* The authors of the 'Jahresbericht der Pharmacognosie,' etc., are wrong in referring this *Ipecacuanha glycyphlœa* to *Cephaelis*. All its characters, exterior and anatomical, agree with those of my "major" striated ipecacuanha.

* Pharm. Journ. [2] vol. XI. p. 141.

§ Pharm. Journ. [2] vol. XI. p. 141.

|| "The Microscope in Pharmacy" (Pharm. Journ. [3] vol. II. p. 921).

** "Remarks on Plants furnishing Varieties of Ipecacuanha" (Pharm. Journ. [3] vol. II. p. 970).

Ipécacuanha strié de la Nouvelle-Grenade, C. Ménier, (Thèse Inaug. p. 15). *Ipécacuanha violet* of commerce, Thénot (Thèse, p. 122); C. Ménier (Thèse, p. 15). *Ipecacuanha of St. Martha* and *Carthagena Ipecacuanha* of commerce.

2. "Minor" Striated Ipecacuanha.—*Ipécacuanha des Côtes d'Or* and *Ipécacuanha noir*, Pelletier (Journ. Pharm. vol. VI. p. 261). *Ipécacuanha strié* and *Ipécacuanha noir* (partim), Mérat and De Lens (Dict. Mat. Méd. vol. iii. p. 643); Guibourt (Drog. Simp. 6th edit. vol. iii. p. 94). *Ipécacuanha strié*, Thénot (Thèse, p. 120). *Ipécacuanha strié*, C. Ménier (Thèse, p. 13). *Ipécacuanha striata seu nigra*, Vogl. (Zeits. Œst. Apot.). *Brittle Striated Ipecacuanha*, Attfield (Pharm. Journ. [2] vol. XI. p. 141).

THE DISTRIBUTION OF ALKALOIDS IN CINCHONA BARKS.*

BY P. CARLES.

The anatomical structure of cinchona barks is one of the points which have most recently attracted the attention of quinologists, who have sought in the aspect of their fracture for an indication of their richness in alkaloids. The characters presented by the various barks are so well established, and are reproduced so regularly, that M. Weddell has been able to attribute all the barks to three principal types.† These facts appear to be well established; but what is much less certain, according to M. Planchon,‡ is the seat of the alkaloids. Upon this point two opinions, diametrically opposed, have been put forth.

"There is," says M. Weddell,§ "one fact well-ascertained; it is that the *Cinchona Calisaya* is the bark richest in quinine, and experience teaches us that the barks which next to *Calisaya* contain most quinine, are precisely those of which the epidermis is removed from the liber by the successive exfoliations of the outer coats, or at least by their junction to the periderm. On the other hand, it is known that the grey cinchonas, which are principally the young barks of other species, contain a much larger proportion of cinchonine than of quinine; this occurs also in old barks that have retained the cellular envelope of their earlier age." The author, therefore, concluded that quinine had by preference its seat in the liber, or, to speak more correctly, in the cellular tissue interposed between the liber fibres. Karsten, in his memoir upon the officinal barks of New Granada, maintains the same opinion.

Wigand also concluded from his observations that the alkaloids of cinchona barks occur in the walls of the liber cells, because those organs have the property of fixing in a remarkable manner the colouring matter of a solution of cochineal. But Müller has pointed out|| that the walls of parenchymatous cells possess the same property in a high degree. Moreover, these walls are so thick that the cavity of the cells themselves is, according to Jussieu,* almost obliterated, and could not, therefore, contain alkaloids. Other circumstances appear to tell in favour of this view of the question. When both surfaces of strychnos bark are touched with nitric acid, it is in the internal or liber part that the acid shows the presence of the alkaloids.† The poisonous alkaloids, morphine, narcotine, strychnine, says Richard,‡ are the product of the cortical cells, being present in the liquid they contain. When young, these cells enclose nutritive juices; later, only air. If, therefore, the analogy were complete with the cinchona barks, the alkaloids would only be found in the younger, that is to say, the innermost fibres. But the foregoing assertions,—if not pure hypotheses,—have the disadvantage of not resting upon direct experiment. One of the first thus to investigate the subject was Mr. Howard,§ who made analyses of barks of *C. lancifolia* and *C. succirubra*, which had been divided into two portions: the one, exterior, consisting of the cellular layer and some cortical fibres; the other, interior, consisting only of the liber layers. From his experiments he arrived at the conclusion that the superficial layers were not only the seat of the quinine, but also contained the largest proportion of both alkaloids.

M. Carl Müller|| has also recorded some experiments upon *C. Calisaya* bark, the parenchyma of which he states contained 9·876 per cent. of quinine, and the liber only 2·462 per cent. The author, however, is inclined to think that M. Müller's mode of operating did not yield the alkaloids in a pure state.

M. Carles, the author of the present paper, in order, if not to decide the question, at least to rest his conclusions upon a wide basis, experimented upon barks of various species. The different layers were separated by means of a knife or a rasp, according to their texture and the thickness of the bark, and each layer was divided into two or three lots. The method adopted was one formerly described by the author.** The quinine was estimated as crystallized sulphate after heating to 100° C.; and the cinchonine and other alkaloids, precipitated from the mother-liquor by ammonia, were weighed after desiccation at the same temperature. In the following tables, showing the results, the designation of the layers is not absolutely anatomically correct, in consequence of the difficulty of separating them; but by cortical parenchyma is meant all the more external layers of the entire bark, and by liber the more internal.

C. Calisaya (fine bark). In 1000 Parts.

	Entire bark.	Cortical parenchyma.	Liber layers
Quinine	20·40	23·40	13·20
Cinchonine	6·40	5·20	4·80

C. Calisaya (thin barks). In 1000 Parts.

	Entire bark.	Cortical parenchyma.	Liber layers.
Quinine	17·70	20·70	14·40
Cinchonine	4·80	4·40	3·60

C. lancifolia (cortical parenchyma, thick and parenchymatous).

In 1000 Parts.

	Entire bark.	Cortical parenchyma.	Intermediate layers.	Liber layers.
Quinine	8·10	24·60	11·10	6.60
Cinchonine	3·60	5·50	4·80	3·20

New Granada Bark (very fibrous, liber abundant).

In 1000 Parts.

	Entire bark.	Cortical parenchyma.	Intermediate layers.	Liber layers.
Quinine	2·01	3·90	traces	none.
Cinchonine	11·20	7·60	8·40	8·00

Bright Red Bark.

In 1000 Parts.

	Entire bark.	Cortical parenchyma.	Intermediate layers.	Liber layers.
Quinine, Cinchonine, Quinidine	20·25	21·60	11·20.	14·80

C. succirubra. In 1000 Parts.

	Entire bark.	Cortical parenchyma	Intermediate layers.	Liber layers.
Total alkaloids	45·40	36·60	23·20	16·40
Quinine (imp.)*	10·60	19·60	12·00	6·40
Cinchonine	34·76	17·00	11·10	10·00

Huanuco Bark. In 1000 Parts.

	Entire bark.	Cortical parenchyma.	Liber layers.
Quinine	traces†	traces	none.
Cinchonine and Cinchonidine	51·40	47·00	45·7

Loxa Bark. In 1000 Parts.

	Entire bark.	Cortical parenchyma.	Liber layers.
Quinine	traces	traces	none.
Cinchonine	2·20	1·40	traces.

These results show that quinine exists in all parts of the bark, but in a much larger proportion in the external than in the liber layers; and analysis of the intermediate layers indicates that the proportion diminishes pretty regularly from the exterior to the interior. The seat of the cinchonine does not however appear to be so well established. If experiments 1, 2, 3, 6, 7, 8 appear to show that, like quinine, it accumulates in the external parts of the bark, experiments 4 and 5 show some indications in favour of the liber layers.

The whole of these results are perfectly in accord with the experiments of Mr. J. E. Howard.

* From the large proportion of cinchonine present in this bark it is very difficult to separate exactly the quinine in the state of sulphate; it being necessary to effect the separation previously by means of washed ether. Now this vehicle carries away together with all the quinine and a little cinchonine, a resinoid matter (quinoidine), which saturates the sulphuric acid, hinders the crystallization of the sulphate, and remains in the mother-liquor. It constitutes about one-third of the products soluble in ether; is precipitated freely by ferrocyanide of potassium, and is not coloured green by chlorine or ammonia. It occurs principally in the external layers.

† It appeared strange not to find quinine in this specimen of cinchona, since authors having spoken of it as containing 5 to 6 parts per 1000. Does the error arise in the separation of the two alkaloids by ether? In every case the cinchonine here noted was partly soluble in washed ether, and showed very feebly some reactions of quinine.

STARCH AND ALBUMEN.*

BY R. ROTHER.

The non-appearance of coagulated albumen, by boiling the percolate obtained in exhausting licorice root which had been previously moistened and heated with a portion of the menstruum, induced the writer to ascribe this effect to the solvent action of starch upon albumen, both of which bodies are normal constituents of the root. But, to obtain more direct and positive evidence, the exigencies of the case required that the pure isolated bodies should be brought in contact under those circumstances in the absence of other extraneous matters of the root that would naturally interfere with or entirely obscure the reaction, consequently the writer employed egg albumen and pure starch.

Pure starch (fifty grains) was mixed with water (one fluid ounce), and the albumen of one egg was diluted with water to three fluid ounces, and strained through muslin. Then after uniting the clear albumen solution with the starch, the mixture was subjected to prolonged boiling; no precipitation however occurred, the liquid having only the opalescent appearance of starch water. The solution filtered quite readily, yielding a clear and transparent filtrate. A drop of strong nitric acid added to this instantly produced a dense gelatinous white coagulum. The solution, when diluted and treated with nitric acid, immediately gave an abundant precipitate of white voluminous flakes, which rapidly deposited, leaving the supernatant liquid clear.

The writer considers that these positive reactions are indubitable evidence that in the presence of starch, albumen is held perfectly in aqueous solution at a boiling temperature, and that only a strong acid can then separate it from such a solution.

LEAD POISONING.†

BY BEVAN LEWIS, M.R.C.S., L.C.R.P.

The manufacture of metallic lead is a process attended by disastrous results to those workmen who neglect, during their employment, those precautions necessary for their safety. Undoubtedly the carbonate is by far the most poisonous salt of lead; yet the fumes which arise round the workmen at the lead works are also extremely deleterious. To illustrate how far these men are exposed to these poisonous influences I cannot do better than rapidly glance at the various processes which the metal undergoes from the condition of rough ore to that of pure lead.

The men more immediately concerned in working the metal belong to four classes—the calciner-men, furnace-men, potmen, and refinery-men. The first of these are occupied in passing the rough ore through its first stage of reduction towards metallic lead. The ore consists of the sulphuret of the metal—the "galena" of commerce, containing usually a large percentage of silver. By the heat of the calciners this argentiferous galena is brought into the condition of sulphate, free oxide of lead, and sulphuric acid; these oxidized products react on the remaining sulphide, producing metallic lead and sulphurous acid. The fumes of sulphurous acid are allowed free exit from the flues into huge culverts which run along the floor beneath the furnaces, branching out to receive the contents of other flues, eventually terminating in a condensing chamber near the stack. Now, it will be observed that during the roasting of the ore the men are perfectly shielded from its fumes, except at intervals of from fifteen to twenty minutes, when the doors are thrown back, and the contents of the furnace well stirred about. During this process of stirring, and still more so on "discharging" the contents of the furnace, huge volumes of the fumes issue from the

* From the 'Pharmacist.'

† From the 'Medical Times and Gazette.'

opening, enveloping all around in a stifling, unhealthy atmosphere, in which the furnace, or calciner-men, are actively employed. The necessity for the use of respirators is undoubted, yet the men wholly disregard this precaution. The rough metal so obtained is now submitted to the furnace, mixed with pieces of old iron, which assist greatly in its reduction from all further impurities; the latter floats in a molten state above the heavier mass of fluid lead, which is now run out into the pots. These pots are huge reservoirs arranged in a long row down the apartment, and in these the lead, by its crystallization, becomes separated from the silver. At this work the potmen are engaged: bathed in perspiration, parched with thirst from their arduous exertions and the heat around, they raise by means of great perforated ladles the crystalline masses of the metal, and, swinging up and down upon the longer arm of the ladle as a lever, effectually shake out all the lead and silver still remaining in a molten state. The crystalline mass is swung round into the pot next to the workman. The same process is repeated here, the lead again passed on to a reservoir still further off, until at the extreme end of the row we may find but half an ounce of silver in a ton of lead; whilst, on the other hand, each successive pot further on is of course poorer in lead, richer in silver, even to the extent of 200 ounces in the ton of lead.

Now as to the hygienic condition of the pot-men. The surface of this molten mass in each huge reservoir is constantly undergoing rapid oxidation. The fumes escaping into the atmosphere around consist almost entirely of oxide of lead. For eight hours a day successively the pot-men are exposed to these fumes—inhaling the poison at every breath, receiving it upon the surface of the skin when in a state particularly favourable to absorption, washing the deposit which must occur upon the lips and tongue into the stomach by the large amount of water which many take to allay their thirst. Such are the ordinary conditions of life to which the pot-men at these smelting works are exposed.

To follow the lead and silver in their further stages will take a brief sketch. The lead, which has been desilverized as above described, is now run into moulds stamped with the proprietor's name, and is ready for the market; whilst the contents of the reservoir so rich in silver are brought into the refinery. Here it is kept at a red heat, and a blast of steam constantly passing over its surface oxidizes the lead, which, being readily fusible, runs off as "litharge" through an aperture in the furnace. The appearance of the interior of this furnace and the formation of litharge must be seen in order that the beauty of the sight may be fully appreciated. The litharge is again reduced into the metallic state, whilst the silver not yet perfectly refined is kept in a molten state in a furnace driven to the intense heat of quite 1873° Fahr. until all impurities are removed, when it is allowed to cool in a mould of calcined bone-ash—the only material known which will answer the purpose, and resist the intense heat of the silver. The formation of this great silver plate at one of our large lead works is the "lion" of the building; and the sea of molten silver once seen is not easily forgotten.

At what expense to the health of the workmen is this interesting process purchased? The exposure to the fumes at the furnaces being only necessitated during the stirring and discharging of the load, the occupation is decidedly less noxious than that in which the pot-men are engaged. A knowledge of this fact evidently has much to do with the hours during which the men are employed; for, whilst the men at the furnaces are on duty for thirty-six hours at a time, the pot-men are divided into three "watches," each of which is occupied for eight hours at a time. The intermittent nature of the duties at the furnaces has the result of securing to the men a far greater immunity from the action of lead on the system than is the case with the pot-men, who, without exception, exhibit every appearance of failing health. They all have a sallow, haggard countenance; the breath is offensive; they complain of a sweet taste in the mouth; their teeth are usually carious in the extreme; often the "blue line" is very evident; their digestive powers are impared; the secretions generally are torpid. With such a state of things as the general rule of their lives—constantly adding day by day to the accumulation of the poison within their bodies,—it may well be supposed that their existence is none of the happiest; constantly handling the metal, inhaling it in a minute state of division into their lungs, swallowing it with every draught of water, bathed in an atmosphere teeming with the fumes of the furnaces and pots, it is indeed not surprising that, unless very strict precautions are taken, they are as likely to suffer from lead-poisoning as are their fellows at the whitelead establishments. The more serious effects of lead result from sheer carelessness on the part of the men; utter want of regard for their personal welfare is the mainspring of these evils; added to which, ignorance of the simplest hygienic principles and total disregard to ordinary cleanliness degrade their moral and physical endowments.

The managers use every expedient which has a protective tendency, and constantly give general directions to the men regarding sanitary measures, which the workmen as constantly neglect—in fact, they all seem to require a severe attack of colic to bring them to be anything like reasonable agents in the matter. The works to which I chiefly allude have an extremely healthy site, in view of the Worm's Head, with the dashing breakers on the Pembrey Sands ozonising the atmosphere; and in such a locality our numerous cases of lead colic would remind us of the lines in 'Lalla Rookh'—

"Full in the sight of Paradise,
Beholding heaven and feeling hell!"

The precautions which should be enforced in these establishments are twofold in nature, and refer to the buildings and the person of the workmen. The apartments should be lofty; perfect ventilation, with a full current of air through the buildings, is absolutely requisite. Each workman, by this means, would secure not only a large cubic volume of air, but the poisonous fumes would be more diluted and more freely conveyed out of the building. The floors should be swept daily, after having been previously damped so as to avoid all dust arising. The men should be directed to use their ladles carefully, so as to disturb the contents of the pots as little as possible. In regard to the person of the workmen more particularly, they should cover themselves with a garment to be used only when at work, and which should be shaken and laid aside as soon as they leave the buildings. Strict cleanliness should be observed in their person—their hands should be washed frequently, and more especially before meals, from the adhering metal. Respirators ought more generally to be worn throughout these establishments, and if they are neglected the mouth should be well rinsed out with water before swallowing their food, or, better still, a gargle of dilute acetic acid or table vinegar might be used with advantage. Even with these precautions the salivary secretion carries a certain amount of lead into the stomach, so it is decidedly advisable that an occasional purge of sulphate of magnesia be taken, as well as the sulphuric acid drink which is used at whitelead-works, and which should be taken two or three times a week. These simple rules, if strenuously adhered to, would render cases of colica pictonum at these works comparatively rare. The buildings here are lofty, allowing of a good current of air, the floors are regularly damped and swept; but, in spite of every persuasion on the part of the managers, the men assiduously neglect the other important items. They often take meals in the same clothing as they work in, frequently avoid washing their hands, and absolutely refuse to wear respirators. One man actually declared he had a great antipathy to these useful little articles, because he feared "the work would get too healthy, and the wages consequently lowered!" It is such ridiculous notions, or else obstinacy of will, which render these workmen blind to their own interests, nor can I see any means of reform amongst them, unles it be the compulsory enforcement of rules, which will eventually prove to them, by incontestable facts, the benefit which managers and workmen will enjoy from their observance.

THE FIFTEENTH REPORT OF THE COMMISSIONERS OF INLAND REVENUE.

This report which relates to the financial year, ending on the 31st March, 1872, contains some interesting and valuable information for those who take pleasure in the commercial progress of the country. It shows that although there was a repeal of assessed taxes, yet the net increase in the income from the Inland Revenue amounted in the year to upwards of four millions—the total sum received being £44,805,895. The Commissioners point out with pardonable pride that upwards of 25,000,000 gallons of spirits were charged with duty, and that the percentage of increase was, in England 8·58, in Scotland 4·89, and in Ireland 7·20. Of the quantities retained in the three countries for consumption, the percentages vary slightly from the above. Thus the increase in England is 6·91 per cent., in Scotland 4·40, and in Ireland 10·30—the total increase in the United Kingdom being 7·08 per cent. Taking the census of 1871 as the basis of the calculation, it is shown that the quantity of spirits actually drunk in the United Kingdom is sufficient for every man, woman, and child to have 0·574 gallon in England; 1·727 in Scotland; and 1·064 gallon in Ireland—the average being 0·781 gallon. The Commissioners direct attention to the fact that with respect to whisky, there has been a great change in public taste. Comparatively speaking, Irish whisky has not been, till recently, a popular beverage; but during the last two or three years it has risen in public estimation, and is now becoming a substitute both for Scotch whisky and brandy. However, as it takes a longer time to mature than Scotch whisky, the revenue authorities have been compelled to provide increased warehouse accommodation; the quantity of whisky in bonded warehouses, at the close of 1871, being over 19 million gallons, as against 11½ millions in 1867.

Before leaving the subject of the spirit duties, the Commissioners state that 1,086,671 gallons of spirits have been methylated—the increase on the year being 84,373 gallons. The increase is considered to be due to the general expansion of trade, and there is no official reason to believe that methylated spirit is used for any other than legitimate purposes. It would appear from the 1144 detections of illicit distillation made during the year, that the heavy duty on spirits of 10*s.* per proof gallon offers a strong inducement to persons to try to evade the duty. This number, however, though large, shows a falling off of over 700 cases; the inference drawn by the Commissioners being that there has been less illicit distillation than for the past twenty years.

Whilst the distillers have been driving such a thriving trade, the malsters have been somewhat less prosperous. In Scotland there was an increase in the quantity of malt made; but in England and Ireland there was such a falling off that the decrease in the year reached 868,382 bushels, or 1·64 per cent. The total quantity of malt charged with duty reached 52,061,010 bushels; and in addition there were 5,336,680 bushels made for distillation and exportation. Of these quantities, it is estimated that 1,740,115 bushels were either exported or used in brewing beer exported on drawback.

From duties the report passes on to licences, and under the head of Establishment Licences (*i.e.* on servants, carriages, horses and mules, horse dealers, armorial bearings, and dogs), it is stated that the amount of revenue collected is more than a million and a half. The licence duty on dogs, although it has been reduced from 12*s.* to 5*s.*, reached for the year 1872 £280,000, as against £231,000, when the licence was fixed at the higher rate.

It appears from the report that 12,854 medicine vendors took out licences, and that the sum paid for the same was £7139.

It may be noticed, in passing, that the amount of revenue yielded from stamps reached £9,739,548, and from taxes £11,680,283. Of this latter, the sum of £9,328,102 was derived from the income-tax.

In the appendix there is a short report from Mr. Phillips, the principal of the Inland Revenue Laboratory, of the work performed in his department during the year. Although the narrative is brief the amount of work performed is very large, the number of samples examined being 12,128; of this number, 2241 were received from the Customs, and 933 from the Board of Trade.

The samples of tobacco examined amounted to 404 in number, and of these 271 were adulterated, the adulterants being rice starch, liquorice, gum, logwood, caramel, sugar and salt of iron.

The amount of adulteration ranged to 4 per cent. rice starch, 44 per cent. liquorice, and 5 per cent. gum. The gum was discovered in tobacco obtained at two manufactories in the north of Ireland; and the novelty of this detection consisted in the fact that manufacturers being aware that tobacco contained gum, appeared to have thought that any kind of gum could be added to tobacco with impunity. Happily, chemistry proved to demonstration that there was a marked difference between the gum found in these two samples of tobacco and that naturally present in all tobacco, and the traders were accordingly fined for this novel evasion of the law.

It appears that during the year 42,656,658 pounds of tobacco were cleared for consumption, and this quantity represents 1 lb. 5½ oz. as being consumed by every man, woman, and child in the United Kingdom. The revenue derived from tobacco amounts to about seven million pounds sterling, and the quantity used is steadily on the increase.

Of 34 samples of snuff examined, 6 were adulterated with umber and lime. 1267 samples of tobacco and 433 samples of snuff were examined for estimation of duty on drawback; and of 15 samples of chicory and coffee examined, 5 were adulterated with roasted biscuit.

Out of 134 samples of beer and materials used in brewing beer, 25 were adulterated with one or other of the following ingredients:—liquorice, caramel, footsugar, grains of paradise, salt, and copperas.

Of 687 samples of malt examined, 89 contained an illegal quantity of ungerminated grain. 6546 samples of beer were tested to determine the original gravity for drawback, and 326 samples of naphtha were examined as to their being of the proper quality and strength for methylating purposes.

The lime and lemon-juice examined for the Board of Trade for the use of the mercantile marine amounted to 761 samples, representing 84,649 gallons; 126 samples, representing 14,208 gallons, were rejected, thus showing that about one-sixth of the juice presented for examination did not reach the fixed standard of strength and purity.

The 356 miscellaneous samples examined include perfumed spirit, methylated spirit, laudanum, and paregoric. It is thus evident that the authorities have a vigilant eye to the detection of the improper use of methylated spirit for medicines for internal use.

This interesting report closes with some observations on the work performed at the Government chemical stations situated at Bristol, Hull, Liverpool, Newhaven, Southampton, Glasgow, Leith, Belfast, Cork, and Dublin, and it appears that the samples examined at these places were about 4000 in number.

The appendix contains other papers of importance, but they are not of sufficient interest to the general public to refer to them in this paper.

The Pharmaceutical Journal.

SATURDAY, FEBRUARY 15, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

THE INLAND REVENUE RETURNS.

BESIDES the numerous matters to which reference is made in the abstract from the Fifteenth Report of the Commissioners of Her Majesty's Inland Revenue which appears on the opposite page, there are one or two other points that are worth noting before they partake of the fate which too often befalls valuable and interesting information contained in "blue books." And, first, we would observe that some of the details given must in one respect disabuse the minds of those who imagine beer is brewed only from malt and bittered with hops. As the law allows brewers to use any substitute for hops which is not a substitute for malt, and at the same time not injurious to health, the report passes over hops in silence. But it is recorded that in the year no less than 29,188,303 lb. of sugar were used by licensed brewers. The quantity is certainly very great; and as it is well known that large quantities of sugar are also used, which the Revenue authorities know nothing about, it must be apparent that the amount of sugar used in the brewing of beer is enormous. Nearly four million pounds of sugar were made in England and charged with duty during the year; however, the greater part of this was made from starch for brewers' use only.

There is a very interesting paper in the report on the mode of charging with duty beet-root sugar made in Belgium. Our readers are doubtless aware that in 1864 this country entered into a convention respecting the sugar duties with France, Belgium, and the Netherlands; and as beet sugar is now made on a considerable scale by Mr. DUNCAN, at Lavenham, in Suffolk, it is necessary that the mode of assessing the duty should be within the terms of the convention. In passing, we may note that whilst Great Britain has but one beet-sugar manufactory, Belgium has 131, France 458, and the Zollverein 284. Why they should flourish on the Continent and not in this country it is difficult to understand, as the climate is favourable to beet cultivation; but of this we may be sure, that if the Lavenham factory be a success, others will soon be started; and thus the agricultural interests of the country may at no distant day be benefited.

The before-named paper shows conclusively that the present method of charging duty on beet juice in Belgium is strongly in favour of the manufacturer, who is able to produce much more refined sugar than the juice is estimated to yield; and he is thus able to pocket the duty on the surplus quantity made, and which is in reality, though indirectly, a bounty from the Government.

This mode of charging duty on the estimated quantity produced, and not on the actual quantity, carries us back to the time when in this country the Government used not to charge a distiller with duty on the actual quantity of spirits produced, but he was simply called on to pay a licence duty according to the size of the still. Of course the distiller took care never to let his still be idle, and the consequence was that the spirit duty was systematically evaded. The Belgians are striving to find a way out of their present difficulties respecting the sugar duties, but class interests appear too strong to allow of the matter being speedily or easily settled; and the amount received for sugar duties is sufficiently small to enable the Belgian Government to bear with patience the present inequalities of the sugar tax, as the duty lost by the present assessment is not so large as to cause the authorities to insist upon an equitable adjustment at any cost.

The Commissioners of Inland Revenue also report they have been surprised to find that a trade in adulterated chicory exists; but this fact need occasion no surprise, for as long as there can be procured such cheap articles as mustard, husks, dog biscuits, roasted rye, locust beans, and other vegetable substances which handily lend themselves to the adulteration of chicory, so long will they be used for that purpose.

CINCHONA CULTIVATION IN INDIA.

MR. J. ELIOT HOWARD, writing to the *Gardeners' Chronicle*, says he has just received letters from Mr. M'IVOR stating that the harvest of Neilgherry bark may now be said to have begun with the year 1873. They are now preparing about 25,000 lb. of bark to be sent home from the Government plantations, as well as a small quantity of renewed bark, the whole being for sale in the London market, and in June or July it is expected that a further supply will be sent home.

Other large importations may be expected from private plantations in the course of this year. So that it appears a fair field for British skill and industry is being opened out in a mountain climate well suited to our race. There is also an equally promising future for this enterprise in the mountain districts of Ceylon and Jamaica.

The number of trees in the Neilgherry plantations of the Indian Government are estimated roughly at rather more than one million, nearly one-half of these being *Cinchona officinalis* and its varieties, the rest *C. succirubra* with a small number of other sorts.

Mr. Howard adds that he has received twenty-three samples of the various kinds of bark under cultivation from Mr. Money. Most of them have an exact resemblance to bark grown in South America, and he considers that they promise well. A novel feature of this consignment, mentioned as presenting a very good appearance, is the bark of a new variety of *C. officinalis* which is said to make extraordinary rapid growth, while it is very hardy and is not injured by wind.

The following remarks, which are taken from a recent number of *Allen's Indian Mail*, are confirmatory of the opinion that the experiment of growing Cinchona in India will prove a successful one financially:—

"The question of growing cinchona at a profit in various parts of India appears to have reached a very promising stage, in spite of the drawbacks incidental to most experiments of the kind. Mr. M'Ivor, Superintendent of the State plantations in Southern India, lately informed his Government that large harvests of the bark might now be reckoned upon, and advised the sending home of not less than 25,000 lb. as a first consignment, to be sold by public auction, with a view to test its quality and market value. It is still open, we believe, to question how often the same trees can be stripped of their bark without injuring the quality of the yield, and many persons predict some kind of deterioration in the trees themselves. Canker also has for some time been at work in several plantations on the Nilgiris and the Sikkim Hills; but its ravages seem to be confined mainly to plantations grown on unkindly soil or in climates more or less unsuitable. The *Darjiling News*, however, speaks with perfect confidence of the results already attained in the Sikkim Hills. It declares that the bark there grown "could be sold with a fair profit at prices which would be ruinous to the producers in any other country where it is cultivated." In South America, where the mere cultivation of the plant costs nothing, the cost of carriage to the sea-coast tends to check the export trade whenever a fall in the market price occurs In India the extent to which Government once carried their experiments in growing Cinchona is said to have frightened a good deal of private enterprise out of the field; but the few speculators who hold on in spite of every hindrance may now expect to "enjoy a golden harvest," after some ten years of anxious waiting. While the private gardens on the Nilgiris show little chance as yet of winning back the sums laid out on them for years past, it is reckoned that the Darjiiling planters will soon be reaping a dividend of 30 per cent. As no return, however, can be expected from a Cinchona garden for the first eight years or so of its existence, none but capitalists are likely to embark in a venture which demands a good deal of ready money combined with a very large stock of human patience."

SPONGE IN ORIGINAL PACKAGES.

The danger of loss resulting from the purchase of sand in original packages of sponge has recently been the subject of a discussion in the correspondence columns of this Journal, and the statements that have been made would appear to lead to the conclusion that, although it might sometimes turn out to be a profitable speculation to buy sponge in that way, the safer plan, especially for small buyers, would be to buy it cleaned from sand. A correspondent has just forwarded to us a further illustration in an *ex parte* statement of his experience in buying sponge in original packages. He says that he was recently induced by a traveller, who showed him a sample, to order a case and to sign a printed agreement to take the sponge in sand as imported at landing weights. A few days after he received an invoice describing the gross weight as 1 cwt. 21 lb., subject to a deduction for tare, draft and sand of 1 qr. 19 lb., leaving a net weight of 3 qr. 2 lb. The following day, the case of sponge arrived, when the carrier's note showed that it had been received in London as 2 qr. 9 lb. gross, or 21 lb. below the net weight given in the invoice, and 2 qr. 12 lb. less than the gross weight given therein. Our correspondent states that he refused to receive the package, and that it now lies at the railway station pending the decision of a London County Court. Without entering into the merits of this particular case, it is evident that a system under which such a proceeding is possible is open to a large amount of fraud, and that the dealings must, in many instances, partake of the nature of a lottery.

THE SALE OF POISONS IN THE SIXTEENTH CENTURY.

"History repeats itself" is a well-worn observation, although probably not entitled to quite so much reverence as is claimed for it by some who quote it. But the following curious letter from Queen Mary to the College of Physicians, requesting them to carry out more efficiently the Act 32 Henry VIII. c. 40, bears a remarkable resemblance to certain more recent documents, and might be fairly cited in support of the theory. We are indebted for the quotation to 'Brabner's Almanack for 1873,' a local almanack published in the Kingsland Road. In the letter the authorities of the College are directed to—

"'Call and convent' before them 'the Wardens the Grocers and all the Apothecaries,' and 'streightly to charge and commande by authoritie that from tyme to tyme hensforthe neither thei nor anye of them do entreprice to sell or retayle any such wares, drugge or druggs as hath in theim any spice of venome or suspicion of poyson, or such other as by receivying of them at the handes of anie unlerned or of anie malitiouse or evyll disposed persons maie by anie means grievously hurte or put in perille or daunger of lief anie of our Subjectes of what estate or degre soever he or thei be, On lesse the seller of any of the said druggs be well assured of the honestie, true dealying, and good intent and skill of the byar; And first examyn the same for what intent or purpose he buyeth the same, and therewithal to note the name of the byar and time of the buying; Or else that the said grocer or apothecarie have with him remaining the handwritting of some discrete, lerned and authorised Physician for his discharge. Willing and streightly commandying the said grocers and apothecaries and every one of them not to faile herof as thei tendre our pleasure, &c., &c. Given under our Signet at our Manor of *St. James* the xxiii daye of *June* in the fourthe and fifthe years of our reignes'" (1557).

In a letter recently received from Baron Liebig he directs attention to the advertisement of a preparation bearing the title of 'Liebig's Invigorative Nervine Essence;" and thinking the association of his name with it likely to impose upon the public, he requests us to state that he is not in any way connected with that preparation.

NORTH BRITISH BRANCH, EDINBURGH.

The third meeting of the present session was held in the Society's rooms, St. Giles Street, on Friday evening, January 31st, at half-past eight; Mr. Gilmore, vice-president, in the absence of Mr. Baildon, president, from indisposition, in the chair. There was a full attendance.

The following is an abstract of an interesting lecture "On Paraffin Oils, with, special Reference to their testing and illuminating Power," by Dr. Stevenson Macadam:—

After referring to the manufacture and rectification of mineral oils, it was stated, that under the Petroleum Act, all mineral oils which evolved inflammable vapour at a temperature less than 100° F. were held to be included under the general term of petroleum, and were subject to certain restrictions as to safe keeping or storage, and sale or exposure for sale. The present plan of testing was in an open vessel surrounded by an outer vessel containing water which is heated by a lamp, and through which the heat is communicated to the inner vessel containing the oil to be examined. The Act provides that the "outer vessel shall be filled with cold, or nearly cold, water;" and that "a small flame shall be applied to the outer vessel." There is a want of precision in the instructions, and hence great irregularities occur in the testing of the same sample of oil by different experimenters. As a general rule, the quicker the oil is heated, the lower the temperature at which sufficient inflammable vapour is given off at one time to take fire or flash when a light is drawn across the surface of the vessel containing the oil; and the more slowly the oil is heated, the higher is the temperature at which the oil flashes, for during the slow heating the oil evolves vapour, little by little, and not sufficient for some time to exhibit the flash when a light is brought near. Another source of difference in the testing is in reference to the *cold* or *nearly cold* water which is required to be in the outer vessel not being rigidly defined, for the instructions might be carried out with water at 32°, 40°, 50°, 60° and even 70° or 80° F. Even the screen which is to surround the apparatus is loosely defined, for it is said "to surround it about two-thirds and to reach several inches above the level of the vessels."

The new testing apparatus which is likely to be introduced during the coming session of Parliament will probably remove all the sources of error. It is covered or is a close vessel, with a small cover which can be removed every now and again for the purpose of drawing the flame across and observing the flash-point. Specific instructions will probably be given as to the temperature of both the water and oil at the commencement of the experiment, and the exact rate of heating, say 2° F. per minute. These precautions will admit of uniformity being obtained in the results of the testing of the same oil by different experimenters.

The illuminating power of paraffin oil was then considered, and the value of mineral oils as sources of light in common or house lamps and in lighthouse lamps was fully discussed. The paper was illustrated throughout by many experiments.

A vote of thanks to the lecturer, proposed by the chairman, seconded by Mr. Young, was carried by acclamation.

Provincial Transactions.

LEEDS CHEMISTS' ASSOCIATION.

The fourth meeting of this society was held in the Clergy-room, Church Institute, on Wednesday, January 22nd; the President, Mr. E. Brown, in the chair.

The minutes of the last meeting having been read and confirmed, Messrs. R. Stevens, W. Denham and Thos. Harpham were elected associates.

The paper of the evening was read by Mr. Thomas Fairley, F.C.S., Consulting Chemist to the Yorkshire Agricultural Society, on "Bone and some of its products," of which the following is an abstract:—

In the lower animals, as the mollusca, oyster, crab, etc., the bone forms the outer protective covering, while in higher animals it is the inner framework. In the case of the skull, spinal column, etc., it also serves as covering for the inner soft parts.

Bone consists of mineral substances, chiefly phosphate and carbonate of lime, and of an organic cartilaginous substance, ossein, which remains when bones are digested in hydrochloric acid, the mineral substances being dissolved by the acid. Ossein is a flexible, comparatively soft substance, forming bone-glue when boiled with water.

The mineral substances remain when bone is burnt in air. In the lower animals carbonate of lime predominates, while in the higher animals we find chiefly the phosphate. In young animals also we find more phosphates than in old.

When bones are heated in close vessels, ammoniacal and oily products distil over, and bone-charcoal is left. The ammoniacal and other products consist of ammonia and its salts, and volatile organic bases, amongst which we find pyridine C_5H_5N, and substances belonging to the same or analogous series. (Exp. showing distillation of bone.)

Bone-charcoal is used for decolorizing sugar syrup, on account of its property of absorbing vegetable colours from their solutions. (Exp. solution of litmus was nearly decolorized by filtration through bone-charcoal.) Its cost requires that the bone-charcoal should be used over and over again. This is effected by re-burning it, by which its properties are restored. After using repeatedly in this manner it becomes clogged, etc., by the lime salts which it also absorbs from the syrup. By treating with dilute acid, these are removed. Hydrochloric acid has been used for this purpose, but it is liable to leave a little chloride of calcium which on burning glazes the charcoal and prevents its action. A recent improvement proposes to use acetic acid. Any acetate of lime then left would form carbonate on burning, which would not interfere.

Bone-ash is valuable as a manure, depending on the phosphate of lime which it contains, and it is our chief source of phosphorus for the manufacture of matches.

It is treated first with sulphuric acid and water when sulphate of lime is separated, and a phosphate rich in phosphoric acid remains. Thus:—

$$\underbrace{Ca_3\,2\,PO_4}_{\text{Bone Ash.}} + \underbrace{2\,H_2SO_4}_{\text{Sulphuric Acid.}} = \underbrace{2\,CaSO_4}_{\text{Sulphate of Lime.}} + \underbrace{CaH_4\,2\,PO_4}_{\text{Acid or Soluble Phosphate of Lime.}}$$

The soluble phosphate is evaporated to dryness, mixed with charcoal and distilled at a white heat. The vapour of the phosphorus is condensed in water.

$$\underbrace{3\,(CaH_4\,2\,PO_4)}_{\text{Soluble phosphate.}} + \underbrace{4\,C}_{\text{Charcoal.}} = \underbrace{Ca_3\,2\,PO_4}_{\text{Bone Ash Regenerated.}} + \underbrace{2\,H_2O}_{\text{Water.}}$$
$$+ \underbrace{4\,CO}_{\text{Carbon Monoxide.}} + \underbrace{4\,P}_{\text{Phosphorus.}}$$

The density of phosphorus vapour is exceptional, and shows that its molecule in the free state instead of being P_2, like most other elements, is P_4. An inference from this is that phosphorus possesses the property of combining with itself in a greater degree than many other elements. Phosphorus like oxygen, carbon, etc., exists in several states. Thus we have red phosphorus quite different from the well-known yellowish, semitransparent, waxlike form of ordinary phosphorus. Now in the case of oxygen, we know that its peculiar form of ozone is produced by a condensation of the atoms into a heavier molecule. Ordinary oxygen has the density 16, and its molecule is O_2. Ozone has the density 24, and its molecule is O_3. The peculiar forms of phosphorus and other elements are probably susceptible of a similar explanation.

Red phosphorus is a brittle, brick-red solid, obtained by heating ordinary phosphorus to 235°–250° C. in carbon dioxide or other inert gas for many hours. A little iodine added greatly quickens the change. (Exp. showing the conversion of ordinary into red phosphorus by heating with a little iodine.) Red phosphorus changes back into the ordinary form when heated above 260°, and does not inflame under that temperature. Hence its use in "safety matches." It is also non-poisonous when purified from any mixture of ordinary phosphorus by washing with bisulphide of carbon, in which the latter is soluble—common phosphorus being exceedingly poisonous.

Phosphorus exists in plants, especially in the seed or in parts such as the bulb of the turnip and other biennials, which are afterwards to supply nutriment for the development of seed. Besides the bone, it exists in the tissues and specially in the brain of animals. Some have associated its presence there with the thinking power of the brain, and others assert its presence wherever animal life in any form is generated. Phosphates are certainly widely diffused, in all rocks, soils, and hence in drinking water; and it has been shown that water, deprived of phosphates, does not develope animal life.

The presence of phosphorus as phosphates is most readily shown by the molydic acid test. Arsenic acid being the only substance which gives similar indications. (Exp. showing the precipitation of the yellow phosphomolydate from a phosphate solution.)

In the absence of iron and alumina, phosphates may be estimated by a standard solution of uranium, which gives a yellow phosphate insoluble in dilute acetic acid. The presence of the slightest excess of uranium salt is shown by the red-brown precipitate which a drop of the solution gives with a drop of prussiate of potash solution placed on a white plate. (Exp. showing the estimation of phosphoric acid in a solution of bone material.)

The estimation of the nitrogen in bone materials is also a problem often occurring. The soda-lime process is that generally used. The weighed finely pounded substance is heated with a mixture of soda and lime, when all the nitrogen is given as ammonia, which is absorbed in an acid bulb apparatus. (Exp. showing the estimation of nitrogen by the soda-lime process, using a test-acid to absorb the ammonia.)

The phosphates in food plants are used by animals, and again restored to plants to be used afresh. At one time this and similar facts in the case of other elements furnished a serious difficulty to believers in the Christian doctrine of the resurrection, but if we remember that the resurrection must be miraculous quite as much as the creation itself, this difficulty disappears. The true scientific spirit consists in doing our duty to the utmost of our ability; in acknowledging that many things are beyond our comprehension; in a sure faith that in due time we shall see all things clearly, and in cultivating the faith and childlike simplicity of the Christian student.

A vote of thanks to the lecturer was proposed by Mr. George Ward, F.C.S., seconded by Mr. S. Taylor, and carried unanimously.

BRISTOL PHARMACEUTICAL ASSOCIATION.

The fourth general meeting of the present session was held at the Museum and Library, Clifton, on the evening of Friday, the 24th of January. The announcement that a lecture on "Musical and Sensitive Flames," experimentally illustrated, would be delivered by Thos. Wills, Esq., F.C.S., of the Royal Institution, London, attracted an attendance which filled the lecture-room to overflowing. The audience included a large number of ladies and several prominent members of the medical profession, and of the literary and scientific world, of the neighbourhood.

The President, Mr. Chas. Townsend, said he had much pleasure in introducing Mr. Thos. Wills, of the Royal Institution, London, who had kindly prepared a lecture upon "Musical and Sensitive Flames." This subject had of late attracted considerable notice in consequence of the interesting researches of Professor Tyndall, but he (the President) believed that it had never before been brought before a scientific audience in Bristol. Mr. Wills had at one time resided in the city, and on that account, also, they were glad to welcome him, and hoped to derive both instruction and pleasure from his address.

Mr. Wills, who was cordially greeted on coming forward, then delivered a lecture on "Musical and Sensitive Flames," of which the following is an abstract:—

"There are some natural facts and phenomena brought to light by scientific inquiry and investigation which, though not occupying an important place in that "Interpretation of Nature" which is called Science, nor, apparently, serving any useful or practical purpose, may, nevertheless, be considered valuable as giving us a glimpse into the inner working, and more subtle influences of nature.

Such facts have already revealed a marvellous susceptibility of matter, when under certain conditions, to the influence of even the weakest forces; the certain conditions, probably, being only necessary so to raise and exalt the effect as to make it perceptible to our somewhat rough senses.

Further, they have shown that the unity—*the oneness*—of nature is traceable, not to any uniformity in its construction, but in reality to the dissimilarity of its various parts, this dissimilarity giving rise to and maintaining the truest form of harmony; this being so, we may, without unduly exercising the imagination, conceive that every atom of the whole universe is influencing and being influenced by every other atom.

These few remarks will find an illustration in the present subject, and will, it is hoped, be a sufficient answer to any who may be inclined to value scientific knowledge only by the direct practical results accruing therefrom, or to limit its scope to those particular branches that bear most fruit to the *commercial* prosperity of mankind.

"Musical Flames" is by no means a new subject, many eminent men having contributed to its history during the greater part of a century. So far as we can make out, the first observations in this direction were made by a Dr. Higgins, of Dublin, in the year 1777, and were mentioned in a letter to the first volume of 'Nicholson's Journal,' published in 1802. Dr. Higgins was a Professor of chemistry, engaged in the tuition of a class of students. While endeavouring, at one of his demonstrations, to show the—at that time—novel experiment of the production of water by the combustion of a "slender stream of hydrogen gas" in air, he inverted over this jet several glass vessels, in order to obtain an effective deposition of water; on doing this with some of the vessels, "several sweet tones were produced;" in fact, almost any vessel, provided it were closed at one end, was found to be capable of giving a musical tone, the only condition, according to Dr. Higgins, being that the vessel should have only one opening; this being fulfilled, the experiments might be repeated.

at pleasure. [The lecturer here placed some glass vessels—bottles, flasks, and closed tubes—over a small jet of burning hydrogen, when the musical tones were immediately produced.]

About 1800, two Italian philosophers, Messrs. Brugnatelli and Pictet, published some experiments upon this subject, and showed that closed vessels were not by any means essential, open tubes with a little care in the manipulation being as successful; to ensure this success, however, they believed that the surrounding vessel or tube must be made of a sonorous or elastic substance, such as glass, earthenware, metal, or dry polished wood; they also further observed the effect of lengthening or shortening the tube, upon the tone produced. [Open tubes of glass, metal, etc., were here placed over the previously used hydrogen flame, when shrill musical notes were emitted; a tube, capable of being lengthened and shortened at pleasure, was also placed over the same flame, when the falling and rising of the note was very evident.]

In 1802, De la Rive published in the *Journal de Physie* some researches upon "The Sounds Produced by Hydrogen Gas in Tubes." This was by far the most elaborate and exhaustive essay upon the subject up to this time, and it contains many new facts, setting forth at the same time a theory which endeavoured to account for the production of these sounds, no explanation having been attempted by either of the previous experimenters. The principal statements in De la Rive's paper were, 1st, it was essential that the tube, or vessel, should be elastic —"suitable for an echo"—capable, that is to say, of reverberation; 2nd, the flame to be obtained from hydrogen gas, all other inflammable bodies being found unsuccessful; 3rd, his conception that the condensation and reformation of aqueous vapour was the origin of the sound vibrations.

All sound of whatever nature is produced by vibration, the body sounding being in a state of rapid motion. In the case of sound that appeals to our sense of hearing as noise, the motion is irregular, and not very rapid. In the case of a musical note, the motion is perfectly regular, periodic, and is also sufficiently rapid. A noise repeated after regular intervals more rapidly than thirty-two times in a second becomes lost or merged in a musical note, the pitch of this note depending upon the rapidity of such vibrations, up to about 40,000 vibrations per second, when most ears lose their power of distinguishing sounds. [These points were well illustrated by the rattling of nails upon a tin tray, and the musical note produced by a vibrating tuning-fork, also by the musical note obtained by the oscillation of a grooved block of hot copper upon the edge of a cold block of lead.]

By De la Rive's supposition these periodic and sufficiently rapid vibrations were set up and maintained by the condensation and rarefaction of aqueous vapour, produced by the combustion of the hydrogen in the air. This theory might possibly have been rejected at once had it not been supported by a most ingenious and favourable experiment. De la Rive was able to succeed in producing a musical note by aqueous vapour alone. Placing a small quantity of water in the bulb of a thermometer tube, and rapidly boiling the water, the steam which was thus formed was unable to issue entirely from the tube, but was to a great extent condensed into drops of water in the stem, whence falling back into the bulb, it became immediately reconverted into steam, this alternation being sufficiently rapid to give rise to a distinct musical note. It was supposed by the author that these primary vibrations were taken up, exalted, and reverberated by the walls of the tube, the final result being quite perceptible to the ear.

The German philosopher Chladni observed in 1802 that the sounds emitted by these "musical flames" were identical with the notes given out by the tubes surrounding the flames when sounded by themselves. He also obtained in one experiment a note and its octave from the same tube.

[A tube being placed in front of the lips, and blown across gave out a certain note which was heard to be identical with the note produced when the same tube was inverted over the burning hydrogen flame.]

Up to this period very little systematic attention had been bestowed upon this subject, but in 1818 Mr. Faraday was requested by some of the members of the Royal Institution to investigate it, and with his invariable care and completeness in work, was speedily able to explain most of the facts hitherto observed in the most satisfactory manner.

De la Rive's theory of aqueous vapour was criticized, and found wanting. Faraday, proving that the tones might be produced as easily, at a temperature far too high to allow aqueous vapour to condense, as at a lower one. Further, he succeeded in obtaining the same sounds from a burning jet of carbonic-oxide, which as it contained no hydrogen was incapable of producing any aqueous vapour whatever. Other inflammable gases and substances were found to yield musical notes, with some little difference of arrangement and care in manipulation; all the inflammable gases—ether, alcohol, and even wax and tallow—being found effective.

The belief held by all previous experimenters that the tube must necessarily be formed of an elastic or sonorous substance was found to be erroneous; tubes of paper, cardboard, and soft wood, answering as perfectly as those of glass or metal.

[A coal gas flame produced these notes as easily as the previously used hydrogen flame, and a sheet of foolscap paper rolled up to form a tube was shown to be effective.]

These experiments enabled Faraday to indicate the true nature of these sounds, which he did by showing that the flame itself was the true origin of the vibrations. When a flame is introduced into a suitable tube, the current of air passing over its surface is sufficiently strong to draw it upwards to such an extent as to sever its connection with the jet; an explosive mixture is at once formed of the air and the issuing gas; this mixture is inflamed, and for a moment the flame and jet become once more united; this action is repeated with sufficient rapidity as eventually to produce a musical note. These vibrations are taken up and exalted to this note, not by the tube, but by the column of air enclosed within it. Faraday called attention to the fact that a similar result to a less extent might be observed in ordinary lamps with chimneys, and in furnaces and fires, burning under tall shafts,—the roar of which was an approach to a musical noise.

[Most of the above points were successfully illustrated as they were mentioned. The vibration of a flame, or its intermittent partial extinction during its song, being strikingly shown by means of its reflection from a rotating mirror on to a white screen, when the flame was quiescent a straight uninterrupted band of light was apparent, but on sounding, this band was broken up into a series of distinct images of the flame, separated from each other by periods of darkness.

Dr. Tyndall commenced his experiments in 1856, and they were published in 1857, but he has frequently returned to the subject since, and by a series of interesting and careful experiments has much elaborated it. Attention was immediately directed by him to the analogy existing between the "Musical Flames" and organ pipes, the two being strictly comparable. In an organ pipe the impinging of a strong current of air issuing from a slit, against a sharp piece of an elastic body called the lip, is the primary cause of vibration; the vibrations thus produced vary in rapidity and in amplitude, but the column of air enclosed by the pipe picks out only those which coincide with its own length, and compels them to vibrate more and more in unison with itself. By this means the result is to strengthen and exalt them to a musical tone. If we now substitute a flame for the first rush of air against the lip of such a pipe, the analogy becomes apparent, the vibrations of the flame being selected by its tube and raised to a note of a definite pitch. Further, an open organ pipe vibrates in two halves when sounding its lowest note, the centre being a node, a place where the air is not in lateral motion, but where its density only is changing, but an open pipe is also capable of vibrating in 4–6–8, etc., divisions, and sounding what are called its harmonics or overtures, in which case the nodes alter their position and number. [This was effectively shown with an organ pipe having three little gas jets at its side, communicating with its interior by means of membranes; on sounding its fundamental note the centre one was extinguished while the two side ones remained burning; on the first harmonic being sounded the two side-jets were extinguished, while the centre one remained alight.] The same result is obtainable with a musical flame, several notes being produced from one tube.

[The connection existing between a sounding, and an exalting or resounding body was here treated of, and by a series of experiments it was shown that a definite relation, depending upon the length of the sound wave, must be maintained between the embouchure of an organ pipe and the column of air enclosed in the pipe,—between a tuning fork and its box or cylinder of air,—also, between a flame and the tube which surrounds it; but in the case of the flame, on account of its great mobility, it was found to be capable sometimes of determining this relation itself, the size of the flame altering the pitch of the note, and being also capable sometimes of even accommodating itself to variously lengthened tubes.]

During Dr. Tyndall's experiments he observed the extreme sensitiveness of a flame on the point of singing to external sound. Just before the point at which a flame would begin to sing in its tube, it stands, as Dr. Tyndall puts it, "on the edge of a precipice" over which any sound in unison with the note it would emit if singing, pushes it, and it at once begins to sound. The external impulse for this effect need not be strong, but it must be in unison, or, at least, so near unison as to produce the effect of musical beats with the flame itself, which is a result of the interference of the sound waves. [A flame was here introduced into a tube and placed in this condition, which, on being sung to from a distance of several yards, or with the back turned, immediately commenced to sound; the note emitted by the flame was D sharp, and it was found to be perfectly indifferent to D natural sounded on a flute, but the D sharp of the same instrument immediately caused it to sing, although the interval between these two notes corresponds to only half a tone.]

Musical flames may be enlarged indefinitely, provided a due relation be kept between the flame and the tube, some very large tubes being caused to sound and giving rise to notes similar to those obtained from 16-feet organ pipes. Considerable credit is due to Count Schaffgotsch, of Berlin, for the independent discovery of some of these effects.

All the flames hitherto experimented with have been enclosed in tubes; some of them have been shown to be very sensitive to certain external sounds, but the general title "Sensitive" Flames has been applied to phenomena more especially connected with unenclosed, or naked flames.

Professor Leconte, of the United States, observed in 1858 the pulsation of two fish-tail gas flames, under the influence of certain musical notes emitted from various instruments, and also observed that these pulsations were not perceptible until the gas flame approached its flaring point, and were further not produced by other external noises. This effect was again observed independently by Mr. Barrett, at the Royal Institution in 1866, who, together with Dr. Tyndall, was able to pursue the experiments to a much greater extent. A jet of gas issuing from almost any orifice becomes sensitive when the pressure is increased to a point just below that at which it would flare; some jets are extremely sensitive to a whistle, dropping down at the sound from a height of about twenty inches to about twelve inches; others are most responsive to a hiss or chirp.

These effects are not the result of the impact of air, which may be easily proved, but depend entirely upon the sonorous vibrations. A gas flame issuing from a jet under pressure is probably thrown into a state of vibration on its passage through the orifice; if this vibration be very pronounced, the flame flares, but just below this point, the flame is sensitive to such vibrations as are synchronous with its own, and which would, if added to those it already possesses, cause it to flare; thus it is seen that a sensitive flame flares only during the continuance of certain sounds, these sounds being equivalent to an increase of pressure. The nature of the sound causing this effect is by no means a matter of indifference; a hiss or chirp is very effective, also the sound of the letter S, the vowels having hardly any effect upon such a flame; shrill notes give a greater result than low ones. If the orifice be very small, and the pressure correspondingly great, extreme and surprising results are obtained.

[A remarkable flame of this kind was exhibited, about twenty inches high; at the sound of a hiss it dropped to half its height, the crumpling of paper, the rustle of a dress, produced the same effect; a musical-box caused it to dance to the tune, and the effect of the ticking of a watch was distinctly seen; further a watch was placed in the focus of one concave mirror and the flame in the focus of a similar mirror, the slight ticking of the watch was thus reflected through a distance of about eight feet, yet its effect upon the flame was distinctly visible.] It was incidently mentioned that many of the so-called facts of spiritualism were not more wonderful than the behaviour of this flame, which, without the key to the explanation, would itself appear almost supernatural.

In conclusion, attention was called to the fact, that flames were not the only things sensitive to slight impulses. The continual observed change produced in nature being, probably, due to infinitesimal movement amongst the molecules of which bodies are composed. This movement—utterly outside the bounds of our perception—being evident to us sometimes, as one of those forces which we recognize as "modes of motion." Innumerable illustrations of this appropriation and exaltation of exceedingly small motion occur. For instance, the growth of plants is dependent mainly upon the power possessed by them of shaking apart the carbonic acid gas present in the air, and of utilizing its carbon in the building up of their tissues and stems. This power is conferred by sunlight and by sunlight alone. The great luxuriance of vegetation almost everywhere, would seem to require the whole power of the sun to be expended in this direction only. But on analysing the sun's rays, we find only a portion of them to be capable of conferring this power; and it has been estimated that at any given time the chemically active portion of these rays present in sunlight only amounts to the $\frac{1}{2300000000}$ of the total energy of the sun given out at that time.

Fermentation, putrefaction, decay, are all due to the presence and growth of the most minute germs of living matter, far beyond the power of the best microscopes to reveal. The "Germ Theory" of disease now gaining ground so rapidly, holds for one of its principal tenets, that the body to contract a contagious disease must be in a certain state of harmony and sympathy with the disturbing cause—like a sensitive singing flame, only susceptible to those vibrations which coincide with its own. Lastly, to take an illustratiom from that profession with which this Association is more intimately connected. It would appear that medicine itself is only availing when the system is in harmony with it, and capable of responding to its counteracting influence.

At the close of the lecture, which was frequently applauded throughout, the President said, "After the hearty reception given to Mr. Wills, it seemed almost needless to present a formal vote of thanks; and yet he felt he should be neglecting his duty if he did not thank Mr. Wills most heartily, on behalf of the Pharmaceutical Association, and the audience, for his most able and interesting lecture. The experiments were not only striking and successful, but many of them were entirely new; and he was glad that Mr. Wills had been favoured by the presence of so appreciative an audience, and amongst them, of so many ladies. It was often difficult to obtain the presence of ladies at scientific lectures, in any number; but he was glad to feel that their interest in science was really awakening; and he hoped the time was not far distant, when that interest would induce them always to be present on such occasions as the present.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The fourth general meeting of the association was held in Anderson's University on 5th February, 1873, at 9 p.m.; Mr. Thos. Davison, president, in the chair.

The minutes of last meeting having been read and approved of, Mr. Alex. Kinninmont brought forward his motion to the effect, "That the subscription fees be reduced, and certain rules of the association be altered." But as it was pointed out that according to the constitution of the association such a motion was out of order, it was left aside to be again taken up at the next annual business meeting.

Mr. J. J. Weir then moved, "That this association instruct their Council to take immediate steps for the formation of such an Assistants' Branch of the Association as is advised by their sub-committee in minute of Conference of date May 20th, 1872."

This was seconded by Mr. J. M. Fairlie, and agreed to.

Mr. Fairlie, then proposed, "That this association instructs Mr. Weir to convene a meeting of the assistants, members of the association, to form an Assistants' Branch, in accordance with his motion."

This was seconded and agreed to.

Mr. J. J. Weir then delivered an interesting and somewhat amusing lecture on "Health."

At the close of the lecture, on the motion of Mr. Fairlie, seconded by Mr. Kinninmont, the lecturer was awarded a hearty vote of thanks.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The half-yearly meeting of the above association was held at the Rooms, Halford Street, on Thursday, Feb. 6th; the president, Mr. S. H. Cadoux, in the chair.

Some preliminary business having been transacted, the honorary secretary, Mr. W. Thirlby, read the following report:—

"In presenting the usual report at the conclusion of their term of office, the committee beg to state what the association has been able to accomplish during the past session. In consequence of the disappointment felt in the previous session at some of the lectures promised not having been delivered, it was found necessary to devote the whole of the meetings to class work. This arrangement has been followed out with the exception of one lecture, which was given by Mr. John Burton. It is hoped that this example will induce others to give the association the benefit of their knowledge. The attendance has been encouraging throughout the term. Forty-five meetings have been held. The average attendance of each class has been as follows:—Materia medica, 13; Dispensing, 11; Chemistry, 10; Botany, 9·5. Two prizes were offered for general proficiency in the subjects taught in the four classes. The first was gained by Mr. Lomas; the second by Mr. Shakespeare. The prizes offered for attendance were obtained by Messrs. J. N. Butler, Mann and Lomas. The preliminary class has been carried on through the kindness of Mr. Walker, and the committee take this opportunity of expressing their appreciation of that gentleman's honorary services. During the session one member has passed the Minor examination, and three have succeeded in the Preliminary. The total number of members has been twenty-nine, viz., fifteen assistants and fourteen apprentices. The library continues to be a source of interest, the books being in constant request. The embryo museum is still in confusion, the valuable specimens of materia medica being nearly useless through the want of a proper cabinet. To meet this want an application has been made to the Pharmaceutical Society for a grant, but up to the present time no definite answer has been received."

The report having been read, a unanimous vote of thanks was accorded to the retiring committee for their past services, special reference being made to the honorary secretary for his assiduous attention to the interests of the society on all occasions.

The names of the gentlemen nominated to serve on the new committee having been read, and Mr. W. B. Clark, vice-president, declining to stand for re-election, the vote of the meeting was taken and the elected members withdrew to choose the officers by ballot, with the following result, Mr. Cadoux persistently declining the honour of re-election as president; Mr. W. Thirlby, A.P.S., President; Mr. S. H. Cadoux, A.P.S., Vice-President; Mr. E. H. Butler, A.P.S., Treasurer; Mr. E. J. Bishop, Hon. Secretary; Messrs. T. W. Elkington, A. Sawden, C. B. Lomas.

It was announced that the classes for the ensuing session would be conducted by the following gentlemen:—Chemistry—Mr. W. P. Clark, P.C.; Botany, Mr. S. H. Cadoux, A.P.S.; Dispensing, Mr. J. J. Harvey; Materia Medica, Mr. C. B. Lomas; Preliminary, Mr. Walker.

BRIGHTON ASSOCIATION OF PHARMACY.

The usual monthly meeting of this association was held at the Hanover Lecture Hall, Church Street, on Friday evening, February 7th; the President, Mr. W. D. Savage, in the chair.

There was a good attendance of members.

A paper "On Water" was read by Mr. W. H. Smith, Dispenser and Teacher of Pharmacy at Sussex County Hospital.

A short discussion ensued, and a hearty vote of thanks to Mr. Smith for his interesting and instructive paper, brought the proceedings to a close.

The gift of books presented to the association by the Executive of the Pharmaceutical Conference, from the Bell and Hills' Fund, were exhibited at the meeting.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, February 6th, 1873; Dr. Williamson, F.R.S., vice-president, in the chair.

After the usual business of the society had terminated, a communication was made by Dr. H. G. Armstrong, "On the Action of Sodium on Aniline."

A paper "On Anthrapurpurine," by Mr. W. H. Perkin was then read by the author. Anthrapurpurine is a colouring matter which accompanies alizarine in the crude "artificial alizarine," now so largely manufactured and employed in dyeing instead of madder. Like alizarine, it is capable of imparting brilliant and fast colours to cloth mordanted with alumina or iron.

The last communication on "Isomerism in the terpene family of hydrocarbons" was also read by the author, Dr. C. R. A. Wright. In it he gives an account of his experiments with oil of nutmegs and oil of orange peel.

The meeting finally adjourned until the 20th instant, when the following papers will be read—"On Aurin" by R. S. Dale and Dr. C. Schorlemmer, F.R.S.; "Researches on the Action of the Copper-Zinc couple on Organic Bodies. I. On Iodide of Ethyl," by Dr. Gladstone and A. Tribe; "Solidification of Nitrous Oxide," by Mr. Wills; "Action of Hydrochloric Acid on Codeine," by Dr. C. R. A. Wright.

ROYAL INSTITUTION OF GREAT BRITAIN.

Friday, January 17th, 1873.

On the Old and New Laboratories at the Royal Institution.

BY WILLIAM SPOTTISWOODE, ESQ., L.L.D., M.A.

A time when, through temporary absence from one chair, and through a change of occupancy of the other, we are deprived of the presence of our two professors, seems to offer an opportunity for reviewing the past history, the scientific results, and the future prospects of our laboratories. A time when, through circumstances which cause us much regret, we are deprived, at our evening meetings at least, of the presence of our secretary, offers perhaps the only occasion when the task of such a review could fall into other hands than his. The fact that it has fallen into mine is attributable to the office in which your votes have placed me, rather than to any individual qualifications of my own; and it would have been impossible for me to undertake the task, had he not placed at my disposal his wide-spread information upon many branches of science, as well as his intimate knowledge of the history of the Institution, to the well-being of which his care and devotion have so largely contributed.

The first dawn of our history is to be sought among those stormy years with which the last century drew towards its close, and out of which many new thoughts and aspirations of men took their birth.

Its character, in accordance with the views of its early promoter, Count Rumford, was at first far more industrial than it eventually became. Its two great objects were "the general diffusion of the knowledge of all new and useful improvements, and teaching the application of scientific discoveries to the improvement of arts and manufactures, and to the increase of domestic comfort and convenience." The Institution was to contain models, or actual specimens of fire-places and kitchen utensils for cottages, farm houses, and large dwellings; a complete laundry for a gentleman's family; grates and chimney-pieces; brewers' boilers; distillers' coppers; ventilators, lime-kilns; steam-boilers; spinning wheels; agricultural implements; bridges, etc. etc.; and at one time some eighteen or twenty young mechanics were actually boarded and lodged in the house. The records of our early proceedings give an instance, illustrating the views of the founders. In January, 1800, when the designs for the theatre, model-room and workshops were formed, the architect proposed that the laboratory should occupy the position which it ultimately held. But with a view to giving more room to the workshops, the proposal was set aside in the very next month, and the space in the basement under the theatre assigned to the purpose. Happily, however, before the building had reached the first floor, this position was found unsuitable; and further consideration devised the laboratory, which we have all known so well as that of Davy, of Faraday and of Tyndall. A staircase leading to it from the front hall, although long since closed, was removed only in 1866, to make room for Tyndall's smoke chamber.

From Count Rumford's final departure from England in 1802 we may date the decline of the industrial element, some echo of which still rings in our motto, "Illustrans commoda vitæ;" and early in the following year a definite proposal to give up that part of the original plan was made.

From a report to the managers in 1803, it appears that, although chemistry had always been a primary object of the Institution, yet from motives of economy nothing more had been done in the way of either laboratory or apparatus than was necessary for the immediate purpose of the lectures. It was consequently proposed that the workshop should be added to the laboratory and fitted with seats for 120 persons, and the forge adapted to chemical purposes. The report ends as follows:—"This laboratory will be equal, or indeed superior, to any in this country, and probably to any on the Continent."

The chemical laboratory was altered in accordance with that report, and remained unchanged until 1863, when, on the appointment of Dr. Frankland to the Professorship of Chemistry, the lecture seats were removed so as to adapt the room more properly to purposes of scientific research.

It is interesting to contrast the verdict of 1873 with that of 1803. "Originally built," to quote Dr. Bence Jones's own words, "as a workshop for blacksmiths, fitted with a forge, and furnished with bellows which only last summer left the Institution, our chemical laboratory was probably the very worst in London."

The physical laboratory remained unchanged; and although Professor Tyndall for himself desired nothing more than to continue his researches in a place which his imagination filled with the recollections of his predecessors, he still acquiesced in the proposal for rebuilding, for the sake of his successors, and in the interest of the sister science of his colleague.

Thus much about the material fabric of our laboratories. Next as to the scientific work of which they have been the birthplace.

Of the great names connected with this building foremost in order of time, and very high in scientific rank, stands that of Dr. Thomas Young. His "Theory of Light and Colours' will always stamp him as one "whose genius has anticipated the progress of science," and whose reputation has risen as men have better understood his worth. His first paper on the subject was presented to the Royal Society in November, 1801; but the earliest printed account of his views is to be found in his 'Syllabus of Lectures at the Royal Institution,' dated January 19th, 1802.

With the criticisms of his theory published in the 'Edinburgh Review,' with the circumstances which led to his withdrawal from the Institution, with his researches in Egyptian hieroglyphics, we are not here concerned. But it is not too much to say of him, that without the Wave Theory of Light (of which he was one of the prime and main founders) to serve as a guiding-thread through the labyrinth of phenomena, the long series of discoveries which have in this place culminated in those of Tyndall in radiation and absorption, would have been impossible.

It is often remarked that little rills, which have threaded their way from distant mountains, ultimately discharge themselves as mighty streams into the sea. Yet between these two stages they flow quietly, but not therefore less usefully, past smiling meadows and the haunts of men. And here is a little scientific pastoral—if it may be so called—flowing out of the highest conceptions of the theory of undulations, and furnishing—to use his own words—a simple instrument "for measuring the diameters of the fibres of different kinds of wool."*

* The King at this time had his flock of merino sheep, and Sir Joseph Banks had the care of them at Kew. On his recovery from his first mental attack the King would only call the P. R. S. his woolstapler.

[The lecturer then described and exhibited on the screen the principle of Dr. Young's eriometer.]

Our next name is that of Davy, an account of whose discoveries would require a volume, and a bare recital of them would be long. I quote the following notes from the pen of our Secretary, and wish that he had been here to give life to the dry bones.

In 1806, when twenty-eight years of age, Davy did the work which formed his first Bakerian lecture, 'On the Chemical Agencies of Electricity.' Six years previously he had written, "Galvanism I have found, by numerous experiments, to be a process purely chemical." In the interim, water had been decomposed by electricity, and Davy began his researches with an inquiry into the changes produced in water by electricity. His main conclusion was that "the kind of polarity of each element determined the electrical and chemical actions shown by it." The French Academy awarded him a medal for this work; and from these discoveries the fame of our laboratories took its rise.

The next year Davy began a new series of experiments on polarity. He exposed different substances to the action of platinum wires coming from a battery of 100 cells; and on October 6th he wrote in his note-book, "Remarkable phenomena with potash." On the 19th he made the following entry:—"A capital experiment proving the decomposition of potash." He worked at the decomposition of other alkalies until the 23rd November, when he was attacked by a fever which proved nearly fatal to him.

The importance of these decompositions to the recent science of spectral analysis, although not dreamt of at the time, can hardly be overrated; and I will therefore venture to interrupt my narrative for a moment by an experiment,—a very well-known one, with a slight modification, which will serve to illustrate the point. [The speaker then exhibited the dark absorption-line of sodium; but so arranged as to show the dark line *in the centre of*, and not entirely obliterating, the bright line; proving that a certain density of vapour is necessary for complete absorption.]

In 1808 Davy began to work on the composition of muriatic acid; and with a new battery, provided for him by subscription, he attacked different substances with increased energy. In 1810 he sent to the Royal Society his researches on oxymuriatic acid and the elements of muriatic acid, on what is in fact now known as chlorine.

In 1811 he made the acquaintance of Mrs. Appreece, and in 1812 wrote to his brother, "In a few weeks I shall be able to return to my habits of study and research. I am going to be married to-morrow, and have a fair prospect of happiness with the most amiable and intellectual woman I have ever known." The issue of these hopes has been written by his biographers; but the disappointment of the last seventeen years of his life is illuminated by the invention, not less original in its conception than benevolent in its object, of the Safety Lamp.

The great value of this contrivance, and of questions arising out of it, will, I trust, be sufficient apology for diverging again from my story in order to mention some very important experiments now in progress by Mr. Galloway. Explosions, it is well known, occur even in cases where the safety lamp is used. And it has been noticed that in these cases they occur most frequently after the firing of a blasting shot in the neighbourhood; and as it was almost certain that the penetration of the fire-damp through the gauze of the lamp was not due to a sudden flow of gas from one part of the mine to another, experiments have been instituted to determine whether the transmission of the sound wave, or wave of compression, may not have been the means of producing the mischief. Through the kindness of Mr. Galloway we have here a tube arranged for making such an experiment. At one end there is the inflammable current enveloping a safety lamp; in the centre is a loose diaphragm, and at the other end a pistol will be fired, by the explosion of which a sound wave will be propagated along the tube. On the arrival of the sound wave at the extremity of the tube, the combustion will penetrate the safety lamp. But I here leave the matter in the hands of Mr. Galloway, of whose experiments we hope to hear more hereafter.

Of the next great name connected with our institution, namely, Michael Faraday, of his life and his discoveries the history has been already written, so far indeed as it can be written, by Bence Jones, by Tyndall, and by Gladstone. "Si monumentum quæris circumspice." These volumes of notes, from 1831 to 1856, will give some idea of the amount of work which he did in our laboratory; and their value will be better appreciated through the consideration that before these notes were made, no less than sixty of his scientific papers had been printed, nine of them in the 'Philosophical Transactions.'

Those of us who were present at Tyndall's two memorable lectures on "Faraday as a Discoverer," are not likely to forget the impression of the man left by them on our minds; and for those who were not present, it would be an office thankless to your lecturer and burdensome to his hearers, to contribute a feeble reproduction of those life-like memoirs. For our present purpose it will be sufficient to say that the entire fabric of those brilliant and manifold contributions to human knowledge were wrought out within the walls of the Royal Institution.

His great experiments have been so often and so well exhibited in this theatre, that some apology is needed for bringing any of them before you again; but in repeating for my own instruction some of those which bear more particularly upon the subject of light, I have been tempted to reproduce one of them here. In doing this I have been perhaps moved more by a fascination of the phenomenon, and by a piece of instrumental good fortune which enables me to introduce an old friend under a new garb, than by any better reason. The experiment in question is that which Faraday called "the magnetization of light, and the illumination of the lines of magnetic force;" we should now term it the rotation of the plane of polarization under the influence of the magnetic field. But in order that we may not even by inadvertence confuse the rotation here produced with that due to quartz, or oil of turpentine, I will draw your attention, by way of memorandum, to the nature of the magnetism produced by spiral currents in given directions, and of the rotations of free currents produced by magnets.

[The lecturer then showed the opposite rotations of two sparks discharged about the two poles respectively of an electro-magnet, and the reversal of those rotations, first by a change of the poles, and secondly by a reversal of the direction of the sparks.]

You now see upon the screen an image of the figures produced by a magnificent piece of heavy glass under the action of polarized light. Its size enables me to make use of about four times the amount of light usually available in this experiment; and I have taken advantage of the figure which its imperfect annealing produces, to vary the effect upon the screen. The dark parts of the figure indicate the parts of the beam in which the vibrations are perpendicular to those transmitted by either polarizer or analyser, and which are consequently cut off. Now if anything should intervene to change the plane of those vibrations a portion of them will be transmitted, and a partial illumination of the screen will ensue. This turning of the plane of vibration is effected by the magnet as soon as its force is developed by the electric current sent through its coils.

[The lecturer then "dispersed" the dark lines of the figure by means of a plate of quartz; and after turning polarizer and analyser so as to colour the centre of the field with the tint intermediate between red and violet (*teinte sensible*), he showed that when the magnet was excited the field was rendered red or green according to the direction of the poles.]

Professor Frankland before coming to us had isolated the compound radicals methyl, ethyl, and amyl, and had proved their resemblance to hydrogen. He had also combined them with the metals zinc, tin, mercury, and boron. By this means he had obtained a very powerful chemical reagent, which proved of eminent service in subsequent operations. An instance of its power will be found in zinc-ethyl, which by its rapid combination with oxygen of the air, bursts into spontaneous combustion as soon as the flask containing it is opened.

In conjunction with Mr. Duppa, Professor Frankland worked in our laboratory at the artificial formation of ethers. They treated acetic ether with iodine and with the iodides of methyl, ethyl, and amyl; and by their means they arrived at a method for the formation of many organic substances which had previously been obtained only through the agency of animals or of vegetables.

In 1866 Dr. Frankland determined by a long series of calorimetric experiments the maximum amount of force capable of being developed by given weights of the different foods commonly used by men.

In the following year he investigated the effect of pressure (up to 20 atmospheres) upon the luminosity of flames of hydrogen and of carbonic oxides. He found that these flames, so feebly luminous at ordinary atmospheric pressure, burn with brilliant light under pressures from 10 to 20 atmospheres, and that the spectra of these brilliant flames is perfectly continuous.

From the latter circumstance he infers that solar light may be derived from glowing gas and not from incandescent solid or liquid matter.

As these researches have so important a bearing upon spectral analysis and solar physics, I will venture to repeat one or two of the experiments. Here are three closed tubes filled respectively with hydrogen, oxygen, and chlorine, at atmospheric pressure. The densities of these substances are in the proportions $1 : 16 : 35\frac{1}{2}$; and if the spark from an induction coil be made to pass through them, the luminosity of the discharge will be found to be nearly in the same proportions.

That this result is really due to the density, and not to the chemical constitution of the gases, may be proved by allowing the discharge to pass through this tube, and by pumping air into it during the discharge. It will then be seen that the brilliancy increases with the pressure.

These researches were suggested by an old experiment of Cavendish's, in which he exploded a mixture of oxygen and hydrogen, first under atmospheric pressure and then under a pressure of from 10 to 12 atmospheres. In the first case there is much noise and little light; in the second, a brilliant flash and no noise. The labours of Dr. Frankland have rendered this experiment intelligible, and have correlated it with other phenomena.

(*To be continued.*)

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

Juries Bill.

On Monday night, February 10, the Attorney-General moved for leave to bring in a Bill to consolidate and amend the law relating to juries. He said that he proposed to introduce the Bill exactly in the shape in which it was left by the labours of the Select Committee which sat last session. That committee sat many days and made many important alterations in the measure. He did not think it would be right for him, without consulting the house, to make any alterations in the Bill as it came from the Select Committee. There were, indeed, several important changes which he desired to effect in it; but, with the permission of the house, he would reserve his statement with reference to them till the second reading.

The motion was agreed to.

Prosecution for the Sale of Laudanum without a Label.

At the Summons Court, Belfast, on Friday, February 7th, Thomas Brennan, grocer, Great George's Street, was summoned by Head-Constable Irwin for having sold, within the last six months, a quantity of opium to one Edward Harkley without having the bottle containing the commodity distinctly labelled with the name of the article and the word "poison."

Mr. M'Lean, jun., prosecuted, and Mr. Sheals appeared for the defendant.

Mr. M'Lean stated the sections of the Act of Parliament under which the prosecution was brought. The defendant had sold a quantity of laudanum in a bottle without complying with the requirements of the Act. A child had died in the General Hospital from the effects of taking that poison, and the defendant had admitted that he had sold the article without having labelled the bottle. He did not press for a heavy penalty, as this was the first case of the sort, but he wished to prevent another infringement of the law.

Head-Constable Irwin remarked that the Coroner had said that grocers should scarcely be allowed to sell such commodities at all.

Dr. M'Gee (who was on the Bench) said the matter was taken up at one time by the Apothecaries' Society in Dublin.

Mr. M'Lean: It is not a proper commodity for a grocer's shop at all.

Mr. Sheals said he submitted his client had sold the laudanum without labelling the bottle which contained it, but it was through ignorance of the law, and he had gone before the Coroner and candidly admitted that he had sold the laudanum. He hoped that the case would be a warning to others not to sell these poisonous ingredients without complying with the law. He would ask their worships to inflict but a mitigated penalty.

Dr. M'Gee (to Mr. M'Lean): Do you press for a high penalty.

Mr. M'Lean: No, your worship; but I want a fine inflicted as a precedent.

Dr. M'Gee: I will impose a fine of 10*s.* and costs, and I hope it will deter others from infringing the law. The fine was paid.

Adulteration of Milk.

At the same sitting of the above Court three cases were heard, where milk sellers were charged with having sold adulterated sweet milk. In one case, in which Dr. Hodges deposed that the specimen contained 13 per cent. of water and but 11 per cent. of solids, and nothing prejudicial to health, it was demanded that a sample should be produced in Court, and the hearing was adjourned for that purpose. In another case, where the certificate of Dr. Hodges stated that the sample contained 22 per cent. of water, but did not give the percentage of solids, or state whether it contained anything injurious to health, it was objected that the certificate did not give sufficiently full details. The objection was allowed and the case dismissed. It was stated that as a result of the prosecutions it was difficult to get farmers to send milk to Belfast.

Robbery by an Assistant.

At Worship Street Police-court, on Tuesday, Feb. 4, Jonathan Kitchen, 36, described as a chemist's assistant, living in How Street, Kingsland Road, was charged before Mr. Bushby with having stolen a quantity of spirits of wine and other things, the property of his employers, Messrs. Charles Bewlay and Son, surgeons, of 174, Kingsland Road.

It appeared from the evidence of Mr. Bewlay, jun., that the prisoner had only recently been engaged as shop assistant, and on Saturday, about two days after he had commenced his duties, a quantity of spirits of wine was given into his care. On Monday when it was wanted it was gone, and the prisoner in explanation said that he had made eau-de-cologne of it. The explanation was accepted, and nothing more was thought of it at the time. Later in the day, however, the prosecutor having left his purse on a table, the prisoner was seen by the shop boy to take some stamps from it and put them into his own pocket. The prosecutor then made inquiries, and found that no eau-de-cologne had been made with the spirits of wine. The prisoner, too, had made false entries in the books, and other drugs were missing. His defence now was, that if drinking the spirits of wine was stealing, he was guilty.

The prosecutor recommended the prisoner to mercy, and Mr. Bushby sentenced him to three months' imprisonment, with hard labour.

Poisoning by Carbolic Acid.

An inquest has been held at the Central London District Schools, Hanwell, upon the body of a lad named John Winter, who was poisoned through drinking carbolic acid from a bottle placed in a cupboard in No. 6 ward. It appeared from the evidence that one of the nurses in No. 6 ward, had in her possession several ounces of the poison for the purpose of cleaning the closets. She placed the bottle in a cupboard where she usually kept her food, leaving the door unlocked. She stated that she had frequently known the lads to take her victuals from the cupboard and go away and eat the food. The deceased is supposed to have reached the cupboard by the aid of a chair, and to have drunk some of the poison in ignorance of its deleterious qualities. He was found insensible upon the floor, half way between his bed and the cupboard. The doctor was sent for, but the lad died in a few hours. The jury, after some consultation, returned a verdict of "accidentally poisoned," adding that for the future more care should be exercised by the nurses in the use of poisons, and that the rules of the establishment should be strictly complied with.

Death from an Overdose of Laudanum.

The death of Dr. Curran, of Wadebridge, from an overdose of laudanum, is reported in the *Western Daily Mercury*. It appears that on the evening of Tuesday, February 4th, the deceased gentleman requested his attendant to fetch him from the surgery the bottle containing laudanum. He then poured some into a wine-glass, and drank it, remarking that he felt it necessary to take a sleeping draught. Afterwards he poured into the glass another smaller quantity, and drank it, remarking that he thought the first was not sufficient to effect the purpose he desired. Soon afterwards he complained of being unwell, and said he feared he had taken too much. Medical assistance was immediately procured, but the unfortunate sufferer gradually sank, and expired at four o'clock the next morning.

Death from an Overdose of Hydrate of Chloral

On Tuesday, February 4th, Mr. Clarke Aspinall, the borough Coroner, held an inquest on the body of John Richards (34), a chemist, at 41, Paradise Street. The deceased had for the last six years complained of his heart, and had for some time been taking hydrate of chloral to make him sleep. He took a dose on Tuesday night, and between eleven and twelve o'clock, as he was sitting smoking in his chair, his pipe fell from his hand. He became insensible, and before a doctor could arrive he was dead. The doctor was of opinion that death resulted from an overdose of hydrate of chloral, and the jury returned a verdict accordingly.—*Liverpool Daily Courier.*

Obituary.

Notice has been received of the death of the following:—

On the 21st December, 1872, Mr. Peter McCrackan, Chemist and Druggist, of Vauxhall Road, Liverpool, aged thirty.

On the 5th February, 1873, Mr. John Watkins, Chemist and Druggist, of Globe Road, Mile End, aged sixty-eight. Mr. Watkins was elected an annuitant on the Benevolent Fund in October, 1871.

On the 7th February, 1873, Mr. George Stevenson, Chemist and Druggist, of Burnley, Lancashire, aged fifty-one.

Reviews.

Year-Book of Pharmacy and Transactions of the British Pharmaceutical Conference. London. 1872.

A Year-Book of Therapeutics, Pharmacy and Allied Sciences. Edited by Horatio C. Wood, jun., M.D. New York. 1872.

Once more a handsome volume containing an abstract of the Pharmaceutical progress during the past twelve months from July '71 to June '72 has been presented to the members of the British Pharmaceutical Conference. It is divided as usual into two distinct divisions; the first portion of four hundred pages being devoted to the Year Book proper; and the remainder to the Transactions of the Ninth Annual Meeting held at Brighton.

Its compilation is highly to the credit of the editor Mr. Charles H. Wood, though he apparently labours under the impression that he is required to produce so large a quantity of matter. If this assumption be correct we strongly suggest to the Committee of Publication to be content with one hundred pages less. If well digested abstracts are provided of communications or discoveries of importance the readers would, we think, have reason to be better satisfied—as it is, whole passages which are in every one's hands and may be consulted with facility are necessarily reprinted. A well digested record, the main facts of which are clearly arranged and conscientiously reported, would prove of the utmost value, and the editor with restricted space would be able to concentrate his energies on his very difficult task.

We are also decidedly of opinion that his editorial duties might be lightened. No one man can possibly know everything. A Pharmacist skilful to the last point in Materia Medica cannot be expected to give us the last best résumé of modern chemistry; neither could an accomplished Chemist offer to his readers a digest of current Botanical investigations such as might be rendered by a Professor of that science. Why cannot certain members of our Conference furnish reports on those subjects with which they are intimately connected, and thus with little trouble to themselves and with great gain as far as others are concerned, increase beyond measure the interest of publications such as the one just now before us. So while we regret the large infusion of republished microscopical characters, and other notices of similar description, we turn with unmixed satisfaction to Mr. Wood's own work. The introduction is beyond praise—it recounts concisely the various novelties that have recently appeared. Abstaining from either censure or approval, it puts the reader in full possession of memorabilia—such as Condurango, Xylol, Guaiacol (Mr. Williams' preparation); the applications of Oleic Acid; the therapeutic uses of Sulphovinate of Sodium; Chloral and its modification; Crotonic Chloral; Glycerine and Aconitia. In our humble opinion the Introduction is the most scholarly portion of the book. The chief points treated of throughout are Materia Medica, Pharmaceutical Chemistry, and Pharmacy, concluding with Sundry Notes and Formulæ. The Materia Medica is arranged in sections under the various Natural Orders without reference to alphabetical system. A strong feature of the volume is the portion allotted to Pharmaceutical Chemistry—but our warmest commendation must be bestowed on the translations from foreign authors and on the numerous abstracts of their investigations.

In the department of Pharmacy we are overwhelmed with American suggestions—good probably, but we can hold our own; though there is a feeling of distress, that we ourselves seem to have contributed so little to advance the trade-science by which we get a living.

'The New York Year Book of Therapeutics and Pharmacy' is a totally different publication. It is devoted to Therapeutics, Materia Medica, Toxicology, Prescriptions and Formulas, and General Receipts, and is mainly a collected reprint of such articles appearing in various Medical and Scientific Journals that have been deemed worthy of notice and preservation. As already suggested to some extent in reference to the Conference Year Book, we are in doubt as to the usefulness of this class of literature. Those who are really interested, have the documents here republished in their possession—those who read simply for trade purposes are not thankful for treatises in extenso.

As regards ourselves and our own particular Year Book, we cannot but think that a short well-written epitome of things and doings Pharmaceutical, would be infinitely more acceptable than the products of the modern mania for presenting a big book as a sort of tangible equivalent for the money paid by subscribers and the benefits derived by association. Meanwhile on one point we shall all be unanimous. Mr. Wood has admirably succeeded in his Editorial capacity, while to Professor Attfield there is due no small credit for the accurate manner in which he has presented the Transactions of the British Pharmaceutical Conference.

Healthy Houses: A Handbook to the History, Defects and Remedies of Drainage, Ventilation, Warming and Kindred Subjects. By William Eassie, C.E., F.L.S., F.G.S. London: Simpkin, Marshall and Co.

The question of constructing houses on more correct sanitary principles has long commanded the attention of medical and scientific men. It is, however, deplorable to find that the public and the individual householder are still but ill informed on all that pertains to healthy houses and healthy towns. The avowed object of the little book now under our notice, is to provide a record of facts, to give the result of acquired experience, and a *résumé* of published inventions relating to house construction. Our homes are too frequently badly built, and situated on unwholesome soil. The drains are often ill-constructed, and the rooms are either insufficiently ventilated or continually swept by uncomfortable draughts of cold air, while poisons lurk underneath the basement and flow around the drawing-room and library. The consequence is that a man's house is too often his greatest enemy, and not until fever runs riot within the walls do many persons become aware of the dangers to which they have possibly for years been exposed.

As a manual for householders and a text-book for builders we know of no work equal to this of Mr. Eassie, whose wide experience at home and abroad has peculiarly fitted him for writing it. In it are described and illustrated all the various forms of tile used in drainage; the latest improvements in ventilation are intelligibly discussed; the modern systems of warming are commented upon; in fact everything from basement to roof that relates to sanitation or the comfort of the inmates of a house in town or country is treated in a popular and at the same time scientific manner. The book exhibits much research; every page contains either valuable information or some novel suggestion. The numerous patent devices in filters, and the use and abuse of disinfectants, also come within the writer's range; and a useful novelty in works of this class is the introduction of the names of vendors of sanitary articles of all description, and the prices at which they can be bought. We cannot enter into any detailed criticism of a book embracing such a vast variety of subjects. The author in concluding his work says, "I have endeavoured on all questions pertaining to my subject to give the best information and the results of the most recent inquiries. My object has been to write a popular treatise which shall embrace all the sanitary requirements of a modern habitation, and to offer the result of my labours in this direction in a work at a price within the reach of every one." We congratulate Mr. Eassie on his labours, and confidently recommend his book to our readers. As far as the price of the book is concerned, we certainly may be allowed to say that it is marvellously cheap, and within the reach of every one. It is a volume of 224 pages, with upwards of 300 illustrations, and the cost only one shilling!

Notes and Queries.

[330.]—"CURIOSITIES IN DISPENSING."—A correspondent forwards the following copy of a prescription which he thinks deserves a place among the curiosities:—

℞	Infus. Ergotæ ad	℥ vj.
	Quinæ Sulph.	gr. xv.
	Acid. Sulph. Dil.	ʒ j.
	Tr. Cinchon. Co.	
	Syrup. Aurant. aa	℥ vj.!!
	Aq. ad.	℥ viij.

Mft. mist.

He says it bears the stamp of a respectable chemist. He would esteem it a favour if some of our pharmaceutical *savants* would say how they would dispense it. The sign for 6 oz. of Tr. Cinchon. and Syr. Aurant. is unmistakable.

[329.]—LIQ. AMMONIAT. VALERIANÆ.—A prescription has been presented containing Liq. Ammoniat. Valerianæ ℥ ij. May I ask if such a preparation is recognised by any authority? A caution was enjoined that it was not to be the brown but a white milky kind of mixture, to be produced by the ammonia. Nevertheless we dispensed tinct. valer. am., and trusted it would produce the desired effect.—J. W.

STYPTIC COTTON.—Dr. Rohland describes (*New York Medical Record*) a styptic cotton for arresting passive hæmorrhage from extensive surfaces. It is prepared by boiling the cotton in a solution of alum and gum benzoin; the cotton is then dried and picked, and afterwards saturated with solution of perchloride of iron.

APPOINTMENT.

Mr. W. T. Crew has been appointed dispenser to the Chorlton-upon-Medlock Dispensary, Manchester, vice Orton, A.P.S. etc., resigned.

VACANCY.

A Resident Dispenser and Secretary is required for the Horton Infirmary, Banbury, to enter on his duties the first week in April. For particulars see Advertising Sheet, p. 18.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

Percolation.

Sir,—The prominent position and the sharp criticism of Mr. Saunders' communication from America, in your Journal of February 1st, compel me to say a few words in reply.

I may state at once that leaving such words as *surprise, sweeping, clumsy,* etc., out of consideration, I feel rather flattered than otherwise by Mr. Saunders. The principal feature in my paper on percolation consisted in the recommendation of certain concentrated solutions to serve for the preparation of proof tinctures, wines, etc., and I feel pleased to hear that in America "*many fluid extracts in use are made practically in the manner suggested by Mr. Schweitzer.*" I have no desire to discuss in your paper mere matters of opinion between Mr. Saunders and myself. It is evident that the American way to arrive at a conclusion is different from ours; Mr. Saunders finds, for instance, "*that pressure has nothing to do with the solvent power of the liquid, and, in some instances, acts injuriously by causing the operation to go on more rapidly than is advisable.*" To us here this looks like proving a nigger to be white because he is so very black. Mr. Saunders also thinks that the subject of percolation is almost overdone and exhausted, but "*hardly used amongst druggists as the great advantages it offers demand.*" I feel grateful for new information, though not quite new in this instance, for Professor Markoe, of Boston, speaking at Philadelphia, is stated to have said, Pharmaceutical Journal, January 25th, page 594, "*Percolation, which is so well understood and so indispensable in the United States, is little known and practised in England.*" It is wonderful how these American professors obtain information! I have lived twenty years in England; practised the process all this time; have learned a great deal from other English pharmacists; know a great many who use the process daily, and never was aware of that deplorable state of affairs until discovered by Professor Markoe in his seven days' stay in England. I always thought we knew a little about percolation, just enough for our purpose, and something to spare, and that we did not neglect it by any means. How excessively grateful we ought to feel to these Transatlantic visitors! Mr. Saunders is unfortunate in those instances where he feels wrath against me, and works himself into an unnecessary rage by misunderstanding me. If Mr. Saunders has to percolate quantities where, instead of adding the menstruum by the ounce from a little glass vessel, he has to pour it from a one or two gallon measure, he will find the addition of a layer of glass stoppers over his blotting-paper anything but a clumsy expedient; and should Mr. Saunders ever prepare purified extract of liquorice I may tell him that no process is better than percolation, and placing layers of solazzi juice between layers of whole straw; while in making tinctura opii from fifty pounds or more of powdered opium or extractum ergotæ liquidum from over twenty pounds of finely powdered ergot, he will find some admixture absolutely necessary, and the residue of extract of opium and rye chaff better than anything else.

But I suppose my reply ought not to occupy more room in your Journal, besides, I think I have sufficiently proved that there are occasions when the introduction of a *little chaff* is the most handy thing for finishing percolation.

J. Schweitzer.

Tinctures and Percolation.

Sir,—I was present at the Brighton Conference and heard Mr. Stoddart's paper on Tinctures read and the arguments that followed, which very much interested, in fact, almost converted me from a very firm faith in the process of maceration and the use of a very powerful press. As the omission of the process of packing made it more likely that a uniform result would be attained, I determined to try an experiment. I therefore proceeded as follows to make a gallon of essence of vanilla with an ordinary tin percolating coffee-pot as the sole apparatus. The pods were bruised in a mortar with an equal bulk of fine sand, and well wetted with the menstruum; a piece of filtering paper having been placed over the bottom of the percolator, and secured by some fine muslin, the marc and menstruum were then transferred to the percolator, and the remainder of the menstruum gradually passed through the marc. The result was most gratifying; I have shown the product to many of my friends, and they agree with me that it is the finest sample of essence of vanilla they have seen for some time. I may observe, that by thus percolating I have obtained one-third more in quantity of a superior essence to that I have procured by the ordinary macerating process. I continued passing the menstruum through the marc till I found it was totally exhausted.

I quite agree with Mr. Saunders in his deductions in his paper on "Percolation," concerning the chaff and glass stoppers, and the proposed concentrated tinctures; but I should like to ventilate another notion, that of using the ordinary extract. What objection can there be to making tinctures from extracts of belladonna, hyoscyamus, gentian, nux vomica? The extracts are prepared in the most approved ways according to the latest scientific knowledge, for obtaining the active principles of the various roots and drugs. Thus, for instance, I have prepared for a medical man, Tinct. Belladonnæ in this way:—

Ext. Belladonnæ,
Spt. Tenuior. ℥j.
Macerate 24 hours and then filter.

The product resembles ordinary B. P. tinct. of belladonna exactly, and in action answers all the purpose. The mode of calculation was to take the doses of the extract and the tincture, and use the corresponding quantity of extract. I should always prefer and use in my business the tinctures as ordered in the B. P.; at the same time I should like this idea to be ventilated, and find out by collating the experience of others, what objections there may be to this process. One can fancy how exceedingly convenient it would be in a country place to feel at liberty to extemporize tinctures in this way.

T. Haffenden.

Brighton.

Milk Testing.

Sir,—Will you kindly permit me to make a brief reply to Mr. Bottle's letter on this subject in your last week's issue. It will, I hope, be clearly understood that in suggesting the volumetric estimation of the sugar which it contains as a convenient test for the quality of milk, I was quite unaware that the method had been published in the Journal nearly a quarter of a century ago. It is well known that scientific discoveries have been occasionally ushered into public notice by more sponsors than one; and in the more humble field in which I aspire to be a worker—the application of known principles to new uses—instances of this are still more frequent.

An apposite illustration is furnished on the page partially occupied by Mr. Bottle's letter, in Professor Redwood's statement of the preparations proposed for admission into the Pharmacopœia.

The employment of acetic acid to obtain an efficient and permanent solution of the active principle of ipecacuanha is there credited to Dr. Dyce Duckworth and Mr. Carteighe, whereas a reference to the paper read by the former gentleman at the evening meeting, March 6th, 1872, will show that the merit of the suggestion is rightfully due to Mr. G. Johnson, of Birmingham, who urged it on the notice of pharmaceutists as long ago as November, 1860; and my own earliest contribution to the Journal, April, 1867, was the formula for a syrup of ipecacuanha prepared as syrup of squills, which I still make and find satisfactory.

I am indebted to Mr. Bottle for pointing out an error in your quotation from my letter, on page 482; since a reference to Attfield will at once show that ·5, not 5 grains of lactose are equivalent to 100 grains of the copper solution; but I can scarcely admit that the question of the reducing power of sugar of milk is finally disposed of by that gentleman's *ex cathedrâ* assertion. Such a point can only be settled by careful experiment, and I can only assure Mr. Bottle that, in the full persuasion that I was entering upon a path hitherto untrodden, I scrupulously tested the strength of the solution employed with a definite weight of pure and dry sugar of milk.

Mr. G. Brownen, on p. 501, and Mr. Ekin on p. 560, both speak from actual experience of this method of testing milk, and they will, no doubt, gladly corroborate, or, if need be, correct, my assumption that lactose equals cane sugar in its reducing power over cupric salts.

J. Fred. Brown.

4, *Market Square, Dover, February* 9*th*, 1873.

THE PRELIMINARY EXAMINATION.

Sir,—We are informed through the reported discussion of proposed bye-laws that there is a general impression the Preliminary examinations as conducted "in the country," are so unsatisfactory that it is desirable to abolish the arrangement.

I will not enlarge on the question beyond saying that I feel personally insulted, and unless the two gentlemen making the statement can qualify or explain it, I would suggest that the local secretaries for the future decline the duty.

John Whitfield, F.C.S., Local Secretary.

Scarborough.

PHARMACEUTICAL WOMEN.

Sir,—In the report of the Council Meeting on the 5th, I find that on the motion that three ladies be elected apprentices or students of the Society, Mr. Sandford moved an "amendment" that those three ladies "be not elected apprentices or students of the Society." I should be glad to know what constituted this proposition an amendment. It appears to me a simple negative of the original proposition which should have been rejected by the President as an amendment, which ought to introduce some condition which would not be decided by a simple vote upon the motion before the meeting.

Henry H. Pollard.

140, *High Street, Ryde, I. W.*
February 10*th*, 1873.

THE NEW BYE-LAW.

Sir,—You would greatly oblige by allowing me through the medium of your columns to ask your readers to *erase* the words "*of the Society*" from the form proposed by me in my communication to the Council upon the new Bye-law, and published in this week's Journal, on page 636. By so doing it will read correctly according to my suggestion, one of the main objects of my letter to the Council having been to point out the error in the use of those three words.

Edwin B. Vizer.

63, *Lupus Street, Belgravia South, February* 8*th*, 1873.

SPIRITUALISM *v.* RHEUMATICS.

Sir,—There has been a great deal of talk of late about spiritualism, and people have wondered what good it was going to do.

It seems at last poor suffering humanity is going to reap a benefit from it in a form little expected. The other day a customer of mine was commissioned by a member of the spiritual community, to obtain some drugs for the preparation of a recipe which had been revealed from the Spirit-land, to cure rheumatics. I was very anxious to get a look at this prescription, but it was so jealously guarded that they had even taken the precaution of getting only part of the ingredients at one shop. The customer informed me they were all vegetable preparations, as *they* believed in herbs. I suppose he meant the spirit, but whether from actual experience of their beneficial results or only from observation, I was unable to learn. Perhaps some of your readers can throw some further light on the subject of spiritual pharmacy.

A Chemist.

J. McKnight.—You will find formulæ in the present series of the Pharm. Journ., vol. I. p. 1042.

W. C. W.—A recipe for "Peppermint Cordial" was given in vol. I. of present series, p. 497.

"*Cecil.*"—Ethyl is the radical of the alcohol series of compounds, and methyl the radical of the wood spirit series. You will find a description of them in Attfield's 'Chemistry' or any elementary work on the same subject.

"*A Working Country Chemist.*"—If you will state definitely your difficulty we will endeavour to remove it.

W. Wood.—(1) Youatt 'On the Horse.' (2) Blaine's 'Veterinary Art.'

R. Emment Charles.—Clause 16 of the Pharmacy Act, 1868, provides that nothing "thereinbefore contained" shall extend to or interfere with the dealing in patent medicines; but clause 17 declares it to be unlawful to sell any poison—either wholesale or retail—unless the box, bottle, vessel, wrapper, or cover in which such poison is contained be distinctly labelled with the name and address of the seller of the poison, and unless the further regulations applying to poisons in the first part of the Schedule A are complied with. At the end of this clause certain exemptions are specified, but patent medicines are not among them; and accordingly, to our apprehension, the provisions apply to such patent medicines as contain poisons belonging to the first part of Schedule A. This subject has already been incidentally mentioned on several occasions, and we may refer to an article in the Journal, vol. II. p. 975.

Messrs. Kay Brothers' communication has been received and the enclosure handed to the Secretary. We are sorry we cannot comply with their request.

A. H. Mason.—We are obliged for the communication.

J. W. Watson.—Apply to Messrs. Butler and M'Culloch, Covent Garden.

"*Tolu.*"—"Cough Lozenges" have been exempted from the provisions of the Act, but probably the recommendation for "relieving hoarseness, bronchitis, asthma," etc., might place them outside the exemption. It would be better, therefore, to communicate with the Inland Revenue authorities and ask their permission to use the label.

M. M. B.—The section on "Physics" in Fownes's work, if thoroughly mastered, will be amply sufficient for the purpose you mention.

"*Pilosus.*"—*Verbascum Thapsus*, Linn., or the Great Mullein.

"*Inquirer.*"—No. Red oxide of Mercury and Ammoniated Mercury are included in the Schedule of Poisons, and it is unlawful for any one to sell them unless he be a pharmaceutical chemist or a chemist and druggist within the meaning of the Pharmacy Act, 1868, and unless he be registered under that Act.

J. S. W.—We are unable to read the name of the article to which your question refers.

Mr. Joseph Leay.—The insertion of your letter would give rise to much angry correspondence, so we prefer not to publish it.

T. F. J.—The Minor examination is conducted entirely *vivâ voce*. According to the published Regulations of the Board of Examiners, which may be had on application to the Secretary, it appears to be not so much the ability to repeat from memory a description of the characteristics of various plants and drugs as to practically apply such knowledge in the recognition of plants and drugs that is required. The arrangement of marks is a matter arranged by the examiners only, but we believe that a certain amount of proficiency is required in each subject.

L. S. A.—Globules of mercury would generally be visible on making such a mass as you mention; the smaller globules have a tendency to aggregate on "working," into a firm pill mass. It shows much of the mercury in the grey powder to be in the metallic state, as it ought to be, and not much oxidised.

T. B. (Lynn).—We believe that a label for "Cough Lozenges" and similar preparations may be used without a stamp, provided it does not contain any words suggesting that it is a secret or proprietary preparation, or recommending it for any disorder. It is doubtful whether the label sent complies with this provision; it would, therefore be better to submit it to the Inland Revenue authorities.

H. F.—Probably you refer to the price list issued last year by the Glasgow Chemists and Druggists' Association, of which, we believe copies may be obtained upon application to the secretary of that association.

F. K.—The latest edition of the Codex was published in 1866, and could be obtained through Messrs. Williams and Norgate, Henrietta Street, W.C., or any respectable foreign bookseller.

George Adams.—Yellow Prussiate of Potash is not a poison, and therefore it is not necessary that its sale should be entered in a "poison book."

G. L. Napier.—We believe its therapeutic qualities to be little inferior to the Pharmacopœia preparation, but it would not be admissible to substitute it in ordinary dispensing for the latter, which is naturally more pure. It is used in many hospitals where cost is a matter for consideration.

Communications, Letters, etc., have been received from Messrs. G. L. Napier, Dr. Muter, J. Squire, Pocklington, Rawlinson, "Spes," "Two Inquirers," H. F., E. B.

PROPYLAMINE OR TRIMETHYLAMINE.

Attention has recently been directed by Dr. Sydney Ringer in some notes in the *Medical Record*, to the revival of the use of a compound ammonia as a remedy for rheumatism, and the use of the substance has been the subject of discussion at some of the French medical societies, as well as the Paris Société de Pharmacie, as will be seen by the report at p. 670, 671. Since the first introduction of this remedy in 1854 by Awenarius, of St. Petersburg, it has also been employed both in this country and in America to some extent, though without any very decided knowledge having been acquired respecting its physiological action and medicinal virtues. However, its use being now a prominent subject of discussion, the chemical history of the substance has an immediate interest for the pharmacist, and this is especially the case since there is considerable uncertainty both as to what precise compound is indicated by the term propylamine, and also what has been used medicinally under that name. Some account of the substance will therefore be useful to the readers of this Journal.

Propylamine is a compound or substituted ammonia in which one of the three molecules of hydrogen belonging to ordinary ammonia is replaced by the radicle propyl (or trityl) C_3H_7, the third member of the ethyl series of radicles; its constitution being represented by the formula—

$$N\begin{cases}C_3H_7\\H\\H\end{cases}$$

It is described by Mendius, who first prepared it, as a very mobile, colourless liquid, possessing a strong ammoniacal odour, boiling at 50°, dissolving in water with evolution of heat, specific gravity ·7134 at 21° C.

With acids, propylamine forms crystallizable salts, the sulphate being deliquescent, and the hydrochlorate NC_3H_9HCl very deliquescent, freely soluble in alcohol, but almost insoluble in ether.

The method first adopted to obtain propylamine was the hydrogenation of ethyl cyanide or propionitrile, a compound intermediate between the ordinary alcohol of the alcohol series and the propionic acid of the parallel series of acids. For this purpose 36 parts by weight of ethyl cyanide, 500 parts alcohol, 200 parts water, and 500 parts of a 20 p.c. solution of hydrochloric acid were mixed and made to act upon metallic zinc added in excess, the whole being distilled and the distillate mixed with 400 parts more hydrochloric acid and poured back again upon the zinc remaining undissolved. After again distilling to get rid of alcohol, excess of caustic soda is added to the residue, and then the propylamine is distilled off together with water.

Besides this normal propylamine there is another compound of the same composition called isopropylamine

$$N\begin{cases}CH\ (CH_3)_2\\H\\H\end{cases}$$

This boils at about 32° C. The hydrochlorate crystallizes in cubes, while that of the normal propylamine forms square plates.

Another isomer of propylamine is trimethylamine, an ammonia in which each of the three molecules of hydrogen is replaced by methyl, its constitution being represented by the formula—

$$N\begin{cases}CH_3\\CH_3\\CH_3\end{cases}$$

This substance was formerly mistaken for true propylamine or tritylamine; and it seems probable that in regard to the remedy now proposed to be used in the treatment of rheumatism, the same kind of confusion still prevails. Trimethylamine is, however, a substance very different from propylamine. It is an oily liquid with a strong odour of stale fish, and boils at 9° C. This substance was first obtained by Hofmann, by the action of ammonia upon methyl iodide. It also exists in herring brine, ergot of rye, and several plants, and is apparently one of the products of the putrefaction of nitrogenous substances, such as urine, guano, dough, fish, etc.

The directions given in Wood and Bache's United States Dispensatory for the preparation of propylamine from herring brine, on the authority of Professor Procter, clearly point to trimethylamine, and it was from the same source that in 1850 Wertheim obtained the base to which he gave the name of propylamine in the first instance. It would appear, moreover, from the accounts given of the substance used under the name of propylamine that it was really its isomer trimethylamine that was referred to. The physical characters of these two substances are very distinct, and the smell of even propylamine is said to be very different from the herring-like odour of trimethylamine, so that there would not be much difficulty in settling this point.

At a recent meeting of the Paris Société de Pharmacie a committee was appointed to inquire into the subject, on the ground of the uncertainty attending it. The price hitherto charged for the material in the state of aqueous solution appears to have been about 5*s.* per ounce; but at a recent meeting of the Société Médicale des Hôpitaux it was stated that it would be procurable at about one-third that cost.

M. Adrian and M. Dassaigne recommend the use of an hydrochlorate of the base as being more convenient than the solution.

SULPHOVINATE OF SODA.

BY CHARLES RICE.

Having prepared this salt some time, and having tried several methods for obtaining it, I can recommend the following, as yielding a good product at a moderate price:

Take of alcohol (sp. gr. 0·815), sulphuric acid (sp. gr. 1·830), each 64 fl. oz. Add the acid to the alcohol, contained in a large flask, in portions, at short intervals. At first the temperature of the mixture rapidly rises to 212° F., and violent ebullition takes place at each successive addition of acid, but this gradually ceases as the specific gravity of the mixture increases, and the last portions of the acid may be added quite rapidly. Cover it well, and allow it to stand for two or three days. The mixture of alcohol and acid should not be raised to the boiling point, since the yield of sulphovinic acid is thereby considerably diminished, while that of oil of wine, ether, etc., is proportionately increased. Pour the mixture slowly, while stirring, into five times its bulk of water, and saturate the acid liquid with carbonate of lime. Strain the liquid, wash the precipitated sulphate of lime, and add the washings to the filtrate, which now contains sulphovinate of lime. Add to the latter a solution of carbonate of soda, until it just ceases to give a precipitate. Instead of carbonate of soda, I have also used oxalate of soda, which, although requiring considerably more water for solution, and consequently a longer time for the final evaporation, has this advantage, that it effectually removes the whole of the lime salts, thus making filtration during evaporation unnecessary. Filter the liquid through filtering paper free from iron, to remove the precipitated carbonate of lime; wash the latter, and evaporate the filtrate until it measures about 70 fl. oz. Filter again from a small quantity of separated sulphate and carbonate of lime, and evaporate until a pellicle forms. Then set it aside for a few days, and remove the crystals. It is very difficult to obtain more than one or perhaps two crops of well-defined crystals; the last mother-liquors deposit a number of hemispherical, knob-like crystalline masses, of a pasty consistence and exceedingly difficult to drain. I now prefer to evaporate the liquid at once to a syrupy consistence, and then, under constant stirring, to evaporate to dryness.

The product is a white granular salt, of a faint ethereal odour, and a cooling, somewhat aromatic taste; it is very deliquescent, soluble in 0·7 parts of water, at 60° F., also soluble in alcohol, with which it is capable of forming a crystalline compound. When pure, BaCl solution should throw down no precipitate, or at least produce only slight cloudiness.—*American Journal of Pharmacy.*

THE MEDICINAL PLANTS OF NEW ZEALAND.

BY JOHN R. JACKSON, A.L.S.

Curator of the Museums, Kew.

New Zealand is a colony especially interesting to Englishmen, not only on account of the variety of its resources, but also on account of the illustrious Englishmen who have visited the island and given us accounts of its geographical features, geological formation and natural history. New Zealand has been particularly fortunate in having amongst its explorers names honoured in the roll of history as bold and intelligent adventurers, as also among the natural history collectors who have visited the colony some of the best that ever left these shores, and as much may be said of those who at the present time are the prime movers and supporters of science in the colony.

The New Zealand Institute, which includes amongst its members such names as those of Dr. Hector, Dr. Haast and others equally well known, has done so much scientific work of a high order that it may justly be compared to our own Royal Society. It needs only to point to the 'Handbook of the New Zealand Flora,' undertaken by Dr. Hooker at the instigation of the Colonial Government, to show with what a liberal hand and enlightened mind that Government has encouraged science in the colony. Nor is the knowledge of the botany of New Zealand confined to a mere list of the plants inhabiting the country, for the properties and uses have also been inquired into and properly recorded. The medicinal plants are those in which the readers of this Journal have most interest, and to which I desire to draw attention.

In a carefully compiled essay on the botany of the North Island of New Zealand, we are told that "it is highly doubtful whether the New Zealanders ever used any vegetable as an internal medicine before their intercourse with Europeans; for severe burns, however, they applied outwardly the ashes and charcoal dust of burnt fern fronds (*Pteris esculenta*) and the fine reddish dust of the large decaying fungus pukuvau (*Lycoperdon Fontanesii*). The blanched leaves of the harakeke (*Phormium*), and the roots of the rengarenga or maikaika (*Arthropodium cirrhatum*), were sometimes roasted and beaten to a pulp, and applied warm to unbroken tumours and abscesses. As a cataplasm for ulcers they used the leaves of the koholio or poroporo ((*Solanum aviculare*); and for wounds and old ulcerated sores, they used the large leaves of the pukapuka or rangiora (*Brachyglottis repanda*), and also the pappus down of the large bulrush (*Typha angustifolia*), but merely as a protection against dust." The stems of this plant are extensively used in New Zealand for making walls and roofs of houses, and the yellow pollen is made into a kind of bread or cake. "Layers of dry totara bark (*Podocarpus Totara*), and the lower parts of stout green flax leaves (*Phormium*) served admirably as splints in cases of broken bones, the New Zealanders being far better surgeons than physicians. And the leaves of several particular plants were in request for their rude steam or vapour baths for rheumatic and other stubborn and chronic complaints, but it is highly questionable whether the benefit derived from such baths did not arise entirely from the warm vapour. They sometimes rubbed the fresh juice of the ngaio (*Myoporum lætum*) over their skin to keep off the persecuting sandfly; and for several years they have used as purgative medicines the juice of the root of the New Zealand flax and the bark of the kowhai (*Sophora tetraptera*); as a tonic, the leaves of the kohekohe (*Dysoxylum spectabile*); as a demulcent in colds, etc., the bark of the houhue (*Hoheria populnea*); as a diaphoretic, *Mentha Cunninghami*; and as slightly alterative a decoction of the bark and stems of the pikiarero (*Clematis hexasepala*) and the root of the tatarahake (*Coprosma acerosa*)."

It is interesting to note that some of the plants here mentioned as being used by the New Zealanders in their rough system of medicine, belong to orders throughout each of which a characteristic principle prevails, and some members of which are acknowledged articles of utility in this country; thus, for example, as the demulcent properties of *Hoheria populnea*, a plant belonging to the well-known natural order Malvaceæ. Some of the plants have, moreover, been tried by Europeans in the colony, and reported upon as being likely to prove valuable in regular practice. Amongst them may be mentioned the root of *Phormium tenax* as an anthelmintic and cathartic; the leaves and bark of *Dysoxylum spectabile* as a tonic, the roots of *Rhipogonum scandens* as an alterative. This plant is a very near ally to the commercial sarsaparilla, and its roots, it is said, "have been beneficially used in New Zealand instead of that medicine, which is so commonly adulterated." The climbing wiry stems are, moreover, used both for cord and for basket work by the natives. Besides the above, the bark of *Hoheria populnea* has been successfully used as a demulcent;

Mentha Cunninghami as a diaphoretic; the aromatic leaves of *Angelica rosæfolia* as a diuretic and remedial in syphilitic cases; and the roots of *Taraxacum Dens-leonis* as an alterative. From these facts, and from the fact that the Flora of New Zealand includes many plants belonging to natural families noted for their medicinal properties, we might expect many at present unknown to prove valuable. In the admirable essay from which we have quoted, the author, speaking on this part of the subject, selects the following as examples:—"The spicy bark of the horopito (*Drimys axillaris*), a species ranking next to the well-known *D. Winteri* of Cape Horn, which produces the valuable Winter's bark; the intensely bitter bark of the kowhai (*Sophora tetraptera*),—it is worthy of notice that both African and East Indian kino is produced by plants of an allied genus of the same sub-order; the leaves of the wharangipiron (*Melicope ternata*), as allied naturally to the genus *Diosma*, species of which genus produce the well-known buchu leaves, which the New Zealand *Melicope* also resembles in taste and smell; the kawakawa (*Piper excelsum*),—many closely allied species of this genus (and of the next genus *Cubeba*) are extensively used as medicinès in various parts of the world; the aromatic succulent stems and roots of various species of *Panax* and of *Aralia*, of which several species are used in medicine, and the roots of *P. quinquæfolium*, are sold by the Americans to the Chinese for real ginseng root; the astringent bark and diuretic seeds of *Sapota costata*; the roots of the two mountain gentians, which are just as purely bitter as those of the officinal *Gentiana lutea*; the aromatic bark of the tawa (*Nesodaphne Tawa*), a plant belonging to the same natural order with those producing the cinnamon, cassia, sassafras, benzoin and camphor of commerce; and lastly the wainatua (*Euphorbia glauca*) may also prove useful as a medicine, seeing so very many species of the same genus have long been medicinally employed."

THE MICROSCOPE IN PHARMACY.

BY HENRY POCKLINGTON.

(*Continued from p.* 582.)

CUSPARIÆ CORTEX.—This bark is readily examined after a few days' maceration in cold water, and presents hardly any difficult features. Commencing with the exterior we find flattened cubic cells, thin walled and devoid of contents, and of no special interest whatever. Beneath these are the more important parenchymatous layers, with specialised cells and liber bundles. The outer cells of this layer are compressed somewhat, are thin walled and contain a yellowish-colouring matter. A few liber bundles and raphide receptacula are seen in these outermost layers, but these latter are much more numerous in the layers of uncompressed cells next in order. These cells are also thin walled, of varied shape, and contain only starch, a little colouring matter, and a granulated nitrogenous substance. They are remarkably irregular in size and shape, and their adhesion to each other by no means complete. Apparent intercellular spaces exist, and are filled with a brown resinoid substance. Special cells containing raphides, acicular and intensely doubly refractive, are frequent in portions of this layer, and require a little care in examination, as at first sight their raphidian contents are not to be distinguished. Rupture of the enveloping membrance of course sets the matter at rest. Interspersed with the raphide-bearing cells are large cells with thin walls, containing a brown colouring matter similar to that already spoken of. Unless care be taken in removing this matter by means of ether, or bisulphide of carbon, and alcohol, the specialised character of the cells containing it will not be evident. Their walls are exceedingly thin, and the whole cell is frequently torn away by the cutting instrument employed, leaving a hole that might be mistaken for a large intercellular space. It is best to watch the action of the solvents employed under a magnifying glass. The cell walls of these receptacula stain intensely with magenta, and are best seen when so stained. On the innermost margin of these layers of large parenchymatous cells are seen large liber bundles, very distinguishable in a magenta stained transverse section, but best studied in a vertical section. The liber cells are of very considerable length, are wholly filled with secondary deposits and not specially interesting. Within these are the newer layers of the bark containing large oval resin-receptacula, a few raphide cells and a variety of granular substances. The medullary rays, extending as far as the liber bundles, are formed of cubic cells filled with a nitrogenous substance which stains intensely with magenta, and containing also small quantities of starch.

The starch present varies in quantity, and is in single, minute, obovate granules with indistinct hilum. It is feebly doubly refractive, and the black cross can only be seen by aid of careful manipulation. And here I will digress a short space for the benefit of those friends who fail to find the black cross in wheat starch, and in Portland arrowroot (*arum maculatum* starch), although they are successful with such starches as those of canna (*tous les mois*) and potato. Certain starches are generally said, even in good text-books, not to give the cross, and this is given as a characteristic feature. It, therefore, is of importance that the matter should be inquired into, and the cause of the error found, if error it be. I have for some years devoted such of my leisure as I could spare from more pressing scientific work to the examination of starches under nearly all possible circumstances, and I find that, rightly treated, nearly all are doubly refractive, and give a cross by polarized light. And further, I am much disposed to think that in the few cases where I have failed to see the cross, it has been from want of sufficiently skilful manipulation. Anyhow, the starch of wheat (as I have before observed) and the starches of arum and rice do give a very distinct cross, but not unless immersed in balsam or dammar. Different starches require different treatment in preparing; some must not be heated in the slightest degree, others will bear a considerable temperature. A few give a decided cross if examined in water or alcohol, others in glycerine. Many require, as wheat, to be immersed in balsam or dammar, and a few others are best in oil of anise or even carbon disulphide. It will be seen from this that the refractive index o the medium, and probably also its penetrative pro perties as regards the starch, seriously affects the optical reactions of the starch, and that we are not justified in saying that no cross can be seen, unless we have tried the effect of fluids of various refractive powers upon the starch in question. This point is so generally overlooked that the digression may be forgiven. It would have been mentioned before had I not supposed it was more generally recognized. One other point is more generally known—it is this, an eye-piece of low power (that known as "A") should be employed, and in doubtful cases the analyser used above the eye-piece. A very thin film of mica, too thin to give colour with the help of the starch, is sometimes useful.

Cascarillæ Cortex.—This bark requires a somewhat more prolonged maceration than the last named, and care must be taken not to place it in an iron or imperfectly tinned iron vessel. Commencing with the exterior, we have cells closely similar to the corresponding cells in Cusparia and not calling for special notice. The layer within this consists of small, somewhat regularly shaped cells, far less angular than the cells usually found in this position, and containing, besides colouring matter, starch. Within this layer are the larger parenchymatous cells, the liber cells, and certain well-defined latex vessels. All of these require careful treatment in order to see them properly. The best plan is to allow a properly-cut vertical section to remain for a considerable time in warm alcohol, then in ether, back to alcohol, and finally stain it in an alcoholic solution of magenta, and having well washed it in alcohol, transfer it to oil of anise and mount in dammar or balsam. In such a section the ramification of the latex vessels can easily be made out, and certain other features distinguished that are not easily seen in an ordinary section. The inner layers of cells are chiefly more or less cubic or oblong cells, many of them containing colouring matter, and becoming black on the addition of solution of an iron salt, whence the necessity for not soaking the specimens in water contained within an iron vessesl. Besides starch, these cells contain an interesting form of raphide, large rhombic prisms intensely and beautifully doubly refractive, but not easily seen excepting in well-prepared specimens by the aid of polarized light. These crystals appear to be situate always in ordinary cells with various other cell contents, and not in special cells, as in cusparia and many other barks, etc. The starch granules are small, doubly refractive, and give a well-defined cross by polarized light.

The most interesting feature of the bark undoubtedly is the system of latex vessels, or resinoid canals, situate between the two layers of cells just mentioned. These are apparently true vessels formed by adhesion end to end of cylindrical cells and absorption, not always complete, of the thin cellulose septa. They are always thin walled, and contain various substances coloured and otherwise. Lying side by side with these vessels are considerable quantities of the raphides, frequently minute and agglomerated into sphæraphides. These vessels are best seen in a section cut parallel with the surface and vertical. The sections had better be cut successively, and each examined until the right one is found. Magenta and Tinct. Ferri Perchloridi are the best reagents for their demonstration, and may be used together or singly, the section being thoroughly washed after the application of each.

(*To be continued.*)

Indelible Writing Ink.—The *Pharmaceutische Zeitung* states that an indelible writing ink may be prepared by adding ferrocyanide of potassium to ordinary ink. The attempt to remove such an ink by use of an acid would cause the formation of prussian blue.

SULPHUR MINES IN ICELAND.

In a recent report upon the trade and fisheries of Iceland, drawn up by Arthur de Capel Crowe, Esq., Her Majesty's Consul at Copenhagen, he states that large deposits of sulphur exist in some districts, which at different times have been the object of commercial speculation. The sulphur mines at Krusavik in the south are at present worked for foreign account, but, owing probably to their partial inaccessibility and difficulty of transport, without much success.

The right of working sulphur mines at Myvatn, in the northern portion of the island, has recently been conceded by the Danish Government to an Englishman on a fifty years' lease. They were worked some years ago for account of a Copenhagen house, but were abandoned in 1851, since which time they have remained closed. Many causes contributed to this result, the chief of which, doubtless, were ignorance of the proper method of gaining the sulphur, the cost of transport on horseback to the seaboard, and the want of remunerative demand.

Since then these conditions have changed, and there exists no reason why these mines should not be worked profitably. They extend over a large tract of country, and their position is most advantageous in the middle of a flat country within an easy distance of Husavik, a convenient shipping port, and during the many years they have been closed the deposits must have very greatly accumulated, and should yield abundantly; indeed, so strong was this conviction in the minds of the natives that they long opposed the leasing except on very onerous terms, although quite unable themselves to work them.

As these mines are now likely to remain in English hands for many years, a short account of their former history may be read with some interest.

They are situated between 65° 20′ north latitude and the Arctic Sea, or more definitely speaking, lying in the tract between Myvatn (Great Lake) on the east, and Iokulsa (Glacier River) on the west. The right of working them was bought from private owners by the Danish King Frederick the Second, in 1563, and this right has ever since been in the possession of the Danish Crown (now the State). During the reign of this king a considerable quantity of sulphur was extracted, amounting to as much as 400 tons annually. In the reign of his son and successor, Christian the Fourth, the produce appears to have fallen off, and his Majesty was unsuccessful in his endeavours to lease them to foreigners. To the falling off of their supply of sulphur in this reign, and the consequent scarcity of gunpowder, the Danes attribute their defeat by the Swedes in Holstein in 1644.

In 1665 the Crown granted a concession for "digging sulphur" to a foreigner, who is stated to have exported large quantities up to the year 1676; since which date no special mention appears to have been made of them until the early part of the eighteenth century, when two foreigners, apparently Germans, acquired in 1724 the right of exporting sulphur from Iceland of which they also shipped considerable quantities during the succeeding five years, when the death of the lessees put a stop to this commerce.

After this date, and up to the beginning of the present century the Danish Government worked the mines for their own account, at times it appears with considerable profit, until 1806, when they were again leased to a foreigner, and subsequently have at times been worked by private speculators up to 1851, since which date, as already mentioned, they have remained untouched.

In 1840 they were visited by some scientific travellers, who calculated that these northern mines might easily yield an annual net profit of £1000 or £1200; but ten years later they were specially examined by a Danish mineralogist, who discredited this statement, and reported them to be less valuable; but in speaking of the Krusavik mines in the south, he says, "these might easily be made to yield 200 tons annually;" and yet they have always been considered inferior to the northern mines. A French geologist, Eugène Robert, who visited Iceland in 1835, and afterwards published a treatise on its geology, calls the attention of the Danes to the value of the Myvatn mines, and advises them not to lease them to the Englishmen (who were then applying for them), as the property might become of great consequence in the event of the sulphur mines of Sicily falling off, of which he affirmed symptoms had shown themselves.

It will thus be seen that opinions are divided as to the productiveness and present richness of these mines, but so much is certain, that they have for several centuries been worked at intervals with varying results, at times with considerable profit, and the history of the country and the experience of so many years points to the conclusion that, if properly worked, they would become a valuable property. The mines, for instance, at Reykjaklidar-Námar are the richest to be found in all Iceland, and produce large deposits of the purest sulphur.

The reproduction is incessantly going on from upwards of a thousand small eminences, called solfatarar, which are found on the ridge along the sides, and at the foot of Námar-fjall. Rich sulphur deposits are also found at the Ketill crater (called Fremri-Námar), while the least rich are the Krafla-Námar, but at all these there is a continual deposition of sulphur going on. They all have the great advantage of lying in the track of one of the few practicable roads in the island, leading to an accessible shipping port.

A NEUTRAL SOAP.

In a recent communication to the French Academy, M. Miahle described a soap which he states combines the advantages of being prepared without heat, and thus avoiding the loss of the glycerine in combination with the fatty matters, and of being free from that alkalinity generally present in soaps prepared in the cold. In its preparation the ordinary toilet soap, made without heat, is cut into shavings and exposed, in a properly closed chamber, to the action of carbonic acid gas. The soap absorbs a quantity of the gas proportional to the quantity of caustic soda which has escaped saponification, and by the transformation of the free alkali into bicarbonate it loses all its causticity. It then constitutes a perfectly neutral soap, containing all the glycerine of the fatty bodies employed in its manufacture, and a certain quantity of bicarbonate of soda.

THE NATIONAL HERBARIA.

The question of the positions which should be occupied by the great national herbaria at Kew and at the British Museum is one which has of late engaged a large share of the attention of the scientific world. The subject was for a time brought under the notice of the general public last year by the attempt at interference on the part of Mr. Ayrton, as Chief Commissioner of Works, with the internal management of Kew Gardens. With the memorial from seven of the foremost scientific men in the country, addressed to Mr. Gladstone, in support of Dr. Hooker's administration, and the abortive debate at the very close of the Parliamentary session, the discussion appeared to have died away; when it was suddenly revived by a letter from Professor Owen, published in the columns of our contemporary *Nature* for November 7th last, hinting at the desirability of incorporating the herbarium with that at the British Museum. Though we cannot but regret the personal element which has been introduced, yet the controversy is one not without its importance, and one which should be fairly and impartially discussed. The plans of the Science and Art Department of the Privy Council, when complete, contemplate the removal of the Natural History collections, and with them the herbarium, from their present locality in the British Museum to the new range of buildings to be erected at South Kensington; and the question naturally presents itself whether, when these arrangements are carried out, there will still be room for a rival establishment at Kew.

The arguments in favour of the amalgamation of the two establishments are sufficiently obvious. The saving of expense by the abolition of one or two of the curatorships or subcuratorships will probably weigh little with the public at large, and still less with the scientific world, if any compensating disadvantages can be shown. A far more forcible line of reasoning is based on the gain which would accrue to the student from the incorporation of the two herbaria, and the consequent great increase in the number of specimens of any one species which he could have under examination at one time, and the filling up of gaps in one collection which might be supplied by the other. In the present state of systematic botany, it is absolutely necessary that any one engaged either in referring a plant to its correct species, describing a new species or genus, or preparing a monograph of a group, should have as large a series as possible of specimens before his eyes at a glance. Our best colonial floras, as those of Australia, New Zealand, Hongkong, British India, the Cape of Good Hope, etc., published under the auspices of the colonial Governments, are, in fact, not drawn up by colonial botanists, who have small series of the living plants before them, but by home botanists from large series of dried specimens. Another argument of less weight is the desirability of having the opportunity of comparing the series of specimens of recent plants with those contained in the British Museum in a fossil condition.

That this, however, is not the view adopted by those most conversant with the practical uses of herbaria is sufficiently shown by a memorial recently presented to Mr. Gladstone, bearing the signatures of nearly all the scientific botanists in the country, unconnected officially with either of the national herbaria, including all the botanical professors at the leading universities. The principal arguments therein presented in favour of the retention, in its integrity, of the magnificent herbarium now at Kew, are the great importance of keeping at least one great herbarium in immediate connection with the botanic gardens and library at Kew, and the greater facilities for scientific work afforded by such a situation as Kew than by one more metropolitan. With regard to the first, one of the duties of the officials at the Kew herbarium which is daily brought into exercise, is the naming, from dried specimens, of plants brought to or flowering in the gardens. The series of botanical works published under the superintendence of the officials at Kew, and consisting of descriptions, with drawings, of new or little known species, monographs of groups, and scientific accounts of the botanical collections brought home by different explorers, would of themselves form a considerable library of great value in systematic botany. Every one also who has worked at systematic botany, and especially at preparing monographs of groups, knows the importance of being able to compare the dried specimens with the nearest allies to be met with in the living state; and still more to have the freest access without delay or interruption to every botanical work which it may be necessary to consult—an advantage enjoyed by the student at Kew, from the unrivalled library there, and not to nearly the same extent anywhere else. On the second point, though it is impossible to consider the arrangements at Kew as perfect, yet the facilities for dissection and microscopic examination of specimens are greater than those afforded by any other establishment. There are also some other advantages in the separation of the two establishments which are alluded to in the memorial; and it is not probable that so great an agreement among the practical scientific men would exist on the subject were not the balance very decided in this direction. It is satisfactory at all events to find from the reply of the Treasury that the Government will make no alteration without ample notice of its intention being given to those concerned. Presuming that this will be the final decision, we venture to make one suggestion for increasing the usefulness of the two herbaria. It is the custom with all the leading continental herbaria for the curators to permit the loan of all the specimens representing a certain group to any botanist engaged in monographing that group, in return for the specimens being worked-up and named by him. Any English botanist, therefore, has access, practically, not only to the herbaria at Kew and the British Museum, but to those also at Paris, Brussels, Vienna, Berlin, Munich, and other continental towns, while continental botanists have not the same access to our collections without coming over to this country. Would it not be possible for one or the other of these two herbaria to permit its specimens to be made use of in the same manner with suitable restrictions?

The enormous value to science of the maintenance of national herbaria will have been sufficiently indicated by the above remarks. A few particulars may be given with regard to the two which we possess. The old palace at Kew combines under its roof the richest botanical library and the richest collection of dried plants in the world. The latter is computed to include from 105,000 to 110,000 species, arranged in 450 cabinets averaging 16 shelves each. The nucleus of this magnificent collection was the private herbaria of the late Sir Wm. Hooker and of Mr. Bentham, President of the Linnean Society, the latter alone numbering between 60,000 and 70,000 species, to which have been made additions from Government expeditions and private explorers from all parts of the world. A very extensive system of exchange is also carried on with continental herbaria, series of authentic "type" specimens being constantly sent out from Kew in return for similar series from those continental collections with which we are in correspondence. The herbarium at the British Museum is estimated to possess 77,400 species of flowering plants, arranged in 306 cabinets of 8 shelves each. The number of duplicates is much larger in the Kew herbarium than in that of the British Museum, but the latter is peculiarly rich in the products of certain districts of the globe and in fossil botany. In both establishments, the energies of the limited staff are severely taxed in adding and incorporating the additions which are constantly coming in, and in preparing the parcels of exchanges to which we have alluded; and both are scientific collections of which the country may well be proud.

THE SALE OF VERMIN KILLERS.

Meeting of Chemists and Druggists at Whitehaven.

A meeting of the chemists and druggists of Whitehaven, called by Mr. A. Kitchin (local secretary to the Pharmaceutical Society), was held on the 15th of February in the Whitehaven Scientific Association's Room, Queen Street, kindly lent for the occasion. The object of the meeting was to consider the conditions under which vermin killers are to be sold with a view of entering into an arrangement as to the scale of charges for and registration of such articles. Most of the chemists and druggists in the town were present. Mr. W. Kitchin was elected to take the chair.

In opening the proceedings the Chairman said that he was not well acquainted with the matter to be brought before the meeting, but no doubt the local secretary was prepared, and he should therefore call upon him. He would only remark before he sat down, that at one time they used to mix together one ounce each of brown sugar, arsenic, and Spanish brown, which was put up in quarter-ounce packets, and sold to poison flies. Thousands of these packets were sold, and yet nobody was ever poisoned by them.

Mr. A. Kitchin (local secretary of the Pharmaceutical Society) said the meeting had been called to take into consideration the sale of vermin killers. Most vermin killers contained either strychnine or arsenic, and came under the regulations laid down for the sale of poisons included in Schedule A of the amended Pharmacy Act of 1868. The law was very clear upon this point, although not generally understood. In the Pharmacy Act, 1868, certain poisons, specified in part 1 of the Schedule, had to be registered; while in the additions to the Schedule sanctioned by the Privy Council in 1869, the preparations of these poisons are required to be registered also. Now vermin killers being mostly preparations of strychnine or arsenic came under, and are included in part 1 of the amended Schedule. It appeared that certain chemists and druggists have been proceeded against and convicted for selling vermin killers without registering them. One or two chemists having spoken to him about the matter, he thought it best to call a meeting, where opinions might be freely expressed, and some arrangement arrived at with respect to the quantity to be sold and the charge to be made for the additional trouble of registration. It was an unpleasant thing for a chemist to be hauled up before a magistrate, even were he not convicted and fined.

Mr. Goss said that in Lancashire chemists and druggists had been registering the sale of vermin killers for some time. He had been informed that the least quantity they sold was threepennyworth. He himself had been registering the sale of vermin killers for the last fortnight or three weeks, and made his lowest charge threepence.

Mr. Hartness said he had been registering vermin killers for some time, and the lowest charge he made was fourpence. People grumbled a little sometimes at the price, but when told that chemists were compelled by Act of Parliament to register, they purchase without further comment. He did not remember ever having lost a customer on that account.

Mr. Grayson asked what Mr. Hartness would do if he had a stock of threepenny vermin killers.

Mr. Hartness said it was the threepenny packet he generally charged fourpence for.

Mr. A. Kitchin remarked that two threepenny packets might be put together and sold for sixpence to those who wanted a larger quantity.

Mr. Hunter asked whether it would not be better to charge a registration fee of, say, twopence, and make the lowest quantity to be sold two pennyworth, which would be twopence for the poison, and twopence for registration? The lowest quantity registered would then be fourpence; and in that way a sixpenny packet would be sold for eightpence, a shilling packet for fourteen pence, and so on.

The Chairman thought there was something tangible in Mr. Hunter's suggestion.

Mr. W. H. Kitchin was of opinion that they would often have some old farmer finding fault and grumbling at being charged twopence registration fee for a twopenny packet of vermin killer when he could buy a sixpenny or shilling packet for the same.

Mr. Grayson and Mr. Goss also objected to this plan.

Mr. Hartness said that seeing Mr. Hunter's suggestion of a registration fee did not meet with much favour, he would propose that a charge of fourpence be made for any vermin killer requiring registration, and that this be the lowest charge.

Mr. Hunter seconded Mr. Hartness's proposition.

The chairman having put this proposition to the meeting, it was carried unanimously.

A vote of thanks having been proposed to Mr. W. Kitchin for presiding, the meeting, which was marked throughout with harmony and cordiality, was brought to a close.

The Pharmaceutical Journal.

SATURDAY, FEBRUARY 22, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

OUTSIDE IDEAS.

THOUGH it was one of the chief hopes of the founders of the Pharmaceutical Society that it should eventually become a body representative of the entire trade, and although this aim has since that time repeatedly become apparent in the course of events, evidence is too frequently to be met with that the attainment of this object must yet be a work of some time. Of such a nature is the letter we publish this week from "AN OLD DRUGGIST," in which he justifies his right to be what is called an "outsider," by the remarks he offers as to the advantage of being a member of the Society. The letter to which we refer is indeed calculated to serve as a practical commentary on the suggested reduction of the entrance fee payable by persons becoming members of the Society, and to raise some serious doubts whether the proposal discussed at the last Council meeting would be found to augment the roll of members.

The writer of the letter candidly confesses to being amused by the discussion of this question, and regards with obvious astonishment the idea that membership involves any privilege beyond what he terms "the very shadowy advantage of voting once a year for a few gentlemen of whom you know little or nothing." The state of mind indicated by these expressions appears to manifest a strange disregard of the fact that the functions now exercised by the Society through its Council are of vital importance to all engaged in the business. If it had not been that our correspondent writes from a town claiming to be foremost in its efforts to secure universal suffrage, the fact might have been less surprising, but in any case if the views he advances are at all representative of those entertained by other "outsiders," there seems to be little cause to regret their relation to the Society, however much we may deplore the existence of a section of the trade which takes no part in supporting its efforts to advance the condition of British Pharmacy. If such be the case indeed, we do not hesitate in answer to another of our correspondent's questions to say that it would be more to the advantage of the Society not to receive the outsiders, for putting aside altogether the idea of a duty to be fulfilled by those who enjoy the right to select the governing body, we should be sorry to see the privilege of voting for members of Council exercised under the influence of such indifference as that indicated by "An Old Druggist."

We believe, however, that this feeling is not general even among those who are not in "the ranks of the Society," though it must be remembered that the necessity of respecting "vested interests" at the passing of the Pharmacy Act involved the registration as members of the trade of a very mixed class. We believe also that the system now in force of reporting the proceedings of the Council will tend to excite an interest in the Society much more general and hearty than has prevailed heretofore. The part taken by individual members of Council in regard to any measure is now month by month ascertainable from the published reports; and if any one who has the right of voting for the election of Councillors neglects to avail himself of this means of information, and of thus becoming acquainted with those who offer themselves for election, the fault will be his own as regards himself; and as regards the general interests of the calling he follows, he will have rendered himself chargeable with a failure in his duty.

VERMIN KILLERS.

IT is with much pleasure that we direct the attention of our readers to the report on a previous page of a meeting of Chemists and Druggists, held at Whitehaven, to consider the conditions under which vermin killers should be sold, and to enter into an arrangement as to the scale of charges for them. The Local Secretary, Mr. A. KITCHIN, in opening the proceedings took it for granted that most vermin killers contained either arsenic or strychnine, and that they consequently were subject, as preparations of Arsenic and Strychnine, to the regulations laid down for the sale of poisons included in the first part of Schedule A of the Pharmacy Act. In taking this view, we think that he acted most wisely; and it is satisfactory to find that this was the general feeling of those present. This having been agreed to, it only became a question *how* the sellers of vermin killers should be remunerated for the additional trouble of registering the sales; and for the settlement of this point Lancashire furnished a precedent, inasmuch as it appears to have been the custom there for some time past to register sales of vermin killers, and to make threepence the smallest charge for them. We believe that the action taken in this matter by the Chemists and Druggists of Whitehaven will have the effect of removing the difficulties that have prevailed; and they have earned the thanks of the trade at large by adopting the principle acted upon in Lancashire, and having thus made a move in the right direction.

THE MEDICAL RECORD.

Professional journalism is well represented in all the three faculties. But of the three, medicine probably has the most numerous as well as the best conducted organs. The *British Medical Journal*, the *Lancet*, the *Medical Times and Gazette*—to say nothing of certain minor journals—are periodicals of which the profession may well be proud; and indeed their circulation not only within but beyond its area is proof positive of their ability to assert for professional subjects an ultra-professional interest. At the same time there was room for another interpretation of the medical journalist's duties. Depending mainly for their contributions on English schools, the journals we have named reflect that insularity of idea and practice which, justly or unjustly, has been advanced as an imputation against English medicine. To gather up, select, and epitomize for the English practitioner, above all for the general practitioner, the latest results of continental observation, research, and induction,—to keep him *en rapport* with the newest principles and practice recognized in the great European, Transatlantic, and colonial schools,—was a task imperfectly performed by the existing journals, and still remaining for a fresh-comer to discharge.

In the *Medical Record*, of which six numbers are now before us, we have an admirable fulfilment of the desideratum. In its dexterously-conducted pages insularity is replaced by catholicity of idea. It gives from week to week a careful digest of medical and surgical opinion and practice as they prevail from Dorpat to San Francisco, from Utrecht to Melbourne. The authorities from which the *Medical Record* quotes are all well-considered and accurately-estimated ones; and nothing but the pith or marrow of the multifarious sources on which it draws is placed before its readers. It is quite astonishing to consider the amount of matter which it compresses into its well-printed columns. The absence of prolixity; of "the vanity of petty authorship;" of the self-satisfied citation of personal and local successes; of the features, in short, which make so much of our medical journalism wearisome and unprofitable, is one of its most effective recommendations.

Fortified by its perusal, no medical practitioner, in whatever department, or even specialty, need blame himself for being behindhand in the theory or practice of his profession; while the suggestiveness of its matter will often indicate and inspire new ideas, methods, or processes in the emergencies which occur to every busy practitioner. We cannot conclude our notice of the *Medical Record* without commending its exceeding elegance of production in matters of arrangement, printing, and even paper. It is, in more senses than one, to medical, what the *Pall Mall Gazette* has been to general, journalism.

THE PRELIMINARY EXAMINATION.

Some letters which appear in another page on this subject, and in reply to Mr. Whitfield, furnish evidence in support of the opinion that the mode of conducting these examinations is not satisfactory, and suggest the propriety of their being handed over altogether to competent bodies whose business is more to deal with such general educational matters. We do not perceive that the views expressed at the Council meeting, or even the remarks of our correspondents, convey anything that can reasonably be construed as insulting to our local secretaries.

The conduct of the Preliminary examination is more a matter for the schoolmaster than for the pharmacist, a fair knowledge of English grammar, arithmetic and Latin being all that is required; and though we have reason to be thankful to those who, in the capacity of local secretaries, have given their time and attention to the conduct of these examinations,—sometimes no doubt at much inconvenience to themselves,—we think that it must be obvious to all, that in the absence of any need for the technical knowledge of the pharmacist on the part of the examiners, it must be only a matter of time when the principle involved in the acceptance of examination certificates from accredited non-pharmaceutical bodies shall become the general rule in the Preliminary examinations of the Pharmaceutical Society.

Of the 12,128 samples reported to have been examined at the Inland Revenue Laboratory during the year ending March 31st, 1872, 2241 were received from the Customs, and 933 from the Board of Trade. We learn that the Admiralty and India Office also have applied for permission to have some commercial samples examined, with a view to guarding themselves against any fraud through contractors sending in goods worse than sample. Complaint is indirectly made of the want of room for practical work and storage of samples, and it is a wonder that such a large amount of work has been done in so limited a space. Any one who compares the well-fitted laboratory of the Pharmaceutical Society, or that recently built at South Kensington Museum, with the inconvenient and badly arranged place where so much and such important work is done for the Government, must feel surprised that better rooms have not been set apart for one of the most useful and important departments of the Inland Revenue.

We are glad to find, from a note appended to the Secretary's list of subscriptions to the Benevolent Fund received during the month of January, that a suggestion made in a former number of this Journal has been carried into practice. Were other of our readers to follow the example there set, they would be able to exercise the double privilege of assisting to educate the public to abandon a very objectionable custom, and of contributing towards the alleviation of the sorrows of some who have suffered from it.

Transactions of the Pharmaceutical Society.

MODIFIED EXAMINATION IN LONDON.

February 14th, 1873.

Examiners present—Messrs. Allchin, Barnes, Carteighe, Cracknell, Davenport, Edwards, Gale, Haselden, Ince, Linford and Martindale.

Thirty-eight candidates presented themselves, of whom *eleven* failed. The following *twenty-seven* passed, and were declared duly qualified to be registered as Chemists and Druggists:—

Andrews, John William ...... Burslem.
Ball, Samuel .... Oxton.
Brown, Roger .... Skipton.
Busby, Henry Horton .... London.
Bush, George .... Chelmsford.
Cooper, Thomas .... Crewe.
Costerton, Horace Arthur .... Oundle.
Courtenay, Alexander .... New Cross.
Dodridge, Thomas Mitchell .... Kensington.
Edwards, John E. .... London.
Edwards, Thomas Roberts .... London.
Fisher, James .... Bourne.
Godolphin, George Frederick Alfred, Notting Hill.
Hancorn, John Thomas ...... Lydbrook.
Hayland, Charles Philip ...... Hereford.
Hough, William .... Doncaster.
Jagg, John Henry .... New Cross.
Lund, William .... Dunnington.
Rawlings, Francis Charles .... Monmouth.
Sharman, William .... London.
Smith, John .... Banbury.
Taylor, William Henry ...... London.
Trick, William Borrow ...... Stoke Newingten.
Turner, Henry Prosser .... Ledbury.
Watson, William .... London.
Welton, Henry .... Coventry.
Westlake, John .... Brixton.

Preliminary Examination.

Certificates of Examination of the undermentioned were received in lieu of the Preliminary:—

Certificates of the College of Preceptors.

Hull, Walter .... Sutton.
Mann, William .... Leicester.

Certificates of the University of Cambridge.

Griffin, James Mold .... Eastbourne.
Robins, George Norman ...... Highgate.

Certificates of the University of Oxford.

Whewell, William Edmund .. Birmingham.
Williams, Frederick .... Bath.

BENEVOLENT FUND.

Subscriptions Received during January, 1873.

SUBSCRIPTIONS.

Provincial Transactions.

HALIFAX AND DISTRICT CHEMISTS AND DRUGGISTS' ASSOCIATION.

At a meeting of this society on Thursday, February 13th, Mr. Jonathan Jessop, president, in the chair, the treasurer read a report respecting the state of the finances, which showed a balance in favour of the societ, of £5. 15*s*. 10*d*. The report was adopted.

The President then drew the attention of the members to a circular referring to the Pharmaceutical Conference to be held at Bradford, and suggested that either individually or as an association the members might do something to assist the Local Committee in that town.

Mr. Farr was of opinion that the society should subscribe to the fund which is being raised, and stated that at the next meeting he would move that the sum of two guineas be voted for that purpose.

On the motion of Mr. Dyer it was resolved that the secretary take steps to ascertain the opinions of the country members as to substituting October for December in which to hold the annual meeting and dinner, so as to obtain a better attendance of members for the future.

Proceedings of Scientific Societies. *

PARIS SOCIÉTÉ DE PHARMACIE.

This society met on Wednesday, January 8th, when M. Stanislas Martin ceded the presidential chair to M. Regnauld, in the absence of M. Grassi, who was unable to attend. After the preliminary business M. Planchon read some letters which had been received from Messrs. Phoebus, of Giessen, and Flückiger, of Bern, relative to the proposed Universal Codex. A discussion ensued, and the society added MM. Buignet, Lefort, Mayet, Jungfleisch, Duquesnel and Méhu to the commission already nominated to consider this subject. M. Bussy was also nominated president of this commission.

M. Limousin brought under the notice of the society a new method which he had devised for the administration of pulverulent medicines. It consisted in enclosing them in envelopes of unleavened bread about the size of a five-franc piece, and closed at the edges. Some specimens were shown containing sulphate of quinine, subnitrate of bismuth, and rhubarb.

M. Jungfleisch communicated to the society the result of his researches upon the various transformations of tartaric acid and of the synthesis of that body by means of bibromosuccinic acid. Starting with a substance of mineral origin, so to speak, and which did not possess rotatory powers, he had obtained tartaric acid, having an action upon polarized light.

M. Buignet called attention to the importance of this result which might lead at some future time to the synthesis of the active alkaloids.

M. Bourgoin having remarked that he had not been able to obtain bibromosuccinic acid at a temperature below 170° C., M. Jungfleisch said that by taking the precaution of placing the tubes transversely instead of vertically, in the oil bath, he had obtained it at 130° C.

M. Latour read a note upon the preparation of the syrups of tolu and of tar.

At the sitting of the society on Wednesday, February 5th, under the presidency of M. Regnauld, a note from M. Husson was read upon a combination of iodine and blood, and proposing the therapeutic employment of iodine combined with hæmatoglobulin, a dry product in the form of spangles, and according to the author very easily assimilated. M. Coulier was appointed to report upon the note and the product.

M. Saint-Martin presented a specimen of concrete aromatic oil, extracted from Tonqua beans, which he had had occasion to prepare during a comparative study of the wild and cultivated beans.

M. Boudet in calling the attention of the society to the subject of propylamine, expressed a regret that medical men should be using so variable a substance, and proposed that it should be remitted to the investigation of a commission.

M. Adrian shortly described the communication that he had made to the Société de Thérapeutique (printed at p. 671); after which the proposition of M. Boudet was agreed to, and Messrs. Baudrimont, Bourgoin, Jungfleisch, Adrian, and Boudet were nominated members of the commission.

PARIS SOCIÉTÉ DE THÉRAPEUTIQUE.

Sulphovinate of Quinine.

At the meeting of the above society on Friday, January 24th, M. Limousin exhibited various specimens of Sulphovinate of Quinine. One, which was in the form of scales, was obtained by decomposing sulphovinate of baryta with sulphate of quinine. Another, which was very white and well crystallized, was obtained by treating an alcoholic solution of sulphate of quinine with an alcoholic solution of sulphovinate of soda. M. Limousin pointed out that this last process, besides yielding a very fine product, had the great advantage of avoiding the use of a salt of baryta in the preparation, especially since the poisonous effects of baryta would be very dangerous in hypodermic injections. He said that he had profited by the labours of M. Schlagdenhauffen, professor in the new School of Pharmacy at Nancy,—who had, in a recent paper on the comparative solubility of the salts of quinine, indicated the sulphovinate as dissolving in the largest proportions,—to prepare the present specimens as especially suitable where it was desired to administer a large dose of quinine subcutaneously. The sulphovinate is so soluble that it deliquesces if exposed in a humid atmosphere, and he thought it would be of great advantage to have a salt sufficiently soluble without the necessity of having recourse to an acid.

M. Bourdon said that he had successfully employed sulphate of quinine acidulated by tartaric acid in subcutaneous injections. The solution so obtained did not provoke inflammation around the puncture, as was often the case when a solution acidulated by sulphuric acid was used.

M. Constantin Paul said that by the use of the sulphovinate of quinine, a very large dose of the alkaloid could be administered; five or six times the quantity of water, even when acidulated, being required to dissolve the sulphate. He had found a solution of the sulphovinate to keep well without undergoing alteration, and it presented the great advantage that it could be used immediately in cases of urgency.

M. Bourdon remarked that salts of quinine administered hypodermically were rapidly absorbed, and were found in the urine much more quickly than when they were administered by the mouth.

PROPYLAMINE AND HYDROCHLORATE OF PROPYLAMINE.

M. Adrian presented to the society specimens of propylamine or trimethylamine, and the hydrochlorate of those bases. The first of these specimens was a solution of propylamine, or rather of trimethylamine, a compound of the ammonia type, which may be looked upon as an artificial alkaloid (C_3H_9N). It may be obtained from herring brine, from ergot of rye, and also from the *Chenopodium vulvaria*, which possesses in a high degree the repulsive and characteristic odour of this compound. It is also found in urine and putrefied blood. M. Adrian said that when this product was obtained from herring brine, which contained it in considerable proportion, it was always accompanied by a large quantity of ordinary ammonia. When commercial propylamine was saturated with hydrochloric acid, a mixture of hydrochlorate of trimethylamine and chloride of ammonium was produced. Moreover, the commercial liquid was far from being always of the same degree of concentration, different specimens having yielded very variable proportions of crystallized salt. He thought, therefore, for medical purposes, there would be great advantage in preparing the hydrochlorate of trimethylamine, free from chloride of ammonium, and he exhibited a definitely crystallized specimen which had been prepared in the laboratory of the Société Française. He showed that when its solution was treated with caustic potash, the characteristic odour of propylamine was given off without ammonia; while from a commercial specimen of propylamine, ammoniacal vapours were plentifully disengaged.

M. Dujardin-Beaumetz, reported that he had repeated with success the experiments of Professor Awenarius, of St. Petersburg, and Dr. G. Namias, of Venice, who have recommended this substance in the treatment of rheumatism: he expressed his agreement with the remarks of M. Adrian, and said that the difference in the degree of concentration of the commercial liquid had attracted his attention. He was desirous to have a pure and definite preparation, in order that he might complete his therapeutic experiments. If the hydrochlorate of trimethylamine should prove to possess the same properties as the solution, which was very probable, there would be no doubt that it should have the preference.

M. Martineau remarked that he had administered this remedy to several patients at the Hôtel Dieu; they had been able to take the solution in doses of two grammes per day, and the results obtained were such as to encourage him to continue his experiments.

ROYAL INSTITUTION OF GREAT BRITAIN.

Friday, January 17th, 1873.

ON THE OLD AND NEW LABORATORIES AT THE ROYAL INSTITUTION.

BY WILLIAM SPOTTISWOODE, ESQ., LL.D., M.A.

(*Concluded from page* 656.)

Of Faraday's successor, John Tyndall, I am greatly at a loss how to speak. In this place his presence seems so near to us, his thoughts so subtle, his words —even when rung back to us from those busy cities far away on the other side of the Atlantic—so familiar and yet so stirring, that it behoves us that ours should be wary and few. Few men have brought so large a burden and bulk of contribution to the common stock of knowledge; but still fewer have inspired in his hearers so strong a love, such ardent enthusiasm for the subjects of his research.

It is now twenty years since Professor Tyndall began his researches in our laboratory. During the first thirteen years he produced no less than thirteen papers, which were printed in the 'Philosophical Transactions:' on Sound, on Diamagnetism, on Glaciers and Ice, on the Radiation and Absorption of Heat, and on Calorescence.

In these he established the important fact that if the various gases be arranged in order according to their power, first of radiating heat and secondly of absorbing radiant heat, the order will be the same in both cases. He further proved that the chief absorbing action of our atmosphere on non-luminous heat is due to its aqueous vapour. He applied his discovery to the explanation of many meteorological facts, *e.g.*, the great daily range of the thermometer in dry climates; the production of frost at night in the Sahara; the cold in the table-lands of Asia, etc.

He discovered also the means of separating the invisible from the visible radiations, and proved that in the case of the electric light the former is no less than eight times as powerful as the latter. He also made the daring experiment of placing his eye at a focus of dark rays capable of heating platinum to redness.

Since 1866 his attention has been largely occupied in examining the action of heat of high refrangibility (instead of low), as an explorer of the molecular condition of matter.

In this investigation one obstacle to be overcome was the presence of the floating matter in the air. The processes of removal of these particles became the occasion of an independent research, branching out into various channels; on the one hand, it dealt with the very practical problem of the preservation of life among firemen exposed to heated smoke; and, on the other, it approached the recondite question of spontaneous generation.

He subjected the compound vapours of various substances to the action of a concentrated beam of light. The vapours were decomposed, and non-volatile products were formed. The decompositions always began with a blue cloud, which discharged perfectly polarized light at right angles to the beam. This suggested to him the origin of the blue colour of the sky; and as it showed the extraordinary amount of light that may be scattered by cloudy matter of extreme tenuity, he considered that it might be regarded as a suggestion towards explaining the nature of a comet's tail.

[The lecturer then exhibited the polarization of light scattered by small particles suspended in the medium traversed by a beam from the electric lamp, employing for the purpose the chromatic effects due to the circular polarization of quartz.]

His volume of contributions to molecular physics in the domain of radiant heat, which contains only his original investigations on this subject, would alone suffice to show what is doing in the laboratory of our institution.

If we compare him to Faraday at the same time of life, he has still many years of intellectual energy, the conversion of which into its scientific equivalent may, perhaps, be effected within these walls.

No one has regretted the destruction of the laboratory of Davy and of Faraday more than Professor Tyndall. He almost prayed for the preservation of the place where their discoveries had been made; but as soon as he saw that in our struggle for existence such material aids as improved buildings would conduce alike to the progress of science and to the permanence of the institution, he withdrew his objections, and threw all his powers into making the new laboratories as perfect as possible for the good of his successors.

I add a few words on the reasons which led the managers to recommend the rebuilding our laboratories, and the consequent demolition of the place where the great discoveries that I have touched upon were made. In the opinion of those best qualified to judge, our chemical laboratory was badly ventilated, badly lighted, badly drained, and quite unfit to be occupied for many hours daily. It was probably the very worst, and certainly all but the worst chemical laboratory in London; and compared with more modern ones both at home and abroad, it was nowhere. The physical laboratory had remained for nearly seventy years in its original state. At first it was said to be equal to any laboratory; but then there were hardly any in existence in this country; and during the last few years such splendid edifices have arisen in London, in Oxford, in Cambridge, in Manchester and in Glasgow, and elsewhere, that the laboratory of Davy, of Faraday, and of Tyndall was much inferior to the private laboratories of the professors who carry on their course of instruction in public rooms of still greater size and extent of resource. The main purpose of our laboratories is research, and instead of offering by their excellence an inducement to professors to come and to stay, the one was a mere makeshift, the other a noble relic. Neither offered facilities which were not offered in a larger measure elsewhere. And those only who know what is going on both at home and abroad can form an adequate idea of the competition which, in this respect alone, will prevail for a generation to come.

By the construction of new laboratories this material disadvantage will be removed. Future professors will have buildings constructed to aid research. Your liberality has spared no judicious expense; and, so far as the site would admit, our laboratories will be as perfect as the skill of our architect and the advice of our professors can make them.

In conclusion, let me lay before you what must still be done, in order that there may be earned for the new laboratories a reputation comparable with that which has hitherto proved both our glory and our support.

Our first and foremost object, beyond bricks and mortar, and money and apparatus, must be to find a succession of professors of the old type; men who love research. But even Faraday would perhaps have been compelled to leave us, on account of the smallness of the sum which we could afford him, had not the endowment of the chemical chair, with £100 a year, by the late Mr. Fuller, happily intervened. This timely endowment was probably a critical turning-point in the history of the institution. We may not easily find successors worthy of the great names who have gone before them; but we may do much toward preventing mistakes in future appointments by keeping steadily in view, that the promotion of natural knowledge is our main object; and that instruction and amusement, and brilliant audiences are all secondary to our principal purpose. Not that these subsidiary purposes are to be neglected or despised;—and I, as your treasurer, should be the last to undervalue them, but we feel confident that if the main purpose is effected, all the others will follow as a simple sequence.

Secondly, when we have found professors of the type that I have described, our next need is that we may be able, from independent resources at the disposal of the institution, to offer them a remuneration which, all things taken into account, shall be an equivalent to what they would receive elsewhere. So that neither Government appointments, nor University professorships, nor the liberality of mercantile men, should be able to lure them from the path of discovery, to tuition, to arts, or to manufactures.

The one act of wisdom, among the many aberrations of an eccentric member of Parliament, saved Faraday to us, and thereby, as seems probable, our institution to the country. The liberality of a Hebrew toy-dealer* in the East of London has made the rebuilding of our laboratories possible.

It is said that Mr. Fuller, the feebleness of whose constitution denied him at all other times and places the rest necessary for health, could always find repose and even quiet slumber amid the murmuring lectures of the Royal Institution; and that, in gratitude for the peaceful hours thus snatched from an otherwise restless life, he bequeathed to us his magnificent legacy of £10,000. If this evening's discourse shall have ensured one such blissful hour to any of his audience, your lecturer's efforts will not have been altogether in vain. But to each such happy individual he would express the hope that, as you have resembled Mr. Fuller in your experience of life, so may you emulate him in your liberality at death. In short, I would conclude almost in the words of old Bishop Andrews: Unum operæ meæ pretium abs te peto, hoc autem vehementer expeto, ut mei peccatoris meorumque in precibus interdum memor sis. Which being interpreted is:—

For these my efforts I beg but one thing in return, and this I beg most earnestly, *viz.* that you will now and then remember me a sinner against your patience and forbearance in your prayers, and that you will also be mindful of our professorships in your wills.

The following table of the principal items of original work done by our professors, taken in connection with their long series of laboratory notes, forms a monument of the intellectual activity, the manual dexterity, and the persevering industry, developed in the laboratories of the Royal Institution:—

Davy.

1806	Chemical Agencies of Electricity.
1807	Decomposition of Potash.
1810	Chlorine.
1812	Discourse on Radiant or Ethereal Matter.
1813	Iodine.
1815–6	Researches on Fire-damp and Flame.
1817	The Safety Lamp.

Faraday.

1820	Alloys of Steel.
1821	History of Electro-magnetism.
,,	Magnetic Rotations.
1823	Liquefaction of Chlorine and other Gases.
1825–6	New Compounds of Carbon and Hydrogen.
1825–9	Manufacture of Optical Glass.
1831	Vibrating Surfaces.
,,	Magneto-Electricity.
1832	Terrestrial Magneto-Electric Induction.
1833	Identity of Electricities.
1834	Electro-Chemical Decomposition.
,,	Electricity of the Voltaic Pile.
1835	The Extra Current.
1837–8	Frictional Electricity.
,,	Specific Inductive Capacity.
1845–8	Magnetization of Light.
,,	Lines of Magnetic Force.
,,	Magnetic Condition of all Matter.
,,	Diamagnetism.
,,	Magne-Crystallic Action.
1849–50	Magnetism of Flame and Gases.
,,	Atmospheric Magnetism.
1856	Relations of Gold and other Metals to Light.
1860	The Regelation of Ice.

* Mr. Alfred Davis, after paying his composition of sixty guineas, as a Member of the Institution, and three annual donations of twenty guineas for the promotion of research, at his death in 1870 bequeathed £2000 for the same purpose. His deafness prevented him from deriving any benefit from the lectures.

Tyndall.

1853	Transmission of Heat through Organic Substances.
1854	Vibrations due to Contact of Bodies at Different Temperatures.
1855	Researches on Diamagnetic Force.
1856	Slaty Cleavage.
1857-8	Physical Properties of Ice and Glaciers.
1859-63	Absorption and Radiation of Heat by Gases.
1865	Calorescence.
1866-7	Action of Heat of high Refrangibility.
1868-9	Formation of Clouds.
,,	Colour and Polarization of the Sky.
1870	Smoke and Dust Respirator.

Frankland.

1863-6	Synthesis of Acids of the Lactic Series.
1863	Mercury-methyl, Mercury-ethyl, and Mercury-amyl.
1864	Transformation of Organo-Mercury Compounds into Organo-Zinc Compounds.
,,	Combustion of Iron in Compressed Oxygen.
1865	Synthesis of Acids of the Acrylic Series.
,,	Synthesis of Fatty Acids.
1866	New Organic Radical Oxatyl.
,,	The Source of Muscular Power. Potential Energy in various kinds of Food.
1867	Source of Light in Flame. Effect of Pressure upon Luminosity of Flame.

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

The Juries Bill.

In moving the second reading of the Juries Bill on Monday night, the Attorney-General stated that, although he had introduced the Bill in exactly the same form in which it left the Select Committee, he should feel bound to take the sense of the House upon two points in which he differed from their decision. He considered that in every common jury there should be a definite proportion of higher educated men to that of what he might call less educated men. The other point was that he did not think it necessary to insist upon unanimity in juries as to their verdict except in cases of treason, treason-felony, and murder.

In the discussion which followed, the proposal in the Bill to reduce the number of jurors from twelve to seven, was opposed by Mr. Chambers, Mr. James, and Mr. Alderman Lawrence. Eventually the Bill was read a second time and set down for committee on Thursday, with the understanding that it should not come on, but that the Attorney-General should then fix a day which would meet the wishes of the House.

In the Bill, which has just been issued, the portion of the clause relating to the exemption of chemists and druggists reads as follows:—"Apothecaries certificated by the court of examiners of the Apothecaries' Company, dental surgeons certificated by the board of examiners in dental surgery of the Royal College of Surgeons in England, and all registered medical practitioners and registered chemists, if actually practising as apothecaries, dental surgeons, medical practitioners and registered chemists respectively."

Supposed Death of a Pharmaceutical Chemist from an Overdose of a Narcotic.

On Tuesday, February 11, an inquest was held at Carlisle, before Mr. J. Carrick, deputy coroner, on the body of Mr. William Moss, pharmaceutical chemist, fifty-three years of age. Mr. Thomas Moss, a son of the deceased, said he was called by his mother about a quarter to four on Sunday morning to see his father, who was then in bed breathing heavily. His father occasionally, though not habitually, took a dose of compound tincture of chloroform when out of health, but he never took more than a drachm. He complained of a pain in his side on Friday, but was in his usual health on Saturday and continued in the shop all day. He was depressed in mind during last week, but witness did not think that his mind was affected.

Mr. Herbert Page said that he saw the deceased at twenty minutes past four, at which time he was in a state of perfect insensibility, and all the other symptoms were such as to induce the belief that he was poisoned by opium. The stomach pump was tried, but he did not expect much result from that, as a sufficient time had evidently elapsed to allow the opium to pass through the stomach. Antidotes were used and every effort made to arouse Mr. Moss from his state of coma, but none of them made the slightest impression upon him. His breathing gradually became worse and at times stopped altogether, when artificial respiration was applied. Mr. Page stayed at the bedside till half-past seven, when he left, sending a message to Dr. Hay to replace him. He was called again before eleven, when Mr. Moss was dead. On Monday afternoon he made a *post-mortem* examination of the body. He found the brain, lungs, heart, liver, and kidneys all healthy, but extremely congested. There was no poison found in the stomach, and no trace either of opium or morphia was found in the fluid drawn from the stomach on Sunday morning, but, as he had said before, they could hardly expect that when they applied the pump.

The Deputy-Coroner: Can you form any opinion as to the cause of death?

Mr. Page: I believe it was caused by opium poison, both from the symptoms before death and from the *post-mortem* examination. The extreme congestion of the viscera and their perfect healthiness were such as we would find under those circumstances, and the death also would take place during coma.

A brief consultation then took place between the Coroner and the jury, the former suggesting that the verdict should be open.

The Foreman: From what I know of him he was not a man who would take poison intentionally.

The Coroner's suggestion was agreed to, and a verdict was returned that the deceased died from an overdose of opium or some other narcotic poison, but how it was taken there was no evidence to show.

The Sale of Poison in Ireland.

On Friday, February 14th, Agnes Munroe was charged at the Belfast Police Court with attempting to commit suicide by poison, and there was also a summons against Dr. George Smith, charging him with having sold poison without complying with the requirements of the Act of Parliament regulating the sale of poisons in Ireland.

It was deposed that the prisoner went to a neighbour's house after quarrelling with a companion, and was seen to drink something out of a small bottle, declaring her intention to poison herself. Another bottle was taken from her by force. The prisoner became very faint and ill, but afterwards recovered.

Head Constable Irwin produced the two bottles which were taken from the prisoner, one of which had not been opened at all, and contained stuff for destroying vermin. He could not produce any evidence to show what had been in the bottle out of which the prisoner took the draught.

Dr. Smith said that Dr. George Smith, against whom the summons was issued, was his son, and acted as his deputy in their Donegal Street establishment. His son could give evidence with regard to the sale, and he himself could give evidence as to what was in the bottle out of which the prisoner took the draught. The defendant had not a drop of poison in his establishment, nor did he ever keep what was strictly speaking poison, such as corrosive sublimate or chloroform; therefore, the draught could not be chloroform. He, some days ago, sent his son over a bottle of chloric ether, when preparing a cough mixture for a gentleman who called. The bottle remained with Dr. Geo. Smith, and the chloric ether which it contained was made up of one drachm of chloroform to twenty drachms of spirits of wine. The chloric ether was quite innocuous, and in the full bottle produced there would not be 1-19th part of a drachm; therefore, it was perfectly innocuous, and would be so even to a child. Chloric ether was not precluded under the schedule of the Act of Parliament, and the Act of Parliament did not speak of chloroform preparation in the same way that it did of the preparation of opium.

Dr. George Smith said that the prisoner bought both bottles of him, and said that she wanted to poison rats.

Dr. Smith said he did not know if the vermin destroyer would kill human beings or not, but he thought it might. It would require to be spread upon bread for rats, and it would have been very difficult to have taken it. Whether the chemicals in question came under the Act of Parliament or not, he would not allow any of them to be sold again without the proper and necessary caution. As to the vermin destroyer, it was sent through the country by the maker in London just as produced there.

The prisoner was discharged, and the explanation of Dr. Smith being deemed satisfactory, the case was not proceeded with.

Inquiry at Sheffield.

An inquest was held on Friday, February 14th, at Sheffield, upon the body of a young woman, who it was supposed had died from the result of attempting to procure abortion. It appeared from the evidence that three weeks since deceased, appearing to be unwell from a cold, medicine was obtained from Mr. Collier, druggist, of Sheffield Moor, who was attending her father. Mr. Collier then saw her every day until the previous Tuesday, when a medical gentleman was called in, but she died the same evening. There was proof that deceased had had a miscarriage. In a *post-mortem* examination no marks of violence were observed, and it was found that death had been caused by intro-peritonitis.

On behalf of Mr. Collier it was stated that he was ready to answer any question the jury might think proper to put to him.

The coroner said there was no complaint at all against Mr. Collier's treatment of the woman, and the jury thought it was not necessary to call Mr. Collier.

The coroner, in summing up, said he was glad the surgeons agreed as to the cause of the death, as at first the case looked a rather suspicious one. Now, however, there did not appear to be blame attaching to any person. The question did not come before them whether Mr. Collier was justified in setting himself up as a surgeon and attending persons who had fever, as Mr. Collier had done, and he should advise them to return a verdict in accordance with the medical testimony. Accordingly the jury returned a verdict "That deceased died from intro-peritonitis."

Alleged Acceleration of Death by a Cough Mixture.

An inquest was held at Grange, Ulverston, on Wednesday, the 29th ult., before Mr. Holden, coroner, upon the body of the infant son of a farm labourer.

Eleanor Booth deposed: Deceased was my child, and he was ten weeks old. He was a very healthy child, but last Thursday he had a little bit of a cold, and I went to the shop of Mr. Downward, the druggist, and I asked for something for the child's cough. A bottle was given to me by some one in the shop, containing some mixture. It was given to me by Mr. Herbert George Forbrooke. He told me to give the child a teaspoonful two or three times a day. On Thursday evening, about six o'clock, I gave the child the first teaspoonful. It slept all Thursday night and all day on Friday, and to about one o'clock on Saturday morning. I went up to its bed four or five times on Saturday to try to rouse it in order to feed it, but it just opened its eyes and went to sleep again. It went without the breast or any food the whole of Friday. From the time it awoke on the Saturday morning it sucked the whole time until I got up at five minutes to six. I then gave it another teaspoonful. It slept all day on Saturday, and until about twelve o'clock on Saturday night. About five I tried it with the breast, but it just gave a draw, and went to sleep again immediately. It was very cross on the Sunday morning, and between four and five o'clock I gave it another teaspoonful of the mixture. It slept until it died at two o'clock in the afternoon. I sent for Mr. Beardsley about half-past nine on Sunday morning. His son came first, and examined it, but did not treat it in any way. He ordered me to give it a little brandy and water, and I did so. About half-past one o'clock he came again with the assistant, and gave it a teaspoonful of some medicine that had previously been sent up. The child died while they were there. During the Friday its breathing was short, but natural. During the Saturday its breathing was noisy, and there was rattling on its chest. On Sunday morning its breathing was short and noisy, and for some time before it died I could hardly tell whether it was living or dead. It opened its eyes before its death, and I tried to see if it was sensible to my touch, but it was not. Its hands were clenched from shortly after it took its first dose of the mixture to the time of its death.

Herbert George Forbrooke, of Ulverston, deposed: I am an apprentice with Mr. Downward, druggist, and have been with him two years and two months. I do not remember Mrs. Booth coming to the shop on the Thursday named. The bottle produced came from our shop, judging from the label and the bottle. I did not compound the syrup. It is kept in a pint bottle in the shop, and given out in small quantities to the customers. Either Mr. Downward or his assistant would make up the mixture. The pint bottle at present in use would be made up on Friday or Saturday week—the week before last Saturday. Looking at the mixture in the bottle, and judging from the colour of it, I would not give it to any customer for a child ten weeks old—if I knew what I was doing.

At the conclusion of this witness's testimony, the Coroner decided to adjourn the inquest till Friday, for the production of further evidence.

The inquiry was resumed on Friday last, when

Mr. C. H. Downward gave evidence as to the nature of the cough mixture sold at the shop of Mr. John Downward. Amongst other ingredients were two ounces of the syrup of poppies.

Dr. Lowther, of Cartmel, said he had made a *post-mortem* examination of the body. He ascribed death to congestion of the lungs with attendant congestion of the brain, which he said in all probability arose from natural causes, accelerated by the mixture administered, the dose being larger than ought to have been given to a child only ten weeks old.

Verdict accordingly.

Poisoning an Hospital Patient by Mistake.

On Saturday, February 15th, Mr. Bedford held an inquest at St. George's Hospital, touching the death of Mary Geary, aged 40 years, who died at the hospital on Thursday morning, from the effects of a dose of carbolic acid, administered to her in mistake for senna by Sarah How, a nurse in the hospital. Mary Keefe identified the body as that of her mother, whose husband is at present abroad.

Harriet Bord, nurse, said she had charge of the ward in which deceased lay. It was part of her duty to administer and to order the administering of medicines under the direction of the head nurse. On the morning of the 13th, when nurse How came to give her report, she inquired whether the draught of senna ordered for the deceased had been administered. How said she had forgotten it, but would administer it immediately. She went into the ward for that purpose, but returned in about a minute, crying excitedly, "Come, I have given the patient carbolic acid." Witness at once hurried to the ward, and ordered some warm water with salt in it, which was brought immediately, but they could not succeed in making deceased swallow it. In the meantime she summoned Mr. Brabant, the resident physician, who arrived in a few minutes. He ordered an emetic and about an ounce of olive oil, the greater portion of which was swallowed by deceased. Dr. Barclay came in soon afterwards, and by his orders the stomach-pump was applied repeatedly, but without effect, and deceased gradually sank, dying at five minutes to ten.

By the Coroner: The medicines are kept in a cupboard in the wall, the carbolic acid being generally placed at the bottom. All the bottles were labelled. Nurse How had 24 patients to attend to. She had been up all night, her hours on duty being from 9.30 p.m. to 9.30 a.m. Should certainly say that nurse How was sober.

Louisa Taylor, another of the nurses, said that she filled both bottles on Wednesday. They were exactly alike, but had each a proper label. (The bottles were then produced; they were precisely similar in make and as to the colour of the contents.)

Sarah How, the implicated nurse, having been duly cautioned, then volunteered a statement on oath to the effect that she found the bottle on the window-ledge above the cupboard, which was a usual place for medicines, but a very unusual place for carbolic acid to be kept. It unfortunately never occurred to her to doubt that the bottle contained senna. She poured out a measure for the deceased, who drank off a portion of the liquid, and then stopped suddenly; upon which she examined the bottle carefully and found the contents to be carbolic acid.

Mr. Todd, secretary to the institution, admitted that bottles of carbolic acid were left lying about in the manner described, but added that the authorities expected the nurses carefully to examine the labels.

The Coroner, having summed up the evidence, the jury, after some deliberation, returned a verdict exonerating the nurse from criminal neglect, at the same time strongly censuring the hospital authorities. The verdict was received with some applause.

The Coroner suggested that carbolic acid should be kept in strong stone bottles, which could be readily distinguished from those containing medicine.—*Standard.*

Poisoning by Essence of Bitter Almonds.

The Wandsworth and Battersea District Times states that on Monday, February 10th, an inquest was held at Battersea on the body of a woman who had died the previous Friday from the effects of essence of bitter almonds, taken while in an unsound state of mind. It was proved that deceased had previously threatened to commit suicide, and a verdict in accordance with the evidence was returned.

Poisoning by Spirit of Salt.

On Saturday, February 15, an inquest was held at the North Riding Pauper Lunatic Asylum on a patient who had drunk some spirit of salt which he found in a tinner's shop on the premises during the absence of the man in charge. Medical assistance was obtained and the stomach pump used, but the patient died a few hours afterwards. It was stated that the deceased was not a suicidal patient, but would eat or drink almost anything that came in his way. A verdict of accidentally poisoned was returned, and the man who had left the poison accessible was cautioned.

Suicide by Vermin Killer.

A case is reported from Driffield in which a young girl aged twelve years committed suicide by taking some Battle's Vermin Killer that had been purchased by her mother. From the evidence it appeared that the child assigned as a reason that she had been beaten by her mother, but there does not appear to have been any cruelty exercised. A verdict was returned accordingly.

Obituary.

WILLIAM MOSS.

On Sunday the 9th inst., Mr. William Moss, Pharmaceutical Chemist, English Street, Carlisle, died suddenly at the age of 53 years. Mr. Moss was the local secretary of the Pharmaceutical Society for that city, and much respected by his brother tradesmen and friends. He was always anxious and desirous of advancing the interests of pharmacy, as instanced by his exertions as local secretary, and also as honorary secretary of the recently formed Carlisle Chemists' Association. In connection with the latter, he undertook to conduct classes in materia medica and botany, but his labours, we regret to say, have been cut short by an untimely death under the distressing circumstances recorded in another column.

Notice has also been received of the death of the following:—

On the 18th February, 1873, Mr. David Russell, Chemist and Druggist, of Dundee. Mr. Russell was one of the Vice-Presidents of the British Pharmaceutical Conference on the occasion of its visit to Dundee in 1867, and exerted himself energetically to secure the success of the meeting.

On the 2nd January, 1873, Mr. Henry Jenkin Bennetts, Chemist and Druggist, of Helston, Cornwall.

Reviews.

A Handbook of Chemical Technology. By Rudolf Wagner, Ph.D., Professor of Chemical Technology at the University of Würtzburg. Translated by William Crookes, F.R.S. J. and A. Churchill.

So much has been said and written lately on the subject of technical education in England, and so many fears have been expressed of our being beaten in the race for commercial pre-eminence by our continental rivals, that the appearance of an English translation of Wagner's Chemical Technology is sure to create considerable interest. English literature is indeed not deficient in excellent works on technology, but, considering the enormously rapid development of applied science at the present day, it is obvious that a very few years are sufficient to render the best treatises on such subjects practically obsolete.

To a certain extent, general works on technology must always be behind the time, since they can only deal with those processes which have been patented or otherwise published by their inventors, and, in a vast number of cases, manufacturers find it more profitable to keep secret the methods of which they have become possessed by experimental investigation, and which give them an advantage over competitors. And even in other cases, a considerable interval must, of course, elapse between the original publication of new inventions and their incorporation in a work of this kind. To take an instance for the purpose of illustrating our remarks: a few years ago the art of dyeing underwent an extensive revolution, owing to the introduction of the coal-tar colours. Many dye stuffs which up to that time had been largely employed suddenly became practically useless, since they were unable to compete with the far finer aniline colours, to the use of which, moreover, fashion gave an enormous impetus. Now it is self-evident that no consumer of these articles could have afforded to neglect the study of them until such time as a complete treatise on the subject should be produced. It would be only in proportion to his avidity in seizing the earliest opportunities of obtaining information, that he would be able to keep his position at all under the severe strain of competition to which every manufacture is at the present day exposed. But this is not all; every manufacturer knows that a laborious attention to the most minute details of his operations is an essential element of success. Now, in a general work on technology, details are almost necessarily omitted; the reasons being, first, want of space; and, secondly, the fact that, as a rule, it is only those who have the practical conduct of the operations who can at all appreciate their practical difficulties. Indeed, so much is this the case that many processes proposed by men eminent in pure science, and apparently perfect both on paper and in the laboratory, have, when attempted on a manufacturing scale, been found so beset with difficulties that they have either been abandoned altogether, or have lain in abeyance till some one combining practical skill with theoretical knowledge (a rare combination by the way) has taken them up and succeeded in overcoming the obstacles. A third objection to such manuals is that to every manufacturer the bulk of their contents will be utterly irrelevant. An iron master does not require information upon brewing, or a tanner upon the making of gunpowder.

These remarks, while applying to technological works in general, are specially applicable to the book before us. Written by a professor of chemistry in a German university, it is impossible to assume a practical acquaintance with many of the branches with which it deals. Indeed, it is hardly surprising that the subjects should be treated very superficially considering the large extent of ground which has been enclosed. This will, perhaps, be best seen from a very brief summary of its contents. The first division consists of chemical metallurgy, and includes the various methods of obtaining and applying the metals,—iron, steel, cobalt, nickel, copper, lead, tin, bismuth, zinc, cadmium, antimony, arsenic, mercury, platinum, silver, gold, manganese, aluminium, and magnesium, with most of their commoner compounds, and a short section on electrometallurgy. The second division treats of the alkalies, acids, and non-metallic bodies, explosive compounds, etc. The third division,—glass, porcelain, pottery, bricks, mortar, and cements. The fourth,—vegetable substances, fibres, paper, starch, sugar (cane, beet, and grape), fermented liquids, bread, vinegar, wood, tobacco, essential oils, and resins. The fifth,—animal substances, silk, wool, leather, glue, phosphorus and lucifer matches, animal charcoal, milk, and meat. The sixth,—dyeing and calico printing, including the manufacture of the coal-tar colours. The seventh,—artificial illumination. The eighth,—fuel and heating apparatus.

This has been crammed (for we can use no other word) into a book of 745 pages; it need hardly, therefore, be a matter of surprise that the omissions are both numerous and important. A great deal more might, however, have been done to increase the value of the work if old and superseded processes had been omitted and replaced when possible by more modern ones. For instance, the space occupied by the mention of Heaton steel, the production of which has, we believe, been entirely unsuccessful, might have been more profitably used for a description of the Danks' puddling furnace, the use of which bids fair to revolutionize the manufacture of wrought iron; and Miller's admirable chlorine process for toughening gold certainly deserved more mention than two lines, while the obsolete methods of refining by antimony or sulphur occupy ten times as much.

This, however, is not the only fault in the book. The omission of details and processes may diminish its value, but actual errors are a more serious matter. A few only out of many can be mentioned. In the description of the Bessemer process, on p. 28 (a very short one considering the importance of the subject), first, "egg-shaped vessels made of boiler plate converters" is rather unintelligible; then, we never saw a converter with "five $\frac{3}{4}$ inch wide fire-clay tubes projecting through the bottom," generally, at least twenty tuyères are used, each of them pierced by numerous channels; thirdly, the apparatus is *not* (in England at least) placed in close proximity to a blast furnace, but the pig iron, which is generally analysed previously, is melted in a cupola before running into the converter; fourthly, there is no fire-clay plug in an aperture at the bottom of the converter, the iron being poured out at the mouth when the operation is finished.

Another instance, p. 112. We think any student would be puzzled by the following sentence and equation:—

"α. By the fusion of the potassium manganate and chloride of potassium—

$$\text{“}6\,MnO_2 + 2\,KClO_3 + 12\,KOH = (3\,K_2MnO_4) + KCl + 6\,H_2O.\text{”}$$

Or, again, p. 91:—

$$\text{“}Mg\,Cl_2 + Hg\,O = HCl + MgO.\text{”}$$

Numerous instances of this sort of thing might easily be pointed out. In fact, nothing so conspicuously indicates carelessness in editing as errors and misprints in formulæ. They are just the points which do not catch the eye on a hurried perusal, and for that very reason require to have more attention directed to them. We do not know how far the original is defective in this respect, but the translation evinces a serious want of that care which a scientific work, above all others, needs.

Whilst on the subject of the defects in the work, we may mention a few more. One is the almost entire absence of references to original sources of information, which is the more to be regretted as a considerable proportion of the book is evidently compiled from original publications. Another is the not unfrequent employment of unusual or little known technical terms without explaining them. The term "abraum salts," on p. 119, will puzzle a good many people.

But we must not be understood to condemn the book completely. Although we certainly consider that the hope expressed in the preface, that it will merit the confidence of the manufacturer and student, has not been fulfilled, yet there is a large class of readers who require information on technical subjects without any intention of making a direct and practical use of it. Science is every day becoming more and more incorporated with our ordinary life, so that in one way or another every one is brought more or less directly into contact with it. A work of this kind places within the reach of unscientific people a very fair knowledge of the manufactures to which they owe a considerable portion of their comforts and luxuries, and enables them better to appreciate any processes with which they may incidentally meet. The amount of information in its closely printed pages is as large as it is varied, and the 336 woodcuts are, as a rule, well drawn, and sufficiently accurate to illustrate the descriptions in the text; indeed, many of them have the appearance of having been drawn from the apparatus itself, instead of being, as is too often the case, mere fancy sketches.

In conclusion, the labour of compiling so highly condensed a treatise must have been very considerable, and probably the attempt to do too much is the principal reason why it has not been done better. If the author could be induced to rewrite it, and make it into five or six volumes of the same size, there is no doubt that it might become a really valuable work.

Health and Comfort in House Building. By J. Drysdale, M.D., and J. W. Hayward, M.D. London: E. & F. N. Spon. 1872.

The system of ventilation set forth in this volume of 114 pages is based upon the assumption that in *our* climate no direct admittance of external air can be made bearable for the major part of the year; that the fire-grates of our rooms can never act efficiently for both heating and ventilating the rooms, although some patterns, Galton's for instance, come very close upon effecting this; that no plans of ventilation for single rooms can supersede the necessity of one general plan for the whole house; that separate inlet and outlet openings are indispensable; that the primary inlet of air should be arranged at one place only and be large enough to transmit a supply sufficient to meet the strain of extra inmates (any excess of inflowing air in ordinary times being reducible by valves); that the incoming air should be warmed—say in the basement of the central hall; that this central hall or corridor should form the reservoir of freshly warmed air, and that the doors of all the rooms, offices excluded, should open out of this; that the fresh warm air out of this hall should be conducted into the rooms just below the cornice; that the vitiated air should be led by outlets in the ceiling of every room into one foul air chamber situated above the ceiling of the uppermost room, and, in order to obtain a regular suction, by a downcast shaft down to below the kitchen fireplace, and so up behind the fire there to a main upcast shaft in the kitchen chimney.

We will shortly describe a house in which this system is carried out. In a chamber below the staircase, containing coils of hot-water pipes—low pressure by the way—the fresh air is admitted, and one branch of these pipes leads round the skirting of the saloon out of which the reception rooms open, whilst another heats the conservatory and passage. The warming apparatus is a boiler heated by coke or gas, and the fresh air for combustion is supplied direct from the external atmosphere. The saloon is in this case made the chief reservoir of fresh warm air, and partly from this and from the staircase the air is admitted into the rooms, either by openings near the cornices, as in the case of the living rooms, or through gratings formed in the architrave lintels as in the case of the bedrooms.

The foul air is led from behind the ceiling ornament through a zinc tube between the joists into a foul air chamber, constructed of zinc, of about six feet diameter by five feet high, made thoroughly air tight, and into this chamber each room leads by a separate tube. The chamber which collects the foul air communicates in a duplicate manner with the bottom of the exhaust shaft in the kitchen chimney, and the vitiated air finds an exit below the coping of the chimney. The section of this exhaust shaft resembles the now stereotyped circular flue inside a square one, the corners outside the circle forming the foul air shaft, and obtaining its heat from the smoke flue inside.

One might naturally ask how the freshly warmed air in the hall, the saloon, or the passage which forms the chief reservoir is to be kept sweet and free from contamination, and so made equal in purity to the air which in an ordinary house is admitted by the open doors or windows, louvres or air-bricks. This is effected by placing the inlet where the air is purest, close to the basement walls. Or, it is done by leading down the fresh air from the level of the top of the house as likeliest to be least loaded with dust and blacks. *Query*, how would this work when the house drain and the soil pipes were all ventilated to the top of the house? A proper condition of atmosphere in the hall is also obtained by leading into the foul air flues and so on to the foul air chamber and down the siphon and eventually up the kitchen flue, all the products of gas combustion, all tobacco fumes, water-closet effluvia and so on. The servants' rooms especially are shut off from ordinary connection with the best rooms, and what is equally important the kitchen smells are withdrawn from their neighbourhood.

We admit that here is an almost perfect system of ventilation, and there can be no doubt that *if it were carefully carried out* the whole house could be replenished with even more fresh air than the conventional three times every hour. It is not attempted to necessarily warm the house by means of heated air, on the contrary, open fire places are recommended to be constructed in the corners of the rooms, and the incoming air heated only to about 65°, or sufficient to suit the requirements of ventilation. It is not a scheme which comes before one laboriously set to the tune of "Buy a broom which shall sweep all other ideas clean away." It is rather an auxiliary system, and does not even disdain the assistance of the now common ventilating globe lights, which are so constructed as to remove the carbonic acid, etc., generated around the burner on through separate tubes into its own foul air flues. If it suggest a fault, it is because the condition of pure comfort and perfect healthfulness is dependent, especially in winter, upon the direct superintendence of the owner, or the supervision of, *alas!* the servants, according as the varying weather, the wind, or the atmospheric pressure makes such attention necessary. Some one must govern the warming apparatus in proportion to the coldness, attend to the valves which regulate the current according to the number of indwellers, know how to occasionally isolate rooms, and how to divert the bulk of the fresh warmed air into certain other rooms occasionally—as, for instance, into bedrooms during a severe winter. But despite all this, there is no doubt whatever that, *if* the size of the primary air inlet in the outer wall be *properly* calculated, the area of the downcast shaft from the foul air chamber *carefully* computed, and the withdrawing capacity of the ultimate upcast shaft *accurately* arrived at,—a house built upon this principle can be made very comfortable indeed. And without doubt a house constructed with inlet and outlet shafts in this way, if not realizing spontaneous or automatic ventilation, *might* soon come to be understood by a responsible servant, and the sliding of the air bricks, which adjusted the inflowing and outflowing of the air fairly averaged by him or her. And we may here say that the application of this plan of ventilation is not necessarily confined to houses or blocks of houses, but can be made suitable for offices, churches, and other large buildings. In the latter cases, the chimney from the heating apparatus would have to contain the suction shaft. Besides, too, a special fire here all the year round, the upcast shaft might require the rarefaction yielded by a few gasburners.

We have entered into the plan of Messrs. Drysdale and Hayward at some length, for it deserves a fair explanation at our hands, holding as we do that hygiene is more a branch of medicine than of architecture, strictly so called. Whether architects will take kindly to the plan evolved will be due entirely to the amount of pressure put upon them by the building proprietors. An architect is very much like a merchant tailor, who will fashion a piece of cloth either into a cloak or a paletôt just as he is instructed. Some there are who will not be influenced by extraneous pressure, and it would be only one of this calibre who dared on all occasions adhere to so gigantic a subversion of what has gone before. The majority will declare, as David declared of the fine armour offered him, that they have not proved it, and go on preferring the old sling and the pebbles from the brook. There is one section of this work for which all architects will be grateful to the authors, and that is the appendix, wherein are some excellent formulæ for calculating the draughts in hot air flues, and also a ready reckoner of velocities.

A Digest of the Statutes Relating to the Public Health; for the use of Members of Urban Sanitary Authorities. By George F. Chambers, F.R.A.S. London: Stevens and Sons.

This work is very well designed, and the legal contents appear to be all that could be desired as far as they go. They deal only with the *urban* side of the question; the rural sanitary authorities having yet to be taught their lesson in a promised digest of similar design.

The legal contents of the present work are so condensed that they give little more information—though enough for the purpose—than a well-arranged index itself would do, though, to make them available, an index is indispensable. In the present case, the index is very imperfect; for instance, the word "Sewage" does not appear in the index at all, nor does "Irrigation," although sewage farming means nothing else; and every urban sanitary authority is now considering this mode of utilization in some shape or other. With a carefully devised index, Mr. Chambers's 'Digest' will become a "handy" work; but it is essential that the rural portion should be dealt with at the same time, and that the promised instructions of the Local Government Board should be attached.

Mr. Chambers has done enough to give him precedence of other writers, who take the great subject of public health legislation in hand, to instruct members of Boards of Health and Boards of Guardians and the numberless officers who will take part in local administration.

Notes and Queries.

[329.]—LIQ. AMMONIAT. VALERIANÆ.—Probably the preparation intended in your correspondent's prescription was that made by Mr. Bastick. A prescription was brought to me some time since in which Sol. Ammon. Valerian. was ordered, and after an unsuccessful attempt to ascertain the proper dose, I used Mr. Bastick's preparation, which is an expensive one, and charged accordingly. Proprietors of such articels would save us a vast amount of trouble and anxiety by adding the usual dose on the labels of their specialities. —H. D. W.

[331.]—YELLOW FLUID FOR CARBOY.—W. R. F. would be glad to be favoured with a formula for preparing a good permanent golden-yellow coloured water for a window carboy.

[*** The following recipes are given in Cooley's Cyclopædia;—(1) $\frac{1}{2}$ lb. of sesquioxide of iron dissolved in a quart of hydrochloric acid, and diluted with water. (2) A solution of equal parts of nitre and chromate or bichromate of potash in water. Filter through glass.—Ed. Pharm. Journ.]

ADULTERATION OF DRUGS IN AMERICA.—Mr. Richard F. Mattison, of Philadelphia, states (Amer. Journ. of Pharm. [4] iii. 13) that having had some supposed heavy magnesia returned to him by customers who complained of its unusual taste, it was submitted to analysis by Professor Maisch and found to be mixed with Rochelle salt. A correspondent of the *American Chemist* also states that he recently found 77 per. cent. of alum in some supposed cream of tartar which he recently examined for a drug broker.

BISMUTH OINTMENT.—An ointment containing bismuth in the proportion of half a drachm of the subnitrate to the ounce of simple ointment, rubbed up with a little spirits of wine, is recommended by a correspondent of the *Medical Times and Gazette*, as giving great relief when applied freely to the skin to allay itching and irritation in chronic eczema and other forms of skin disease. Dr. McCall Anderson, to whom the suggestion was originally due, observes that the ointment must not be made with benzoated lard or the reverse of a soothing effect may be produced.

FLAVOURING OF INVALID DIET.—A correspondent of the *Medical Times and Gazette* refers to the importance of knowing how to flavour a sick person's food, so as to make him eat it with relish, which is often wanting where even well prepared beef-tea has been long taken. He says, "I have often found that the addition of some vegetable flavouring matter has enabled the patient to resume his food with relish. I do not mean that the vegetable food is to be swallowed; but after being strained off the broth retains its flavour. The use of burnt onions among all classes of cooks is well known; and though I am not prepared to advocate the use of such a robust vegetable, there are others equally accessible and more delicate. Chief among these is celery, which during a certain portion of the year may be used bodily, but during certain seasons it cannot. For this reason I am in the way of using from time to time small quantities of celery seed, which may be easily procured. A very small proportion of the seed added to the beef-tea gives to it a totally different flavour from the insipid mawkish taste it often possesses, and I have been rewarded by seeing patients turn to their food when so seasoned with a zest they had long ceased to exhibit.

Correspondence.

The School of Pharmacy.

Sir,—An article appeared in this month's issue of the 'Chemist and Druggist' which would seem to convey the impression that everything connected with the School of Pharmacy at 17, Bloomsbury Square, is in a disgraceful condition, and that the students themselves are grossly neglected. A reply addressed to the editor of the *Chemist and Druggist* could not appear without considerable delay, and, therefore, I should feel obliged by your allowing the following to appear in your columns. As I am *now* working in the laboratory, I think I may be allowed, as well as "one who *has been* there," to make a statement concerning the present state of affairs.

This morning I made a sort of canvass of the students at present working in the laboratory in order to obtain their opinions. I am glad to say that in no case did a student consider he was neglected, but each agreed that if he were in any difficulty, by applying either to the Director or his assistants during their visits, or when at their desks, he always received a most courteous reply and a full explanation.

From a number of twenty-five to whom I mentioned the subject, there were three who complained that they were not pushed on sufficiently, but this differs materially from neglect, for I contend that the student who, after proper direction, is left to work for himself, is much more likely to succeed than one who has knowledge continually thrust upon him.

Sydney Plowman.

17, *Bloomsbury Square, February* 20*th*, 1873.

The Admission of Outsiders.

Sir,—Though what is called an "outsider," yet as an old druggist, having been apprenticed 44 years ago, I have been often amused in reading what has been said on several occasions on the subject of admitting outsiders as members of the Pharmaceutical Society, and the fee to be charged. I notice that in discussing this question, invariably both speakers and writers assume that it is a very great privilege to be such a member—that by becoming such, a man is put into possession of some very great advantage. Hence at the last meeting of the Council, Mr. Shaw asked, whilst a member who had fallen into arrears had to pay five guineas in order to be reinstated, "what justice was there in admitting another man on payment of one guinea only?" And the President "did not think it would be just to those who had paid two guineas to reduce the entrance fee to new comers."

Will you allow me very civilly and most respectfully to ask, except the very shadowy privilege of voting once a year for a few gentlemen of whom you know little or nothing, what advantage accrues to an outsider on becoming a member of the Society? What is there to make a man ardently desire such a thing? In answer to this question I was once told that in return for a yearly subscription of a guinea I should receive the Journal; in answer to which I replied that as it was I received it for 17*s.* 4*d.* a year.

I seriously ask, is it not much more to the advantage of the Society to receive the outsiders, than to that of the outsiders to receive the Society?

An Old Druggist.

The Preliminary Examinations.

Sir,—The indignation so warmly expressed by Mr. Whitfield in his letter in the Journal may be perfectly justifiable so far as he personally is concerned, as also a great many others who honestly do their duty. But Mr. Whitfield may rest assured it is not universally so with all local secretaries. From what I have heard any amount of cribbing can be done. At the same time, I should deeply regret to see a bye-law passed that would necessitate all future candidates to go to London for this purpose, and I should consider it a point deserving the strongest opposition of the whole trade.

F. M. Rimmington.

Bradford, February 15*th*, 1873.

Sir,—Respecting Mr. Whitfield's letter in the Journal of the 15th, it is obvious that he cannot be held responsible for the failings of his colleagues in office; neither can his virtues be imputed to them. I should be sorry to bring a sweeping charge against local secretaries in general; but I should wish to put some personal questions to a youth, as to the manner in which his Preliminary examination had been conducted, before signing his indentures. Only a few days since, a friend was conversing with me about the unsatisfactory manner in which two examinations attended by his apprentices had been conducted. There had been no supervision, the candidates helped one another as they listed; nor was there any safeguard against the introduction of crutches for the lame in the shape of ready-made translations and sundry useful "keys." Local secretaries are sometimes appointed for their long standing and the general esteem in which they are held as townsmen rather than for any special qualification for the office, or for any zeal they have manifested in the cause of pharmacy. They have probably been consulted by the parents of the candidates, and are unwilling to be thought harsh or severe. They are too good-natured to place obstacles on the threshold of a calling to which youths aspire; and so by the manifestation of mistaken kindness in the form of leniency at the outset, apprentices enter the trade with false views of the stringency and importance of examinations; they get a false start, and after toiling halfway up the hill, they abandon the task in despair, having lost two or three of the most valuable years of their life.

In these days a journey to London is no great undertaking. But if it is considered impracticable, might not special examiners attend at half-a-dozen provincial centres, at stated periods, to conduct the "Preliminary"?

In such a connection it would be invidious to mention names or places, from which unjust inferences might be drawn against individual secretaries.

Henricus.

February 17*th*, 1873.

Sir,—As the Preliminary examination is now attracting attention, allow me to state an instance which has come under my notice:—A local secretary and pharmaceutical chemist conducted the examination of his apprentice and another young man; he, not keeping an assistant, was obliged to leave them by themselves, in order to attend to some customers; they expecting this, had some books at hand. Of course they both passed.

An Associate.

Pharmaceutical Women.

Sir,—Before the admission of ladies to the privileges and membership of our Society, I think it only fair and just that the rising generation of chemists should be permitted to give their views on this important subject; or that we should be represented in the Council by one of ourselves, in order that we may have some voice in a matter that will principally affect us in the future.

It appears to me that the present position of chemists' assistants is far from being an enviable one; and that our salaries are not so high, that we can afford to have ladies enter into opposition to us, especially as it is a well-known fact that women are paid at a smaller rate than men, and their establishment would certainly tend to lessen our own too small pay, and must ultimately lead to the absence of good men from the Society.

I think with others our field of competition is quite large enough, and the admission of women would damage the profession, and more than is at present understood or even thought of. The present aspect of the Pharmaceutical Society, that an assistant ought to look forward to as a means of ascending a little higher "the tree of knowledge," has commenced to give him a shadow of hope for the future, and this would I think be too great a concession.

I trust that this matter will be taken up by abler hands than mine, and gain the support it most certainly ought from the ones most concerned.

"Pharm. Brit."

London, February 18*th*, 1873.

A Valentine.

To the President, Vice-president, and Council of the Royal Pharmaceutical Society of Great Britain.

"O, woman! . . . . .
"When pain and anguish wring the brow
"A ministering angel thou!"

Ye gentlemen of England so loyal, free, and grand,
Who in the realms of "Pharmacy" have gained the foremost stand,
A "young man from the country," with reverence would draw near
And seek permission, if you please, to whisper in your ear.
'The Journal' hints that you have held a long and warm debate;
Yea, more—that what with "pros" and "cons" you kept it up till late;—
Your lovely wives and daughters, too, I'm sure would all feel sad,
When you got home at last and said what a "stormy day" you'd had.
And, O! methinks they'd almost weep when you with feverish brow
Began to say that *they* had been the cause of all the row!
And each one to her partner dear—or fond Papa—would say,
"Do tell me quickly! tell me, love, how *we* have caused this fray?"
"I'm glad at least that *you* were there—with true and noble heart—
"For like a freeborn Englishman *you'd* take the women's part;
"*You'd* ne'er consent that we should be the slave of any man—
"But seek to help us all to *gain* and *do* what good we can."

Well, gentlemen, if this be true, why should you still delay
To grant the privilege they seek, until the month of May?
If they desire to learn the art which soothes our pain and woe,
You surely will not close your door and coldly answer "*No.*"
If by the bedside of the sick they watch with sleepless care
And tenderly administer the medicines you prepare,
Methinks it cannot be a sin—if they desire to try—
To let them learn to *mix* the drugs, as well as you or I;
The only fear is lest they should surpass us by-and-by!
But now that they have once begun, I'm sure they won't be still;
What man on earth could ever turn a woman's steadfast will?
That they have good abilities was proved last month by *three*,
Especially by *one* who stood the highest on the tree!
A "Royal charter" you've obtained, and published certain rules,
But none of these, I think, excludes the *Women* from our schools.
If they obey the law laid down, we cannot keep them out,
And, O! they're wide enough awake to know what they're about.
Be gallant, just, and graceful, then—let prejudice give way—
Admit them freely to your ranks, nor wait another day.
Come, then, most noble "President," let them beside you stand;
The "Vice," I'm sure, will proudly join and help with generous hand.
Had but your final "casting vote" been given the *other* way,
Some dozen fragrant Valentines you might have had to-day!

W. B.

A.-u.-L., February 14*th*, 1873.

Passing the Examinations.

Sir,—I trouble you with the following, in the hope that it will diminish the number of trifling communications you receive upon the subject of preparing for the examinations.

I was recently much astonished on looking over the list of those who had passed the Minor examination, to see the name of a gentleman with whom I am acquainted. Only sixteen months ago we were behind the counter together, I having passed my apprenticeship with him as assistant. I, therefore, know something of his capabilities. At that time he was complaining (as many are now) of the hardship of passing that examination. He had had little or no education to assist him in his vocation, small pecuniary means, and was rather inclined to give up and despond; but by a good stern resolution and patient industry, he has in the few months mentioned, overcome those so-called hardships and become *victor*, even with "honours."

I really think if some of those who occupy their time so much in writing to the Journal were, after reading the above, to put their "shoulder to the wheel," they would soon find their difficulty to disappear.

Geo. F. H. Bartlett.

Cirencester, January 31*st*, 1873.

E. W. B.—It is unlawful for any person not registered under the Pharmacy Act, 1868, to sell poisons or to keep open shop for retailing, dispensing, or compounding poisons; and it is equally unlawful for such unregistered persons to carry on the business of a chemist and druggist if they employ a registered chemist to manage for them. See Pharmacy Act, Clause I., also Clause XV., for the penalties attaching to infringements of the law, and Clause XVI. for the exemptions.

R. Rawlinson.—Several assumptions in your letter are, to say the least, open to question, and therefore until you furnish something like tangible evidence in their support we must decline to give currency to the remarks based upon them. In the first place, the Registrar's report does not show a decrease in the number of members. It is true that there is a slight decrease in the number of pharmaceutical chemist members, but this is due rather to the small number of men who pass the Major, than to any disinclination to join the Society, for the increase in the chemist and druggist members is more than double the decrease in the other section, while there is also a very much larger increase in the number of associates in business, who are to be regarded as members as far as it is likely the great majority of those belonging to the Society could ever expect to enjoy all the fruits of membership. As to the examinations, we are at a loss to guess from whom you learned that your friend was plucked, although he had obtained one hundred marks more than were necessary. Was it from the supposed delinquent examiner? For our own part we hope your apparent fear that by the time you have passed the "Major" the Pharmaceutical Society will be on the point of disruption will not turn out to be true. At any rate, should the events prove to be synchronous, you will still preserve the knowledge to acquire which we presume is the primary object of your study.

"*Rogdon.*"—If you will read the report of the discussion upon the subject, printed on pp. 634–636, you will find that the third paragraph of the proposed alteration in section 10, clause 16 of the bye-laws, by which Preliminary examinations would have ceased in all places except London and Edinburgh, was rejected. Therefore as the presumed occasion for your strictures does not exist, we do not think it necessary to publish your letter.

W. Booth.—Perhaps you would find what you require in Maunder's 'Treasury of Botany,' edited by Lindley and Moore, and published by Messrs. Longmans, in two parts, 12s., cloth.

E. B.—*Mentha sativa*, or common mint.

"*Spes.*"—(1) You might obtain the information at Apothecaries' Hall. (2) Apply to the Secretary of the Pharmaceutical Society for a copy of a pamphlet entitled 'Hints to Students.'

S. A. Pring.—There is no restriction as to when, where, or how a candidate for examination shall acquire his knowledge.

W. G. B.—It does not come within the wording of the Act, but inasmuch as it is a very dangerous poison, it would be desirable in the interests both of the seller and the public to observe every possible precaution in the sale of it.

"*Two Inquirers.*"—Put the syrup into the bottle, add first the tincture of benzoin, then the oil of cubebs, and lastly the copaiba. Add the camphor mixture gradually.

M. P. S. writes in reference to requests which are sometimes made to chemists and druggists by their customers that they would translate and write prescriptions. He suggests that such a practice should be strenuously resisted as unjust to the person who wrote the original prescription, and suicidal on the part of the chemist and druggist.

Communications, Letters, etc., have been received from Messrs. J. F. Barrett, J. Roberts, H. Rogerson, E. J. Bishop, G. W., C. D., H. D. H., "An Assistant," and "Apprentice."

B. B. and "A Chemical Student" are referred to the rule respecting anonymous communications.

THE COLOUR OF THE WING CASES OF CANTHARIDES.

BY HENRY POCKLINGTON.

As every one knows who has read the B. P. description, *Cantharis vesicatoria* is furnished "with two wing-covers of a shining metallic green colour." This characteristic holds good only when dried insects are looked at in a certain way, for it happens, as perhaps many readers know, that by properly managing matters it is possible to see these wing-cases of almost any colour. For instance, if one be examined by lamplight, the colour varies very sensibly as the positions of the lamp or wing-case are varied with respect to each other. These variations are much intensified when a wing-case is immersed in alcohol or carbon bisulphide in a narrow test-tube, and the test-tube containing the case held so that the lamp is between, but in a line or nearly so, with the eye, the colour appears no longer green but a rich golden copper. Slightly varying the position of the tube, the colour changes to a more decided yellow, and quickly to green. Again changing the position, the colour appears to be a beautiful blue, and then a purple. A peculiarity of shade in these last colours induced me to test the light with a Nicol prism. In two positions of the prism the light was nearly wholly quenched. In two other positions it was transmitted. I quench the light and lower the slide, the green appears; I slightly turn the Nicol, the green is partially quenched and becomes more yellow. I interpose the Nicol between the light and the wing-case, and I find that in two positions of the prism I cannot obtain the blue colour, and that these positions of the prism are complementary to those in which the blue light was previously quenched. Whence it is quite clear that whatever causes the blue colour, it is something which alters the plane of vibration of the reflected light. So far for lamplight.

If I view the wing-case by daylight, I find the blue is much more intense, and using the magnesium light, that it is even more beautiful; whence it may be suspected that this blue colour is due either to fluorescence, or to dispersion by reflection. I think it is probably due to both. The purple and the major part of the blue are clearly due to reflection, otherwise the interposition of a Nicol between the light and the wing-case would not so nearly quench it as it does. That the Nicol so placed does not wholly quench the light goes a long way to show that part of the colour is due to reflection; and the fact that when the emergent blue light is examined by a Nicol, it is never wholly quenched, nor *wholly* transmitted, I think places the matter almost in the region of certainty. The blue is not a pure blue; it contains a little green; and this is pretty constant however the wing-case may be viewed by reflected light. So we may suspect that although most of the colours of the case, as variously viewed, are due to interference, or selective dispersion by reflection, or to lowering of refrangibility if fluorescence be also a factor, there is also what we generally denominate a colouring matter—a substance that is persistently selective and sends out, in this case, light with a continued balance on the green side of the account. With a view to ascertaining the nature of this colouring matter, a few wing-cases were immersed in ether, in alcohol and in water for several days, and these fluids were examined spectroscopically.

Ethereal Solution.—A small quantity placed in a specimen tube, or homœopathic pilule tube, and examined by a Sorby Browning spectroscope, or a student's stand spectroscope, kindly lent me by Mr. J. E. Winspear for the purpose. (A micro-spectroscope is the more convenient instrument for use in these researches, but it is advantageous to check the reading of one instrument by another.) I was much surprised to see a sharply defined band in the red, suggestive at once of a chlorophyll band I once saw, but unhappily could never trace the origin of, and a shaded band in the green with partial absorption of the blue, and general absorption beyond. In other words, there was a well-defined narrow absorption band at $1\frac{1}{2}$ of Sorby's scale, a shaded band extending each side of $5\frac{1}{2}$, and the partial and general absorption already spoken of. In many respects the spectrum resembles that of the privet, and exactly corresponds with that given by the chlorophyll of a portion of a leaf I examined some time since, but have not as yet succeeded in tracing. It differs from the privet spectrum as given to Herapath's diagram in the presence of the shaded band at $5\frac{1}{2}$, and also, if the diagram be correctly printed, very slightly also in the position of the band at $1\frac{1}{2}$.

Alcoholic Tincture.—The spectrum of this is essentially similar, excepting that the shaded band at $5\frac{1}{2}$ is absent.

The *Aqueous Solution* gives an entirely different spectrum. There is general absorption of the violet head of the spectrum and no well-defined bands (entire absorption from 8 to violet; shaded or partial absorption, 8 to 7). The wing-cases removed from the water, dried and digested in alcohol, give a well-defined band at $1\frac{1}{2}$, and general and partial absorption as in the alcoholic tincture, the $3\frac{1}{2}$ shaded band being absent. Ether added after alcohol has been removed gives the $3\frac{1}{2}$ shaded band by daylight, if care be paid to adjust the slit very exactly, and to focus sharply for that part of the spectrum.

There are thus, I think, grounds for concluding that the green colouring matter (the green oil of some analyses) is due to chlorophyll, and it is an interesting question whether the spectrum (the $1\frac{1}{2}$, $5\frac{1}{2}$ shaded and absorption beyond 8) characteristic of this will not be found to vary in ethereal tinctures prepared from cantharides collected from off different feeding grounds. And it is with a view of suggesting the inquiry to those who, perhaps, have more leisure and better opportunities of procuring the raw material than I have, that I send the foregoing rough and incomplete notes for publication.

The reagents that I have used, *e.g.*, sulphide of soda, ammonia, acids and iron salts, do not give results which permit at present of reduction into conformity with each other, and I reserve any account of them for a future paper which will include an account of the colouring matter of the contents of the stomach, of the thorax and other parts not now noticed; I will only remark that so far they confirm my opinion as to the chlorophyll nature of the green colouring matter.

In conclusion, I may just remind my readers that the reference spectrum spoken of is that devised by Mr. Sorby, and described by him in Dr. Beale's 'How to Work with the Microscope,' 4th ed., page 225, and is an interference spectrum produced by a plate of quartz interposed between two Nicol prisms. The spectrum is divided by 12 distinct bands of equal optical value, of which 3 and 4, counting from the red end of the spectrum, are respectively on each side of the well-known Fraunhofer's line D, or the sodium line (3½).

COMPARATIVE SOLUBILITY OF VARIOUS SALTS OF QUININE IN WATER AND GLYCERINE.*

BY M. SCHLAGDENHAUFFEN.

The inconveniences attending the ordinary modes of preparing a concentrated solution of a salt of quinine for the purpose of hypodermic injection, in cases where its administration in any other way is not so well tolerated by the patient, have caused M. Schlagdenhauffen, who is *pharmacien en chef* of the civil hospitals at Nancy, to undertake a thorough investigation of the subject, with the object of determining the salt and the solvent best suited for the purpose. Beginning with a series of experiments as to the solvent powers of pure water and acidulated water at varying temperatures upon the better-known salts as well as several more seldom met with, he next proceeded to test their solubility in glycerine. The general results of these experiments may be summed up as follows :—

Sulphate of Quinine.—The relative insolubility of this salt in cold water renders it unsuitable for use in subcutaneous injections. The author found that to dissolve 1 gram of the sulphate it required

25 c.c.	of water at	100°C	120 c.c.	of water at	50° C
40 c.c.	„	88°	200 c.c.	„	30°
55 c.c.	„	80°	255 c.c.	„	20°
85 c.c.	„	65°	265 c.c.	„	15°
100 c.c.	„	58°	300 c.c.	„	0°

When sulphuric acid was added in the proportion of 5, 10, or 15 drops to 100 c.c. of water, it required to dissolve 1 gram of sulphate of quinine—

	5 drops.	10 drops.	15 drops.
At 100° C.	24 c.c.	17 c.c.	9 c.c.
80°	—	—	12 „
70°	—	20 „	—
62°	40 „	—	—
55°	—	—	15 „
35°	54 „	27 „	—
30°	—	—	16 „
18°	—	30 „	—
0°	70 „	35 „	17 „

When water acidulated with hydrochloric acid was used to obtain similar results, 7, 13, and 18 drops of the acid were required, and of lactic acid 10, 15, and 20 drops. In a mixture of lactic acid, chlorides and phosphates, corresponding to the composition of the gastric juice, the sulphate dissolves with facility,—1 gram requiring 40 c.c. at from 30° to 40°. From this the author concludes that the quantities usually administered in powders by medical men may be completely dissolved in the stomach.

M. Schlagdenhauffen considers that these aqueous solutions of sulphate of quinine are at once too feeble and too acid for hypodermic injection; since the addition of so much acid would of necessity cause irritation, while the quantity of sulphate contained in each syringeful—not more than from 0·015 gram to 0·060 gram—would be insufficient probably for any practical good.

But in *glycerine* the sulphate is much more soluble, one gram of that salt dissolving—

At 100° C.	in 4	grams of glycerine.
65°	„ 10	„ „
40°	„ 20	„ „
0°	„ 40	„ „

Hydrochlorate of Quinine.—The hydrochlorate, as is well known, is more freely soluble than the sulphate, one gram dissolving in—

24 c.c.	of water at	0° C.	5 c.c.	of water at	40° C.
18 „	„	15°	4 „	„	55° to 100°
12 „	„	22°			

The addition of hydrochloric acid augments the solubility, the following being the quantity of water required to dissolve one gram, when 1, 2, or 8 drops of acid are added to each 100 c.c. :—

1 drop.		2 drops.		8 drops.	
0·5 c.c.	at 52° C.	0·5 c.c.	at 45° C.	0·5 c.c.	at 42° C.
1 c.c.	„ 45°	1 c.c.	„ 40°	1 c.c.	„ 34°
4 c.c.	„ 37°	2 c.c.	„ 35°	3 c.c.	„ 25°
6 c.c.	„ 30°	5 c.c.	„ 25°	10 c.c.	„ 12°
17 c.c.	„ 0°	16 c.c.	„ 0°	14 c.c.	„ 0°

It will thus be seen that by using an aqueous solution of the hydrochlorate—especially if two drops of acid be added, in which state its acidity is not discernible by litmus paper—a syringe containing one cubic centimetre would introduce a much larger proportion of quinine than when the sulphate is used.

In *glycerine* the hydrochlorate is very soluble, requiring only two or three times its weight to dissolve completely and to remain dissolved at 0° C.

A comparison of the solubility of these two salts in glycerine and in water, shows that at the temperature of melting ice they are both about eight times more soluble in the former vehicle than in the latter, and that this difference diminishes in proportion as the temperature is raised. The same remark applies to the butyrate of quinine described further on. The acetate, formate, lactate and sulphovinate are also more soluble in glycerine than in water, but the difference is not so great as in the preceding.

Hypophosphite of Quinine.—If one equivalent of sulphate of quinine be heated to boiling in a sufficiency of water to completely dissolve it, and added to two equivalents of hypophosphite of baryta, also dissolved in boiling water, the sulphate of baryta removed by filtration, and the solution carefully evaporated, a neutral hypophosphite of quinine is obtained, one gram of which after drying in a water bath, dissolves in the following proportions of water :—

At 87° C. to 100°	1 c.c.	At 37° C.	6 c.c.
70° „	2 „	24° „	8 „
50° „	4 „	0° „	12 „

At a temperature of 12° C. 1 c.c. of water dissolves 1 decigram of this salt, and a neutral solution is thus formed, containing enough salt of quinine to allow of febrile attacks being treated with one or two syringefuls. This solution has already been successfully employed in the Strasbourg Civil Hospital. The superior solubility of the hypophosphite is shown by the fact that if an alkaline sulphate or very dilute sulphuric acid be added to such a solution as that mentioned, the precipitate formed is so abundant that the vessel containing it might be

* Abstracted from papers in 'L'Union Pharmaceutique,' vol. xiii. pp. 101, 132, and 352.

reversed without its contents running out. The hypophosphite is also precipitated by chloride of sodium, acetate of potash and acetate of soda.

Formate of Quinine.—If the sulphate of quinine be decomposed by formate of baryta, neutral formate of quinine is obtained, which is still more soluble than the hypophosphite, one gram being soluble in 1 c.c. of water at 100° C. If the solution be cooled slowly, it does not deposit above 37° C.; so that between those temperatures the formate is soluble in its own weight of water.

Between 25° and 37° 1 gram requires 2 c.c. of water.
" 10° " 25° " " 3 " "
" 0° " 10° " " 4 " "

If, however, an excess of water be added a precipitate is thrown down, soluble by heat, but reforming in the cold, which is probably a basic salt.

Acetate of Quinine.—Obtained in shining acicular crystals by double decomposition of acetate of baryta and sulphate of quinine. At high temperatures its solubility is near to that of the hydrochlorate, but at lower temperatures it is much less soluble. Thus 1 gram requires—

1 c.c. of water at 100° C.	25 c.c. of water at 13° C.
10 c.c. " 30°	35 c.c. " 0°

Butyrate of Quinine.—When 1 equivalent of sulphate of quinine is treated with 2 equivalents of butyrate of baryta, the baryta is precipitated, and a limpid solution of neutral butyrate of quinine is obtained, which, if concentrated in a water-bath until it contains about ten per cent. of the salt, throws off some oily drops, and, upon further concentration, forms a syrupy transparent mass that crystallizes in shining needles after four or five days. If the solution be left to evaporate spontaneously, the syrupy mass is not formed, and the salt crystallizes in long needles. The salt is not very soluble, 1 gram requiring—

13 c.c. of water at 100° C.	105 c.c. of water at 15° C.
70 c.c. " 32°	130 c.c. " 0° C.

These solutions if left to evaporate spontaneously yield a magnificent crystallization in silky tufts, consisting probably of anhydrous salt, since it does not comport itself in the same manner as the original crystals when redissolved.

Lactate of Quinine.—Obtained when sulphate of quinine is precipitated by lactate of baryta. The lactate is freely soluble in water in proportions similar to the formate, over which it has the advantage, however, that it is not precipitated when an excess of water is added. 1 gram requires—

0·5 c.c. of water between 70°–100° C.
1·0 " " at 45°
1·5 " " " 38°
2·5 " " " 30°
3·0 " " " 10°
3·5 " " " 0°

As this salt allows of the preparation of such concentrated solutions, which are always slightly alkaline, the author thinks it would probably be found particularly suitable for subcutaneous injection.

Sulphovinate of Quinine—This new salt is much more soluble than any of the foregoing. It was obtained by the precipitation of 5·48 grams of sulphate of quinine with 3·06 sulphovinate of baryta,* evaporating the solution at a temperature below 40° C. to crystallization. The crystals may be heated in a water-bath to 100° without undergoing alteration. When dry and powdered, it dissolves in water in the following proportions:—

1 gram dissolves in 0·3 c.c. of water at 100° C.
" " 0·5 c.c. " 50°
" " 0·9 c.c. " 0°

Its solution is abundantly precipitated by alkaline sulphates, chlorides and acetates, and sulphuric acid; but not by free hydrochloric or acetic acid. This salt the author thinks to be especially well suited for subcutaneous injection, since at 10° C. at least 1 gram is soluble in 1 c.c. of water.

Sulphomethylate of Quinine is prepared in a similar manner to the sulphovinate, and has about the same degree of solubility.

Sulphoamylate of Quinine, also prepared in a similar manner, requires at from 15° to 35° C. about 100 parts of water to dissolve one of the salt, but it is very soluble in alcohol.

From the foregoing it would appear that the proportion of the various salts of quinine present in 1 c.c. of aqueous solution, or the quantity contained in a Pravas syringe,* is—

	30° C. gram.	20° C. gram.	10° C. gram.
Acetate	0·091	0·037	0·027
Hydrochlorate	0·092	0·049	0·031
Hypophosphite	0·12	0·097	0·065
Formate	0·33	0·296	0·272
Lactate	0·35	0·31	0·29
Sulphomethylate	0·80	0·71	0·60
Sulphovinate	0·80	0·72	0·60

Solutions in Glycerine.—The glycerine solutions of the salts of quinine present a peculiarity worthy of remark, in a species of supersaturation in which they remain after being cooled suddenly, a phenomenon that does not occur when they are allowed to cool slowly. Thus a solution of 1 part of hydrochlorate in one part of glycerine cooled suddenly to 0° C. remains about three hours without crystallization, whilst if cooled slowly to 15° C. the crystals commence to deposit at the end of a quarter of an hour. The addition of a larger proportion of glycerine allows of the preparation of solutions which remain transparent for a longer time. Thus a solution, consisting of one part of hydrochlorate and three parts of glycerine, cooled slowly to 15°, remains limpid during eight hours, and only after sixteen hours commences to deposit a few acicular crystals. With four parts of glycerine the solution remains perfectly transparent for a week. The lactate dissolved in its weight of glycerine remains soluble for about two hours.

The following table shows the characteristic behaviour of solutions of some of the salts of quinine

* M. Limousin proposes to use sulphovinate of soda, and avoid the possible danger attending the use of a barium salt.—*Ante,* pp. 651.—Ed. Pharm. Journ.

* One point, however, should not be lost sight of in estimating the efficacy of these various solutions, and that is the proportion of the normal alkaloid present in a given quantity of any of these salts, a proportion that would vary considerably, for instance, in the hydrochlorate and the sulphovinate. This subject has been already dealt with by M. Adrian, in a paper of which an abstract appeared at p. 2 of the present volume. The possible modification in the physiological properties of the alkaloid which might result from the different states of combination would also appear to require further investigation.—Ed. Pharm. Journ.

in glycerine under various conditions; one gram of the quinine salt being used in each case:—

Nature of Salt. 1 grain.	Quantity of Glycerine.	Temperature.		Cooled suddenly to 0° C.	Cooled slowly to 15° C.	
		Boiling.	30° C.		Time employed.	Effect on Solution.
Sulphate	2 gr.	sol.	ins.	ins.	10 min.	Deposited in a mass.
	12 gr.	sol.	sol.	ins.	1 day	A few crystals.
	24 gr.	sol.	sol.	sol.	8 days	Remained clear.
Hydrochlorate	1 gr.	sol.	sol.	sol.	8 hours	Crystals in mass.
	3 gr.	sol.	sol.	sol.	15 hours	Remained clear.
	5 gr.	sol.	sol.	sol.	8 days	Remained clear.
Lactate	1 gr.	sol.	sol.	sol.	4 hours	Remained clear.
	2 gr.	sol.	sol.	sol.	24 hours	Remained clear.
	4 gr.	sol.	sol.	sol.	4 days	Remained clear.
Acetate	4 gr.	sol.	sol.	sol.	10 hours	Remained clear.
	4 gr.	sol.	sol.	sol.	3 days	Deposited in a mass.
	12 gr.	sol.	sol.	sol.	8 days	Remained clear.
Sulphovinate	2 gr.	sol.	sol.	sol.	4 hours	Remained clear.
	4 gr.	sol.	sol.	sol.	1 day	Remained clear.
Formate	2 gr.	sol.	sol.	sol.	8 hours	Remained clear.
	4 gr.	sol.	sol.	sol.	3 days	Remained clear.
Hypophosphite	4 gr.	sol.	sol.	sol.	4 days	No crystals.
Tannate	3 gr.	sol.	sol.	sol.	3 days	Cloudy without crystals.
	5 gr.	sol.	sol.	sol.	1 month	Remained clear.

M. Schlagdenhauffen has found the tannate of quinine to be more soluble than has been previously stated,* he having obtained both warm and cold solutions containing 0·33 gram in each cubic centimetre of glycerine. It is necessary, in preparing these solutions, to heat the glycerine to boiling point, but once dissolved, the tannate is retained in solution during upwards of two months if kept in stoppered bottles. Exposed to the air the syrupy liquor commences to form a whitish crust, which augments rapidly after a few days, and consists of amorphous tannate. So concentrated an infusion would be too thick for injections, but one containing 0·22 gram to the cubic centimetre might be used.

The conclusion drawn by the author from his experiments is that a glycerine solution of a salt of quinine may be used for hypodermic injection some time after its preparation, since a sufficiently concentrated solution remains perfectly clear without deposit of crystals. The following table shows the length of time during which glycerine solutions of the different solutions remain serviceable:—

Sulphate	containing 0·04	gram per c.c.	1 day.
Hypophosphite	,, 0·25	,, ,,	4 days.
Hydrochlorate	,, 0·33	,, ,,	16 hours.
Formate	,, 0·50	,, ,,	8 hours.
Acetate	,, 0·25	,, ,,	10 hours.
Sulphovinate	,, 0·50	,, ,,	19 hours.
Lactate	,, 0·50	,, ,,	1 day.
Tannate	,, 0·33	,, ,,	3 days.

The necessity for using these solutions shortly after their preparation, because of their tendency to crystallize,* is undoubtedly an inconvenience, but if they be kept at a temperature of 30° C. (86° F.) they will remain perfectly clear and fit for use during a week or a fortnight.

The glycerine solutions of quinine are precipitated by water, and also in the presence of albuminous liquids, for which reason they would appear to be unsuited for use hypodermically, lest nodosities should be formed. But careful experiments in the civil hospitals of Strasbourg appear to have shown that in using the hypophosphite, hydrochlorate, sulphovinate and lactate no such inconvenience has resulted. Experiments with the tannate, however, have not at present been made.

* See Journ. Pharm. et de Chim. vol. xii. p. 211.

FENNEL FLOWER SEED, OR BLACK CUMIN SEED.

BY P. L. SIMMONDS.

In the very interesting paper "On Some Drugs from Morocco," read by Dr. Leared and published in the Journal of the 8th ult., under the name of Sanous, an unidentified seed is mentioned. From a sample of it shown me by Mr. T. Greenish, there appears to be no doubt that it is that of *Nigella sativa*, a pungent seed much used in Northern Africa, India, and Turkey. Commander F. Jones, whilst surveyor for the Hon. East India Company in 1857, included it in his catalogue of the articles of the materia medica sold in the bazaars of Baghdad, under the Arabic name of Hubbeh es Sauda. Mr. M. C. Cooke, in a descriptive article on these drugs in my 'Technologist' (vol. iv. p. 537), says that the Hub-sindie of Egypt is identical with the Siah-daneh of Persia and the Mugrela of Bengal. The Singalese name is Kallodooro, and it is used as a condiment in Ceylon. I stated in my work on 'The Commercial Products of the Vegetable Kingdom' (1853), that the aromatic seeds of some of the species of fennel-flower were formerly used instead of pepper, and are said to be still employed in Europe in adulterating it. A dark and fragrant oil is extracted from the seeds in India,

* Another possible source of inconvenience might exist in the rise of temperature which takes place when concentrated glycerine comes in contact with water. In a paper read before the American Pharmaceutical Association, Mr. J. P. Remington stated that under certain circumstances this amounted to 10° F., and the late Professor Parrish said that he had met with cases when the use of concentrated glycerine in preparations for the eye had caused such pain as to give rise to a charge against the druggist of having used sulphuric acid for the purpose of dissolving the alkaloid (see Pharm. Journ. [3] vol. ii. p. 908).—Ed. Pharm. Journ.

and appears to be principally used in medicine. It is called jungle-geerah oil in Mysore. The oil obtained from the same source in Egypt is limpid and colourless, and with but little odour. A specimen from Egypt, with the seeds, was shown at the first London Exhibition in 1851.

The seed is called gitta by the Arabs. Lady Calcott, in her 'Scripture Herbal,' states that the seed is much esteemed in the East, where it is common to strew it over the floor of the oven before the bread is put in, and to sprinkle it over the loaves, and even to knead it into the dough, as is done with poppy seeds in Bohemia and some parts of Germany. The seed of the Nigella is used in this manner and also by way of pepper in Egypt, Persia and India, as well as in Syria and Palestine, and very powerful as well as healthful qualities are ascribed to it. Under the strange name of fennel-flower, this plant was formerly cultivated in our gardens as a pot-herb, but like many others it has been displaced by the more common and pungent Eastern spices.

CONTRIBUTIONS TO THE PHYSIOLOGICAL CHEMISTRY OF MILK.*

BY F. SOXHLET.

Soxhlet investigates the question as to the identity of casein and alkali-albuminate, concerning which there exist considerable differences of opinion.

He first discusses the relation of alkaline phosphates to alkali-albuminate.

Hoppe-Seyler opposes the identity of casein and alkali-albuminate on the ground that in the milk no alkali-albuminate can be present, inasmuch as the fluid generally has an acid reaction, whereas solutions of the latter substance are precipitated even on neutralisation. Rollett, however, has proved that solutions of alkali-albuminate are not precipitated by acids in presence of neutral sodium phosphate, and it is owing to the presence of such phosphates in the milk that casein, which behaves exactly like alkali-albuminate, is not precipitated, even though the milk exhibits an acid reaction. Following out Rollett's researches, Soxhlet seeks to determine the quantitative relation of the acids and salts in the liquids in which, notwithstanding an acid reaction, no precipitation of albuminate occurs. By experiments with volumetric solutions of neutral sodium phosphate, acid potassium phosphate, neutral sodium sulphate, sulphuric, acetic and phosphoric acids, he arrives at the result, that on the addition of an acid to a solution of alkali-albuminate in presence of neutral sodium phosphate, the albuminate begins to be precipitated at the moment when all the neutral phosphate has been converted into the acid salt. The quantity of acid required for precipitation stands in intimate relation to the quantity of alkaline phosphate present, and the precipitation depends, not on the absolute amount of acid phosphate formed, but on its relative proportion to the neutral phosphate still remaining. The sodium sulphate which is formed when sulphuric acid is added to the albuminate solutions in neutral sodium phosphate, is without influence on the precipitation of the albuminate.

A relatively small amount of acid phosphate causes precipitation in pure alkali-albuminate solutions. In order to cause precipitation when neutral phosphate is present, a much larger proportion of the acid salt is required, because if the former is in excess, the albuminate remains in solution. In order to cause precipitation, it was found that acid phosphate of alkali-metal must be added until the quantity of neutral phosphate, which is formed from the base of the alkali-albuminate and from a part of the acid phosphate, stands in the relation of one molecule to thirty-two molecules of the acid phosphate. If more neutral phosphate is present than is expressed by this proportion, no precipitation occurs.

Reaction of the Milk and other Animal Fluids.—The solution of casein in milk with an acid reaction must, as shown by the foregoing experiments, depend on the simultaneous presence of a certain proportion of neutral phosphate together with the acid phosphate which gives the acid reaction. Such solutions, however exhibit not merely an acid but also an alkaline reaction at the same time. And this is really the case with the milk, for it at the same time reddens blue litmus and turns red litmus-paper blue. This *amphoteric* reaction of milk can be demonstrated best on gypsum plates coated with litmus, after the manner suggested by Liebreich. To this amphoteric reaction of the milk, the author ascribes the different statements made in regard to the normal reaction of the fluid. The alkaline reaction becomes more evident when the milk is heated. The same is shown by very dilute solutions of so-called neutral sodium phosphate and caustic soda. Violet solutions of litmus also become more blue on heating. The change is not due to concentration by evaporation, as the original colour reaction returns on cooling. Fluids which contain vegetable albumen become more alkaline when heated, and it has been supposed that this is due to the liberation of an alkali when the albumen is coagulated. That it is not due to this cause is proved by the fact that solutions free from albumen, but containing the same salts as the albuminous liquids, likewise exhibit the same intensification of the alkaline reaction when heated. A similar explanation is given of the fact observed by Du Bois Reymond, that a muscle dipped in boiling water becomes more alkaline than before.

In connection with the amphoteric reaction of animal fluids, difficulties are pointed out in the estimation of the so-called free acid of the urine. The presence of acid sodium phosphate in the urine renders it difficult to say exactly when all the acid is neutralised by the addition of alkali, because it is impossible to hit a point when the liquid will react exactly neutral, as there is no solution of a phosphate which reacts precisely neutral.

A third objection to the identity of casein and alkali-albuminate is supposed to exist in the different behaviour of these two substances towards rennet. Milk is coagulated, while alkali-albuminate is not. It has been shown, however, that alkali-albuminate is coagulated by rennet when milk sugar has been added to the solution. Soxhlet agrees with Simon in referring the coagulation to the lactic acid developed by the action of rennet on milk-sugar. Heintz, however, and subsequently Völcker found that casein might be coagulated by rennet, and yet the fluid remain alkaline, and hence considered that rennet may coagulate casein, not only by the formation of lactic acid, but also by some specific action. For this specific action a higher temperature is necessary. Soxhlet explains the differences by the amphoteric reaction. Rennet develops lactic acid from the milk-sugar; by which the neutral alkaline phosphate of the milk is converted into acid phosphate. When in consequence of this acidification, that relation between the neutral and acid phosphate is established in which the albuminate remains just dissolved and no more, then when the temperature is raised albumen is precipitated while the fluid is still alkaline. Along with the alkaline reaction, however, an acid reaction is also to be observed. This, however, had not been noticed by former observers.

The statement that the casein precipitated by acid is easily soluble in sodium carbonate, while that precipitated by rennet is not so, depends merely on the physical, and not on any chemical differences of the precipitate.

Rennet belongs most probably to the non-organised ferments. Zahn states that alkali-albuminate may be filtered through porous earthenware, but casein not; and

* Journ. f. pract. Chemie. [2], vi., 1—52; and from the 'Journal of the Chemical Society.'

considers this to be a proof against the identity of the two substances. Soxhlet shows that this depends on the presence of fat-globules in the milk, and finds that alkali-albuminate, when emulsionised by fat, is likewise incapable of filtration (or with difficulty) through such earthenware cells.

Zahn also states that the casein of the milk can be precipitated by sodium carbonate, but that solutions of alkali-albuminate cannot. This, however, does not depend on any chemical difference between the two substances, but on the fact that in the milk other substances are present. The precipitation of casein from milk may likewise be effected by caustic alkalis and sodium phosphate, as well as by sodium carbonate. The cause of the precipitation is the formation of calcium phosphate, which carries down the albuminate mechanically in the form of a finely granular precipitate. If alkali-albuminate is treated with calcium chloride and emulsified with fat, a like precipitate is caused on the addition of sodium phosphate. The statement made by Hoppe-Seyler that alkali-albuminate does not, like casein, yield potassium sulphide when treated with caustic potash, Soxhlet finds to be incorrect. He obtained a distinct evolution of hydrogen sulphide on the addition of acetic acid to the mass resulting from the treatment of alkali-albuminate with concentrated caustic potash.

Still, another difference is stated by Hoppe-Seyler to exist between casein and alkali-albuminate, namely, the specific rotation exerted by these two substances on a ray of polarised light. Soxhlet thinks that this is no sufficient ground for establishing a chemical difference between the two, because the specific rotation is liable to be greatly influenced by the presence of salts and by other conditions of the solutions.

From these various considerations the author comes to the conclusion that casein and alkali-albuminate are identical in every respect.

PROFESSOR TYNDALL ON LIGHT.*

The series of lectures from which the following notes are taken was delivered by Professor Tyndall at the Cooper Institute, New York. At the commencement of the first lecture, he said that the favour with which his writings have been received in America had led to his being invited to lecture in that country. Having been given to understand that experimental lectures would probably be preferred, he decided to meet the wish, so far as he could, by selecting and transporting such apparatus as was suitable for such lectures, and to take some single department of natural philosophy, and illustrate the growth of scientific knowledge under the guidance of experiment. In his first lecture, he would describe certain elementary phenomena; then point out how the theoretic principles by which such phenomena are explained take root and flourish in the human mind, and afterward apply these principles to the whole body of knowledge covered by the lectures. The science of optics lends itself to this mode of treatment, and on it, therefore, he purposed to draw for materials. He thought it best to begin with the few simple facts regarding light which were known to the ancients, and to pass on from them in historic gradation to the more abstruse discoveries of modern science.

All men's notions of nature have some foundation in human experience. This is the broad foundation on which intellectual structures ultimately rest. The notion of personal volition in nature had this basis. In the fury and the serenity of natural phenomena the savage saw the transcript of his own varying moods, and he accordingly ascribed these phenomena to beings of like passions with himself, but vastly transcending him in power. Thus the notion of causality—the assumption that natural things did not come of themselves, but had unseen antecedents—lay at the root of even the savage's interpretation of nature. Out of this bias of the human mind to seek for the antecedents of phenomena all science has sprung.

The first sciences were those of observation, when the matter of thought was provided by man's environment, and he had no notion of creating it himself. The apparent motion of sun and stars first drew toward them the questionings of the intellect, and accordingly astronomy was the first science developed. Slowly, and with difficulty, the notion of natural forces took root in the mind, its seedling being the actual observation of electric and magnetic attractions. Slowly, and with difficulty, the science of mechanics had to grow out of this notion; and slowly at last came the full application of mechanical principles to the motions of the heavenly bodies. We trace the progress of astronomy through Hipparchus and Ptolemy; and after a long halt, through Copernicus, Galileo, Tycho Brahe, and Kepler; while from the high table-land of thought raised by these mighty men, Newton shoots upward like a dominant peak overlooking all others from his stupendous elevation.

But other objects than the motions of the stars attracted the attention of the ancient world. Light was a familiar phenomenon, and from the earliest times we find men's minds busy with the attempt to render some account of it. But without experiment, which belongs to a later stage of scientific development, no progress could be made in this subject. The ancients accordingly were far less successful in dealing with light than in dealing with solar and stellar motions. Still they did make a little progress. They satisfied themselves that light moved in straight lines; they knew also that these lines or rays of light were reflected from polished surfaces and that the angle of incidence was equal to the angle of reflection. These two results of ancient scientific curiosity would constitute the starting point of the present course of lectures.

Professor Tyndall continued—Both of these are capable of the easiest experimental illustration, but in the first place it may be useful to say a few words regarding the source of light to be employed in our experiments. The rusting of iron is, to all intents and purposes, the slow burning of iron. It develops heat, and if the heat be preserved a high temperature may be thus attained. The destruction of the first Atlantic cable was probably due to heat developed in this way. Other metals are still more combustible than iron. You may light strips of zinc in a candle flame, and cause them to burn almost like strips of paper. But beside combustion in the air we may also have combustion in a liquid. Water, for example, contains stores of oxygen, which may unite with, and thus consume a metal immersed in it. It is from this kind of combustion that we are to derive the heat and light employed in the present course.

Their generation merits a moment's attention. Before you is an instrument—a small voltaic battery—in which zinc is immersed in a suitable liquid. Matters are so arranged that a strain is set up between the metal and the oxygen; actual union, however, being avoided. Uniting the two ends of the battery by a thick wire, the attraction is satisfied, the oxygen unites with the metal, the zinc is consumed, and heat, as usual, is the result of the combustion. A power, which for want of a better name, we call an electric current, passes at the same time through the wire.

Cutting the thick wire in two, I unite the severed ends by a thin one. It glows with a white heat. Whence comes that heat? The question is well worthy of an answer. Suppose in the first instance, when the thick wire was employed, that we had permitted the action to continue until 100 grains of zinc were consumed, the amount of heat generated in the battery would be capable of accurate numerical expression. Let the action now continue with this thin wire glowing until 100 grains of

* Abstracted from a report in the *New York Tribune*.

zinc are consumed. Would the amount of heat generated in the battery be the same as before? No, it would be less by the precise amount generated in the thin wire outside the battery. In fact, by adding the internal heat to the external we obtain for the combustion of 100 grains of zinc a total which never varies. By this arrangement then we are able to burn our zinc at one place, and to exhibit the heat and light of its combustion at a distant place. In New York, for example, we have our grate and fuel; but the heat and light of our fire may be made to appear at San Francisco. We have here an illustration of the constant law that in physical nature we have incessant substitution but never creation.

I now remove the thin wire and attach to the severed ends of the thick one two thin rods of coke. On bringing the rods together we obtain a small star of light. Now the light to be employed in our lectures is a simple exaggeration of this star. Instead of being produced by 10 cells it is produced by 50. Placed in a suitable camera, provided with a suitable lens, this light will give us all the beams necessary for our experiments.

And here, in passing, let me refer to the common delusion that the works of nature, the human eye included, are theoretically perfect. The degree of perfection of any organ is determined by what it has to do. Looking at the dazzling light from our large battery you see a globe of light, but entirely fail to see the shape of the coke-points whence the light issues. The cause may be thus illustrated: On the screen before you is now projected an image of the carbon points, the whole of the lens in front of the camera being employed to form the image. It is not sharp, but surrounded by a halo which nearly obliterates it. This arises from an imperfection of the lens, called spherical aberration, due to the fact that the circumferential and central rays have not the same focus. The human eye labours under a similar defect, and when you looked at the naked light from fifty cells the blur of light upon the retina was sufficient to destroy the definition of the retinal image of the carbons. A long list of indictments might indeed be brought against the eye—its opacity, its want of symmetry, its lack of achromatism, its absolute blindness in fact. All these taken together caused an eminent German philosopher to say that if any optician sent him an instrument so full of defects he would send it back to him with the severest censure. But the eye is not to be judged from the standpoint of theory. As a practical instrument, and taking the adjustment by which its defects are neutralized into account, it must ever remain a marvel to the reflecting mind.

[He now employed the larger battery, using the electric light as occasion required in any one of three or four lanterns in which the carbon points were moved by clockwork. The first image obtained on the screen of the carbon points looked like a faint drawing in brown pastel on a pure white circular ground. The circular ground represented the globular light as seen by the eye. A transparent screen was then interposed, which cut off the halo, and the carbon points seemed like two burning volcanoes, one upside down and its crater overhanging the other, which was conical. Between them there was a space that looked like the burning gas of a blast furnace, where the elements would melt with fervent heat.]

And now we are ready for work. The rectilineal propagation of light may be beautifully illustrated by making a small hole in a window-shutter, before which stands a house, or tree, or animal, and placing within the darkened room a white screen at some distance from the orifice. Every straight ray proceeding from the object stamps its colour upon the screen, and the sum of all the rays forms an image of the object. But as the rays cross each other at the orifice the image is inverted. An image of the carbon points produced by a pinhole in tinfoil will be employed to illustrate this point of rectilineal propagation.

[In each of these images the carbon points were apparent; they gradually overlapped each other as their number and proximity was increased, until the audience were ready to accept the statement of the lecturer that the total circle of light from the lens was merely the intricate and complete overlapping of images of the carbon.]

The law that the angle of incidence is equal to the angle of reflection is illustrated in this simple way: A straight lath is placed as an index perpendicular to a small looking-glass capable of rotation. A beam of light is received upon the glass and reflected back along the line of its incidence. Though the incident and the reflected beams pass in opposite directions, they do not jostle or displace each other. The index is now turned, the mirror turns along with it, and at each side of the index the incident and the reflected beams are seen tracking themselves through the dust of the room. The mere inspection of the two angles inclosed between the index and the two beams shows their equality. The same simple apparatus enables us to illustrate a law of great practical importance, namely, that when a mirror rotates the angular velocity of a beam reflected from it is twice that of the reflecting mirror.

For more than 1000 years no step was taken in optics beyond this law of reflection. The men of the middle ages, in fact, occupied themselves on the one hand in trying to develop the laws of the universe out of their own consciousness, while on the other hand they were so occupied with the concerns of a future world that they looked with a lofty scorn on all things pertaining to this only. As regards the refraction of light, the course of real inquiry was resumed in 1100 by an Arabian philosopher named Alhazen. Then it was taken up in succession by Roger Bacon, Vitellio and Kepler. One of the most important occupations of science is the determination by precise measurements of the quantitative relations of phenomena. The value of such measurements depends upon the skill and absolute conscientiousness of the man who makes them. Vitellio was such a man, while Kepler's habit was to rummage through the observations of his predecessors, look at them in all lights, and thus distil from them the principle which united them. He had done this with the astronomical measurements of Tycho Brahe, and had extracted from them the celebrated "laws of Kepler." But in the case of refraction he was not successful. The principle, though a simple one, escaped him. It was first discovered by Willebord Snell, about the year 1621.

Less with the view of dwelling upon the phenomenon itself than of introducing it to you in a form which will render intelligible the play of theoretic thought in Newton's mind I will show you the fact of refraction. The dust of the air and the turbidity of a liquid may here be turned to account. A shallow circular vessel with a glass face, half filled with water, rendered barely turbid by the precipitation of a little mastic, is placed upon its edge with its glass face vertical. Through a slit in the hoop surrounding the vessel a beam of light is admitted. It impinges upon the water, enters it, and tracks itself through the liquid in a sharp, bright band. Meanwhile the beam passes unseen through the air above the water. A puff of tobacco smoke into this space at once reveals the track of the incident beam. If the incidence be vertical, the beam is unrefracted. If oblique its refraction at the common surface of air and water is rendered clearly visible. It is also seen that reflection accompanies refraction, the beam dividing itself at the point of incidence into a refracted and a reflected portion.

[This experiment was performed with a small drum containing liquid. The lecturer remarked that milk having a slight bluishness answered the purpose. London milk was particularly well suited. There was also visible in the smoke above the water a faint reflected beam, probably reflected from the surface of the water.

Snell connected the angle of incidence with the angle of refraction, by proving that the sine of the one divided by the sine of the other is absolutely constant for the same medium, whatever the obliquity of the incident ray may be. The lines answering to these "sines" will be pointed out in the lecture. The constant quotient here referred to is called the index of refraction. The discovery is one of the corner-stones of optical science.

Quickly following Snell's discovery, is the application of it by Descartes to the explanation of the rainbow. The bow is seen when the back is turned toward the sun. Draw a straight line through the spectator's eye and the sun, the bow is always seen at the same angular distance from this line. This was the great difficulty. Why should the bow be always, and at all parts, 41 degrees distant from this line? Taking a pen and calculating the track of every ray through a rain-drop, Descartes found that at one particular angle the rays emerged from the drop almost parallel to each other; being thus enabled to preserve their intensity through long atmospheric distance; at all other angles the rays quitted the drop divergent, and through this divergence became practically lost to the eye. The particular angle here referred to was the foregoing angle of 41 degrees, which observation had proved to be invariably that of the rainbow.

But in the rainbow a new phenomenon was introduced —the phenomenon of colour. And here we arrive at one of those points in the history of science when men's thoughts and labours so intermingle that it is difficult to assign to each worker his precise meed of honour. Descartes was at the threshold of the discovery of the composition of solar light. But he failed to attain perfect clearness, and it is certain that he did not enunciate the true law. This was reserved for Newton, who went to work in this way.

Through the closed window-shutter of a room he pierced an orifice, and allowed a thin sunbeam to pass through it. The beam stamped a round image of the sun on the opposite white wall of the room. In the path of this beam Newton placed a prism, expecting to see the beam reflected, but also expecting to see the image of the sun after refraction, round. To his astonishment it was drawn out to an image whose length was five times its breadth; and this image was divided into bands of different colours. Newton saw immediately that this image was due to the fact that some constituents of the solar light were more deflected by the prism than others, and he concluded, therefore, that white solar light was a mixture of lights of different colours and of different degrees of refrangibility.

The elongated image here referred to is called the spectrum. Newton divided the spectrum into seven parts, red, orange, yellow, green, blue, indigo, violet; which are commonly called the seven primary or prismatic colours.

This was the first analysis of solar light by Newton; but the scientific mind is fond of verification, and never neglects it where it is possible. It is this stern conscientiousness on the part of those who pursue it that gives adamantine strength to science, and renders all assaults on it unavailing. Newton completed his proof by synthesis. For instance, he refracted the colours back, reblended them, and thus reproduced the white light out of which they came.

In the lecture, Newton's experiment in Newton's own form is made; it is afterwards made with instruments which yield larger and richer effects than those seen by Newton. The synthesis of white light is effected in three different ways. Firstly, the colours of the spectrum are squeezed together and blended by a cylindrical lens, white light being the result of their mixture; secondly, an image of the carbon points, whence the light issues, is built up from the colours of the spectrum; thirdly, in virtue of the persistance of luminous impressions upon the retina, the prismatic colours may be mixed together in the eye itself, the impression of whiteness being the result. The drawing out of the white light into a spectrum is called dispersion. And here historic completeness renders necessary a brief reference to an error of Newton's. He supposed that refraction and dispersion went hand in hand, and that if you abolished the one you at the same time abolished the other. He maintained this opinion to the end of his life, and thus retarded the progress of discovery. Dolland, however, proved that by combining two different kinds of glass the colours could be extinguished, still leaving a residue of refraction, and he employed this residue in the construction of achromatic lenses—lenses which yield no colour—which Newton thought an impossibility. This point is illustrated in the lecture by combining a prism of water and one of glass; the colour is destroyed but not the refraction.

The refraction and dispersion of bisulphide of carbon are compared with those of water, in order to explain why the first mentioned liquid is used when our object is to obtain spectra of great extent and richness of colour.

[The spectra exhibited in this part of the lecture, and from then till its close, were of great beauty. The one upon which the final experiments were made, by which the actual character of colour was explained, must have been at least two and a half feet wide, and its length, when dispersed by two prisms, covered the whole screen.]

Having unravelled the interwoven constituents of white light, we have next to inquire what part the constitution so revealed enables this agent to play in nature? To it we owe all the phenomena of colour; and yet not to it alone, for there must be a certain relationship between the ultimate particles of natural bodies and light to enable them to extract from it the luxuries of colour. But the function of natural bodies is here selective, not creative. There is no colour generated by any natural body in any kind of form. Natural bodies have showered upon them, in the white light of the sun, the sum total of all possible colours, and their action is limited to the sifting and appropriating from the total the colours which really belong to them, and rejecting those which do not. It will fix this subject in your minds if I say that it is the portion of light which they reject, and not that which belongs to them, that gives bodies their colours.

Let us begin our experimental inquiries here by asking what is the meaning of blackness? Pass a black ribbon in succession through the colours of the spectrum; it quenches all. This is the meaning of blackness—it is the result of the absorption of all the constituents of solar light. Pass a red ribbon through the spectrum. In the red light the ribbon is a vivid red. Why? Because the light that enters the ribbon is not quenched or absorbed, but sent back to the eye. Place the same ribbon in the green or blue of the spectrum; it is black as jet. It absorbs the green and blue light, and leaves the space on which they fall a space of intense darkness. Place a green ribbon in the green of the spectrum. It shines vividly with its proper colour; transfer it to the red, it is black as jet. Here it absorbs all the light that falls upon it, and offers mere darkness to the eye. When white light is employed, the red sifts it by quenching the green, and the green sifts it by quenching the red, both exhibiting the residual colour. Thus the process through which natural bodies acquire their colours is a negative one. These colours are caused by subtraction, not by addition. The action of various liquids and solids upon the spectrum is also illustrated; some cutting off the one end, others cutting off the other end, and some selecting for absorption the middle of the spectrum.

These experiments prepare us for the consideration of a point regarding which error has found currency for ages. You will find it stated in books that blue and yellow lights mixed together produce green. They do not. Blue and yellow are complementary colours and produce white by their mixture. The mixture of blue and yellow pigments undoubtedly produces green, but the mixture of pigments is totally different from the mixture of lights. Helmholtz has revealed the cause of the green in the case of the pigments. No natural colour is pure. A blue liquid, or a blue powder permits not only the blue to pass through it but a portion of the adjacent green. A yellow powder is transparent not only to the yellow light but also in part transparent to the adjacent green. Now when blue and yellow are mixed together the blue cuts off the yellow, the orange, and the red; the yellow, on the other hand, cuts off the violet, the indigo, and the blue. Green is the only colour to which both are transparent, and the consequence is that when light falls upon a mixture of yellow and blue powders, the green alone is sent back to the eye. The explanation of the mixture of pigments will be subjected to the test of experiment; and in a subsequent lecture the mixture of coloured lights will be employed to prove that blue and yellow, by their blending, produce white. This question of absorption is one of the most subtle and difficult in molecular physics. We are not yet in a condition to grapple with it, but we shall be by-and-by.

Meanwhile we may probably glance back on the web of relations which these experiments reveal to us. We have in the first place in solar light an agent of exceeding complexity, composed of innumerable constituents refrangible in different degrees. We find, secondly, the atoms and molecules of bodies gifted with the power of sifting solar light in the most various ways, and producing by this sifting the colours observed in nature and art. To do this they must possess a molecular struction commensurate in complexity with that of light itself. Thirdly, we have the human eye and brain so organized as to be able to take in and distinguish the multitude of impressions thus generated. Thus the light at starting is complex, to sift and select it as they do natural bodies must be complex. Finally, to take in the impressions thus generated the human eye and brain must be highly complex. If we were permitted to inquire into the intention of Nature we might well ask whence this triple complexity? If what are called material purposes were the sole end of nature, a much simpler mechanism would be sufficient. But instead of simplicity—instead of the principle of parsimony—we have prodigality of relation and adaptation, and this apparently for the sole purpose of enabling us to see things robed in the splendours of colour. Would it not seem that Nature harboured the intention of educating us for other enjoyments than those derivable from meat and drink? At all events whatever Nature meant, and it would be mere presumption to dogmatize as to what she meant, we find ourselves here as the issue and upshot of her operations, endowed not only with capacities to enjoy the materially useful, but also with others of indefinite scope and application, dealing alone with the beautiful and the true.

PREMIUM LIST OF THE SOCIETY OF ARTS.

The Council of the Society for the Encouragement of Arts, Manufactures and Commerce have just issued the "Premium List for the Sessions 1873-4-5." In their address they say that they are aware that some of the suggestions put forth may, at first sight, appear difficult of realization. "In some instances the thing sought involves the use of known substances in the industrial arts in a manner in which they are not at present employed, but in which there is reason to believe they are capable of being used with economy. In other cases the aid of the chemist is sought to develope such a form of action upon the material used as will induce the creation of new industries, or aid the extension of old ones by economizing processes, render them less detrimental to health, or lessen the risk of accident to those employed. Steam is the motive power now generally employed, but its use on common roads seems at present, for various reasons, inadmissible. Other agents, such as mercury, gunpowder and petroleum have been tried, but hitherto without success. There are, however, many other materials in nature to which scientific men and others may well turn their attention for the development of power, and put them in a form which shall render them available to the engineer and mechanist."

First on the list of the subjects for which prizes are offered we find some relating to economy in the use of coals for domestic purposes. They are—

1. For a new and improved system of grate, suitable to existing chimneys as generally constructed, which shall, with the least amount of coal, best answer for warming and ventilating a room.—*The Society's Gold Medal and Fifty Pounds.*

2. For a new and improved system of grate, suitable to existing chimneys as generally constructed, which shall with the least amount of coal, best answer for cooking food, combined with warming and ventilating the room.—*The Society's Gold Medal and Fifty Pounds.*

3. For the best new and improved system of apparatus which shall, by means of gas, most efficiently and economically warm and ventilate a room.—*The Society's Gold Medal and Fifty Pounds.*

4. For the best new and improved system of apparatus which shall, by means of gas, be best adapted for cooking, combined with warming and ventilating the room.—*The Society's Gold Medal and Fifty Pounds.*

5. For any new and improved system or arrangement not included in the foregoing, which shall efficiently and economically meet domestic requirements.—*The Society's Gold Medal and Fifty Pounds.*

The Council reserve to themselves the right of withholding all or any of the above prizes, as the judges appointed by them may determine.

Preserved Fresh Meat.—The sum of £100, placed at the disposal of the Council by Sir W. C. Trevelyan, Bart., with the Society's medal, is offered for the discovery of a process for preserving fresh meat in an uncooked or raw state better than by any method hitherto employed, applicable to the preservation of meat in countries where it is now almost valueless, so as to render it an article of commerce.

Uninflammable Wood.—The Society's Gold Medal is offered for the economic production of an uninflammable wood, so as to render buildings in which it is employed less destructible by fire.

A Gold Medal is offered for the discovery or manufacture of a means for safely and economically generating power suitable for use in place of steam. It should be free from refuse, noxious fumes, and injurious effects on the metals with which it may be brought into contact, or on the workmen employed.

Among the general prizes of gold and silver medals are—

Coating Vessels.—For an economical method of coating large vessels of zinc, such as baths, so as to present a bright and clean surface not readily oxidizable, and as durable as a tinned or japanned surface.

Vacuum.—For the introduction and use of a vacuum, for the drying and preservation of fruits and vegetables, either with or without heat of low temperature.

Vacuum.—For any new and economic application of a vacuum in the preparation or finish of manufactured goods.

Elastic Tubing.—For an elastic material for tubing suited to the conveyance of gas, and not liable to be affected by moisture, alterations in temperature, or to be acted upon by the gas itself.

Improved Chemical Balance.—For the best chemical and assay balance, suitable for the use of students and experimentalists, which (loaded with 600 grains in each pan) will show a difference of ·005 or less. To be sold at a moderate price.

Incombustible Wick.—For the production of an incombustible wick, suitable for use in lamps.

Waste Coal.—For a more economical and efficient method than any at present in use of preparing waste coal, so as to render it available as fuel for engineering or domestic purposes.

Lighting Coal Mines.—For a means of lighting coal mines, so as to increase the light in the workings, and at the same time reduce the risks arising in the use of the ordinary miner's lamp.

Freezing Machine.—For a machine or process, either chemical or mechanical, for lowering the temperature of substances by the abstraction of heat more effectually, and at less cost than is done by machines at present in use. The machine must be capable of working efficiently in the tropics.

For the Application of Lithography or Block Printing to stopping grounds, for etching upon glass or metals by means of chemical agents.

A Varnish or coating which can be applied to iron wires so as to protect them against rust, and which shall not be liable to chip off when the wire is bent or rubbed.

A Galvanic Element which shall combine the constancy of the Daniells's cell with the low resistance and high electromotive force of a Grove's cell.

An Electric Condenser which shall combine high capacity with small bulk, and small residual charge.

A Sensitive Pocket Galvanometer.—The size should not exceed that of a watch.

New Edible Roots.—For the discovery and successful introduction into this country of any new edible root or tuber useful as food for men or cattle, capable of resisting frost, and suitable for extensive and improved cultivation.

Electric Weaving.—To the manufacturer who first practically applies electricity to the production commercially of figured fabrics in the loom.

New Gums or Oils.—For any new resin, gum, or oils, the produce of India or Africa, calculated to be useful in the arts and manufactures, and obtainable in quantity at a moderate price. Samples of not less than 25 lb. of gum, and 50 lb. of oil, to be transmitted to the Society.

Telegraphs.—For an economic and permanent means of telegraphing through uninsulated wires, between places not less than 1000 miles apart.

Gunpowder.—For a method of constructing magazines for the storing of gunpowder, gun-cotton, nitro-glycerine, and other highly explosive compounds, so as to give increased security against explosions, and more effectually to provide against the possibility of large masses of material exploding, or, in case of explosion, communicating with other and adjacent quantities of explosive material.

Petroleum and other Light Oils and Spirits.—For a cheap and efficient method of constructing storehouses for the stowage of petroleum and other light oils, in towns and cities, so as to give greater security to the adjacent properties.

Peat.—For the introduction into commerce, as a substitute for coal, of fuel manufactured from peat, and suitable for combustion in domestic fireplaces, the furnaces of steam-engines, and for industrial purposes generally.

ANNUAL DINNER OF THE SHEFFIELD PHARMACEUTICAL AND CHEMICAL ASSOCIATION.

The annual dinner in connection with the above association was held in the rooms of the Society on Wednesday evening, February 12th; Mr. W. Ward, F.C.S., President, in the chair. There was a fair attendance of members, and amongst the guests were Dr. Hime, Wm. Baker, Esq., F.C.S., A. H. Allen, Esq., F.C.S., E. Birks, Esq., J. W. Harrison, Esq., M.R.C.S., etc.

The tables were very tastefully arranged, a large quantity of silver having been kindly lent for the occasion by a firm in the town. This is the first time the dinner has been held in the Society's own rooms; and it being somewhat of an experiment, it is gratifying to find that the arrangements gave universal satisfaction.

After the usual expressions of loyalty, "The Sheffield Pharmaceutical and Chemical Association" was proposed in an able speech by Mr. Allen, and was acknowledged by Mr. G. A. Cubley. Mr. J. T. Dobb proposed "The Medical Profession," Dr. Hime responding in an eloquent manner. "The Pharmaceutical Society," proposed by Mr. E. Birks; "The President," proposed by Mr. W. V. Radley; the Vice-President, Treasurer, Council, Secretary, and other officers being among the remaining toasts which were duly honoured. These proceedings, which were enlivened from time to time by music and singing, were of a thoroughly enjoyable nature, and were evidently appreciated by those present.

Perhaps one of the most interesting events of the evening was the presentation of a timepiece to Mr. W. V. Radley, Pharmaceutical Chemist (member of the Pharmaceutical Council), as a slight mark of esteem from a few of those who, as fellow-townsmen, have been acquainted with him in business, and who, holding him in high regard, have chosen this method of giving it expression. The clock, which is encased in a handsome black marble pedestal, inlaid with malachite, bears on a gilt plate this inscription:—"Presented to W. V. Radley, Esq. by a few friends, as a token of the respect in which he is held by the Pharmaceutical Chemists and Chemists and Druggists of Sheffield, February 12th, 1873."

Mr. Ward, President, in introducing the subject, alluded most feelingly and gracefully to the services rendered by Mr. Radley for years past to the Society at large, and particularly to the active regard he has ever evinced for the welfare and prosperity of the trade in this town.

Mr. Dobb followed in an eloquent speech, fully endorsing the remarks of the President, who, on again rising, amidst great applause, formally made the presentation.

Mr. W. V. Radley thanked sincerely and heartily those who had so kindly united to do him honour, and at the same time expressed the pleasure it had ever been to him to meet and work with those with whom it was his pride and happiness during many years to have been associated.

ANNUAL DINNER OF THE MANCHESTER CHEMISTS' ASSISTANTS' ASSOCIATION.

The third annual dinner of the above association was held at the Blackfriars Hotel on Wednesday evening, February 19; covers were laid for thirty-three. The after-dinner proceedings commenced by the President (Mr. W. Lane) calling upon the Secretary (Mr. Pidd) to read a short report of the proceedings since the commencement of the present session, which showed that eight fortnightly meetings had been held, at each of which a paper on some subject connected with pharmacy had been read and discussed. In regard to the number of members now on the roll, it was very gratifying to the Committee to see that the number this session is ten in excess of last,—last year being thirty-six and this forty-six. The usual loyal toasts were proposed, followed by that of the "Pharmaceutical Society," the "Manchester Chemists and Druggists' Association," and the "Manchester Chemists' Assistants' Association." The President, in responding to the latter toast, urged upon all those present not already members of the association the necessity of becoming so, assuring them that great benefit may be derived from the existence of such an association. With song and friendly discourse a most enjoyable evening was brought to a close.

The Pharmaceutical Journal.

SATURDAY, MARCH 1, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE REGISTER OF CHEMISTS AND DRUGGISTS AND THE CALENDAR OF THE PHARMACEUTICAL SOCIETY.

THE publication of the Register of Pharmaceutical Chemists and of Chemists and Druggists for 1873,—which, as will be seen by the Registrar's notice in our advertising columns, is now ready,—taken in conjunction with the recent issue of the Calendar of the Pharmaceutical Society, furnishes a favourable opportunity for laying before our readers some statistics partly drawn from them, and tending to throw light upon the effect the Pharmacy Act may possibly have in limiting or otherwise the number of persons entitled to carry on business as chemists and druggists. Another point, certainly of at least as much importance, which they will serve to illustrate, is the growing proportion of examined men that each year's Register contains, as well as the nature of the examinations they pass; and also, incidentally, the numerical relations of the Pharmaceutical Society to the whole body of chemists and druggists.

The Register of Chemists and Druggists for 1873 shows a gross total of 12,750 names; the first Register of the kind, published in 1869, a few months after the passing of the Pharmacy Act, 1868, contained 11,650. On the surface, therefore, it would appear that in four years there had been an increase of 1100 names. But among the rights reserved by the Pharmacy Act were those of the unexamined men, who were already engaged in the business as assistants, but who, not having kept open shop on their own account, were not entitled by the terms of the 5th section of the Act to be placed on the Register; for them it was provided that there should be a "modified" examination, the passing of which should entitle them to registration. About 2900 persons of this class, by sending in proper notices, took the necessary steps to secure this right, and of that number 1298 now appear upon the Register as "Chemists and Druggists: Modified Examination." Of these only 201 appeared upon the Register of 1869, showing an increase in 1873 of 1097. If this number 1097 be added to the 11,650 of the first Register,—as representing persons who were then virtually as much in the business as they are now,—it gives a total of 12,747, or very nearly the number on the Register for 1873. At any rate it will be better to adopt this number in estimating the proportion the examined men bear to the whole.

In 1869 there were 2443 Pharmaceutical Chemists on the Register, being 19·16 per cent. of the whole body of Registered Chemists and Druggists; in 1873 there are 2367 Pharmaceutical Chemists, or 18·56 per cent. Of these 1036, or 8·13 per cent. of the whole number on the 1869 Register, were Pharmaceutical Chemists, by virtue of having passed the "Major" examination, and 1138, or 8·93 per cent. on that for 1873. Of men who had passed the "Minor" examination,—the examination which is now required before registration—there were 462 in 1869, or 3·62 per cent.; in 1873 this number has increased to 1003, or 7·87 per cent. The result may be thus tabulated:—

	1869.				1873.			
	Number		Per cent.		Number		Per cent.	
Pharmaceutical Chemists:—								
Non-examined	1407	2443	11·03	19·16	1229	2367	9 63	18·56
Examined . .	1036		8·13		1138		8·93	
Passed the Minor		462		3·62		1003		7·87
Remainder, including 1097 "Modified" not on the Register in 1869.		9845		77·12		9,363		73·57
Total		12,750		100·00		12,733		100·00

In thus distinguishing between examined and non-examined men there is no intention to draw invidious inferences, but simply to place on record the facts by which in future years it will be most easy to ascertain the relative position of the trade.

If we take the list of Members and Associates of the Pharmaceutical Society, issued in 1859, ten years before the issue of the first Register and seven years after the passing of the first Pharmacy Act, the number of members (Pharmaceutical Chemists) contained in it was 2079, of whom only 47 were examined men. The Associates numbered 316. In 1868 the number of Members was 2022, of whom 600 had passed the examination. If to these be added the Associates, numbering 413, a gross total is arrived at of 2435, and upon comparing this with the total number contained in the first Register, it will be seen that about 20 per cent. of the whole trade were connected with the Society at the passing of the Pharmacy Act 1868. In 1872 the number of Pharmaceutical Chemist members was 2062, of whom 785 were examined, and of Chemist and Druggist members (a new class created by the Act of 1868) 669; giving a total of 2731. Add to these 940 Associates, and the total of registered Chemists and Druggists connected with the Society in that year amounts to 3671. In 1873, the Pharmaceutical Chemist members are 2027, of whom 790 have passed the "Major;" Chemist and Druggist members, 754; Associates, 941; giving a total of 3722, or upwards of 29 per cent. of the entire number on the Register, or an increase of nine per cent. in four years.

But, as might be expected, the largest relative proportions of persons connected with the Pharmaceutical Society, is to be found in the Register of Pharmaceutical Chemists. Thus in 1869 there were 2443 Pharmaceutical Chemists on the Register, of whom 2022 were members and 170 Associates of the Society: total, 2192 or nearly 90 per cent. This year, of 2367 Pharmaceutical Chemists on the Register, 2027 are members of the Society, or nearly 86 per cent. This apparent decrease is attributable to the putting in force of a bye-law which had been left in abeyance, as recently described in these columns, by which 163 names of persons who have passed the Major examination were erased from the Calendar. It is satisfactory to know that at least one half of these gentlemen have already applied for election as Members, a number quite sufficient to raise the per centage to as high a point as in 1869.

Lastly, of Registered Students or Apprentices of the Society, there were in 1859, 416; in 1868, 567; in 1872, 526; and this year there are 764.

The following table represents the foregoing figures:—

	1859.	1868-9.	1872.	1873.
Members:—

DR. LYON PLAYFAIR ON PROFESSIONAL EDUCATION.

One of our chief authorities on education, whether in its preliminary or professional aspects, is Dr. Lyon Playfair. He has had experience of the subject both practically and theoretically—practically as an *alumnus* of Scotch and German Universities and as the holder of the chemical chair in his Edinburgh *alma mater*; theoretically, as one of the chief promoters of science as an element in school instruction, and particularly of technology. As the representative in Parliament of the combined constituencies of St. Andrew's and Edinburgh Universities, he has commanded the attention of the House on every occasion when primary and middle-class instruction has been the topic of debate; and now that Irish University Reform has been announced as one of the main features of the session, he may be expected to take a prominent part in its discussion.

In an address delivered the other day before the St. Andrew's Medical Graduates' Association he has given some anticipation of the line he means to adopt in university education in general, and professional education in particular. The great difficulty, he maintains, in the culture of professional men is to secure an efficient preliminary course, which shall complete itself before the commencement of strictly professional studies. The day is done when Latin, Greek, and Mathematics can pretend to engross all the student's time up to his twentieth year. These subjects will never lose their value as parts of a liberal education; but it is idle to claim for them the exclusive or even the principal place in the future professional man's curriculum. Why, he asks, cannot the professional aspirant gain from the modern languages, from elementary physics and chemistry, and from natural history all the training that the classics and geometry have hitherto been held to give? Dante, Corneille, Goethe, to say nothing of our own Shakspeare and Milton, form as refining agents in mental culture as Homer or Horace; while observation and induction—the best of all logical disciplines—can be better acquired from the study of physics and natural history than from algebra or the formal syllogism. Such being so, why should not the University make these newer and not less valuable subjects qualify for the B.A. degree; while still retaining the older ones for students who care as possibly the future barrister and divine may care, to take them up for the same degree? In this way the student whose destination is medicine may, in his preliminary course, be pursuing a discipline which, while accelerating his subsequent progress in his professional studies, entitles him to the University's imprimatur as a graduate in arts; in other words, to the B.A. degree.

This suggestion will, doubtless, engage much attention from University Reformers, as opening up the sphere of academic education in general and placing our seats of learning more *en rapport* with the spirit of the age. The B.A. degree—the stamp of University recognition—will be thrown open by Dr. Lyon Playfair's policy to the future pharmacist, agricultural chemist, or engineer; and the Universities themselves, by thus widening their curriculum, will not put themselves in competition with institutes which are now usurping so much of the education of the national youth. His plan, indeed, is essentially a conservative one, so far as the influence of the Universities is concerned; and its principle is already being admitted in practice by the usage of even Oxford and Cambridge. These seats of learning are now giving courses of chemistry and physics which, while counting for much in the arts curriculum, at the same time enable the future medical student to prosecute his professional studies from a coign of vantage denied to him before; and at Edinburgh and Glasgow, the day is not far distant when the B.A. degree will be open to candidates whose "little Latin and less Greek" will be condoned in consideration of their proved proficiency in chemistry, physics, and natural history.

The next Evening Meeting of the Pharmaceutical Society will be held on Wednesday next, March 5th. The following papers are announced to be read:—"Legal Pharmaceutical Preparations," by Charles Symes, Ph.D.; "On the Proposed Appendix to the British Pharmacopœia," by Professor Redwood; "Tincture of Quinine," by Mr. T. H. Hustwick, "Emulsions," by Mr. Herbert G. Rogerson.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

February 19*th*, 20*th and* 21*st*, 1873.

Examiners Present—

19th and 20th—Messrs. Allchin, Barnes, Carteighe, Cracknell, Davenport, Edwards, Gale, Haselden, Ince, Linford, Martindale, and Southall.

21st—Messrs. Allchin, Barnes, Carteighe, Cracknell, Davenport, Edwards, Gale, Haselden, Ince, Linford, and Martindale.

Major Examination.

Five candidates presented themselves, of whom *two* failed. The following *three* passed, and were declared to be duly qualified to be registered as Pharmaceutical Chemists:—

	*Evans, Gwilym	Swansea.
	Little, Arthur Nicholas	Bristol.
	Rossiter, John	London.

Minor Examination.

Fifty-six candidates presented themselves, of whom *twenty-two* failed. The following *thirty-four* passed, and were declared to be duly qualified to be registered as Chemists and Druggists:—

	*Howell, John	Carmarthen.
	*Cann, Charles John	Greenwich.
	*Heyland, Charles Philip	Hammersmith.
	*Cumming, James	Camberwell Road.
	*Baxter, William, jun.	Wisbeach.
	Stoddart, Joseph	Alresford.
	Radford, John Storer	Nottingham.
	Symons, William Henry	Barnstaple.
Equal.	Bradshaw, John	Runcorn.
	Rees, Llewellyn Vosper	Mumbles.
	Dyson, Alfred	Brighouse.
Equal.	Gerring, Charles	Worthing.
	Marin, Ferdinand Baptist	London.
	Rhodes, Samuel	Oldham.
Equal.	Barnes, Edward	Cosham.
	Davies, John	London.
	Weddell, Arthur	Stamford.
	Dangerfield, Edward	High Wycombe.
	McLean, Kenneth	London.
Equal.	Prust, Thomas William	Leeds.
	Stables, Walter Banks	Bradford.
	Thomas, James Phillip	Hay.
	Little, Henry	Surbiton.
Equal.	Betts, Alick Stephen	Woodbridge.
	Short, William	March.
	Bake, Alfred Benjamin	Guildford.
	Steele, Samuel	Plymouth.
	Miller, Edward	Oakham.
	Thompson, Harry	Norwich.
	Breadner, Charles Gibson	Manchester.
	Davies, Henry Morgan	Cardigan.
	Harris, Francis George	Leamington.
	Stevens, Stephen Nobbs	Swaffham.
	Hinds, Howell David	Pontardulais.

The above names are arranged in order of merit.

Preliminary Examination.

A Certificate of Examination by the University of Oxford was received from the undermentioned in lieu of the Society's Examination:—

Brookfield, Samuel .... Hanley.

* Passed with Honours.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The eighth general meeting was held at the Royal Institution on Thursday evening, the 13th inst.; the President, E. Davies, Esq., F.C.S., in the chair.

The following donations were announced:—'Proceedings of the Architectural and Archæological Society;' 'Calendar of the Pharmaceutical Society;' 'The Year Book of Pharmacy.'

Mr. T. Williams, F.C.S., exhibited a specimen of artificial galena which he had made, and described the process.

A discussion on the solubility of pure lead in sulphuric acid followed in which the President, Messrs. Armstrong, Williams and Mason took part.

A discussion also took place in reference to a recent case of death following the inhalation of nitrous oxide gas, and as to whether the accident was due to impurities contained in the gas, or to the state of the patient when inhaling it, in which the President, Messrs. Abraham, Mason, Williams and Redford took part.

The Hon. Secretary then read a paper on "Guaraná," and exhibited specimens of the seeds from which this substance is prepared, also samples of guaraná, including very pure, average, and inferior qualities, which he had procured from Messrs. Rigaud and Leconte, of Paris. Specimens of some other pharmaceutical products manufactured by the same firm, were shown, including chloral hydrate, medicinal "perles," etc.

The meeting terminated with a vote of thanks to the reader of the paper.

BRISTOL PHARMACEUTICAL ASSOCIATION.

The fifth general meeting of the session was held at the Museum and Library, Bristol, on Friday, the 14th of February.

The President, Mr. Townsend, occupied the chair, and briefly introduced Dr. Tilden, who delivered a lecture upon "The discoveries of Scheele," of which the following is an abstract:—

Carl Wilhelm Scheele was the son of a small tradesman at Stralsund, in Swedish Pomerania (now a Prussian province). He was born on 9th December, 1742, and at an early age was placed in apprenticeship with an apothecary at Gottenburg, where he remained about six years. After some years spent as assistant in different pharmacies Scheele went to Upsal, where he made the acquaintance of Bergmann, who was at that time a celebrated chemist and held a Government appointment. Scheele's reputation as a chemist was so soon established that at the instance of Bergmann he was invited to accept a chair in the University of Upsal. He also received then and afterwards various other flattering offers, not only from the Swedish Government, but from those of other countries. His sole anxiety, however, being to secure leisure for the pursuit of his favourite studies, he rejected all these opportunities of advancement, and retired to a small pharmacy which was then vacant in the town of Kœping. Here he made all the great discoveries with which his name is associated.

It is a fact which must be interesting to all who have at heart the advancement of scientific culture among the members of the pharmaceutical calling that these great discoveries, though they necessarily demanded the expenditure of much thought, time and labour, were accomplished in the very short period of about fourteen years, at a time too when the attention of the author must have been considerably distracted by the cares of business. It is further worthy of remark that that business was by no means neglected, and at the death of the proprietor, in 1786, was left in a prosperous condition.

The Essays of Scheele were translated into English, and published in the year 1786, by Dr. Beddoes, whose name is connected with the establishment of the Medical Pneumatic Institution, in Bristol, where, with the assistance of the young Humphry Davy, experiments were made on the cure of diseases by the aid of "factitious airs" or gases, nitrous oxide amongst the number.

Dr. Beddoes relates in his preface the origin of the compliment, a paraphrase of which was afterwards spoken of Davy, which in its first application was so deservedly paid to Scheele. It was observed to him, he says, "by a near relation of Bergmann, *that the greatest of Bergmann's discoveries was the discovery of Scheele.*"

It was then pointed out by the lecturer that great as the memory of Scheele actually is, and lasting as it must be, he receives credit for only a part of his work. A man of extremely retiring disposition, he sometimes omitted to publish his work till some time had elapsed, and other experimenters had gone over the same ground. This was the case with his treatise on 'Air and Fire,' in which is announced the independent discovery of both oxygen and nitrogen.

The lecturer then proceeded to give a rapid sketch of the theories which had been maintained up to Scheele's time, with reference to the phenomena of combustion and the nature of fire.

The ancients and even the alchemists regarded fire as an element or simple substance. In the act of burning, a thing was supposed to lose something, the escape of which was assumed to give rise to the appearances ordinarily attendant upon combustion.

Many of the metals were known to become converted, by exposure to heat in the air, into calxes. According to the views current at that time the metals were supposed to be compounds of these calxes, with a hypothetical element called sulphur, or inflammable earth, which, during the calcination, was believed to escape from them.

This idea is stated clearly in the following passage from Scheele's essay on 'Air and Fire.' "Iron consists of an earth *sui generis*, united with a certain quantity of phlogiston. and a certain quantity of heat: all metals agree in that point: the difference is in their earths, which, according to their nature, have absorbed either more or less phlogiston."

Every different kind of combustible substance was supposed to contain an inflammable constituent peculiar to itself.

At the beginning of the last century this idea was modified in an important respect by the celebrated Stahl, whose theory of *phlogiston*, though necessarily abandoned at the foundation of modern chemistry by Lavoisier, will always be remembered with respect. The leading idea of the theory was the existence of a universal element of combustibility, the presence of which in a substance rendered it capable of burning.

It is remarkable that throughout the progress of these ideas, developed so slowly, two circumstances inseparable from all ordinary cases of combustion whether slow or rapid had been systematically ignored.

These were the facts that, on the one hand, the presence of air is necessary for combustion, and on the other that metals when calcined in the air increase in weight.

The results of these experiments had been confirmed by men so able and eminent as Robert Boyle and others, but the facts had remained unnoticed or were disposed of by superficial explanations.

This was the state of matters when Scheele commenced his experiments on "Air and Fire," about 1774. In his essay on this subject, a translation of which, by J. R. Forster, LL.D., is bound up in the volume belonging to the library of the Pharmaceutical Society together with the rest of his essays, Scheele demonstrated the existence in air of two kinds of elastic fluids, of which one was completely absorbed by burning phosphorus, by solution of liver of sulphur, by alkaline sulphites, by turpentine, and all such oils as will dry in the air and may be changed into a resinous substance; also by moistened iron filings, and by many other substances. In all these cases a kind of air is left in which "neither a candle will burn nor any spark be visible." And "this air which is unserviceable for the fiery phenomenon, and which makes (as he stated erroneously) about two-thirds of common air, he called "corrupted or foul air" (nitrogen)." The other constituent of air which in the experiment with the phosphorus is absorbed by it, Scheele called "empyreal air," and obtained in a state of purity by several processes.

In the course of his experiments with this kind of air he observed and described correctly not only all the ordinary properties of oxygen gas, but was careful to note that it was entirely absorbed by phosphorus and those other substances which he had employed in the analysis of atmospheric air.

"Therefore these experiments prove that *empyreal air* is that kind of air by means of which fire burns in common air, and it is in common air mixed with a kind of air which has not the least attraction of the inflammable; and it is owing to this that some hindrance is made to rapid and violent conflagration; and most certainly if all the air consisted of empyreal air, the water would be of little service for extinguishing of fires."

One of the earliest of Scheele's essays was on 'Fluor Mineral and its Acid.' His attention had doubtless been attracted to this subject, "on account of the beautiful phosphoric light which this stone yields in a dark place when it has been heated. But its constituent parts are as yet little known." An observation which, notwithstanding the numerous experiments since made in the hope of isolating fluorine, is scarcely less true at the present day than it was in 1771. Scheele's first experiments upon the action of acids on fluor were made in glass retorts, and the consequent formation of white silicious earth in the water which he had placed in the receiver, together with the corrosion of the glass, caused him much perplexity, and led him not unnaturally into some serious errors.

Another very early essay was that on Manganese, or, 'Magnesia Vitrariorum,' published in 1774.

It has already been pointed out how, in the course of trying the effect of vitriolic acid upon this mineral, Scheele discovered pure empyreal air or oxygen. When he came to use muriatic acid, he made the discovery of another gaseous element scarcely less important in the eyes of the chemist. This substance was called, by Scheele, "dephlogisticated muriatic acid," in accordance with the views current in his day; and did not receive the name chlorine till many years afterwards, when its character as an element was established by Sir H. Davy.

The leading properties of chlorine are described quite correctly in Scheele's memoir, and were experimentally illustrated by the lecturer. One of its most striking peculiarities, which was of course unknown to Scheele, is its power of uniting with hydrogen gas, regenerating the muriatic acid from which it was obtained. Under the influence of light of sufficient intensity and especially of the more refrangible violet rays of the spectrum, this combination is effected so rapidly that explosion ensues. It is interesting to note that although Scheele was not acquainted with this particular instance of chemical action promoted by the agency of light, he was the first to observe and explain the photographic action of sunlight. For having exposed *luna cornua* to the sun, he found that a black powder was formed and muriatic acid generated. "Hence it follows that the blackness which the *luna cornua* acquires from the sun's light is silver by reduction."

One discovery of Scheele's will always be associated, at any rate, in the minds of pharmacists, with the memory of the illustrious Swede. The discovery of prussic or hydrocyanic acid was the result of some excellent and well-directed experiments upon Prussian blue, the origin of which is described (1782) by the author in the following terms: "Towards the beginning of the present century Mr. Diesbach, a manufacturer of colours at Berlin, with the assistance of Dr. Dippel, accidentally discovered the blue colour, since called Berlin or Prussian blue. They kept this preparation with great secrecy, till Woodward published the whole process in 1724."

The source of the colouring matter was, in the first instance, and long after, a solution of the ashes of blood, or, as it was called, *lixivium sanguinis*.

Scheele, in the course of his inquiries, soon found that, although the lixivium underwent rapid change when kept, the addition of vitriolated iron in some manner fixed the colouring matter in the lixivium so that it retained the power of furnishing, with a solution of iron, prussian blue.

He also found out that the colouring matter, for this was the name he applied to the prussic acid, was volatile and inflammable. The wonder is that he did not experience its poisonous action. He made a great many experiments with the view to discover the constituent parts of his colouring matter, and not altogether without success. At one time he was disposed to believe that it was a compound of volatile alkali and an oily substance. This view, however, he afterwards modified, as he could obtain no oil from it, neither could he produce the colour from fatty substances. But he retained the belief that volatile alkali had something to do with it, and here he was quite right, modern chemistry having taught us not only the relationship which connects the two, but also how ammonia may be transformed direct into hydrocyanic acid.

No account, however meagre, of Scheele's labours could be fairly undertaken without, at least, passing allusion to two discoveries which, from a practical point of view, present the highest interest. These are the discovery of the "New Green Pigment" (1778), ever since called Scheele's green, and of glycerine, which he prepared from oils and fats by a process which is carried on up to the present time almost precisely as described by Scheele in 1784.

In conclusion it was pointed out that Scheele was essentially an experimenter, and meddled very little with theory. In the opinion of the lecturer the more diligent cultivation of experiment is the one thing needful in the chemistry of the present time.

[The lecture was illustrated by appropriate experiments.]

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The ninth session of the above association was opened on Thursday, Febuary 13th, with a lecture by F. T. Mott, Esq., F.R.G.S., on "The Classification of Plants;" Mr. F. Parsons, pharmaceutical chemist, in the chair. The lecture, which was of a very interesting and exhaustive character, was illustrated with various coloured diagrams, and was listened to with marked attention. The lecturer described the different systems of classification originated by Ray, Jussieu and Linnæus; and in remarking upon their various merits, expressed an opinion that the system now usually adopted is open to many objections, as to whether it can be a truly natural arrangement. In connection with the classification, the geographical distribution of plants was also mentioned, and an outline of the manner in which groups of species are distributed in various parts of the World given.

At the conclusion, a very hearty vote of thanks was given to the lecturer, who briefly responded. The usual vote of thanks to the chairman having been passed, the meeting terminated.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL ASSOCIATION.

The monthly meeting was held on Wednesday, 19th February, when a lecture was delivered by Mr. W. Ward, F.C.S., President, "On Potassium and some of its Formations." The lecture, which was well delivered and profusely illustrated by capital experiments, was listened to with great attention, and at its close a cordial vote of thanks was accorded to Mr. Ward. The attendance was not so satisfactory as the Council wish it to be; and this was the subject of serious comment at the close of the lecture, it being felt to be injurious to the best interests of the Society if these meetings are not well attended. The election of two gentlemen as associates concluded the business.

MANCHESTER CHEMISTS' ASSISTANTS' ASSOCIATION.

The ninth ordinary meeting of the session was held on Monday evening in the class-room, 37, Blackfriars Street; the President in the chair. Mr. Pidd read an interesting paper "On the Alkalies and their Tests." The remaining part of the evening was taken up with a discussion on the poison regulations.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, 20th February, 1873; Dr. Frankland, F.R.S., President, in the chair.

The first paper read, after the usual business of the society had been transacted, was entitled "Solidification of Nitrous Oxide," by Mr. T. Wills. The gas, having been previously liquefied by compression in a strong iron vessel, can be caused to solidify by the rapid evaporation of the liquid in a current of air. It somewhat resembles solid carbonic acid in appearance.

A paper "On Aurin," by R. S. Dale, B.A., and C. Schorlemmer, F.R.S., was then read, giving an account of the author's investigation of the composition and chemical properties of this dye. "Researches on the action of the copper-zinc couple on organic bodies. I. on iodide of ethyl," by J. H. Gladstone, F.R.S., and A. Tribe, was read by Dr. Gladstone; and the last communication, "On the determination of ammonia in the atmosphere," was read by the author, Mr. A. H. Smee, jun. The method employed is to collect and examine the moisture condensed from the atmosphere on the external surface of a suitable glass vessel filled with ice. The lecture was illustrated by carefully made drawings of the magnified crystalline forms which are left on evaporating the liquid. The meeting finally adjourned until Thursday, 6th March, when papers will be read "On the action of hydrochloric acid in codeine," by Dr. C. R. A. Wright; "New process for mercury estimation, with some observations on mercury salts," by P. Hannay; "On a method of estimating nitric acid," by T. E. Thorpe; and a "Note on the action of acetates upon solutions of plumbic salts, with remarks on the solubility of plumbic chloride," by F. Field.

Parliamentary and Law Proceedings.

Prosecutions for Adulteration in the Isle of Man.

A short time since a series of prosecutions were instituted under the Manx Adulteration Act, when several of the most respectable merchants in Douglas were fined in small sums for selling brandy of a less strength than seventeen degrees under proof, the Manx Act providing that any spirit so sold shall be considered for the purposes of the Act as being adulterated. These were followed by prosecutions against four leading tradesmen, named William Allen, James Coole, D. E. Gelling, and Messrs. F. and W. Stephen, for selling adulterated tea.

Dr. Campbell Brown, of the Royal Infirmary, Liverpool, the public analyst for the Isle of Man, certified that the sample of tea purchased from Mr. Allen was adulterated and faced with mineral matter, Prussian blue, and other colouring matter, and was weighted with sand.

For the defence, a witness named Gill, a shopman in Mr. Allen's employ, was called, and deposed that the tea was purchased from Messrs. Peake Brothers, of London, and was sold in the same state as that in which it was received.

Mr. D. D. Lewin, a merchant, who had been in the tea trade over thirty years, gave evidence that the colour of green tea was artificial entirely, and was coloured in China, and the very finest quality was slightly coloured.

In the case of F. and W. Stephen, the certificate of Dr. Campbell Brown stated that the tea was adulterated, and was faced with mineral matter and Prussian blue.

For the defence, Mr. D. D. Lewin gave similar evidence to that above quoted.

In the case against Mr. Coole, Dr. Brown's certificate was exactly similar to that given in Stephens' case. In the case against Mr. D. E. Gelling, the certificate was also similar. The cases having been held over for consideration.

His Worship, the High Bailiff of Douglas, gave judgment on Saturday last. He said,—In the cases of the adulteration of green tea he was of opinion that they all more or less come under the operation of the Manx Act, which was very much more stringent than the Act passed in England, under which several cases have been dismissed, on the ground that the seller had no knowledge that the articles he sold were adulterated. He could not find any reported cases in other parts of the kingdom in reference to the colouring of tea. Under the Manx Act the teas in these cases were, according to the evidence, undoubtedly adulterated, and he should, therefore, be compelled to fine the defendants; but he was very desirous that the opinion of the Appellate Court should be had on the subject. He considered that the colouring matter used in the tea was a sufficient adulteration of the material to justify him in fining the defendants, but he thought it very desirable that in case of an appeal the question should be argued before the Court whether, under the Manx Act, the party selling without a guilty knowledge of the fact that the articles were adulterated is liable to be fined. In those cases they had the evidence of the public analyst that the adulteration was effected by means of mineral substances and colouring matter. He saw no difficulty, therefore, in deciding that there was adulteration, but there appeared to be a difference in the four cases; that against the defendant, William Allen, was the worst, and it would be necessary to inflict a heavier penalty on him than on the others. The fact, however, appeared to be that all the parties sold the teas as unadulterated—at least they gave no notice they were adulterated. There was no notice of adulteration in the knowledge of the sellers. No doubt the defendants sold the teas as they got them, and, therefore, it was desirable that there should be an appeal, in order to decide whether, under such circumstances, the defendants were strictly liable. He would, therefore, draw the attention of the learned counsel to the fact that the law is different in England to what it is in the Isle of Man. In the case of William Allen, the certificate was as follows:—"This sample is adulterated and faced with mineral matter, Prussian blue, and other colouring matter, and is weighted with sand." Under the circumstances of this case the defendant was fined twenty shillings and costs, or twenty-one days' imprisonment in default of payment. The certificates in the other three cases—those of James Coole, Daniel Edward Gelling, and F. and W. Stephen—were all alike, viz., that the teas were "adulterated, faced with mineral matter, Prussian blue, and other colouring matter." In each of those cases the penalty would be ten shillings and costs, or fourteen days' imprisonment in default of payment.—*Liverpool Daily Post.*

The Compounding of Prescriptions in Ireland.

On February 22nd, an undefended action was heard in the Court of Queen's Bench, Dublin, before Mr. Justice Barry and a special jury, in which the Governor and Company of the Apothecaries' Hall sought to recover two penalties of £20 each, under the Apothecaries Act, from the defendant, Mr. Robert Croskerry, of Portrush, for having practised the art and mystery of an apothecary, without having obtained the necessary certificate from the plaintiffs, authorising him to do so, as required by the Act of 31 George III. chap. 34.

The defendant is the proprietor of two medical establishments—one at Portrush and the other at Coleraine. He had lately presented himself for examination at Apothecaries' Hall, but was unsuccessful.

Mr. Purcell, Q.C. (with whom were Mr. Anderson and Mr. Kaye, instructed by Mr. G. H. Belas), in stating the case, said the defendant possessed the diploma of surgeon from the College of Surgeons, England, and the diploma from the College of Physicians, Edinburgh. His name did not appear on the medical register as an apothecary, and this was conclusive evidence under the Act. The offence was committed on the 16th and 17th October last, when Mr. Croskerry compounded prescriptions.

Mr. Thomas Hanley and Dr. Charles Henry Leet, Secretary to the Apothecaries' Hall, having been examined, a verdict was returned for the amount.

His Lordship certified for a special jury, as it appeared the defendant had intimated that he would take the case to the House of Lords.

The West Auckland Poisoning Cases.

On Tuesday, February 25th, Mary Ann Cotton, who at West Auckland on the previous Friday was committed to Durham Assizes on a charge of having murdered Joseph Nattrass, a former lodger, was again brought up on a charge of having murdered her stepson, Frederick Cotton, aged ten, and Robert Robson Cotton, her own child, aged fourteen months.

The evidence of the neighbours showed that the prisoner would allow no one but herself to attend to the children, and one witness stated that although she made some beef-tea for Frederick Cotton after he had told her that he wanted something, still Mrs. Cotton would not allow him to have it.

Dr. Scatterwood, of Leeds School of Medicine, said he had no doubt whatever that the children died from arsenical poison.

A witness named Thomas Detchon, assistant to Mr. Owen, chemist, Newcastle, said, in January, 1869, a woman who called herself Mary Ann Booth, came with another woman to the shop and purchased three pennyworth of soft soap and arsenic. That woman was the prisoner, and he pointed her out among a dozen women at Durham Gaol. He saw her photograph in the early part of November, and he pointed her out in the latter part of the same month.

A witness named Jane Hedley, formerly a neighbour of the prisoner, said she had employed Mrs. Cotton to assist her in cleaning her house. On one occasion Mrs. Cotton recommended a composition of arsenic and soap, in order to kill the vermin. Witness went to the prisoner's house for it, and found it there.

Dr. Kilburn, who attended Robert Robson Cotton, said he saw him early in the morning, and apparently in excellent health, prattling on his mother's knee. He was astonished at nine to hear that the child was dead, for there was nothing the matter with him to cause death.

At the conclusion of the examination the prisoner was committed on a charge of wilful murder in each case. In answer to the usual question as to whether she had anything to say, prisoner replied in the negative. During the hearing of the case the prisoner complained that the person to whom she had intrusted her defence was not fulfilling his duty. The Bench assured her that she would be provided with an able counsel. Her case comes on at the assizes. During the proceedings prisoner has not shown much anxiety, and she has only put one question—a question of time—through the whole examination.

Review.

THE OWENS COLLEGE JUNIOR COURSE OF PRACTICAL CHEMISTRY. By HENRY E. ROSCOE, B.A., F.R.S., Professor of Chemistry in Owens College, Manchester, and FRANCIS JONES, Chemical Master in the Grammar School, Manchester. Macmillan and Co. 1872.

This little book of 171 pages is evidently intended to be used along with Professor Roscoe's popular 'Lessons in Elementary Chemistry.' It is indeed a partial embodiment of such experiments as would fitly illustrate the course of reading given in the larger volume.

The first forty pages (Part I.) contain directions for the preparation of the gases, and their chief compounds, of iodine, bromine, and caustic soda. The apparatus to be employed and the mode of fitting them up are described with a minuteness and clearness which will recommend themselves to teacher and pupil alike; and that nothing may be wanting to give a clear conception of the meaning of the author, the description is occasionally illustrated by the judicious insertion of a well-executed woodcut. Every chemical change in this part of the book is represented by an equation, the value of which to the young student is augmented by the addition of a second equation showing what are the reacting proportions by weight, thus—

$$\begin{aligned} 2P + O_5 &= P_2O_5 \\ 62 + 80 &= 142. \end{aligned}$$

This is one step in the right direction: another (in respect of gases) would be the introduction of a third equation, pointing out the reacting volumes. These double (and triple) equations will doubtless be more extensively employed both in text-books and in class-teaching than they have been hitherto. They may be introduced to the young student as soon as he has been told that the different forms of matter unite in definite proportions to form chemical compounds, and they should be held before him until his mind is so saturated with facts illustrative of this, that they may rapidly crystallize into those general expressions which are the primary forms enabling us to classify and explain the multifarious and sometimes apparently contradictory aspects presented to us by experiment; expressions which are only too frequently the uncertain result of a slow process of painful elaboration.

We presume that the equations employed in the 'Junior Course' are intended to be nothing more than short representations of chemical changes, without any reference to theoretical considerations. But even supposing this to be so, we venture to think that greater uniformity in the representations would make the book more valuable to the young people for whom it is intended; who, are only too apt to see difficulties where there are none, especially the more painstaking among them. For example on page 6 we find—

$$H_2 + O = H_2O$$

and on page 11— $2H + O = H_2O$;

a difference which is sure to be puzzling to a student who is anxious to apply his knowledge of molecules, and of the functions of figures according as they precede or follow the symbol of an element in the free state. The equation previously quoted would be a still greater puzzle. We trust to see these defects remedied in the next edition.

The rest of the book is devoted to qualitative analysis. In fourteen pages which treat of the blowpipe is found an exceedingly good introduction to the employment of this useful but somewhat neglected instrument. How to use the blowpipe is clearly indicated; and no intelligent boy can fail to obtain the different blowpipe flames and to understand their properties, and the properties of the different parts of the Bunsen flame, after carefully reading the two or three pages in which they are described, and following the plain directions given therein. If we mistake not, this will be the most popular part of the book with those who use it, and the author has done well to give it such prominence. Then come tables of directions for the Preliminary examination of single salts, soluble or insoluble, followed by the reactions of the commoner metals grouped in the ordinary way according to their analytical relations, and by schemes for the separation of the metals. As far as possible the acids are grouped similarly. Notice of the organic acids is restricted to eight, two or three of which we should have thought of minor importance as compared with others that are omitted.

The least satisfactory part of the book is that which gives tests for organic alkaloids and certain other organic bodies,—the list of bodies might be, and we think should be, extended.

On the whole we congratulate Mr. Jones on his work, and think it so good that we could well wish there were more of it. We hope, however, not to be told in a subsequent edition as we are in this, that "certain metals such as zinc yield hydrogen gas when they are acted on by acids."

Professor Roscoe's three injunctions (given in the preface) should be taken to heart by every young chemist.

1. Be sure you understand the theoretical explanation, as well as the practical part of the experiment.
2. Keep careful notes of each day's laboratory work.
3. Learn to work neatly.

Notes and Queries.

[329.]—LIQ. AMMONIAT. VALERIANÆ.—'H. D. W.' speaks from personal knowledge of Mr. B.'s preparation, and had some difficulty about dose. "L." writes to say, that the following formula for such a preparation is given at page 637, in M. Ferrand's 'Aide Mémoire,'

"VALÉRIANATE D'AMMONIAQUE (Pierlot):
Pr. Eau dist., ... 95
Ac. Valérianique 3
Carbonate d'Amm. q.s.
Jusqu'à saturation; ajoutez,
Extrait de Valériane 2
F. dissoudre, filtrez.—6 à 30 gouttes et plus en potion," etc.

M. Ferrand previously states:—"—— il est nécessaire d'employer du carbonate provenant de l'urine, plutôt que de la fabrication du gaz."—L.

If the prescription in which liq. ammon. valerianæ appeared hailed from Southsea, it would, I believe, be a solution of the salt in aq., strength about 3 grains in each dose. I remember meeting with precisely the same difficulty, and was fortunately able to ascertain, beyond any question, that the above was intended.—ALPHA.

A Valentine's Reply.

"Press me not, 'beseech you, so;
There is no tongue that moves, none, none i' the world,
So soon as yours, could win me; so it should now,
Were there *necessity* in your request, although
'Twere needful I denied it."—*Winter's Tale.*

Did I possess a trace of wit and the pen of a ready writer,
The ladies' virtues I'd describe, and nothing should be brighter.
How much I prize their loving hearts when in their proper places,
And how I sorely dread to see them kicking o'er the traces!
I know that at the bedside of the dear and suffering sick
Their kindness and their gentleness, their ready help and quick,
Are loved beyond the sympathy that man can ever show,
And sometimes valued more than all the *skill* he can bestow.
How well they shine at Christmas-time in the merry mazy dance,
In all the little children's games of forfeits and of chance!
At conversaziones and at private scenes theatrical,
Garden fêtes and croquet too, pleasures good and practical;
In *magazines* of many kinds they are never out of place,
Could man descant as well as they on *point* and *Brussels* lace;
Or measure, make, and well design the newest bridal dresses,
And fit their little feet with shoes and curl their golden tresses?
I cannot reconcile the thought e'en in imagination
That ladies, like the Yankee, should expect to beat creation.
I could not bear to see their hands as soft as alabaster
Begrimed all o'er with dirty pill and nasty smelling plaster.
Oh! may I never see them with their chignons in profusion
Attempt to shake the tinctures or prepare the cold infusion.
How could they climb the shaky steps to clean the bottles dusty,
Or go below amongst the *wets* into the cellar musty?
Their sleek round arms were never made to work the iron mortar,
But some opine they might assist to cut the *salary* shorter.
How gladly, I ween, would he resign unto the beauteous fair
The cares, the trials, the honours too, of the Presidential chair,
Could he but be persuaded that the *shades* of Allen, Payne, and Bell,
Would whisper in his ear *these words*, Mr. President, 'Tis Well.

M. P. S.

L-nd-n, 24th February, 1873.

Pharmaceutical Women.

Sir,—The question of admitting ladies to the ranks of the Pharmaceutical Society will probably be a subject of discussion at our next annual meeting, and as the action of the Council regarding their admission has recently been commented on by the editor of the *Chemist and Druggist* in a way to mislead readers who are not fully acquainted with the difference between *registration* under the *Pharmacy Acts of* 1852 *and* 1868;" and *enrolment* in the *Pharmaceutical Society*, I venture (knowing how extensively that journal is read by men who also read your Journal) to trouble you with a few remarks. I feel the more at liberty to do this because my name has appeared somewhat prominently in opposition to the ladies—an unenviable position it may be, but one which my sense of the welfare of the Pharmaceutical Society has compelled me to assume.

The *Chemist and Druggist* says of the refusal to elect three females as "Apprentices of the Society:"—

"The Board of Examiners had no authority to refuse these ladies; the Board simply enacts definite requirements, and these were complied with to the letter. Putting it in the mildest form, it was scarcely delicate in the Council to upset the natural working out of the decision of the Examiners."

Your readers should be informed that the Council had neither the power nor the inclination to upset the decision of the Board of Examiners. On the report of the Board, the *Registrar* places the names of all who pass the examinations on their respective registers without reference to the *Council*, and persons so registered have all the rights of exercising their business to the fullest extent under the Pharmacy Acts.

The only question which came before the Council on the 5th of February was, whether Alice Marion Hart, Louisa Stammwitz, and Rosa Coombes Minshull should be admitted as apprentices *of the Pharmaceutical Society.*

Now, Sir, these ladies are utter strangers to me, therefore no personal feeling could influence me in moving that they be not admitted; but as I have always held that the Pharmaceutical Society was intended to be a Society of men, that certain disadvantages would arise from its being a mixed Society of men and women, and that the admission of females as apprentices would be only a stepping-stone to their admission as members, I felt bound to oppose them on the threshold.

As to the concluding words of the *Chemist and Druggist*, that the decision of the Council is "*as illegal as it is unjust*," I cannot dispute that point, because it is neither one nor the other. It is not unjust, because these ladies will still be allowed to continue their studies, and, if they pass future examinations, to become chemists and druggists or pharmaceutical chemists, just as men do who never connect themselves with the Pharmaceutical Society.

It is not illegal, because all power to elect or reject candidates for admission to the Society is vested in the Council, and having given my "*serious attention*" to the remarks of your contemporary, I rise from the consideration with my "*sense of honour*" unembarrassed. I should indeed be sorry to throw any impediment in the way of ladies who desire to work out for themselves a means of self-support, *and in this case I am not doing so.* I think, however, there may be more fitting occupations for them than listening to the description of bodily ailments over our shop counters. It is true you may retort on me that in our bodily afflictions none can minister so well to our sufferings as women, but this is in the privacy of the household, and I cannot help thinking the tendency of the present day is too much towards upsetting that natural and scriptural arrangement of the sexes which has worked tolerably well for four thousand years.

George W. Sandford.

February 24th, 1873.

Sir,—Albeit that I am generally considered a peaceably disposed man, I cannot but feel the call that is made for the expression of a strong and unqualified protest against the steps that are now being taken to open the gates of pharmacy to female students.

Now, Sir, I have never had the slightest objection to partake of such preparations from the hands of my fair friends as emanate from the department of culinary chemistry. I drink my cup of tea with a grateful acknowledgment of the rights of the sex; I am content to remain silent on the subject of untinned copper vessels, and the cleansing of leaden cisterns; my wife's bottle of home-made pickles is consumed with absolute trustfulness and mental tranquillity. But I must say that if in a state of semi-consciousness from serious illness, I were dependent on the feminine perception of the distinction existing between Croton oil and its milder brother Castor, or again oxalic acid and magnesic sulphate, I say that I should hasten to make my peace with this world. Do not we read continually of hospital nurses dosing their patients with carbolic acid? Can we forget the ludicrous incident of the nurse who exhibited diluted sulphuric acid, in immediate sequence to chalk mixture, and so converted the internal arrangements of her patient into a gasometer?

We have, Sir, in the present day, female colliers, fishmongers, clerks and doctors. The aspirations of the sex have been encouraged until they have overstepped the bounds of decorum of by-gone days. The landmarks have been removed, and encroachments, whose results are visible in the universal depreciation of all labour, both in quality and remuneration, force themselves at length upon our notice, and demand our indignant appeal.

When we consider how immeasurably the feelings of women surpass those of men in delicacy of organization, we can well believe that if the trifling incidents of ordinary business life affect them so strongly, how great must be their mental confusion, when harassed by some disappointed affection, or family affliction, they are called upon to unravel the mysteries of a death-dealing or life-giving prescription! It is age alone which gives to women care and prudence, and I can only look with terror on the proposition to confide to young and possibly thoughtless girls the issues of life and death.

And, Sir, let me add a word in justice to the thousands of assistants who, after a severe apprenticeship, honestly fulfilled, after a well-tried service in duties of the most precarious and important character, see themselves confronted with the vision of female competition, and its inevitable pecuniary results. It is not the mere question of jealousy or rivalry that prompts the impulse of opposition, although in this respect the success of female candidates at Examinations might serve as a stimulus to laggards. Nor can we look for the cause in the prospect of fair traders in drugs. It is rather to be believed that the duties themselves, which, though laborious and inadequately paid, convey yet to the performer a sense of pride and reposed confidence, are the points really at stake. When these attractions are removed, and the functions rendered purely clerical in their nature, there remains but the trifling remuneration, soon to be reduced by competition, to contend for.

But, Sir, there is another, and, I apprehend, clearly fatal objection to the employment of female pharmaceutists. I refer to the common occurrence of prescriptions and remedies dealing with maladies of the most revolting nature. It is impossible to suppose that these cases could be entirely prevented from passing through their hands, and necessarily arousing an inquiry, whose inevitable tendency would be to blunt the moral feelings, and open the pathway to an exceedingly undesirable field of investigation. I cannot for a moment believe, although we have lady doctors, that a truly conscientious and right-minded mother would knowingly expose her child to familiarity with subjects which possess the power to appal and disgust the sternest member of the sterner sex.

THE EXAMINATIONS.

Sir,—Perhaps you will not consider a few animadversions on the Preliminary and Minor examinations out of place in the Journal.

With regard to the Preliminary, I think *Cæsar*—whose Latin is little more than a concatenation of military terms—might be advantageously replaced by *Celsus*, since it is not military but medical technicalities which we want to learn.

I think, moreover, that besides the metrical system which is, in the curriculum for 1874, very properly transferred from the Minor to the Preliminary, botanical geography should be, likewise—or, rather, that a general knowledge of geography should be required therein. The same may be said of algebra (to simple equations), a knowledge of which would be most useful in working the chemical equations required in the Minor.

With regard to the Minor itself, all I have to say is that it seems to me hard, when a candidate fails in only one subject, that he should be held to have failed in all; supposing one to have got even honour marks in all except pharmacy, is it fair because his memory proved a little treacherous in this dry branch that he should have the anxiety of keeping up his other subjects to the boiling-point for another three months?

In conclusion, allow me a word on the subject of our titles.

An Associate is nothing more than the lowest grade of all scientific societies; therefore, why not give this title to those who have passed the "Preliminary?" A "Chemist and Druggist" is to all intents and purposes licensed to practise pharmacy; then let him be called a "Licentiate of the Pharmaceutical Society," and since "Major" men may fairly consider themselves something better than oddfellows, why not call them "Fellows of the Pharmaceutical Society?" At present, I assure you, Sir, they are frequently mistaken for the former.

L. V. REES.

520, Oxford Street, London, W.C.

P.S.—I know that with reference to "minors" being called licentiates, it may be objected that it is the examination diploma, not the belonging to the Society, which licenses one to practise pharmacy. To this my answer is, that the sooner the Pharmaceutical Society is converted from an anomaly of this sort into a society such as that of the apothecaries (to belong to which does not cost a guinea a year—to swell surplus funds—but simply an examination) the better.

Sir,—A few weeks ago I noticed in the Journal an unusually large number of rejected candidates for the Minor examination—twenty-five being rejected out of a total number of forty-two. This state of things is much to be regretted, but I think if the candidates would adopt a very simple precaution, much disappointment would be avoided.

I need scarcely say at the onset, that the success of every student depends entirely upon his own exertions, and it matters not whether he be at Bloomsbury Square or in a remote country town, he has to depend upon his own individual efforts; and I would say, in passing, that there is nothing required in the Minor examination, but what a little determination can successfully accomplish. My experience has taught me that the best precaution any young man can take to prevent his rejection, is to get some one who possesses the Major qualification to ask him a few questions now and then upon the several subjects upon which he will be examined. It takes little time, but does an immense deal of good; for it not only gives him an idea of the questions that will be asked, but it points out to him his deficiencies, which a really earnest student will soon master. Fortunately, it is a remedy that is in the reach of nearly every one who will seek it, as there are few towns that do not contain one or more persons who have passed the Major, and I venture to say, there are but few (if any) who would decline to render such a simple though useful service to any really anxious young man. I have seen so much good done by it, that I recommend every student to adopt it.

Out of many instances which have come under my notice I will mention two. One was that of a gentleman actively engaged in business on his own account, and with but little spare time for study—he attended for a very short time a chemistry class, but was entirely self taught in pharmacy, materia medica and botany. He called upon me one day and asked me to allow him to come some spare evening with a view of my examining him as to his fitness to pass—it was easily seen he had worked well, but the first six questions I asked him he could not answer; he said they were questions that never occurred to him, and yet they were very simple; after spending an hour with me he went home, and I never saw him again until I had read his name in the Journal, when I saw he had passed with honours.

The other instance was an assistant, who, when he came to reside with me, literally knew nothing either of chemistry or botany, but had within him a great desire to know them and also to pass the then voluntary examinations. He attended no class or lecture whatever, either in botany or chemistry, but was entirely self-taught, the only assistance I rendered him being to answer an occasional question he would ask me, and these were mostly appertaining to the subjects it was necessary to be perfect in. But there was no mistake about it; he worked well, and entirely out of business hours. He went to London on Monday morning, and with the kind assistance of Mr. Hills obtained a ticket for the Botanical Gardens, where he saw the majority of medicinal plants for the first time. The next day he passed his Minor examination, and not only passed, but passed with honours, and at the end of the year received the prize of books for passing the best during that year, and it is with much pleasure I occasionally see his name in the Journal as a lecturer to the students of a provincial pharmaceutical institution.

Compare this with the state of things that exists in most of the large towns where classes and lectures are provided. Ask the gentlemen who lecture how many students they see at the end of a course, or how many they see at all, compared with the number they should. No; it is now as it was sixteen years ago, when I heard a laboratory pupil at Bloomsbury Square ask the assistant there, if there was any difficulty in passing the examinations; his answer was, "You will pass if you try," and that is the great secret.

I should also like to add that there is often much harm done by the examiners asking the candidates for the Minor questions, which I consider, should only be asked in the Major; such questions rapidly spread among intending candidates, which sometimes have the effect of frightening them, and preventing their appearance at all. There were two young men from this part rejected about a year or so ago, who, residing in the heart of the black country, have about as much opportunity of studying live plants as they would in Clerkenwell Green, and yet they were asked questions in botany, which in my humble opinion were far too difficult. I think the examiners cannot be too particular in this respect, as perhaps they are not aware that the questions asked are most freely sought after by others who are now compelled to go through the same ordeal.

WILLIAM YATES BREVITT.

Wolverhampton, February 24th, 1873.

MILK ANALYSIS.

Sir,—The milk question seems to have excited more than an average amount of interest, and induced a variety of correspondence. There are a few remarks I should like to make before the subject is closed, as sources of error or misapprehension have been introduced by some of your correspondents.

Mr. Slade, page 580, has noticed a yellow colour in milk, and attributed it to annatto; and Mr. Bottle, page 640, suggests yellow from eggs. I have seen this yellow colouration a few times—once in boiled milk thickened by the addition of some farinaceous substance as the milk gave the blue reaction with iodine; the colouring matter in this instance was probably the turmeric of some culinary powder and the adulteration performed in the kitchen.

The colouring matters of anatto, turmeric, or eggs, may be extracted from milk by precipitating the casein and fat in the manner I have before indicated (page 501). Most of the colouring matter remains in the alcoholic solution; evaporate the alcohol from this solution of lactose, etc., and shake with ether. The colouring matter is then abstracted by the ether, and may be obtained by its evaporation; turmeric and anatto give a solid, and eggs an oleaginous residue. Either of these are harmless, and unimportant, except as adulterants. Eggs, however, would be rather expensive a matter for the vendor's consideration; but I have seen another yellow colouring matter in milk connected with disease. We must carefully guard against confounding this indication of disease with either of the above-named harmless adulterants. The sample of milk I now refer to was slightly coagulated and became more so when boiled, indicating albumen, and with the microscope I detected pus, and some curious misshapen globules, some of these latter having the character of ferments and produced strings of ovoid cells. This sample was obtained from a cow having an inflammatory complaint affecting the nostrils and udder, and the colour, etc., was owing to disease.

Since the analysis was made I have been gratified by the confirmatory evidence afforded by a paper of Dr. Husson "On the Analysis of Cows' Milk taken from Animals while attacked by Typhus" (Compt. Rend., Dec. 1871) in which he notices "the yellowish rose hue" and the partial substitution of albumen for casein in febrile disorders—partial coagulation and a yellow colour must not, therefore, be considered as a proof eggs and milk; a careful microscopical examination is then absolutely necessary.

I recommended Vogel's lactoscope for two reasons. 1st. It gave with *unskimmed* milk the useful information of a preliminary analysis; and, 2nd, it could be used without incurring loss of the milk; with skimmed milk it is not quite so trustworthy and must be used with an altered scale.

Farina, eggs, dextrine, etc., must not be calculated as "milk residue," or that item will be worthless; other and more conclusive data of adulterations are necessary, as this calculation makes poor milk and diluted milk synonymous terms. It is also materially affected by the soda often added to milk as a preservative. The estimation of milk sugar by the copper test (I prefer Fehling's formula) cannot be calculated as glucose, it is somewhat less than glucose in reducing power, (about seven-tenths, Watts, Dict. vol. iii.). I have easily avoided this difficulty by titrating my copper solution with milk sugar instead of glucose. The calculation may be confirmed if necessary in analysis by dividing the milk-whey into two equal parts: in A, estimating the sugar by the copper test, and in B, by the separation process of Mr. Ekin, (page 482). I have, however, perfect confidence in the accuracy of the first method.

An abstract of Mr. Wanklyn's paper on the "Analysis of Milk by the Ammonia Process" will be found in the Pharm. Journ., August 12th, 1871, page 123. Of course Mr. Bottle's eggs must be coagulated and removed from the milk before the albuminoid ammonia can be correctly estimated as casein—or some other plan of analysis than Wanklyn's must be adopted.

GEO. BROWNEN.

Laboratory, 143, *New Bond Street, February 24th* 1873.

TINCT. QUININE.

Sir,—Every one has noticed the considerable deposit that occurs in making the tinct. of quinine, B.P. Having lately had a considerable quantity of the preparation required for immediate use, I tried the experiment of gently heating it in flasks over a water bath; it soon became quite clear, but on cooling deposited an abundant crop of crystals, which arranged themselves with remarkable symmetry like feathery stars.

I was at first disposed to consider these crystals as due to a contamination; but on examination under the microscope found the *stellar rays* were composed of true acicular crystals.

Herewith I beg to forward for your inspection a bottle containing some of this curious deposit.

The inference that may be drawn from this circumstance is, either that there is a larger proportion of quinine employed than is necessary, or that the menstruum of proof spirit is not sufficiently strong to effect the solution of the drug. Were it not contrary to instructions, the practical pharmacist would most likely add a little acid to the tincture, thus rendering available the full quantity of quinine, and preventing unnecessary waste of a costly article.

Your kindly directing attention to the subject will be esteemed a favour by

Richmond. R. GOODWIN MUMBRAY.

COST OF DISPENSING.

Sir,—Let me suggest to your correspondent 'One of the Hornets,' in reference to those people who go round to all the chemists asking the price of dispensing a prescription, that many pharmaceutists refuse altogether to quote a price before dispensing, and that others take the opportunity of referring to the dispensing counter and there just marking the prescription. I have known this plan answer on more than one occasion, and strongly recommend all chemists to adopt it. If there is no recognized trade mark, Bell's "you and them" may be used, as it is known everywhere.

W. J. CHURCHILL.

Birmingham.

W. Fox.—We think the opinions you express are very mistaken ones, and that the suggestions you make could not be carried out with advantage.

"*A Chemical Student.*"—So far as we are able to decipher the name, we are unacquainted with the substance referred to.

"*Bell.*"—The examiners are not restricted to any particular book.

"*Unbeliever*" writes to recommend "A Chemist" to read Dr. Zerffi's 'Spiritualism and Animal Magnetism,' published at 1*s*. 6*d*., by Hardwick, in which book he is of opinion that the pretensions of the spiritualists are disposed of most satisfactorily.

The Preliminary Examination.—*An Apprentice* writes in reference to this subject, that on the occasion of his own examination, the local secretary brought the examination papers into the room already opened, and after staying a few minutes, left the room, and with the exception of looking in now and then, he left the candidates to themselves. *Apprentice* adds, that after the examination the secretary put the papers open into his desk, so that they were neither opened nor sealed up in the candidates' presence.

J. Roberts.—See a description of Anatto in the last volume of this Journal, p. 574.

J. Rawlinson.—The method proposed by Professor Attfield (Pharm. Journ. [2], vol. iv. p. 338) for obtaining a solution of quinine in cod-liver oil was to produce an oleate of quinine by digesting the alkaloid, well-dried, with thrice its weight of oleic acid at 212° F. for an hour or two. The oleate of quinine, which has the consistence of a soft resin, is perfectly stable, and may be diluted whenever necessary, and to any required extent.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. J. T. Holmes, Mr. T. Collier, Mr. J. G. Evans, Mr. Fox, Mr. Brownen, Mr. J. Hughes (Sydney, N. S. W.), Mr. Rogerson, Mr. A. J. Pidd, "An Older Druggist," "Alpha."

LEGAL PHARMACEUTICAL PREPARATIONS.*

BY CHARLES SYMES. PH.D.

The intimation given by Dr. Redwood at the last Pharmaceutical Meeting, that an Appendix to the Pharmacopœia is under consideration, calls up to the mind of the pharmacist some of his past reflections whilst perusing that book of pharmaceutical authority.

It is very generally admitted that the present work is far more perfect than its predecessors; and in being so is, of course, in accordance with the progress of science and advancement of the age; nevertheless, imperfections crop up here and there—most of them are very palpable—are probably oversights, and have from time to time been pointed out either in the Journals or at Pharmaceutical meetings.

Now the adoption of the formulæ in this work is not optional, but is enforced on us under certain pains and penalties; hence it becomes in itself a book of pharmaceutical law, and its preparations the only legal ones of the same name. It is nothing uncommon for imperfections to be legal, but that deviation from them should be illegal is an anomaly which, in our profession at least, we should all be gratified to have remedied.

Let us take as a familiar example liquor bismuthi; probably 95 per cent. of samples in the market answer the B.P. characters and tests, and yet it is equally probable that not 50 per cent are prepared strictly according to the B.P. process, *ergo*, 50 per cent are illegal.

The only inducement, however, to deviate from the process given would be greater facility or economy in manufacture, or the production of a better article. Were it a question of a new edition of the Pharmacopœia, these difficulties could be readily got over by a more complete description in many cases of what the article should be, and an extension of the license which already exists with regard to some chemicals, viz., to use any process which will produce the article possessing definite and uniform characters, and answering the tests given. In the case of the chemicals, for example, sulphate of magnesia, no process is given; but in the case of preparations, a formula capable of producing the article described should in every case be given; but this should be open to real improvements, provided the strength and general characters be not interfered with. It is a somewhat difficult question to deal with perhaps, and that more particularly in the issue of an appendix; but it is in good hands, and we can hope that Dr. Redwood's deep perception will enable him to see his way well through it.

We shall also probably see a page of "Errata," including not only the corrections which were pointed out shortly after the publication of the work, such as the addition of suppos. plumbi co. to the opium preparation; confect. opii and confect. scammonii as preparations into which syrup enters; but one or two more important, viz., under the head of syr. ferri phosph., for "the product should measure exactly twelve fluid ounces," read "the product should measure from ten and a half to eleven fluid ounces," varying slightly according to the greater or less amount of moisture left in the precipitate,—if it be pressed between folds of bibulous paper as directed (which, by the way, is quite unnecessary), it never measures more than ten ounces and six drachms.

Under the tests for the purity, etc., of calcis phosph., for "the solution continues clear when an excess of acetate of soda is added," read "the solution continues clear when a *dilute* solution of acetate of soda is added in excess," for if the solutions are concentrated, a precipitate does occur on their admixture, even if the phosphate is all that can be desired.

As a matter of course, preparations not included in the Pharmacopœia are lawful to dispense when prescribed by the medical practitioner; and for the sake of uniformity, as many of these in general use as have been proved to be effectual as remedies, should be included in the appendix. Succus digitalis, succus belladonnæ, amyl nitris, chloral hydras, tinct. aurantii recentis, etc.

Syr. phosph. co. has been largely prescribed throughout the country for many years past, and has every right to find itself in the appendix. It is not a secret preparation, the formula having been published by the late Professor Parrish, the originator. Then, syr. ferri et quinæ et strychniæ phosph. has a well-established reputation as a remedial agent, and should also be added.

I do not advocate that the Pharmacopœia should recognize all new medicines that are introduced, or even that become popular, otherwise it would have to include Winslow's syrup, Allcock's plasters, Brown's troches, etc.; but it must be borne in mind that a great number of the preparations contained therein were originally popular remedies, such as Gregory's powder, Dovers' powder, James' powder, etc. Now, the object of the work under consideration is to ensure uniformity in character and effect of medicines recognized by the medical profession and in general use. In this way we get ext. opii liq. as a substitute for liq. opii sed., made by Battley and a score of imitators. It is still competent for medical men to prescribe Battley's preparation, and they do so very frequently. We know, too, that a liq. chloroformi co. was contemplated, and even printed in the proof sheets of the present B.P., but why it was withdrawn and replaced by so absurd a substitute as tinct. chloroformi co. is a matter we are not quite so clear about. It is even questionable if the proprietor of "the original chlorodyne" would have suffered by its retention, as medical men would still have prescribed "Brown's" if they wished it used, and the public would doubtless be duly "cautioned against purchasing any other."

As it will be some time before the appendix is in print, we shall probably have expression of various opinions as to what substances and preparations should be legally recognized.

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, March 5, 1873.

EMULSIONS.

BY HERBERT G. ROGERSON.

The appearance in a recent number of this Journal of a paper bearing the above title, transcribed from the *New York Druggists' Circular*, leads me to offer a remark or two on the same subject.

The paper referred to was mainly devoted to a consideration of the merits of a combination of gum acacia and glycerine, in the preparation of emulsions of various kinds. Believing, however, that gum tragacanth affords us a mucilage which, when prepared under certain conditions, is capable of giving results in every respect superior to any producible by the combination recommended in the paper, I propose briefly to outline its more advantageous applications, and extremely convenient method of preparation. In doing this I am led to recur to a formula sent by me to this Journal some three years ago, and published under the title of "Cod Liver Oil Cream," which may be taken as a type of this class of emulsions; and the fact of the extensive and successful adoption of that formula having come to my knowledge, emboldens me to reproduce it in a slightly modified and improved form.

Before doing so, however, I may state it as a *sine quâ non*, that the tragacanth employed for this and allied preparations should be of exceptionally fine quality. It should possess a pretty uniform whiteness, and freedom from dark patches and specks, or if these latter be present they should be broken off and rejected. The selected pieces are then cut up into fragments about one quarter of an inch square, and immersed in soft or distilled water for 48 or more hours in the proportion of about 2½ oz. to the gallon, stirring at intervals to prevent agglomeration. The addition afterwards of a small percentage of glycerine ensures almost indefinite keeping qualities. To avoid disappointment and secure the best results it will be well not to rely on any ordinary sample of the gum, but to apply to one's wholesale house for a small parcel of exceptional quality. In this way we succeeded in obtaining a sample almost free from blemish, and requiring no material weeding; while but for this precaution one might improve but slightly on the Pharmacopœial mucil. tragac., a dark and muddy product.

The formula referred to above, as amended, runs thus—

℞	Ol. Jecor. Aselli . . .	℥ v.
First shake together.	Ess. Limon	
	,, Amygd. (1 in 16) aa	♏ xxiv.
	Spts. Vini Rect. . . .	℥ iss.
	Syrup	℥ ss.
	Mucil. Tragac. (prepared as above) ad . . .	℥ xvi.

The mere act of shaking together these ingredients for an instant or two suffices to unite them into an elegant semi-transparent, and permanent emulsion, with attractive custard-like flavour that can scarcely fail to commend itself to the votaries of "Elegant Pharmacy."

Other oils as castor, almond, turpentine, etc., or balsams may be substituted for the one above specified. The proportion there given may be held to be only *relative*, the precise quantity of any oil "emulsifiable" by a given quantity of mucilage depending directly upon the degree of viscosity of the latter. If it be desired to combine an oil in much larger proportion than appears in the formula given, this may be effected to an almost incredible extent by substituting brisk stirring in a mortar during the adding of an oil, for the mere agitation that sufficed in the former case. It is probable that a great variety of substances upon which I have not yet experimented may be treated advantageously as above.

My experience has been mainly with the oils of castor, cod-liver, olive and turpentine, and the success attending the use of these was perfect, none of them showing any disposition to separate after many months keeping, and retaining then a degree of sweetness and freshness that proved keeping qualities of a very perfect order.

THE MICROSCOPE IN PHARMACY.

BY HENRY POCKLINGTON.

Continued from p. 664.

Canellæ Albæ Cortex.—A somewhat harder but not more difficult bark than either of the preceding. It requires a little care to secure a perfect section, on account of the ease with which certain cells on the exterior tear away from the softer cells beneath, but if the cutting be from the outer surface inwards, this source of difficulty is reduced to a minimum. The usual reagents are used, with the additional use of the B.P. solution of indigo, which in this case has advantages over the magenta solution generally used.

Beginning with the outside of the bark, we have first, 'stellate' cells, analogous to those found in cassia and cinnamon, but somewhat different in size and shape, and are wholly situate on the outer surface of the bark, where they form a tolerably continous layer of varying thickness, ranging from two to six or eight cells thick. They are porous, the pores being few and large. The successive deposits of thickening matter are not very evident without the use of powerful reagents, and they stain intensely with magenta, prolonged boiling in alcohol not removing the colour entirely. Indigo and logwood solutions do not permanently stain them, but the latter stains the original cell wall of these thickened cells and also the pores, rendering these latter very perceptible. This latter reaction is probably not chemical but mechanical, the minute pores retaing the dye longer than the exposed cell surfaces. The whole of the other tissues of the bark excepting the resin receptacula, it may be noted, permanently stain with the logwood fluid. The general shape of the thickened cells is ovate, but more or less globose ones are frequent. Within the layers of stellate cells are many layers of thin-walled parenchymatous cells containing various minute granules of starch and other matters, some of which, apparently allied to chlorophyll, stain intensely with magenta. Amongst these cells are distributed very irregularly large receptacula containing a light yellow coloured oleo-resinoid substance. On removing this it is found that the walls of the containing-cell are thin, imperforate, that they stain intensely with magenta, and do not permanently stain with logwood. That their walls are very thin is shown by their slight action upon a selenite plate by polarized light; for when freed from their contents they scarcely raise or depress the colour of even the *teint sensible* film, the very delicate red-violet. With these parenchyma cells are a few liber bundles, not many. The liber proper forms the lighter internal surface of the B.P. description. It is chiefly remarkable for the great number of sphæraphides arranged linearly among the liber cells, as seen in cross section, and apparently composed of oxalate of lime. These are almost wholly confined to the layer bounding the inner surface of the bark. The liber cells are hollow, little thickened, and frequently contain minute granules of starch and other granular substances. The medullary rays and oblong or sub-cylindrical cells associated with the liber are not very interesting. The cells of the medullary rays are nearly square, with incomplete parietal adhesion and contain considerable quantities of minute starch granules, spherical or ovate, doubly refractive, and giving a black cross. A large number of cells associated with these square cells, and forming part of the medullary rays, contain, each cell singly, sphæraphides imbedded in a semi-granular substance (probably semi fluid when the bark is fresh) of apparently a saccharine nature, and unless this be removed by maceration in water, and subsequently alcohol, the polariscope and chemical reactions of the crystals will be but feeble.

In conclusion it may be remarked that the structure of *Canella alba* bark is somewhat complex, but not difficult of study to a microscopist of moderate experience, although there are features, such as the nature of the contents of some of the cells, notably of the liber cells and medullary rays, that are almost or quite beyond the reach of present micro-chemical histology.

Granati Radicis Cortex. — Pomegranate Root Bark.—The cells of this bark are altogether very different from either of the preceding both as regards size and shape. The external cells are small, subglobose and some of them porous. The cells of the layers beneath, excluding certain ligneous cells, are sub-cylindrical, thin-walled and small in cross outline. Their contents are starch granules, very minute and sphæraphides of which each cell contains one, imbedded in a substance of which I am unable to determine the nature. These raphides are minute, with feeble optical qualities, and their prismatic constituent crystals not clearly discernible as is usual in this class of crystalline cell contents. Their great number is the first thing one notices in examining the section, and further study shows that the inner layers of cells contain by far the greater number of them, very few cells in this position being without one. The more external cells contain fewer, the outermost cells none. The starch granules are very minute and most numerous in the middle layers. Their polariscope reactions are obscure. The ligneous cells are distributed in twos and threes, are large, porous, much thickened, and the successive layers of thickening deposits very evident without the aid of reagents.

In conclusion it may be remarked that the only difficulties in the examination of this bark arise from the minuteness of the cells, and their being filled with various matters that are difficult to remove without altering the general structure. Maceration in very dilute sulphuric acid for a few hours appears to be most effectual in preparing sections for examination, so far as a general view of the size and shape of the cells is concerned.

THE CHEMICAL RELATION OF PHOSPHORUS TO OIL OF TURPENTINE.

The result of an investigation by Köhler and Schimpf into the chemical relation of phosphorus to oil of turpentine, and the action of the latter as an antidote in cases of phosphorus poisoning, has been published recently in the *Chemisches Centralblatt*. The authors state that a crystalline white solid having an acid reaction, is obtained upon cooling, if ¾ of an ounce of phosphorus be gradually added to two pounds of ordinary oil of turpentine containing oxygen, while heated to 40° C. This substance is separated from excess of phosphorus by crystallization from alcohol. It changes, upon exposure to the air, into a resinous substance with the smell of pine oil and slightly of phosphoric acid. Placed in a stream of hydrogen at 40° C., inflammable phosphoretted hydrogen is evolved, and at above 50° C. it undergoes decomposition into a resinous mass. The name of turpentine phosphorous acid has been given to this new acid. When oil of turpentine is administered as an antidote in cases of phosphorus poisoning, it appears to form this compound, and as such to be discharged in the urine, being found in the alkaline distillate when the urine is distilled. The distillate has the property of reducing mercuric to mercurous chloride, and also of precipitating metallic silver from solutions of silver salts.

SYNTHESIS OF TARTARIC ACID.*

BY M. JUNGFLEISCH.

The synthetic researches of chemists have, during the last twenty years, yielded such marvellous results as to make it appear possible that the artificial production of the principal materials of which living beings are composed would be accomplished within a comparatively short time. Meanwhile, however, a physical property, the rotatory power, common to a great number of natural compounds, has not hitherto been found in any of the organic substances obtained by chemical synthesis. According to certain opinions, put forth first by Biot, and shared in by many scientific men, substances possessed of rotatory powers were considered to be produced solely in living organisms and by agencies that science was powerless to set in motion. This is the problem which I believe I have solved. In fact, taking olefiant gas, a compound easily obtained by synthesis, I have transformed it into tartaric acid optically inactive; then I have separated the product so obtained into two acids symmetrical between themselves, clearly characterized by optical and crystallographic phenomena. The one possesses a dextro-rotatory power; the other a lævo-rotatory power: the dextro-acid is identical with the natural acid.

The splendid researches of M. Pasteur have established that there exist four varieties of tartaric acid, viz.—

(1). Natural tartaric acid, hemihedral, and possessed of a power to rotate a beam of polarized light to the right.

(2). Lævo-tartaric acid, hemihedral, and possessed of a power to rotate to the left.

(3). Racemic acid, an optically neutral combination of the two active acids, which may both be reproduced from it.

(4). Inactive tartaric acid, like the preceding, neither hemihedric nor possessing rotatory powers, but not decomposible into the two active acids.

In a former series of researches, I studied the conditions under which inactive tartaric acid is transformed into racemic acid, and I have demonstrated how this transformation can be realized in a regular manner and on large quantities of material. I have also shown that the racemic acid so obtained may be broken up into dextro- and lævo-tartaric acids conformably with the method of Pasteur.

In 1860 Perkins and Duppa showed that† succinic acid could be transformed into tartaric acid; the acid which they obtained was examined by Pasteur and recognized by him to be a mixture of racemic and inactive tartaric acids.‡ But the researches of these eminent English chemists, although remarkable in a chemical point of

* 'Comptes Rendus,' vol. lxxvi., p. 286.

† Quarterly Journal of the Chemical Society,' vol. xiii. p. 102.

‡ 'Annales de Chimie et de Physique' [3] vol. ix. p. 234.

view, did not settle the question of the artificial production of the rotatory power. The researches were made with ordinary succinic acid, which is obtained, as is known, from various natural substances, a fact which justified Pasteur in asking,* whether, this succinic acid "is really inactive by nature," whether it were not rather "inactive by compensation," or even whether it were "not an active body, the action of which upon polarized light was so feeble as to be demonstrated with difficulty."

A short time after the publication of the experiments of Perkins and Duppa, Maxwell Simpson formed the happy idea of extending to the polyatomic compounds the facts relative to the nitriles discovered by Dumas, Malaguti and Le Blanc; he thus formed, among other remarkable syntheses, succinic acid by means of olefiant gas or ethylene, by the intervention of cyanide of ethylene. Ethylene may be easily obtained from acetylene, produced by the direct union of the elements, carbon and hydrogen, as shown by Berthelot. If then, starting with olefiant gas, succinic acid could be prepared, and with it the experiments of Perkins and Duppa repeated; and if the tartaric acid so obtained could be split up into two acids, optically active, the question would be completely elucidated.

I therefore first prepared succinic acid from ethylene. The yield was very small, and I operated upon no less than 3800 grams of pure bibromide of ethylene. This product was transformed by portions of 300 grams into dicyanide of ethylene, according to the method of Simpson; the coloured dicyanide obtained was dissolved in five or six times its volume of water and heated in a water-bath. Nitric acid diluted with its own weight of water was then added little by little, giving nitrate of ammonia and succinic acid.

$$C_4H_4\,(C_2N)_2 + 2NO_5, HO + 4H_2O_2 = C_8H_6O_8 + 2NO_5,NH_4O.$$

or in the modern notation—

$$C_2H_4\,Cy_2 + 2HNO_3 + 4H_2O = H_2C_4H_4O_4 + 2NH_4NO_3$$

The acid was neutralized by potash and precipitated by a salt of lead, and the acid of the succinate of lead afterwards set free by sulphuretted hydrogen. The quantity of pure and perfectly crystallized succinic acid thus obtained, notwithstanding the inevitable loss attending a lengthened manipulation, was upwards of 300 grams.

Following the methods indicated by Perkin, Duppa and Kekulé, with a few modifications, 247 grams of the succinic acid obtained from ethylene yielded 62 grams of crystalline and colourless tartrate of lime, identical with that obtained from the succinic acid of commerce. The lime salt was converted into free acid and all the inactive acid into racemic acid.

Lastly, the racemic acid was converted into the double tartrate of soda and ammonia, according to the method of Pasteur. The liquor yielded three kinds of crystals; some, very clearly hemihedric to the left, identical with the laevo-tartrate, and forming a solution possessing the power of rotating polarized light to the left; others hemihedric to the right, identical with the dextro-tartrate, a solution of which was capable of rotating it to the right.

These facts appear to demonstrate that the rotatory power can be produced without the intervention of life, and by means of compounds formed entirely by synthesis from the elements.

OPIUM TRADE OF INDIA.

The official annual 'Statement of the Progress and Condition of India' has been issued. It relates to the financial year 1870–71. The balance-sheet shows revenue and receipts amounting to £51,413,686 and expenditure amounting to £49,930,696, presenting in the net result an improvement of £1,387,678 over the preceding year, whereof £961,801 was due to the increase of the Income-tax. The accounts show an increased expenditure on opium, the results of increased cultivation and manufacture in Bengal and the North-West Provinces. The gross receipt from opium was £8,045,459, which was reduced to a net sum of little more then six millions by an expenditure amounting to £2,014,425. Opium, however, is still the most lucrative source of the Indian Revenue next to the land, and will remain so while a preference is shown to the Indian drug in the Chinese market. The systems of raising opium revenue in Bombay and Bengal are different. In the former all that is done is to levy a heavy export duty on the opium as it enters British territory from the native States of Central India, where it is grown and manufactured. On the Bengal side advances of money are made by Government to the ryots to enable them to grow the plant, and the manufacture is under the charge of a special department. The sales are made in the open market in Calcutta, and the profits are even larger than those realized by the export duty at Bombay. The opium thus sold in Calcutta is termed "provision" opium, while that portion which is sold at the Government treasuries to licensed retail vendors for consumption in the country is called Abkaree opium. The land under cultivation in the Behar and Benares agencies in 1870–71 was 530,557 acres, against 500,750 in 1869–70. There were 49,030 chests of provision opium sold, being 3350 in excess of the sale in 1869–70. Abkaree or excisable opium—that is, the opium consumed in India—bears a very small proportion to the quantity exported to China, and brings in hardly 5 per cent. of the entire opium revenue. Its value, however, has been much increased by the prohibition in 1860 of opium cultivation in Assam, where the drug was and still is largely consumed by the Indo-Chinese races. This prohibition has largely restricted the use of opium by raising its price, and has been followed by a perceptible improvement in the physical condition of the people. In the North-Western Provinces the monopoly of opium is farmed out in each district. The Bombay report shows pass fees paid in the year on the large number of 39,978 chests, nearly all from Indore. The habit of opium-eating is described as now almost universal in Rajpootana and Central India. In 1820 the ordinary value of opium land was 4*s.* the beegah (in Malway a little more than half an acre), but within 20 years it quadrupled, and now it will command from 20*s.* to 100*s.*, and in many places even more. So long as the free cultivation of the poppy is prohibited in India, no produce can be so remunerative in the native States; and the report on Central India states that it is computed that there are now 900,000 beegahs of the best land devoted to it, to the exclusion of the food supplies of the people. With the growth or sale of the drug in native territory the British Government has nothing to do; the cultivator and trader sell to whom they please, and, after paying the duty, the owner receives a pass authorizing him to remove the chest when and where he chooses. Recently permission has been given to Sindia to provide an establishment within his own territory for weighing the opium intended for export; and during the last year 12,643 chests were brought to scale at Onjein, an old city which had become almost deserted, but is now fast recovering its former importance. Scales are also established at Oodeypoor.—*Times.*

MEETING OF CHEMISTS AND DRUGGISTS AT GREENOCK.

At a recent meeting of the chemists and druggists in business at Greenock it was unanimously resolved to raise the prices of drugs to the new Glasgow standard. At the same meeting it was also unanimously agreed to close entirely at eight o'clock on ordinary nights, and at nine o'clock on Saturdays.

The Pharmaceutical Journal.

SATURDAY, MARCH 8, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the Editor, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to Elias Bremridge, *Secretary,* 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. Churchill, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE PROPOSED APPENDIX TO THE BRITISH PHARMACOPŒIA.

Professor Redwood's remarks on the necessity for an Appendix to the British Pharmacopœia were characterized by his usual sagacity, and they will doubtless be read with much interest. Therapeutical remedies are multiplying in such a ratio as to make the interval of ten years between successive editions of the Pharmacopœia far too long for the scientific pretensions or practical usefulness of that work. Since the publication of the last issue numerous remedial agents have been discovered or invented; their virtues tested and approved; and their existence made known throughout the medical and pharmaceutical professions by the various periodicals, English and foreign. Not only so; but better modes of preparing drugs already in use are from time to time being suggested and adopted, to say nothing of alterations in the doses according to the varying types of disease and the practice of physicians. To insist on having a new edition of the Pharmacopœia on every occasion when a useful accession has been made to its subject-matter would, of course, be absurd. Even to abridge by a few years the ten-year interval between successive editions, for the embodiment of new matter, would be attended by many inconveniences. But the occasional issue of an appendix is open to no objection whatever; while the benefits it would confer on practitioner and pharmacist alike are as great as they are incontestable.

We need not follow Professor Redwood into his observations on the new preparations. In many cases their addition to the Pharmacopœia requires no justification. In others, the disposition *stare vias super antiquas* may prompt resistance to innovation; and that conservatism which has its legitimate place in science as well as politics may evoke defenders of old usage even in the face of justice and convenience. All this may be looked for in the discussion which will take place on the Professor's remarks at the next meeting, But no divergence of opinion prevails as to the necessity for supplementing the Pharmacopœia from time to time, so as to make it a fair reflex of contemporary pharmacy. Nor should this be deferred till the admission of new drugs and new modes of preparation is forced into recognition. A vigilant look-out should be kept on the progress of pharmacy, whether continental, transatlantic, or colonial. Every suggestion or well-founded criticism should be welcomed at head-quarters. Pharmacist and physician should be in constant and amicable communication for the common benefit of the work, until an amount of matter has been accumulated sufficient to justify the issue of a supplement or appendix.

"Alterius sic
Altera poscit opem res et conjurat amicè."

While no limit should be put to the number of cooperators in the work; while information or criticism should be courted from every good quarter; it would be a mistake to spread the responsibility for the issue of an appendix, or of a new edition, over too great a body of men. The present Pharmacopœia Committee of the Medical Council is sufficiently, though not more than sufficiently, numerous; and the principle on which it has been composed—that of leaving the responsibility for the work in as few hands as is compatible with efficiency—will be endorsed by every candid and intelligent well-wisher to the cause of sound pharmacy and therapeutics. At the approaching meeting of the General Medical Council, the issue of a supplement to the Pharmacopœia will be discussed; and while it is difficult to suppose that the necessity for such an issue will not be admitted and practically recognized, there is no doubt that the Council will have been materially assisted towards such a conclusion by the able remarks of Professor Redwood.

THE SALE OF POISONS.

When we referred to the proceedings of the Whitehaven chemists and druggists a fortnight since, as being calculated to ensure the sellers of vermin poison against those annoying and perhaps injurious expressions of censure which we have had so frequently to record as coming from magistrates, coroners and juries in cases of poisoning, we believed that the desirability of preventing the recurrence of such incidents would be sufficiently obvious to all who were engaged in dealing with these commodities, and that they would both understand as well as appreciate the idea that the action taken by our brethren at Whitehaven was commendable as a politic means of self-protection. But the letter of Mr. Tibbs, which will be found at page 719, shows that we were to some extent mistaken in this belief; and since there may be others who take the same view of the matter that he does, it will not be superfluous to state more specifically the grounds on which we base the views which have caused him so much surprise, and at the same time to point out some grave misconceptions under which our correspondent labours.

First, then, let us repeat that in recommending the registration of "vermin killers" in accordance with the regulations applying to poisons comprised in part 1 of Schedule A, we had in view simply the interests of chemists and druggists dealing in such preparations. We offered this suggestion as indicating a means by which they could protect themselves against the inconvenience and damage likely to result from charges of negligence in the sale of such poisonous materials. Practically, it matters little, in this respect, whether or not there be any grounds for charges of the kind; and those against whom they have been made will doubtless know that, however unfounded they may have been, it is very difficult to avoid their disadvantageous consequences.

It was from this point of view, and bearing in mind the numerous instances in which chemists and druggists have been regarded as in some way blamable in cases of poisoning, that we regarded the subject when, speaking in terms of commendation of the course taken at Whitehaven, we remarked that the chemists and druggists of that place had earned the thanks of the trade at large for having set a good example. The contrary opinions expressed by Mr. Tibbs appear to be the result of exaggerated ideas as to interference with trade supposed to be involved in the observance of regulations as to the sale of poisons.

Such ideas we regard not only as illusory but mischievous, inasmuch as they make a self-protective proceeding appear as a grievance and a hardship. It must also be remembered that the demand for the observance of certain regulations in the sale of poisons was urged in the interest of the public, and that it was upon this basis that they were made obligatory. The law having defined what the chemist and druggist is bound to do in order to satisfy the demands of the public, it is unnecessary for him to consider whether or not the prescribed regulations affect the safety of the public: his duty, however, is clearly that of complying with the regulations; for his extra trouble in doing so he has a right to be remunerated by the public in whose interest they have been prescribed; and for his own sake it is desirable that his observance of precautionary measures should rather exceed than fall short of the literal requirements of the Act. It is for this reason that we have recommended registering the sale of "vermin killers" containing phosphorus, for although this substance is not a "poison" according to the Act, it is, in fact, a very dangerous poison; and while the course we have suggested is in accordance with the spirit of the Act, its adoption is consistent with that careful discretion on the part of the Trade which we have always regarded as the most real and thorough safeguard against poisoning which the public can hope for.

We trust that these remarks will contribute towards "setting right," not only Mr. Tibbs, but others who may share what we feel bound to call his mistaken notions. With the same object it may be well to correct some errors he has fallen into. First, as regards the interpretation of the Act by Mr. Kitchin; while we cannot look upon Mr. Tibbs's argument that a vermin killer containing strychnine is not a preparation of strychnine as anything but an evasion of fact, it is also necessary to remind him that he is totally wrong in stating that the addition made in 1869 to Schedule A of the Pharmacy Act ignores preparations of strychnine, for, in fact, it specifically introduced them for the first time.

Again, though Mr. Tibbs holds it to be a fallacy to regard paregoric as a preparation of opium, and is astonished that it is held to be one by so many chemists, we think few will be found to agree with him, inasmuch as that view would involve a disregard of the fact that in many of the cases where paregoric or even syrup of poppies are used they are undoubtedly poisons, and should therefore be treated as such.

While speaking of poisons and their sale, we may take the opportunity of replying to some correspondents' inquiries as to the yellow prussiate of potash, or ferrocyanide of potassium. This substance is well known not to be a poison; and for that reason it would be unnecessary to observe any of the prescribed poison regulations in selling it. One of our correspondents, writing from Manchester, says that this salt is "beyond a doubt" a metallic cyanide, and refers to Davis's poison-book as indicating that its sale must be registered. He is, however, in error on this point. The salt is not a metallic cyanide, but a ferrocyanide—a compound as distinct from cyanides as formates are from acetates. And, further, the work he quotes as an authority is also in error; and we may here add, that it is entirely a mistake to suppose that book is certified by Mr. Bremridge as correct. The only authoritative publications on this subject are the Schedules to the Act of 1868, and the addition to it in 1869. These are to be found in the Register and in the Society's Calendar, and in the *résumé* recently issued by order of the Council of the Pharmaceutical Society.

HOSPITAL OUT-PATIENT SYSTEM.

At a recent meeting of the Association for reforming the system of furnishing medical attendance and medicine to out-patients, it was proposed that "a lay officer attached to each hospital be instructed to see that the charity is not abused by persons being admitted as out-patients while well able to pay the usual fees of practitioners, or to obtain medical attendance by provident dispensaries or otherwise. Also that patients shall no longer be tempted to crowd to hospitals by the offer of medicine gratuitously, and therefore that no medicines should be supplied to out-patients at hospitals, but that advice and prescriptions be alone given."

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

March 5th, 1873.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.
MR. W. SCOTT BROWN, VICE-PRESIDENT.

Present—Messrs. Atherton, Betty, Bottle, Frazer, Greenish, Hampson, Hills, Mackay, Radley, Sandford, Savage, Schacht, Shaw, Stoddart, Urwick and Williams.

The minutes of the last meeting were read and confirmed.

ELECTIONS.

The following, being duly registered as Pharmaceutical Chemists, were respectively granted a diploma stamped with the seal of the Society:—

Evans, Gwilym .... Swansea.
Little, Arthur Nicholas ...... Bristol.
Rossiter, John .... Queenstown.

MEMBERS.

Pharmaceutical Chemists.

The following Pharmaceutical Chemists were elected members of the Society:—

Bemrose, Joseph .... Montreal.
Clayton, Francis Corder...... Birmingham.
Colchester, Wm. Markham, jun. Hoxton.
Cryer, Henry .... Sydenham.
Iredale, George.............. Leeds.
Jackson, John Pim .... London.
Munro, John Morrison ...... Edinburgh.
Paine, Charles .... Usk.
Rimmington, Felix Wm. Elgey Bradford, Yorks.
Robertson, Fredk. Freer Leslie. Camberwell.
Rossiter, John .... Queenstown.
Samuel, Edward .... London.
Swift, William Philip .... Spalding.
Walton, George Chapman .... Dartford.
Wharton, William .... London.

Chemists and Druggists.

Curtis, Theophilus .... Kensington.
Dawson, William .... Slough.
Dyson, Joseph Edward ...... Sheffield.
Guthrie, John .... Edinburgh.
Noble, John .... South Shields.
Richards, James Edgcome .... Truro.
Taylor, Matthew .... Peckham.
Woolstencroft, John .... Carnforth.

ASSOCIATES.

The following, having passed their respective examinations, and being in business, were elected Associates in Business of the Society:—

Minor.

Banks, Edward.............. Pendlebury.
Crossby, Richard Summerby .. Stony Stratford.
Field, Alfred William .... Taunton.
Hinds, Howell David .... Pontardulais.
McLean, Kenneth .... Lofthouse.
Smith, Richard Fox .... Barton-on-Humber.
Williams, Joseph Bower...... Kingswinford.

Modified.

Backhouse, Headley Noah .... London.
Blunt, Walter Buswell ...... Derby.
Bush, George .... Chelmsford.
Courtenay, Alexander .... London.
Cutforth, John Dixon .... London.
Hardy, George.............. Malton.
Harrington, Philip John...... Middlesbro'-on-Tees.
Hill, Edward .... Wellington, Somerset.
Meredith, John.............. Brecon.
Orton, William Billing ...... Stockport.
Plumridge, Charles .... London.
Romans, Thomas Wood ...... Wrotham.
Sheel, Robert .... Gateshead-on-Tyne.
Sirett, Henry, jun. .... Brackley.
Stafford, John .... Ross.
Steed, Robt. Owen .... London.

The following, having passed their respective examinations, were elected Associates of the Society:—

Minor.

Bake, Alfred Benjamin ...... Guildford.
Barlow, Frederick............ Macclesfield.
Barnes, Edward .... Cosham.
Betts, Alick Stephen .... Woodbridge.
Cann, Charles John .... Greenwich.
Carroll, George.............. Bath.
Harris, Francis George ...... Leamington.
Hefford, Charles .... Sydenham.
Heyland, Charles Philip...... Hammersmith.
Kirton, Christopher Henry .. Hull.
Maitland, Alick .... London.
Newhill, John William ...... Huddersfield.
Radford, John Storer .... Nottingham.
Rayson, Arthur John .... Diss.
Russell, George Hannah ...... Frome.
Steele, Samuel .... Plymouth.
Stoddart, Joseph .... Alresford.
Thomas, James Phillip ...... Hay.
Weddell, Arthur .... Stamford.

Modified.

Ball, Samuel................ Oxton.
Beer, James Henry Elias .... London.
Brown, Roger .... Skipton.
Busby, Henry Horton........ London.
Edwards, Thomas Roberts .... London.
Godolphin, Geo. Fredk. Alfred.. Notting Hill.
Hough, William .... Doncaster.
Miller, William Edwin ...... Liverpool.
Sharman, William .... London.
Trick, William Borrow ...... Stoke Newington.
Turner, Henry Prosser ...... Ledbury.
Watson, William .... London.
Welton, Henry .... Coventry.

APPRENTICES OR STUDENTS.

The following, having passed their Preliminary examination, were elected Apprentices or Students of the Society:—

Abbott, Thomas Eastoe ...... Darlington.
Ashweek, John Sydney ...... Torquay.
Baker, Matthias .... Hanley.
Balchin, Edward Samuel...... Devizes.
Barcham, Henry .... Hackford.
Bennett, Samuel Kingdom.... Harlesden Green.
Bibbings, John Henry ...... Exeter.
Brooks, Charles Theodosius.... London.
Clegg, Edmund.............. Manchester.
Clegg, James................ Heywood.
Collier, William James ...... Reading.
Cullingford, Lewis James .... Bletchingley.
Dear, Theophilus............ Hornsey Rise.
De Carle, Horace Edward .... Norwich.
Gadd, Charles Frederick...... Lincoln.
Garratt, Arthur .... Guildford.
Hobson, George William .... Buxton.
Jackson, Henry John .... Bawtree.
Jones, William.............. Bagillt.
Lawson, John Robert .... South Shields.
Maxwell, James Ashworth .... Altrincham.
Morgan, Alfred William...... Rochester.
Owen, John Edward .... London.
Perkin, Thomas .... Stourbridge
Pickup, John Arthur .... Bacup.
Porter, William .... Bury Bridge.
Radford, Charles .... Nottingham.

Robins, George Norman......Highgate.
Swindle, Norman Vickers ....Northwich.
Warren, Francis William ....Weston-super-Mare.

ERRATA.

In the list of persons elected last month printed at p. 629, *under* "*Associates in Business* (*Minor*), *Geo. D. Wenham*" *should have been included in the list of* "*Associates* not *in business.*"

"*Associate in Business* (*Modified*), *Black, James, Leslie, N.B.*" *should have been included in the list of* "*Minors.*"

FINANCE.

The Report of the Finance Committee was received and adopted, and sundry payments were ordered to be made.

Mr. BETTY suggested that the Committee should be authorized to engage the services of a professional accountant to assist them and the auditors in preparing the annual statement of accounts.

Mr. SAVAGE thought such a measure quite unnecessary and uncalled for.

Mr. URWICK approved of Mr. Betty's suggestion, but after some conversation, the matter was dropped.

BENEVOLENT FUND.

The report of the Benevolent Fund Committee was received and adopted.

On the recommendation of the Committee, a grant of £10 was made to a registered chemist and druggist residing at West Derby, Liverpool.

An application for relief from a registered chemist and druggist, aged 87, residing at King Stanley, Gloucestershire, was submitted to the Council, the application having been received too late for consideration by the Committee. A grant of £10 was also made in this case.

The Chemists' Ball.

The Secretary reported that a subscription of ten guineas had been handed over to the Benevolent Fund by the Committee of the Chemists' Ball. A vote of thanks to the Committee was recorded.

PARLIAMENTARY COMMITTEE.

The report of this Committee was read and received. The PRESIDENT said he had a long letter from Mr. Vizer, with reference to the proposed new bye-law. He did not know whether the Council would like to have it read.

Mr. FRAZER said, in his opinion, it would be quite irregular to read such a letter. Any letter on such a matter should be sent to an individual member of Council, and not to the Council generally, or they might have letters from members all over the country, and they would never get through the business.

The VICE-PRESIDENT being of the same opinion, the letter was not read.

AMENDED BYE-LAWS.

The Solicitor attended the Committee, and submitted draft of proposed bye-laws as approved by himself, which, on comparison with the suggested alterations printed last month, were found to contain in some places considerable verbal alteration. The whole of the proposed alterations were considered *seriatim*, with the following result:—

FIRST SCHEDULE. PRESENT.	SECOND SCHEDULE. PROPOSED.
SECTION 1.	
Clause 10.	*Clause* 10.
All subscriptions for the current year shall become due upon election, and all annual subscriptions shall become due on the first day of January in every year; and if any Member, Associate, or Apprentice or Student, shall not have paid his annual subscription before the first day of May in any year, his name shall be omitted from the Register of Members, Associates, and Apprentices or Students of the Society, certified by the Council at the annual meeting.	All subscription for the current year shall become due upon election, and all annual subscriptions shall become due on the first day of January in every year; and if any Member, Associate, or Apprentice or Student shall not have paid his annual subscription before the first day of May in any year, his name shall be omitted from the Register of Members, Associates, and Apprentices or Students of the Society, certified by the Council at the annual meeting.
It shall be competent to the Council to restore any defaulter to his former status in the Society on payment of his arrears and any fine which it may be thought fit by the Council to impose, not exceeding half-a-guinea.	It shall be competent to the Council to restore any person whose name has been so removed to his former status in the Society on payment of his subscription for the then current year, and a sum not less than the amount of half of one year's subscription nor exceeding five guineas as for and in commutation of his arrears of subscription.
SECTION 3.	
Clause 3.	*Clause* 3.
The Common Seal shall not be set or affixed to any deed, instrument, or writing whatsoever, unless in the presence of the Council of the Society, and in pursuance of an order or minute entered in their books.	The Common Seal may be set or affixed to any deed, instrument, or writing in pursuance of an order or minute of the Council entered in their minute book, and in the presence of the President, or Vice-President, or two Members of the Council, and not otherwise.
SECTION 4.	
BYE-LAWS.	BYE-LAWS AND REGULATIONS.
The making, altering, or abrogating any Bye-law shall be in the following manner:—	The making, altering, or abrogating of any Bye-law or any Regulation, to be prescribed by the Society, in accordance with any statute, shall be in the following manner:—
Clause 1.	*Clause* 1.
A written formula for any proposed Bye-law, or for altering or abrogating any Bye-law, being delivered by a Member of the Council to the Chairman, shall thereupon be read, and, if seconded and approved, shall be referred to two subsequent ordinary or special Meetings of the Council for confirmation, and then to a special General Meeting of the Members of the Society, and afterwards to the Privy Council, according to the provisions of the Statute, 1852, as amended by the Act, 1868.	A written formula for any proposed Bye-law or Regulation, or for altering or abrogating any Bye-law or Regulation, being delivered by a Member of the Council to the Chairman, shall thereupon be read, and, if seconded and approved, shall be referred to two subsequent ordinary or special Meetings of the Council for confirmation, and then to a special General Meeting of the Members of the Society, and afterwards to the Privy Council, according to the provisions of the Pharmacy Act, 1852, and the Pharmacy Act, 1868.

Present.	Proposed.
Section 9.	
Clause 1.	*Clause* 1.
This Committee shall consist of not less than four Members, two of whom shall constitute a quorum. The Committee shall meet once in every month, and report from time to time to the Council.	This Committee shall consist of not less than five Members, three of whom shall constitute a quorum. The Committee shall meet once, or oftener, in every month, and report from time to time to the Council.
Section 10.	
Clause 1.	*Clause* 1.
The Board of Examiners heretofore appointed shall continue in office until the first monthly meeting of the Council after the general meeting in the year 1869.	The Boards of Examiners respectively heretofore appointed shall continue in office until the end of the year 1873.
Clause 2.	*Clause* 2.
The Council shall, at the first monthly meeting of the Council after the general meeting in 1869, and in every subsequent year, appoint such competent persons as they shall think fit, to be examiners to conduct all such examinations as are provided for or contemplated by the Charter or by the Statute, 1852, and the persons so appointed shall constitute and be called the Board of Examiners for England and Wales.	The Council shall, at their first meeting, in December, 1873, and in every subsequent December appoint such competent persons as they shall think fit, to be examiners for the year to commence on the then following first day of January, to conduct all such examinations as are provided for or contemplated by the Charter or by the Statute 15 and 16 Vict. c. 56, and the persons so appointed shall for the period of their appointment constitute and be called the Board of Examiners for England and Wales.
Clause 3.	*Clause* 3.
The Council shall, at the first monthly meeting of the Council after the general meeting in 1869, and in every subsequent year, appoint fit and proper persons in Scotland to be examiners, and to meet in Edinburgh or Glasgow, or such other place or places as the Council may think desirable, and to conduct there all such examinations as are provided for or contemplated by the Statute, 1852, and the persons so appointed shall constitute and be called the Board of Examiners for Scotland.	The Council shall, at their first meeting in December, 1873, and in every subsequent December, appoint fit and proper persons in Scotland to be examiners for the year to commence on the then following first day of January, and to meet in Edinburgh or Glasgow, or such other place or places as the Council may think desirable, and to conduct there all such examinations as are provided for or contemplated by the Statute 15 & 16 Vict. c. 56, and the persons so appointed shall for the period of their appointment constitute and be called the Board of Examiners for Scotland.
Clause 4.	*Clause* 4.
The President and Vice-President of the Society shall, *ex officio*, be members of the Boards of Examiners, and shall preside at all meetings of such Boards at which they shall be present.	The President and Vice-President of the Society shall, *ex officio*, be members of the Boards of Examiners, and either of them present at any meeting of either of such Boards shall preside thereat.

Present.	Proposed.
Clause 5.	*Clause* 5.
After the first day of January, 1871, the Council shall not appoint any person who has attained the age of sixty-five years at the time of the appointment to be an examiner, unless such person shall be the President or the Vice-President of the Society.	The Council shall not appoint any person who has attained the age of sixty-five years at the time of the appointment to be an examiner.
Clause 6.	*Clause* 6.
After the first day of January, 1871, no person shall be appointed an examiner who at the time of appointment is, or who during one year prior to the time of appointment has been, a Member of the Council, other than the President or Vice-President; and the election of any examiner to be a Member of the Council shall vacate his appointment as an examiner.	No person shall be appointed an examiner who at the time of appointment is, or who during the six months prior to the time of appointment has been, a Member of the Council, unless he shall within the said six months have been the President or Vice-President; and the election of any examiner to be a Member of the Council shall vacate his appointment as an examiner.
Clause 12.	*Clause* 12.
All persons who shall tender themselves to the Examiners for Examination in accordance with the Charter and the Statute, 1852, shall be examined in their knowledge of the Latin language, in English Grammar and Composition and Arithmetic, which Examination shall be called the First Examination.	All persons who shall tender themselves to the Examiners for Examination in accordance with the Charter and the Statute, 1852, shall be examined in their knowledge of the Latin language, in English Grammar and Composition and Arithmetic, which Examination shall be called the First Examination.
Such of the said persons as shall desire Certificates of competent skill and qualification to be engaged or employed as Assistants shall be examined in the First Examination, and also in the translation and dispensing of Prescriptions, in Botany, in Materia Medica, in Pharmaceutical and General Chemistry, the Chemistry of Poisons and Posology, which examination shall be called the Minor Examination; and such of the said persons as shall desire Certificates of competent skill and qualification to exercise the business or calling of Pharmaceutical Chemists shall be examined in the Minor Examination, and in more extended knowledge of Botany, Materia Medica, the translation and dispensing of Prescriptions, Pharmacy, General Chemistry, the Chemistry of Poisons and Posology, which examination shall be called the Major Examination.	Such of the said persons as shall desire Certificates of competent skill and qualification to be engaged or employed as Assistants shall be examined in or produce Certificates of having previously been examined in the First Examination, and shall be examined in the translation and dispensing of Prescriptions, in Botany, in Materia Medica, in Pharmaceutical and General Chemistry, the Chemistry of Poisons, and Posology, which examination shall be called the Minor Examination; and such of the said persons as shall desire Certificates of competent skill and qualification to exercise the business or calling of Pharmaceutical Chemists shall be examined in or produce Certificates of having previously been examined in the Minor Examination, and shall be examined in more extended knowledge of Botany, Materia Medica,

	the translation and dispensing of Prescriptions, Pharmacy, General Chemistry, the Chemistry of Poisons, and Posology, which examination shall be called the Major Examination.
Clause 16.	*Clause* 16.
All persons before registration as Apprentices or Students shall pass the First Examination, and shall pay a fee of Two Guineas, whereupon they shall be registered as Apprentices or Students.	All persons before registration as Apprentices or Students shall pass the First Examination, and shall pay a fee of Two Guineas, whereupon they shall be registered as Apprentices or Students.
	After the 31st day of December, 1874, no person shall be admitted to the Major or the Minor Examination who shall not have attained the full age of twenty-one years; and after the 31st day of December, 1876, no person shall be allowed to pass the Major or the Minor Examination unless he shall satisfy the Examiners that for three years he has been registered and employed as an Apprentice or Student or has otherwise for three years been practically engaged in the translation and dispensing of prescriptions.
	Persons who have passed the Minor Examination at least three months previously may be admitted to the Major Examination, and all other persons desirous of passing the Major Examination may make application to the Board of Examiners for special leave in that behalf.

Mr. Sandford moved:

"That the bye-laws shall be altered in the sections numbered respectively 1, 3, 4, 9, and 10, by erasing therefrom the several portions of the said sections in that behalf appearing in the first schedule hereto, and substituting for the respective portions of sections so erased, the several clauses and words in that behalf appearing in the second schedule hereto."

Mr. Williams seconded the motion.

Mr. Betty then proposed another alteration which he thought would be generally accepted, although, when he mentioned the same matter at an earlier period of the meeting, it came upon some members by surprise. It was to add to the 2nd clause of section 8, which defines the duties of the Finance Committee, the words "with the assistance of a professional accountant," so that the last clause would read as follows: "This Committee shall also prepare *with the assistance of a professional accountant* a balance-sheet for the auditors previous to the annual meeting."

Mr. Williams suggested the addition of the words "if necessary."

Mr. Mackay said the motion as proposed by Mr. Betty would render it imperative on the Committee to obtain professional assistance.

The Vice-President thought it would be perfectly out of the question to pass such a bye-law.

Mr. Urwick seconded the proposition, thinking it was much more desirable to call in a professional auditor when everything was going on smoothly, and when all were satisfied with the way in which the accounts were kept, than it would be to do so if it should ever happen that things were not so satisfactory. As they were altering the bye-laws, he thought this addition might easily be made.

The Vice-President said the present alterations of the bye-laws had been referred to a committee, which, after discussion with the solicitor, had sent them back to the Council, and he considered it was perfectly out of order to add to them any other matter without notice having been given. He had no doubt that if the committee really required the assistance of an accountant they might obtain it at any time without a bye-law being made for the purpose.

Mr. Betty then withdrew the motion, saying he would introduce the matter in another form.

Mr. Hampson moved the following amendment:—

"That the proposed new bye-laws be accepted, save and except the one,—viz. section 10, clause 16,—beginning at the words 'after the 31st day of December, 1876, no person shall,' etc., to the end of the paragraph."

He said the solicitor had endeavoured to carry out the wishes of the majority of the Council by the proposed alterations, and to which he objected he was using a process of "fine steering" to keep as near to the law as possible, rather than preparing such bye-laws as would carry out the full intention of the Act of Parliament. He contended that this restriction as to the three years, this hard and fast line, was unnecessary. and was not the intention of those who framed the Acts of Parliament. In the majority of cases, a youth entered the business in the usual manner as an apprentice, and acquired practical knowledge. But cases might occur in which it would be difficult to conform to the three years' regulation, and why should a man who was capable in two and a half or two years of qualifying himself be restricted from passing his examination? He maintained that the examination might be, and was about to be, made thoroughly practical. It appeared also that whereas some months ago it was usual for forty candidates a day to be examined, now only twenty were examined in a day. This showed that greater time was taken, and that a more practical turn was given to the examinations. The position he took was this, that the Statute did not give power to the examiners to inquire into the antecedents of any man who presented himself for examination, but only to test his practical knowledge, and this he maintained the examiners were perfectly competent to do without insisting on a three years' apprenticeship. He therefore asked the Council to pause before they stretched the powers of the Act of Parliament in this way, especially as it appeared to him there was no imperative necessity for such a change.

Mr. Williams said this subject had already been discussed several times and voted upon, and he did not think it was in order to bring it forward again.

The Vice-President said it was perfectly in order to propose an amendment at this stage of the proceedings, though he did not agree with the one brought forward by Mr. Hampson.

Mr. Bottle called attention to the 4th section of the Pharmacy Act, 1868, to show that the Legislature did intend that persons should have been three years engaged in the business before they were admitted to pass the Modified examination. He therefore thought it must also be their intention that any one entering the business in future should conform to the same rule.

Mr. Urwick said he had great pleasure in seconding the amendment, and he did not think Mr. Bottle's observations at all touched the point, as they referred entirely to the Modified examination, which in future would be entirely abrogated; and the qualification would be shown by the candidate passing the Minor examination, which could be made strict and practical. It lay with the examiners to test candidates in any way they thought proper; and if they could pass the examination, no certificate of servitude ought to be required in any shape or form. He perfectly understood that it was desirable, and most members would insist in their private capacity, on an assistant having at least three years' experience, but what they did in their individual establishments must not be made the foundation for a formal bye-law when opposed to the Act of Parliament.

Mr. Mackay supported the bye-law as it stood, and thought that the daily practice of each individual should be the guide of what should be recommended to others. He looked upon this proposition which Mr. Hampson now sought to set aside as one of the best in the new code. Three years formed the minimum time in which any one could acquire a practical knowledge of the business, and that term ought to be insisted upon. In his own establishment young men were never taken as apprentices unless they agreed to serve for five years.

Mr. Schacht said these regulations came from the Board of Examiners, upon whom the responsibility rested of testing the candidates; and unless for some very strong reason their recommendations ought to be adopted. These gentlemen stated over and over again that they felt it would be a great assistance to them in giving credentials to candidates who came before them, if this regulation were introduced. And he might mention in corroboration of this that at the recent conference, at Brighton, Dr. Michael Foster said that one of the most arduous portions of his public duty was to properly estimate the capabilities of candidates presenting themselves before him, and that he was greatly assisted in so doing when he had some knowledge of their antecedents.

Mr. Frazer supported the amendment, not so much because he thought it was in any way sailing very near to the law, but because it appeared to him that it was an unnecessary restriction upon trade, tending to add another to the many difficulties which now existed in the way of getting assistants. He deprecated the age being limited to twenty-one for the same reason; but he should certainly support the amendment.

Mr. Williams said that the bye-law as passed at the last Council would have excluded a young man who had been dispenser to a surgeon, or to an hospital, or any post of that kind, which there was no wish to do; and the solicitor had therefore taken some pains to alter the words so as to include all those who really had a practical knowledge of the business.

Mr. Hills said three years was the very least a young man should spend practically learning the business; and, in fact, his experience was that the longer a young man was engaged in the trade the more interested was he in the studies connected with it, and the more efficient he became. He certainly considered three years was the minimum.

Mr. Stoddart said there was no difficulty in getting young men, the only difficulty was in getting good ones; and that would, he thought, be diminished rather than increased by the new regulation.

The Vice-President also thought that the proposed bye-law would have the effect of making young men learn their business thoroughly, before coming up to pass the examination, and that a better class of assistants would be the result.

Mr. Hampson said he must not be understood as intending to say a word against the advisability of apprenticeship. What he objected to was what he believed to be the illegality of the action about to be taken. He valued experience as much as any one, but as to this being a recommendation of the examiners he contended it was the duty of the Council to subject their proposition to the test of argument and discussion, and decide for themselves. He desired to leave the trade as free as possible, and to obey the statute. And he also thought there had been no argument of any kind brought forward to show the necessity of the change about to be introduced. The examiners were constantly rejecting large numbers of young men who were not able to pass, which showed that they were making the examination more practical and stringent. That was quite sufficient without drawing a hard and fast line, which they were now asked to adopt.

The amendment was then put with the following result:—

For—Messrs. Frazer, Hampson and Urwick.

Against—Messrs. Atherton, Betty, Bottle, Brown, Greenish, Haselden, Hills, Mackay, Radley, Sandford, Savage, Schacht, Shaw, Stoddart and Williams.

The amendment was therefore negatived.

Mr. Frazer then moved an amendment for omitting the clause limiting the age to twenty-one years; but as he failed to find a seconder, it fell to the ground.

The original proposition was then put and carried.

Regulations made in Pursuance of Section 9 of the Pharmacy Act, 1868, for Regulating the Register.

The Secretary presented the following Form of Regulation and Forms of Application for Restoration to the Register, under the provision set forth in section 10 of the Pharmacy Act, 1868, of the names of such persons whose names have been erased from the Register in pursuance of the provisions of the said section. The forms had been prepared by the Society's solicitor:—

"Application for restoration to the Register, pursuant to clause 10 of the Pharmacy Act, 1868, shall be made by a writing signed by the applicant and attested by a person whose name appears on the Register for the time being, and shall be supported by a Statutory Declaration made by the applicant, verifying that he is the person who was formerly registered, and disclosing his addresses and occupations from the first day of the year of publication of the printed Register in which his name last appeared to the date of his application, together with words importing that his name has not been erased from the said Register for any offence against the Act; and no such application shall be received by the Registrar unless accompanied by the sum of One Guinea, to be received by him for the purposes of the Pharmaceutical Society of Great Britain in discharge of all expenses incurred in relation to the erasure of the name of the applicant and the presentation of the application."

"*To the Council of the Pharmaceutical Society of Great Britain.*

"I, the undersigned, whose name appeared in the Register of the names of Pharmaceutical Chemists and Chemists and Druggists, printed and published in year 18 , under the direction of the Pharmaceutical Society of Great Britain, pursuant to the Act passed in the 31st and 32nd years of the reign of Her Majesty Queen Victoria, c. 121, entitled 'An Act to regulate the Sale of poisons and alter and amend the Pharmacy Act 1852,' by the name and description following, that is to say [*The name and description to be here inserted should correspond with that in the printed Register*] do hereby make application that my name may by your direction be restored to the Register of [*Pharmaceutical Chemists or Chemists and Druggists*].

"Dated this day of 18 .

"Witness to the signature of the said

Signature ,,
Address

"*Description whether Pharmaceutical Chemist or Chemist and Druggist.*"

"I, of
in the County of
do solemnly and sincerely declare that I am the person whose name appeared in the Register of the names of Pharmaceutical Chemists and Chemists and Druggists printed and published in the year 18 under the direction of the Pharmaceutical Society of Great Britain pursuant to the Act passed in the 31st and 32nd years of the reign of Her Majesty Queen Victoria, c. 121, entitled 'An Act to Regulate the Sale of Poisons and Alter and Amend the Pharmacy Act, 1852,' by the name and description following that is to say [*The name and description to be here inserted should correspond with that in the printed Register.*] And that since the first day of the said year of publication I have at the several dates resided at the several places and exercised the occupations following, that is to say [*The applicant should here account for the time.*]

"And I further solemnly and sincerely declare that I have not within the meaning of the 26th Section of the said Act been convicted of any offence against the said Act. And I make this solemn declaration conscientiously believing the same to be true, and by virtue of the provisions of the Act made and passed in the fifth and sixth years of the reign of His late Majesty King William the Fourth, intituled 'An Act to Repeal an Act of the present Session of Parliament intituled An Act for the More Effectual abolition of Oaths and Affirmations taken and made in various Departments of the State, and to substitute Declarations in lieu thereof, and for the more entire Suppresion of voluntary and extra-judicial Oaths and Affidavits and to make other Provisions for the abolition of unnecessary Oaths.' [*To be declared before a person duly authorized to administer oaths.*]

"Taken and declared at
"This day of 18
"Before me ."

Mr. Williams moved that these forms be adopted, but in doing so he called the attention of the Council to that part of the Regulation which provided that a fee of One Guinea should be paid by the person applying to have his name restored to the Register. He thought this provision a very proper one, as unless some kind of penalty were incurred by the negligence of the registered person in allowing his name to be struck off when so much trouble was taken to find him, the trouble and expense of keeping the Register in anything like a correct state would be enormous.

Mr. Savage thought that half a guinea would meet all the requirements of the case.

Mr. Bottle supported the guinea fee most decidedly. Any one who wilfully neglected to comply with the conditions of the Pharmacy Act, and had his name removed from the Register in consequence, ought to pay at least a guinea in order to be restored.

The Secretary explained that there was a great expense incurred in keeping the register correct. Although much care and trouble were taken last year to correct the Register, and the corrected Register was used in addressing the poison regulations just issued, between three and four hundred had been returned through the "dead letter office."

Mr. Mackay said it must also be remembered that nearly all these parties had been put on the Register in the first place without the payment of any fee.

Mr. Shaw said that a person carrying on business and whose name was not on the Register was open to various pains and penalties for so doing, and he thought they were sufficient without imposing a fine.

The Secretary said the guinea was not a fine, but a fee to cover the expenses of his removal and reinstatement.

The regulation and forms of application were then approved of and adopted.

Library, Museum and Laboratory.

The report of this committee was received and adopted. It recommended the purchase of the following books:—'Annuaire Pharmaceutique;' and 'United States Pharmacopœia' (new edition). It also recommended the purchase of a drying stove, a sketch of which was presented by the curator of the museum, and of a wooden press for the purpose of pressing botanical specimens.

House.

The report of this committee was received and adopted.

North British Branch.

Mr. Mackay presented a list of specimens which the Edinburgh Board of Examiners suggested would be desirable for their use in conducting the examinations. He said the list was rather a long one, and it might be a question whether all the articles there named were required, but he was quite willing that the matter should be referred to any members of the London Board to pick out such specimens as it was thought desirable should be obtained, or the board in Edinburgh could do the same thing. He also drew the attention of the Council to the approaching examination in April, when he hoped a deputation would come down and inspect the new arrangements.

It was resolved that the list of specimens be referred to the Library, Museum and Laboratory Committee, with power to make a selection and to arrange for a supply of all that was deemed to be necessary. A grant of £100 was also made to the North British Branch for current expenses, and the President, Vice-president and Secretary were appointed a deputation to attend at the approaching examination in Edinburgh.

Annual Statements of Accounts.

Mr. Betty then moved—

"That the Finance Committee so desiring it be assisted by a professional accountant in preparing the statements of accounts of the year 1872."

Mr. Radley seconded the motion.

Mr. Williams asked if any gentleman had been selected?

Mr. Betty said he was prepared to name a gentleman if required, who he believed would be perfectly acceptable to all, but, of course, it would be in the hands of the committee or of the Council to make the appointment.

Mr. Williams thought the Council should appoint the accountant if such assistance were decided upon.

Mr. Savage said he believed it was understood that if the Finance Committee required the services of a public accountant, they should be allowed them. He thought the reasons ought to be stated for adopting such a course.

Mr. Betty said he brought forward this motion because the Finance Committee felt themselves individually and collectively somewhat in a false position in presenting the auditors with a statement of accounts to the amount of some £10,000 per annum without that assistance which a commercial firm carrying on business to the same amount would, in such a case, call in. They looked upon it as necessary to relieve themselves, and everybody connected with the accounts, from a position of very grave responsibility. The Committee, in fact, were unanimous in their request that this assistance might be granted to them.

The Secretary said as far as he was concerned individually, he should be very glad if a professional accountant were called in. This question had been brought forward for the last two or three years, and it would be a satisfaction to him if a first-class man went over the books in order to examine and report as to whether the accounts were kept properly.

The Vice-President did not think it was desirable that any individual should be specified. He saw no objection to passing the resolution if it simply authorized the Committee to call in an accountant, but if it rendered it imperative upon them to do so, he should certainly vote against it.

Mr. Schacht said if it was the opinion of the Finance Committee that this would be a necessary annual charge upon the Society, he could see many objections against such a course. At the same time he thought there might be a feeling at the present moment that the accounts were not kept in the best possible form, and that if they were improved in form, the work, in future, might be done as it had been done without requiring assistance of this kind.

Mr. Urwick, as a member of the Committee, said, as far as his observation went, the accounts were kept in the most perfect way.

Mr. Betty, in reply to Mr. Schacht, said the desire of the Committee was to get the assistance of a professional accountant on this occasion, to see if any improvement could be made in the form in which the accounts are presented to the general body of members. If they found that one investigation of this kind was sufficient, they need not have it repeated, but, on the other hand, if it were necessary to continue it, then the Finance Committee next year could make a similar request.

This motion was then agreed to.

Report of Examinations.

February, 1873.

ENGLAND AND WALES.

Examinations.	Candidates. Examined.	Passed.	Failed.
Major	5	3	2
Minor	56	34	22
Modified	38	27	11
	99	64	35

Certificates received in lieu of the Preliminary examination:—

University of Cambridge	2
,, ,, Oxford	3
College of Preceptors	2
	7

Provincial Education.

The report and recommendations of this committee were received and adopted, including a grant to the Nottingham and Notts Chemists' Association of £5 for the purpose of purchasing chemical specimens and diagrams, and £10 for glass cases for chemical and materia medica specimens for the museum. Application had also been received by the committee from the Society of Chemists and Druggists at Aberdeen, and the committee were of opinion that that society should be informed that a grant of £10 had been made to them in 1871, which was still at their disposal.

The Conversazione.

It was resolved—

"That a Conversazione be held on Wednesday the 21st of May, and that the Secretary be instructed to apply to the Lords of Her Majesty's Council on Education for permission to use the South Kensington Museum on the evening of that day for such purpose."

Lecture Class Prizes.

Mr. Hampson, pursuant to notice, then moved:—

"That inasmuch as according to the Regulations, published in the Calendar, all students attending the Courses of lectures delivered by Professors Redwood and Bentley are entitled to compete for the Prizes and Certificates given in those classes, this Council hereby revokes a decision to the contrary passed at the Council of January 8th ult."

He did not wish to trouble the Council with any lengthy remarks on the present occasion, but thought they ought to be consistent in the matter. And in order to remove any doubt as to the eligibility of ladies to compete for the prizes referred to, he brought forward this motion.

Mr. Sandford seconded the resolution, thinking that the Council had rather committed a mistake in saying that all students were not eligible to compete for these prizes. This matter had nothing whatever to do with the question of the admission of ladies as members of the Society, on which point he had in no way changed his views.

Mr. Williams opposed the proposition, thinking it inconsistent with the honour and consistency of the Council to pass resolutions at one meeting and rescind them at another.

Mr. Bottle rose to order, and requested that the Secretary might refer to the minute of January 8, referred to in the motion.

The Secretary read the motion referred to, which was one proposed by Mr. Hampson, that all persons attending the classes, etc., should be eligible to compete for the prizes, which motion was lost. There was, therefore, no resolution passed which could be rescinded.

The Vice-President, as seconder of the motion proposed in January, thought Mr. Hampson was out of order in bringing it forward on the present occasion in the shape he had, and suggested he should give notice for the next meeting to bring it forward in the proper manner.

Mr. Sandford said it was difficult to understand what was the meaning of the vote come to in January. They had decided that all persons were not eligible, but they did not say who were not to compete for these prizes. It might be contended on that resolution that the Professors might pick out any three or four candidates, and say that the rest were not to compete. The matter stood in the most awkward position, and therefore he thought it would be better to make it clear by passing the resolution which Mr. Hampson now brought forward.

Mr. Hills said he had taken a long time to consider whether ladies should compete for these prizes, or whether they were confined to registered apprentices or students of the Society; but the more he thought of it, the more he was inclined to the conviction that all students should have the same privilege, and he hoped the matter would be settled then and there. With regard to the prize given by himself, he would only add that if it were decided that ladies should not compete, he would give a similar prize which should be restricted to them.

After some further discussion the President said, in his opinion, Mr. Hampson would do well to withdraw the resolution and leave the matter as it stood. There was nothing on the records of the Council to prevent ladies being eligible for *certain* prizes, and he thought the best course would be to leave the matter just as it was according to the bye-laws and regulations. At the close of the session the Professors would report the successful candidates; this report would come before the Council, and then the Council would say to whom the prizes should be given, and he did not believe for one moment if a professor awarded a prize to a lady, the Council would say she should not have it. He would remind Mr. Hampson, that on a former occasion, a gentleman belonging to the medical profession attended the laboratory course and obtained the largest number of marks. The next candidate to him also obtained sufficient number of marks to obtain the prize, and when the matter came before the General Purposes Committee, the opinion was expressed that a gentleman outside the

Society was not a person who should compete for this prize, but in order not to appear ungenerous, a medal was given to that gentleman, and a second medal was voted to the second candidate.

Mr. HAMPSON said he was quite in the hands of the Council. He did not wish to weary them by the continual reproduction of this subject, and if it were generally understood that ladies were eligible to compete for these prizes, that was quite sufficient; but still he should wish this to be clearly understood.

Mr. WILLIAMS said that was a matter which ought to be decided one way or the other. He did not agree in the opinion expressed by the President.

Mr. BOTTLE said he would give notice of a motion for the next Council, which would raise the question clearly, and in the meantime he would ask that the solicitor's opinion be taken upon it.

Mr. SHAW thought it was not a matter for legal opinion, but was rather one of grace on the part of the Council.

After some further discussion,

Mr. HAMPSON said he would withdraw the resolution, and take care that when he reproduced it there should be no informality or misunderstanding as to its purport.

Mr. BOTTLE then read the notice of motion which he had prepared for the next meeting, to the effect that it having been brought under the notice of the Council that lecture and laboratory pupils not connected with the Society had been permitted to compete for prizes, it be an instruction to the professors that no class of pupils other than those registered as apprentices or students of the Society be admitted in future to such competition.

Mr. SCHACHT suggested that as Mr. Hampson had withdrawn his resolution, Mr. Bottle should do the same, and allow the whole matter to stand over until after the annual meeting, when no doubt it would be further ventilated.

Mr. BOTTLE said he was quite willing to do so.

Mr. HAMPSON then moved pursuant to notice:—

"That notice be given to the members, by advertisement in the PHARMACEUTICAL JOURNAL, of all resolutions to be brought before the next annual meeting, of which sufficient notice has been given to the Secretary."

Mr. BETTY seconded the motion, which was unanimously agreed to.

REGISTRAR'S REPORT.

The REGISTRAR presented the following report:—

REGISTRAR'S REPORT.

ANALYSIS OF EXAMINATIONS.

ENGLAND AND WALES, 1872.

Number of meetings for Major, Minor and Modified Examinations 24

PHARMACEUTICAL MEETING.

Wednesday, March 5, 1873.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

The minutes of the last meeting were read and approved.

The following donations to the library were announced, and the thanks of the Society were voted to the donors:—

'Proceedings of the Royal Society,' from the Society; 'Pharmacopœia of the United States,' and 'Proceedings of the American Pharmaceutical Association,' from the Association; 'Pharmaceutical Times,' vols. i. ii. (1846–7), from Professor Attfield; 'Remarks on the Ipecacuan Plant,' by Professor Balfour, from the Author.

Legal Pharmaceutical Preparations.

A paper upon the above subject, by Charles Symes, Ph.D., was, at the request of the Chairman, read by Professor Attfield. The paper is printed at p. 701.

Fluid Extracts Illustrative of American Pharmacy.

Mr. Umney placed upon the table several fluid extracts illustrative of American pharmacy.

Upon being requested by the President to make some remarks upon them, he said that he had placed these fluid extracts upon the table that evening to call the attention of the meeting, and of pharmacists generally, to fluid extracts as prepared by the formulæ given in the recent edition of the United States Pharmacopœia, published in January of this year. Of the forty-six there enumerated (twenty-two of which were introduced for the first time), he had experimented with six, the selection having been made from the drugs in daily use in this country, viz. cinchona, calumba, ergot, rhubarb, taraxacum, pareira. Percolation was the mode of preparation entirely resorted to in the production of these fluid extracts, the menstruum being a novel one (at any rate to this country), a mixture of alcohol, glycerine, and water. The proportions might be expressed generally as about 50 per cent. of alcohol, 20 per cent. (fluid) of glycerine, and 30 per cent. of water; they varied, however, according to the drug to be operated upon. By alcohol was intended a spirit of wine about 57·5 per cent. overproof (·835), a little stronger, in fact than our officinal rectified spirit, and not alcohol as we understand it. The drug having been brought into the proper state of division, it is moistened with a portion of the menstruum. And here he would remark that the American Pharmacopœia defines its powders by giving a table of the number of meshes to the inch through which they are to pass; for instance, the powder passed through a sieve of eighty or more meshes to the linear inch being designated *very fine*, through one of sixty meshes *fine*, one of fifty meshes *moderately fine*, one of twenty meshes *coarse*, and so on. This he thought the compilers of our British Pharmacopœia might copy with advantage. The drug then was allowed to stand in a moderately warm place for four days, the rest of the menstruum then added, and percolation proceeded with as slowly as possible to call it percolation at all. Displacement of this menstruum was then carried on by diluted alcohol, a spirit about 20 under proof (Sikes hydrometer), or ·941 sp. gr. Operating upon sixteen troy ounces of the drug, the first fourteen fluid ounces were reserved, the remaining percolate of ten ounces or more according to the drug operated on was evaporated, one ounce of glycerine being previously added. This being reduced to two fluid ounces was mixed with the first fourteen ounces, making in all sixteen fluid ounces, equal to sixteen troy ounces of the drug, corresponding in strength very nearly to some of the fluid extracts of the British Pharmacopœia. As far as one could judge the aim of our American friends had been to economise alcohol, labour, and fuel, of course not losing sight of the most essential points—reliability and stability of the extracts themselves. As to the elegance of these preparations, he would ask the meeting to judge. He was personally of opinion that they far surpassed the fluid extracts of British pharmacy, as prepared by several aqueous infusions of the drug, and concentration by evaporation. He might add the preparation of taraxacum was much stronger than any officinal preparation we have of the same root in our Pharmacopœia; it is, at least, ten times the strength, as far as the weight of dry taraxacum root it represents, as the succus taraxaci of the British Pharmacopœia, and has therefore a more decided bitter flavour.

Mr. Sandford said that he had examined with interest the specimen of fluid extract of pareira brava, as it was a preparation to which he had given considerable attention, and he was of opinion that it by no means excelled, if even it were equal to, the preparation made according to the British Pharmacopœia.

Material for Suppositories.

Mr. A. W. Gerrard called the attention of the meeting to some specimens of suppositories and pessaries which were on the table. He said that through the remarks of Professor Redwood, at the last evening meeting, concerning some objections which had been made by medical men to the present basis used in their preparation, he was induced to make a number of experiments with the view of obtaining a substance which should not have the objections then urged. It was not necessary for him to give the details of every experiment, but it would suffice if he mentioned that he tried combinations of glycerine and isinglass, glycerine and gelatine, glycerine and starch and glycerine and soap, but had disdiscarded them all as unsuitable for the purpose. With respect to glycerine and soap he might mention a curious fact, and one he believed not generally known,—it was that those substances can be made to combine on heating them together, in the proportion of 80 per cent. of the former to 20 of the latter. The mixture on cooling had a solid consistence, and moulded easily, forming apparently an elegant suppository; but he found that in a few hours the suppositories so prepared were covered with an exudation of glycerine which rendered them objectionable, as would be seen by some that were on the table. The other specimens were mixtures of paraffin and oil of theobroma and wax and oil of theobroma in various proportions. Paraffin was a substance of a somewhat novel character to the pharmacist, having a melting-point varying from 111° to 130° F., and being remarkable for its want of chemical properties; hence it had been suggested to him for the purpose, and he thought it gave excellent results. The combination to which he should give the preference would be that of equal parts of paraffin and theobroma oil. Such a combination softened readily at the temperature of the body, which is about 98° F. He trusted that on some other occasion he should be able to give the results of further experiments.

Mr. Mackay said that the use of suppositories was to a great extent introduced into medical practice by the late Sir James Simpson, of Edinburgh, who attached very considerable importance to that mode of administering medicines. He had even expressed the opinion that by the application of certain drugs in the form of suppositories, the use of medicines by the mouth might to a certain extent be superseded. Several materials had from time to time been used as bases for the preparation of suppositories and pessaries, and at first the mixture was principally wax and oil. These, however, proved awkward, as they required to be varied according to the season of the year, the preparations answering the purpose in hot summer weather requiring to be varied in cold wintry weather. Among the most successful substitutes for the above were found to be a mixture of gelatine and glycerine, and such a combination still continued to be used in Edinburgh in the preparation of both pessaries and suppositories.

The great object to be gained is of course to have a material which will stand the heat of the hand, and yet melt slowly but surely when introduced. Now, he thought nothing could be found better fitted for the purpose under discussion than the theobroma oil or fat, but considered the introduction of a certain portion of paraffin well worthy of a trial.

The Proposed Appendix to the British Pharmacopœia.

Professor Redwood said that when he brought the subject of the proposed appendix to the British Pharmacopœia before the Society at the last meeting, he had not the opportunity of saying as much as he otherwise might have said, in consequence of the lateness of the hour. He was very happy to find that the few observations he made on that occasion had to a great extent realized already what was contemplated, namely, the eliciting certain suggestions and remarks bearing upon the subject, which could not fail to be of very great value and assistance to those who were engaged in considering what additions should be made to the Pharmacopœia when the reprint came out. He had given a sort of implied promise to make some further remarks, and had intended to bring before the meeting a more formal communication than he was now in a position to make; but when it was considered that the subject had not yet come before the Medical Council officially, and that it was merely suggestive matter, it would be seen that he could not enter very much into detail. At the same time, the desire was to elicit as much information as possible, and especially to elicit information from those who were acknowledged to be most capable of giving information, namely, the members of the Pharmaceutical Society. He believed there was no body to which the Medical Council and all connected with them looked with so much confidence, for aid and assistance and guidance, for determining what alterations or additions should be made in reprinting the Pharmacopœia, as the Pharmaceutical Society. He proposed to refer briefly to what had already been suggested for the consideration first of the Pharmacopœia Committee of the Medical Council, and subsequently of the Council themselves, when they met towards the end of this month. The Council had not yet determined to make any additions, but the Committee were in favour of such a course, and he had no doubt that the Council would endorse the recommendation of the Committee in that respect. The question then was, what should this appendix or supplement consist of? In the first place it must be obvious that on the present occasion they could make no essential alteration in any of the existing processes of the Pharmacopœia. They could add to, but not alter the present Pharmacopœia. Once in ten years was thought quite often enough for a new edition, but nevertheless certain additions at intermediate times might properly and advantageously be made. New medicines could be superadded to those already existing, and what was under consideration now was what new medicines or new forms of medicine it would be desirable to recommend for insertion in the appendix. At the last meeting of the Society he had mentioned a certain number of proposed additions, but the list had since been somewhat extended, and it now included the following:—Acetum ipecacuanhæ, æther aceticus, ammoniæ nitras (now so extensively used for the preparation of nitrous oxide), amyl nitris, aqua chloroformi, bismuthi oxidum, calcis hypophosphis, charta sinapis, chloral hydras, extractum glycyrrhizæ liquidum, hydrargyri oxidum præcipitatum, liquor magnesiæ citratis, oleum phosphoratum, oxymel ipecacuanhæ, pepsina, pilula jalapæ composita, pulvis elaterii compositus, sapo animalis, sodæ hypophosphis, succus belladonnæ, succus hyoscyami, suppositoria carbolica cum sapone, suppositoria morphiæ cum sapone, suppositoria tannica cum sapone, tinctura aurantii recentis. Some of these might be thought unworthy of the position proposed for them, and others might be suggested as being of equal or greater importance; and it was open to the Pharmaceutical Society as well as the medical profession to express their opinion in reference to those points, and also as to the forms which should be adopted, and the processes which should be recommended or enjoined. Taking the first, acetum ipecacuanhæ, a process had been given a short time ago by Dr. D. Duckworth, which could not well be improved upon. With regard to acetic ether, he thought it was unnecessary to give a detailed process for its production, and that it would be sufficient to express in general terms the method by which it was produced. He agreed with the spirit of the suggestion made by Dr. Symes, that there should be something to indicate at least the manner in which the various products were obtained. Next came amyl nitris, a therapeutic agent, he believed, of great value, although very potent, and in some respects dangerous. It was most important if its use in medicine was to be extended that there should be some definite description given of it, and some means of identifying and testing it. Then there was aqua chloroformi. Some doubts were thrown upon the advisability of introducing another form of chloroform, but this had some strong claims. It was a saturated aqueous solution, and he considered it one of the most agreeable and elegant of the aqueous menstrua that had been introduced into medical use, calculated to assist the action of a certain class of medicines, and to cover the flavour of others. With regard to bismuthi oxidum, it had been suggested that it was scarcely required in addition to the other forms of bismuth; but he thought that this would be more uniform and more to be relied upon with regard not only to its purity but also to its perfectly definite nature. It was suggested to be introduced not merely as a substitute for either of the other solid preparations of bismuth, but with a view to its subsequent employment in the preparation of liquor bismuthi itself. Then there was,—of course there was,—chloral hydras. It was not necessary to do more than describe its production in general terms, leaving it to the chemical manufacturer to carry out the details or vary them as he thought proper, but putting into the hands of the pharmacist and medical man such tests as could not fail to indicate any of the known impurities or adulterations which might find their way into it. At the last meeting, he (Professor Redwood) had suggested that some liquid form of liquorice might be added to the appendix. He had received communications from one or two gentlemen. One of them stated that after a good deal of experience he had come to the conviction that fluid extract was preferable to a syrup. He (Professor Redwood) agreed with that opinion, and he had commenced preparing a fluid extract of liquorice according to the instructions given in the new 'American Pharmacopœia,' but he soon gave up that process, considering it unnecessarily prolix and troublesome, and that an equally good result could be obtained much more easily by dissolving extract of liquorice of the pharmacopœia in a mixture of glycerine and proof spirit. It was suggested that in addition to the present red precipitate, a precipitated oxide of mercury should be added. Then among the liquors, he thought a solution of citrate of magnesia would be desirable. The French Codex had had such a preparation for many years, and he had made some of it, though not exactly as directed in the Codex, nor exactly as directed in the American Pharmacopœia, which had copied from the Codex, because the solutions there seemed to be unnecessarily strong. It was an exceedingly agreeable purgative draught, and entirely devoid of the bitter taste which the sulphate of magnesia possessed. One advantage probably in introducing it would be that as citrate of magnesia had become so thoroughly established as a popular medicine, we should have a true citrate which might either replace the fictitious citrate of magnesia, or at any rate lead to the adoption of some less objectionable name than that which was now given to an article which really was not citrate of magnesia at all. Another substance included in the list was phosphorated oil. It had been a question among medical men what was the best form for the administration of phosphorus in different kinds of disease. It had been found that in certain cases phosphorus, not in any state of chemical combination but simply in solution, was more efficacious than in any other form. The phosphorated oil was a solution of phosphorus in oil of almonds. Such a preparation was found in the Paris Codex, but the formula there given was not by any means satisfactory. Some few years back a very valuable paper, or a notice of it, appeared in the Society's Journal, detailing the results of investigations made by M. Méhu, upon the best means of producing a solution of phosphorus in oil of almonds that should be uniform in composition and permanent also. If phosphorus were simply dissolved in ordinary oil of almonds as directed in the Paris Codex, the solution very speedily underwent a change, and a reddish yellow precipitate was thrown down, which appeared to be caused by some organic compound in the oil—albumen and resinous matter. By heating the oil up to a temperature of 300 degrees for a quarter of an hour, the aqueous vapour was driven out. Then the temperature was raised to 480 degrees for another quarter of an hour, and during that time the organic matter was decomposed, and the oil as it cooled became slightly opaque. When it was filtered it was found to be colourless, and this purified colourless oil dissolved phosphorus to the extent of something more than one part in 100 parts by weight of the oil. It would keep for a length of time without undergoing change. It appeared that the most satisfactory mode of administering phosphorus in its unaltered condition was in oil. Other things had been tried, but not so successfully as oil. Then there was oxymel ipecacuanhæ which had been already described in the Journal. Pepsin was also down in the list. He felt a little difficulty as to what form of pepsin should be recognized in the Pharmacopœia. All persons seemed to agree that the time had arrived when it was imperative upon them to recognize pepsin as a therapeutic agent. He believed it to be a really efficacious and very important medicine. There were, however, a great many different preparations of pepsin; and the manner in which it was originally introduced and in which it gradually got into medical practice had led to the employment of it in several different forms. There was pepsin with starch, and pepsin without starch, and pepsin with different proportions of starch, and pepsin with acid and pepsin without acid. Some medical men preferred administering it in one form; and other medical men preferred administering it in others. If we could get pepsin in the greatest state of purity in which it could be produced practically for use in medicine, it would be still but a mixture of substances. But what was contemplated in the Pharmacopœia was to have something which should be as far as possible definable. With regard to the compound powder of elaterium, which he referred to at the last meeting, it was suggested by a distinguished member of the Medical Council some time ago; and the reason for suggesting it was that elaterium, a powerful medicine, was liable either in process of dispensing or otherwise not to be accurately weighed or uniformly mixed with the other materials to which it was to be added, and that in a more diluted form it could be more safely and advantageously administered. Then came the question of suppositories. Now he had been making experiments upon suppositories, because it was suggested that a new form was very desirable; and he was glad to find that so much light had been thrown upon the subject at this meeting. He gave up gelatine and glycerine, because there was a good deal of trouble in preparing a combination which should contain these substances in proper proportions, and such a mixture could not be made extemporaneously. His suggestion was to use soap. Curd soap, made with pure animal fat, consisting principally of stearine, would have some valuable applications in place of the olive oil, soap, or castile soap. With regard to morphia suppositories he used, in addition to the curd soap, half its weight of glycerine of starch; but in making carbolic acid suppositories, the glycerine of starch was not required. Then, lastly, tincture of fresh orange-peel was one of the suggested additions, and he proposed that this should be made with rectified spirit.

The President said he thought it would be useless to attempt to enter into any discussion of this subject at so late an hour.

The discussion was therefore adjourned to the next meeting, which will be held on Wednesday, April 2.

NORTH BRITISH BRANCH, EDINBURGH.

The fourth meeting of this society for the present session was held on Friday evening, February 21st, in St. Giles Street; Mr. H. C. Baildon, president, in the chair. A lecture was delivered by Dr. J. G. M'Kendrick, Assistant to the Professor of Physiology in Edinburgh University, on "Muscles and Nerves." In a most lucid and interesting style the lecturer explained the structure and function of these wonderful tissues which enter so largely into the formation of sentient beings, and with the help of delicate apparatus, the contractility of muscles was illustrated; and it was shown that contraction could be produced either by stimulating the muscle itself by means of a current of electricity or by stimulating the nerve connected with it. The force exerted through this contractility was also brought to the test of ocular demonstration, a small muscle from a frog being, by the mere passage of an electric current, made to lift 900 grains. The structure of muscle and nerve was shown in a series of microscopic preparations, and the lecturer explained the apparatus by which it could be proved that living muscular tissue evolves electricity, and that impulses travel through nerves very considerably slower than the electric current through a wire. The lecturer succeeded in inspiring his audience with his own enthusiasm, and maintained their attention unflaggingly for a couple of hours. At the close, on the motion of the president, seconded by the vice-president, a cordial vote of thanks was accorded to Dr. M'Kendrick.

CARLISLE CHEMISTS' ASSOCIATION.

The monthly meeting of the Carlisle Chemists' Association was held on Tuesday evening, February 25th. There was a fair attendance of associates, but few members were present. A paper, by Mr. Sawyer, on "The Human Heart," describing its formation and its functions, was in the absence of that gentleman read by Mr. Sawyer, jun. The paper was listened to with great interest and attention, and at its conclusion a vote of thanks to the author was passed.

It was resolved that the president of the association should be requested to write a letter to Mrs. Moss of sympathy and condolence with her in the great affliction she has sustained in the loss of her husband, and also to convey to her the feeling of great respect the members had for him and how sincerely they deplore his loss from among them.

The class lately under the care of Mr. Moss (materia medica) will be taken by Mr. Hallaway, who will also combine with that subject practical pharmacy.

The committee have great pleasure in announcing that Mr. Joseph Pattinson, of Baldwin Holm, has kindly undertaken charge of the chemistry class, and it is hoped that a large number of students will thus be brought together.

Mr. Hallaway was requested to perform the duties of secretary *pro tem.* to the association.

OLDHAM CHEMISTS' ASSISTANTS' ASSOCIATION.

On Wednesday, Feb. 26, the annual meeting of the Oldham Chemists' Assistants' Association was held in the Church Institute, Mr. John Taylor, president of the association, in the chair. The report, read by Mr. S. Bateman, the secretary, stated that the committee, in presenting their annual statement, felt great pleasure in congratulating the association on the arrival of its third anniversary. In accordance with the decision of the members, no meetings were held during the summer, and during the recess the business of the association was conducted by a committee of five. Weekly meetings were recommenced in October, and in the intervening time two lectures had been given, the first by Mr. Nield on "The Natural History of Chalk," which was well illustrated by diagrams and prepared slides of foraminifera, etc., exhibited under several binocular microscopes, kindly lent by Mr. Pullinger. The second lecture, which was on "Mercury and its Preparations," was delivered by Mr. F. A. Johnson, the subject being elucidated by experiments. In conclusion, the committee was glad to inform the members that the funds of the society were in excess of former years, and the number of members encouraging, when it was remembered that more powerful inducements were offered by the Manchester Association than can be afforded at Oldham. The election of officers for the coming year was then proceeded with. Mr. Taylor was re-elected president; Mr. W. Potts was appointed vice-president; Mr. F. A. Johnson, secretary; and Mr. Bateman treasurer and librarian. The usual votes of thanks were accorded to the officers for the past year, after which the proceedings terminated.

UNITED SOCIETY OF CHEMISTS AND DRUGGISTS OF IRELAND.

A meeting of the above society was held on Monday evening, March 3rd, at 12, Grafton Street, Dublin. There was a very large attendance, nearly all the principal druggists of the city being present.

In the absence of the president of the society, Mr. J. Brooks was elected chairman.

The hon. secretary, Mr. W. Hayes, said the chief subject to be brought before the meeting was the consideration of the means best adapted for elevating the trade and obtaining a status similar to that of the Pharmaceutical Society of Great Britain. He would put forward three suggestions for the consideration of the meeting. First, that it should endeavour to make some terms with the Apothecaries' Company of Ireland, with a view to the establishment of an examination similar to that of the Pharmaceutical Society, as a qualification for compounding physicians' prescriptions; secondly, that it should petition the Pharmaceutical Society of Great Britain to extend its operations to Ireland; and, thirdly, that an attempt should be made to obtain a special Act of Parliament for the purpose.

Mr. Wells said he was of opinion that the most practicable method of attaining their object would be in connection with the Apothecaries Hall, as he had reason to believe that that body would be disposed to meet them.

Mr. Marshall considered the Pharmaceutical Society would, from its present position, be the most likely quarter to apply to for support.

After considerable discussion, in which Messrs. Goodwin, Simpson, Bermingham, Grindley and Holmes took part, it was proposed by Mr. J. T. Holmes—"That a deputation from this society, consisting of Messrs. Hayes, Goodwin and Wells, with power to add to their number, wait upon the governor and company of the Apothecaries' Hall, and ascertain their views on the subject.

Mr. Brownrigg seconded the proposition, which was carried unanimously.

After some further business, principally in connection with the financial position of the society and the desirability of possessing permanent offices and reading-rooms, the meeting adjourned.

The Sale of Poisons.

Sir,—I shall be very glad to be put right if I am wrong in my ideas, but I cannot endorse the action taken by our Whitehaven brethren in the matter of vermin killers, nor the views with which (to my surprise) you support them. I think Mr. Kitchin misinterprets the Act when he says, "Vermin killers being mostly preparations of strychnine and arsenic come under and are included in part 1 of the Amended Schedule." Now, so far as arsenic is concerned, there is a special Act; and as to strychnine, in part 1 of Schedule in 1868 Bill, it is put, "Strychnine *and its preparations,*" which in the Amended Act of 1869 is altered to "Strychnine and *all poisonous vegetable alkaloids and their salts,*" so that the amended Act really ignores "preparations of strychnine." But I maintain that vermin killers are not preparations of (although they may contain) arsenic or strychnia, any more than paregoric is a preparation of opium, a fallacy which I am astonished is still held by so many chemists. The registration of the sales of those articles scheduled in the Act was instituted for the prevention of their being employed as poisons for the purpose of poisoning; what, then, shall we say to such a commentary on the Act, that those things known to be, published as and required and used only for poisons should be registered also?

And, Sir, you will not be able to stop here. If we are to register vermin killers because they contain (or are supposed to contain) arsenic or strychnia, shall we not also have to register preparations for the hair containing (or supposed to contain) cantharides; lotions, such as Gowland's, containing (or supposed to contain) corrosive sublimate; cough remedies, containing (or supposed to contain) tartar emetic? Who is to say that the many female pills do not contain both cantharides and savin? In short, where are we to stop? As I said at first, I shall be glad to be set right if all this is mythical, but these were the thoughts of my mind when I had recovered from the surprise that the editor of the PHARMACEUTICAL JOURNAL should have considered anybody initiating such a system, worthy " of the thanks of the trade at large."

FREDK. TIBBS.

81, *Chalk Farm Road, N.W., March 5th,* 1873.

WOMEN *versus* MEN.

" O would some power the giftie gie us
To see ourselves as others see us;
It would from many a blunder free us
And foolish notion."—*Robert Burns.*

Dear Sir,—It is no trifling thing again to seize the lance,
And strive against *three* mighty foes " the ladies' cause t' advance."
An " M. P. S." in flowing verse gives a " Valentine's Reply "
And seeks to whisper in our ear ' O do not let them try;
To all things else they may aspire, but *not* to Pharmacy."
Then the " ex-President " defends the course *he* took before,
And says they may be " *C's* and *D's* " but we will close *our* door.
Tho' for 4000 years and more, they've *nursed* and *trained* as well,
They must not touch the " garment's edge " of *Allen, Payne* and *Bell.*
Two years ago we were *advised* " Inspectors " to admit,
But when three ladies gently knock—" *Away!* you are not fit! "
Our " peaceful " friend from " Shepherd's Bush " would almost lose his life
If a lady mixed his medicine or used the palette knife!
Though his arguments, if rightly used, cut his own throat, I think,
For *ignorance*, not knowledge, gave the wrong " effervescing drink."
'Tis true that " earnest WOMEN " now on every hand we view,
But they've a *right* to push their way as well as I or you;
And if amidst ten thousand sons old " *Celsus* " trains a daughter,
O, never fear! she'll hurt us not! nor " cut our *salaries* shorter."
H. L. hints—if some recipes of a " peculiar " kind
Were brought to *females* to dispense, 'twould hurt their virtuous mind!
Nay, rather like their Lord, they'd seek the *fallen* to restore;
And while administering relief say, " Go and sin no more."
Some would even make them tools, and to be like *beasts* " inspected,"
But God made them " helpmeets " for man, to be *honoured, loved, respected.*
Yea, e'en within our ranks there's room for such as Mrs. Fry,
To raise the downcast and to shed the tear of sympathy.
Mothers, and wives, and daughters too, have nobler work on earth,
Than to *dress* and dance and spend their time in vanity and mirth.
If some desire or *duty bids* that they midst drugs should dwell,
I'd kindly whisper in their ear, " Cheer up! 'twill all be well;
You never *would* have been cast out by Allen, Payne, or Bell.
Yea, I believe the gallant knights who took your part before
Will shortly cheer ' our President ' as he unlocks the door;
Till then, with steady careful steps, your onward course pursue,
And rest assured the distant prize will *yet* be won by you."

And now, dear Editor, " Good night;" I'll cast this pen away,
Calmly peruse what *others* write, and *wait* the " Event " of May.

Ashton-under-Lyne, March 4th, 1873. W. BOSTOCK.

PHARMACEUTICAL WOMEN.

Sir,—I think the arguments adduced against the admission of women to the Pharmaceutical Society are senseless, selfish, narrow-minded, and unworthy of the profession to which we belong. Certainly neither William Allen nor Jacob Bell would sympathize with the doggerel rhymes of M.P.S. They were large-minded men who, from their association with the Society of Friends, had learned to value woman at her true worth; not as the puppet and thing which society has hitherto valued her at—a doll, an amusement, a toy, but at her true estimate, the equal and the helpmate of man. This true esteem is not felt by those who flatter with sickly gallantries, and who would bar every avenue to a dignified and worthy position. I believe it may be considered an axiom that the true civilization and position of any nation may be gauged by the place women hold in it.

The time has passed in England when the true position of woman could be ignored. One by one the learned bodies are glad to open their doors to her, and it must come in our Society; it is only a question of time? Shall the benighted obstructives who are half a century behind the age make us the last to do this simple duty. I do not suppose we shall ever be inundated with applicants—a few here and there—perhaps the wife or daughter of a poor member in some village or small town whose death might otherwise destroy the comfort of his family, some one or two studiously disposed girls; but there is no likelihood that a profession involving such brainwork as ours at such small remuneration would, like drapers and milliners, attract any numbers of the fair sex.

F. P. BALKWILL, M.P.S., F.L.S., etc.

Plymouth, March 1st, 1873.

TINCTURE OF QUININE.

Sir,—In reply to Mr. Mumbray's communication in your last week's issue, I beg to inform him that if tincture of quinine is made by using a tincture of orange made with spirit of *full-proof* strength, there will then be no deposition of quinine crystals, except perhaps in very cold weather.

I have found the same difficulty with this preparation as Mr. Mumbray has, but on investigation I traced the cause to insufficient strength of the spirit; since then I have had no trouble at all.

With regard to the addition of sulphuric acid, my experience is that it does not in the least tend to keep the quinine in solution; indeed, upon two occasions when I tried the effect of adding a small quantity of the dilute acid, I got if anything more crystals than before, certainly larger ones.

Seeing, however, that the Pharmacopœia process if strictly followed so as to have a really *proof* spirit, yields a perfectly satisfactory preparation, we need not trouble ourselves about the addition of another agent which would change the character of the preparation, and, worse still, be taking liberties with official formula, which there is already too much disposition to do.

J. H. BALDOCK.

South Norwood, March 3rd, 1873.

" *Inquirer.*"—We should prefer the dry specimen of iodide of potassium and should reject the specimen you describe. Iodide of potassium contains no water of crystallization, therefore any water present (and we imagine it would be less than 5 per cent.) must be adherent or hygroscopic. The crystals in the London market of British manufacture are not very variable, as they are produced by two makers. The pressure upon manufacturers last month for immediate delivery of iodides consequent upon the sudden decline in value of iodine in January, with the chances of advance for forward delivery, was doubtless the cause of the crystals having been less perfectly drained and dried than usual.

" *Jestyn.*"—The deposit consists principally of kinate o lime, and we believe contains little of the cinchona alkaloids. The amount of deposit varies according to the variety and age of the bark used. We have noticed it in Battley's Liquor, P. L. Infusum Spissatum, as well as the B.P. preparation you refer to. See PHARM. JOURN., 2nd ser., vol. V. pp. 110, 162, and 328.

T. Collier.—Your letter was returned, accompanied by a note stating the reasons for its non-publication.

A. P. S.—Your communication should have been addressed to the advertising department of the Journal.

Hugh M. Williams.—We are compelled to defer the publication of your letter until next week.

B. B.—The designation of such a firm as that described by you as " pharmaceutical chemists " would be incorrect, and therefore illegal.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. J. Abraham, Hickling, Chaplin, Houghton. R. T. Clarke, Green, Martin, Fourness, Thompson, Hustwick, Williamson, Wise, Country Pharmaceutical Chemist, Two Apprentices, Cornubia, An Associate, Deva, Minor Associate, Dallas, G. C., A. P. S., J. C., W. B. B., W. C. M.

LEGAL PHARMACEUTICAL PREPARATIONS.

BY ALFRED E. TANNER.

Having been struck—not for the first time—by the singularly happy title Dr. Syme has chosen for his paper, I take the liberty of making use of the same, and venture to offer some remarks upon what seems to me at this present time a most important subject. How many of my brother pharmacists, while perusing, and still more while working out, the formulæ contained in our Pharmacopœia, must have regretted being bound down hard and fast by the rigid details of the processes therein contained, and being allowed no latitude for the carrying out of modifications which an extensive experience perhaps has from time to time pointed out as conducive to a more perfect product; and no one who makes it his practice to manufacture for himself his own preparations instead of buying them (as I have more than once in these pages advocated), can fail to see that in a very large proportion of the processes given some improvements or modifications of working are desirable. To take an example which must be familiar to every one who makes his own tinctures even,—why is it that with all the various substances which are formed into tinctures, we have only two strengths of spirit allowed, ·838 and ·920? A moment's consideration must convince any one these are wholly inadequate for the purpose of extracting completely and satisfactorily the principles contained in all the drugs we operate upon in forming our tinctures. I would wish to see each drug separately considered as to its soluble constituents, and as to those constituents which it is wished to have present in the tincture, and a particular strength of spirit assigned to each in accordance with these considerations. This, it appears to me, would be far more rational than rigidly assigning but two strengths of spirit for every possible contingency. And while on the subject of tinctures, I would suggest that more particular directions be added for carrying out the process of percolation, as adapted to each particular drug, and the degree of fineness expressed in meshes to the inch to which each drug should be reduced. Experience has shown me that for many tinctures it is better to pack dry in the percolator and pour on sufficient of the menstruum to moisten the whole, and either proceed with percolation at once or allow maceration to take place for a stated time. With regard to vin. ipecac. treated in this manner, I have found in operating on 1 gallon all the soluble matter of the root in the first ounce, the root being reduced to No. 30 powder. In these particulars it seems that American pharmacy leaves us considerably behind.

The sp. gr. of each tincture would also be a useful guide to its correctness, and should be given. Very excellent and useful work in this department has been done by Messrs. Stoddart and Tucker, and forms the subject of a paper read before the Pharmaceutical Conference last year. Surely, if necessity exists for it in syrup. rhamni it exists also in the case of that far more important class of preparations, the tinctures; and if in syrup. rhamni, why not in syrup. rhei.? Liq. am. acet. also would be better for the addition of this information.

Liq. bismuthi, which Dr. Symes has chosen as an example in which *illegal* pharmacy is practised to a considerable extent, seems scarcely a happy choice, so far as my experience goes. I should say very far from "95 per cent. of samples in the market answer the B.P. characters and tests," some containing more ammonium nitrate, some less, some none at all, being prepared probably by the process given by Wood, and which, by the way, I should very much wish to see introduced in the place of the present liquor, as it seems to me in every way satisfactory. A more forcible example of this (illegal pharmacy), to my mind, is the much-handled compound sp. ether. nit., which, as I understand, is seldom or never prepared by the B.P. process, excepting by those who, like myself, prepare it for their own consumption and sale. I see no reason why this and others of its class may not be prepared by any process so long as they answer the description and tests required of them; but, of course, with a vast number of preparations, whose characteristics cannot be so described, and whose reactions are not sufficiently marked to be tested by ordinary chemical means, the case is different. We should then have the process minutely described so as to produce a certain result. The process of sp. ether. nit., excellent though it be, is still capable of some improvement and modification. Experience in the working of it has shown me that a much larger proportion of finished product may be produced from the quantity of spirit ordered than is indicated in the B.P., and this result is obtained by continuing the addition of small quantities of HNO_3 until something like 50 per cent. more is used than ordered. I produce by this means about 35 per cent. more of the finished product, answering the B.P. tests; but as I intend shortly making this the subject of a separate paper, I will do no more here than state the bare results obtained.

Then as to the difficulty with regard to the syr. ferri phosph., which so many have stumbled over, complaining that it will not make the quantity ordered; I take it to be more imaginary than real. Surely the paragraph stating how much it *should* measure is unmistakable; and if it does not measure this it ought to do so, and, indeed, should be made to do so by the addition obviously of aq. dest., nothing else being admissible. A much graver error exists, I think, in the information contained in the concluding paragraph. To assert dogmatically that it contains 1 grain of phosphate of iron in 1 fluid drachm, when the quantity of $FeSO_4$ ordered is only just sufficient to produce this quantity, carries with it its own refutation; for if any one will take the trouble to test the filtrate produced in the first part of the process, he will find it contains a considerable quantity of iron salt, and that the introduction of acetate of soda to prevent this is, as the formula now stands, a failure. But if the solutions, after being mixed, be heated to boiling for a few minutes before being filtered, none of the iron is lost.

With an addition to our Pharmacopœia in the form of an Appendix as proposed by Dr. Symes and others, I fully agree.

Syr. phosph. co. has now become quite an established remedy and should on no account be omitted, the formula published by the late Professor Parrish producing a preparation in every way unexceptional if the directions be carefully carried out. Nitrite of amyl certainly deserves a place, together with a process for its preparation in a state of medicinal purity, and for this purpose no process seems so well adapted as that of Professor Redwood for the preparation of nitrous ether, if the precaution be adopted of using the HNO_3 diluted, as pointed out by myself in the Pharm. Journal, 3rd series, vol. II. p. 225.

Trusting to see this important matter taken up with spirit by the whole of our profession, and result in an appendix which will do us honour, I here for the present leave it.

TINCTURE OF QUININE.

BY T. H. HUSTWICK.

The subject I am desirous of bringing forward is apparently so trivial as to have escaped, in this age of research, the attention of those who, from calling and experience, are better able than myself to deal with it; but considering the importance that apparently trivial matters sometimes possess on the bearings of our profession, and this in particular belonging to the domain of pharmacy, and being near to that of chemistry, will, I trust, be a sufficient excuse.

Tincture of quinine has been an official preparation only since 1851, but some time before then it was evidently recognized as an extra-pharmacopœial preparation, from the fact that in vol. V. of the first series of our Journal, amongst answers to correspondents, a form is given for its preparation similar to the present one, except that it contained one minim of dilute sulphuric acid to each grain of quinine. We may suppose therefore it has long been a favourite method of exhibiting the alkaloid, the dead bitter of the quinine being modified and aromatized by the warm and pleasant flavour of the orange-peel; while the appearance, portability, and convenience of the preparation cause it to be held in favour by both patient and prescriber. It is one of the simplest preparations of the pharmacopœia, being merely a solution of sulphate of quinine in tincture of orange-peel, in which menstruum, when slightly warmed, the salt is, or should be, completely soluble; yet the result is not always satisfactory, sometimes there is considerable deposition of quinine in a crystalline form, and invariably a precipitate, occasionally necessitating more than one filtration before it is finally got rid of. The directions given in the London Pharmacopœia, 1851, are simple digestion for seven days, with subsequent filtration; this, however, is insufficient, the quinine salt being very slightly soluble in cold tincture, but in the translated edition the editor recommends the tincture to be slightly warmed, in order that complete solution may take place. This suggestion is embodied in the recent Pharmacopœia, where the quinine salt is ordered to be dissolved with the aid of a gentle heat, and a subsequent digestion for three days. Now as the solution is complete on warming the tincture with the quinine salt, and since it is permanently effected at the first if too much heat be not used, what is the use of the subsequent digestion? The tincture, on cooling, is very nearly bright, no appearance of undissolved sulphate being visible; however, within a short time we have evidence of a change taking place, the tincture becomes a shade lighter in colour, and a precipitate shows itself. I conclude that it is to allow time for this precipitate to form completely and entirely, that the term of digestion is ordered, and then the extraneous matter is got rid of by filtration. Supposing the tincture be filtered immediately after it is made, a second filtration would ultimately be required. I have frequently heard this precipitate spoken of as tannate of quinine; and that it is so seems to have been taken for granted, especially when we consider that orange-peel does contain tannin, as is shown by its behaviour with a salt of iron, and that tannates are generally insoluble, so that it is easy to jump at the conclusion that the precipitate in question is tannate of quinine. In the first volume of the Pharmaceutical Journal Professor Donovan is cited as an authority for the statement that an insoluble tannate is formed from a solution of quinine in tincture of orange-peel, as it is with tincture of cinchona. Ten years afterwards Mr. Bastick suggests a similar proposition; and later, Mr. Squire, in his 'Companion,' assumes the same to be the case. Whether this be so or not seems hardly to have been thought worth the while of any one to question, till Mr. Groves casually mentioned, at a recent evening meeting, that he had ascertained the deposit in tincture of quinine, prepared from fresh orange-peel, to be a salt of lime; a remark that will apply equally to a tincture of dried peel. Having often noticed a deposit in tincture of quinine, and vainly speculated as to its character and composition, this suggestion seemed to offer a ready solution of the question; and such few opportunities as have presented themselves to me have been devoted to this subject. The precipitate from four pints of tincture was collected on a filter and washed with two ounces of proof spirit in small quantities at once (in my first attempt, distilled water was used for washing, but I found the precipitate gradually diminishing); this when dried, I found to weigh on different occasions from 16 to 26 grains; the variation is probably owing to different lots of peel being used; it was nearly all soluble in boiling distilled water, what was left being apparently only a mechanical residue from the filter. A solution of ferrous sulphate, containing a small quantity of a ferric salt, gave no evidence of tannin; both oxalate of ammonium and chloride of barium gave copious precipitates of their respective compounds of lime and sulphuric acid, while exposure of the precipitate to a red heat produced no change beyond turning it from white to ash grey, showing its comparative freedom from organic matter, such as quinine.

Having so far settled the composition of the precipitate, the next question was, How came it there? The quinine salt furnishes one of the constituents; the other must be supplied either by the water of the proof spirit or by the orange-peel, but as I have always used distilled water, that, as a source, is out of the question. I am unable to find any published analysis of orange-peel, but two or three experiments seem to show that the lime is derived from that ingredient, for infusions both recent and concentrated, as well as tincture, give ample evidence of the presence of lime by their behaviour with oxalate of ammonium. But what may be relied on as the most conclusive test is that afforded by the ash of the peel; this, when well incinerated, is to be treated with hydrochloric acid, evaporated to dryness, and the residue boiled with distilled water; then filtered and the oxalate added, showing at once that lime is present. From these premises we may build up a theory as to the formation of this salt; the quinine supplying the acid, and the orange-peel the base, a mutual decomposition takes place, which is doubtless completed within the three days ordered in the Pharmacopœia, for if the tincture be then filtered, no further deposit of lime takes place. Some time ago, being under the impresion that this supposed precipitate of tannate of quinine might be diminished or prevented by reducing the amount of tincture of orange-peel one-eighth, and substituting for it that proportion of water with the addition of half a minim of dilute acid to each grain of quinine, I adopted this plan, but without any noticeable change, save that tincture made in this way would deposit its quinine in a crystalline form on a reduction of temperature, the deposit, however, being easily redissolved by a gentle heat, when the solution remained permanent. When the tincture is made according to B. P., I have not noticed this change.

It is only reasonable to suppose that a tincture made with absolute quinine would be free from this deposit; and to satisfy myself, I recently prepared a small quantity. The proper quantity of sulphate was dissolved in acidulated water, precipitated by ammonia and washed till no smell of that reagent was perceptible. The precipitated quinine was then well pressed between blotting-paper, and at once dissolved in the tincture; a little cloudiness was apparent, which, in a few days, settled down into a light brownish flocculent precipitate; very different in appearance from the white dense deposit of the former. This, when collected on a filter, was very small in quantity, and after washing with proof spirit, remained brown. It was insoluble in boiling water, but nearly all dissolved in water acidulated with sulphuric acid; so that I conclude it was principally quinine, contaminated with and possibly thrown down by colouring and astringent matter, especially when a little placed on a white slab and touched with a drop of solution of sulphate of iron gave a slight blackish discoloration, showing the presence of tannin, but in so minute a quantity as to be hardly worth notice. My object in making these experiments was to learn, first, if the precipitate ordinarily occurring in tincture of quinine was a compound of that alkaloid; and, second, if the tincture could be better prepared from freshly precipitated quinine. As to the first, we may conclude from the evidence already produced that it is little more than sulphate of lime; and as to the second, I think there is nothing gained. In the one case we get rid of the lime salts by filtration; and in the other, prevent their formation by a process requiring more time and labour, the result in the end being just the same. As regards the best method of preparing the tincture, my idea is to dissolve the quinine in as large a portion of the tincture of orange-peel as possible, say, not less than one-half, using a minimum of heat, and, of course, no acid, as I believe that addition besides being unnecessary is one cause of the deposition of quinine instead of preventing it; and I am quite of opinion that a fair trial of the B. P. formula and close adherence to its direction will lead to a satisfactory result.

COSTUS ROOT.

Aplotaxis Lappa, Dcne.

BY JOHN R. JACKSON, A.L.S.

Curator of the Museums, Kew.

Under the name of *Aucklandia Costus*, Dr. Falconer described a composite plant, growing on the mountain slopes of the Cashmere Valley, at an elevation of from 8000 to 9000 feet; and the aromatic root of the plant was considered to be identical with the costus of the ancients. The plant, which is a gregarious herb, six or seven feet high, with an annual stem and a thick perennial root, is now referred to *Aplotaxis Lappa*, and has some interest attached to it beyond its ancient history, from being at the present time, or at any rate when Dr. Falconer wrote, an extensive article of Oriental trade. It is sent in large quantities to Bombay, and from thence is shipped to the Red Sea, the Persian Gulf and China; also through Hindostan to Calcutta. As many as 200,000 lb. are said to be annually collected and disposed of in this way at a considerable profit to the collectors, for it is estimated that about 2*s*. 4*d*. per cwt. covers the cost of collecting and transport to a mercantile depôt in Cashmere, while in Canton as much as 47*s*. to 48*s*. per cwt. is realized. The article moreover requires no preparation for market, the roots being simply dug up in September and October, and cut into pieces from two to five or six inches long. Its chief use is by the Mohamedans for burning as incense, but the Chinese also use it as an aphrodisiac. In Cashmere its only use is for preserving the celebrated Cashmere shawls from the attacks of moths, pieces of the root being put into the bales in course of packing. When dry the root is of a dark brown colour, very brittle and apparently full of resin, but it does not burn freely. It has a strong but agreeable odour similar to that of orris-root. I am not aware that it is an article of import in this country; but not long since I received a fine sample for the museum from a celebrated London perfumer. It is known in Cashmere as Koot, and in Bengal as Putchuk.

COMPLETE ANALYSIS OF CINCHONA BARKS.*

BY P. CARLES.

The immediate analysis of cinchona barks has already been partly made by Pelletier and Caventou. Those chemists found in each species, among other products, quinine, quinovic and cinchotannic acids, colouring matter, fats, gum, starch, etc. Besides these I have found sugar, or rather glucose, the presence of which did not appear to be normal, but seemed to proceed from the splitting up of the cinchotannic acid, which is rather a glucoside than a true acid. Analysis has in fact shown that glucose is more abundant in the external layers of the bark which have also been found to be more rich in the tannin principle.

There exists yet another element in cinchona, namely, ammonia, which I have carefully investigated, although its presence had been previously announced by Fourcroy, Reichel, Howard and De Vry; for I thought it might furnish a glimpse of the truth as to the genesis of quinine and chinchonine. I also sought whether any relations existed between the proportions of this alkali and those of the vegetable alkalies. I therefore operated upon the three types of pharmaceutical species of bark, of which the proportions of alkaloids were already known, the huanuco, succirubra and calisaya barks. In order to make the results more conclusive, experiments were

* 'Répertoire de Pharmacie,' (N. S.) vol. i. p. 60.

made with the entire bark, and with the various layers of the same bark separated. The ammonia was removed in the cold, and estimated according to Schloesing's method. One hundred parts of bark yielded—

	Entire bark.	External layer.	Intermediate layer.	Internal layer.
Succirubra	traces	traces	traces	traces.
Calisaya	0·016	0·012	0·012	0·016.
Huanuco	0·048	0·049	,,	0·028.
Calisaya leaves	0·061	,,	,,	,,

This table shows that the barks richest in alkaloids are least charged with ammoniacal salts. The relation between the quantities of those salts existing in the external and internal layers is not constant. The only conclusion which can be drawn is that the organs which contain the most ammonia are the richest in tannin and the youngest, provided, however, that the grey cinchonas are the younger branches from the same trees as produce the yellow bark. However this may be, the leaves contain a much more notable proportion of the volatile alkali, whilst they rarely yield any traces of the alkaloids.

Analysis of the Ash.—Another point in the history of cinchonas that appears to have been neglected is the analysis of the ash. This would appear to be important, because most of these mineral principles pass into the greater part of the preparations of cinchona, carrying with them their characteristic action, which is thus added to those of the organic principles, and also because of the part they play in the growth of the cinchona plant. The effects of temperature, altitude, and the action of light upon the growth of the plant have been studied, but the nature of the soil, and the improvements which may be made in it, have hitherto been somewhat neglected.* The study of the ash might enlighten the cultivator upon this point and lead to the collection of a richer product.

Three officinal species of cinchona barks were chosen for experiments: the grey huanuco, the yellow calisaya, and the red succirubra, two specimens of each species being used for greater certainty. The results were obtained in each case with from 4 to 6 grams of ash arising from the combustion of 300 or 400 grams of bark.† The quantities of ash indicated in the following table are the residues of 100 grams of cinchona.

	Huanuco bark.		Calisaya bark.		Succirubra bark.	
Ash	1·831	1·885	1·350	1·361	1·402	1·741.
Insoluble Silica	0·263	0·241	0·023	0·032	0·020	0·031.
Soluble Silica	0·041	0·047	0·024	0·031	0·025	0·018.
Alumina	0·061	0·050	0·030	0·020	0·062	0·052.
Iron	0·061	0·042	0·065	0·049	0·053	0·070.
Manganese	0·048	0·026	0·027	0·032	0·042	0·025.
Lime	0·376	0·383	0·382	0·379	0·546	0·720.
Magnesia	0·034	0·034	0·016	0·031	0·021	0·018.
Potash	0·429	0·540	0·340	0·252	0·215	0·298.
Soda	0·081	0·069	0·041	0·052	0·048	0·034.
Copper	traces	traces	traces	traces	traces	traces.
Carbonic acid	0·309	0·318	0·338	0·345	0·280	0·291.
Sulphuric acid	0·027	0·034	0·036	0·038	0·035	0·034.
Phosporic acid	0·074	0·053	0·048	0·067	0·045	0·042.
Chlorine	0·015	0·009	0·008	0·010	0·014	0·012.

A glance at this table will show that iron, manganese, and lime (united with the phosphoric acid), are present in notable proportions. These various principles are, it should be remarked, found in the infusions, decoctions, extracts and wines of cinchona, where their presence by the side of tannin and the salts of quinine is not a matter of indifference. In order to detect the copper, it is necessary to ignite the carbon as completely as possible, and it is advisable to carry on the operation in the muffle of a cupelle furnace. The proportion of copper is so small that there is no fear of its poisonous effects. M. Sarzeaud estimated that cinchona contained one-five-hundred-thousandth part.

Considering the statement long since made by Fourcroy, that cinchona barks were rich in chlorides, the proportion of chlorine given in the above table might appear small, but probably his experiments were made with specimens which had been injured in their transport.

It has also been said that the barks richest in quinine were generally those which abounded in lime salts. The foregoing figures tend to demonstrate the contrary, for the proportion of lime is the same in huanuco and calisaya barks and higher in the succirubra.

* See, however, an article in the present volume of the Pharmaceutical Journal, p. 521.—Ed. Pharm. Journ.

† When some cinchona barks are burned, especially the yellow cinchona, a rather agreeable odour is given off, which is not met with in the less esteemed species. It is due to the decomposition of quinine and quinovic acids into benzoic acid, salicylic aldehyde, etc, It appears to be more manifest in proportion as the bark is rich in quinine, or rather, quinate of quinine.

ACTION OF VARIOUS SUBSTANCES AS ANTIFERMENTS.*

BY M. A. PETIT.

The importance, in a medical point of view, of the recent communications of M. Dumas and MM. Rabuteau and Papillon relative to the action of borate of soda † and silicate of soda upon ferments has induced M. Petit to repeat the experiments; and as a result he reports that he has not found those substances to be possessed of peculiar properties as antiferments.

The solutions operated upon contained 50 grams of cane sugar per litre, and a sufficiency of ferment (0·50 gram of German yeast per 10 c.c.) to set up regular fermentation in a few minutes. A solution containing one per cent. of silicate of soda was coloured yellow through the alkaline action of the silicate upon the yeast. Fermentation did not commence for an hour; but once commenced it was rapid and regular. One per cent. solution of borate of soda fermented as rapidly as the saccharine liquor itself.

A solution of sulphate of protoxide of iron (1 to 100) fermented slowly, but regularly. A similar solution of sulphate of copper commenced to ferment, but the fermentation afterwards stopped. In experiments made under the same conditions with phosphorus, oil of turpentine (1 to 100), creasote in small proportions, mustard flour (1 to 100), and sulphuric and tartaric acids (1 to 100), fermentation was not hindered.

Arsenious acid in solution (1 to 100) retarded the fermentation, which, however, continued very regular. Oxalic acid (1 to 300) slackened it very considerably. In equal quantities acetic acid seemed to be more antifermentive than the mineral acids.

The bodies which appeared to be the most antifermentive were the bichloride and especially the binoxide of mercury. A solution of one per cent. of sublimate agitated with the yeast, gave no preci-

* 'Journal de Pharmacie et de Chimie,' vol. xvii. p. 119.

† See ante, p. 565.

pitate with sulphuretted hydrogen, the metal being combined with the albumen. The oxide of mercury in smaller proportion exercised a still more energetic action; ½ per cent. of the yellow oxide introduced into a tube in full fermentation immediately arresting the action.

The sulphites did not prevent fermentation; they were transformed into sulphates. A solution containing one per cent. of sulphite of soda, five per cent. of cane sugar, and two per cent. of German yeast gave the following results when tested with solution of iodine in the presence of starch. The fermentation took place in a closely stoppered flask and the delivery-tube plunged in water.

10 c.c. required before fermentation	16·4	c.c. iodine sol.
,, ,, after decomposition of $\frac{1}{7}$ of sugar	6	,, ,,
,, ,, ,, ,, $\frac{2}{3}$,,	2	,, ,,

It would thus appear that the transformation of sulphites into sulphates does not take place before, but during, fermentation, and progressively.

THE GREEN PUTCHUK OF THE CHINESE.*

With some remarks on the antidotal virtues ascribed to Aristolochiæ.

BY H. F. HANCE, PH.D.

Amongst the drugs held in high estimation by the Chinese is one known by the names of *Ch'ing muh hsiang*, or *T'u ch'ing muh hsiang*, *i.e.*, "Green Putchuk," or "Native Green Putchuk," derived from some fancied resemblance to the rhizome of *Aucklandia Costus*, Falc., which latter is largely imported into Southern China, for the purpose of making incense sticks, etc. In the current number of the 'Journal of Botany,' Dr. H. F. Hance gives an interesting and elaborate description of this drug and the plant producing it, from which the following details are taken. The drug consists of pieces of rhizome, of a light brittle texture, varying in thickness from the diameter of the thumb to that of a crow-quill, white internally, and covered with an ash-grey epidermis. When fresh, it has a hot camphoraceous peppery odour, and a powerful camphoraceous and bitter taste. Mr. Hanbury, in his 'Notes on the Chinese Materia Medica,' speaks of it in a dried state as having a slightly aromatic taste, with but little smell. Dr. Hance, however, has found that rhizomes dried by himself have lost their scent almost entirely, but have retained their flavour for the most part. The Chinese 'Illustrated Nomenclature and Description of Plants,' published twenty-five years since, gives an outline of the plant which is reproduced in the 'Journal of Botany,' together with the following translation of the description:—"The *T'u ch'ing muh hsiang* grows on the slopes of hills in Hu peh province. It is a trailing plant, the small branches, leaves and fruit like those of *Ma tao ling* ("Horse-head bells"); the roots are yellow, small and fragrant. In medicine it is employed to cure burns and indigestion. It produces flowers in the form of a tube, at first small, afterwards larger, curved like a buffalo's horn, the sharp end being raised and of a rather deep purple-black hue. The sexual organs are visible within." Dr. Tatarinov appears to have been the first to have referred this product to an *Aristolochia;* and, subsequently, Dr. Porter Smith,—who remarks that "it is a powerful purgative, emetic, and anthelmintic remedy,"—in his 'Contributions to the Materia Medica' of China, erroneously referred it to *A. contorta*, Bunge. Mr. E. C. Bowra, in his Report on the Trade of Ningpo for 1868, states that in the neighbourhood of that port, whence the drug is largely exported, the plant yielding it is a common garden creeper. By the kindness of that gentleman Dr. Hance was supplied with several living plants, one of which flowered lavishly and set a single fruit. Upon a careful examination Dr. Hance came to the conclusion that the plant belonged to an undescribed species, and in his paper he describes it under the name of *Aristolochia recurvilabra*. He says that the immediate allies of the Chinese plant are to be found in those species which inhabit the region of the Mediterranean basin, and amongst those it is nearest to *A. altissima*, Desf., *A. Pistolochia*, Linn., and especially *A. bætica*, Linn., and *A. parvifolia*, Sibth. et Sm. The only East Asiatic species with which it is likely to be confounded are *A. debilis*, Sieb. et Zucc., and *A. Sinarum*, Lindl.

With regard to the antidotal properties ascribed to Aristolochiæ, Dr. Hance remarks that undoubtedly no genus comprising a large number of species, widely diffused over both hemispheres, has been so universally credited with alexiteric properties as *Aristolochia*, and this, too, in all ages, and in every condition of society, alike by the wandering savage and the polished citizen or learned physician of a highly civilized commonwealth. In the forcible language of Endlicher, "Species plurimæ vasorum, imprimis secernentium, nervorum et cutis vitam sollicitantes, in eliminandis e corpore potentiis morbificis, veneno potissimum animali, efficaces, adversus serpentum morsus *unanimi gentium præconio* celebrantur." As regards those species which are natives of the Mediterranean basin, Theophrastus praises *A. pallida*, Willd., as a remedy for the bites of snakes, when infused in wine and drunk, and used also as a topical application;* and this or other species, probably *A. bætica*, Linn.. *A. parvifolia*, Sibth. et Sm., and *A. Pistolochia*, Linn., entered as ingredients into the wonderfully complex *alexipharmaca* of the Greek physicians. Cicero alludes to the virtues of *Aristolochia* in cases of snake-bites as a universally recognized fact, and Pliny notes the employment of *A. pallida* in such cases. The pseudonymous Macer, in his poem 'De viribus herbarum,' written during the tenth century, and which for more than five hundred years was the recognized authority on vegetable materia medica, holding in this respect an equal rank to that conceded to the renowned 'Regimen Salernitanum' in all cases of diet, exercise, and the daily conduct of life, thus refers to *A. rotunda*, Linn:—

> "Pestiferos morsus, cum vino sumpta, rotunda
> Curat, et assumptis prodest sic hausta venenis."

And this belief was universal during the middle ages. Nor can the dull green foliage, twining habit, lurid tubular flowers, and heavy scent of these plants have led to such a belief,† founded on an attachment to the "doctrine of signatures;" not only because it seems clear that it was inherited from antiquity, but also because, remarkably enough, one of the most curious works devoted to the exposition of this fanciful theory, the 'Phytognomonica' of Giambatista Porta—a contemporary of our Gerarde—first published at Naples in 1588, though several times alluding to the presumed virtues of *Aristolochiæ*, never once attributes to them antidotal power. The Arabs are reported to use the leaves of *A. sempervirens*, Linn., when bitten by poisonous snakes, and *A.*

---

* Abstract from a paper in the 'Journal of Botany,' March, 1873, p. 72.

* Hist. Plant. ix. 13, 3; ix. 20, 4 ed. Wimmer. One hundred and forty years later, Nicander extols the same specific in verse, thus:—

> "Τὴν ἤτοι ἔχιος τε καὶ αἰνοπλῆγος ἐχίδνης
> ἀγρήσεις ὄφελος περιώσιον. ἔνθεν ἀποῤῥὼξ
> δραχμαίη μίσγοιτο ποτῷ ἐνὶ κιῤῥάδος οἴνης."
> —Theriac. 517—19.

† Dr. Alexander Prior, however, asserts (Popular Names of Bri. Pl., ed. 2, p. 22) that the fancied virtues of *Aristolochia Clematis*, Linn., in assisting difficult parturition were ascribed to it ob formam oris perigonii adhuc inexpansi feminali haud absimilem; and it is noteworthy that the Jamaica negroes have given a coarse popular name to *A. grandiflora*, Sw., from a similar resemblance.

indica, Linn., is similarly employed in India. The early settlers on the Atlantic sea-board of North America found *A. serpentaria*, Linn., held in high esteem by the Indians as a remedy for wounds inflicted by the rattle-snake and other venomous reptiles, a reputation perpetuated both by the trivial name and the popular designation "Snake-root." A very large number of species enjoy an equal fame in the Caribbean Islands and throughout the entire South American continent, amongst which may be mentioned *A. trilobata*, Linn., *A. pandurata*, Linn. (the "Raiz de Mato" of the Venezuelans), *A. odoratissima*, Linn., *A. cordiflora*, Mutis, *A. anguicida*, Linn., *A. fragrantissima*, Ruiz (the celebrated "Bejuco de la Estrella" of the Peruvians), *A. macroura*, Gomez, *A. cymbifera*, Mart. et Zucc., *A. ringens*, Vahl., *A. Galeata*, Mart. et Zucc., etc. Dr. Weddell was assured by the Bolivians in the province of Yungas that the crushed leaves of the "Vejuco," *A. brasiliensis*, Mart. et Zucc., used topically, are an infallible cure for snake-bites, and Señor Triana, the accomplished investigator of the flora of New Granada, found *A. tenera*, Pohl, in daily use in similar cases, as a never-failing remedy, under the name of "Matos."

Modern physicians seem with one accord to regard these plants as diaphoretics, stimulant tonics, and emmenagogues only; but the array of testimony from all quarters of the globe, and extending over a period of more than two thousand years, in favour of their alexiteric properties, is so overwhelming, that it is in my judgment incredible that these virtues should be imaginary. In the words of Cicero, "Utililate et ars est et inventor probatus," and the subject seems to me to demand a very careful and dispassionate investigation.

In a note appended to the article Mr. D. Hanbury remarks, "To the very interesting article of my friend Dr. Hance on *Green Putchuk* may be added a few lines showing how large a trade there is in this drug. Mr. Bowra, in the report referred to by Dr. Hance, estimates the total value of the export trade of Ningpo in 1868 at 6,073,709 taels, or about £2,026,903, of which amount 239,559 taels (£80,274), represent drugs; and of these latter fully *one-third* (or to the value of, say, £26,700), is *Green Putchuk*. The drug, he says, is worth from 10 dols. to 15 dols. per picul, equal to, say, 4*d.* to 6*d.* per lb. But the Chinese have several qualities, some of which are far dearer. The supplies are chiefly derived from the plant which is cultivated, but the root of the wild plant is also collected, though to a very small extent.

CHINESE BLISTERING BUGS.*

BY JOHN M. MAISCH.

At the meeting of the American Pharmaceutical Association in 1871, it was stated in the report on the drug market that twenty cases of blistering flies had been imported from China, and, although of a brown colour and not as good-looking as the European flies, proved to possess equal vesicating powers and went into consumption. It was interesting to ascertain of what species these bugs consist; and soon after the meeting adjourned, the writer endeavoured to procure some of the commercial article, but was unable to obtain any; the whole amount that had been imported having apparently been consumed. Subsequently Dr. Squibb kindly sent me a specimen from his private collection, which proved to be the *Mylabris cichorii* of Fabricius. My thanks are especially due to Messrs. McKesson and Robins, who were kind enough to import a pound for me from London, to enable me to make the necessary experiments, with the view to ascertain the amount of cantharadin contained therein.

The genus Mylabris comprises a large number of species, many of which were described in a monograph by M. C. Cooke. M.A., on 'Vesicating Insects,' which was published in vol. II. third series of PHARMACEUTICAL JOURNAL AND TRANSACTIONS.

In addition to the above, the following, taken from the Pharmacopœia of India, may well deserve a place.

MYLABRIS CICHORII, *Fabr.*, Telini fly.

Habitat.—Southern Europe, extending from Italy through Greece and Egypt to China. It is of common occurrence throughout India.

Officinal Part.—The dried insect (*Mylabris, Telini fly*). It has the following characters: About an inch in length and a third of an inch broad; the elytra of an obscure yellow, with three large somewhat zigzag transverse bands. The first band is interrupted and sometimes reduced to three or four spots. Active principle, *cantharidin.*

Medical Properties and Uses.—The same as *Cantharis vesicatoria*, for which it affords a complete substitute as a vesicant. As an internal remedy it should not be substituted for the tincture of cantharides, as the strength and operation of the latter is well ascertained, which is not the case with our present article. It is regarded as more powerful than the European article.

The same authority also mentions a number of other East India blistering bugs of the genera *Meloe*, *Lytta*, *Mylabris*, and *Epicauta;* but, it continues, with *M. cichorii* existing plentifully in most part of India, the necessity of increasing the number of these vesicating agents is lessened.

The Chinese bugs, which I received from Messrs. McKesson and Robbins, consist mainly of the *M. cichorii*, intermixed, however, with a considerable portion of *M. phalerata*, the latter perhaps not exceeding one-sixth of the whole weight, and readily distinguished by their much larger size, notwithstanding the similarity in the banded appearance of the elytra of both species. If ochraceous-yellow is taken to be the ground colour of the elytra of *M. cichorii*, the relative width of the three black bands is as follows: the one at the apex is the broadest, next in width is the one just above the middle, leaving the one above the base as the narrowest. This latter band in some specimens is sometimes interrupted, leaving on each side of the suture an undulated semilunar figure, and occasionally merely a spot. In other specimens which appear to me to belong to the same species, the second band is removed to the centre, and the third one quite to the base, so that there are but two broad yellow bands left, against three of the same colour in the typical form. In the cabinet of the Philadelphia College of Pharmacy is a specimen marked *Mylabris cichorii*, *female*, in which the number of black bands is reduced to two, an apical and a basal one, the latter usually with two small yellow spots, and the yellow portion of the elytra occasionally with quite a small black dot on each side of the suture.

In *M. Phalerata* the black colour predominates on the elytra, which are marked by two undulated bands, one just above, the other below the middle, both being of a brownish-yellow colour, of a deeper shade than in *M. cichorii;* at the base and near the suture are two nearly circular spots of the same brownish-yellow, and two smaller ones on the lateral edges near the base, the basal spots rarely becoming larger and confluent at the suture with the lower band. The transverse impression on the thorax is pretty large, and the scutellum is punctate, but not hairy. In *M. cichorii* the impression on the thorax is smaller, and has scarcely a transverse direction, and the scutellum is often covered with hairs.

The commercial article appears to be always a mixture of these two species (with occasionally a few individuals of other species), as has been pointed out by Mr. Cooke; the relative proportion of the two species must, therefore, considerably influence the appearance of the commercial Chinese blistering flies.

Cantharidin was discovered in 1810 by Robiquet* in

* Reprinted from the 'Proceedings of the American Pharmaceutical Association.'

Spanish flies (*Lytta vesicatoria*, Fabr.). Bretonneau* isolated the same principle from the Chinese blistering flies about the year 1828. The process used for many years for the preparation of this principle was the one suggested by Robiquet, in which the aqueous extract of the powdered bug is exhausted by hot alcohol, the solution evaporated to dryness, the residue treated with warm ether, the ethereal solution evaporated spontaneously, and some yellow matter removed by washing the crystals with cold alcohol. This process is based upon the observation made by Robiquet and other investigators, that cantharidin, when pure, is insoluble in cold and hot water, but taken up by this menstruum directly from cantharides in consequence of the presence therein of a yellow matter which renders this principle soluble in water. Ed. Rennard† has recently denied the correctness of this statement, he finding that cold water dissolves 0·02, and boiling water between 0·290 and 0·297 per cent. of pure cantharidin; the same author also found that this principle volatilizes with the vapours of boiling water, alcohol, and even chloroform.

Thierry‡ used ether or alcohol of specific gravity ·85 for exhausting the cantharides, distilled the ether and the alcohol, removed the oil, and obtained the cantharidin from the aqueous residue by crystallization and subsequent purification.

In 1851 Professor Procter observing that chloroform is a good solvent for cantharidin, proved§ the practicability of obtaining it by this menstruum directly from different blistering bugs. This process was improved by Mortreux‖ in 1864, by treating the residue left after the evaporation of chloroform (or if ether had been used, after the evaporation of this solvent) with bisulphide of carbon to dissolve the fat, and recrystallizing from hot alcohol. A. Fumouze** corroborates this statement, using for the recrystallization of the cantharidin, chloroform.

Bluhm and Dragendorff†† state that a portion of the cantharidin is contained in cantharides in a combination in which it is not dissolved by alcohol, ether or chloroform; in order to obtain the whole amount of this principle, they recommend to mix the powdered cantharides with water and calcined magnesia, exsiccate the mixture, and treat the dry mass with dilute sulphuric acid in slight excess, when the cantharidin may be extracted by solvents; or the acidulated mass is again exsiccated and then exhausted with ether or chloroform. Rennard‡‡ improves on this by saturating the mixture obtained after exsiccation with magnesia, with chloroform, and then supersaturating with sulphuric acid; the chloroform prevents the crystallization of the liberated cantharidin, which is for this reason dissolved by a much smaller quantity of ether.

The above contains nearly all the scientific literature on the preparation of cantharidin, and all the processes which may lay claim to at least approximate accuracy in their results. In experimenting with the Chinese flies, various questions that presented themselves could not be solved in time for the present meeting; among them an inquiry into the usefulness of petroleum-benzine in the preparation of cantharidin, and also the estimation of that portion of this principle, which according to Bluhm and Dragendorff is not taken up from the blistering bugs by the usual solvents.

In regard to the quantity of cantharidin obtainable, I can find no earlier researches than those made by William R. Warner,* who employed Robiquet's process mentioned above for determining its quantity, and obtained from *Lytta vesicatoria* 0·41, from *Lytta vittata* 0·40, and from *Mylabris cichorii* 0·43 per cent. of cantharidin. Mortreux† gives the average percentage of cantharidin in good cantharides as 0·5 per cent., estimated by his process. According to Fumouze's experiments, cantharides collected in 1866 in different parts of Europe, yielded 0·275, 0·435, 0·48, 0·48, and 0·50 per cent. of this principle, while three samples one year old yielded but 0·17, 0·215, 0·375 per cent., and the worm-dust separated from the next to the last sample 0·425 per cent., or double the quantity obtained from the cantharides from which the dust had been sifted.

Bluhm and Dragendorff found in commercial cantharides only 0·264 per cent. of cantharidin isolated by their process mentioned above; in *Mylabris quatuordecim-pustulata*, however, 0·486 per cent. Rennard separated from cantharides of unknown age, 0·38 and 0·431 per cent.; from cantharides one year old, collected near Heidelberg, 0·489 per cent., and from a sample eight months old, collected near Pultawa, 0·57 per cent. of cantharidin.

Fumouze's estimation of the value of the hard and soft parts of cantharides deserve mention yet; he found in the former 0·118, in the latter 0·778 per cent., and in the whole bugs 0·415 of cantharidin.

It appears from these essays that the amount of cantharidin which should be contained in the cantharides, ought not to be less than two-fifths of one per cent., and might probably be placed at a somewhat higher figure. It also appears probable that the cantharides lose in strength by age; but it seems likely that in all cases cited above, the bugs were freed as much as possible from the worm-dust which Fumouze has shown to be rich in cantharidin, and since the mites destroy only the soft parts which contain a large amount of the active principle, its decrease in the remaining portions of the bugs is easily accounted for.

Regarding the comparative strength of the Chinese blistering bugs, which by O'Shaughnessy is placed at one-third, by Warner only at one-twentieth above the officinal cantharides, these discrepancies are easily accounted for, since the statement of the former doubtless refers to the recently collected Mylabris, while the experiments of the latter were made with commercial bugs of uncertain age, and probably separated from the worm-dust. I find, however, no notice of any analysis made by O'Shaughnessy, and it is possible that his statement is based upon the epispastic properties of the bugs in question.

In estimating the amount of cantharidin in the commercial Chinese bugs, I determined for reasons stated before, not to separate the worm-dust. Fumouze's process was used for this purpose in the following manner: 600 grains of the powdered mylabris were introduced into a wide mouth glass-stoppered bottle, which was then filled with chloroform; after macerating for three days the liquid portion was poured off and filtered through a little cotton. The maceration with chloroform was repeated several times, until a drachm of the filtered portion left on evaporation merely a faint yellowish spot. Twelve ounces of chloroform were consumed in this operation. To avoid any loss of the active principle by transferring the chloroformic tincture into other vessels, the liquid was at once collected in a porcelain capsule, and the chloroform allowed to evaporate spontaneously. The residue, which was of a brown colour, was then treated with bisulphide of carbon, and the solution, including the undissolved cantharidin, transferred to a small filter, which was subsequently well washed with bisulphide of carbon. After the odour of this liquid had disappeared from the funnel, chloroform was poured

upon the filter in small quantities, and after all the crystals had dissolved, the filter was filled with chloroform twice to extract any cantharidin which might have been absorbed by the paper. The chloroformic filtrate was collected in a tared capsule, evaporated spontaneously, and the residue weighed.

In this way 6·097 grains of pure cantharidin of merely a pale yellow colour were obtained, which is equal to 1·016 per cent. If two-fifths per cent. of cantharidin is regarded as the yield of fair medicinal cantharides, it will be seen that the Mylabris is two and one-half times stronger; it is fully twice the strength of the best commercial cantharides, and it yields 1·78 times more cantharidin than the best yield recorded.

PROFESSOR TYNDALL ON LIGHT.*

(*Continued from p.* 688.)

We might vary and extend our experiments on light indefinitely, and they certainly would prove us to possess a wonderful mastery over the phenomena. But the vesture of the agent only would thus be seen, not the agent itself. The human mind, however, is so constituted and so educated as regards natural things, that it can never rest satisfied with this outward view of them.

Let us, then, inquire what this thing is that we have been generating, reflecting, refracting, and analysing. In doing this we shall learn that the life of the experimental philosopher is two-fold. He lives, in his vocation, a life of the senses, using his hands, eyes, and ears, in his experiments; but such a question as that now before us carries him beyond the margin of the senses. He cannot consider, much less answer, the question, "What is light?" without transporting himself to a world which underlies the sensible one, and out of which, in accordance with rigid law, all optical phenomena spring. To realize this subsensible world, if I may use the term, the mind must possess a certain pictorial power. It has to visualize the invisible. It must be able to form definite images of the things which that subsensible world contains; and to say that, if such or such a state of things exist in that world, then the phenomena which appear in ours must, of necessity, grow out of this state of things. If the picture be correct, the phenomena are accounted for; a physical theory has been enunciated which unites and explains them all.

This conception of physical theory implies, as you perceive, the exercise of the imagination. If we are to get anything done in physical science, we must invoke this faculty of imagination. Without it we cannot take a step beyond the bourne of the mere animal world, perhaps not even to the edge of this. But, in speaking of imagination, I do not mean that riotous power which those good and timid people appear to be alone acquainted with, but a well-ordered and disciplined power whose sole function is to form the conceptions which the intellect imperatively demands. Imagination thus exercised never really severs itself from the world of fact. This is the storehouse from which all its pictures are drawn; and the magic of its art consists, not in creating things anew, but in so changing the magnitude, position, and other relation of sensible things, as to render them fit for the requirements of the intellect in the subsensible world.

One of my objects in these lectures is to show you by what processes, or in what way, the scientific mind attains the deepest knowledge it is capable of attaining, which is a knowledge of the invisible sources of phenomena. I will take, as an illustration of this subject, the case of Newton. Before he began to deal with light, he was intimately acquainted with the laws of elastic collision, which all of you have seen more or less perfectly illustrated on a billiard-table. As regards the collision of sensible masses, Newton knew the angle of incidence to be equal to the angle of reflection, and he also knew that experiment had established the same law with regard to light. He thus found in his previous knowledge the material for theoretic images. He had only to change the magnitude of conceptions already in his mind to arrive at the Emission Theory of Light. He supposed light to consist of elastic particles of inconceivable minuteness shot out with inconceivable rapidity by luminous bodies. Such particles impinging upon smooth surfaces were reflected in accordance with the ordinary law of elastic collision. The fact of optical reflection certainly occurred as if light consisted of elastic particles, and this was Newton's sole justification for introducing them.

But this is not all. In another important particular, also, Newton's conceptions regarding the nature of light were influenced by his previous knowledge. He had been working at the phenomena of gravitation, and had made his mind at home amid the operations of this universal power. Perhaps that mighty mind at this time was too freshly and too deeply imbued with these notions to enable it to form an unfettered judgment regarding the nature of light. Be that as it may, Newton saw in refraction the action of an attractive force exerted on the particles of light. He carried his conception out with the most severe consistency. Dropping vertically downward toward the earth's surface, the motion of a body is accelerated as it approaches the earth. Dropping in the same manner downward on a horizontal surface, say of glass or water, the velocity of the light particles, when they came close to the surface, was, according to Newton, also accelerated. Approaching such a surface obliquely, he supposed the particles, when close to it, to be drawn down upon it, exactly as a projectile is drawn by gravity to the surface of the earth. This deflection by an attractive force exerted upon the particles of light, was, according to Newton, refraction. Finally, it was supposed that differences of colour might be due to differences in the sizes of the particles; a big particle, by its impact against the retina, producing one colour, and a small particle a different one. This was the physical theory of light enunciated and defended by Newton; and you will observe that it simply consists in the transference of conceptions born in the world of the senses to a subsensible world.

But though the region of physical theory lies thus behind the world of senses, the verifications of theory occur in that world. Laying the theoretic conception at the root of matters, we determine by rigid deduction what are the phenomena which must of necessity grow out of this root. If the phenomena thus deduced agree with those of the actual world, it is a presumption in favour of the theory. If as new classes of phenomena arise they also are found to harmonize with theoretic deduction, the presumption becomes still stronger. If, finally, the theory confers prophetic vision upon the investigator, enabling him to predict the existence of phenomena which have never yet been seen, and if those predictions be found on trial to be rigidly correct, the persuasion of the truth of the theory becomes overpowering. Thus working backward from a limited number of phenomena, genius, by its own expansive force, reaches a conception which covers all the phenomena. There is no more wonderful performance of the intellect than this. And we can render no account of it. Like the scriptural gift of the Spirit, no man can tell whence it cometh. The passage from fact to principle is sometimes slow, sometimes rapid, and at all times a source of intellectual joy. When rapid, the pleasure is concentrated, and becomes a kind of ecstasy or intoxication. To any one who has experienced this pleasure, even in a moderate degree, the action of Archimedes when he quitted the bath, and ran naked, crying "Eureka!" through the streets of Syracuse, becomes perfectly intelligible.

---

* Abstract of a series of lectures delivered in the Cooper Institute, New York, and reported in the *New York Tribune.*

How, then, did it fare with the theory of Newton' when the deductions from it were brought face to face with natural phenomena? To the mind's eye, Newton's elastic particles present themselves like particles of sensible magnitude. The same reasoning applies to both; the same experimental checks exist for both. Tested by experiment, then, Newton's theory was found competent to explain many facts, and with transcendent ingenuity its author sought to make it account for all. He so far succeeded that men so celebrated as Laplace and Malus, who lived till 1812, and Biot and Brewster, who lived till our own time, were found among his disciples.

Still, even at an early period of the existence of the Emission Theory, one or two great names were found recording a protest against it; and they furnish another illustration of the law that, in forming theories, the scientific imagination must draw its materials from the world of fact and experience. It was known long ago that sound is conveyed in waves and pulses through the air; and this truth once well-housed in the mind, was transformed into a theoretic conception. It was supposed that light, like sound, might also be the product of wave-motion. But what, in this case, could be the material forming the waves? For the waves of sound we have the air of our atmosphere; but the stretch of imagination which filled all space with a medium trembling with the waves of light was so bold as to shock cautious minds. In one of my latest conversations with Sir David Brewster he said to me that his chief objection to the undulatory theory of light was that he could not think the Creator guilty of so clumsy a contrivance as the filling of space with ether in order to produce light. This, I may say, is very dangerous ground, and the quarrel of science with Sir David, as with many other persons, is that they profess to know too much about the mind of the Creator.

This conception of an ether was advocated by the celebrated astronomer, Huyghens, and by the celebrated mathematician, Euler. They were, however, opposed by Newton, whose authority at the time bore them down. Or shall I say it was authority merely? Not quite so. Newton's preponderance was in some degree due to the fact that, though Huyghens and Euler were right in the main, they did not possess sufficient data to prove themselves right. No human authority, however high can maintain itself against the voice of Nature, speaking through experiment. But the voice of Nature may be an uncertain voice, through the scantiness of data. This was the case at the period now referred to, and at such a period by the authority of Newton all antagonists were naturally overborne.

Still, this great Emission Theory, which held its ground so long, resembled one of those circles which, according to Emerson, the force of genius periodically draws round the operations of the intellect, but which are eventually broken through by pressure from behind. In the year 1773 was born, at Milverton, in Somersetshire, one of the most remarkable men that England ever produced. He was educated for the profession of a physician, but was too strong to be tied down to professional routine. He devoted himself to the study of natural philosophy, and became in all its departments a master. He was also a master of letters. Languages, ancient and modern, were housed within his brain, and to use the words of his epitaph, "he first penetrated the obscurity which had veiled for ages the hieroglyphics of Egypt." It fell to the lot of this man to discover facts in optics which Newton's theory was incompetent to explain, and his mind roamed in search of a sufficient theory. He had made himself acquainted with all the phenomena of wave-motion; with all the phenomena of sound; working successfully in this domain as an original discoverer. Thus informed and disciplined, he was prepared to detect any resemblance which might reveal itself between the phenomena of light and those of wave-motion. Such resemblances he did detect; and spurred on by the discovery, he pursued his speculations and his experiments, until he finally succeeded in placing on an immovable basis the Undulatory Theory of Light.

The founder of this great theory was Thomas Young. Permit me, by a kind of geometrical construction to give you a notion of the magnitude of this man. Let Newton stand erect in his age, and Young in his. Draw a straight line from Newton to Young, which shall form a tangent to the heads of both. This line would slope downward from Newton to Young, because Newton was certainly the taller man of the two. But the slope would not be steep, for the difference of stature was not excessive. The line would form what engineers call a gentle gradient from Newton to Young. Place underneath this line the biggest man born in the interval between both. He would not, in my opinion, reach the line; for if he did he would be taller intellectually than Young, and there was, I believe, none taller. But I do not want you to rest on English estimates of Young; the German Helmholtz, a kindred genius, thus speaks of him: "His was one of the most profound minds that the world has ever seen; but he had the misfortune to be too much in advance of his age. He excited the wonder of his contemporaries, who, however, were unable to follow him to the heights at which his daring intellect was accustomed to soar. His most important ideas lay, therefore, buried and forgotten in the folios of the Royal Society, until a new generation gradually and painfully made the same discoveries, and proved the exactness of his assertions and the truth of his demonstrations."

It is quite true, as Helmholtz says, that Young was in advance of his age; but something is to be added which illustrates the responsibility of our public writers. For twenty years this man of genius was quenched—hidden from the appreciative intellect of his countrymen—deemed in fact a dreamer, through the vigorous audacity of a writer who had then possession of the public ear, and who in *The Edinburgh Review* poured ridicule upon Young and his speculations. To the celebrated Frenchmen Fresnel and Arago, he was first indebted for the restitution of his rights, for they, especially Fresnel, remade independently, as Helmholtz says, and vastly extended his discoveries. To the students of his works Young has long since appeared in his true light, but these twenty blank years pushed him from the public mind, which became in turn filled with the fame of Young's colleague at the Royal Institution, Davy, and afterwards with the fame of Faraday. Carlyle refers to a remark of Nevalis, that a man's self-trust is enormously increased the moment he finds that others believe in him. If the opposite remark be true—if it be a fact that public disbelief weakens a man's force, there is no calculating the amount of damage these twenty years of neglect may have done to Young's productiveness as an investigator. It remains to be stated that his assailant was Mr. Henry Brougham, afterward Lord Chancellor of England.

Our hardest work is now before us. And as I have often had occasion to notice that capacity for hard work depends in a great measure in the antecedent winding up of the will and determination, I would call upon you to gird up your loins for the labours now before us. If we succeed in climbing the hill which faces us to-night, our future labours will be comparatively light. In the earliest writings of the ancients we find the notion that sound is conveyed by the air. Aristotle gives expression to this notion, and the great architect Vitruvius compares the waves of sound to waves of water. But the real mechanism of wave-motion was hidden from the ancients, and indeed was not made clear until the time of Newton. The central difficulty of the subject was to distinguish between the motion of the wave itself, and the motion of the particles which at any moment constitute the wave.

Stand upon the sea-shore and observe the advancing rollers before they are distorted by the friction of the bottom. Every wave has a back and a front, and if you clearly seize the image of the moving wave you will see that every particle of water along the front of the wave is in the act of rising, while every particle along its back is in the act of sinking. The particles in front reach in succession the crest of the wave, and as soon as the crest is passed they begin to fall. They then reach the furrow or *sinus* of the wave and can sink no farther. Immediately afterwards they become the front of the succeeding wave, rise again until they reach the crest, and then sink as before. Thus while the waves pass onward horizontally, the individual particles are simply lifted up and down vertically. Observe a sea-fowl, or, if you are a swimmer, abandon yourself to the action of the waves; you are not carried forward, but simply rocked up and down. The propagation of a wave is the propagation of a form, and not the transference of the substance which constitutes the wave.

The length of the wave is the distance from crest to crest, while the distance through which the individual particles oscillate is called the amplitude of the oscillation. You will notice that in this description the particles of water are made to vibrate across the line of propagation.

And now we have to take a step forward, and it is the most important step of all. You can picture two series of waves proceeding from different origins through the same water. When, for example, you throw two stones into still water, the ring-waves proceeding from the two centres of disturbance intersect each other. Now, no matter how numerous these waves may be, the law holds good that the motion of every particle of the water is the algebraic sum of all the motions imparted to it. If crest coincide with crest, the wave is lifted to a double height; if furrow coincide with crest, the motions are in opposition, and their sum is zero. We have then still water, which we shall learn presently corresponds to what we call darkness in reference to our present subject. This action of wave upon wave is technically called interference, a term to be remembered.

Thomas Young's fundamental discovery in optics was that the principle of Interference applied to light. Long prior to his time an Italian philosopher, Grimaldi, had stated that, under certain circumstances, two thin beams of light, each of which, acting singly, produced a luminous spot upon a white wall, when caused to act together partially quenched each other and darkened the spot. This was a statement of fundamental significance, but it required the discoveries and the genius of Young to give it meaning. How he did so I will now try to make clear to you. You know that air is compressible; that by pressure it can be rendered more dense, and that by dilatation it can be rendered more rare. Properly agitated a tuning-fork now sounds in a manner audible to you all, and most of you know that the air through which the sound is passing is parcelled out into spaces in which the air is condensed, followed by other spaces in which the air is rarefied. These condensations and rarefactions constitute what we call waves of sound. You can imagine the air of a room traversed by a series of such waves, and you can imagine a second series sent through the same air, and so related to the first that condensation coincides with condensation and rarefaction with rarefaction. The consequence of this coincidence would be a louder sound than that produced by either system of waves taken singly. But you can also imagine a state of things where the condensations of the one system fall upon the rarefactions of the other. In this case the two systems would completely neutralize each other. Each of them taken singly produces sound; both of them taken together produce no sound. Thus, by adding sound to sound we produce silence, as Grimaldi in his experiment produced darkness by adding light to light.

The possible analogy between sound and light here at once flashes upon the mind. Young generalized this observation. He discovered a multitude of similar cases, and determined their precise conditions. On the assumption that light was wave-motion, all his experiments on interference were explained; on the assumption that light was flying particles, nothing was explained. In the time of Huyghens and Euler a medium had been assumed for the transmission of the waves of light; but Newton raised the objection that, if light consisted of the waves of such a medium, shadows could not exist. The waves, he contended, would bend round opaque bodies and produce the motion of light behind them, as sound turns a corner, or as waves of water wash round a rock. It was proved that the bending round referred to by Newton actually occurs, but that the inflected waves abolish each other by their mutual interference. Young also established a fundamental difference between the waves of light and those of sound. Could you see the air through which sound-waves are passing, you would observe every individual particle of air oscillating to and fro in the direction of propagation. Could you see the ether, you would also find every individual particle making a small excursion to and fro; but here the motion, like that of the water-particles above referred to, would be across the line of propagation. The vibrations of the air are longitudinal, the vibrations of the ether are transversal.

It is my desire that you should realize with the utmost possible clearness the propagation of waves, both in ether and in air. And with this view, I bring before you an experiment wherein the air particles are represented by small spots of light. These spots are parts of spirals drawn upon a circle of blackened glass, and when the circle is caused to rotate, the spots move in successive pulses over the screen. You have here clearly set before you how the pulses travel incessantly forward, while the particles that compose them perform any oscillation to and fro. We have in this case the picture of a sound wave, in which the vibrations are longitudinal. By another arrangement of our glass wheel, we produce an image of a transverse wave, and here we observe the waves travelling in succession over the screen, while each individual spot of light performs an excursion to and fro across the line of propagation.

(To be continued.)

EDUCATION AND EXAMINATION.

If the Board of Examiners or the Council of the Pharmaceutical Society required any extra-pharmaceutical support for their proposition that after a stated date candidates must present a certain amount of evidence of education in pharmacy before entering for examination, that support would be found in the arguments by which the portion of the Irish University Education Bill relating to uncontrolled examination has been assailed during the recent Parliamentary debates. In a speech on the Address to the Throne on the opening night of the Session, and therefore before the Bill was presented to the House of Commons, the eminent leader of the Opposition, touching on the forthcoming measure, and the conflicting interests of "the advancement of learning" and the "rights of conscience," hoped that the solution of the problem might not turn out to be the sacrifice of a famous and learned University in order to substitute for it the mere mechanical mediocrity of an examining board. Abundant justification for this remark was apparent when the Bill was read a first time. A new university was to be established which should absorb that of Dublin as well as the Queen's, Trinity and other colleges, and which should examine all comers, no matter where educated or where "*prepared.*" It is true a professoriate was to be organized, but attendance at the classes was to be incumbent on no one. This portion of the Bill has met with opposition in all directions. Even the CHIEF SECRETARY for IRELAND, who, as a prominent member of the Government, was bound to defend the Bill, admitted that a teaching and examining university was a very superior thing to a merely examining university; that the character of a university was greatly influenced by its teaching as well as by its examinations; and that the Government in bringing forward the measure had fully recognized that fact by endeavouring to make the University of Dublin a teaching as well as an examining body. Here, by the way, is encouragement for those who maintain that our own Society should continue its educating as well as its examining functions as hitherto, or at least adopt some means of preventing the substitution of "cram" for education. Such a course seems more than ever necessary at the present time, when the successful *preparation*, a different thing from the *education*, of candidates for our examinations is becoming quite a popular calling. The Member for Dublin, in giving a qualified support to the Bill, recapitulated the old reasons for admitting all persons, wherever educated, to degrees if they possessed the requisite qualifications, but he threw no light on the question as to how qualification could be thoroughly tested; alluded to former immoral means of obtaining certificates of attendance at college, a practice which has since been checked, and went over the well-worn argument that a teaching as well as an educating body would be open to the suspicion that its examinations might be characterized by partiality. The Member for Galway, who spoke immediately afterwards, considered, however, that this portion of the Bill would lead to cramming; and in answer to the remark that University men had recourse to private tuition, said there was a vast difference between a careful course of academic study, supplemented by the occasional assistance of private tuition, and that unmitigated and desultory cramming which the Bill would encourage. The *Times*, also, which unquestionably reflects current opinions on public matters of importance, treated that part of the Bill enacting that a student may matriculate and graduate without attending any lectures or pursuing any academical course anywhere, as one which would discourage teaching and encourage "cram," and considered that the excision of this provision from the Bill was essential to the maintenance of higher education in Ireland. "Every academic body, in Ireland, in a word, condemns the proposal, and any pretence to treat it as essential would justify an instant rejection of the Bill. . . . The true course of academic reform in Ireland is to maintain and improve its two existing Universities as teaching bodies, differing in their apparatus and form of teaching just as Oxford and Cambridge differ, but agreeing in this—that education, and not mere cramming, shall be the necessary condition of entering for an examination."

The second reading of the Bill has been negatived, as our readers already know, but there can be no question that had it gone to committee, its embodiment of the free-trade principle in education would have been rejected by an overwhelming majority. That a candidate for our own examinations shall be twenty-one years of age, and shall give trustworthy evidence of having been engaged in practically acquiring knowledge in pharmacy for a space of three years, are recommendations that come from our Board of Examiners with all the force of reason and common-sense. The mere testing of a youth's power of memory, even though a considerable amount of time be spent over a candidate by an examiner, is a system imported from China, where it has been in-existence a thousand years, and where intellect is a thousand years behind the times. Something better than the mere testing of, it may be, a too rapidly charged memory, or, rather, something in addition thereto, such as is found in the conducting of actual experiments in the pharmaceutical examinations and in the proposed preliminary qualifications for examination, is now generally recognized as necessary before titles of any value can be worthily conferred.

REGISTRATION OF FIRMS BILL.

In legislation as well as in all other things there is a *juste milieu*, to attain which, without passing beyond into mischievous meddling or improper inquisitiveness, is a fair test of true statesmanship. As an illustration of this view we may refer to a Bill lately introduced into the House of Commons, and of which an abstract is given at p. 735. The object of this Bill is to provide for the discovery and registration of the names of partners in firms trading under a designation that does not disclose them. This may appear to some to trench upon dangerous ground, and to have an offensively inquisitorial character. Doubtless, on the other hand, in these days when "and Co." and other sounding titles are so freely used, the Bill will find admirers among those who have suffered from not knowing exactly with whom they were doing business. Putting aside, however, these *pro* and *con.* opinions, there is one respect in which the Bill is specially interesting to registered chemists and druggists. A recent prosecution in the north illustrated how the name of a medical man may be used as a cloak for illegally carrying on the business of a chemist and druggist; and it is not improbable that the name of a registered chemist and druggist is frequently used in a similar way. Such a law as that now proposed, if efficiently carried out, would at least put within the reach of the Registrar the means of ascertaining whether such alleged partnerships were fictions, and thus greatly assist him in carrying out the provisions of the Pharmacy Act.

ADULTERATION OF DRUGS IN THE FOURTEENTH CENTURY.

England in the "good old times" appears to have suffered from evils very similar in their nature to some that at present exist, although the measures by which our ancestors tried to remedy them evinced a spice of originality altogether wanting in the uniformity of the fines and imprisonments of the present day. In the 'Memorials of London and London Life in the 13th, 14th and 15th Centuries,' compiled by Mr. Riley, and published by order of the Corporation, we read that in 1394 an Inquisition was taken before the Mayor and Aldermen, at the Guildhall, to inquire whether or not William Whitman, "citizen and felmongere," did on a certain day "falsely and deceitfully deliver to one "Thomas Keys, merchant, of Stowe St. Edward, in the "county of Gloucester, divers small bags filled with "various powders, made of rape, roots of radiche, "and old setuwale [zedoary], rotten, and unwhole- "some for mankind, as being good powdered ginger; "and other like bags filled with tansy seed, of no "value whatever, for genuine seed called 'worm "seed'; and also divers barrels of rosyn for frank "ensense." The jury declared upon their oath the said William Whitman to be "guilty of the deceit and falsehood aforesaid," and it was adjudged, "in order that others might in future beware of "doing the like," he should "on the same day, be- "tween the hours of 10 and 11 of the clock "before noon, be put upon the pillory, there to remain "for one hour of the day, the said false powders "being then burnt beneath the same." On the Saturday and Monday after he was again to be put upon the pillory for one hour each day, and on each occasion the reason for such punishment was to be proclaimed.

We have much gratification in being able to state that Dr. Redwood, the Professor of Chemistry in the Society's School of Pharmacy, has been appointed to the office of Analyst to discharge the duties required by the Adulteration of Food Act, 1872, for the Parish of Clerkenwell and the Districts of St. Giles's and Holborn. We understand that there was a brisk competition for the appointment, and that especial care was taken by the electing bodies to ascertain the extent to which the several candidates possessed the various forms of qualification required by the Act. We heartily congratulate the inhabitants of the important districts to which this appointment applies upon the result of the election, and on their having secured the services of a gentleman who possesses so extended an experience of the kind of questions that are likely to be raised in the working of the Adulteration Act.

In a letter just received from Dr. F. A. Flückiger, he informs us that he has relinquished his appointments in Switzerland in favour of the post of Professor Ordinarius of Pharmacy in the new University of Strassburg. Dr. Flückiger was until now Professor Extraordinarius of Pharmacy and Pharmacognosy in the University of Bern and Director of the Staats-apotheke of that town; he is also an Honorary and Corresponding Member of the Pharmaceutical Society of Great Britain, and has published several valuable papers in our pages. His familiarity with the German and French languages, no less than his distinguished scientific acquirements, render him eminently qualified to fill with advantage his new position, which we are glad to learn will probably also enable him to become a more frequent contributor to this Journal than hitherto.

Dr. Hooker, of Kew Gardens, is to be proposed by the Council of the Royal Society to succeed Sir George Airey as President.

Provincial Transactions.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The annual festival of the chemists and druggists, under the auspices of the Glasgow Chemists and Druggists' Association, was held in the Albert Hall, on the 27th Feb. 1873. Thomas Davison, Esq., President, in the Chair. On the platform were Messrs. Kinninmont, J. Hatrick, Currie, Walker, McDonald (Glasgow Apoth. Co.), J. A. Clarke (Sec.), McAdam, Galbraith, Fairlie, Drs. Robertson and Clark, etc.

Tea being over, the chairman apologized for the absence of several gentlemen, who from illness or other causes were unable to be present. He then delivered the following address:—

Three years ago when I was honoured by being elected president, and on my first taking the chair at our opening meeting, I had to address you as "Ladies and Gentlemen." Now, almost my last meeting as president, I have again to address you as "Ladies and Gentlemen." As the question of ladies being admitted to our Society is now being agitated, I will, with the permission of the gentlemen, address myself to the ladies first.

I am not going to advocate what is popularly termed "women's rights." I think that expression wrong; for women have had their "rights" ever since the creation, when she was made a helpmeet for man—the only true place a woman should occupy. Many will say that to be a helpmeet women can assist in the shops, and occupy a place on the School Board, Parochial Board, etc. But to soothe the cares of the sterner sex, and when troubled and perplexed to give a word of comfort and encouragement, and in a thousand little ways make our lives sweeter and happier, is, I think, the true meaning of helpmeet. But, let women have their say in the turmoil of contested elections, enter universities, and become professional women, legal as well as medical—and pharmaceutists if they please—I would not oppose them, for they soon would become weary of the hard rough work we of the sterner sex have to undergo. The example of the London University is sufficient to show how soon they wearied; do not oppose their becoming pharmaceutists, which they can without becoming members of the Pharmaceutical Society.

But let the ladies pass their Preliminary and Minor examinations, and the Major if their ambition is great. Still just hear what Professor Blackie said the other day on this point:—"He sometimes did not know what the women wanted; but he promised that if they stated distinctly what they wanted, he would not stand in the way. If they had strength to snuff the foetid horrors of the dissecting-room, or withstand the heartless wrangling of the bar—if they thought it would be a dignity to their sex to wear a wig, in the name of all the wrangling angels, let them go in and do it. He would not oppose them. But he would not stand up for them in reference to these matters; because they ought to thank God for being free from some of that hard, harsh, angular, gritty work which took the hearts out of us, if we had any to take out at all. Therefore, ladies, do not give up your true, dignified, and exalted position *at home*. You can achieve more there, than becoming—

> "A short-haired woman, frizzy, curled,
> Her flag for woman's rights unfurled,
> Her middle finger black with ink,
> Her staring eyes that will not wink,
> Her spectacles—a double-barrelled terror to men that think."

The application of ladies for admission to the Pharmaceutical Society ought to be a stimulus to young men who have for some years been at the trade. Surely they will not sit still and let young ladies pass them in the race for the title of chemist and druggist, or pharmaceutical chemist. I fear there is very much indifference in this matter; too much of the spirit of Micawber—hoping and expecting "something to turn up." Now, gentlemen, don't give way to any such spirit as that; it is day-dreaming, a pernicious way of wasting time—

> "The child may dream; the man must act
> With reverence for the world's great fact;
> And look to toil, and sweat, and bleed,
> And gather his energies, all compact."

Those young men who will be the future chemists and druggists of this great city, I would urge at once, and without any delay, to get through their minor examination; every year it will become more difficult and more expensive. The original intention of the founders of the Pharmaceutical Society was that the Preliminary examination should be for apprentices, Minor for assistants, and Major for those entering into business. But as the law says that those who can pass the Minor and Modified may "keep open shop," the Council of the Pharmaceutical Society think, as the Minor is to be the entrance into business, it must be made more stringent; and the fee for it should be £5. 5*s*. with the title, Chemist and Druggist. The Major with the title of Pharmaceutical Chemist will then become more an honorary title, not one of qualification. This surely ought to be a stimulus to every young man here to be up and doing; and not sit grumbling about want of opportunity, and little remuneration to be had after he does pass. You have the future as it were in your own hands; the proper remuneration will come if you show yourselves worthy of it. Remember the fable of Jupiter and the waggoner, and the lesson taught by it. "The gods help them who help themselves." To those who have to pass the "Modified Examination"—and I regret to say there are yet many who have to do so—according to a statement by the Registrar, 2900 registered themselves for the Modified, and only 1430 have passed,—to them, I hardly know what to say. They got the privilege of passing it by making a declaration that they had been three years previous to the passing of the Act, engaged in dispensing, and practical pharmacy. It is now more than four years since the passing of that Act, making as it were an apprenticeship of seven years. All that is required of you in that examination, is to show you are practically acquainted with those things you are daily handling.

Now, gentlemen, I would make an effort, and don't let it be said of Glasgow that there are so many here who have not passed the Modified examination. Delays are dangerous. A sad instance occurred very lately—a gentleman who had for twenty-five years held a first position in a London house, died suddenly, leaving a wife and family. Application was made a few weeks ago for a grant from the Benevolent Fund, but it could not be granted. Her husband was not a registered chemist and druggist; he not having passed the Modified examination, which privilege I suppose he had claimed.

Now, just a word or two for our association. Some blame, I know, is attached to those in office for not more particularly attending to the special wants of the assistants; but you must remember it has been a summer and winter of work with a price list—a work of which we may be proud, even with all its faults. Then, again, a class was begun this winter by Mr. Currie, of which the assistants might have taken advantage in greater numbers, and it has been a very interesting one. To those who have regularly attended that class, it has been great gain. But to those who have not, it has been a positive loss. Mr. Currie deserves great praise for giving up so much of his valuable time for the benefit of assistants. I must say you have advantages here above any city in the kingdom. I might just say here that there is a small pamphlet, published by the Council of the Pharmaceutical Society, called 'Hints to Students,' which you would find very useful, and which can be got by applying to the secretary here, Mr. Kinninmont. By way of encouragement to those who are in business, I might mention that two druggists have been fined for want of qualification, and others are being looked after.

Many faces here to-night we would like to see at our monthly meetings; their presence would cheer those who have the work to do. The association is much indebted for the interest taken in all our work, and for the aid which frequently comes to us, to the noble chief at the head of the firm to which I have the honour to belong—a right noble one he is of the clan McDonald. I wish all the employés under that chieftain would follow his example by giving us their countenance; then we might be able to make a pull, a strong pull, a pull alltogether. The last festival we had, Mr. McDonald said the time would soon come when all druggists would close at eight o'clock; that has now almost been accomplished, a very few keep open after that hour. Before I sit down, allow me to say that two prizes will be presented this evening to two members of Mr. Currie's class.

At the close of the meeting the President presented to Mr. Wm. Cleghorn, Bentley's 'Manual of Botany,' for excelling in exercises on B.P.; and to Mr. Rob. Wallace Squire's 'Companion to the British Pharmacopœia,' for excelling in exercises in Latin.

The concert was effectively carried out by a lady (professional) and several gentlemen (amateurs); the latter, with one exception, being chemists.

An assembly followed the concert.

The fifth general meeting of the Glasgow Chemists and Druggists' Association was held in Anderson's University on 5th March, 1873.

Owing to the absence of the President (through illness) and Vice-President, Mr. Arch. Paterson was called to the chair.

The Secretary was then called upon to read the minutes of last meeting, also minutes of meeting held on 19th February, for the purpose of forming an assistants' branch of the association. He afterwards read a brief report of the "Annual Festival," held on 27th February, 1873, and stated that a full statement of income and expenditure had not yet been made out, but he felt warranted in saying that there appeared every probability of a fair surplus being left after paying all expenses.

A vote of thanks was then accorded to the committee for their labours in connection with the festival.

Mr. James M. Fairlie read a paper on "Artificial Silicates," in which he gave an interesting account of the history and manufacture of glass. In passing he briefly alluded to the process of etching upon glass, and said he thought that the names on pharmacists' bottles and drawers might be etched instead of painted as at present, which, although likely to cost more at first, would in the end be found to be the more economical method.

On Mr. Fairlie resuming his seat, a little discussion on the paper, by Messrs. Brodie, Fenwick and Paterson, took place.

Mr. Fairlie was awarded a cordial vote of thanks for his paper.

Mr. Cassels was then elected a member.

A vote of thanks to the chairman brought the meeting to a close.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION AND SCHOOL OF PHARMACY.

The last ordinary monthly meeting of the session was held in the rooms of the association, 37, Blackfriars Street, on Friday evening, March 7th; Mr. W. Scott Brown, president, in the chair.

Mr. F. B. Benger delivered a lecture on "Telegraphs," treating the subject under the following heads:—

Early Modes of Transmitting Intelligence—Static or Frictional Electricity—Various more or less unsuccessful Attempts to use it as a means of Communication—Current or Voltaic Electricity—Batteries—Conductors—Three effects produced by the Electrical Current taken advantage of in instruments now used:—1. Its power to decompose chemical salts. 2. To deflect the magnetic needle. 3. To convert a bar of soft iron into a temporary magnet. These effects were shown, and working models of the following instruments used to illustrate the subject:—Bain's chemical telegraph; single needle do. mirror or reflecting do.; alphabetical do.; type printing, do. Electrical fire- frost- and thief-alarms were also shown in action and their construction explained.

The Chairman announced that it was the intention of the association to make considerable additions to the museum, and urged those present to use their influence to obtain new members, as it was the desire of the association to remain entirely self-supporting.

It was also stated that the examination for prizes in the chemistry class would be held on the following Thursday evening, at eight o'clock, and that in the materia medica and botany classes on Thursday, March 20th, at the same hour.

MANCHESTER CHEMISTS' ASSISTANTS' ASSOCIATION.

The tenth ordinary meeting of the session was held on Monday evening, March 10th, in the class room, 37, Blackfriars Street.

Mr. Broughton read a very instructive paper on "Spectrum Analysis," illustrated with numerous experiments, diagrams, etc.

A hearty vote of thanks was awarded to Messrs. J. Woolley, Sons and Co., for their kindness in providing the apparatus used on the reading of Mr. Broughton's paper, also in replenishing about fifty new specimens for the materia medica cabinet.

Proceedings of Scientific Societies.

PHILADELPHIA COLLEGE OF PHARMACY.

At a pharmaceutical meeting, held January 21st, 1873, William McIntyre in the chair, Mr. Remington presented samples of some of the fluid extracts made according to the new U.S. Pharmacopœia. He said that he had found in several cases that the quantity of menstruum reserved for moistening the powder was insufficient for this purpose. The extract of rhubarb left nothing to be desired, having the characteristic features of the root. Buchu was also of very superior quality. Calumba, so very difficult to obtain clear, was spoken of as being almost always cloudy when diluted. Professor Maisch suggested that the precipitate contains a considerable amount of berberina, and that the glycerine recommended in this fluid extract tends to prevent the precipitation.

In the case of colchicum seed, Mr. Remington did not think the menstruum strong enough to dissolve the essential oil which floats upon the preparation, and prefers the use of strong alcohol to take up the oil.

As a class the preparations containing alcohol without glycerine were considered beautiful preparations and representing fully the medical properties of the drugs used.

The preparation of ergot was exhibited, and presented the characteristics fully, having the odour of the fresh ergot. Mr. Remington's experiments with ipecac were not successful; there remained a considerable amount of undissolved resin which glycerine will not dissolve; the alcohol seems too weak to dissolve the resin, and the finished preparation contains one half glycerine. Professor Maisch had four or five samples perfectly clear, made substantially by the officinal process. These were made by himself, the heat carefully regulated, not above 140°; the powder should not be finer than 60. In this preparation the temperature is of great importance.

Mr. Remington said that the ipecac used by him was the strongest he had ever seen. The fluid extract of wild cherry was next discussed, as being made so entirely different from the process directed in the last U.S. Pharmacopœia, being percolated with water and stronger alcohol.

Professor Maisch made some general remarks about the fluid extracts in the U.S. Pharmacopœia, stating that the Committee endeavoured to make these formulæ as simple as possible, that they might be understood by the student and those of little experience in the business. The processes were general ones, and were found to meet the requirements of the profession, based on the experience of those best acquainted with the subject. After moistening the drug with the amount of menstruum directed and adding the remainder, the soluble portion of the drug would be dissolved in a very concentrated form after the required time for maceration, and could then be driven out by the addition of an additional quantity of liquid. The fluid extract of wild cherry was in nowise intended to take the place of the syrup.

Mr. Remington recommended particularly keeping the percolator closely covered, otherwise during the four days' maceration fissures would be formed in the drug, and the extract be an imperfect one.

Mr. Boring exhibited samples of cinnamon and cassia water, made from the oils by distillation, and by the ordinary process of dissolving the oil by the aid of carbonate of magnesia. The water prepared from Ceylon cinnamon by distillation seemed to be the most fragrant and most characteristic.

Professor Maisch exhibited a sample of what was offered as cultivated dandelion root, which upon examination, proved to be chicory.

Mr. A. P. Brown, of Camden, N.J., gave a formula, as follows, for preparing Goulard's cerate:—

Benzoated lard	℥ viiiss.
Yellow wax	℥ iiiss.
Solution of subacetate lead	f℥ iiss.
Camphor	℥ ss.

Melt the wax and lard in a water-bath, add the solution of subacetate of lead gradually, digest for fifteen minutes, stirring it constantly, remove the mixture from the bath, stir it till cool; lastly add the camphor. This preparation keeps for months, retaining its properties.

Professor Maisch read a paper upon spiritus æther. nit. as a supposed test for some of the alkaloids, which was ordered for publication.

Professor Maisch exhibited several varieties of fig plants grown in the neighbourhood of Norfolk, Va., which embraced the white, brown, black and celestial fig. It is not known whether figs may be profitably raised in the Southern States on a large scale.

Several varieties of rhubarb were presented, and it was stated that in all varieties raised in Europe the red medullary rays ran from centre to circumference, while in the true rhubarb the rays are dispersed irregularly over the fractured surface. A specimen of true Russian root was exhibited, which came directly from St. Petersburg about three years ago.

The Professor also exhibited models for the illustration of botany. These were manufactured by R. Brendel, Breslau, Germany, and were beautiful in appearance, resembling as near as possible in colour the natural objects. The models are made large enough to be seen by a class of students, and by coming apart exhibit the internal arrangements of portions of the plants, and the process of germination in the mono- and dicotyledonous plants. A section of rye was shown, and the manner of growth explained. A beautiful flax-plant was shown, showing the structure of the flower, with the stamens and pistils distinctly visible; also models of various fruits, showing the seeds attached, and displaying the embryo. These specimens were made of materials of various kinds most resembling the parts of the plant.

CHEMICAL SOCIETY.

Thursday, 6th March, 1873; Dr. Gladstone, F.R.S., Vice-President, in the chair.

After the minutes of the previous meeting had been read and the other ordinary business of the society transacted, the following communications were read:—"On the action of Hydrochloric Acid on Codeine," by Dr. C. R. A. Wright, being a continuation in the codeine series of the author's former researches on morphine. 2. "On new processes for Mercury estimation, with some observations on Mercury Salts," by J. B. Hannay. 3. "On a method of estimating Nitric Acid," by T. E. Thorpe, F.R.S.E., the process depending on the ease with which nitric acid is converted into ammonia by the copper-zinc couple of Messrs. Gladstone and Tribe. 4. "Note on a reaction of the Acetates upon Lead Salts, with remarks on the solubility of Lead Chloride," by F. Field, F.R.S. 5. "Observations on the nature of the black deposit in the Copper-zinc Couple," by J. H. Gladstone, F.R.S., and A. Tribe, F.C.S. 6. On "An air-bath of constant temperature between 100° and 200° C.," by Dr. H. Sprengel. This consists of a bath similar to the ordinary chemical hot water oven, but made of sheet lead, and filled with dilute sulphuric acid of such a strength as to boil at the desired temperature.

The meeting was finally adjourned until Thursday, 20th March, when a lecture "On Iron and Steel" will be delivered by C. W. Siemens, Esq., F.R.S., etc.

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

The Juries Bill.

On Monday, March 10, the consideration in committee of the Juries Bill was again postponed until Friday, March 14.

Colonel Barttelot has given notice that he will propose to insert the words, "also members of the Royal College of Veterinary Surgeons actually in practice," in the paragraph relating to "exemptions." (See before, p. 673.)

The Metric System.

On Wednesday, March 5, Mr. J. B. Smith moved for leave to bring in a Weights and Measures (Metric System) Bill, "to establish the metric system of weights and measures after a fixed period." Leave was granted, and the Bill was brought in and read a first time the same evening. Mr. Stevenson has given notice that on the motion for the second reading, which is set down for Tuesday, April 1, he will move an amendment that it be read that day six months.

Registration of Firms Bill.

This Bill, which bears the names of Mr. Norwood, Mr. Charles Turner, Mr. Whitwell, and Mr. Barnett, was brought in and read a first time on the 13th February. In the preamble it states that "it is expedient that the real constitution of all private firms carrying on any trade or profession should be known," and this object it proposes to accomplish in the following manner:—

Clauses 1 and 2 refer to the title of the Bill and the time when it should come in force. Clause 3 deals with the interpretation of terms. It defines that "partnership" shall mean two or more persons lawfully associated for the purpose of carrying on any trade or profession, and not incorporated by or in pursuance of any Act of Parliament or by Royal Charter; and "firm" shall mean any person singly or any partnership who shall adopt for the purpose and in the course of carrying on any trade or profession as the name, title, or designation by which such person or partnership shall be known or designated any name, title, or designation other than or in addition to the full name by which such person is ordinarily known and designated, or the full names of all the persons forming such partnership.

Clause 4 provides that every "firm" which at the commencement of this Act shall carry on business in the United Kingdom shall, within one calendar month from the commencement of this Act, and every firm thereafter commencing to carry on business shall, within one calendar month from the time of commencing such business, transmit by post or deliver to the registrar appointed, a statement containing the following particulars:—The name of the firm; the nature of the business carried on; the part of the United Kingdom in which the registered office of the firm is intended to be situated; the full name, usual residence, and other occupation, if any, of the person or persons constituting the firm.

According to clauses 5 and 6 every registered firm is to have a registered office which shall be the chief or a principal place of business of such firm under a penalty, and notice of the situation of such registered office, and of any change therein, must be given to the registrar, and recorded by him.

Clause 7 provides that a firm removing its registered office to another part of the United Kingdom must re-register.

By clause 8 a registered firm which shall use or adopt, in relation to or in course or for the purpose of the business of the firm, any fictitious name or style other than the registered name of the firm, shall incur a penalty not exceeding *fifty pounds* for every occasion on which such fictitious name is so used or adopted; provided that nothing in this Act contained shall prevent any registered firm from transacting business in the name of the person, or of one or more of the persons constituting the firm.

Clauses 9 and 10 provide that every change in the constitution of any registered firm shall be notified to the registrar within one calendar month after such change; and that any registered firm changing its name, title, or designation, shall be registered under its new name in all respects as if it were a new firm.

By the succeeding clauses penalties are imposed upon persons making false declarations or omitting to comply with the requirements of the Bill, but a discretionary power is given to the Registrar in cases where it has not been possible to register within the time prescribed. A register is to be kept, to be open to inspection for a small fee, and certified extracts from this register are to be *primâ facie* evidence in a court of justice. The Bill also proposes that the registrar and assistant registrar of joint-stock companies shall be the registrar and assistant registrar under its provisions.

The West Auckland Poisoning Case.

At the Durham Spring Assizes Mary Cotton has been put on trial charged with the wilful murder, by poisoning with arsenic of her stepson, aged eight years, under circumstances which have now for some time been before the public. The following are the chief points of the evidence having medical and chemical interest.

Mr. Kilburn, a surgeon, who had attended the child, and certified that it died from gastric fever, said that not being quite satisfied in his own mind, he experimented on some of the contents of the stomach, found traces of arsenic, and gave information to the police. In consequence, the body was exhumed, and parts of the viscera and contents of the stomach were sent to Mr. Scattergood, surgeon and analytical chemist, of Leeds.

He had prescribed morphia, prussic acid, and bismuth to the child. The child had had fits and convulsions before it died, and morphia had been known to produce convulsions, but not, it was said, when it was administered in the doses which he prescribed. Prussic acid was a dangerous poison, but not taken in the doses he prescribed; and bismuth was an irritant poison which, taken in large doses, might inflame the stomach and bowels, but he had only prescribed it in small quantities. He had sent 12 doses to the child. The preparations of bismuth, the trisnitrate, and sub-carbonate, were frequently impure and contaminated with arsenic, but only in minute quantities. He kept his poisons on a nest of five or six shelves. Arsenic was on the second shelf in a bottle, about No. 5; prussic acid was in a bottle next or next but one to it, about No. 6, and the sub-carbonate of bismuth was in a bottle at the other side, about No. 2 or 3. His assistant, Mr. Chalmers, proved that he made up the preparation for the deceased. There was a liquid preparation of bismuth at the other side of the shop, which he believed he used. Mr. Kilburn was the parish doctor, and at two o'clock on the day when he made up the prescription there were half-a-dozen people in the surgery waiting for their medicines, and he spoke to them and asked them what they came for, as he was making up his prescriptions. It was proved by a charwoman that about six weeks before the death of the child, she was sent by the prisoner to a chemist's for two-pennyworth of soft soap and arsenic, which were supplied to her mixed together. The chemist proved that he put in the soft soap from four to six drams of arsenic and mixed them. This mixture the charwoman rubbed into the joints and crevices of an iron bedstead to kill bugs, and also twice rubbed it over and between the iron cross-belts under the bed. A 4-in. mattress was placed on this, and was sometimes turned, to prevent its wearing all on one side against the iron cross-bars. Some of the soap was also used for the skirting-boards and near the fire-place on the floor. Nearly all was used, and the remainder was placed in a small jar in a lumber-room. On a search being made at the house this jar was not found, and nothing containing arsenic. The paper of the room had a bright green fluffy flower on a stone-coloured ground. Mr. Kilburn stated he was aware that chronic poisoning by arsenic had been caused by the use of arsenical or green papers to walls. He did not think that the fumes of arsenic could arise from the arsenic used in the room, as fumes were only thrown off at a high temperature, about 280 degrees.

Mr. Scattergood proved having received the jars containing the viscera and the contents of the stomach, and also some articles found in the house of the prisoner. None of these latter contained poison of any kind. He found traces of arsenic in the contents of the stomach, in the substance of the stomach, in the contents of the bowels, and in the substance of the bowels, in the liver, and in the kidneys—none in the spleen. He estimated the total quantity at 2·60 grains. In his judgment on these facts he thought repeated doses of arsenic had been administered, and that arsenic had been given shortly before death, because it was found in the stomach. Two or three grains were sufficient to cause death, and half that quantity for a child. In his judgment the deceased had died from poisoning by arsenic.

In the course of his cross-examination in the case, Mr. Scattergood admitted that soft soap and arsenic would dry from exposure to air, that a heated room would assist to dry it, and that a mattress on any portion of it would absorb moisture from the soap. If dry the attrition of the cross-bars of the bed over one another from getting in and out of bed would be likely to cast dry particles on the floor. If nearly all the soft soap and arsenic had been used by Mrs. Dodds on the bedstead, about 300 grains of arsenic must be there. This, by trampling on the floor and on the carpet, might be raised as dust floating in the air, and, like Scheele's green wall-papers, might cause irritation and dryness in the throat and eyes, and, by means of the lungs, become absorbed into the system, but could not get into the contents of the stomach. No doubt the quantity of arsenic was much greater than could be rubbed off any wall-paper.

In his speech for the defence, Mr. Campbell Forster urged among other things the quantity of arsenically poisoned dust there would be floating about the room arising from the attrition of the large quantity of arsenic and soap put upon the bedstead. Every time the child ran about the room, played with his toys, or jumped into bed a cloud of these poisonous atoms must have arisen and been inhaled by him, as proved to be, a delicate, susceptible boy. These atoms, inhaled into the lungs, would enter the circulation of the blood, and every part of the substance of the viscera would become tainted by arsenical poisoning. Much of that inhaled would adhere to the tongue and moist parts of the mouth and the throat, and be swallowed with the saliva into the stomach, and after five days and nights, while ill in bed, of such constant influences, was it surprising that as much as 26 grains of arsenic had been found in the child's stomach after death? The child might accidentally have drunk water or milk from the poisonous jug, and thus have become poisoned. It was also proved that when ill a prescription had been made up for him by Dr. Kilburn, and also by Mr. Chalmers's assistant, consisting of bismuth and prussic acid, and these poisons were on the same shelf with the arsenic bottle, and closely adjacent, and it was possible that some unfortunate mistake had been made in the bottle and that this arsenic might have been administered as medicine.

The jury returned a verdict of guilty and the prisoner was sentenced to death.

Reviews.

The Useful Plants of India: with Notices of their Chief Value in Commerce, Medicine, and the Arts. By Col. Heber Drury. Second edition; with additions and corrections. London: W. H. Allen and Co. 1873.

Nearly fifteen years having elapsed since the publication of the first edition of this useful book, much has, during that time, been added to our knowledge of the vegetable wealth of our Indian possessions. The attention of the local governments has been called to the subject, and much has been and is being done, not only in preserving the forests, which are of great value in both a climatological and an economical point of view, but also in introducing foreign trees and herbaceous plants suited to the climate. The prodigious fecundity of the country may be inferred from the fact that we have in this volume an enumeration of 600 trees, shrubs, and herbs possessed of more or less useful properties. They are arranged in alphabetical order, the natural order of each species being given, followed by its English and native names; then a sufficiently full description, with reference to previously published diagnoses and plates; and, finally, an account of its medical and economic uses. In the case of the more important species, native or introduced, these latter items are given at considerable length. Among officinal plants omitted in the first, but included in the second edition, the culture of which is rapidly increasing in commercial importance, may be mentioned the cinchona, tea, cacao, tobacco, and the Australian eucalyptus. We do not however, find any reference to the introduction and cultivation in India of the ipecacuanha, which seems likely to rival even that of cinchona in importance. An illustration of the amount of useful information contained in the book is afforded by Col. Drury's account of the different kinds of Indian ebony. Under the head of "Diospyros melanoxylon," he says, "The bark is astringent, and, reduced to an impalpable powder, is applied to ulcerations, and, mixed with black pepper, is administered in dysentery. The true ebony of commerce is obtained from the *D. ebenum* (Linn.), a native of Ceylon; but in fact other species scarcely differing from one another yield this timber. This species yields a fine kind of ebony; it is only the centre of the larger trees that is black and valuable, and the older the trees the better the quality. The outside wood is white and spongy, which, decaying or destroyed by insects, displays the central ebony. Sir E. Tennent has some valuable remarks upon the different species of ebony growing in Ceylon. The true ebony, *D. ebenum*, grows in great abundance throughout all the flat country west of Trincomalee. It is a different species from the ebony of the Mauritius, *D. reticulata*, and excels it and all others in the evenness and intensity of its colour. There is another cabinet-wood of extreme beauty, the *D. ebenaster*, in which the prevailing black is stained with stripes of rich brown, approaching to yellow and pink. The most valuable cabinet-wood of the island, resembling rosewood, but much surpassing it in beauty and durability, and which has at all times been in the greatest repute in Ceylon, is the *D. hirsuta*. The *D. montana* (Roxb.) is a timber variegated with dark and white veins; it is very hard and durable. The *D. tomentosa* (Roxb.) is a native of the northern parts of Bengal; the wood is black, hard, and heavy. Roxburgh compares this latter tree to a cypress, from its tall and elegant form. The leaves all fall off in the cold season. The *D. calycina* (Bedd.) has been found in the Tinnevelly district and southern provinces of Madura, being very abundant up to 3000 feet of elevation. It is called in those districts 'Vellay Toveray,' and yields a valuable light-coloured wood much used in those parts." The appendices to the volume embrace reports on the culture of the bamboo, cinchona, indigo, and other vegetable products, a table of exports and their value, and index of Hindostanee, Bengalee, Tamil, Teloogoo, and Malayalim synonyms. The volume is altogether indispensable to any one interested in the natural history of our vast Indian Empire.

Change of Air and Scene: A Physician's Hints, with Notes of Excursions for Health amongst the Watering-places of the Pyrenees, France, Switzerland, Corsica, and the Mediterranean. By Alphonse Donné, M.D., Rector of the Academy of Montpellier. London: Henry S. King. 1872.

"Running to and fro upon the earth" has increased our knowledge in many ways, but in none more than in the therapeutic virtues of climate and mineral waters. Medical climatology, since the publication some thirty-five years ago of Sir James Clark's well-known work, has become a branch of professional literature, and not a year elapses without the accession to it of one or more volumes.

Dr. Alphonse Donné's treatise is one of the most acceptable of these. Himself an accomplished teacher and practitioner of the physician's art, he has had experience, in his own person as well as in that of his patients, of the curative virtues of the health-resorts of south-western Europe. He can determine with accuracy the mean temperature of the climate as well as the chemical properties of the waters characteristic of those places. He can indicate with skill the peculiar types of malady in which a particular health-resort may prove efficacious; while he can also suggest to the patient the resources available to him for that moral and intellectual recreation which in so many cases is found to be the main element of cure.

His work has a high reputation in France not only for its scientific and professional merits, but for its charm of style, and much credit is due to its English translator for having preserved the latter while faithfully reflecting the former. An introduction supplies the reader with useful hints as to the kind of cases in which benefit may be derived from change of climate and scene; after which comes a lucid exposition of the "hygiene of the seasons" and the best resorts for the maladies peculiar to winter, spring, summer and autumn. Next follows a series of "Excursions and Travels in Quest of Health," in which the practical mind of the author shows itself in the shrewdness of his recommendations, down even to the details of hotel-life and itinerary disbursements. As a specimen of the completeness with which he inspires the health-seeking invalid with all the requisite information, we may cite his chapter on the winter excursions in the mountains of Lozère and the Haute-Loire, which will have a special interest at present when the *Times* and other lay journals are filled with controversial correspondence as to the conflicting claims of "winter sanitaria."

The section on mineral waters constitutes the bulk, as it is certainly the most important part of the book. Dr. Donné takes us through the Pyrenees, through Provence and Dauphiné, through Corsica, Savoy, France and Switzerland, and describes their peculiar virtues and the cases in which they have proved beneficial. Comprehensive and minutely detailed as it is, this section does not pretend to be exhaustive, omitting as it does nearly all reference to the German and particularly to the Austrian watering-places. Such a charming resort as Soolbad Aussee, on the river Traun, for example, it does not even allude to. Is is, as we have said, almost entirely confined to the Latin countries, and even of these the preference is given to France.

Some excellent remarks on special points of hygiène, as that of the lungs, of the teeth, of the stomach, of the eyes, and of the nervous system, will be found at the conclusion of the volume. They combine very happily scientific insight with popular exposition. The reader will also admire the fairness with which Dr. Donné gives the arguments for and against what Dr. T. K. Chambers terms "that ill-assorted union of medicine and innkeeping called hydropathy."

Obituary.

At Liverpool, on the 1st March, 1873, Mr. Edwin Barnes, of Durham. Mr. Barnes studied in the School of Pharmacy, Bloomsbury Square, in 1859, and was honourably distinguished in the Professors' Examinations. In 1860 he passed the Major examination, and was elected a member of the Society in 1870. He lived at Alton, Edinburgh, and Liverpool, and will be remembered by his numerous friends as a man of genial manners and varied attainments. As a student he was enthusiastic, and he carried the same heartiness and thoroughness into all that he afterwards undertook. His death, which was from pneumonia, will be regretted by many readers of these lines.

Notice has also been received of the death of the following:—

On the 7th December, 1872, Mr. Robert Errington, Chemist and Druggist, of Bradford, Yorkshire.

On the 5th February, suddenly, Mr. Robert Procter, Chemist and Druggist, of Castle Gate, Newark.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

The Sale of Poisons.

Sir,—After reading the editorial remarks upon the above subject in last week's Journal, I scarcely think it necessary for me to say much in reply to Mr. Tibbs. The sale of "Vermin Killers" is a very troublesome question, and I am sure all will agree with me that the sooner chemists and druggists generally come to some understanding in the matter the better. I am afraid Mr. Tibbs would find his theory, that "Vermin Killers" containing arsenic or strychnine are not preparations of these substances, of little use to him in a court of justice. I hold, that it is the duty of every chemist when he sells a "Vermin Killer," knowing it to contain arsenic or strychnine, to register it in the same way as he would any other preparation of those substances. I think, Sir, Mr. Tibbs has not studied the law with sufficient care, for if he will carefully read over the Pharmacy Act, 1868, and the list of additions to the schedule published in 1869, he will find that he need have no fear he is doing wrong when he sells "lotions" containing cantharides or corrosive sublimate, or "cough remedies" containing tartar emetic, without registration, for he will see that preparations of the above substances, are not named in the first, and only those of cantharides and corrosive sublimate in the second part of the schedule.

Archibald Kitchin.

Whitehaven, March 11th, 1873.

The Examinations.

Sir,—There appearing to be considerable interest shown in regard to the examinations, perhaps you will allow me, as one who has passed all at no very distant date, to say a few words.

I will begin, Sir, with the "Preliminary." Most, I think, will admit that at present this examination is not so hard but that a boy leaving school should be able to pass it without difficulty, providing that Latin was one of the subjects he has been taught there, and that he has taken (and had taken with him) moderate pains to accomplish the object for which he had been sent; but I am certainly of opinion that it ought either to be held entirely in London, or it should be totally separated from the Society and placed under some independent examining board; for not only is the present system liable to abuse, but, to my knowledge, it has been abused and not carried out in the manner intended and ordered by the Council of the Society.

Secondly, the "Minor." I would remind and encourage those who are preparing for this, that a little *method, perseverance* and *industry* are all that is required not only to pass it, but to pass it with honours. It is essentially a practical examination, which an apprentice, having completed his term, should be able to pass. The examiners will be found to give every allowance to those who are at all nervous; for I doubt not that their experience enables them easily to distinguish those who are competent but lack self-reliance, from those who are incompetent and those who show but artificial cramming.

Thirdly, the "Major." Of this I will only say, that those who have passed the two previous examinations have only to continue in the course they have hitherto pursued, and they will find that this one only requires the three requisites already recommended for the "Minor;" and when they have "done it," they will acknowledge that the pleasure of attaining the object is well worth the labour and trouble bestowed on it.

I can from experience assure all who try and wish to succeed that success will undoubtedly attend them if they give their attention to what they profess to be studying, remembering that "Diligence in execution is the mistress of success."

York. W. M. Thompson.

Pharmaceutical Women.

Sir,—I take up my pen in the hope of clearing this subject from some of the fogs which have been thrown around it. The question lately discussed by the Council of the Pharmaceutical Society was not whether women should be allowed to become registered chemists or pharmacists, but whether they should be admitted as members of the Pharmaceutical Society—a body in which, through its Council, are vested certain legislative powers; and the Council has stepped in and wisely refused such an innovation.

Now, at the risk of being called a "benighted obstructive" by your Plymouth correspondent (Mr. Balkwill), I would maintain that it is not desirable to lift woman out of that sphere which she is well qualified to fill as the help-meet of man, and place her in the unlovely position of his rival. I would even question the propriety of admitting her in common with male students into the lecture theatre, as I think the indiscriminate intermixture of the sexes at that age without proper female supervision is fraught with serious moral and social evils. Mr. Balkwill admits that the cases of girls requiring pharmaceutical education would be comparatively few;—might they not be met by the appointment by the Society of a competent lady teacher?

It is surely unnecessary to drag in the names of such men as William Allen and Jacob Bell into such a discussion as this; but as Mr. Balkwill has drawn certain inferences from the fact of their being members of the Society of Friends, I would remind him that that body, whilst recognizing many of woman's gifts, which have been largely ignored by former generations, still studiously denies her any legislative power in the body.

I venture boldly to dispute the correctness of the statement that we are behind the other learned bodies in not granting degrees to women; for whereas a lady of my acquaintance has passed the examination of the University of Cambridge with mathematical honours, but is denied her degree of Bachelor of Arts (possibly from the incompatibility of the title with the sex), there is nothing to prevent any lady with the necessary ability from taking our highest academic degree (such as it is), and announcing herself as "Pharmacist with honours."

I trust that these remarks may tend to place the question of admitting women as members of the Society on its proper footing.

Chas. Fryer.

Scarborough, March 10th, 1873.

Sir,—In your issue of the 22nd February I notice a letter signed "Pharm. Brit." on the subject "Pharmaceutical Women."

Now, Sir, although it might be pertinent to argue that in such a case the sex has a fair title to be considered "persons within the meaning," etc., and that they are the more acceptable sex of advisers in most of the simple cases which come before the druggist, I feel disposed to ask "Pharm. Brit." only for a little stretching of his imagination, which I trust may console him for his fancied "loss of cash."

Let him then picture himself enjoying his future "on his own account," avenging his past in the present, by receiving service from *one* entirely confidential and trustworthy, wholly devoted to his interests, and of qualifications equal to his own; and all this at the cost of not even a low salary for mere "*pin money!*" May he attain it!

Deva.

Mr. Hugh M. Williams writes to say that he would admit the ladies by all means, and that he thinks they would be as harmless to the trade as they used to be prior to the compulsory examination.

Apprentices and Members.

Sir,—I send you a few "notions" from the country upon two matters which are now receiving attention. Imprimis—the apprentice.

This distressing complaint shows a variety of remarkable phases, phases which change as rapidly as those of the moon, and from the extreme absurdity they at times exhibit they might be supposed to be influenced by the lunar body. A short time ago the malady was at its height in representing the poor fellow as being dreadfully imposed upon and compelled to submit to scandalous indignities, even to soiling his fingers by handling a duster. Now we have the other extreme, that the master in the form of a local secretary (in condonation of former cruelties?) is unlawfully assisting or by his absence tacitly acquiescing in the future apprentice illegally passing the Preliminary examination. Were this latter charge a myth, members of the Council would not have spoken so pointedly of it. But Mr. Whitfield, in the intensity of his indignation, boldly puts his heart outside his waistcoat to be pecked at, and invites his *confrères* to follow his example. As a local secretary, I politely decline his invitation, because I, in common with the "insulting" members of the Council, not only believe the statements to be true, but that the facts were stated in much milder terms than the abuses merited. And I also wholly disapprove of the Preliminary examination as at present conducted. Following the example of the College of Surgeons, I should prefer seeing this examination placed under the management of the College of Preceptors. I can see no hardship in adopting this plan, for the fact of going to one of the "centres" where the college holds the examinations, would not prevent a parent or guardian allowing a youth to enter the trade. Moreover, the trifling expenses connected with the journey are scarcely worth notice, and those connected with the Minor or Major examinations might as reasonably be objected to. But would there not be substantial satisfaction to the neophyte in presenting himself before a properly constituted examining body and finding the examination fairly conducted? Would he not conceive a greater respect for the trade and its examinations than the present slovenly system suggests? And would he not also learn that such unworthy aids as "cribs" and "crams" would be of no avail, whilst industry, coupled with straightforward, honest conduct, could not pass unrewarded among a body of examiners who gave to all "a fair field and no favour?" If the Preliminary examination be necessary, as much care should be bestowed over it as over the two subsequent ones.

2nd. The relative positions of chemists and druggists and of members of the Pharmaceutical Society:—

We have read much in the pages of this Journal upon the subjects of "pharmaceutical titles" and of "outsiders." I can only see one satisfactory solution of the difficulty in arranging the former titles, and that is by entirely abolishing the latter class. We members who have passed our examinations must not approach this subject with narrowed views, but endeavour by a bold and generous policy to at once snuff out all these petty misunderstandings and jealousies respecting trade status. Previous to the passing of the Pharmacy Act of 1868, the Pharmaceutical Society governed those only within their fold. Now that they have the sole management of the drug trade throughout Great Britain, they ought to be assisted in that responsibility by every chemist and druggist in the country. Therefore, I would suggest that we should make, not permit to be made, every druggist in Great Britain a member of the Pharmaceutical Society. This membership should be a *sine quâ non* to his being in business. There should be an annual sum payable, which should include registration and membership and also the weekly receipt of the Journal. The annual payment would not be a heavy one, and when accustomed to, would be looked upon as a protection to the trade as much as the payment of licences for other matters. The duties of compiling the Register would be materially lightened, and absolute accuracy might be attained in its compilation if in the keeping open shop it should be made necessary to pay such registration fee before a given day in each year. The circulation of the Journal throughout the whole of the trade would also create a greater interest in the higher branches of pharmacy amongst those who more need that taste encouraging. And the knowledge that we were not only under one pharmaceutical government, but that each and all of us had a voice in the formation of such government would conduce to healthier legislation upon purely trade matters, and lead to the speedy abandonment of sentimental grievances. Being all "Members of the Pharmaceutical Society," the title of "Pharmaceutical Chemist," would remain unchanged, while such pretentious designations as "Fellow," "Licentiate," etc., would be unneeded.

Following the rule observed at our trade gathering, I imagine, though with the greatest respect for the fair sex, that "success to pharmacy" is at our meeting entitled to the precedence of "the ladies." Hence I suggest these subjects, which I consider calculated to advance our improvement and success, as more suitable for ventilation at our ensuing annual meeting than the wasting of the time of the members upon the question of admission of female students to the laboratory at Bloomsbury Square.

A Country Pharmaceutical Chemist.

PHARMACEUTICAL TITLES.

Sir,—Would you kindly insert the following in your widespread Journal.

Having read with great satisfaction the letter of your correspondent, Mr. L. V. Rees, in the Journal of March 1st, on the subject of pharmaceutical titles, we think that his proposal is a step in the right direction. Out of eight apprentices employed in the establishment to which we belong, there are at least five who are not intending to remain in the ranks of pharmacy. And what is the reason of this? They have all had a liberal education, and, finding that it would be as easy to pass the medical examinations as to attain to the Major qualifications of pharmacy, and, coupled with this, the great social difference between a pharmaceutical chemist and a medical man, they would rather expend a considerably larger sum of money, and a greater amount of time, so as to gain to themselves a higher position in society. The remedy for this, we think, will be partly found, if more acceptable titles were accorded to those who pass the examinations of the Pharmaceutical Society. Let us endorse the statements of Mr. Rees, that "an Associate is nothing more than the lowest grade of all scientific societies; therefore why not give this title to those who have passed the 'Preliminary?'"

If "Major" men were called "Fellows of the Pharmaceutical Society," it would be an inducement and stimulus to young men of position to strive to gain that qualification. And why not also let those who pass the "Minor" be called "Licentiates of the Pharmaceutical Society," seeing that they are LICENSED to practise pharmacy? We believe that if this suggestion were carried out, it would give general satisfaction to all connected with the profession,

At present there seems a great lack of young men willing to join and follow up the profession, but we think that were these titles recognised a different state of things would prevail.

TWO APPRENTICES.

Edinburgh, March 4th, 1873.

TINCTURA QUINIÆ.

Sir,—I cannot agree with Mr. Baldock that the official formula for Tinct. Quinine is "perfectly satisfactory." It is beyond dispute that tincture of quinine of the official spirituous strength will deposit copiously of crystallized quinine at such temperatures as are common in English winters; and this must be acknowledged to be objectionable. The inconvenience might, I think, be avoided by increasing the alcoholic strength to the proportion of three parts rectified spirit to one part water; but, although I have experimented in this way, amongst many others, with a view to improving the formula, I failed to make notes of the result in this respect.

I would take the opportunity of referring to another matter connected with quinine, viz., the great waste which characterizes the medicinal employment of cinchona products, a waste for which medical and pharmaceutical prejudice is to a great extent responsible. The demand for quinine appears to increase like the consumpton of coal; and like coal, there seems to have been some apprehension as to the duration of the supply. In the meantime, what becomes of the valuable medicinal alkaloids yielded by the cinchonas other than quinine? I ask the question, but am totally unable to give an answer. Messrs. Howards have recently issued a circular inviting attention to the merits and relative cheapness of cinchonidine, said to be little, if at all, inferior in medicinal efficacy to quinine, yet sold for about one-third its price! Why is it made a matter of conscience to separate this valuable alkaloid from quinine, and to exclude it from all official preparations? I have the strongest belief that a *mélange* of all the cinchona alkaloids would prove a more digestible and therefore a more efficacious tonic than any one of them stark-naked; and I should much like to see tincture of quinine, and, still more, quinine wine (which is admirably suited for a popular tonic) replaced by pharmacopœiai formulæ for tincture and wine containing all the cinchona alkaloids in a state of natural admixture.

Pursuing the same subject I may add that there seems to me room for addition and improvement in the galenical preparations of the bark itself. The only preparation worth naming is the liquid extract (the equivalent of the liquor cinchonæ introduced by Mr. Battley), but although this was a great advance upon any previous formula, it fails to furnish a complete epitome of cinchona bark, so that both in its galenical preparations and its chemical products, this most important medicine is but imperfectly utilized. The subject is worthy of the skilled investigation of Dr. Redwood, and if successfully worked out would prove a most valuable feature in the proposed supplement to the British Pharmacopœia.

RICHARD W. GILES.

Sir,—Referring to Mr. Mumbray's letter in the Journal of March 1, I think it is generally known by practical pharmacists that the addition of an acid even in considerable quantity does not give a satisfactory result.

Why not separate the undissolved quinine and make a solution with dilute sulphuric acid, precipitate with ammonia, wash the nearly pure quinia, and add it to the tincture in which it is readily soluble?

Greater liberties are often taken with Pharmacopœia processes to attain results of less importance.

WALTER WISE.

Sir,—In reply to the letter of Mr. Mumbray in last week's issue, respecting Tr. Quiniæ Co., I beg to say that I have at last succeeded in obtaining a tincture free from any deposit. I make it strictly P. B., using Howard's quinine, *no acid of any kind*, but taking care to make the tr. aurant. with rectified spirit 5 parts, and distilled water 3 parts. Then, after pressing and filtering, dissolving the quinine in it at a very gentle heat. I have some tr. quiniæ thus prepared still in a shop bottle, and it is at least ten months old, and has never thrown down any precipitate whatever.

R. T. CLARKE.

131, *Milton Road, Gravesend.*

"*An Associate.*"—We think it is sufficiently well established that the present mode of conducting the Preliminary examination is unsatisfactory, without particularizing further instances.

Y.—A formula for the preparation of Tinct. Prun Virginianæ was given on p. 477 of the first volume of the present series of the PHARMACEUTICAL JOURNAL.

"*Cornubia.*"—The best and most appropriate way of obtaining the object suggested would be through the College of Preceptors.

"*Inquirer.*"—We have no acquaintance with the practice of medicine, and therefore cannot give you the information for which you ask.

"*Mence.*"—Three molecules of iodine are taken because that is the proper proportion for the quantity of hydrate of potash. If you read the sentences preceding the equation you will there see described what change takes place.

"*Hanging Ditch.*"—See PHARM. JOURN., 2nd ser. vol. VIII. p. 467. The subject has been referred to in the present volume also, at p. 384.

J. Hickling.—The number of British insects is some 12,000 to 15,000, so you will easily understand that a manual of entomology such as Babington's or Hooker's is an impossibility. The only manuals in existence that we know of are Stephens' 'Manual of British Beetles,' which is now quite out of date, and Stainton's 'Manual of British Butterflies and Moths,' which is more modern and reliable. On the Lepidoptera there is also a popular book (illustrated with woodcuts) by Newman, and published by Tweedie in the Strand. Stainton is published by Van Vorst, and Stephens by Longmans. Maclachlan has published some monographic treatises on British Neuroptera in the 'Entomological Transactions,' and Smith has published descriptive catalogues of 'British Bees and British Fusorial Hymenoptera' in the series of British Museum catalogues. These, so far as we know, complete the set of systematic treatises on British Entomology. If our correspondent wants a general guide to entomology and can read German, he cannot do better than get the second volume of Carus, Peters and Gerstäcker's 'Handbuch der Zoologie;' but the number of foreign books on the subject is enormous.

"*Camphora.*" — The lotion would not be clear if the quantity of camphor ordered were used, probably the excess over and above what was dissolved was filtered out on the previous occasions; this would not be justifiable, but would make a more sightly preparation. A few drops of spirit should of course be used to powder it in the first instance before adding the borax.

COMMUNICATIONS, LETTERS, etc., have been received from, Messrs. J. Kirkup, A. W. Gerrard, J. Barker Smith, C Ford, H. Pocklington, E. A. Webb, W. Tearle, Mumbray. H. L., J. B. B.

AFRICAN AMMONIACUM.

BY DANIEL HANBURY, F.R.S.

The first writer to mention Ammoniacum is said to be Dioscorides,* who flourished in the first century, and who relates that the drug is the juice of a species of *Ferula* growing about Cyrene in Libya, and that it is produced near the temple of Ammon. Whether the drug received its designation from the deity or the deity from the drug, or whether both took their names from the Greek word Ἄμμος, *sand*, in allusion to the parched and sandy desert where both were found, were open questions in the time of Pliny. The story however of the Libyan origin of ammoniacum remained current for centuries among writers on materia medica, and considering that the drug was not unfrequently brought from Alexandria, it had about it nothing improbable.

Chardin, who passed many years in Persia (1666–1677), is probably one of the first to point out that ammoniacum is a production of that country.† He says that the Persians call the plant *Ouchag*, and that it grows in abundance on the southern confines of Parthia,—that is to say south of Ispahan, which is exactly where it has been found by many travellers in modern times.

Jackson, an English merchant who resided for sixteen years in Morocco and wrote an instructive account of that country,‡ described a sort of ammoniacum produced there by a giant fennel called in Arabic *Feshook*. This plant, he says, grows on most of the plains of the interior, but especially about El Araiche and M'Sharrah Rummellah. The gum exudes from the stem in consequence of the puncture of a beetle, and falling to the ground becomes contaminated with earth, for which reason it does not suit the London market; but it is used in all parts of the country for cataplasms and fumigations.

Lindley, from the examination of specimens sent to England from Tangier in 1839, determined the plant affording African ammoniacum to be the *Ferula Tingitana* of Linnæus.§

Notwithstanding the statement of Jackson that a kind of ammoniacum is a production of Morocco, it was difficult to believe that this Moroccan drug could be the *Ammoniacum* which the ancients, and especially Dioscorides, described as brought from Libya. Pereira‖ and Guibourt** having examined specimens of the gum sent to Lindley from Tangier, concurred in regarding it as a very different substance from Persian ammoniacum. The latter writer even maintained that Dioscorides had slipped into an error, and that his ammoniacum was probably none other than that of our own times.

It was also pointed out that the word *ammoniacum* was sometimes written *armoniacum*, which might well be a corruption of *armeniacum*, and point to Armenia or some country beyond as the source of the drug.

The works of a Persian writer†† recently made accessible have also proved that ammoniacum was a production of Persia as early as the tenth century.

†† Abu Mansur Mowafik ben Ali, *Liber Fundamentorum Pharmacologiæ*, ed. Seligmann, 1833.

The appearance in London drug sales of a very impure kind of ammoniacum, differing notably from the worst variety of the Persian drug, attracted my attention so long ago as 1857; and I was interested in observing a much larger quantity of the same article in the year 1871. On this occasion 37 packages were offered for sale. I was unable to ascertain whence they had been shipped, but the former lot (1857) I found had been imported from Mogador.

The drug may be described as in large, compact, dark, heavy masses, formed of agglutinated tears of a gum-resin of hard, waxy consistence. The tears are opaque, white, and milk-like, or of a pale greenish yellow, or of a fawn colour, mixed with others of a dark blackish brown, which with earthy and vegetable impurities constitute a large proportion of the mass. The drug has a very weak odour not suggestive of ammoniacum, and a slightly acrid but very persistent taste.

Having recently had to investigate anew the history of ammoniacum, I was led to look into the various memoirs on the subject, and also to search for some information respecting the Morocco drug described by Jackson. In the latter inquiry I was fortunate enough to have the aid of Mr. Moryoseph, a drug merchant of London having connexions with Mogador, who not only at once supplied me with a sample of the African drug according exactly with that I had noticed in the brokers' salerooms, but also kindly wrote to Morocco for some of better quality, which proved to be less impure and to contain milky tears exactly like Persian ammoniacum.

I also enlisted the services of my friend Dr. Leared, who during a short visit to Morocco in the past autumn ascertained a few interesting particulars, which are to this effect:—

The plant is called *kelth*, and grows up rapidly after the first rains. Its gum is not much shipped to Europe, but a great deal of it is taken by pilgrims to Egypt and Mecca, where it is used as incense. Its chief shipping-port is Mazagan; a little is sent from Mogador but none from other ports. The "*Greatham Hall*," the vessel in which Dr. Leared embarked, took on board 25 serons of the gum at Mazagan for Gibraltar, where they were to be reshipped for Alexandria. The shippers call it *Fasoy*.

The facts I have narrated show that African ammoniacum is still an object of commerce, and that it is consumed not only in Morocco, but that it finds its way even to Egypt and Arabia. It can hardly be doubted that this traffic is very ancient. Nor is there, as it seems to me, any improbability in assuming that the ammoniacum which the ancients describe as brought from Libya (under which name the whole of Northern Africa westward of Egypt was included) is identical with that still collected in Morocco. That this Morocco drug resembles the Persian or ordinary kind, is evident from the fact that London drug brokers have classed it as *ammoniacum* in their catalogues,—and it is probable enough that the two drugs were confounded together at a very early period.

The Morocco gum-resin is used in fumigation: it is worthy of note that the ammoniacum spoken of by Celsus, Galen, Oribasius, Alexander Trallianus, Paulus Ægineta and Actuarius, that is to say by the Greek and Roman physicians who lived between the first and thirteenth centuries, is frequently described as *thymiama* or *suffimen*, *i. e.* an incense, or something used for fumigation.

CHEMICAL NOTES ON AFRICAN AMMONIACUM.

BY JOHN MOSS, F.C.S.,

Demonstrator in the Laboratory of the Pharmaceutical Society.

These notes are supplementary to the paper on African Ammoniacum by Mr. D. Hanbury, to whom I am indebted for the material on which the experiments were made.

African ammoniacum softens between the fingers more readily than the Persian drug, and retains its softness for some time. It also differs from the latter in that it does not become orange-coloured with solution of chlorinated lime. Gently heated with dilute nitric acid, African ammoniacum becomes bright yellow and spongy, and floats to the surface of the liquid. Strong nitric acid in the cold, acts upon it very slowly at first; but suddenly the action is intensified, the mass swells up, and dense ruddy fumes escape. What is left varies in colour from pale lemon yellow to pink, the depth of tint increasing with the duration of contact with the acid; it is soluble in nitric acid, but on diluting the solution, is reprecipitated; it is also soluble in spirit, and possesses great colorific power.

African ammoniacum does not contain sulphur. This was conclusively shown by experiments conducted as I shall describe in a note on Persian ammoniacum.

The sample employed in all the quantitative experiments detailed below, was obtained by simply powdering the crude drug in a mortar, sifting through muslin, and returning the coarser particles to be further reduced. In this way the whole piece with which the operation was commenced (about four ounces) was reduced to a uniform powder without ing.

Volatile oil and water:—When heated in the air-bath to 100° C., the ammoniacum softens, and, fusing, gives off whatever volatile oil and water it may contain. During the operation, its peculiar odour (quite distinct from that of Persian ammoniacum) is very evident. 1·751 gramme lost ·075 gramme.

Ash:—On igniting the drug in a platinum capsule the organic matter burns away very readily with a black voluminous smoke, and leaves a grey ash consisting chiefly of carbonate of calcium, lime, and sand, with oxide of iron, alumina, and a trace of sulphate of calcium. No indication of the presence of phosphate could be obtained from this ash, nor yet from the gum-resin after oxidation with fuming nitric acid. 3·697 grammes of the gum-resin gave ·498 gramme of ash.

Resin:—26·314 grammes were boiled with spirit containing 70 per cent. of alcohol, and the spirit was poured from the undissolved matter on to a tared filter warmed by a hot water jacket. This process was repeated two or three times with fresh portions of spirit, after which the whole was thrown upon the filter and washed with spirit until nothing more was removed. The spirituous solution having been received into a previously weighed dish, was evaporated on the water bath, and finally in the air bath at 100° C., till it ceased to lose weight. The residue weighed 17·83 grammes. This resin is of a reddish-brown colour, shining, and so soft as to be elastic, and to receive readily and retain for some time the impression of the nail. It breaks wi a wavy fracture, has no particular taste, and has, to a small degree, the peculiar odour of the crude drug. It melts at 38°·5 C., dissolves readily in solutions of the fixed alkalies, and in oil of vitriol, especially on the application of a very gentle heat, forming a red liquid which is decomposed by water, the mixture becoming opaque and pink—at a somewhat higher temperature the solution in oil of vitriol becomes black. The alcoholic solution reddens litmus.

Gum:—The matter insoluble in spirit was exhausted by repeated digestion with hot water in the filter. This was effected by slipping one end of a piece of india-rubber tubing over the tube of the funnel holding the filter, and supporting the free end of the tubing at a level above that of the liquid in the filter. After each digestion the liquid was transferred to a weighed porcelain dish by lowering the free end of the india-rubber tube. There was left on evaporation a dark brown, brittle, gummy residue, weighing 2·372 grammes. The gum has a faintly bitter taste; it burns almost without flame, leaving a white ash of carbonate of calcium. The aqueous solution is entirely precipitated by solution of subacetate of lead, but gives no precipitate with solution of the acetate; oxalate of ammonium gives a white precipitate of oxalate of calcium. When boiled with nitric acid diluted with half its bulk of water some oxalic acid is produced.

Non-volatile matter insoluble in water and spirit:—The material left on the filter after the removal of the gum was found to weigh 4·96 grammes. It consisted of red sand, chalk, fragments of straw, seeds, etc., held together in thick flakes by a substance of a gummy nature—very likely bassorin, for when one of these flakes was boiled with water it swelled a little, but did not fall to pieces for some time; when this occurred the liquid was somewhat thick and mucilaginous. The flakes gave a trace of oxalic acid when boiled with nitric acid as above.

The results obtained are represented in per-centages in the following table, side by side with which I have placed, for the sake of comparison, the result of an examination of Persian ammoniacum by Hagen:—

African Ammoniacum. (Moss.)		*Persian Ammoniacum.* (Hagen.)	
Resin	67·76	. . . .	68·6
Gum	9·014	. . . .	19·3
Water and Volatile Oil	4·29	Gluten	5·4
Bassorin and insoluble matter	18·85	Extractive	1·6
		Sand	2·3
		Volatile Oil and Water	2·8
	99·914		100·0

The ash left by African ammoniacum (13·47 per cent.) consists partly of lime etc. from the gum, and partly of insoluble earthy matter, and must be computed separately.

BORAX—ITS ACTION ON FERMENTS OF THE DIASTASE GROUP.

BY S. DARBY.

Being interested in the property ascribed to borax by M. Dumas in a paper presented by him to the French Academy, a translation from which in the *Comptes Rendus* appears in the PHARMACEUTICAL JOURNAL of January 18th, I was led partially to repeat the experiments; believing that such action, if existing, might be due to the alkalinity of the borax. On treating both bitter almonds and black mustard-seed with borax solution, I found the odour of the essential oil peculiar to each to be exhaled; but my experiments, though convincing me that M. Dumas was in some degree under an error, were not complete enough to warrant their publication. However, the February number of the *Journal de Pharmacie* gives a paper by M. Petit, read before the Paris Academy of Sciences, to which it would seem my crude experiments may be fairly and usefully appended. This paper has appeared in the PHARMACEUTICAL JOURNAL of March 15th.

M. Dumas states that the essential oil noticed on treating the black mustard with borax solution existed previously in the seed; this, however, is contrary to one's usual experience, as no odour whatever of the oil is perceptible when the freshly crushed seeds are treated with lime water. My tests were confined to crushed black mustard-seed and bitter almonds (the latter in lieu of amygdalin and emulsin employed by M. Dumas).

The solutions I employed were borax, containing 30 grains of the salt in two ounces of water; bicarbonate of soda, 30 grains in two ounces of water; carbonate of soda, 20 grains in two ounces of water; and lime water.

Crushed black mustard-seed and bitter almonds, in quantities of about half an ounce each, were severally treated with the above solutions and digested, at a temperature of 60° F., in closed flasks, which were from time to time carefully examined. The experiments were repeated more than once, with the following results:—

	Black Mustard Seed.	Bitter Almonds.
Bicarbonate of Soda Solution.	Oil evolved within 5 minutes.	Oil evolved within 1 hour.
Borax.	Oil evolved within 30 minutes.	Oil evolved, faintly, within 90 minutes, but strongly within 6 hours.
Carbonate of Soda.	Oil evolved within 40 minutes.	Oil not evolved until after 16 hours, and then only faintly.
Lime Water.	No evolution of oil in 36 hours.	No evolution of oil in 36 hours.

M. Dumas stated that borax neutralizes the action of yeast, synaptase, diastase, and myrosin; but it would appear, from the experiments of M. Petit, that a one per cent. solution of borax possesses no power in arresting the action of yeast upon cane-sugar solution; and from my own, that it only slightly retarded the formation of essential oil in a mixture of either black mustard-seed or bitter almonds with water.

THE EMBRYO APPENDIX.

BY CHARLES SYMES, PH.D.

The statement of Professor Redwood "that it is undesirable to publish a new edition of 'The Pharmacopœia' more frequently than once in about ten years" is fully borne out by experience. One point will suffice as an illustration. In the B.P. of 1864 more important changes were necessarily made than in any previous editions of the various pharmacopœias, this being the first published jointly by the united kingdoms, and the most obscure medical practitioner felt it incumbent on him to peruse at least some epitome indicating the principal differences in strength, etc., of the preparations; he found Liq. ammoniæ acetatis five times as strong as its prototype, and prescribed accordingly. Now this work proving a failure it became necessary in three years to issue a new edition, and the pharmacist, desirous of keeping pace with pharmaceutical progress, soon renders himself conversant with this last edition; not so the medical practitioner—he feels the change to be a bore rather than otherwise (of course there are many exceptions), and only slowly adopts the various improved preparations, and we find some even to the present day prescribing twenty minim doses of Liq. ammoniæ acetatis, presuming that quantity to be equivalent to 100 minims of the P.L. preparation.

In an appendix then, which it is intended to publish intermediately between the editions of the B.P., no alteration in the strength or general characters of any existing preparation should be made; but clearly it is desirable as far as possible to correct all the errors of the work it is intended to supplement, to introduce improvements in manufacture, to make such additions as seem desirable, and thus bring the work up to pharmacy of the day.

Ferri sulph. granulata is an acknowledged mistake: could it not be corrected by something like the following paragraph?—"Where ferri sulph. granulata is ordered, use ferri sulph. cryst., answering to the following characters and tests," etc.

Ungt. plumbi subacetatis comp. soon becomes discoloured by the formation of oxide of lead: this is readily prevented by the addition of a few drops of acetic acid, and such addition could easily be sanctioned in the appendix.

Introducing specific gravities of tinctures would, I fear, be less valuable than its advocates suppose. Two samples of opium, containing the same percentage of morphia, will contain varying amounts of extractive matter soluble in proof spirit, hence will produce tinctures of different specific gravities: to dilute the tincture of greater density, so as to bring it to the standard of the other, would of necessity reduce the percentage of morphia in the finished product, and yet uniformity of strength is of vastly greater importance than specific gravity. Again, the finest myrrh does not always produce a tincture of the greatest density, often the reverse, and yet if a tincture of *good quality* does not come up to the pharmacopœia standard of sp. g., what is to be done? macerate, of course, with a fresh quantity of myrrh—a very troublesome process, and one that would not often be followed. Instances might be multiplied, but it is unnecessary; if the specific gravities of tinctures are to be introduced, they can only be approximate and should not be imperative.

THE STUDY OF BOTANY AND MATERIA MEDICA.

BY PROFESSOR G. PLANCHON.*

It is now a long time since the sciences of observation found their true path, and, resting upon the principle of induction, first advanced surely towards the solution of the problems set before them. And still, to the extent

* Abstract of a Lecture delivered at the Paris School of Pharmacy, and published in 'L'Union Pharmaceutique,' vol. xiv., p. 18.

this route across unknown ground is thus traced out, the processes of exploration are multiplied and perfected, new points of view are discovered, the horizon is extended, and at every halting-place fresh features are revealed full of interest to the student. In this progressive march the sciences no longer remain isolated from each other; on the contrary, they lend a reciprocal support and unite their efforts against common difficulties. Some there are, which, having the most intimate relations with others, follow step by step their movements, borrow their processes, and benefit by their progress. Such a one is materia medica. Itself a science of application, it is naturally dependent upon other more general sciences. Therapeutics furnishes it with materials for study; the incessant explorations of chemistry in the organic world throw new light upon the composition of the products which it puts into use. But it is principally to natural history that it is subordinated, being, so to speak, but one of the branches of that science; the study of the products necessarily implying that of the beings which furnish them. The entire subject, however, is too vast to be dealt with under all its aspects, and here only the relations of the science of materia medica with that of its most important collateral science, botany, will be noticed.

The Renaissance was a critical period in the history of these relations; before that time of scientific renovation botany scarcely existed. Theophrastus, the disciple of Aristotle, it is true, sought to do for it what his master had done for the history of animals. He tried to co-ordinate all the knowledge of the time respecting the organs, functions, and mutual relations of plants, but his attempt remained without influence. Vegetables were only looked upon as alimentary and medical materials; they were only studied in their application to the healing art; botany became a branch of materia medica. During the centuries of the schoolmen the science was entirely confined to the works of the ancients, and botany was represented only in sterile commentary on the books of Dioscorides. In vain some few men, as remarkable as they were rare, such as Albert le Grand or Roger Bacon, tried to restore the spirit of direct observation; their voices were lost in the void, and the majority of authors clung without cessation to the errors of the time.

But with the sixteenth century all this was changed. Botany was emancipated; it broke the yoke of materia medica, and, under the inspiration of observation, shone more brilliantly than in the time of Theophrastus. From this time it took its proper rank; a phalanx of distinguished men studied plants for themselves, and not only in respect of their medical properties. Clusius brought to the service of these new studies the elegance of his style and clearness of his descriptions; Lobel his dogmatic ardour and scrupulous exactitude; the Bauhins their immense erudition; and all brought their intense desire to learn from and understand the great book of Nature.

How did materia medica fare during this movement? Did it lose anything by this overturning of parts, by this subordination of a science which had hitherto dominated? On the contrary; from this epoch must be dated its real progress. It is worthy of a remark, too, that the authors of this scientific revolution were all medical men, attached to their art, and little disposed to sacrifice one of its most important branches; the truth being, that by putting it into its proper place, they raised it from the vain and fastidious study of a book to an intelligent and free research in the field of nature. But, then, what progress there was, and how the history of medical products profited by more generally directed botanical researches! Open one of those old books, too often neglected in our day, and one may be astonished at the matter which they contain. Instead of the vague and indecisive indications of Dioscorides, in which the commentators sought, often without success, to recognize the remedies of ancient medicine, there will be found descriptions of an exactitude previously unknown; and figures, often very coarse, but nearly always of remarkable fidelity, in which may easily be recognized the plants or medicinal products employed at the time. And under a less superficial scrutiny the number of important facts brought under notice by these men will cause admiration.

Hitherto nomenclature had been a veritable chaos. Whilst plants were looked upon only as medicaments, they were not compared with each other except in regard to their virtues and their uses, and thus the same generic name would be sometimes given to species the most dissimilar. It was thus that a Ranunculaceous and a Melanthaceous plant both bore the name of hellebore; while a species of larkspur, the easter daisy and the comfrey were united under a common name. On the other hand, the commentators, seeking chiefly to discover the plants of Dioscorides, sometimes thought they had found them in countries where they were unknown, and sealed their error by giving to the new species the name which belonged only to the old one. To this was added the embarrasment caused by the fact that the names of some species were multiplied by every author who studied them. But with direct observation, the study of plants in their true aspects became the occupation of scientific men; little by little these arbitrary distinctions disappeared; a common language began to be used, and one of the promoters of this scientific renovation, Gaspard Bauhin, gathering together in a sort of table all the complicated synonomy of his day, laid the first foundations of a regular nomenclature. His "Pinax Theatri Botanici" became the scientific code accepted by authors, until Linnæus, crowning the work, applied to natural history the plan adopted by men of distinguishing each other by a family and a baptismal name, or, in scientific language, the name of the genus and the name of the species. Henceforth materia medica was assured of having at its service, together with exact descriptions, a precise nomenclature, so that it might escape the confusion and uncertainty of former times.

But botany did still more. It not only rid materia medica of the shackles which impeded its advance, but contributed directly to its progress by tracing out certain general laws. The fundamental problem of natural history is to discover the relations which exist between different orders of beings and their reciprocal affinities. This problem Tournefort partly solved by classing all the species known in his time into genera so natural that later observations, while modifying their extent, have not overthrown their foundations. But scarcely were these groups constituted when a law, most important in the application of plants in medicine, was discovered; it was that an intimate relation appeared to exist between the natural affinities of plants and their medicinal properties; that species of the same genus resembled each other not only in their organization but in their properties; formulated by Linnæus in the adage, "Plantæ quæ genere conveniunt, virtute conveniunt." This is not the place to discuss this law. Many objections have been raised against it; many exceptions, difficult if not impossible to explain, appear to invalidate, if not to disprove it. But it cannot be denied that its promulgation has exercised a considerable influence upon the progress of materia medica. It has given to researches, previously isolated, an object and a direction; it has added the attractions of generalizations, generally seductive to the *savant*, to the interest which always attaches to the study of useful products; it has led minds of a truly philosophic mould to the study of pharmacology. Finally, the discussions which it has raised have contributed to enrich with valuable facts the natural history of medicaments.

The investigation of natural affinities has rendered yet other services to materia medica: it has given rise to the idea of the relative importance of characters, an idea that has exercised, and may still exercise, a considerable influence upon pharmacological studies. The various modes by which objects are revealed to our senses, and which serve to distinguish one from another, and to gather them into natural groups, are not all of the same value

There are some, such as size, colour, etc., which vary in individuals of the same species; others, on the contrary, are remarkably constant and definite. Those of the one class are of primary importance, and are termed dominant characters; the others are subordinate to them. In seeking to find the place of any being or product of nature it is necessary to estimate the value of the characters which it presents.

These principles have made a great revolution in all sciences which pretend to group the objects of their study according to their true affinities. Applied in particular to botany, by Jussieu, De Candolle, and Robert Brown, they have led to the establishment of groups, expressing still very imperfectly the real relations of the plants, but which, perfected by later investigation, reveal better and better the plan of nature. These investigations have at the same time shown the preponderating value of certain characters, such as the constitution of the embryo, that of the seed and of the fruit, and the respective position of the various parts of the flower, inducing botanists to found their natural groups upon the consideration of these floral organs.

Pharmacologists have profited from these results for the solution of two essential questions which presented themselves: to discover in a substance the true characters which permit the recognition of its nature, and to establish the origin of such a substance by comparing its characters with those of plants which might yield it.

These researches may be applied to products of three different orders. One order consists of the liquid or concrete juices, which have not preserved any trace of the organism that furnished them, and which are thus placed outside the domain of botany. Physiology has, it is true, already been able to show the manner in which some of them have been formed in the vegetable economy; it has thus traced the transformation into gum tragacanth of the medullary cells of certain species of *Astragalus;* but in the conditions in which they are presented to the pharmacologist, it is only by the ordinary physical and chemical tests that their characters, relations, and sometimes even their origin, can be established.

At other times the product is an entire plant or part of a plant, containing the characteristic organs of the genus and species. It is then a simple case of botanical determination. If the species yielding the substance be already known, it is naturally referred to it; if not, the product takes its rank in the genus or family to which it belongs. The groups adopted by botanists thus become the natural framework where each medicament finds its place, and this is why the writers on materia medica, abandoning former errors, have adopted as the most logical arrangement for their works that of the series of natural orders.

There remains a third group of products, which deserves a little longer attention, namely vegetable organs, such as roots, branches, and barks, which do not themselves contain the characters employed in the determination of living plants, and therefore become difficult to classify. What part of them will best furnish their important characters? Should they be sought in the exterior aspect, dimensions, form, colour, or organoleptic properties? Is it not preferable to penetrate profoundly into the structure of these organs, and to study their anatomical constitution as a means of assisting in this determination? The reply cannot be doubtful. The value of a character may be estimated by its constancy, and that which is the most constant in these products is the anatomical structure. Varying conditions of the vegetation and development of a plant may and do influence considerably the dimensions, colour, and sometimes even the taste and smell of its root, bark, and leaves. It cannot be affirmed that these influences do not in some cases modify slightly the structure of these organs; but this modification would in any case be very slight, and would never affect the constancy of these characters, which gives them their true value.

An example will illustrate the services that can be rendered to materia medica by anatomical research. One of the most difficult questions is that of the sarsaparillas. To distinguish among roots so closely resembling each other those which belong to the true *Smilax* is not always easy, and everybody knows by experience how the difficulty augments in determining the various commercial varieties, and especially in referring them to the plants from which they originated. Apply anatomical investigation to these roots. Nothing is more easy than to recognize a true sarsaparilla; a transverse section suffices even to the unaided eye to show a special structure. Then if account be taken of the relative size of the zones which succeed from the circumference to the centre; if armed with a microscope, certain easily distinguished characteristics are studied, the various kinds may be determined with a surety that cannot attend an examination of the exterior characters. Moreover, in comparing the structure of Mexican sarsaparilla with that of the roots of *Smilax medica*, their resemblance is seen to be striking, and to furnish a nearly conclusive proof of an opinion already put forth upon the origin of this commercial variety.

In the same manner, if it be wished to throw light upon the plant which yields the officinal rhubarb, attention is not confined to the characters of form, colour, and odour; but regard is principally paid to the peculiar structure of this root. The same structure not being found in any of the species of *Rheum* to which the drug has been successively attributed, it is still looked upon as the product of an unknown plant in Central Asia. It would be easy to multiply examples, but sufficient has been said to show the part that anatomical researches may take in the establishment of the essential characters of certain products of the materia medica. This idea of seeking a means of classification elsewhere than in the floral organs has not originated in the present day. The first botanists who applied the principles of the natural method thought a series of parallel characters might be found in the organs of vegetation which could be employed to greater advantage. De Candolle laid down this proposition clearly in his 'Théorie Elémentaire de la Botanique,' and sought to apply it in his classification. But now, when botanists devote so much attention to vegetable anatomy, the theory has become one of the maxims of the science, and has extended from the domain of botany to that of materia medica. It was applied in France, twenty years since, by Weddell, in the difficult study of the cinchonas; in Germany, by Schleiden, in his investigation of the sarsaparillas; and in England, by Howard, in his magnificently illustrated work on various species of cinchona.

The principal phases through which materia medica has passed, in becoming a useful auxiliary instead of an obstacle to botany, have thus been traced, showing how it has acquired from the contact exactitude of description and precision of language, and been brought under the influence of general laws which have greatly contributed to its progress. The lesson to the student of the present day is, that he should no longer content himself with the study of the purely exterior characters of these products, but penetrate into the internal structure; for there he will find a new field opened to his energies.

THE RELATION OF ANIMAL AND VEGETABLE OILS TO FIRE.

BY PROFESSOR ATTFIELD.

In their relation to combustion, oils of animal origin, such as sperm or whale oil, and those obtained from vegetables, as olive and colza, differ from mineral oils, by not igniting at low temperatures, and in not giving off vapour which, when mixed with a certain proportion of air, explodes in contact with flame. But in their liability to spontaneous ignition when freely exposed to the air under certain conditions, animal and vegetable oils possess a dangerous property from which mineral oils are free. In a series of letters to *The Times*, Professor Attfield recently discussed the question of the origin, extension, and prevention of fires, and the relation of mineral and vegetable oils and other materials to fire. These letters have now been issued in a pamphlet form, together with an Appendix, in which the Professor gives the results of some experiments made by him, and from which we have taken the following.

Various animal and vegetable oils differ considerably in the rate with which they cause the generation of heat when exposed freely to the air upon the surface of wool, cloth, paper, cotton, jute, saw-dust, lamp-black, ivory-black, ground charcoal, or any similar highly porous substance; but all are more or less liable to this result of the chemical action of air when they are exposed in very thin films, or in any other minute state of division. The so-called "drying" oils are peculiarly susceptible to such atmospheric influences. Common paint exposed on wood-work becomes "dry" and glossy because the oil of which it is largely composed is converted by the action of the air into a kind of resin, and during the whole of this action heat is evolved. Thus the true chemical nature of the effect termed the "drying" of oils is one in which oil is resinified and heat concurrently produced. It is not an operation of drying, in the sense in which a cloth wetted with water is said to dry. In the latter case the wetness or moisture passes off into the air in the form of vapour of water, whereas in the drying of oil no such vapour escapes. Nor does oil "dry," as varnish dries. Varnish is a solution of hard resins in spirit; in drying, the spirit evaporates and leaves the resin. But the oil on any surface exposed to air "dries" to a solid resin by absorption of the oxygen of the air. A piece of oiled paper, unlike water-wetted or varnished paper, positively increases in weight while drying. The true nature of this drying process is, therefore, as already indicated, one of oxidation or resinification, and simultaneous evolution of heat. The emission of heat is not noticed because one painted surface affords but little, and because what is produced is at once conducted away by currents of air. But when allowed to accumulate its presence is most obvious: thus a heap of oiled rags soon becomes so hot in the central part that the temperature cannot be borne by the hand. As a result of direct experiment, I find that paper, cotton, or wool, slightly impregnated with different kinds of oil and exposed to air under similar conditions, rises in temperature from 25 to 200 degrees, according to the variety of oil, the amount of surface in contact with the air, and the duration of exposure.

Number of experiment.	Temperature at commencement of experiment.	Temperature on completion of experiment.	Total rise of temperature during experiment.
1	65°F	125°F	60°F
2	80	275	195
3	75	100	25
4	70	220	150
5	70	160	90
6	70	223	153

It will be understood that in these experiments the escape of heat was purposely prevented. They illustrate the statement that during the drying of certain oils heat is produced, and will serve to show the extreme importance of observing all precautions against the accumulation in factories, stores, and warehouses of heaps of oiled rags, papers, or other porous materials. In some of my experiments the oiled paper or wool was warmed to about the temperature of boiling water before being subjected to the influence of air in a closed vessel; in these cases the rise in temperature was more rapid, and in two instances increased till the mass charred and ignited. Moreover, I found that when very large quantities of oiled fabrics were exposed in a chamber, the temperature of the air in which was made to imitate that obtaining on a hot summer's day, a considerable quantity of vapour, irritating to the eyes and readily inflammable, was produced. Such vapours would greatly facilitate the spread of flame once started.

The drying of vegetable or animal oil on any surface is, in short, a true process of combustion,—spontaneous combustion,—differing from ordinary combustion of coal in fire-grates, or gas or oil in lamps, not in kind, but only in degree. To say that coal, wood, fat, etc., burn, is another way of stating that they absorb oxygen from the air with such avidity as to produce heat and light. So oiled surfaces absorb oxygen from the air and produce heat, and if the heat were not carried away as fast as generated, would become warm, then hot, and next burst into flame. There can be no doubt that many fires in oil-shops and warehouses where oil is stored or used are caused in this way, by the intensified spontaneous combustion of the oil exposed on cotton-waste, sawdust, textile fabrics, etc. I was recently consulted in a case where numbers of oiled sheets were crowded in a comparatively small room in which another operation involving the use of a stove was also being conducted. Here were all the conditions for spontaneous inflammation. A hot day occurring, or the stove being unusually warm, or an ordinary temperature with a larger number of sheets than usual, or hung unusually near together; either circumstance, or perhaps an unusual combination of them, would be sufficient to convert the drying or oxidising action, or modified spontaneous combustion, into one of spontaneous ignition, or ordinary combustion. In another case in which my advice was sought in order that steps might be taken to prevent recurrence of fire, a similar room was used for the desiccation of oiled fabrics. It appears also that a sheet-iron flue passed through one corner, carrying the smoke and other products of combustion of a furnace employed in an adjoining apartment. This flue had often been noticed to be red-hot. The men were sure that on the day of the fire this furnace was being used, and they said that the lowest line of oiled articles would be about eighteen inches distant from the flue. Here, again, it will be evident—bearing in mind the exact chemical nature of the oil-drying operation—that the conditions were most favourable for spontaneous ignition. I was of opinion, that in this case also the oxidizing action (or drying) was sufficiently intense spontaneously to produce flame—to produce fire, that is to say, among the oiled articles nearest the exposed portion of the furnace chimney; fire which, considering the character of the contents of the room, would spread with the greatest rapidity.

To prevent the occurrence of spontaneous combustion in cases where the exigencies of manufacture require the employment of fibres or fabrics soaked in vegetable or animal oils, such arrangements must be made as shall render the accumulation of heat impossible.

NOTES ON THE QUICKSILVER MINE AND WORKS OF VALLALTA.*

The Vallalta quicksilver works are situated in the province of Belluno (Venetia), at the south-western extremity of the Mis valley, where the two torrents, Mis and Pezzea, come together, marking the boundary between Italy and the Tyrol. The works are about ten miles from Agordo, and 2,339 feet above the level of the sea. The cinnabar mine itself lies a short distance from the works, on the right bank of the torrent Pezzea.

The rocks that are met with are chiefly clay-slate, and a reddish porphyry; the latter having broken through the former and altered it. Those who desire to study the special geological conditions of the mine can consult the small geological map accompanying the original memoir, which will give a far better idea than a tedious

* Extracted from a paper in the *Bollettino del Club Alpino Italiano* for 1871, by Cavaliere G. Antonio de Manzoni, and printed in the *Journal of the Society of Arts.*

verbal description. We will simply note the fact that the metalliferous rocks are surrounded on the north-east by black and occasionally graphitic clay-slate, in an elliptical manner, and this part of the formation has been proved to be the richest in cinnabar, not only in the upper but in the lower beds. Where the slate dies away, the porphyry widens out, and the cinnabar becomes less concentrated, and this renders the explorations more uncertain and more costly. The cinnabar occurs disseminated, both in the porphyry and the metamorphosed rocks, sometimes in the form of lumps or grains, sometimes in veins and little strings, but invariably in an altogether irregular manner. The masses occur in the form of "shoots," varying very much in dimensions and orientation.

The porphyry and slaty metamorphic rocks contain, besides cinnabar and a little native mercury, iron pyrites, gypsum, calcspar, mica, and chlorite.

As the work consists in discovering and excavating the masses of cinnabar, Vallalta mine may be said to be in a state of continual exploration.

About a century ago traces of cinnabar, disseminated through the porphyry in a valley on the right bank of the torrent Pezzea, induced two Venetian noblemen, Nani and Pisani, to commence work there. Two old levels, known by their names, still testify to the work they did. It seems, however, that soon after beginning to work they were obliged to stop, on account of a great error—viz., that of going to the expense of carrying the ore to the island of Murano, near Venice, where it is said to have been distilled. At the commencement of this century, Melchior Zanchi, a Venetian of great natural talent and a clever miner, set to work alone to reach the centre of the metalliferous zone of Vallalta; his plan was a very bold one, and was carried out eventually in 1867. Zanchi did not go on very far with his undertaking, as he was obliged to stop for want of means.

Later on, some persons named Schena, Fusina, and Nogarola, of Agordo, and Bosio of Primiero, took up the works abandoned by Nani and Pisani, and made some rude attempts to smelt the ore on the spot.

In the year 1852 the mineral rights of Vallalta belonged to three partners—Fusina, Levi, and Bosio. It was then that the Venetian Mining Company obtained the permission to search for ore wherever it liked. This company adopted the project of the Government engineer, Joseph Bauer, who afterwards became managing director, and, with the O'Conor adit, began that series of works which were destined to render Vallalta one of the most interesting of mining establishments. The O'Conor adit, after having been driven 196 metres, cut the first vein in 1854, the ore being quite sparking with native mercury condensed at the contact with the slate.

Encouraged by this success, the company bought up all the rights of the above-mentioned proprietors, and continued its explorations, not only with the O'Conor adit, but also above and below it. The year 1855 saw a large metallurgical establishment spring up rapidly and almost by magic in the unknown and hitherto solitary Vallalta, with two double cupola furnaces, a double reverberatory furnace, the necessary condensing apparatuses, buildings and houses for sundry purposes, bridges and roads. These furnaces failed, however, and it was not until 1857, with new furnaces, that the actual production of mercury may be said to have begun. Since then the production has gone on pretty regularly, although the mine suffered great damage from an inundation in 1860, and the works were partly washed away in 1868. In the following year, Cavaliere G. A. de Manzoni, the actual lessee, took mine and works off the company's hands, and continues to carry them on at the present time on his own account.

The mercuriferous rock has now been worked to a vertical depth of 122 fathoms. It is reached by various adit levels, and the workings are arranged in thirteen horizontal floors. The deepest workings are fifty-four fathoms below the lowest adit. The mode of proceeding is as follows: As soon as the existence of a mass which will pay for working has been proved, a winze is sunk through it, and then it is worked away entirely by successive horizontal floors. The timber employed is generally larch. As fast as the ore is worked away, the vacant space is filled up with unproductive rock, sometimes quarried on purpose, to prevent the chambers from falling in.

The ventilation is effected by means of a blast produced by a great fall of water and carried by wooden pipes to the workings.

The ore arriving from the mine is picked, and unproductive rock thrown away; the fine stuff or "smalls" is moistened with acidulated water, which runs away from the condensers, and, made up into compact lumps of nine pounds each, can then be treated in the cupola furnaces.

The cupola furnaces in use at Vallalta are cylindrical, lined with fire-brick, and 3 feet 11 inches in diameter by 21 feet high. They are built in pairs. Near the base is an iron grating, on which the ore rests, and the ore is charged from the top by a hopper. The cover of the hopper has a water-joint, so the top of the kiln is closed hermetically. Before putting in a charge two men work away with bars of iron through the grating, and draw out some of the burnt ore. The charge is composed of ore in large and small pieces, lumps of agglomerated fine stuff, and charcoal in the proportion of two per cent. by weight. Under the action of heat, in the presence of a good draught of air, the cinnabar is decomposed, and the mercury liberated passes off as vapour with the products of combustion into two chambers near the furnace, and thence into two rows of pipes, 3 feet 3 inches in diameter, and 49 feet long, in the open air and continually exposed to an artificial rain. The major part of the mercury is condensed in these tubes, and the residual vapours pass through four chambers at the end of the apparatus, and then by a third tube to the chimney. In former days there were occasionally difficulties with the mercurial vapour, which on a sudden change in the temperature would sometimes escape from the lower part of the furnace, and occasion thereby not only a notable loss of mercury, but also serious injury to the health of the workmen, who could not always be cured by the internal use of chlorate of potash. Besides, the sulphurous acid which escaped from the chimney exercised a very pernicious effect upon the surrounding vegetation.

These evils have been entirely cured by means of a most simple exhausting apparatus. To the top of the chimney is fixed a descending wooden pipe, which joins an almost horizontal pipe, and to the lower end of this is attached another vertical pipe, which leads into a subterranean drain. A column of water is brought into the side of the last pipe near the top, and, falling through some 16 feet, draws with it the gases from the chimney. In this manner the chimney always draws properly, and the amount of draught can be regulated at pleasure by altering the quantity of water. A double cupola furnace can treat as much as 150 tons of ore in 24 hours; and as the use of wood for the condensers allows the mercury to be drawn off at pleasure, the furnace may remain alight for two years or more, in fact, until it requires repairs.

All the mercury is not obtained with its usual bright lustre; the tubes and chambers contain a sooty deposit, from which some mercury may be extracted by mechanical means on inclined planes, whilst the residue is made up into lumps and returned to the furnaces.

As at Idria, it has been found most convenient to send away the mercury in sheepskins.

The perfection of the metallurgical process at Vallalta is proved by the low produce required for profitable working. Up to 1870 the average contents of the ore did not exceed half a per cent. of mercury; the loss of metal is less than 8 per cent. The mine and works employ about two hundred men, the majority being miners. The miners work eight-hour shifts, and get about 1 fr. 20 c. a-day; most of them possess a little land. Two per cent. of their wages is kept back, and goes to the sick club fund, the capital of which at the beginning of 1871 exceeded 18,000 francs. The quantity of mercury produced at Vallalta during fifteen years—ranging from 533 kilograms in 1856 to 34,776 kilograms in 1870—amounted to 324,856 kilograms, or nearly 320 tons.

PROFESSOR TYNDALL ON LIGHT.*

(*Continued from p.* 730.)

The most familiar illustration of the interference of sound-waves is furnished by the beats in music, which are produced by two musical sounds slightly out of unison. When two tuning-forks which are in perfect unison, are agitated at the same time, the two sounds produced flow without roughness, as if they were but one. But, by attaching to one of the forks a two-cent piece, we cause the loaded fork to vibrate a little more slowly than its neighbour. Suppose that one of them performs 101 vibrations in the same time as the other performs 100, and let us assume that at starting the condensations and rarefactions of both forks coincide. At the 101st vibration of the quickest fork they will again coincide, the quicker fork at this point having gained one vibration, or one whole wave upon the other. But a little reflection will make it clear that, at about the 50th vibration, the two forks will be in opposition; here the one tends to produce a condensation where the other tends to produce a rarefaction; by the united action of the two forks, therefore, the sound is quenched, and we have a pause of silence. This occurs where one fork has gained half a wave-length upon the other. At the 101st vibration we have again coincidence, and, therefore, augmented sound; at the 150th vibration, we have again a quenching of the sound. Here the one fork is three half-waves in advance of the other. With two forks so circumstanced, we obtain those intermittent shocks of sounds separated by pauses of silence, to which we give the name of beats (such beats were rendered audible to all in the lecture).

I now wish to show you what may be called the optical expression of those beats; and here we have to fall back upon the fact that a luminous impression persists for a certain interval upon the retina. Attached to a large tuning-fork is a small mirror, which shares the vibrations of the fork, and on to the mirror is thrown a thin beam of light, which shares the vibrations of the mirror. The fork is now still, and the beam reflected from it is received upon a piece of looking-glass, and thrown back upon the screen, where it stamps itself as a small luminous disk. The agitation of the fork by a bow converts that disk into a band of light, and if you simply shake your heads to and fro you will be able to reduce that band to its elements: you draw it, in fact, out to a sinuous line, thus proving the periodic character of the motion which produces it. By a sweep of the looking-glass we can also cover the screen from side to side by this luminous scroll, the depth of the sinuosities indicating the amplitude of the vibration.

We now pass on to the optical illustration of these beats. The large fork which we have just employed remains in its position; but instead of receiving the beam reflected from it on a piece of looking-glass, it is received upon a second mirror attached to a second fork, and cast by it upon the screen. We now sound both forks, and both of them act in combination upon the beam. It is drawn out, as you see, as before, the band of light gradually shortening as the motion subsides. Finally, when the motion ceases we obtain the disk of light. Weighting one of the forks as we did before with a two-cent piece, we throw it out of unison with the other, and now observe the screen. Sometimes the forks conspire, and then you have the band of light drawn out to its maximum length. Sometimes the forks oppose each other, and then you have the band of light diminished to a circle. Thus the beats which address the ear express themselves optically as the alternate elongation and shortening of the band of light. If I move the mirror of this second fork, you have a sinuous line, as before, drawn out upon the screen; but the sinuosities are sometimes deep, and sometimes they almost disappear, thus expressing the alternate increase and diminution of the sound, the intensity of which is expressed by the depth of the sinuosities.

Every complete vibration of our tuning-fork produces a wave of sound, and, as all sounds travel with the same velocity through air, the more rapid the vibration the shorter are the sound-waves. The pitch of a sound is wholly determined by the rapidity of the vibration, as the intensity is by the amplitude. The rise of pitch with the rapidity of the impulses may be illustrated by the syren, which consists of a perforated disk rotating over a cylinder into which air is forced, and the end of which is also perforated. When the perforations of the disk coincide with those of the cylinder, a puff escapes; and when the puffs succeed each other with sufficient rapidity, the impressions upon the auditory nerve link themselves together to a continuous musical note. The more rapid the rotation of the disk the quicker is the succession of the impulses, and the higher the pitch of the note. Indeed, by means of the syren the number of vibrations due to any musical note, whether it be that of an instrument, of the human voice, or of a flying insect, may be accurately determined.

In the undulatory theory, pitch is the analogue of colour. The waves of light have been measured, and it is found that the more refrangible the light the shorter are the waves which produce it. The shortest waves of the visible spectrum are those of the extreme violet; the longest, those of the extreme red; while the other colours are of intermediate pitch or wave-length. The length of a wave of the extreme red is such that it would require 36,918 of them placed end to end to cover one inch, while 64,631 of the extreme violet waves would be required to span the same distance.

Now the velocity of light, in round numbers, is 190,000 miles per second. Reducing this to inches, and multiplying the number thus found by 36,918, we obtain the number of waves of the extreme red in 190,000 miles. All these waves enter the eye, and hit the retina at the back of the eye in one second. The number of shocks per second necessary to the production of the impression of red is, therefore, four hundred and fifty-one millions of millions. In a similar manner, it may be found that the number of shocks corresponding to the impression of violet is seven hundred and eighty-nine millions of millions. All space is filled with matter oscillating at such rates. From every star waves of these dimensions move with the velocity of light like spherical shells outward. And in the ether, just as in the water—indeed, more truly than in the water—the motion of every particle is the algebraic sum of all the separate motions imparted to it. Still, one motion does not blot the other out; or, if extinction occur at one point, it is made good at some other point. Every star declares by its light its own undamaged individuality, as if it alone had sent its thrills through space.

The principle of interference applies to the waves of light as it does to the waves of water and the waves of sound. And the conditions of interference are the same in all three. If two series of light-waves start at the same moment from a common origin, crest coincides with crest, sinus with sinus, and the two systems blend together to a single system of double amplitude. If both series start at the same moment—one of them, however, being, at starting, a whole wave-length in advance of the

---

* Abstract of a series of lectures delivered in the Cooper Institute, New York, and reported in the *New York Tribune*.

other—they also add themselves together, and we have an augmented luminous effect. The same occurs when one system of waves is any number of whole wave-lengths in advance of the other. But if the one system be half a wave-length, or any odd number of half wave-lengths in advance, then the crests of one system fall upon the sinuses of the other system; the one system, in fact, tends to lift the particles of ether at the precise places where the other tends to depress them; hence, through their joint action, the ether remains perfectly still. This stillness of the ether is what we call darkness, which corresponds, as already stated, with a dead level in the case of water.

It has been stated, with reference to the colours of absorption, that the formation of natural bodies is selective, not creative; that what they did was to pick out certain constituents of the white solar light for extinction, this causing them to appear in the colours of the unextinguished light. It must at once flash upon your minds that, insomuch as we have in interference an agency by which light may be self-extinguished, we have in it the conditions for the production of colour. But now the question faces us, How is it that certain constituents are quenched by interference, while others are permitted to remain? This is entirely due to the difference in the lengths of the waves of light.

The subject is most easily illustrated by the class of phenomena which first suggested the undulatory theory to the mind of Hooke. These are the colours of thin films of all kinds, which are known to men of science as the colours of thin plates. In this relation no object in the world possesses a deeper scientific interest than a common soap-bubble. And here, let me say, emerges one of the difficulties which the student of pure science encounters in the presence of "practical" communities like those of America and England; it is not to be expected that such communities can entertain any profound sympathy with labours which seem far removed from the domain of practice. Imagine Dr. Draper spending his days in blowing soap-bubbles and in studying their colours! Would you show him the necessary patience, or grant him the necessary support? And yet be it remembered it was thus that Newton spent a large portion of his time; and that it was on such experiments that has been founded a theory, the issues of which are of incalculable importance to the human race.

Whence, then, are derived the colours of the soap-bubble? Imagine a beam of white light impinging on the bubble. When it reaches the first surface of the film a known fraction of the light is reflected back. But a large portion of the beam enters the film, reaches its second surface, and is again in part reflected. The waves from the second surface thus turn back and hotly pursue the waves from the first surface. And, if the thickness of the film be such as to cause the necessary retardation, the two systems of waves interfere with each other, producing augmented or diminished light, quadrupling it, or totally extinguishing it, as the case may be. But, inasmuch as the waves of light are of different lengths, it is plain that, to produce self-extinction in the case of the longer waves, a greater thickness of film is necessary than in the case of the shorter ones. When, therefore, the red is quenched, the blue and green are not quenched: hence the production of colour in the case of thin plates.

The experimental illustrations to be introduced in the lecture are the colours of oil upon water; the colours of a film of air inclosed between two glass plates; the colours of films of oxide used as a guide in the tempering of polished steel; the colours of the soap-bubble by transmission and reflection; finally, the celebrated experiment by which Newton determined the thickness of a soap-bubble from its colour, and known as the experiment of Newton's Rings. To account for these rings was the greatest difficulty that Newton ever encountered. He quite appreciated the difficulty; over his eagle-eye there was no film, no vagueness in his conceptions. At the very outset his theory was confronted by the question, Why, when a beam of light is incident on a transparent body, are some of the light-particles reflected and some transmitted? Is it that there are two kinds of particles, the one specially fitted for transmission and the other for reflection? This cannot be the reason; for, if we allow a beam of light which has been reflected from one piece of glass to fall upon another, it, as a general rule, is also divided into a reflected and a transmitted portion. Thus the particles once reflected are not always reflected, nor are the particles once transmitted always transmitted. Newton saw all this; he knew he had to explain why it is that the self-same particle is at one moment reflected and at the next moment transmitted. It could only be through some change in the condition of the particle itself. The self-same particle, he affirmed, was affected by "fits" of easy transmission and reflection.

If you are willing to follow me while I unravel this theory of fits, the most subtle, perhaps, that ever entered the human mind, I think the intellectual discipline will repay you for the necessary effort of attention. Newton was chary of stating what he considered to be the cause of the fits, but there cannot be a doubt that his mind rested on a mechanical cause. Nor can there be a doubt that, as in all attempts at theorizing, he was compelled to fall back upon experience for the materials of his theory. His course of observation and of thought may have been this: From a magnet he obtained the notion of attracted and repelled poles. What more natural than that he should endow his light-particles with such poles? Turning their attracted poles toward a transparent substance, the particles would be sucked in and transmitted; turning their repelled poles, they would be driven away or reflected. Thus, by the ascription of poles, the transmission and reflection of the self-same particle at different times might be accounted for.

At the point which we have now attained, Newton's ingenuity in preserving a theoretic conception entire reached its climax. Regard these rings of Newton as seen in pure red light; they are alternately bright and dark. The film of air corresponding to the outermost of these rings is not thicker than an ordinary soap-bubble, and it becomes thinner on approaching the centre; still Newton, as I have said, attempted to measure the thickness of every ring, and to show the difference of thickness between ring and ring. How he did this may be thus made plain to you. Suppose the water of the ocean to be absolutely smooth; it would then accurately represent the earth's curved surface. Let a perfectly horizontal plane touch the surface at any point. Knowing the earth's diameter, any engineer or mathematician could tell how far the sea's surface will lie below this plane, at a yard, at ten yards, at 100 yards, at 1,000 yards' distance from the point of contact of the plane and the sea. It is common, indeed, in levelling operations, to allow for the curvature of the earth. Newton's calculation was precisely similar. His plane glass was a tangent to his curved one. From its refractive index and focal distance he determined the diameter of the sphere of which his curved glass formed the segment, he measured the distances of his rings from the place of contact, and he calculated the distance between the tangent plane and the curved surface, exactly as the engineer would calculate the distance between his tangent plane and the surface of the sea. The wonder is, that where such infinitesimal distances are involved, Newton, with the means at his disposal, could have worked with such marvellous exactitude.

Now mark the result. For the sake of convenience let us call the thickness of the film of air corresponding to the first dark ring d; then Newton found the distance corresponding to the second dark ring $2\,d$; the thickness corresponding to the third dark ring $3\,d$; the thickness corresponding to the tenth dark ring $10\,d$, and so on

Surely there must be some hidden meaning in this little distance d, which turns up so constantly? One can imagine the intense interest with which Newton pondered its meaning. Observe the outcome of his thought. He had probably endowed his light-particles with poles, but now he is forced to introduce the notion of periodic recurrence. How was this to be done? By supposing the light-particles animated, not only with a motion of translation, but also with a motion of rotation. Newton's astronomical knowledge rendered all such conceptions familiar to him. The earth has such a motion. In the time occupied in passing over a million and a half of miles of its orbit—that is, in twenty-four hours—our planet performs a complete rotation, and in the time required to pass over the distance d, Newton's light-particle must be supposed to perform a complete rotation. True, the light-particle is smaller than the planet, and the distance d, instead of being a million and a half of miles, is a little over the ninety-thousandth of an inch. But the two conceptions are, in point of quality, identical.

Imagine, then, a particle entering the film of air where it possesses this precise thickness. To enter the film its attracted end must be presented. Within the film it is able to turn once completely round; at the other side of the film its attracted pole will be again presented; it will, therefore, enter the glass at the opposite side of the film and be lost to the eye. All round the place of contact, wherever the film possesses this precise thickness, the light will equally disappear—we shall have a ring of darkness.

And now observe how well this conception falls in with the law of proportionality discovered by Newton. When the thickness of the film is $2\,d$, the particle has time to perform two complete somersaults within the film; when the thickness is $3\,d$, three complete somersaults; when $10\,d$, ten complete somersaults are performed. It is manifest that in each of these cases, on arriving at the second surface of the film, the attracted pole of the particle will be presented. It will therefore be transmitted, and, because no light is sent to the eye, we shall have a ring of darkness at each of these places.

The bright rings follow immediately from the same conception. They occur between the dark rings, the thicknesses to which they correspond being also intermediate between those answering to the dark ones. Take the case of the first bright ring. The thickness of its film is $\frac{1}{2}\,d$; in this interval the rotating particle can perform only half a rotation. When, therefore, it reaches the second surface of the film, its repelled pole is presented; it is, therefore, driven back and reaches the eye. At all distances round the centre corresponding to this thickness the same effect is produced, and the consequence is a ring of brightness. The other bright rings are similarly accounted for. At the second one, where the thickness is $1\frac{1}{2}\,d$, a rotation and a half is performed; at the third, two rotations and a half; and at each of these places the particles present their repelled poles to the surface of the glass. They are therefore sent back to the eye, producing the impression of brightness. Here, then, we have unravelled the most subtle application that Newton ever made of the Emission Theory.

[The phenomena of interference rings, obtained by curved glasses pressed together, was vividly shown upon the screen, and much enlarged by double reflection. Then coloured glasses were interposed, and the number of rings apparent very much increased, so that the whole of the light circle given by the instrument seemed covered by their ripple; but they were all of one colour, alternating only between light and darkness.]

Thus Newton, by an exceedingly artificial assumption, vaulted over the difficulty presented by the colours of thin plates. And as further difficulties in process of time thickened round the theory, his disciples tried to sustain it with an ingenuity worthy of their master. The new difficulties were not anticipated by the theory, but were met by new assumptions, until at length the Emission Theory became what a distinguished writer calls a "mob of hypotheses." In the presence of the phenomena of interference the theory finally broke down, while the whole of these phenomena lie as it were latent in the theory of undulation. Newton's "fits," for example, are immediately translatable into the lengths of the ether-waves.

Numerous other colours are due to interference. Fine scratches drawn upon glass or polished metal reflect the waves of light from their sides; and some, being reflected from opposite sides of the same furrow, interfere with each other and quench each other. But the obliquity of reflection which extinguishes the shorter waves does not extinguish the longer ones; hence the phenomena of colour. These are called the colours of striated surfaces. They are well illustrated by mother-of-pearl. This shell is composed of exceedingly thin layers, which, when cut across by the polishing of the shell, expose their edges and furnish the necessary small and regular grooves. The most conclusive proof that the colours are due to the mechanical state of the surface is to be found in the fact that, by stamping the shell carefully upon black sealing-wax, we transfer the grooves, and produce upon the wax the colours.

SEIZURE OF UNWHOLESOME DRIED FRUIT.

At the meeting of the City Commissioners of Sewers on Tuesday last, Dr. Tidy, the acting medical officer of health for the City, reported that during the last few weeks he had condemned as unfit for human food, and ordered to be destroyed, 1674 barrels of rotten and diseased figs, weighing no less than 187,488lb., and 22 barrels of currants, and that 490 barrels of figs in addition were now lying at Custom House Quay in a similarly bad condition. The fruit was used almost entirely in the manufacture of the cheaper kinds of jam and various sorts of "sweet stuff," which were largely consumed by the children of the poor. He had every reason to believe that the immense quantity already seized was but a moiety of the unsound and unwholesome fruit now lying in bonded warehouses, and constantly being delivered out, and he urged that a frequent supervision of bonded articles of food was imperatively necessary. Dried fruits, after being delivered at the various warehouses, remained in bond for eighteen months or two years, and no inspection was ever made by the wharfingers, who did not consider themselves at liberty, except with the owners' consent, to examine the goods. The result was that the fruit became completely rotten before any notice was taken of it, and after any sale the wharf premises were strewn with thousands of maggots. Dr. Tidy pointed out how such a condition of things placed in jeopardy the whole contents of the warehouses, and showed forcibly the delay which arose, in the present state of the law, in obtaining the goods for destruction, for, after the orders of the sanitary inspector, the medical officer, the magistrate, and the Customs authorities had been obtained, the wharfingers would not deliver them unless an order from the owner was in addition procured. He also explained the difficulty in obtaining the requisite information to enable the sanitary authorities to act, seeing that the wharfingers had an interest in concealment, and there was, unfortunately, a market even for rotten figs. He suggested the necessity, in the interests of the owners and wharfingers themselves, and especially of the public, of some periodical examination of bonded articles, of giving to the sanitary inspectors increased facilities for inspection, and of providing that the orders of the medical officer and a justice should be sufficient authority for the destruction of goods unfit for food, and likely to become a common nuisance. The report was referred to the sanitary committee, to take such steps in the matter, under the advice of the solicitor and medical officer, as they might think desirable.

The Pharmaceutical Journal.

SATURDAY, MARCH 22, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

PHARMACY IN IRELAND.

IT has been suggested in some sort, as a consolation to Mr. Gladstone for the break-down of his Irish Education Bill, that if it had been passed the Irish would have been reduced to a state of total destitution in the matters of grievances; but this is not strictly the case, for there is, besides the grievances complained of by Irish Catholics in regard to University Education, an old standing Pharmaceutical grievance, to which attention has several times been directed in these columns. In Ireland the dispensing of medicines is entirely in the hands of the apothecaries, and it is unlawful for chemists and druggists to dispense any prescription.

About two years since some move was made towards attempting to assimilate the law as to the practice of Pharmacy in Ireland with the enactments which exist for Great Britain. A draft Bill was prepared by the Company of Apothecaries, which was to have been introduced into Parliament by Sir Dominic Corrigan. That body proposed to grant licences to persons—other than medically qualified apothecaries—to assume the title of Pharmaceutical Chemists, and to keep open shop for the retailing of drugs and for dispensing medicines. Some opposition was offered on the part of the chemists and druggists, and at a meeting held in Dublin it was resolved that they would not place themselves under the control of the Apothecaries' Hall of Ireland.

Since that time the matter has remained in abeyance, but not without some advance having been made towards more harmonious action between the apothecaries—who have the command of the position at present—and the druggists, who desire to enjoy equal advantages in regard to dispensing. Only a few weeks since we announced the formation of a Society of Chemists and Druggists, which was to aim at raising the condition of the trade and obtaining for Pharmacists in Ireland a status similar to that secured by the Act of 1868 for the rest of the kingdom. At a recent meeting of this society, attended by all the principal druggists in Dublin, it was proposed that an endeavour should be made to arrange terms with the Apothecaries' Company, with a view to establishing a system of examination similar to that of the Pharmaceutical Society of Great Britain, as a qualification for compounding physicians' prescriptions. A deputation was authorized to communicate with the Governor and Company of the Apothecaries' Hall on the subject, and to ascertain the views of that body.

At this meeting the clauses of the draft Bill, drawn up two years since, were read and discussed *seriatim*, and it was finally arranged that the United Society of Chemists and Druggists of Ireland should frame a Bill and submit it for approval to the Apothecaries' Company preparatory to its being introduced into Parliament.

It seems, therefore, that an opportunity exists now for effecting some satisfactory reform, and in all probability the importance of the subject will attract the attention of the Council at its next meeting in April, especially since it has been suggested by the Irish chemists that they should petition the Society to extend the general operation of the Pharmacy Act, 1868, to Ireland, in the same way that the provisions of that Act relating to sale of poisons has already been made to apply in that portion of the kingdom.

No doubt there are certain difficulties which stand in the way of such an extension of the Pharmacy Act. It would certainly be opposed by the apothecaries if it were to give any person on the register of chemists and druggists a right to practise pharmacy in Ireland, and we can well understand that in any compromise they may agree to, they would insist on some higher test of qualification than that which now suffices for obtaining in Great Britain a licence to keep open shop for compounding medicine and for the sale of drugs.

The great argument by which the licentiates of the Apothecaries' Hall have hitherto maintained their monopoly was based upon the incompetence of the druggists, as a class, for dispensing medicine. In the present temper of society, however, the Hall could scarcely expect to maintain its monopoly any longer than it could guarantee to the public the superiority of its licentiates' qualifications over those of a class of pharmacists, admittedly better educated than it was the wont to be. In short, we cannot perceive what reasonable objection can be raised to throwing Irish pharmacy open to examined pharmaceutical chemists. Such a course would, we believe, do away with much dissatisfaction in Ireland, and it would, we hope, be of some avail on this side of St. George's Channel towards awakening a healthier appreciation of that higher qualification which it has been the chief aim of the Pharmaceutical Society to make general in the trade.

Altogether this subject is one eminently deserving of the most careful treatment by our Council, and the need for its consideration at the present moment comes opportunely as a means of diverting the current of its deliberations from the vexing question of woman's rights in matters pharmaceutical.

THE SALE OF DRUGS IN FRANCE.

A few of our correspondents, if we may judge by the tone of their communications, have a certain vague impression that the Pharmaceutical Society is empowered to regulate not only the sale and dispensing of poisons, but also the sale of almost every other substance which finds a place in a druggist's shop. Of course this is not the case, and the Council, even if it were desirous to do so, is not able to prevent grocers or any other tradesmen from retailing articles not included in the poison schedule of the Pharmacy Act, nor is it likely to be. "Monopoly" is a word peculiarly obnoxious to the Englishman of the present day, and it was pertinently remarked at the last annual meeting that the Pharmacy Act,—even so far as it goes,—is the only legislation in restraint of trade existing in this country. At present, therefore, it would be wise to rest content with the vantage ground that a registered qualification and the sole right to deal in certain indispensable drugs imparts; to assist individually in securing the privileges—not so inconsiderable as some would pretend—which the present law accords, rather than by over-reaching to make both these and those that are desired impracticable.

> "We must not make a scarecrow of the law,
> Setting it up to fear the birds of prey,
> And let it keep one shape, till custom make it
> Their perch and not their terror."

In France, however, with its greater capabilities for paternal government, they manage things differently. Recently our pages recorded penalties imposed upon unauthorized persons for selling cod liver oil and quinine wine; to-day the point may be further illustrated by a letter which has been issued by the Préfet of the Haute-Saône. That functionary having been informed of the existence in some communes of medicine stores kept by undiplomatized and unqualified persons, warns such persons that they are violating the law, and that it is his duty to proceed against them. But, recognizing the inconvenience sometimes experienced in districts at a distance from an authorized pharmacy, he announces his intention to carry into effect, as an experiment, the recommendations of a commission appointed to consider the subject. Medicine stores will be allowed to be established in such communes, upon tolerance; the privilege to be revoked in case of abuse. The drugs are in no case to be sold; and are to be delivered to the patient by the doctor in person. These communal *dépôts* are to be subject to an annual visit from the inspector of pharmacy, and the stores are to be limited exclusively to the following:—

1. Emetic (ten packets of 5 centigrams each).
2. Ipecacuanha in powder (four packets of 1 gram each).
3. Sulphate of Quinine (four packets of 1 gram each).
4. Chloroform (30 grams in a stoppered bottle).
5. Laudanum (20 grams in a stoppered bottle).
6. Solution of Perchloride of Iron (30 grams in a stoppered bottle).
7. Mustard Leaves (ten).
8. Sulphuric Ether (30 grams in a stoppered bottle).
9. Calcined Magnesia (50 grams in a wide-mouthed bottle).
10. Carbolic Acid, in crystals (30 grams in a stoppered bottle).
11. Solution of Ammonia (50 grams in a stoppered bottle).
12. Ergot of Rye (5 packets of a gram each).
13. Extrait de Saturne (100 grams in an ordinary flask).

"Aliæ nationes servitutem pati possunt: populi Romani est propria libertas." At least, so said Cicero.

PATENT MEDICINE LICENCE.

Occasionally we are asked the question whether one licence empowers a person to deal in patent medicines in more than one place. The following letter from the Assistant-Solicitor of Inland Revenue is a reply to an inquiry made with the object of setting the matter at rest:—

Inland Revenue,
Somerset House,
22nd February, 1873.

Dear Sir,—

In answer to your letter of the 20th February instant, I beg to acquaint you that a person holding a £2 licence as a medicine vendor may sell anywhere in any number of places in Great Britain; and a person holding a more limited licence may sell in any number of places if they are not within the places mentioned in the reservation in his licence.

I am, Dear Sir,
Your obedient servant,
Stephen Dowell,
Assistant-Solicitor of Inland Revenue.

E. Bremridge, Esq.

The cultivation of the poppy for the production of opium seems to be occupying some attention in South Africa just now. A commercial firm at Port Elizabeth, Cape of Good Hope, having received a parcel of fresh poppy seed from Calcutta, have distributed it to persons in the colony desirous of cultivating it and giving it a fair trial. It is stated to be the opinion of competent judges at the Cape, that the poppy can be grown successfully on the coast lands, where there is little or no danger to be apprehended from frost; consequently there seems to be no reason in the opinion of the colonists why the production of opium should not be successfully carried on, and another valuable article of commerce added to the Cape list of exports.

A curious case of poisoning by carbolic acid is reported from Wurtemberg. Two men suffering from the itch were each supplied by a medical man with 30 grams of carbolic acid dissolved in alcohol and water, which they were told to rub briskly on the parts affected. This they did so effectually that one of them died within an hour, and the other narrowly escaped with his life. The prescriber, so it turned ut, had somewhere read that carbolate of soda was an efficacious remedy for the disease in question.

Provincial Transactions.

BRIGHTON ASSOCIATION OF PHARMACY.

At a meeting of this Association on Friday, March 6th, in the Hanover Lecture Hall—the President, Mr. W. D. Savage, in the chair—an interesting paper on the potato and its commercial products, was read by Mr. J. Mathews. After showing that the subject of his paper was an interesting one, Mr. Mathews observed that next to wheat the potato is of the greatest importance as an article of human food. It has this advantage over the cereal grains, that it affords food three months earlier. As compared with wheat, its nutritive properties are low, yet one acre of potatoes give more food for man than two acres of oats. The potato consists of the tuber of *Solanum tuberosum*, a plant of the natural order *Solanaceæ*. It was introduced into England probably about the year 1597, by Sir Walter Raleigh; but before its introduction, considerable quantities of sweet potatoes, consisting of the tubercules of *Batatas edulis*, a plant of the natural order *Convolvulaceæ*, were imported into this country from Spain and the Canary Islands. This is the potato alluded to by Shakespeare, and which is still cultivated in tropical countries, though not now in England.

Potatoes, the lecturer said, contain a large quantity of starch, which is all found very near the surface, the heart containing very little. Hence potatoes should be pared thin, or better still, should be merely washed. The starch is separated from potatoes in large quantities, and is sold as potato flour, British arrowroot, etc. It may be distinguished from arrowroot by the naked eye, and by the touch, but the only means of detecting its presence with certainty is by the microscope. By a peculiar manufacturing process it is converted into substances resembling tapioca and sago, and is used to adulterate those articles. Large quantities of it are converted into dextrine, and a great deal is also consumed in the manufacture of potato spirit, which is much cheaper than grain spirit, and is therefore extensively employed in making cheap perfumery. It has a disagreeable smell, owing to the large amount of amylic alcohol contained in it. This amylic alcohol, which used to be rejected, is now converted into a number of beautiful flavouring essences, such as essence of jargonelle pear, apple, etc., and it is also the source from which the nitrite of amyl, a powerful medicine, is obtained.

At the conclusion of the paper, a hearty vote of thanks was given to Mr. Mathews for his instructive address, and the president gave a description of the method of making sugar from starch, as seen in operation by him.

Mr. W. H. Smith observed that it was quite new to him that potatoes did not contain starch in their centre, and although he was unable to make a positive statement about it, yet the section he would presently exhibit was at any rate taken very near the centre of a potato, and every cell was full of starch granules. He was also surprised to hear the potato spirit was used in perfumery for cheapness because the actual cost of grain spirit was very little; it is the duty imposed upon it which makes it so expensive.

Mr. Schweitzer explained that potato spirit is employed in perfumery because its peculiar odour is preferred, and not on account of its cheapness.

Mr. Cornish thought that if the centre of the potato did not contain starch it would not present a floury appearance.

An interesting discussion ensued as to the best way of planting potatoes. The President said he had found by experience that an entire potato, the size of a pullet's egg, gave the best results.

The meeting then resolved itself into a *conversazione*, and specimens of fruit essences, etc., were exhibited by Mr. Mathews, and various starches under the microscope by Mr. W. H. Smith.

NORTHAMPTON PHARMACEUTICAL ASSOCIATION.

A special meeting was held on Monday, March 10th, 1873. The President being unavoidably absent, Mr. Druce was voted to the chair. Donations were announced of the Calendar and Journal from the Pharmaceutical Society, a large number of prescriptions from Mr. F. P. Brown, and twenty-four specimens of officinal materia medica from Messrs. P. Jeyes and Co. The Chairman said that he had noticed with great satisfaction the large and in every way successful classes that had been conducted during the winter session. He was also pleased to say that three new members had recently joined them. The examination in Botany would be held on March 17th; Materia Medica, March 21st; and Pharmacy on March 24th—the first two conducted by Mr. W. Sandall, and the latter by Mr. G. N. Maxwell, and he was sure the Association was to be congratulated upon obtaining two such able gentlemen to perform such onerous duties.

Mr. Wallis then read a very interesting and instructive paper on Sponge: its Structure and Position in the Animal Kingdom—remarking that it was his first paper. He proceeded to describe the appearance of sponge, and to notice the very slight claim it had to the name of an animal, seeing that its power of locomotion was limited to its youth, and that it had no blood-vessels or alimentary canal. But that it did belong to the animal kingdom had been first proved by Mr. Ellis, and, with few exceptions, it was classed as such by the leading naturalists of the day. He then went on to describe its habitat—the various species of sponge, both British and foreign—the manner in which commercial sponge was collected by divers, and its preparation for use by steeping it in cold water, the concretions which it contained being separated by occasional beatings, afterwards washed in water acidulated with hydrochloric acid, and sometimes bleached by means of sulphurous acid. Having referred to the spicula so generally present in sponge, and to their composition, he explained how burnt sponge was prepared, and gave its composition, referring any medicinal effect it might have to the iodide and bromide of potassium it contained. He concluded by expressing his belief that the study of even animals so low down in the scale as sponge would repay the trouble of the investigator.

Mr. Druce then read a paper on Guarana, descriptive of its origin, composition, therapeutical effects, and mode of preparation.

Votes of thanks to Messrs. Wallis and Druce, to the various donors, including one to Mr. Mayger for the loan of chemical apparatus and one to Mr. W. Marriot for the loan of a microscope, were passed.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL ASSOCIATION.

The general monthly meeting was held on Wednesday evening, March 12th inst.—Mr. W. Ward, F.C.S., President, in the chair. There was a somewhat better attendance than at the last monthly meeting.

After some preliminary business, a lecture was delivered by A. H. Allen, Esq., F.C.S., on "The True Nature of the Phenomena attributed to the Agency of Spirits." In the course of the lecture, which was listened to with great attention, Mr. Allen said, that the spiritualistic phenomena were of several distinct kinds. First, there was mere meaningless table-rapping and turning; secondly, the interpretations of the knocks into distinct and intelligible communications from spirits. These simpler "manifestations" were merely the result of unconscious muscular action. The lecturer had himself taken part in table-rapping, and though some of the answers were sufficiently curious, a careful consideration of the effects and proper modification of the arrangements invariably proved the rapping to be directly, but unconsciously, produced by the operators themselves. A third and more complicated set of phenomena were those in which so-called "levitation" came into play. Pieces of furniture were said to be raised from the ground, musical instruments played, and various other effects produced by the spirits. It was a suspicious circumstance that the musical instruments chosen were always those very easily played, such as accordions, but it would be interesting if the spirits would blow a flute or a whistle, as it would prove they had lungs as well as hands. In some cases it was stated that a profusion of flowers were showered suddenly on the tables, none having previously been in the house. But, on inquiry, it never seemed as if the observers had taken the trouble to notice what kinds of flowers were produced. If such a manifestation had occurred in his presence, it would have been the lecturer's first impulse to take the flowers to a competent botanist for him to decide whether they were normal specimens or "monstrosities." If normal, one of three things would be proved—that the botanical productions of the spirit-world were identical with those of our earth; that the spirits stole the flowers from some neighbouring garden; or that they were not produced by spirits' aid at all. If, on the other hand, the flowers proved to be monstrosities, there would be the strongest reason for believing them to have been produced by preternatural aid.

It was a curious fact that the most successful manifestations took place in the dark: suspicious as this condition seemed to outsiders, the spiritualists explained it by saying that light destroyed the visibility of the spirits, but that in the non-actinic light of a photographer's dark room, the spirits became visible. If so, they ought to be equally visible by moonlight, and a successful midnight *séance* in an open field would go farther to convince sceptics of the truth of spiritualism than a hundred meetings in the artfully prepared reception rooms of professional mediums of doubtful antecedents and reputation. Mr. Allen remarked that with proper arrangements all the astonishing manifestations of the professional mediums could be imitated by mechanical or scientific aid. The lecturer asked a number of questions of a glass bell suspended from the ceiling by a silken cord, the bell correctly replying to all by the number of strokes given by its clapper. Similar "spiritualistic" effects were obtained from a suspended drum and from a chair—Mr. Allen subsequently explaining the methods employed in producing the manifestations. The lecturer said that scientific men were often accused of ignoring the spiritualists without due cause, but this was scarcely the case. The phenomena had been investigated by Faraday, Tyndall, Carpenter, and others who had succeeded in explaining them. The organised attempt at investigation made by Mr. Crookes had resulted in a manner eminently unsatisfactory to the spiritualists, for Mr. Crookes, and those associated with him, had come to the conclusion that there was no evidence that the effects were due to the agency of spirits, but there seemed to be a power possessed by Mr. Home, and a few other persons, of overcoming the force of gravity by the power of their will; and although the experiments were in some instances very badly devised, the general impression was that the subject deserves further consideration. Any investigation of the sort is attended with great difficulties, as the power alleged by Mr. Home to be possessed by him is only met with in rare cases. Mr. Crooke's experiments have been tried again in America by some of the most eminent mediums, but have never succeeded.

At the conclusion a vote of thanks, proposed by E. Birks, Esq., and seconded by Mr. Booth (Chesterfield), was unanimously tendered to Mr. Allen, much pleasure being expressed at the way in which he had clearly explained many of those knotty points which are rather puzzling to ordinary observers. This brought the meeting to a close.

UNITED SOCIETY OF CHEMISTS AND DRUGGISTS OF IRELAND.

A deputation from the United Society of Chemists and Druggists of Ireland waited, by appointment, upon the Governor and Court of the Apothecaries' Hall on Friday, the 14th of March. The following gentlemen constituted the deputation:—Mr. Hodgson, President of the Society; Mr. Hayes, Hon. Sec.; Mr. Goodwin, Treasurer; Mr. Boyd; Mr. J. T. Holmes, and Mr. Wells. There was a full attendance of the members of the Court. Mr. Hodgson introduced the deputation, and said its object was to ascertain the views of the Court of Apothecaries on the subject of forming a Pharmaceutical Society in Ireland similar to the society in England. The clauses of a draft Bill, which had some time ago been prepared by the Apothecaries' Company, were then read seriatim by the Governor, and discussed. (The Bill was printed in the present series of the PHARM. JOURN., vol. i. p. 405.)

After each clause had been fully discussed, and several amendments suggested by the deputation and approved by the Court, it was arranged that the Chemists' Association should frame a Bill and submit it to the Apothecaries' Company. If approved of, the Attorney-General would be requested to introduce a Bill on the subject without delay.

The Governor wished the deputation to go away with the understanding that the Court was in every way disposed to assist in the matter, and no doubt a Bill similar to the draft Bill discussed will be adopted.

Proceedings of Scientific Societies.

PHILADELPHIA COLLEGE OF PHARMACY.

A pharmaceutical meeting of the Philadelphia College of Pharmacy was held on Tuesday, February 18; Mr. Samuel S. Bunting in the chair.

Mr. Shinn said that, at the meeting held in December last,* reference was made to a preparation, somewhat in demand in Philadelphia, containing fifty per cent. of cod-liver oil and a certain amount of lacto-phosphate of lime. Many experiments, before and since that time, have been made by him to devise an eligible method of combining these remedies in a palatable form, resulting in the following formula, made to contain twelve grains lacto-phosphate of lime to the ounce:—

Take of Cod-liver Oil	Oj,
Oil of Bitter Almonds .	
,, Peppermint . . .	
,, Wintergreen, each	gtt. x,
Powd. Gum Arabic . .	℥iv,
,, Sugar	℥vi,
Solution of Lacto-phosph. Lime (ʒi to f℥i) . .	f℥viss,
Lime Water	f℥viss.

Mix the gum and sugar in a capacious mortar, and make a smooth mucilage with the lime water and three ounces of the solution of lacto-phosphate of lime. Add the volatile oils to the cod-liver oil, and gradually triturate them with the mucilage until a perfect emulsion is formed. Finally, add the rest of the solution of lacto-phosphate of lime, and mix thoroughly.

The solution of lacto-phosphate of lime is made as proposed by Mr. Neergaard in the *American Journal of Pharmacy*, June, 1871, by saturating a solution of lactic acid with freshly precipitated phosphate of lime.

The magma obtained from 16 ounces of phosphate of lime dissolved in muriatic acid, precipitated by ammonia, quickly washed and pressed, will be sufficient to saturate a pound of the commercial acid mixed with 4 pints of water. After filtering the solution it is assayed by evaporating a fluid ounce to dryness and weighing the result-

---

* See before, page 594.

ing lacto-phosphate of lime, when it can be made of a definite strength. In the formula given it contains 60 grains to the fluid ounce, which is about equal to 30 grains of phosphate of lime, and is of convenient strength. It has a slightly acid taste, which, however, is not unpleasant, but rather renders the emulsion less cloying than if entirely sweet. As made by the formula, the preparation will keep in good condition for two or three weeks, but will eventually spoil, as shown by the blowing out of the stopper, although the taste and character are not materially altered.

If meant for sale to the trade, the addition of about 20 per cent. of alcohol renders it more permanent, and in most cases may not be therapeutically objectionable.

This led to some remarks upon the preparation, during which Mr. Chiles gave a formula (which will be published in a future number). The question of the legality of selling the preparation was discussed, there being a patent for the manufacture of a similar compound. Mr. Chiles stated that he also prepared a lozenge of lacto-phosphate of lime and pepsin.

Parliamentary and Law Proceedings.

Prosecutions under the Adulteration Act.

At the Clerkenwell Police Court, on Friday, March 14, George Brown, a tea-dealer and grocer, of 27, Central-street, St. Luke's, was summoned before Mr. Barker, by James Neighbour, sanitary inspector, appointed by the vestry of St. Luke's, Middlesex, under the Act to Amend the Law for the Prevention of Adulteration of Food and Drink and Drugs, 35th and 36th Vict., cap. 74, "for unlawfully selling tea, and knowing the same to be mixed with another substance, with intent fraudulently to increase the weight and bulk, and without declaring such admixture to the purchaser thereof, before delivering it."

Mr. Parkes opened the case at some length, and having stated the provisions of the act under which these proceedings are taken, said that the vestry, anxious to repress the illicit trade in adulterated food and drink, and other articles, prevailing in the parish, at the earliest opportunity determined to put in force the provisions of the act, and for that purpose appointed Dr. Pavy, of Guy's Hospital, M.D., F.R.S., analyst, and Mr. James Neighbour (sanitary inspector of the parish), inspector under the said act. As soon as the appointments were ratified by the Local Government Board, samples of apparently adulterated articles of food and drink were procured by the inspector and submitted to Dr. Pavy, for the necessary analysis, and the result had been the taking out the present summons. The case before the magistrate was a most flagrant one, and the fraudulent intent was clearly palpable, for upon analysis the rubbish sold as tea in each case was found to contain ingredients consisting of iron filings and clippings, gritty matter, small fragments of wood, and foreign stalks which could be plainly seen by the aid of a microscope, and the iron filings adhered in profusion to a magnet placed in it. He contended that the defendant, being a professed dealer in tea, could not but know that the articles so sold were fraudulently increased in weight and bulk, and he asked for a conviction, as this case came within the meaning of the act. He then called

Mr. James Neighbour, who deposed that on the 19th of February last he entered the defendant's shop, and asked for 4oz. of 1s. 4d. tea, which was supplied, also 4oz. of 8d. tea, and that was also supplied, he paying 6d. for the whole. The person who served him did not declare that there was any other substance or admixture in the tea purchased, or that the tea was in any way adulterated, and he saw no notice of any admixture or adulteration. He took the packets of tea and delivered the same to Dr. Pavy, the analyst, in the same condition, and in the same packets, as delivered to him by the person who served him. Each packet was divided into two parts, one of such parts being retained by Dr. Pavy for analysis, and the other parts were sealed up in his presence, and have remained in the same state as now produced. He received the two certificates produced from Dr. Pavy, who certified that both samples of tea were in an adulterated condition, one sample being adulterated with iron filings and clippings, gritty matter, and foreign stalks, whilst the other consisted of tea dust, with adulteration composed of iron filings and clippings, gritty matter, small fragments of wood, and foreign stalks.

By Mr. Ricketts.—He did not expect to get a good and unadulterated tea at 8d. per lb. He did not see in the defendant's shop placards, "This capital mixture 8d. per lb.," nor "Our noted mixture 1s. per lb.—try it." He did know that tea got between the lead and the chest, and that it was knocked out and sold as tea. He should not say that that would make "noted mixture."

Mr. Barker looked at the mixture through a microscope, and also applied the magnet to it. When the magnet was taken out there were many particles adhering to it.

Mr. Parkes said that was the case for the prosecution.

Mr. Ricketts said if that was so there must be an end of the case, for the certificates of the analyst did not comply with the provisions of the act. By the 9th section the analyst had to certify whether such article in his opinion submitted to him was adulterated, and also whether, if it be an article of food or drink, it is so adulterated as to be injurious to the health of persons eating or drinking the same. He had a good answer to the case on its merits.

Mr. Parkes said that by the 3rd section the words cited by this section were not necessary.

Mr. Barker said he should adjourn the case for a fortnight to consider the point. There was no doubt from the samples he had seen that they were very much adulterated.

Mr. Ricketts said he hoped that the prosecutors would not be allowed to re-open their case, or to supplement it with fresh evidence.

Mr. Barker adjourned the case for a fortnight.

Ellen Jones, of 151, Lever-street, and David Jones, of 5, York-road, St. Luke's, were also summoned by Mr. James Neighbour, for selling adulterated milk; and these were adjourned to know the result of the objections taken in the last case.—*Standard.*

Attempted Suicide by Red Precipitate.

A few days since Emily Thompson was charged at the Worship Street Police Court with attempting suicide. It appeared from the evidence that the prisoner, being in liquor, put some red precipitate powder into a cup of tea and drank it off. She was attended by a doctor, but did not appear to suffer much. Upon her were found two papers which were labelled "Red precipitate—poison," and Mr. Hannay said that he should like to know how these poisons came to be sold. For that purpose he sent for the chemist whose name was upon the packets. The witness, carrying on business at 70, Hyde-road, Hoxton, stated, in reply to Mr. Hannay, that red precipitate was red oxide of mercury. The two packets would contain about two scruples—quite sufficient to destroy life. He put in the regulations recently made by the Pharmaceutical Society as to the sale of the poison in question, but said that he had no recollection of selling to the prisoner. It was a very common thing to sell either red or white precipitate, and witness sold about a hundred packets a week.

Mr. Hannay, after looking into the law as to the sale of poisons, said that the witness had complied with it.

The prisoner said that she was sorry, and her husband promised to take care of her for the future. He thought her attempt was the result of grief.

Mr. Hannay, after cautioning the prisoner, discharged her.—*Standard.*

The Sale of Laudanum.

A man was charged at Portsmouth last week with attempting to commit suicide. In a letter which he had written he bade his landlord good-bye; and he was afterwards found with a bottle in his hand containing laudanum, which he said he had obtained in pennyworths at a number of chemists in the town. The prisoner was remanded.

Suicide of a Commercial Traveller.

On Monday, March 17, an inquest was held in Little Britain on the body of Alexander Jackson, aged 39 years. Joseph Houldsworth, chief clerk to Messrs. Maw, Son, and Thompson, Aldersgate Street, said deceased was one of their town travellers. On Friday morning witness saw him at No. 12, Aldersgate Street, and told him that a customer had written stating that an account which they had rendered to him had been paid. Deceased replied, "Yes." Witness then said, "It's a very serious matter, and I shall inform the firm of it." Deceased was accountable to witness for moneys he received, and this was not the first time he had mentioned it to him, but not to the firm, but told him he must do so if it occurred again. On Friday deceased entreated witness not to tell the firm, but he told deceased he must do it, and accordingly told Mr. Thompson, the junior partner. Soon after, Mr. Maw arrived, and witness told deceased to tell Mr. Maw himself the whole particulars, as it would be much better than if witness told him. Witness saw deceased again afterwards, and said to him, "Have you told Mr. Maw?" He said, "No, I cannot; what use is it?" and he turned round and left the counting-house, and went down stairs. Soon after the charwoman called witness, and he went down, and saw the deceased standing near the kitchen with his head resting on the steps leading into the street. He was not sensible, and a doctor was sent for. Sophia Warr, charwoman, said, when deceased came down stairs he had a blue bottle in his hand; he held it to his mouth, and drank the contents, and then threw the bottle across the kitchen. Witness called for assistance. John Prior Parkes, compounder at Messrs. Evans and Lescher's, Bartholomew Close, wholesale druggists, said he knew deceased, whom he met on Friday morning in Aldersgate Street. Deceased said, "I want you to let me have an ounce of prussic acid, for killing cats. I have some at home, but it is decomposed." Witness objected to go back at first, but, knowing deceased was a chemist and druggist, he let him have the prussic acid. Witness saw nothing peculiar in his manner. He said people ought to be very careful with prussic acid; he had seen many accidents with it himself. Mr. W. Wallford, surgeon, said he was called in, and found deceased in a chair, perfectly insensible. He died directly. The cause of death was poisoning by hydrocyanic acid. Verdict, "Temporary insanity."—*City Press.*

Reviews.

A Course of Qualitative Chemical Analysis. By Wm. Geo. Valentin, F.C.S. London: J. and A. Churchill. 1873.

We had an opportunity a few weeks ago of commenting on the "Introduction to Inorganic Chemistry," constituting the first of the two volumes into which Mr. Valentin has thought it expedient to divide his original work. We now have before us the second volume, which is devoted to a systematic course of experiments arranged for exercise in practical qualitative analysis.

The general principle which appears to have guided the author in the arrangement of his work is not new, but we do not think any the worse of it on that account.

The book commences with a short chapter devoted to an explanation of the objects of qualitative analysis, in which the author says, "Chemical analysis consists in the performance of certain experiments with the object of putting, so to speak, certain questions to a substance, in order to ascertain the presence or absence of certain bodies. It is termed *qualitative* analysis, if the answer which is received reveals merely *what kind* of matter is present without regard to quantity." It is quite true that this is the primary object of qualitative analysis, and the one which is usually kept in view by both teachers and students, to the almost complete exclusion of another object which in some respects may be regarded as no less important. By studying the action of reagents upon bodies, and systematizing the knowledge so obtained, we may learn not only how to recognize definite chemical compounds, and to detect any one or the whole of the constituents of a complex mixture, but we ought to be able to base upon that knowledge methods for the complete separation of the constituents of bodies, so that they may be presented in an isolated form in a condition of chemical purity. It is quite true that separations are universally practised by students according to the well-known system of classification, by the aid of group and special reagents. But we think a very useful set of exercises might be devised, in which a student should be required to carry to completion this process, which, according to the usual practice, is considered to have served its purpose, and to be finished when, by the use of certain tests, corresponding appearances have been produced. In other words, we think it would have a beneficial influence on both the mental and manipulative habits of the student if he were expected occasionally, and when practicable, to produce, in a state of chemical purity, and by the usual analytical method, specimens of the sulphides, oxides, and other compounds of the elements towards the discovery of which search is commonly directed. It would have the effect of informing the student as to how far the processes which he employs are really serviceable for the true separation and isolation of chemical species, and in many cases work of this kind would tend probably more than anything to check the slovenliness which in some students is a constant source of difficulty both to their teacher and themselves.

In this same introductory chapter, the author gives some hints as to manipulation, short but sufficient. He then goes on to give the usual "tests" for the metals, taking them in order, and commencing with the alkaline group. At the end of each group those reactions which may be called diagnostic are indicated, and the student left to construct for himself a process for the separation of the members of the group, one from another. Tables for his guidance are afterwards introduced. This is a very good plan, and when faithfully carried out, is calculated to diminish the injurious influence which the injudicious employment of tables undoubtedly exercises. The work is done more intelligently, and there is far less risk of the study assuming the character of a mere mechanical art.

With regard to the tables given in the book we have no fault to find. The processes recommended are very good, probably the best, that could have been adopted. In many cases the methods of separation possess the advantage of being those which are practically available for quantitative purposes.

The author insists very properly upon the necessity for washing precipitates; this is an important point, and one which is too often neglected by students.

It generally seems to be considered necessary to draw up very elaborate tables for what is called the "preliminary examination."

Any attempt to make such a table complete we should regard as superfluous and almost useless, inasmuch as the power to interpret correctly the results of preliminary experiments can only be the result of experience, and must be based on a previous knowledge of the appearance and properties of a large number of substances. To those, therefore, who possess that knowledge, such a table would be of very little use, and those who have it not, the table, even if complete, would do very little to enlighten, and its employment would consume a great deal of time.

We most cordially commend Mr. Valentin's book, so far as its practical aspect is concerned, and, in all but one point, we consider it as nearly perfect as possible. We allude to the notation. It is certainly a most unfortunate thing that so many otherwise admirable books should be objectionable in this one respect. We could, at this moment, name several other chemical manuals in which some eccentricity in the notation adopted is actually a bar to their use by a great many teachers.

The author in the work under review employs constitutional formulæ, written on Frankland's system, throughout the book, tables and all. He reminds one of a boy with a watch. He is not content with referring, when necessary, to see what o'clock it is, but must for everlasting be telling you the time of day. Added to this, the system employed is, as we have before taken occasion to point out, one which has a tendency to cramp the ideas of the student worse than almost any that can be conceived. We should not grumble if the author would consent to alter the shape of the formulæ just now and then, but it seems to us preposterous to introduce into analytical tables formulæ which are not unfrequently written on two or three lines, and are full of brackets and dashes.

We have the same kind of objection, and one equally decided, to the invariable employment of systematic names, and indeed to the use of any one class of names to the exclusion of others. As very justly observed by Whately,* the disposition to do "this is that which chiefly constitutes what is called narrowness of mind"—a complaint from which chemists are no more exempt than other mortals.

But to return to the book;—though, as we have already explained, we have a strong objection to the system of notation employed, and should be glad to see it at least partially supplanted by some other and less rigid style of formulæ, we confess to having thorough confidence in the practical part of its contents, and should have no hesitation in recommending it to students as a very excellent and trustworthy manual of qualitative analysis.

Posological Tables; being a Classification of all Officinal Substances, for the Use of Students and Practitioners. By W. Handsel Griffiths, Ph.D., etc, etc.

The compiler of this broad-sheet has endeavoured to provide for the student who would learn the authorized doses of medicines, and for the practitioner who may for the moment have forgotten them, a means of obtaining the required information more easily than by turning over the pages of the Pharmacopœia.

The first part of his design is, he says, to make the Tables useful to students as an aid to memory, and we presume he calculates on doing this by a certain method of grouping.

The tables are arranged under three headings, "Inorganic Substances," "Organic Substances," and "Pharmacopœial Groups."

The classification under each heading, instead of being alphabetical as commonly adopted, appears to be made with reference to the active power of the articles. Thus in the group of acids we find the dose of the first, "Acid. Nitric." to be ♏ j—v; two others follow singly, marked respectively ♏ ij—viij and ♏ v—xx; then we have five bracketed as ♏ v—xxx, and two more singly ♏ xxx—ʒj and ʒj—ʒij. A notable deviation from the ordinary method of posological tables is seen here in the fact that "Acid. Nitric. Dil." does not immediately follow the strong acid, but stands among the five bracketed with the dose ♏ v—xxx. This necessarily involves some previous acquaintance with the acids in question and the proportions of their dilution, so that Dr. Griffiths' table will be less likely than it otherwise might be, to be used as a kind of parrot-lesson by students.

We have mentioned the acids because they meet the eye in the first column, but the last column gives a more perfect idea of the system of classification according to doses. We there find tinctures divided into groups, the first those of which the dose ranges from ♏ v—xx, then ♏ v—xxx, ♏ v—ʒj, ♏ xxx—ʒij. Where the same medicine is given in varying doses for different purposes we find it put down at different points of the scale—thus, third under "Zincum," "Sulphas (Tonic) gr. j—iij," and eighth, "Emetic gr. x—xxx," and similarly with "Ipecacuanha;" but we here notice that, doubtless by inadvertence, the word emetic is omitted where the larger dose is stated.

On the whole we think the Posological Tables form a convenient chart for reference; and we like them the better because they are compiled apparently on the understanding we hinted at before, that those who use them will do so with some previous knowledge of the power of the medicines passing through their hands, and would not, for example, when seeking the authorized dose of "Senna" expect to find it immediately following "Sabina" and "Scilla."

* 'Logic.'

Obituary.

Notice has been received of the death of the following:—

On the 6th January, 1873, Mr. Thomas Simpson, Pharmaceutical Chemist, of Stowmarket. Aged 72. Mr. Simpson had been a member of the Pharmaceutical Society since 1842.

On the 28th January, 1873, at the Cape, whither he had gone in the hope of re-establishing his health, Mr. R. C. Hopgood, Pharmaceutical Chemist, late of Chipping Norton. Aged 30. Mr. Hopgood had been a member of the Pharmaceutical Society since 1868.

On the 7th March, 1873, Mr. Alexander Hugh Douglas, Chemist and Druggist, of Cheshunt. Aged 31.

BOOKS RECEIVED.

Grundlagen den Pharmaceutischen Waarenkunde. Einleitung in das Studium der Pharmacognosie. Von Dr. F. A. Flückiger. Berlin: Julius Springer. 1873. From the Author.

The Origin, Extension, and Prevention of Fires, and the Relation of Mineral and Vegetable Oils, and other Materials to Fire. Four Letters to The Times, and an Appendix. By John Attfield, Ph.D., F.C.S., etc. London: Van Voorst. From the Author.

Nugæ Canoræ Medicæ; Lays by the Poet Laureate of the New Town Dispensary. Second Edition. Edinburgh: Edmonston and Douglas. 1873.

Outlines of Physiological Chemistry, including the Qualitative and Quantitative Analysis of the Tissues, Fluids, and Excretory Products. By Charles Henry Ralfe, M.A., M.B. London: H. K. Lewis. 1873.

APPOINTMENT.

Mr. R. W. Houghton, pharmaceutical chemist, formerly of Bermuda, has been appointed Dispenser in charge of medical stores at the Royal Naval Hospital, Jamaica.

VACANCY.

A Dispenser is required for the Southern Dispensary, St. Marylebone, W., who must be a Licentiate of the Apothecaries' Company or registered under the Pharmacy Act. For particulars, see advertisement.

Notes and Queries.

[332.]—FATTY OAK VARNISH.—Having got a quantity of old fatty oak varnish, can any correspondent inform me the best mode to adopt to liquefy it and render is serviceable?—G. W.

MONOCHROMATIC LIGHT FOR ALKALIMETRIC OPERATIONS.—The difficulties attending the use of litmus by gas or other artificial light, in delicate operations, has been the subject of a communication by M. L. d'Henri to the French Academy. He suggests the use in a darkened room of the non-luminous flame of a Bunsen burner into which a platinum wire, previously moistened with a paste of common salt and water, is made to pass. In the intense yellow light so produced the red colour of litmus appears as colourless as water, while the blue appears as black as ink.

DETECTION OF NITRATE OF POTASH MIXED WITH NITRATE OF SILVER.—M. Pollacci (*Bollettino Farmaceutico*) states that an adulteration of Nitrate of Silver with Nitrate of Potash may be detected by heating about a gram of the suspected nitrate to redness in a porcelain crucible, allowing it to cool and adding to the residue a few drops of distilled water. If the liquor be alkaline to test-paper, it is proof that the specimen contained nitrate of potash. The test is based upon the reaction by which nitrate of potash is converted into the oxide when heated in presence of metallic silver (arising from the reduced nitrate), and afterwards into the hydrate by combination with water.

SUCCUS APARGIÆ.—Upon treating the roots of *A. autumnalis* according to the process for succus taraxaci I found the yield of juice small, the albuminous deposit large, and the product intensely bitter, with a strong odour of succus taraxaci. The extract treated with menstrua gave nothing crystallizable.—J. B. S.

SUPPOSITORIA EXTEMPORANEA.—For suppositories containing cacao butter, a strong jelly of glycerine and tragacanth will be found a useful excipient (about one part of jelly to two parts of cacao butter). Incorporate the active ingredient with the glycerine of tragacanth, add the cacao butter in small pieces, and weld into a mass, roll and mark divisions on an ordinary pill machine. The suppositories can be moulded by the hand, they soon harden, keep well in a dry place, require no heat in their preparation, and melt at the ordinary temperature of the body.—J. B. S.

DEPILATORY.—Boettger (Neues Jahrbuch f. Pharm. xxviii. 230) recommends as a safe depilatory, one part of crystallized sulphydrate of sodium rubbed to a very fine powder and mixed with three parts of prepared chalk. He states that it should be mixed with water and applied to the skin for two or three minutes only, at the end of which time the hair becomes soft and is easily removed by water. A longer contact is liable to corrode the skin.

The following journals have been received:—The 'British Medical Journal,' March 15; the 'Medical Times and Gazette,' March 15; the 'Lancet,' March 15; the 'London Medical Record,' March 19; 'Medical Press and Circular,' March 14; 'Nature,' March 13; 'Chemical News,' March 15; 'Gardener's Chronicle,' March 15; the 'Grocer,' March 15; 'Journal of the Society of Arts,' March 15; 'Grocery News,' March 15; 'Produce Markets Review,' March 15; 'Scientific American,' March 15; 'New York Druggists' Circular' for March; 'American Journal of Pharmacy' for March; 'Anti-Adulteration Review' for March; 'L'Union Pharmaceutique' for March; the 'Educational Times' for March; 'British Journal of Dental Science' for March; the 'Practitioner' for March; 'Journal of Applied Science' for March; 'Florist and Pomologist' for March; 'Journal de Pharmacie et de Chimie' for March; 'Chemist and Druggist,' March 15; Zeitschrift des allgemeinen österreichischen Apotheker-Vereines,' March 10.

Correspondence.

Benevolent Fund.

Sir,—In looking down the list of Members of the Pharmaceutical Society, I was surprised to see how few subscribed to the Benevolent Fund. The reason is, I think, very evident; viz., the non-subscribers see how little good is done at present by means of the Fund. There is upwards of £13,000 in the Consols, yielding about £400 per annum interest; and the latter sum is divided, I believe, among about twelve annuitants, yielding the paltry sum of £30 each,—about enough to find them in *coal* at the present price.

Now, Sir, my proposition is that the £13,000 remain as at present, and the interest of that sum, together with all donations and subscriptions, be distributed every year in grants of not less than £50 a year. Then I feel sure, when members see such an amount of good being done, they will almost all be eager to subscribe, and we shall have a report something like the following:—

2,300 Pharmaceutical Chemists, £1 each	£2,300
10,000 Chemists and Druggists, 5s. each	2,500
Interest on £13,000	400
	£5,200

This would give 100 persons £50 per annum each; and surely there must be as many candidates as that for our bounty throughout all England, and many of these are now rejected with aching hearts.

It has just struck me that if this scheme is thought too radical, we might have two classes of subscribers; the one whose money might go to swell the principal, as at present, and the other who might request their money to be immediately bestowed.

If you think my proposition worthy of consideration, I hope you will use your powerful influence in that direction.

Reading. J. B. B.

The Sale of Poisons.

Sir,—I trust you will believe me when I say that in writing the letter which appeared in Journal of the 8th inst., and which you noticed in your leader, I wished not to cast the slightest slur upon the sincerity of your motives for expressing the views from which I differed, but in this, as in all other matters, whether agreeable to my own ideas or not, I believe you have "in view simply the interests of chemists and druggists." I wish to say this because, on reading your article, it gave me the impression that you felt I had entertained a different feeling. And, on the other hand, allow me to say that "interference with trade" was far from the motive that led me to address you: so far as the trouble went, I would register every sale I made, if I could see any real good in it. I desire to see this matter discussed simply on principle. I believe the system of registering vermin-killers to be *not* in accordance with the spirit of the Act. "Charges of negligence in the sale" of vermin-killer I do not think any sane magistrate would make after once reading the Act; and I was glad to see the magistrate at Worship Street yesterday made no remark about a brother chemist at Hoxton, who stated he sold 100 packets of red precipitate a week, because, "as to the sale of poisons, witness had complied with the law." But I find what I was ignorant of before (having been out of business till recently, and not knowing what had been done in the way of poisons), that the Pharmaceutical Council can add to the schedules whatever they consider comes within the spirit of the Act—that, I suppose, if I keep diarrhœa mixture in bulk, that is to be considered a preparation of opium, and must be registered if they will it so. And, under *this* view of the matter only, I must apologise for alluding to Mr. Kitchin.

Fredk. Tibbs.

81, *Chalk Farm Road, N.W., March 13th*, 1873.

Tincture of Quinine.

Sir,—I regret to differ from such an authority as Mr. Giles, but I must still maintain that the B.P. formula for this tincture does yield unexceptionable results, and not only so, but that the closer the instructions are followed the more successful is the preparation.

Many of your correspondents, Mr. Giles apparently among the number, appear to have assumed that the crystalline deposit was either quinine or some salt of that alkaloid, whereas in point of fact it contains no quinine whatever, it is not bitter, and is insoluble in dil. sulph. acid.

If to a tincture of orange made with *fully proof* spirit a few drops of dilute sulphuric acid are added, exactly the same result is obtained, *no quinine being present.*

The crystals are in reality "sulphate of lime" (see also Mr. Hustwick's paper in last issue), and are derived partly from the quinine salt and partly from the orange peel.

The *quantity* will vary with the quality of the peel used, and depend partly also upon whether the peel is *thinly* or *thickly* cut, the lime salts of some organic acids (probably citrate and malate) residing in the white portion of the peel.

As, therefore, sulphate of lime is less soluble in a *fully proof* spirit than in one of less strength, there is but little probability of sufficient being left in solution to give any subsequent crystals.

The objection to using dilute sulphuric acid is also apparent, for by its use the formation of the crystals which it is desired to prevent is actually favoured.

J. H. Baldock.

South Norwood, S.E., March 17th, 1873.

Sir,—Had Mr. Hustwick been present at the pharmaceutical meeting of November 6th, 1872, or had the report of the discussion that followed the reading of Mr. Haselden's paper been accurate, he would have learned that I recognized the precipitate as sulphate of lime, and assigned its origin to a double decomposition between the sulphate of quinia and a soluble salt of lime, present in the fresh peel, but not apparent in the old dried peel.

Mr. Hustwick finds the reaction take place in tincture of the *dried* peel, but does not specify the age of the specimen. I think he will find the fresh peel yield a very much larger proportion of the substance than the dried, especially if the latter have been kept in the dry state a considerable time.

I write not merely for the sake of correcting my evidence, but also to suggest to Mr. Hustwick a continuance of the investigation he has so well begun. Could he not endeavour to isolate and identify this salt of lime that is soluble both in water and in weak spirit? I some time since made a few experiments with that view, but discontinued them before arriving at any definite result.

I should be very pleased to have the matter cleared up. Although it seems of little importance, facts of an interesting character could hardly fail to be brought to light by such an investigation.

Weymouth, March 17th, 1873. Thos. B. Groves.

Suppositories.

Sir,—I am sorry to see that new compositions are being talked of for making suppositories; I have made many with cacao butter, and have never had that base objected to.

Can the following ready method of making suppositories be easily beaten?—I must premise that I keep cacao butter ready in a bottle in fine shavings, according to a suggestion which appeared in this Journal. Take a small mortar, and invert it, with the pestle inside, over the gas stove. Reach out the suppository mould, and smear the inside with glycerine; weigh out the ingredients and sufficient shaved cacao butter. By this time the mortar is ready; mix in it the ingredients with a little cacao butter, and then the remainder, stir in the mortar till just melted, and pour into the mould, then set the mould to cool.

A very little experience will show the desired temperature of the mortar, and I would suggest to young dispensers the advantage of weighing materials for one or two extra suppositories to allow for waste in pouring.

W. J. Churchill.

Birmingham, March 18th, 1873.

Aqua Chloroformi.

Sir,—I just wish to throw out a very simple suggestion with regard to aq. chloroformi, one of the preparations mentioned by Professor Redwood as likely to be inserted in the reprint of the "Pharmacopœia." Forty-eight minims of chloroform will dissolve in one pint of distilled water, and such a solution is one-tenth the strength of sp. chloroformi, one very convenient to remember in prescribing. Thus:—

Sp. Chlorof.	Chloroform.	Aq. Chlorof.	Chloroform.
1 fl. oz. =	24 mins.	1 fl. oz. =	2·4 mins.
$\frac{1}{2}$ fl. oz. =	12 „	$\frac{1}{2}$ fl. oz. =	1·2 „

Ilfracombe. W. Tearle.

Public Analysts.

Sir,—I am glad to find by your report that the electing bodies of Clerkenwell, St. Giles's, and Holborn have seen the wisdom of appointing a professor of chemistry as public analyst, and have not allowed the mania of the moment to blind their discretion by appointing medical officers of health, as in the majority of cases, simply because the word "medical" was inserted in the Act of Parliament. I strongly advocated this course in St. Pancras a short time ago by moving an amendment (lost by eight votes) that the officer appointed should be *bonâ fide* a professor of chemistry, who could devote the necessary time to the requirements of the office. I did so, not from any doubt which I entertained as to the ability of the medical officer, but from a strong conviction that, as medical officer of health, he could not possibly afford to give the necessary time and attention required for analysis.

Surely it was never intended by the promoters of this Act that medical officers of health should monopolize these appointments, and then engage the services of an assistant to perform the duties; a fact admitted during the debate in St. Pancras. This system of seeking an appointment upon certain merits, and afterwards transferring such important duties into the hands of an assistant whose ability and qualifications are entirely unknown to the electing board, is not only objectionable, but fraught with very serious consequences; from the fact that the character, reputation, and commercial morality of the trading community are at stake, and in all probability, upon the positive or negative assertion of this unknown deputy, they either stand or fall. But when we find such men as Dr. Redwood appointed, it becomes a passport of safety to the public interest on the one hand, and a guarantee to the Act on the other.

There are, doubtless, many difficulties in the way of working this Act effectually; but in sanctioning such an appointment, the Local Government Board will at least have the satisfaction of knowing that, as far as regards the appointment of public analyst, they have placed the right man in the right place.

Tollington Park, March 18th, 1873. T. C. Jones.

Pharmaceutical Students in Edinburgh.

Sir,—Just now, when the subject of providing schools and libraries for students of pharmacy, is deservedly attracting so much attention, perhaps an apprentice's opinion would not be out of place.

The branch of the Pharmaceutical Society in Edinburgh, with praiseworthy intention, have at length succeeded in providing handsome and lofty rooms for the use of all connected with the profession, as a place of meeting and mental recreation. They have also provided a museum, library, and reading-room,—but to what purpose? No doubt many useful and instructive journals are to be found on the table, and books of the highest class, well fitted to cultivate a taste for scientific knowledge, are obtainable from the library. There are also specimens, etc., from which an inquiring mind might obtain a great insight into the mysteries of botany; but the old saying still presents itself forcibly, "The harvest is ripe, but the labourers are few."

On looking at the visitor's book, we see on one day four or five names, and on some only one or two. One naturally asks the reason of this. Here is a fine reading-room, in the centre of a town which has been long and worthily called "the seat of learning," and in which are many enthusiastic disciples of the pestle and mortar; but why is it not taken more advantage of?

At first it may be thought that the young men are not of a studious or diligent temperament, but on looking more carefully into the facts of the case, we find the true reason. Till the beginning of this year, only a few shops were shut at eight o'clock, while the great majority were open till ten or half-past ten o'clock. Even take the favoured few who shut at that preposterously early hour (?) eight o'clock, and see what opportunities were afforded to assistants and apprentices to cultivate their minds or to take advantage of the reading-room.

After working from nine in the morning till eight o'clock at night, they go home tired and weary, and sit down to puzzle out the intricacies of the artificial alkaloids, or perhaps a difficult chapter in Cæsar, Scoresby-Jackson, or Bentley. A large number of them are attending classes, and how can they prepare themselves for class or other examinations, and spend even a short time in the Society's rooms?

There are remedies for everything, and if the masters would show that they were anxious for the welfare of their *employés*, by either allowing some of them away every day for an hour to the rooms, or by giving each one a half-holiday once a fortnight, I am sure there would be a better attendance. Even if the masters went themselves, it would be a great inducement; but I am afraid that they are still more seldom there than their assistants.

We have been hitherto looking at the bright side of the question, but if we turn to the other side, we find that by far the larger number of shops are open till nine o'clock; in these, a half day is never thought of. How, then, can young men ever be expected to enter our profession (?), when they have examinations to pass, no time to prepare for them, and after all a paltry £50 per annum. Our trade is the only one which has examinations to pass, and yet its business hours rival those of the public-house or tavern, while drapers, booksellers, etc., close their shops at seven o'clock on weekdays and four o'clock on Saturdays. Let us, then, be up and doing, so that at least one ray of hope may be left for the chemist's apprentice.

Edinburgh, March 14th, 1873. A Prenty Cuss.

Pharmaceutical Women.

Sir,—Will you allow a small space to enable one who, though not a pharmaceutist, is a regular reader of your Journal, to state the impression conveyed to his mind by the recent discussion in your columns. The continued exclusion of women from the profession has been defended on three grounds: first, that it will introduce a new element into the already too crowded field of competition; second, that women are not competent to perform the duties of pharmaceutical chemists; third, that if competent, it is still undesirable that they should do so. The first ground—although I have been surprised to see it taken up by some of your correspondents—is surely not one that can be seriously held. Have Englishmen so lost their sense of chivalry and of regard for women, that we must fall back on the old barbaric maxim, that—

"They should take who have the power,
And they should keep who can;"

that in order to increase or maintain our own incomes we must exclude from all share in the emoluments of the profession the weaker half of the nation? This argument is revolting to every honorable mind, and I, for one, sincerely thank Mr. Balkwill for entering his protest against it; and I would strongly advise your correspondents "M.P.S." and "H. L.," unless they want to raise a *furore* in favour of women pharmaceutists, to abstain from using such arguments in future. The second ground of objection is scarcely more tenable, seeing the road to the profession is guarded by adequate examinations. If women are unable to pass these examinations, it is needless to forbid them to try; if any are able, it is unjust. We presume that every man, whatever his other qualities, who is able to pass these examinations, is fit to be a pharmaceutical chemist; what right have we to say that sex shall be the only disqualification for an otherwise qualified person? The only ground of objection, then, that can be seriously argued is the third. Monopolies of all kinds are opposed to the genius of the English constitution; but if the opponents of the admission of women to the profession can show that grave social or political evils will result from persons otherwise qualified, being allowed to practise pharmacy because they are females, their arguments must deserve the fullest consideration. At present I have met with none such, either in your columns or elsewhere. It is not proposed, as far as I am aware, to lower the standard of examination in order to let in women; and the argument of "H. L." on the ground of prescriptions for the cure of noisome diseases, falls to the ground as long as we employ female nurses in our hospitals and applaud the labours of a Florence Nightingale. Until such arguments are presented to me in a far more forcible way than they have been at present, I must heartily wish success to those who are endeavouring to break down these barriers, and to enable women to enter those fields of usefulness for which they themselves believe they have a vocation.

London, March 17th. Outsider.

Sir,—As the question of woman's rights in general, and her pharmaceutical rights in particular, have long been, and are likely yet to be, abundantly discussed, with more benefit, perhaps, to the printer than to the interesting object herself, I beg leave to request the favour of your publication of my reflections thereon, in her own best interests.

Sober-minded men ask themselves the cause of the restless agitation and unsatisfied hankering after the fruit of forbidden knowledge, which stamp the female tastes of the present day. We remember that our mothers "cared for none of these things;" and yet they succeeded in life precisely where their daughters have failed. They understood the secret of woman's influence and success, and they were content to work it out *at home*, to their own honour, and to the comfort of those about them. Their daughters despise their ways, and they reap a reward accordingly in blighted hopes. These offer poor encouragement to young men to select them for partners in life, and in their vexation they dare their opposition as competitors in business. Defeat is, of course, the foregone issue.

If woman would only devote herself to that which is, above all else, *woman's speciality*, the art of making man happy and home comfortable, then the old demand for her would be revived; her faculties would find their true, ample, and congenial sphere; and her reward would be great in this life, and, it may be, in that also which is to come. If, on the other hand, she will venture beyond her depth, then both the substance and the shadow of her happiness will be alike lost to her.

Thomas Saunders.

30, *Conduit Street, Bond Street.*

"*An Old Girl*" is thanked for her communication, but we think sufficient space has already been given to our rhyming friends.

A. G.—We do not know that any reaction would take place under the circumstances.

G. T. Green.—Christison's work on Poisons, or Taylor's 'Medical Jurisprudence.'

J. C.—(1) The Latin portion of the Preliminary Examination includes "translation into English of a paragraph from the first book of Cæsar ('De Bello Gallico'), or a passage from each of the following works: Pereira's 'Selecta è Prescriptis,' and the last edition (Latin) of the 'London Pharmacopœia.'" (2) The regulation concerning the metric system of weights and measures comes into force on the 1st October, 1874.

T. R.—"Cinnabar of Antimony" is a synonym of Mercuric Sulphide.

Sunday Closing.—"*An Assistant*" writes complaining of the practice adopted by some chemists and druggists of keeping the door-shutter down on Sunday and a light burning in the shop during the evening of that day, as one justified neither by poverty nor necessity. He asks whether steps cannot be taken to enforce Sunday closing.

W. B.—The plan you mention might answer the purpose, but for several reasons it would be inadmissible.

Communications, Letters, etc., have been received from Mr. Andrews, Mr. Pocklington, Mr. Hutchinson, Mr. Webb, Mr. De Lancy (Paris), Mr. Mumbray, Mr. Taylor, Mr. Jackson, "Combustion," "Clodhopper," "Glycerine."

DOES PERSIAN AMMONIACUM CONTAIN SULPHUR?

BY JOHN MOSS, F.C.S.,

Demonstrator in the Laboratory of the Pharmaceutical Society.

No one consulting the various works on materia medica for an answer to this question would feel very well satisfied at the close of his search. Some of them make no reference to sulphur, whether present or absent; others affirm decisively that it is *not* present, leading to the inference that there are yet others who affirm that sulphur *is* present. The doubt that has existed on this point seemed so easy to be resolved, that one wonders why it has not led to special and conclusive experiment before now. At the suggestion of my friend Mr. Hanbury, I undertook to make such experiment, and now publish the result.

Assuming that sulphur, if present in ammoniacum, existed in combination, forming a sulphur oil as in assafœtida, the readiest plan for its detection which presented itself, was to oxidize with nitric acid and test for sulphuric acid; but the difficulty of obtaining nitric acid free from traces of sulphuric, led me to prefer the use of pure nitrate of potassium.

Process:—Eight grammes of the pure nitrate were brought to a state of tranquil fusion in a platinum capsule supported over a Bunsen flame by an iron plate having an orifice in the centre. This plate extended round the capsule for a distance of four inches from the edge, so as to prevent sulphurous gases from the flame passing so near to the contents of the capsule as to be absorbed. The nitre being in this condition, ammoniacum, from carefully scraped tears of the largest and purest kind, was added little by little to the extent of about one gramme. When the action had ceased, the lamp was first removed, and then the capsule was turned round obliquely so that the fused contents should solidify in a thin crust over the sides, and so be more rapidly dissolved away by the water which was subsequently added. During the action of the fused nitre on the ammoniacum, a quantity of tarry matter condensed on the inner edge of the capsule where it was not in contact with the flame, and as it was found to be impossible to burn away this tarry matter without introducing sulphur, it became necessary to remove it from the aqueous solution by filtration. The filter employed was washed with acidulated water, and the washings examined with nitrate of barium. A solution being thus obtained presumably holding, in the form of sulphuric acid, whatever sulphur was present in the ammoniacum, a second solution was prepared in a precisely similar manner, with the important exception that no ammoniacum was used. The two solutions were placed side by side in beakers of equal size, and now a few drops of barium nitrate solution were added to each, and the beakers covered; at the end of three days no precipitate had appeared in either. To prove that the test was delicate enough, two drops of a liquid containing 1 in 300 of sulphuric acid were added to the contents of each beaker, and in a few minutes, three at the most, there was a marked turbidity produced in each. In a few hours a white film covered the bottom of each beaker.

This experiment, *one of nine*, demonstrates the fact that ammoniacum contains no sulphur.

Conditions necessary to secure the above result:—

1. The reagents and apparatus employed must be free from sulphuric acid.
2. The operation must be conducted in an atmosphere free from sulphuretted hydrogen and other sulphurous gases—a condition not easy to be attained in the laboratory, save in the early morning, before general work commences, at which time the fusions spoken of were made; even an additional lamp burning in the fume closet where the operation was conducted, seemed to affect the result.
3. The gas flame employed must not come in contact with the edge of the capsule.

A strip of silver leaf partially immersed in an emulsion of ammoniacum is not darkened after many days.

THE MICROSCOPE IN PHARMACY.

BY HENRY POCKLINGTON.

Continued from p. 703.

Ulmi Cortex.—As generally met with in commerce, the thickness of this bark very greatly exceeds the $\frac{1}{24}$th of an inch allotted to it in the B. P. description, but this is a matter of secondary importance, as the astringent principles are quite as present in the thicker as in the thinner specimens. It is an easy bark to examine, and will not present any features of special interest. The details of structure are best studied in ordinary transverse sections and in vertical sections cut parallel with the surface, and, therefore, cut across the medullary rays.

Seen in cross section the tissues may be grouped in three divisions: liber cells, either isolated or in twos and threes; the oblong thin walled cells of the medullary rays; and irregularly sized and shaped thin walled parenchymatous cells, amongst which the liber tubes are distributed with an apparent attempt at regularity. The medullary rays alone can be best studied in transverse sections, and are most easily examined in carefully stained specimens. In a well prepared logwood stained section the nature of the cell wall and the cell contents, with nuclei, etc., can usually be seen with a comparatively low power. As also the liber cell-structure may be best studied in similar sections from which the greater portion of the staining fluid has been removed by the aid of hydrochloric acid, the colour being subsequently redeveloped by ammonia. But the general arrangement of the liber tubes, with relation to the other tissues, can only be studied in vertical sections, and preferably in thin sections that have been treated with dilute solution of caustic soda or potash, and very slightly stained with magenta. The liber is seen to be very fibrous, almost cordlike, and is sufficiently tough to permit of easy separation from the other tissues. Two or three liber cells would appear to lie side by side in the normal state; medullary rays, composed of a considerable number of cells, passing between the fibres, force them into, what is seen in cross section to be, a loop or mesh of a net-work of vessels, the fibres intimately cohering again after they have encircled the ray. Some of the liber cells bifurcate, and, after having run some distance, unite by an imperfect natural graft (anastomose is hardly the word) with their neighbouring liber cells. They are imperforate and devoid of any other contents than fluid, which appears to possess in small degree the astringent properties of the bark.

In the cells of the parenchymatous tissue, which does not itself require other notice, and lying chiefly alongside the liber cells, are great numbers of small crystalline bodies, irregularly prismatic in shape and intensely doubly refractive. They are precisely similar to the crystals found in the testa of the seed, and figured by Quekett in his "Lectures on Histology" as a typical form of this particular "raphide." The liber cells are also very doubly refractive, and a carefully mounted section (in balsam) forms a very effective polariscope object, and admirably adapted for exhibition at "Chemists' Association Soirées."

Quercus Cortex.—The structure of this bark is somewhat complex, and requires considerable skill in the use of reagents to avoid errors of interpretation. Not itself adulterated, it plays sometimes the part of an adulterant, and on this account it is desirable that we should make ourselves familiar with its structure. To fully describe every detail of its structural element would occupy considerable space, and prove tedious to most. It will perhaps suffice if I indicate the more important points, and the mode of their demonstration. The general tissues of the outer barks do not differ greatly from those of other barks. Certain sclerogenous cells aggregated in groups of a dozen or more, and liber tubes are alone of importance. Many of these hard cells or "stellate cells" are of abnormal form, and will strongly remind the diatomist of the well-known campylodiscus. They are porous, their pores being of two characters, one very minute, the other large and bifurcate. The central cavity is frequently large and filled with a nitrogenous substance, probably the original cell substance, that stains intensely with magenta. The large, bifurcate pores also frequently stain, and then remind one forcibly of Dr. Beale's celebrated drawing of the capillary exudation of fluid bioplasm through the cell walls of Torula, but it is not easy to believe that these excessively hard cells can be sufficiently alive and active to manifest such a phenomenon, and it is much more probable that the staining of these pores is purely mechanical. At the same time it must be mentioned that the whole bearing of the central cavity and these stained pores towards reagents is that of active, living bioplasm. The question, however, is one hardly suited for discussion here. The stellate cells now spoken of differ widely in size, and are also found singly amongst the cells of the outer barks. They are easily recognisable in the powdered bark, and are very well shown by Dr. Hassall in his "Adulterations Detected," where typical cells only are shown. Their form is much more varied than is indicated in that work.

The inner bark is the most interesting and the most difficult. It can only be studied in very carefully cut sections stained with magenta or with solution of indigo (B. P.). The chief difficulty in the examination is caused by the great variety of cells present, and by the fact that these are in all stages of development. A well stained (indigo) section, shows the relations of the cell contents to the cell wall very beautifully, and also demonstrates very admirably the various germinal cells of the new bark. The liber tubes are best studied in radial sections (sections cut downwards and parallel with the surface) very slightly stained after slight washing in dilute liquor potassæ. And in this portion of the bark lies a *pons asinorum*, which cost me considerable trouble to cross. The liber cells themselves do not differ from ordinary liber to any extent, but with these are rows of somewhat globose cells, very inaccurately depicted in the drawing in Dr. Hassall's book, where they are shown as long cells —longer than the liber cells, with internal septa. This is exceedingly wide of the truth, the fact being that the length of these cells does not exceed the width of the liber cells, and that their contents are not granular or chlorophyllian, but crystalline and fluid. The error has evidently arisen from not using reagents. A simple section examined in water or glycerine does look somewhat as shown, and specimens of the powdered bark similarly examined are seen to contain similar structures.

These cells are exceedingly interesting and characteristic. Their walls are thin, beautifully transparent, and imperforate. They contain only fluid, and, each cell, a single flat four or six-sided prismatic crystal, beautifully doubly refractive and consisting of some salt of lime. A carefully made section, washed with dilute potash and alcohol, and mounted in glycerine, at once shows the true nature of the tissue, and is also a very splendid object (of doubtful permanence) when examined by polarized light. Stellate cells are also found with the liber, and but somewhat rarely, embryo vessels, or cells partaking of the first stage of the characteristic vessels of the oak.

A thin transverse section of the bark, stained with dilute perchloride of iron, shows the whereabouts of the astringent principle of the bark very successfully. In such a section the liber cells are seen to be wholly unstained, whilst the parenchymatous cells and the cells of the more purely cellular tissues are stained a deep blue-black. The stellate cells also, as a rule are not stained. The contents of the central cavity of the liber cells stain always, but the contents of the stellate cells either do not stain or not so deeply. This observation, it may be remarked, requires careful use of a moderately high power on a very successfully prepared section. This use of ferrous salts gives rather divergent results from the results of chemical analysis of the different portions of the bark. For whereas the outer barks are said to be comparatively inert (as regards tannic acid), the whole of the sections that I have examined show large quantities present in the mesophlœum cells,—weight for weight far larger quantities than in the liber region proper, if depth of colour produced may be taken as a guide. It is quite possible, and, indeed, likely, that in the outer regions the acid may not be so easily removed from the tissues, and therefore those portions may be of less economic value.

(*To be continued.*)

FALSE CHINA ROOT.

BY E. A. WEBB.

At the weekly drug sales on the 6th inst., there was offered, among other things, by public auction, a parcel that was described as China Root, but which in reality was nothing more than that curious fungoid production that has been named *Pachyma cocos*, a full description of which may be found in a paper, illustrated by very truthful engravings, in the "Linnæan Transactions," vol. xxiii. page 94, also in the Pharmaceutical Journal, in a paper entitled "Notes on Chinese Materia Medica," by Mr. Daniel Hanbury.

Mr. Hanbury there describes this drug (for so it may be called) as resembling "large ponderous rounded tubers, having a rough blackish-brown bark-like exterior, and consisting internally of a compact mass of considerable hardness, varying in colour from cinnamon brown to pure white." He tells us they are found attached to the roots of fir trees, or sometimes buried in the ground in localities where firs no longer grow.

They seem to occur in South Carolina, and parts of China and Japan.

That these are not tubers, but the production of a fungus, there seems to be but little doubt, as they contain no trace of starch, but when examined under the microscope are found to consist of what appears to be a mass of mycelium.

Dr. Macbride states that this *Pachyma* originates between the wood and the bark of the living roots; that it gradually detaches the bark while it spreads round the wood, and converts it into a substance similar to itself.

It is curious that, as the old writers and naturalists considered this production to be a species of China root, it should now be offered on our market as the same thing—the first time of its appearance in commerce in this country. Like many other strange things that from time to time are offered at our sales, it has probably been sent over here to see if there is any use for it, and, not being taken up by the medical profession or the trade, will probably never appear again for some years.

But from accounts which have been published of this *Pachyma cocos*, it is by no means without its medicinal and economic value. In China it is used in a variety of complaints, and made into edible cakes, which are offered for sale in the towns. In America it has also been used as an article of food, and hence derived the name of Indian Bread, by which it is there known.

It may readily be distinguished from true China root by its general appearance, and by its containing no traces of starch. In fact, it is difficult to understand how it could ever be mistaken for it.

EXAMINATION OF CITRATE OF IRON AND QUININE.

BY A. W. GERRARD,

Pharmacist, Guy's Hospital.

Eight samples of citrate of iron and quinine were obtained from various sources and different makers, for the purpose of ascertaining whether they contained the percentage of quinine directed to be obtained by the B.P., thus:—"Fifty grains dissolved in a fluid ounce of water and treated with a slight excess of ammonia, give a white precipitate, which, when collected on a filter and dried, weighs eight grains."

No.	Weight taken.	Weight of Precipitate.
1	50 grains	6 grains
2	"	2·5 "
3	"	5 "
4	"	8 "
5	"	4 "
6	"	8 "
7	"	6 "
8	"	4·5 "

These results show that there is great variation in the strength of this preparation: a prescription prepared with number six would contain more than three times as much quinine as that dispensed with number two. This may in some measure account for cheap dispensing. The sale of these lowered preparations is unjust and dishonest, for the prescriber is deceived, and the progress of the patient retarded, for no other purpose than increasing the gains of the seller.

On reference to wholesale price lists, I observe that some of them quote three qualities, each I suppose containing variable quantities of quinine, one perhaps B.P., two undoubtedly lowered, and therefore not "legal pharmaceutical preparations," although they are sold by the same name as the legal. Now it may not have occurred to those who sell and dispense these cheap preparations, that they render themselves liable to a prosecution under the "Adulteration Act;" yet such is the fact, and it requires their serious consideration and attention, especially as those upon whom the working of the Act devolves are not at all inclined to view the retailer as innocent; they argue that he should have that knowledge of his business which will enable him to test and judge of the purity and strength of all preparations which have a definite standard.

[As an appendix to the foregoing may be quoted from the *New York Druggists' Circular* some remarks of Mr. P. W. Bedford, who has recently had occasion to inquire into the respective value of six different specimens of this preparation, obtained from as many prominent American manufacturers. With the exception of one (which probably was made strictly by the formula of the U.S.P.) the specimens were of the variety which is soluble in cold water, the scales being of a greenish golden yellow colour, and somewhat deliquescent, and containing more or less citrate of ammonia.

One hundred grains of each specimen were dissolved in water, in a test-tube, to which first ether, and afterward water of ammonia in slight excess were added, the ethereal solution was poured into a small porcelain capsule which had been previously carefully tared, and after another portion of ether had been shaken with the solution in the tube and decanted into the capsule, it was set aside to allow the ether to evaporate. Exposure to a temperature of 120° F. for a few moments completed the drying. The increase in weight gives the amount of quinia present. Three experiments were made with each specimen, and the result is as follows:—

The weight of quinia obtained from 100 *grains of the salt, in grains and tenths of a grain:*—4·3—8·2—10·0—11·5. One specimen contained quinia 10 grains and cinchonia 2 grains, and another specimen contained quinia, 7·7 grains, cinchonia, 1·5 grains.

As this salt is a specimen of many others in which neither price nor appearance is any guide to the quality, we have been particular to give the mode of examination. If in applying this test there should be an insoluble white powder in a stratum between the ethereal and the watery solutions, it is cinchonia, and the amount may be found by carefully collecting it on a tared filter, and weighing.

The weights given above are of the simple alkaloid quinia, not the citrate. As the combining equivalent of citric acid free from water is 165, and quinia 324, the amount of citrate of quinia present is about 50 per cent. greater than the amount of quinia given as the result of the above assays—the sample assaying 11·5 of quinia having 17·39 of citrate of quinia.]

CHURRUS.

BY JOHN R. JACKSON, A.L.S.,

Curator of the Museums, Royal Gardens, Kew.

Three well known products of the Hemp plant (*Cannabis sativa*) are known in India as Gunja, Bhang, and Churrus: the first being the dried flower branches pressed together while in a fresh state, and used for smoking like tobacco; the second, the leaves and capsules, from which an infusion or intoxicating drink is made; and the third, a kind of an earthy resin, which is always described as the most powerful of all. Churrus varies, however, in quality, three or more kinds being known: the first or highest quality occurring in large irregular lumps, the second in smaller lumps, and the third in finely broken pieces, with a large proportion of dust. All these have a more or less earthy fracture, but there are two small samples in the Kew Museum which have been apparently moulded by pressure into hard and compact masses, each about two inches long, and about half as thick again as a man's thumb, rounded at each end, and which have a somewhat greenish fracture, and a perceptible odour of musk. Whether this has been imparted to them in the course of preparation, or by contact with other articles, I am not able to say. The specimens formed part of the collection of the Medico-Botanical Society of London, and were obtained for the Kew Museum in 1853, since which time they have been kept in a glass jar, separate from other specimens, sufficient time, one would think, for them to lose any perfume not actually incorporated into their substance. Churrus is said to be seldom or never the pure resin as it exudes from the leaves, stems, and flowers of the hemp plant, so that it is not improbable that musk may sometimes be mixed up with it. And, as a further proof of the system of adulteration, the following fact may also be stated:—Amongst some fruits, seeds, and other botanical specimens recently received at the Kew Museum from Yarkand, were some of the mealy fruits of the Trebizonde date (*Elæagnus hortensis*). The information which accompanied them was to the effect that the tree was cultivated for the sake of the fruits, which were largely consumed as food, and were carried in quantities in caravan journeys. The wild fruits, however, are not eaten, but the meal obtained from them is used entirely to adulterate Churrus. In India the hemp is an officinal plant, its principal use being in tetanus, hydrophobia, and neuralgia, in its various forms; but it has also been used, it is said, with success in such diseases as cholera, rheumatism, asthma, and some phases of skin disease. It is applied in the forms of extract and tincture, and has been recommended for use in this country. In the Indian Pharmacopœia are some remarks by Sir Robert Christison, who speaks of it not only as an excellent substitute for morphia, but as being suitable in cases where morphia could not be applied, or was objected to by the patient. He further says, he has "long been convinced, and new experience confirms his conviction, that for energy, certainty, and convenience, Indian Hemp is the next anodyne, hypnotic, and anti-spasmodic to opium and its derivatives, and often equal to it." All the products of the hemp are, however, so much adulterated, that the difficulty seems to be in obtaining Gunja of good quality from which to prepare the extract, which Sir R. Christison considers the best of all forms in which it can be used.

Under the name of "Majoon," a compound is used in India composed of Bhang, butter, sugar, flour, and milk.

FERROUS MANNATE.

BY M. GHYSEN.

The author has reported to the Medical Society of Liége the result of some experiments he has made to obtain a preparation of iron in the ferrous state which could be kept without undergoing change, and in which he used manna as a preservative agent. The method adopted was as follows:—75 grams of pure crystallized sulphate of iron was pulverized and mixed intimately with 100 grams of manna in tears. 80 grams of solution of ammonia (sp. gr. ·905) was then added, and the mass rubbed up so as to obtain a thoroughly homogeneous mixture. To this was added, a little at a time, 130 grams of alcohol (94°), which mixture separated clearly into a soft mass and a supernatant ammoniacal liquid that was rejected. The residue was again washed with 130 grams of fresh alcohol, and the product afterwards dried quickly and pulverized. The liquors rejected weighed together 310 grams. The quantity of ferrous mannate so produced consisted of 125 grams of a beautiful green powder, entirely unalterable in the air. The powder, suspended in water, coloured it green without dissolving, and the liquor passed through a filter colourless. Nevertheless, directly the iron entered into solution it oxidized with great rapidity, turning the liquor yellow, and showing that water acts injuriously by causing the iron to pass into the higher state.

Ammonia was used in preference to potash or soda, in order easily to eliminate by evaporation the excess of alkali, and so obtain a product composed entirely of manna and iron. As a ferruginous preparation, M. Ghysen believes the mannate, in regard to the quantity of active principle it contains, to be one of the richest. It may be administered in powder, in doses of from a few centigrams to a gram, or in pills. The following formula he has found to yield a good result:—

Ferrous Mannate, in powder . .	10 grams
Water	150 "

Make into pills of 20 centigrams.

He states that the mass is hard, but may be rolled and divided with facility, while the pills keep perfectly without being coated.

THE DISCRIMINATION OF GOOD WATER AND WHOLESOME FOOD.*

In the second of a course of lectures on sanitary science now being delivered weekly in Dublin, under the auspices of the Royal Dublin Society, Dr. Emerson Reynolds said that the impurities often present in water used for drinking purposes, and the numerous adulterations to which articles of food are liable, have frequently formed subjects for able and interesting discourses. Most of these objec-

* Printed, but not published, by Thom and Co., Dublin, for H. M. Stationery Office; from the *London Medical Record*.

tionable bodies can only be *identified* by the chemist and microscopist; but it is often possible by very simple means to ascertain whether or not a particular article is impure or adulterated—whether it exhibits the characters that serve to distinguish the substance, though it is not possible to name the particular impurity or adulterant without the possession of that "competent medical, chemical, and microscopical knowledge" required by the Adulteration Act. Information of the first kind should be possessed by every medical man, and even by the head of every household, and the lecturer's aim was to afford as much of this class of information as happens to be available at present. The chief subject-matter of the lecture is condensed in the following short notes; but mention is therein made only of the more important articles of food, excluding most of the so-called condimental foods on one hand, and alcoholic liquids on the other.

Potable Water.—Its impurities are mineral (lime and magnesia compounds, iron, sulphuretted hydrogen, etc.), and organic "sewage contamination," including animal and vegetable nitrogenous matter, either capable of, or in process of decomposition, and the products of such change). *Good water* should be free from colour, unpleasant odour and taste, and should quickly afford a good lather with a small proportion of soap. If half a pint of the water be placed in a perfectly clean, colourless, glass-stoppered bottle, a few grains of the best white lump sugar added, and the bottle freely exposed to the daylight in the window of a warm room, the liquid should not become turbid, even after exposure for a week or ten days. If the water become turbid, it is open to grave suspicion of sewage contamination; but if it remain clear, it is almost certainly safe. We owe to Heisch this simple, valuable, but hitherto strangely neglected test. Frankland has shown that it is extremely delicate, and that the production of turbidity under the circumstances named is due to the minute quantity of phosphoric acid present in sewage.* The Vartry water, as delivered from the street mains in Dublin at present, withstands this test perfectly; but it often becomes very impure when allowed to pass through ill-kept cisterns.

Tea.—Adulterations. There are two chief classes of teas—the green and black varieties. Under the first head are included the Hysons, Twankay, and Gunpowder; and under black teas, Pekoe, Souchong, Congou, and Bohea Both classes are subject to many serious adulterations at the hands of the exporters, and again on arrival in Europe. Mixtures of different kinds of tea are legitimately made in the course of trade for the purpose of suiting special tastes; but inferior varieties are often dishonestly mixed with the more costly kinds in order to increase profits. Leaving aside the consideration of "tea-mixing," we find that to green and black teas have often been added the leaves of other plants. Those of plum, sloe, ash, willow, poplar, hawthorn, beech, plane, orange, elm, horse-chestnut, elder, and oak have been detected. These leaves are dried and prepared by roasting and "facing" so as to resemble genuine tea very closely. The product is sometimes called "Maloo mixture." Facing is used for the purpose of colouring the leaves and increasing weight. The bodies employed are china clay, gypsum, chalk, French chalk, black lead, Prussian blue, indigo, chromate of lead, carbonate, and even arsenite of copper, Venetian red, and fine white sand. The powders are attached to the leaf-surface by a convenient adhesive material. Spent (exhausted) tea-leaves are often dried, coloured with catechu and an iron salt, then faced, and the product mixed with good tea, "Maloo mixture," or Lie tea. The last-named substance is made up of the tea and other leaves, sand, or plaster of Paris, bound together by starch or gum, so as to form granular particles that can be "faced," so as to resemble black or green gunpowder. *Genuine Tea*, when placed in a muslin bag and kneaded in warm water for a few minutes should not give up any powder, quickly subsiding when the water is allowed to stand.

Coffee.—Adulterations. Chicory, acorns, sawdust, roasted roots of various kinds, and grain, tan, croats, lentil seeds, baked livers, Venetian red, burnt sugar. Admixture with chicory is allowable if the compound be truly labelled. *Genuine Coffee* should not cake when pinched between the fingers. When a little is thrown on cold water it floats, and very slightly tinges the water. Adulterated coffee sinks, and rapidly colours the water brown.

Cocoa. — Adulterations. Chicory, cocoa-husk, fats, starches, sugar, Venetian red, bole. *Genuine Cocoa* should not have a sweet taste, nor red colour. As much cocoa as can be piled up on a threepenny piece, when placed on a square of platinum foil, and strongly heated by a spirit-lamp flame should burn almost completely away, leaving a very minute quantity of reddish coloured ash.* The same remarks apply to *chocolate.*

Sugar.—Adulterations and Impurities. Fine white loaf-sugar is rarely adulterated, but coloured sugars sometimes contain chalk, sand, clay, starch, sugar, flour, dextrine, plaster of Paris: as impurities, fragments of cane, molasses, vegetable albumen, and sugar-mites or acari. *Good Sugar* should be free from the least bitter taste, and ought to dissolve completely in water. Loaf-sugar should give a perfectly clear and colourless solution; brown sugar, a clear but coloured liquid. If insects be present they float on the syrup, and appear as small specks, which can be easily removed for microscopic examination. *Bon-bons*, unless when mixed with harmless starch or injurious white or coloured mineral powders, produce clear solutions when dissolved in water. If any insoluble residue be left, the deposit should be allowed to settle, the liquid poured carefully off, and the powder collected, dried, and heated on platinum-foil. If white, and wholly combustible, it probably consists of starch. Chromate of lead (yellow), arsenite of copper (green), china clay and gypsum (white), and most other injurious mineral pigments, give insoluble and fixed powders. Sulphide of mercury or vermilion, though volatile when heated on platinum-foil, is easily recognised by affording a heavy red powder on treatment of the sweets with water.

Milk.—Adulterations. The chief is undoubtedly water; but skim-milk, annatto, brains, chalk, gum tragacanth, and other gums; sugar, decoction of white carrots, starch, and turmeric, are stated to be used occasionally. *Good Milk* should be free from acidity, and when allowed to stand in a vessel ought not to deposit solid matter. When placed in a tall graduated glass cylinder, it should throw up at least 10 per cent. of cream after standing for twelve hours. This is on the whole the least objectionable rough test that can be used.

Butter.—Adulterations. Water, much salt, starch, flour, dripping, and lard. *Good Butter* should not have a rancid smell. When a quantity is melted and poured into a small narrow phial, and the latter allowed to stand near to a good fire, the milky layer of water that falls to the bottom of the bottle should not form more than one-tenth of the total bulk of fluid. When the melted butter is poured off, the water should not strike a blue colour when shaken with a drop of tincture of iodine.

Bread.—Adulterants. Water, rice, potato, and other starches, salt, alum, bone-dust, clay, carbonate of magnesium, chalk, gypsum, and sulphate of copper; or impure from bad flour. *Good Bread* is sweet and agreeable to the taste. It does not present a mouldy appearance, and ought not to give a thick liquid when steeped in water. If bread become soft and sodden on standing, it is probably adulterated with rice. When a piece containing much alum is dipped in a very weak solution of the colouring matter of logwood, the bread is quickly dyed of a purple tint.

---

* The turbidity is caused by fungoid growths.

* The microscope is alone able to detect mixtures of many organic bodies, as starches, fats, chicory, etc., in this and other cases. The simple tests given usually serve simply to exclude injurious substances.

Good bread ought not to contain more than 38 per cent. of water, and should burn to a very minute ash when heated on platinum foil.

Flour (Wheaten).—Adulterants and Impurities. Rice, barley, dari, bean-flour, "cones" flour, Indian corn, rye, potatoes, alum, gypsum, clay, ergot, darnel. *Good Flour* should not be acid or musty, but ought to have a pleasant flavour. When a small quantity is burnt on platinum-foil (see Cocoa) a scarcely perceptible residue of mineral matter should remain. As flour containing ergot is poisonous, it is a matter of importance to be able to distinguish this dangerous product of disease in the wheat. We can accomplish this easily by shaking up the suspected flour with a mixture of one part of chloroform and six parts of strong spirit of wine. The ergot, if present in the flour, will float on the liquid and form a brown scum.

Arrowroot (West Indian). — Adulterants. Potato-starch, sago-meal, rice, gypsum, china clay, chalk. *Genuine Maranta Arrowroot* is a dull white powder, which crackles strongly and in a peculiar manner when pressed between the fingers. When mixed with twice its weight of strong hydrochloric acid, it yields an opaque jelly. Potato-starch, under similar circumstances, affords a transparent jelly. When burnt on platinum-foil, arrowroot should leave a scarcely perceptible residue if unadulterated with mineral powders. A fragment of iodine placed on a warm plate near to the sample, colours Maranta arrowroot chocolate brown, sago-starch yellowish, wheaten starch violet, and potato-starch a dull lilac colour.

Meat.—Beef: Mutton. Good meat should possess the following easily observed characters. 1. It ought to be of a full, slightly brownish, red colour; neither of a pale pink tint on the one hand, nor of a deep purple hue on the other. If pink, disease is indicated; and if purple, the animal has probably not been slaughtered, but has died with the blood in it, or has suffered from acute fever. 2. It should have a marbled appearance, from the ramifications of little veins of fat among the muscles. 3. It should be firm, and elastic to the touch, and should scarcely moisten the fingers. Bad meat is usually wet, sodden, and flabby, with the fat looking like jelly or wet parchment. 4. It should have little or no odour, and not disagreeable; for diseased meat has a sickly cadaverous smell. Any disagreeable odour is most easily detected when the meat is chopped up and drenched with warm water. 5. It should not shrink or waste much in cooking. 6. It should not become very soft and wet on standing for a day or so, but should, on the contrary, dry on the surface (Letheby).—*Pork*, if unsalted, should present the characters above stated; but the colour of the meat, if sound, is of very pale red tint. When infested by the dangerous parasite, trichina spiralis, the meat is usually of a dark colour. Unfortunately, the animal itself can scarcely be detected by the unaided eye; not so the cysticercus, or measle, whose little sac is often as large as a hempseed, and can be easily seen.—*Sausages* are liable to partial decomposition, and then become poisonous, from whatever kind of meat they may have been prepared. Good sausage-meat should be firm, not moist, gelatinous, and vesicular. It should be free from disagreeable smell and taste, and from acidity.—*Poultry.* It is unnecessary to say more under this head, than to point out that this class of meat should fulfil the conditions 4, 5, and 6, given above.—*Fish* should only be used when fresh, and this condition can be easily ascertained. Fresh fish is free from offensive smell, and the flesh is not soft or gelatinous. It may be well to mention that fresh salmon or trout should not only have the well-known pink-coloured flesh, but, when the finger is drawn quickly and firmly across the fish, the depression so caused ought to fill up quickly, find a corresponding elevation or ridge soon appear. Sea-ash is not tested in this way, but the rigidity of the fish is sufficient to indicate its fresh condition. The bright red colour of fish-gills is a sign of very little importance, as the gills are often artificially tinted.

Isinglass.—Adulterants. Though the best, or Russian isinglass, is an unimportant article of food, it may be well to mention that it is sometimes adulterated with gelatine and with inferior Brazilian isinglass. *Genuine Russian Isinglass* occurs in opaque white filaments, which do not become transparent when placed in water, nor do they swell to a material extent. Gelatine, on the contrary, becomes transparent, and swells considerably. Russian isinglass affords a firm, translucent jelly; the Brazilian variety, for corresponding weights of material and water, does not afford nearly so firm a jelly, and it is much more milky.

Vegetables and Fruit.—Under this head it is only necessary to say that these articles of food should be invariably used in a fresh and ripe condition. It is, however, often a matter of importance to be able to distinguish poisonous *Mushrooms* from those that are edible. It may be generally stated that mushrooms which have a disagreeable, styptic taste and a pungent smell should always be rejected. The edible mushroom used in this country has a white top and pink gills; as the fungus grows the gills change to a brownish or even nearly black colour. *Preserved Fruits*, etc., should not be eaten if mouldy or in a state of decomposition, as evidenced by effervescence or slight frothing, and an unusually acid taste. All preserves, if made in copper vessels, should be tested for copper by stirring a thick bright needle for some time through the preserve, mixed with a little warm water. If, after stirring and standing for an hour or so, the needle, on removal and rinsing with water, be free from any of the well-known reddish deposit of metallic copper, the preserve cannot contain any sensible quantity of the poisonous metal. The same test should always be applied to *Pickles.*

Vinegar. — Adulterants. Sulphuric acid, and other mineral acids, water, "grains of paradise," chilies, corrosive sublimate (?). Arsenic and copper as accidental impurity. *Unadulterated Vinegar* is allowed by special enactment to contain one-thousandth of oil of vitriol. When paper moistened with vinegar containing this proportion of sulphuric acid is dried before the fire, no charring takes place until the paper is rather strongly heated; but if the proportion of acid be much greater, blackening results before the paper seems quite dry. It must be remembered that this is but a very rough and indecisive test. When a piece of clean and bright copper wire is immersed in vinegar, diluted with a little water, and heated nearly to boiling in a glass vessel, the copper quickly loses its colour and assumes a leaden hue if arsenic or mercury be present. Copper may be detected in a fresh sample, much diluted with water, by means of the steel needle, as described under *Preserved Fruits.* Pungent substances, "grains of paradise," for example, may be detected by evaporating a quantity of the vinegar nearly to dryness in any convenient porcelain vessel. The residue should not have a fiery taste.

Mustard.—Adulterants. Ordinary mustard is rarely free from admixture with one or other of the varieties of flour, turmeric being added to improve the colour. The addition of flour in moderate proportion may be permitted on the score of convenience, but turmeric should not be added. For flour, china clay, plaster of paris, or chalk have been substituted, the colouring material being yellow ochre, or even the poisonous chromate of lead. *Mustard* should not become brown when moistened with a little "spirit of hartshorn," and when burnt on platinum-foil should leave but a small quantity of nearly white ash.

Cayenne Pepper.—Adulterants. Dense flours or starches, mustard, turmeric, ochre, vermilion (?), red lead. *Cayenne*, when shaken with cold water, the mixture allowed to stand for a minute, and the liquid poured off, should not leave any heavy red powder at the bottom of the vessel. It ought to leave but little ash when burnt on platinum-foil.

Cheese. — Adulterants and Impurities. Setting aside such colouring matters as annatto, saffron, &c., we find that the mineral pigments, Venetian red (red lead ?), are used, and various flours or starches to increase weight.

Cheese should not be eaten when in a mouldy condition, or when containing "jumpers." It ought not to become blue when touched with dilute tincture of iodine, and it should leave but little ash when burnt on platinum.

CHERRY JUICE.*

BY A. W. MILLER, M.D.

Large quantities of cherry juice are now imported from Germany into the United States, no less than 1500 casks, each containing from 150 to 200 gallons, being entered at the New York Custom-house within the year. This juice is chiefly manufactured in the vicinity of Magdeburg, by expressing the common black cherries cultivated there for the express purpose. In the United States it is principally used by the compounders of liquors; but the author believes that it could also be employed with advantage for pharmaceutical purposes.

Cherry juice is a richly-coloured, dark-red liquid, somewhat glutinous, but perfectly bright and clear. Its taste is rather pleasant, fruity, slightly acidulous, and somewhat alcoholic. Without the addition of sugar it is rather too sour to be agreeable as a beverage. The specific gravity of a specimen examined was 1·041, but this may vary materially.

The importers state that its alcoholic strength ranges from 10 to 15 per cent. In one gallon of it subjected to fractional distillation, the proportion of alcohol was about 12½ per cent., or one-eighth of the entire bulk. The above amount of alcohol seems to be sufficient to preserve the juice under ordinary circumstances, although it will occasionally ferment during the hot weather of summer, particularly when left in half-filled barrels.

As the importer's price for German cherry juice is usually rather less than one dollar (gold) per gallon, this low figure is one of its main recommendations. The small proportion of alcohol contained in the cherry juice connot be held to detract from its merits, as it can readily be expelled by heat. The fact of the juice being perfectly clear and transparent, so that it will mix in all proportions with syrupy and alcoholic liquids without producing the slightest turbidity, is another important point in its favour. Besides this, the juice is always ready for immediate use, requiring neither filtering, straining, nor any other troublesome and tedious preparation, and it is not near so liable to spoil as solutions of cochineal. Indeed, it will be very difficult to find any other article, by means of which an equally beautiful tint can be given to elixirs, Curaçoa cordial, or other elegant pharmaceutical preparations, in so convenient a manner.

Cherry juice seems also to be specially suited for the compound syrup of phosphates, with the colouring of which most manufacturers have heretofore had trouble. Used in the proportion of one ounce of juice in a pint of the syrup, it produces a brilliant claret-red colour, which is not affected by either muriatic or phosphoric acids, and which is neither precipitated nor bleached by exposure to the light. The fruity flavour imparted to the syrup, of course, is rather an advantage than otherwise.

Soda-water syrups, prepared from strawberry and raspberry juice, particularly when it is a year old, have often less colour than is desirable. While most druggists are reluctant to add anilin or any other artificial colouring matter, there can be no possible objection raised to the crimson-tinted cherry juice, about four ounces of which will be found to be sufficient to bring one gallon of strawberry syrup up to the proper shade. Professor Parrish, in his 'Practical Pharmacy,' even highly recommends the admixture of black cherries with raspberries in the preparation of the syrup; and the same suggestion occurs in several French works. For enriching the colour of raspberry syrup, eight ounces of cherry juice can be used advantageously to a gallon.

The following formulæ illustrate some additional applications of cherry juice. All of them have been thoroughly tested, and most of them have been in use for some time, having met with general approbation among the consumers:—

Cherry Soda Water Syrup.

German Cherry Juice	1 quart.
Water	1 quart.
Best Crushed Sugar	7½ lbs.
Citric Acid	½ oz.

Boil in a porcelain capsule and strain. This yields a finely flavoured and richly tinted syrup, which is much admired by the frequenters of the fountain.

Cherry Wine.

German Cherry Juice	3 quarts.
Grape Sugar Syrup	1 pint.
Simple Syrup	1 pint.

This furnishes a cheap, palatable, and gently stimulating beverage. Its taste resembles the best of the popular domestic fruit wines.

Cherry Jelly.

Gelatine	1½ drachm.

Wash with cold water, and add

White Sugar	1 ounce.
German Cherry Juice . . .	½ „
Boiling Water	5 ounces.

Stir until all the gelatine and sugar have been dissolved, and then set aside in a cool place to gelatinize. As a pleasant variation in the diet of invalids, this can be highly recommended. It is also occasionally quite acceptable as a dessert for the table.

Translated into the language of the kitchen, the above may be directed to be made by putting two heaped spoonfuls of gelatine into a coffee cup, washing it with cold water, adding a heaped tablespoonful of sugar and one tablespoonful of cherry juice, then nearly filling the cup with boiling water, and stirring until all is dissolved.

Imitation of the Syrup of Red Oranges of Malta.
(Sirop d'Oranges rouges de Malte.)

Simple Syrup	1 gallon.
Cherry Juice	6 oz.
Essence of Curaçoa orange (containing 2 oz. of oil in a pint) .	½ oz.
Citric Acid	1 oz.

The quality of this syrup depends almost entirely on the purity and freshness of the essence of Curaçoa, which is difficult to obtain of good flavour. The syrup itself should be made in small amounts, as it is liable to be changed to an unpleasant rancid flavour on long exposure.

Imitation Strawberry Syrup.

Simple Syrup	1 gallon.
Cherry Juice	4 oz.
Tincture of Orris Root . . .	1 oz.
Citric Acid	6 drachms.
Strawberry Flavour	3 „

Imitation Raspberry Syrup.

Simple Syrup	1 gallon.
Cherry Juice	8 oz.
Tincture of Orris Root . . .	2 oz.
Citric Acid	6 drachms.
Raspberry Flavour	3 „

The compounders of liquors use cherry juice chiefly, if not exclusively, for manufacturing cherry brandy (known also as cherry bounce or guignolet), blackberry brandy, and an imitation of port wine. For the benefit of those who may be desirous of knowing the composition of these fancy liquors, which have a large sale in the South, the following receipts are appended, which have been obtained from trustworthy sources:—

---

* Abstract from the *American Journal of Pharmacy* [4], vol. iii. p. 99.

Cherry Brandy.

Cherry Juice	15 gallons.
Pure Rectified Spirits . . .	20 ,,
Simple Syrup	5 ,,
Oil of Bitter Almonds . . .	1 drachm.

Rectified spirit is understood to be whiskey, which has been thoroughly deodorized by percolating through charcoal, and which is of first proof = 50 per cent. alcohol.

Blackberry Brandy.

Cherry Juice	3 gallons.
Pure Rectified Spirits . . .	25 ,,
Simple Syrup	5 ,,
Clear Water	5 ,,
Oil of Cinnamon	1 drachm.
Oil of Cloves	1 ,,

The oils are to be first dissolved in about a pint of alcohol, or high wine, and then to be mixed with the spirits before the addition of the other ingredients.

PROFESSOR TYNDALL ON LIGHT.*

(*Continued from p.* 750.)

In our last lecture we sought to familiarize our minds with the characteristics of wave-motion. We drew a clear distinction between the motion of the wave itself and the motion of its constituent particles. Passing through water-waves and air-waves, we prepared our minds for the conception of light propagated through the luminiferous ether. The analogy of sound will fix the whole mechanism in your minds. Here we have a vibratory body which originates the wave-motion, we have, in the air, a vehicle which conveys it, and we have the auditory nerve which receives the impressions of the sonorous waves. In the case of light we have in the vibrating atoms of the luminous body the originators of the wave-motion, we have in the ether its vehicle, while the optic nerve receives the impression of the luminiferous waves. We learned, also, that colour was the analogue of pitch, that the rapidity of atomic vibration augmented, and the length of the ether-waves decreased, in passing from the red to the blue end of the spectrum. The fruitful principle of interference we also found applicable to the phenomena of light; and we learned that, in consequence of the different lengths of the ether-waves, they were extinguished by different thicknesses of transparent films, the particular thickness which quenched one colour glowing with the complementary ones. Thus the colours of thin plates were accounted for.

But one of the objects of our last lecture, and that not the least important, was to illustrate the manner in which scientific theories are formed. They, in the first place, take their rise in the desire of the mind to penetrate to the sources of phenomena. The desire has long been a part of human nature. It prompted Cæsar to say that he would exchange his victories for a glimpse of the sources of the Nile; it may be seen working in Lucretius; it impels Darwin to those daring speculations which of late years have so agitated the public mind. We have learned that in framing theories the imagination does not create, but that it expands, diminishes, moulds and refines, as the case may be, materials derived from the world of fact and observation.

This is more evidently the case in a theory like that of light, where the motions of a subsensible medium, the ether, are presented to the mind. But no theory escapes the condition. Newton took care not to incumber gravitation with unnecessary physical conceptions; but we have reason to know that he indulged in them, though he did not connect them with his theory. But even the theory as it stands did not enter the mind as a revelation dissevered from the world of fact. The germ of the conception that the sun and planets are held together by a force of attraction is to be found in the fact that a magnet had been previously seen to attract iron. The notion of matter attracting matter came thus from without, not from within.

The general facts of magnetism are most simply illustrated by a magnetized bar of steel, commonly called a bar magnet. Placing such a magnet upright upon a table, and bringing a magnetic needle near its bottom, one end of the needle promptly retreats from the magnet, while the other as promptly approaches. The needle is held quivering there by some invisible influence exerted upon it. Raising the needle along the magnet, but still avoiding contact, the rapidity of its oscillations decreases, because the force acting upon the needle becomes weaker. At the centre the oscillations cease. Above the centre the end which had been previously drawn toward the magnet retreats, and the opposite end approaches. As we ascend higher, the oscillations become more violent, because the force becomes stronger. At the upper end of the magnet, as at the lower, the force reaches a maximum, but all the lower half of the magnet attracts one end of the needle, while all the upper half attracts the opposite end. This doubleness of the magnetic force is called polarity, and the points near the ends of the magnet in which the forces seem concentrated are called its poles.

What, then, will occur if we break this magnet in two at the centre? Will each of the separate halves act as it did when it formed part of the whole magnet? No; each half is in itself a perfect magnet, possessing two poles. This may be proved by breaking something of less value than the magnet—the steel of a lady's stays for example, hardened and magnetized. It acts like the magnet. When broken, each half acts like the whole; and when these parts are again broken, we have still the perfect magnet, possessing, as in the first instance, two poles. Push your breaking to its utmost limit; you will be driven to prolong your vision beyond that limit, and to contemplate this thing that we call magnetic polarity as resident in the ultimate particles of the magnet. Each atom is endowed with this polar force.

Like all other forces, this force of magnetism is amenable to mechanical laws; and knowing the direction and magnitude of the force, we can predict its action. Placing a small magnetic needle near a bar magnet, it takes up a determinate position. That position might be deduced theoretically from the mutual action of the poles. Moving the needle round the magnet, for each point of the surrounding space the needle takes a definite direction and no other. A needle of iron will answer as well as the magnetic needle; for the needle of iron is magnetized by the magnet, and acts exactly like a needle independently magnetized. If we place two or more rods of iron near the magnet, the action becomes mere complex, for then the iron needles are not only acted upon by the magnet, but they act upon each other. And if we pass to smaller masses of iron—to iron filings, for example—we find that they act substantially as the needles, arranging themselves in definite forms, in obedience to the magnetic action.

Placing a sheet of paper or glass over this bar magnet and showering iron filings upon the paper, I notice a tendency of the filings to arrange themselves in determinate lines. They cannot freely follow this tendency, for they are hampered by the friction against the paper. I help them by tapping the paper; each tap releases them for a moment, and enables them to follow their bias.

The aspect of these curves so fascinated Faraday that the greater portion of his intellectual life was devoted to pondering over them. He invested the space through which they run with a kind of materiality; and the pro-

* Abstract of a series of lectures delivered in the Cooper Institute, New York, and reported in the *New York Tribune*.

bability is, that the progress of science by connecting the phenomena of magnetism with the luminiferous ether, will prove these "lines of force," as Faraday loved to call the magnetic curves, to represent a condition of this mysterious substratum of all radiant action. But it is not with the magnetic curves as such that I now wish to occupy your attention; it is their relationship to theoretic conceptions that we have now to consider. By the action of the bar magnet upon the needle we obtain a notion of a polar force; by the breaking of the strip of magnetized steel, we attain the notion that polarity can attach itself to the ultimate particles of matter. The experiment with the iron filings introduces a new idea into the mind; the idea, namely, of structural arrangement. Every pair of filings possesses four poles, two of which are attractive and two repulsive. The attractive poles approach, the repulsive poles retreat; the consequence being a certain definite arrangement of the particles with reference to each other.

Now, this idea of structure, as produced by polar force, opens a way for the intellect into an entirely new region, and the reason I ask you now to accompany me into this region is, that our next inquiry relates to the action of crystals upon light. Before I speak of this action, I wish you to realize the process of crystalline architecture. Look then into a granite quarry, and spend a few minutes in examining the rock. It is not of perfectly uniform texture. It is rather an agglomeration of pieces, which, on examination, present curiously defined forms. You have there what mineralogists call quartz, you have felspar, you have mica. In a mineralogical cabinet, where these substances are preserved separately, you will obtain some notion of their forms. You will see there, also, specimens of beryl, topaz, emerald, tourmaline, heavy spar, fluor-spar, Iceland spar—possibly a full-formed diamond, as it quitted the hand of nature, not yet having got into the hands of the lapidary. These crystals, you will observe, are put together according to law; they are not chance productions; and if you care to examine them more minutely, you will find their architecture capable of being to some extent revealed. They split in certain directions before a knife-edge, exposing smooth and shining surfaces, which are called planes of cleavage; and by following these planes you sometimes reach an internal form, disguised beneath the external form of the crystal. Ponder these beautiful edifices of a hidden builder. You cannot help asking yourself how they were built; and familiar as you now are with the notion of a polar force, and the ability of that force to produce structural arrangement, your inevitable answer will be, that those crystals are built by the play of polar forces with which their ultimate molecules are endowed. In virtue of these forces, atom lays itself to atom in a perfectly definite way, the final visible form of the crystal depending upon this play of its molecules.

Everywhere in nature we observe this tendency to run into definite forms, and nothing is easier than to give scope to this tendency by artificial arrangements. Dissolve nitre in water, and allow the water slowly to evaporate; the nitre remains, and the solution soon becomes so concentrated that the liquid form can no longer be preserved. The nitre molecules approach each other, and come at length within the range of their polar forces. They arrange themselves in obedience to these forces, a minute crystal of nitre being at first produced. On this crystal the molecules continue to deposit themselves from the surrounding liquid. The crystal grows, and finally we have large prisms of nitre, each of a perfectly definite shape. Alum crystallizes with the utmost ease in this fashion. The resultant crystal is, however, different in shape from that of nitre, because the poles of the molecules are differently disposed; and if they be only nursed with proper care, the crystals of these substances may be caused to grow to an enormous size. The condition of perfect crystallization is, that the crystallizing force should act with deliberation. There should be no hurry in its operations; but every molecule ought to be permitted, without disturbance from its neighbours, to exercise its own molecular rights. If the crystallization be too sudden, the regularity disappears.

Water may be saturated with sulphate of soda, dissolved when the water is hot, and afterward permitted to cool. When cold, the solution is supersaturated; that is to say, more solid matter is contained in it than corresponds to its temperature. Still, the molecules show no sign of building themselves together. This is a very remarkable, though a very common fact. The molecules in the centre of the liquid are so hampered by the action of their neighbours that freedom to follow their own tendencies is denied to them. Fix your mind's eye upon a molecule within the mass. It wishes to unite with its neighbour to the right, but it wishes equally to unite with its neighbour to the left; the one tendency neutralizes the other, and it unites with neither. We have here, in fact, translated into molecular action, the well-known suspension of animal volition produced by two equally inviting bundles of hay. But if a crystal of sulphate of soda be dropped into the solution, the molecular indecision ceases. On the crystal the adjacent molecules will immediately precipitate themselves; on these again others will be precipitated, and this act of precipitation will continue from the top of the flask to the bottom, until the solution has, as far as possible, assumed the solid form. The crystals here formed are small, and confusedly arranged. The process has been too hasty to admit of the pure and orderly action of the crystallizing force. It typifies the state of a nation in which natural and healthy change is resisted, until society becomes, as it were, supersaturated with the desire for change, the change being then effected through confusion and revolution, which a wise foresight might have avoided.

Let me illustrate the action of crystallizing force by two examples of it: nitre might be employed, but another well-known substance enables me to make the experiment in a better form. The substance is common sal-ammoniac, or chloride of ammonium, dissolved in water. Cleansing perfectly a glass-plate, the solution of the chloride is poured over the glass, to which, when the plate is set on edge, a thin film of the liquid adheres. Warming the glass slightly, evaporation is promoted; the plate is then placed in a solar microscope, and an image of the film is thrown upon a white screen. The warmth of the illuminating beam adds itself to that already imparted to the glass-plate, so that after a moment or two the film can no longer exist in the liquid condition. Molecule then closes with molecule, and you have a most impressive display of crystallizing energy overspreading the whole screen. You may produce something similar if you breathe upon the frost-ferns which overspread your window-panes in winter, and then observe through a lens the subsequent recongelation of the film.

Here the crystallizing force is hampered by the adhesion of the film to the glass; nevertheless, the play of power is strikingly beautiful. Sometimes the crystals start from the edge of the film and run through it from that edge, for the crystallization being once started, the molecules throw themselves by preference on the crystals already formed. The solid chloride of ammonium possesses a power of provoking precipitation upon itself which is not possessed by the solid glass. Sometimes the crystals start from definite nuclei in the centre of the film; every small crystalline particle which rests in the film furnishes a starting-point. Throughout the process you notice one feature which is perfectly unalterable, and that is, angular magnitude. The spiculæ branch from the trunk, and from these branches others shoot; but the angles inclosed by the spiculæ are unalterable. In like manner you may find alum-crystals, quartz-crystals, and all other crystals, distorted in shape. They are thus far at the mercy of the accidents of crystallization; but in one particular they assert their superiority over all such accidents—angular magnitude is always rigidly preserved.

My second example of the action of crystallizing force is thus: By sending a voltaic current through a liquid you know that we decompose the liquid, and if it contains a metal we liberate this metal by the electrolysis. This small cell contains a solution of sugar of lead, and this substance is chosen because lead lends itself so freely to this crystallizing power. Into the cell dip two very thin platinum wires, and these are connected by other wires with a small voltaic battery. On sending the voltaic current through the solution, the lead will be slowly severed from the atoms with which it is now combined; it will be liberated upon one of the wires, and at the moment of its liberation it will obey the polar forces of its atoms, and produce crystalline forms of exquisite beauty. They are now before you, sprouting like ferns from the wire, appearing indeed like vegetable growth rendered so rapid as to be plainly visible to the naked eye. On reversing the current, these wonderful lead-fronds will dissolve, while from the other wire filaments of lead dart through the liquid. In a moment or two the growth of the lead-trees recommences, but they now cover the other wire. In the process of crystallization, Nature first reveals herself as a builder. Where do her operations stop? Does she continue by the play of the same forces to form the vegetable, and afterward the animal? Whatever the answer to these questions may be, trust me that the notions of the coming generations regarding this mysterious thing, which some have called "brute matter," will be very different from those of the generations past.

There is hardly a more beautiful and instructive example of this play of molecular force than that furnished by the case of water. You have seen the exquisite frond-like forms produced by the crystallization of a film of water on a cold window-pane. You have also probably noticed the beautiful rosettes tied together by the crystallizing force during the descent of a snow-shower on a very calm day. The slopes and summits of the Alps are loaded in winter with these blossoms of the frost. They vary infinitely in detail of beauty, but the same angular magnitude is preserved throughout. An inflexible power binds spears and spiculæ to the angle of 60°. The common ice of our lakes is also ruled in its deposition by the same angle. You may sometimes see in freezing water small crystals of stellar shapes, each star consisting of six rays, with this angle of 60° between every two of them. This structure may be revealed in ordinary ice. In a sunbeam, or failing that, in our electric beam, we have an instrument delicate enough to unlock the frozen molecules without disturbing the order of their architecture.

According to the emission theory, the velocity of light in water and glass is greater than in air; according to the undulating theory, the reverse is the case. This point has been subjected to the test of an experiment proposed by Arago, and executed by Foucault and Fizeau, and decided in favour of the undulatory theory. Whenever the two theories have come into collision this has been the result.

Consider a small portion of a wave issuing from a point of light so distant that the portion may be regarded as practically straight. Moving vertically downwards, and impinging on a horizontal surface of glass, the wave would go through the glass without change of direction. But, as the velocity in glass is less than the velocity in air, the wave would be retarded in passing into the denser medium. But suppose the wave, before reaching the glass, to be oblique to the surface; that end of the wave which first reaches the glass will be the first retarded, the other portions as they enter the glass being retarded in succession. This retardation of the one end of the wave causes it to swing round and change its front, so that when the wave has fully entered the glass its course is oblique to its original direction. According to the undulatory theory, light is thus refracted.

The two elements of rapidity of propagation, both of sound and light, in any substance whatever, are elasticity and density, and the enormous velocity of light is attainable because the ether is at the same time of infinitesimal density and of enormous elasticity. It surrounds the atoms of all bodies, but seems to be so acted upon by them that its density is increased without a proportionate increase of elasticity; this would account for the diminished velocity of light in refracting bodies. Now, in virtue of the crystalline architecture that we have been considering, the ether in many crystals possesses different densities in different directions; and the consequence is that some of these media transmit light with two different velocities. Now, refraction depends wholly upon the change of velocity being greatest where the density is greatest. Hence in many crystals we have two different refractions, a ray of light being divided by such crystals into two. This effect is called double refraction.

In water, for example, there is nothing in the grouping of the molecules to interfere with the perfect homogeneity of the ether; but, when water crystallizes to ice, the case is different. In a plate of ice the elasticity of the ether in a direction perpendicular to the surface of freezing is different from what it is parallel to the surface of freezing; ice is, therefore, a double refracting substance. Double refraction is displayed in a particularly impressive manner by Iceland spar, which is crystallized carbonate of lime; the difference of ethereal density in two directions in this crystal is very great, the separation of the two halves of the beam being, therefore, particularly striking. Upon the screen is now projected an image of our carbon points. Introducing the spar, I permit the beam which builds the image to pass through it; instantly you have the single image divided into two others. Casting upon the screen an image of the aperture through which the light issues from the electric lamp, and introducing the spar, two luminous disks instead of one appear immediately upon the screen.

The two beams into which the spar divides the single incident-beam do not behave alike. One of them obeys the ordinary law of refraction discovered by Snell, and this is called the ordinary ray. The other does not obey the ordinary law. Its index of refraction, for example, is not constant, nor do the incident and refracted rays always lie in the same plane. It is, therefore, called the extraordinary ray. Pour water and bisulphide of carbon into two cups of the same depth; looked at through the liquid, the cup that contains the more strongly-refracting liquid will appear shallower than the other. Place a piece of Iceland spar over a dot of ink; the two dots are seen, but one appears nearer than the other. The nearest dot belongs to the most strongly-refracted ray, in this case the ordinary ray. Turn the spar round; the extraordinary image of the spot rotates round the ordinary one.

The double refraction of Iceland spar was first treated of in a work published by Erasmus Bartholimus, in 1669. The celebrated Huyghens sought to account for the phenomenon on the principle of the wave theory, and he succeeded in doing so. He made highly important observations on the distinctive characters of the two beams transmitted by the spar. Newton, reflecting on the observations of Huyghens, came to the conclusion that each of the beams had two sides; and from the analogy of this two-sidedness with the two-endedness of a magnet, wherein consists its polarity, the two beams came to be described as polarized.

(*To be continued.*)

SYRUP OF LACTO-PHOSPHATE OF LIME.

Take of Chloride of Calcium . . . ℥i
Phosphate of Soda . . . ℥iv
Concentrated Lactic Acid . ℥i.

Dissolve the chloride of calcium and phosphate of soda separately, and mix the solutions; wash the precipitate and dissolve in the acid. Filter and mix with sufficient syrup to make two and one-half pints.—E. CHILES, *in American Journal of Pharmacy.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE BENEVOLENT FUND.

NOTWITHSTANDING the whirl and din arising from conflicts between chivalric feminine advocates and "benighted obstructives," added to denunciations of alleged excessive examination fees, lamentations because of long hours and low prices, and endless discussions about education, examination, cramming, crammers, and a host of other subjects, there is one question that is always put forward in these columns in the same spirit, and that is, How the pharmaceutical world may best deal with its heritage of poor and distressed brethren. Common ground this, where friendly rivals strive for the same goal. The Pharmaceutical Benevolent Fund is enriched alike by the gifts of the prosperous few and of the many who, to judge from their own reports, are compelled to "live upon their losses," and the desire of all is that the money given shall be funded or spent so as to do the greatest good to the greatest number. It therefore needs but little excuse to draw attention to some remarks that appeared in our correspondence columns last week, and are reiterated this week by other writers.

Fifteen months since Mr. STEVENSON called attention to the fact that the income for the year 1871 did not represent one shilling per annum from each of the twelve or thirteen thousand chemists and druggists upon the Register, and he urged that an effort should be made to render the interest in the Fund more general. Shortly afterwards Mr. SCHOLEFIELD gave as his reason for not subscribing to the Fund, that the subscriptions were invested instead of being spent, and said he considered that the reserve fund ought not in such a Society to exceed the amount of five years' expenditure, and that, with the exception of large sums arising from legacies and special donations, the whole of the yearly income should be divided amongst the deserving applicants for relief. The fact that those who criticize do not subscribe does not invalidate the claims of their suggestions to careful consideration, to see whether it be possible, by a removal of any defects in administration, to secure a more general response to the appeal for more funds.

What proportions, then, should the funded capital, the year's income, and the year's expenditure bear to each other? With upwards of £13,000 invested in the Consols, is it advisable that in future the expenditure in the shape of grants should more nearly balance the income, or should the operation of the fund be restricted to its present extent until a larger reserve fund has been accumulated? The question has been propounded before, but has not yet received an authoritative and decisive answer; and yet it is one of considerable importance in its influence upon the future of the Fund.

Probably a principal reason for the existing uncertainty is the equal indefiniteness of ideas as to the ultimate limits and nature of the relief to be given. The donor of a guinea, who complains that little more than sixpence of his money is spent, while the remainder is put by for the benefit of posterity, has some plausibility and reason in his complaint; but it is not to be forgotten that the sixpence is spent yearly, and that it will be required yearly, if the relief takes the form of an annuity. This is shown by the fact, that the interest on the funded property is but little more than sufficient to meet the engagements already incurred in the shape of annuities, leaving the fresh income available for temporary grants, and to form the nucleus for future annuities.

Still it may be that there are some who would prefer that their subscriptions should be bestowed immediately, and the suggestion of our correspondent that there should be two classes of subscriptions is therefore worthy of the attention of the Council. But that, even with this opportunity, the time will ever come when every pharmaceutical chemist will be eager to subscribe his guinea, and every chemist and druggist his five shillings, our knowledge of human nature forbids us to hope, however much we may desire it. For notwithstanding the efforts that have been and are continually made to explain to the whole trade the nature of the Benevolent Fund, there are many persons who still fail to comprehend its true character, to say nothing of the percentage who always ignore such things until they are open to receive a service from them.

Nevertheless, much more can be done than at present is done; and if any of our readers who do not subscribe should feel disposed to forward subscriptions with an intimation of their wish that the money should be spent at once, we have as little doubt that their wish will be complied with, as that the Council will find objects for its proper disposal. Mr. BRETON, however, suggests visions of homes for those whose

"Length of life is length of woe,"

and schools for those who, like the proverbial bear, have all their troubles to come. To these forms of benevolence may be added the proposition of those who think that much expensive machinery may be saved and an objectionable pauperizing influence avoided, by giving to widows of deceased chemists and druggists,—who may have been left in straitened circumstances but not sufficiently so to induce them to come, as it were, *in formâ pauperis* upon the Fund,—assistance in providing a sound education for their children without taking them from their own homes. For such ends not only will a large increase of spending money be required, but also a considerable augmentation of the reserved funds. So that there is plenty of work cut out for the advocates of both plans.

CONTINENTAL EDUCATION.

Foreign travel, according to Lord Bacon, is the appropriate *finale* to a course of education at home, It "crowns the edifice" of culture. It adds a grace and a harmony to the solid substructure of native discipline. In a profession cognate to our own—that of medicine—nothing is more usual, nothing more advantageous, than to supplement English training by a visit to foreign schools. Why should not the young pharmacist more frequently go and do likewise? The "provinciality" engendered by our insular life and traditions is common to all our professions, and receives its proper corrective by a well-devised course of foreign experiences. At the close, therefore, of the curriculum at home, we would counsel the young aspirant to pharmaceutical fame to avail himself of the first opportunity to spend a few months at some of the continental seats of learning. France is open to him; so is Italy; so is Germany. But of the three the last named is richer in the men and the materials wherewith to deepen knowledge, to correct prejudice, and to enlarge the mind.

The pharmaceutical chemist might do worse than reside for a session at the University of Leipzig, for example, which, especially since the war, is gaining rapidly on Vienna and Berlin in scientific attractiveness. Physics, Chemistry, and Botany are admirably represented there. In the physico-chemical laboratory of Professor Wiedemann, the student can either obtain or supplement his culture in that special branch under the most favourable auspices; while the physical cabinet of Professor Hankel and the physico-technological apparatus under the direction of Professor Marbach may also be consulted with advantage. In Chemistry Leipzig stands very high. Dr. Kolbe, of European reputation, is its professor; and in connection with his chair there is the chemical laboratory, one of the largest and most practically constructed and appointed to be found in any seat of learning. Botany is not so well represented; but the deficiencies of the Botanical Garden are being rapidly repaired; while there is an excellent Botanical Laboratory and Herbarium under Professor Schenke. Life in Leipzig is not nearly so expensive nor so seductive as at Berlin or Vienna; while in a hygienic point of view it is far pleasanter, not to say safer, than the former, and certainly not inferior to the latter. Add to this, that all the faculties are ably, and in some chairs brilliantly, represented, giving to the academic *ensemble* a tone and an atmosphere at once bracing and expanding. "For every language one knows," said Charles the Fifth, "he is so much the more a man;" and the aphorism holds good for the scientific culture of foreign civilizations, and for the development—the intellectual new-birth, so to speak—it can vouchsafe. Wherefore, say we to those of our aspiring pharmacists who can afford the time and the money, "Try Leipzig."

ENGLISH PHARMACISTS IN CANADA.

At the semi-annual council meeting of the Ontario College of Pharmacy on the 5th February, it was resolved that certificates of proficiency or diplomas of the Pharmaceutical Society of Great Britain, the Pharmaceutical Association of Quebec, and the Philadelphia College of Pharmacy, should be recognized by the College, provided that the holders had been four years in business; and the production of such diplomas is to be considered by the Board of Examiners under the Ontario Pharmacy Act sufficient evidence of qualification. At the same meeting it was decided to elect Professor Redwood and Professor Attfield of London, Mr. H. B. Brady of Newcastle, Professor J. M. Maisch of Philadelphia, and Dr. E. R. Squibb of Brooklyn, Honorary Members of the College.

The Atlantic cable of 1865 is broken, and speculation are rife as to the cause. In a letter to the *Daily News*, Mr. Highton expresses his opinion that the breakage is due to the formation of rust upon the iron wire sheath, and the action of this rust upon the hemp within, and he points to analogous results in the rotting of linen where spots of "iron mould" occur. Mr. Fleming Jenkin, however, combats this conclusion, saying an extended experience has shown that in submarine cables no such action takes place, hemp in contact with iron lasting perfectly sound for twenty years at least, if covered with the iron. At present the only thing certain upon the subject is that the cable is broken.

Dr. Henry Bence Jones having been compelled, by ill-health, to resign the office of Secretary to the Royal Institution, which he has so ably filled for many years, it is proposed to acknowledge his services by a testimonial in the shape of a bust of himself, to be placed in the Royal Institution, and a fund is being raised for the purpose.

Professor Balfour has been appointed Lecturer on Botany to the Edinburgh Veterinary College in the place of the late Professor Davidson.

Berthelot has at length been elected a member of the French Academy of Sciences.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

March 19*th*, 20*th*, *and* 21*st*, 1873.

Present—Messrs. Allchin, Barnes, Brown, Carteighe, Cracknell, Davenport, Edwards, Gale, Haselden, Linford, and Martindale.

Dr. Greenhow was present on the 21st, on behalf of the Privy Council.

MAJOR EXAMINATION.

Four candidates presented themselves, of whom *one* failed. The following *three* passed, and were declared duly qualified to be registered as "Pharmaceutical Chemists:"—

*Colling, Robert .... Stockton-on-Tees.
Dunn, Henry .... Shipley.
Botterill, George Thomas ...... Boston.

MINOR EXAMINATION.

Sixty candidates presented themselves, of whom *twenty-one* failed. The following *thirty-nine* passed, and were declared duly qualified to be registered as "Chemists and Druggists:"—

	*Tooke, George Stannard	Norwich.
Equal.	*Hunt, Freeman William	London.
Equal.	*Severs, Samuel Thomas	Leeds.
	*Bramley, William	Uppingham.
Equal.	*Askew, John	Grange-over-Sands.
Equal.	*Blackmore, James	Doncaster.
Equal.	*Hodges, Edwin Goodall	Bristol.
	Thorp, John	Manchester.
	Roberts, William	London.
	Shrimpton, Frederick George	London.
Equal.	Bennett, Henry Charles	Leigh, Lancashire.
Equal.	Scott, Thomas Alexander	London.
Equal.	Clement, Joseph	Coleford.
Equal.	Gould, Robert George	Poole.
Equal.	Adams, Richard	Market Drayton.
Equal.	Ward, William Edwin	Nottingham.
	Cox, William Dennis	Grantham.
	Kitchen, William	Kendal.
	Wilson, Richard	Hull.
	Laycock, John	Skipton.
	Roach, Herbert William	London.
	Cartwright, William Adam	Hyde.
	Dixon, Daniel	Preston.
	Smithard, Herbert Henry	Guernsey.
	Walker, William	Stockport.
	Horsfield, Robert Francis William	Walworth Road.
	Basker, John Anthony	Grantham.
	Lockwood, Charles Henry	Dorking.
	Lawson, Edward James	Whitstable.
Equal.	Barnes, William James	Dover.
Equal.	Pownall, Thomas	Mold.
Equal.	Prettejohn, Robert Froude	Torquay.
	Tripp, Zeno	Plymouth.
	Aris, George Henry	Wellingborough.
	Currah, George Ingersoll	London.
Equal.	Cronkshaw, John	Manchester.
Equal.	Matthews, Ernest	Royston.
	Gibbs, Henry	Aylesbury.
	Stephens, Henry Isaac	Bristol.

The above names are arranged in order of merit.

* Passed with Honours.

PRELIMINARY EXAMINATION.

The Certificates presented by the under-mentioned were received in lieu of the Preliminary Examination:—

Certificate of the College of Preceptors.

Price, Robert John .... Wrexham.

Certificate of the Royal College of Surgeons.

Dawson, George Alan .... Hanley.

Certificates of the University of Cambridge.

Basker, John Anthony .... Grantham.
Clarke, Herbert .... Lowestoft.
Green, Arthur .... Halifax.
Hands, Henry Joseph .... Chipping Campden.

Certificate of the University of Durham.

Marshall, John Colville .... York.

Certificates of the University of Oxford.

Cotterell, Edward .... Weymouth.
Currah, George Ingersoll .... London.
Hulland, Charles Richard .... Bath.
Phillips, Frank Leslie .... Birmingham.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The ninth general meeting was held at the Royal Institution, March 15th; the President, E. Davies, Esq., F.C.S., in the chair.

Mr. Edmund B. Ewart, B.A., was elected a member of the Association.

The following donations were announced:—'Proceedings of the American Pharmaceutical Association for 1872,' 'The New York Druggists' Circular,' current numbers of the PHARMACEUTICAL JOURNAL.

Mr. A. H. Mason, F.C.S., showed a beautiful specimen of guaranine made by Mr. J. Williams, and gave some particulars of his process for producing it.

Mr. Samuel Shaw Brown then read the paper for the evening, on "The Manufacture and Relative Therapeutic Characteristics of the Lints of Commerce."

A discussion on the subject of the paper followed, in which the President, Messrs. Brown, Abraham, Shaw, Mason, Tanner, and Hallawell took part, and the proceedings terminated with a vote of thanks to Mr. Brown.

The following paper on guarana was read at the meeting on the 13th ult., by Mr. J. Hallawell.

GUARANA.

Some time ago, on the occasion of Mr. T. H. Abraham presenting to this Association a specimen of guarana, I promised to give a notice at a future meeting of the history and uses of this medicine, with which I was familiar during my residence in Brazil, where it is extensively employed, having in fact a place in the Pharmacopœia used in that country.

Mr. Tanner not being able to read his paper this evening enables me to choose the present occasion to fulfil my promise.

When last in Paris I was fortunate enough to meet with a complete series of specimens of guarana, including seeds and medicinal powder, which were kindly placed at my disposal by M. Rigaud, one of the present proprietors of Grimault's establishment there. This gentleman also favoured me with a copy of a paper on guarana, written by his partner, Dr. Leconte, who had devoted considerable time and attention to the study of this product, and I found this paper so complete in itself that I obtained permission to translate what I thought proper for the present occasion, and I have drawn very largely on Dr. Leconte's composition in the following remarks, some paragraphs being almost a literal translation of his.

As a question in therapeutics formerly much discussed and subsequently abandoned, guarana is once more a subject of considerable attention. American doctors are carefully studying its effects, and English physicians are discussing its merits in the *Lancet*. We believe we may with some advantage step in, and take part in elucidating the subject, by publishing the documents we possess in reference thereto.

Guarana is a substance prepared by the South American Indians for commerce, from the seeds of the *Paullinia sorbilis*, a climber of the family of the *Sapindaceæ*, growing in Brazil. The cultivation of this plant, called also "Narana," *i.e.*, *a climbing plant*, has during the last few years enormously increased, owing to its introduction into Europe as a medicinal agent. The exportation of it at the present time, according to Brazilian returns, in one year, being put down as 30,000 kilos., about 30 tons.

Paullinia, in a wild state, grows to a height of from 10 to 12 metres (or about 36 to 40 feet), but its seeds are only used by the natives themselves. Those of the cultivated plant are reserved exclusively for the preparation of guarana intended for sale. The plant is propagated from the seed, but still better from cuttings of the plant. It produces fruit from the third year after planting, and after that period requires to be pruned, exactly as a vine. It flowers in July; the fruit is ripe in November. You will remember that these are the earliest months of spring in that latitude. The fruit, said to be scarcely larger than a walnut, contains five or six seeds. By careful cultivation, each stem will furnish four kilos., or about 9 lbs. of seed annually, and will live for forty years. The fruit of the plant cultivated in the neighbourhood of Mauhé is preferred. Topiriambaranas had for a long time the monopoly of the production of guarana, but subsequently it was found at Moxos and Chiquitos, and lastly at Villa Boa.

The Mauhées prepare it as follows: they remove the seeds from the capsules in November and dry them in the rays of the sun. After having slightly roasted them over a charcoal fire, they reduce them to a fine powder in stone mortars, or in stones hollowed for the purpose; they then moisten the powder with a little water, and expose it to the dew by night. In this way they produce a hard paste, often increased in bulk by mixing seeds and fragments of seeds. They afterwards roll it into cylinders of 12 to 16 oz. each, rounded at each extremity.

These cylinders or rolls are dried in the sun or in the chimneys of their huts. They measure 10 to 20 centimetres (4 to 8 inches) in length and 3 to 5 centimetres (or $1\frac{1}{4}$ to 2 inches) in breadth.

These cylinders are so hard that they have to be broken with an axe, or reduced to powder by means of a rasp. The different manipulations by which the mass is rendered hard, conduce to its preservation in a perfect state for many years. For exportation, the cylinders are enveloped in cocoa-nut leaves, and packed in baskets. It is in this form that the guarana appears in the European markets, though the samples sent from the Province of the Amazons to the Paris Exhibition resembled pine apples in form.

In reference to the seeds, they are very difficult to procure. According to Silva Continho, the mode of preparation varies a little from that described above, in that the Indians previously macerate the fruit in water, in order to detach more easily the pericarp from the seed, and of which they make a yellow pigment. The fruit also furnishes them with a red colouring-matter, with which they dye their teeth.

Guarana is not generally exported in a state of great purity, either being sometimes prepared from seeds in a state of fermentation, or mixed with cocoa-berries or tapioca flour. All authorities are agreed that seeds in a state of fermentation give a product of inferior quality; nevertheless, according to the Brazilian catalogue of the Paris Exhibition, the mass of "Guarana prepared and moistened, ought to be submitted to a slight fermentation." I think that the different manipulations to which the seeds are submitted, and during which it is dried three times, appear, on the contrary, to have for their object to preserve the preparation from fermentation. Peckholt asserts that the substance of the seeds alone is not sufficient to produce a firm mass, and that the Indians, to obtain this result, are obliged to add tapioca flour,—an addition, in this case, which does not constitute a fraud.

Jules Wiesner is not, however, of this opinion, and he brings as proof of his views, facts which it is in the power of every one to verify. He says, "At first sight one might think that the hard compact mass of the cylinders of guarana no longer possesses the organic structure of the seeds. It is not so. If we immerse a morsel of guarana in distilled water, the mass will give to the water a brownish colour, which changes to a kind of light pulp, from which the bulkier grains separate. If this matter be spread out and examined by the microscope, it will be seen clearly that the grains and fractions of grains are nothing more than fragments of seeds, readily recognized by their alveolar texture, and that the earthy portion of the mass represents well-defined histological elements. Among all the samples that I have analysed, I have not found one mixed with tapioca. It is, then, an error to suppose that that substance is necessary for the preparation of the mass of guarana."

We must agree with this conclusion; it carries with it not only the force of the authority of Professor Wiesner, and that of a microscopic examination, but is confirmed by other circumstances of which we shall speak hereafter.

Guarana, when perfectly pure, has the appearance, when fractured, of a piece of mosaic-work, generally of a darkish colour. The surface is of a shiny or greasy appearance, and the structure amygdaloid. In the middle of somewhat uniform masses are embedded smaller morsels of two to three millimetres in diameter ($\frac{1}{12}$ in. to $\frac{1}{8}$ in.), of which some are of a darker, and others of a lighter shade than the mass itself. Almost all of these are covered over with a whitish layer, not clearly definable. The substance is very hard and is crushed with difficulty in a mortar. The powder is of a bright brown or cinnamon colour, but with very little smell. But when it has been closely corked up for some time, or when it has been left a few instants in contact with the sides of a hot vessel, it acquires a peculiar odour. Heated slightly in the open air it has the smell and taste of roasted coffee. Guarana in a mass has the bitter styptic taste of the cocoa-berry; it softens in water, giving the liquid a brownish colour, while the insoluble portions lose little by little all their colour in the menstruum.

True guarana is distinguished from the inferior qualities by its greater hardness and specific gravity; the powder being of a reddish grey, whilst that of the sophisticated product is of a whiter appearance.

All these details, which appear more minute than useful, are important, as the end in view is to put the pharmacist on his guard against fraud,—so frequently the cause of unfavourable judgment when the merits of a new medicine, procurable with difficulty, are in question.

Guarana is for the Indians, at the same time, an indispensable aliment and a universal remedy. They live almost entirely on what is called "agua branca," a mixture of the powder and cold water, somewhat resembling chocolate. They reduce the mass to powder by means of a particular kind of fishes' bone or by sharp stones. The Indians have all the appearance of the freshness and vigour of those who live on animal food. They make use of it, medicinally prepared, with great success in the cases of diarrhœa and dysentery so frequent and so serious in their country; and in convalescent stages it is used as a tonic and stomachic.

The Brazilians and the civilized Indians learnt from the Mauhées the value of guarana, and at first bought it at very high prices. They employ it for the same purposes, modifying its bitter and styptic taste by means of sugar. It is now to be found in several Pharmacopœias, and is considered specially efficacious in cases of sick-headache.

Martius was the first to introduce to us this substance, in his work 'Travels in the Brazils.' Since then many authors have noticed it, amongst others Gavarelle, Petzholt, and Silva Continho. The subject, abandoned for a time, was taken up again by Jules Wiesner, who published a remarkable notice of it in the 'Ausland.' Latterly Dr. Wilks, of Guy's Hospital, has communicated to the 'British Medical Journal' a series of observations that leave no doubt as to the active properties of guarana. Dr. Leconte adds:—

"We were not at all surprised at the results obtained by Dr. Wilks; we were cognizant for a long time before of the properties of guarana. In our hands it has rarely failed, and we are convinced that its success is certain if it is employed pure and without any admixture or adulteration."

The powder of guarana prepared by Grimault is an alcoholic extract of guarana, and represents in a small bulk all the active principles of "Paullinia."

Dechastilus has found in this plant the following substances,—gum, starch, a resinous matter of a reddish-brown colour, a fatty oil coloured green by chlorophyll, tannin, colouring solutions of iron, green, and a crystallizable substance containing the chemical properties of caffeine.

More recent analysis, due to Trommsdorf, Petzholt, and Stenhouse, have shown that the crystallizable substance alluded to by Dechastelus is identical with the alkaloid of tea and coffee. These chemists have found in addition, saponine, carbonates and phosphates of soda, potassa, and lime. While tea contains but ·06 to 2 per cent. and coffee ·02 to ·08 per cent. of caffeine, these chemists have found in guarana 4 to 4·28 per cent. and as much as 5 per cent. of this substance.

Trousseau gave guarana in quantities of 1 or 2 grams (15 to 30 grains), not all at once, but distributed into several doses. This dose, he says, is sufficient to remove the most severe headache. Recent trials have proved, however, that this quantity may be increased; two grams (30 grains) may be administered at once, and repeated in a couple of hours if necessary.

The introduction of this remedy has been attributed to several sources, but there is no doubt its medicinal value was first discovered by the Indians, who in South America differ greatly from their brethren of the northern hemisphere. While the latter take interest in little except what pertains to the war-path or hunting, the former are a quiet, laborious, and patient race, living in a country especially rich in medicinal products, few of which have been brought before the notice of civilized mankind; and for a long time past they have learnt the uses and applications of many medicinal agents, the names of which are unknown to us. Formerly (for of late years there have been fewer of these visits) it was a common thing for the Indians to travel thousands of miles with a collection of these medicines to sell their "specifics" in the towns and villages of the whites; amongst these was guarana, which, on account of its superior merit, claimed special attention, and thus became known. It was sought for and procured, but until recently, in very small quantities, and could only be bought at a very high price. As the demand increased, the supply was found to be readily met, and at the present time the exportation has reached a very considerable figure. We believe the reason why it has sometimes failed in this and other European countries, is, that, on its being largely sought for, it was sent out in a very mixed and adulterated state, some specimens which I have seen not containing more than sufficient guarana to give a colour and appearance to the substance, the bulk being merely a mass of hardened farinaceous matter; and the characteristics of the true guarana being so little known, the mixture passed undetected. But I am convinced that a full and fair trial of its medicinal properties, made with specimens unmixed and unadulterated, would lead to its adoption in numerous forms of biliary and stomachic derangements, and that ultimately the medicine would take rank in this country, as in that in which it is found, as a valuable and indispensable therapeutic agent.

Lastly, as to the dose. Of the powder made from an average sample of guarana from 30 to 60 grains is, I believe, the right quantity. It remains to be tried how and in what manner a certainty is to be arrived at in its administration—whether an alcoholic or other extract may not be made, which shall be invariable in strength, for at present the samples received vary so greatly, that, except to an expert, it is difficult to ascertain the exact value of the material as imported. Messrs. Rigaud and Leconte have introduced what they state is an alcoholic extract, and of a certain and fixed strength; but should guarana be found to have the merit its advocates claim, it will be very easy to discover the best form for employing it with certainty and exactness. It has been suggested to import the seeds, and prepare in this country from them, either the guarana or a better form still for embodying the active principles of this substance. This suggestion is worth attention, meanwhile the substance as known already might be thoroughly tried, from reliable samples; and its value once established, the seeds might possibly be procured in sufficient quantity to enable the pharmacist to make his own guarana, or something better still to substitute it.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The fourth meeting of the session was held in the rooms of the Society, Exchange Buildings, on February 28th; the President, Mr. J. H. Atherton, in the chair. The following donations were announced: The Calendar of the Pharmaceutical Society, from the Society; Specimen of Scammony Root, from Mr. Ransome Kitchen; Variety of chemicals, from Messrs. Hearon, Squire, and Co. The thanks of the Society were cordially given to the respective donors.

Three new members were elected. After which the president introduced the subject of the "Recent Schedule of Poisons" sent to chemists and druggists throughout the country; and elicited some discussion respecting the sale of vermin killers.

Dr. Souter delivered an interesting lecture on the "Cryptogamics of the Coal Measures." A hearty vote of thanks was awarded to the lecturer.

The fifth general meeting of the Association was held on Friday evening, March 21; the President, Mr. J. H. Atherton, in the chair. Several members and associates were elected, and the thanks of the Society given to donors to the library and museum. The president congratulated the Society on the receipt of a donation of £15 towards the museum from the Pharmaceutical Society of Great Britain, and announced that a sub-committee had been formed to arrange for glass cases to hold the chemical and other specimens. Subsequently a special vote of thanks was accorded to the Pharmaceutical Society for the valuable assistance given.

Mr. Smith then gave an illustrated lecture on the "Construction and uses of the Microscope." The lecture was one of an exceedingly practical nature, and the lecturer was warmly applauded at its conclusion. Before and after the lecture many interesting objects were shown by various members of the Society who had kindly brought their microscopes.

LEEDS CHEMISTS' ASSOCIATION.

The fifth meeting of the present session was held in the Clergy-room, on Wednesday, February 12th; the President, Mr. E. Brown, in the chair. The minutes of former meeting having been read and confirmed, Messrs. J. W. Longley and H. B. Young were elected members. The President introduced Mr. O. Pegler, associate of the Royal School of Mines, who proceeded to read a paper on Mineralogy and Crystallography. He said that mineralogy treats of the properties of mineral substances and comprehends the study of all inorganic substances in the earth or on its surface—as a science it holds as high a position as botany and zoology, and offers to the diligent student ample scope for investigation, opening out the storehouses of nature for the fertile discoveries and application of the chemist. Referring to the variety of colour, form, and physical properties of the minerals constituting the earth's crust, the lecturer pointed out that these modifications were merely due to a rearrangement of a few of the known elements, the smallest portion of a mineral possessing the same constituents, form, and colour as the largest crystal or the mountain mass, the growth of a mineral being by accretion of its particles, illustrating his remarks by reference to a great number of minerals arranged upon the table. In consequence of the lapse of time, Mr. Pegler was unable to go into the subject of crystallography as fully as he had hoped to do; but, at the request of the President, he consented to bring the subject forward at another meeting. A cordial vote of thanks was given to the lecturer upon the motion of the President, seconded by Mr. S. Taylor.

ROCHDALE CHEMISTS' ASSOCIATION.

The fourth ordinary meeting of this Association was held at the Public Baths, Rochdale, on Wednesday evening, the 19th inst.

Mr. Alderman Booth read a paper on Guarana, giving a clear and interesting account of the plant *Paullinia sorbilis*, and the method adopted for the manufacture of the drug. The description was illustrated with a complete collection of specimens of the fruit of *Paullinia sorbilis*, guarana in rolls, and alcoholic extract. There were also exhibited a fine sample of pyrophosphate of iron and soda, and some elegant French preparations.

After a short discussion on the subject of the paper and an examination of the various objects on the table, a vote of thanks was unanimously passed to the President, to which he replied, "That he received their thanks as wholly due to Mr. Joseph Hallawell, of Liverpool, who had furnished at his request the illustrative specimens as well as the instructive paper on guarana, to which they had listened with so much interest; and to whom he would express their thanks."

ABERDEEN SCHOOL OF PHARMACY.

A course of lectures by Dr. Beveridge, for the summer session of the Aberdeen School of Pharmacy, Hospital Court, Gallowgate, in connection with the Society of Chemists and Druggists in that city, is announced to be commenced on Tuesday, April 1, at half-past eight, and continued every Tuesday, Wednesday, and Thursday evening, at the same hour, until July 31. The subjects will be the Practical Study of the Materia Medica, with the Chemistry and Botany of the Pharmacopœia. Fee for the Course, 20*s*.

It is earnestly hoped that assistants and apprentices will avail themselves of these lectures specially provided to assist them in qualifying themselves for passing the necessary examinations of the Pharmaceutical Society, and as the course will only be proceeded with on the condition of a certain number coming forward, it is requested that those desirous of attending it will leave their names as early as possible with Mr. Andrew Ross, 43, Castle Street.

The library is open every Friday evening from 8 to 10 o'clock.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, 20th March, 1873, Dr. Frankland, F.R.S., President, in the chair. The names of the visitors having been announced, and the minutes of the previous meeting read and confirmed, the President called on Mr. C. W. Siemens, F.R.S., etc., to deliver his lecture "On Iron and Steel." The lecturer, after adverting to his former discourse delivered before the Society in 1868, and describing the various experiments he had since made to obtain malleable iron direct from the ore, gave an account of the process by which he had succeeded in completely attaining that object. It consists essentially in fusing the ore in a revolving furnace, and then adding the requisite amount of carbonaceous matter to reduce the iron to the metallic state. The malleable iron thus precipitated in the molten mass becomes aggregated into balls by the revolution of the furnace, and can then be easily removed. It is free from sulphur, phosphorus, and other impurities, and dissolves readily in a bath of molten cast iron, producing steel of a quality equal to that made from the best Swedish bar iron.

After some discussion, the Society adjourned until the anniversary meeting, which will be held on Monday, the 31st March. The next ordinary meeting will be on Thursday, 3rd April, for which the following papers are announced:—

1. "A Way of Exactly Determining the Specific Gravity of Liquids," by Dr. H. Sprengel. 2. "On Cymene from Various Sources," by Dr. C. R. A. Wright. 3. "Researches on the Action of the Copper-Zinc Couple on Organic Bodies, II. On the Iodides of Amyl and Methyl," by J. H. Gladstone, F.R.S., and A. Tribe. 4. "Contributions from the Laboratory of the London Institution, No. XI., Action of the Acid Chlorides on Nitrates and Nitrites," by Dr. H. G. Armstrong.

Parliamentary and Law Proceedings.

Suicide by Strychnine.

An inquest was held at Doncaster on Thursday, March 20, upon the body of Joseph Mordue. It was shown that the deceased, who was a butler, had received notice to leave his situation, and his employer, upon going to his room to settle accounts with him, found the door locked. An entrance was forced, and Mordue was found to be dead. A bottle containing strychnine was on the mantel-piece. It was labelled "Strychnine," but no information could be obtained by the police as to its purchase.

The coroner remarked that the bottle had at one time been filled with strychnine, sufficient to kill two hundred persons. There was enough left to poison five or six. It was a mystery where the poison had been obtained.

Dr. Sykes, the foreman, said that probably the deceased had had the bottle by him a long time.

The jury returned a verdict that death had been caused by strychnine, taken while in an unsound state of mind.

Suicide by Chloral Hydrate.

On Friday afternoon, March 21, Mr. Humphreys held an inquiry at the Workhouse, Mile End, respecting the death of Mr. Charles Carter Bewley, aged 21, who committed suicide under very painful circumstances.

Mr. Charles Bewley, surgeon, of Kingsland Road, stated that the deceased was his son, and that he was a medical student at the London Hospital. About one o'clock on last Tuesday afternoon he left his house in good spirits, being more cheerful than usual. He was engaged to be married in a fortnight's time. He was in the habit of taking a large quantity of chloral to procure sleep.

Mr. Alfred James Mitchell, a medical student, said that about half-past five o'clock on last Tuesday evening the deceased called upon him, when they both went out together in the direction of Stepney Green. The deceased went to the post office, and sent a telegram to his lawyer's stating that he would call the next day and explain all. He said that it was his intention to go to Belgium the next day, and that he had written to his friends to meet him at the evening boat. He then went to a tavern, called the King Harry, where a disturbance took place, in which he was concerned. Witness afterwards saw the deceased coming out of a chemist's shop. He said he had been to get a draught to quiet himself. They then went into the King Harry together, and about five minutes afterwards the deceased said, "Will you have a parting glass with me, as we shall never meet again." Shortly afterwards he exclaimed, "I am a dead man," and added, "I have taken a drachm and a half of chloral." The deceased was taken to Dr. Todd's, and as soon as they laid him on the surgery floor he expired. He believed that he took the poison whilst in a state of excitement arising from the disturbance.

Mr. Alfred Rushton, chemist, 285, Mile End Road, said that about eight o'clock on Tuesday night the deceased came to his shop for a draught, which he gave him. He came in a second time, at a quarter to ten o'clock, and asked to be served with two drachms of chloral, when witness said that he had not so much in the house, but would give him what he had, which was 1 drachm 25 grains, which he had put into a one and a-half ounce bottle. The bottle was labelled, "Poison—a teaspoonful to be taken three times a day." He knew him to be a medical man, or he should not have served him with it, he having been in his shop several times before. He was perfectly sober at the time he served him.

The Jury returned a verdict of "Suicide whilst in a state of Temporary Insanity."—*Standard.*

Reviews.

THE FIRST BOOK OF BOTANY. By E. A. YOUMANS. London: H. S. King and Co.

The Pharmaceutical Calendar is a rather respectable looking book, containing a good deal of valuable information, but the Calendar proper to be found therein is very meagre and destitute of interest. We find a few Pharmaceutical "fixtures," and here and there are references to the illustrious departed, but saints are unknown in the Pharmaceutical Calendar. There is no *Beatus Paracelsus* nor *Beatus Gerardus*, Raymond Lully and Cornelius Agrippa have no name days; Dioscorides and Pliny, the early Pereiras—so to speak, are not claimed as apostles of the craft. This blankness struck us in dipping into the Calendar—between its two pages we should say—but we referred to it to see if there was any notice of the Pharmaceutical seasons. We have no doubt that Francis Moore, Physician, gives information on many points of Pharmaceutical interest, at least he did formerly, but here we find naught but empty spaces. It is probable, however, that very few people consult the Calendar as an almanack, but who knows how many might not, if it was made generally interesting?

What then are seasonable considerations? Is this the season for dandelion roots and colchicum corms, or for coltsfoot flowers? According to ordinary almanacks the sun enters Aries this month, when, of course, it follows that spring commences, though it is difficult sometimes to assure ourselves of the fact. The incipient botanist may therefore leave mere book study and look out for flowers on which to apply his sharpened intelligence. *Helleborus niger* and *Viola odorata* were in flower in January, *Daphne Mezereon* and *D. laureola*, also pharmaceutical plants, are now bursting into blossom. *Corylus Avellana*, *Alnus glutinosa*, and other amentaceous trees are putting forth their catkins. The male junipers are golden. Primulas and many herbaceous exogens are already in bloom, whilst the early bulbs supply almost daily new endogens. A crocus or a Dutch tulip furnishes *multum in parvo*, and garlic will soon be to hand, with the additional charm of odour. Last year, during March, we were staying in Somersetshire, beloved of Flora, and in a short time noted nearly seventy plants in flower. Any sunny old wall will be sure to repay research in spring, later on in the season its plants will have withered away. On such a place we may look for the lovely little crucifer *Draba verna*, which is already in fruit by the end of the month, when its white seed-vessels glitter in the sun an inch above the surface, whilst a whole plant would safely bear removal on a halfpenny. Coltsfoot, almost neglected by the pharmaceutist, thrusts up his flowering-stems and golden heads. Sweet violets are to hand, but the dark blue pansies that do much duty instead of them, are early summer flowers. *Arum maculatum*, "Lords and Ladies," hunted after by boys, allied to pharmacy, and having Rosicrucian affinities, will soon thrust up its pale membranous spathes, sheathing its mysterious spadices. The sallow, *Salix caprea*, not rich in salicine, but renowned for its golden "Palms," feathery and redolent of pollen, will be ready by Palm Sunday. Butcher's Broom, *Ruscus aculeatus*, sole English representative of shrubby endogens, produces at this time of year its small green flowers, curiously placed in the centre of its spiny leaves or cladodes. It may be found, in gardens at least, in most of the southern counties. *Amygdalus communis*, the almond tree, though not a native, is frequent in gardens, and its early flowers have great beauty. Its relative, the common or cherry laurel, flowers rather later. These and many others display their treasures to the young pharmaceutical botanist, and show clearly that it is time to begin out-of-door's work. Many features of structural botany may also be studied now better than at any other time. Vernation is one of these, and in working it out a good deal of information will be picked up respecting the formation of stems and branches as well as of leaves. A juvenile botanist often despises buds when he has leaves and flowers to work upon; but every leaf-bud has a history, and the buds of the horse-chesnut and garden rhubarb, for example, are large enough to resist the attacks of the most rudimentary of beginners.

The little work, the title of which is placed above, is an attempt to carry out in a simple manner the schedule system of the late Professor Henslow. It is compiled by an American lady, who claims for the system that it is not merely a course of botanical instruction, but a good method of carrying out the systematic training of the perceptive faculties. It is properly described as a "First Book," being evidently intended for children. The child uses it, not to read or to learn off by heart; but by its aid is enabled to distinguish, by the comparison of living specimens with the figures and descriptions which it contains, what are the actual characteristics of any leaf or flower. The first exercise is on the parts of a leaf. A leaf is found, pinned to a piece of ruled paper, and on referring to the book, it is seen that the several parts are called blade, petiole, and stipules. These terms are written down on the paper and constitute a schedule, proper forms for preparing schedules being given in connection with each exercise.

In this manner the different features of roots, stems, leaves, flowers, etc., are described and examined. The language is simplified as much as possible, the work being intended for children; and of course so small a volume can include only a preparatory course; but the groundwork of knowledge obtained in this way appears pretty sure of being efficient. It may be asked how far such a plan is likely to prove acceptable to ordinary children, and the answer is said to be favourable wherever it has been tried. Our own experience is limited to the fact that our little girl of twelve, seeing the book, was in stantly seized with a passion for making schedules. It may also be said with truth that any knowledge respecting plants or animals or other objects around us, is much more valuable than a great deal taught at schools which has no reference in particular to anything on the earth beneath or in the waters under the earth.

NUGÆ CANORÆ MEDICÆ: Lays by the Poet Laureate of the New Town Dispensary. Second Edition. Edinburgh: Edmonston and Douglas. 1873.

Besides his well-earned reputation and position as a medical practitioner and academic teacher, Dr. Douglas Maclagan, of Edinburgh, enjoys considerable local fame as a song-writer and singer. The "grey metropolis of the north," in all her professions, has been distinguished for the number of her wits and versifiers,—London herself having few better names to show than Aytoun and Martin (who wrote under the well-known *nom de guerre* of Bon Gaultier), Lord Neaves, Patrick Robertson, Outram, Ballantine, Sidey, and Blackie. Nor can Dr. Douglas Maclagan be omitted from the list. His "Nugæ Canoræ Medicæ," of which the second edition is now before us, abounds with lyrics, nearly all humorous in their tenor, in celebration of the annual social gatherings of the past and present officers of the Edinburgh New Town Dispensary. Wonderful command of metre, dexterous rhyming, and a happy flow of animal spirits, rather than wit, are the chief characteristics of the volume. Dr. Maclagan makes no pretension to the exquisite humour and liquid versification of the authors of the "Bon Gaultier Ballads;" nor even to the far inferior effusions of Lord Neaves, as reprinted from *Maga*. Add to this that his vein is almost purely local, and in its expression so essentially Scotch as almost to necessitate a glossary for us Southrons. With all these drawbacks, however, he has certainly contrived to amuse us; though not, of course, in the degree in which he must have tickled the midriffs and shaken the sides of his fellow-convivialists, when a good dinner, with floods of champagne, followed by the grateful tumbler of his native land, had promoted "good will towards men," if not "peace on earth." We are afraid to give our readers a specimen of his Scottish vein, as the effort to pronounce the words might seriously affect the muscles of articulation, or probably end in tetanus, let alone aphasia. But the following on "Liebig's Physiological Chemistry," may be read with safety, and even considerable enjoyment:—

"If you please, Mr. Preses, make use of your time,
And don't let's get dry in the throttle,
But take my advice, as the claret is prime,
And order us in a fresh bottle.
We've Liebig's authority, well you're aware,
That we men of the North can consume
More alcohol far than the Southrons dare,
Without being the worse for its fume.

"This Liebig has found out our life's golden rule,
And much will it please honest people,
To find that he proves Father Mathew a fool,
And that life is maintained by the tipple.
For by oxygenation to vapour we turn;
This, he says, one of Nature's strange laws is;
And without hydrocarbons within us to burn,
We perish by eremacausis.

"Teetotallers dabble in coffee and tea,
And think themselves wise all the while;
But if Liebig be right, these'll not do for me,
For he says that they turn to bile.
No! a taste of the alcohol's nearer the thing
For a man of poetic vocation;
For your bard couldn't laugh, and still less could he sing,
Without elements of respiration.

"Thus, man's but a big spirit-lamp, as we see;
And lamps all require you to cram 'em
With plenty of spirit of good density,
In order to *alere flammam*.
Then keep up the alcohol stimulus all;
Thus alone you'll preserve your condition;
Or you'll find yourselves soon in what Bennett would call
A state of abnormal nutrition."

The "Battle o' Glen Tilt" is a long and, in some respects, felicitous account of the repulse sustained by Dr. Balfour and a company of botanists at the hands of the Duke of Athol, in their attempt to pierce the unbroken solitudes of the Glen. This poem, it is right to add, is most effectively illustrated by the Brothers Faed, Ballantyne, Douglas, Archer, and Crawford, names well known to the artistic world on both sides of the Tweed. Their sketches are photographed for the present volume by Mr. E. W. Dallas, and most ludicrous, occasionally weird, they are. "A Dinner at Douglas's Hotel," in Irish dialect, is not unworthy of Father Prout; though we hope the unprofessional prostration to which the medical convivialists were reduced on the occasion, was the result of poetic, not of vinous, license. Another capital lyric is that intitled the "Æsculapian," from which we extract the following humourous reference to the ex-Professor of Chemistry in the University of Edinburgh:—

"Lyon Playfair last winter took up a whole hour
To prove so much mutton is just so much power;
He might have done all that he did twice as well
By an hour of good feeding in Slaney's Hotel;
And instead of the tables he hung on the wall,
Have referred to the table in this festive hall;
And as for his facts—have more clearly got at 'em
From us than from Sappers and Miners at Chatham.
Whilst like good jolly souls,
We emptied our bowls,
And so washed down our grub
In a style worth the name,
Wealth, honour, and fame
Of the Royal Society Club."

Dr. Douglas Maclagan intimates that the proceeds, *if any*, of his volume are to be dedicated to the New Edinburgh Infirmary. We can assure him that the qualification which we italicise is out of place, and that his 'Nugæ' will owe their success, not so much to their charitable object as to their intrinsic merits.

BOOKS RECEIVED.

HANDBOOK FOR THE PHYSIOLOGICAL LABORATORY. By E. KLEIN, M.D., J. BURDON-SANDERSON, M.D., F.R.S., MICHAEL FOSTER, M.A., M.D., F.R.S., and T. LAUDER BRUNTON, M.D., D.Sc. Edited by J. BURDON-SANDERSON. Two Volumes. London: J. and A. Churchill. 1873. From the Publishers.

A HANDBOOK OF HYGIENE. By GEORGE WILSON, M.D. Edin. London: J. and A. Churchill. 1873. From the Publishers.

OZONE AND ANTOZONE: THEIR HISTORY AND NATURE. When, Where, Why, and How is Ozone observed in the Atmosphere? Illustrated with Wood Engravings, Lithographs, and Chromo-Lithographs. By CORNELIUS B. FOX, M.D. Edin. London: J. and A. Churchill. 1873. From the Publishers.

ON PUTREFIERS AND ANTISEPTICS. By JOHN DOUGALL, M.D. Glasgow. 1873.

Notes and Queries.

[333.]—ESSENCE OF RENNET.—"*Edina*" would feel obliged by any reader of the Journal favouring him with a receipt for making Essence of Rennet that will keep.

[The following formula was sent to this Journal some years since by Mr. Houlton, of Wetherby:—

"One Fresh Rennet (or Calf's Stomach).
¾-gallon Boiling Water.
20 oz. Salt.

Set by for twelve hours and strain; then add—
Spirit of Wine, 6 oz."—ED. PH. JOURN.]

DR. LOCOCK'S HAIR LOTION.—"*Glycerine*" is informed that the following is the formula for this preparation as given in Cooley's 'Cyclopædia of Practical Receipts':—

"Oil of Mace (Nutmeg) . . 1 oz.

Liquefy at a gentle heat with—
Olive Oil . . . . ½ oz.

When cold form into an emulsion by agitation with—
Rose Water . . . . . ¼ pint.
Spirit of Rosemary . . . 2½ fl. ozs.
Stronger Liquor of Ammonia 1½ fl. drs."

SYRUP OF PHOSPHATE OF LIME. — Carlo Pavesi, of Mortara, describes (*L'Indipendente*, Feb. 15) a syrup of phosphate of lime made of 1½ part of subphosphate of lime, 1½ part of bicarbonate of soda, a sufficiency of lemon juice, 18 parts of saturated decoction of wheaten bran, and 12 parts of refined sugar. The phosphate of lime and decoction of bran are introduced into a strong glass bottle; the bicarbonate of soda is then added, and after it the lemon juice. The bottle is now tightly closed, and shaken gently; this is repeated from time to time for forty-eight hours, so as to leave a slight excess of lemon juice. The fluid is then filtered through blotting paper: it contains citrate of soda and subphosphate of lime dissolved in the bran decoction, which itself contains phosphates, gluten, etc. The sugar having been added, the fluid is evaporated to the consistence of a thick syrup.—*London Medical Record.*

LINIMENTUM AMMONIÆ IODIDI.—The following is published in the *Druggists' Circular* as the formula of an Iodide of Ammonia Liniment prescribed for many years by medical practitioners in New York, and formerly known under the name of Rourke's Iodine Liniment:—

Iodine . . . . grs. xv
Alcohol . . . . ℥viij
Camphor . . . . ʒij
Oil of Lavender,
Oil of Rosemary, each . ʒj
Solution of Ammonia . ℥j.

The liniment soon becomes of a pale straw colour, and is free from the objections of being either greasy or soapy.

The following journals have been received:—The 'British Medical Journal,' March 22; the 'Medical Times and Gazette,' March 22; the 'Lancet,' March 22; the 'London Medical Record,' March 26; 'Medical Press and Circular,' March 21; 'Nature,' March 20; 'Chemical News,' March 22; 'Gardener's Chronicle,' March 22; the 'Grocer,' March 22; 'Journal of the Society of Arts,' March 22; 'Grocery News,' March 22; 'Produce Markets Review,' March 22; 'Scientific American,' March 22; 'Brewers' Guardian,' March 25; 'Neues Repertorium für Pharmacie,' January and February; Doncaster, Nottingham, and Lincoln Gazette;' 'Manchester Evening News;' 'Philadelphia Press;' 'Goulburn's Courier.'

BENEVOLENT FUND.

Sir,—I, with many others, more particularly country members and chemists, quite agree with J. B. B. in your issue of the 22nd inst., that if some more active steps are not adopted, the subscriptions will be found to fall off very materially. I have heard it frequently expressed, that if I give a guinea it yields only about sixpence to the purpose it was contributed for, the principal being "Consoled" for posterity. What have we to do with them? Sufficient unto the day is the evil thereof. Build schools, provide suitable dwellings for decayed chemists and their widows, relieve orphans, and subscriptions will then come in amply to meet all demands; members of the trade would give then with a willing heart and liberal hand.

CAMDEN.

Greenwich, S.E.

Sir,—I am glad to see some one entertains the same opinion as regards the use of this fund as myself, and I indorse J. B. B.'s ideas and propositions with respect to its distribution. I have often thought of asking the question, What will be done with the principal? I have been a member of the Pharmaceutical Society from its birth, but have never given one penny to this fund, neither shall I as long as the yearly receipts are placed out at only 3½ per cent. What is the object for the accumulation of such a fund? If the PARENT dies, is there any power to will it to A., B., or C., or to whom will it go? How many poor druggists, or their widows, or their orphans, might have been saved from beggary and starvation, and have been placed by its aid in a position to earn their own bread, if the yearly subscriptions and donations were so divided, instead of as now, when only a few candidates are receiving the paltry pittance of £20 or £30 per annum. A shilling will buy six pounds of bread; but what good will a *farthing* be to any one? Let J. B. B.'s proposition be carried out, and the receipts for 1872 be divided in 1873, and so on in each succeeding year, to as many candidates as will give to each £50 per annum, to be paid quarterly with the interest thereon, which will be something more by the time the last quarterly sum be paid. This, in my humble opinion, would be doing some GREAT GOOD, and be an untold relief to hundreds, instead of, as now, to only a few. I cannot help thinking that subscriptions would increase yearly, for many could give a shilling when £1 could not be spared. Poor as I am, I shall be pleased to contribute my mite to the fund that is so yearly distributed, as I feel confident those entrusted with it will see to its being rightly bestowed.

M. J. M.

London, March 26th, 1873.

THE PHARMACY ACT OF 1868.

Sir,—I was very much gratified when I read a few days since in the PHARMACEUTICAL JOURNAL that a different state of things, in a pharmaceutical sense, existed in France to what we have in our famous forward England, both as to the law itself and the carrying out of the same. I refer to the case of some persons being fined for selling cod-liver oil (because it was for medicinal use). I have often wondered what a French pharmacien would think if he came into the town in which I live, and became convinced, as I am, that the druggist is quite as open to competition as any other trader; that drugs still remain a marketable commodity. If he went into almost any shop doing a mixed business in the town, he might purchase articles called paregoric (with no label and without its active ingregient), also tincture of rhubarb (made with cake saffron), and any other tincture except, perhaps, opium, and the thirty articles named in the schedule, the tinctures being supplied at 3*d.* per oz., for which the druggists charge 4*d.* He might also obtain of these dealers bottles of diarrhœa mixture at 6*d*. and 1*s*., bottles of castor and cod-liver oil, and glycerine, and, in point of fact, drugs, feeding-bottles, surgical appliances, and everything that is not contained in the schedules of the late Pharmacy Act, viz. about three dozen things which are not wanted once in a dozen times. Methinks I should hear him express his disgust with such a half law, and say it reminded him of a chair with no legs. However, whatever the Frenchman might say I will not venture to really decide; but of this I am convinced, that the Act has not, under my observation, done much good to either the public or ourselves, and I verily believe that the public are quite as much gulled as they were before the Adulteration Act: and with regard to the Poisons Act, I say that the individual who is bent on destroying his or her life *will* do it, and can, as the present law stands, easily, with laudanum as the Pharmacy Act stands. We qualify ourselves—for what? simply for the sale of a few poisons, and just such other things in the shape of drugs as the *few* sensible public like to purchase, but what is more frequently the case, such things as they cannot get any *cheaper* at the other shops. Losing the sale of our drugs, alas! we lose nearly all; for prescriptions are generally, curious to say, done between half a dozen in each town or city of any size. The natural result follows; we must either starve or sell pickles, sauces, whiting, red ochre, etc. I prefer the latter in self-defence, but I am anxious that this state of things should be ventilated, for in the majority of cases the vendor is not so much to blame as those who stand behind the scenes (I refer to the suppliers of the shopkeepers of pills without poison, Godfrey's without opium, but henbane substituted). Away with such a hollow law! If the public are to be protected, and we are to be remunerated for protecting it, why not compel it to come to us for everything for medicinal use, internal or external. The Pharmacopœia should be our standard; that is, I would restrict the sale of drugs and chemicals, or go further, and say, the contents of the B. P.—with the exception of half a dozen or so articles, as mustard, pepper, the soaps, lard, etc. I do not hesitate to say that, under the last-named circumstances, I might make £100 more annually; and, alas! I am not alone; I am one of hundreds, I fear. We cannot go directly against one particular neighbour and get him fined for infringing the law, when often it is not his fault. Similar things exist in some of the London italian warehouses. There ought to be some means whereby the local secretaries could act in giving information against offenders. The fact is, this state of things is so keenly felt by so many, that no stone ought to be left unturned to put a stop to it, or else we need expect to see very few at Bloomsbury, seeing that they can carry on a business nearly ours without any trouble. It only requires management. I only wish the Council would give this matter the same ventilation as pharmaceutical education has had from them.

GEORGE BEALE.

Holderness Road, Hull.

PHARMACEUTICAL WOMEN.

Sir,—Having read the different letters on the above subject, I must ask you to allow me to add my protest against women receiving any encouragement to enter the profession. Here in France it is very usual for the wife of the pharmacien to sit in the pharmacy to keep the books and take the money. I very much doubt whether any modest Englishwoman would like to be obliged to sit and see many things sold, and afterwards take the money for them, which it is usual for a chemist to keep in stock, and which are sold generally to men of not the highest moral character. Again, there are those customers who take us aside and ask a few minutes' quiet talk with us; would any man like his wife to be a witness of those sort of things?

If women do come amongst us, I should advise all my collaborateurs not to take an appointment in a pharmacy in which there is a woman engaged. For my part I am determined never to take an appointment again in any pharmacy in which there is one, either in England or on the continent.

MAURICE DE LANCY.

2, *Place Vendôme, Paris, March* 16*th*, 1873.

Sir,—There have been a great many opinions with regard to ladies being admitted into our profession. Allow me to give you an instance of faithlessness in taking medicine, where the customer *only thought* a woman had made or helped to make up the mixture. A gentleman took his prescription to be dispensed by a pharmaceutical chemist, in a flourishing seaside town in Kent, where the wife of the chemist was wont to help her husband for some years, in the summer season, behind the counter. He waited for the same, and after some time elapsed, the wife came from behind the scenes (the dispensing department), presented the customer with his mixture and took the money for it; the gentleman, fearing the wife had had something to do with the manipulation thereof, had not the proper confidence in taking it, so went to another chemist to have the contents of the bottle thrown away and the prescription dispensed afresh.

March 12*th*, 1873. J. B.

Sir,—It is probable the new Council will have to decide, for a short period at least, the admission of women. Allow me to suggest, for the guidance of members in filling up the voting papers, that the words "for admission of women" or "not for admission of women" be attached to the name of every candidate for the Council.

If this cannot be done, perhaps you can make room in the Journal for the list with the above remarks.

R. M. ATKINSON.

Leeds, March 24*th*, 1873.

TINCTURE OF QUININE.

Sir,—Although we have heard upon distinguished authority that explanations are generally waste of time, I wish to excuse myself from the superficial error—attributed to me by Mr. Baldock—of so far mistaking the character of the constant deposit in tinct. quinine as not to distinguish between it and that which takes place only at low temperatures, and often after the lapse of many months.

I had long noticed that this first deposition was not bitter and not appreciably soluble in proof or rectified spirit, therefore presumably not quinine; but *after* this has been filtered out a further separation takes place of what I still believe to be sulphate of quinine in the form of feathery crystals of very pretty appearance when the temperature falls sufficiently low. These crystals differ from the first deposit conspicuously in crystalline character and in being easily redissolved at the ordinary temperature of an inhabited room.

Mysterious remarks have been made as to the advantage of using a spirit composed of 5 parts rectified spirit and 3 parts water for preparing tinct. quinine; but as this is the standard strength of proof spirit,—as proof spirit is officially directed for tinct. of orange, and tinct. orange is the basis of tinct. quinine,—the information is somewhat superfluous. Certainly it will not enable us to avoid the objection which in my previous letter I referred to as inherent in *officinal* tinct. quinine.

RICHARD W. GILES.

Clifton, March 25*th*.

T. F. W.—The plant forwarded is *Tussilago Farfara.*

G. W. Taylor.—We are not certain as to the composition of the preparation referred to, but we know that in some parts of the country syrup of white poppies is supplied under the same name.

E. W. B.—(1) Our acquaintance with the multitude of proprietary preparations is not sufficient to enable us to answer your question safely. (2) You would probably obtain the information required from the Trade Mark Protection Society, 18, King Street, Cheapside. (3) We know of no *legal* prohibition to the assumption of such a title by a registered chemist and druggist.

G. Johnson.—We have forwarded to you the PHARMACEUTICAL JOURNAL containing the original communication to which you refer, and you will see that the omission to give you credit for your suggestion occurred in the abstracting of the paper for the work in which it was reproduced.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Ross, Dr. Wilks, Mr. H. J. Lutwyche, Mr. Groves, Mr. Proctor, Mr. Bessant, Mr. Symes, "X. Y. Z.," "Registered Chemist and Druggist," "Ignoratio," "Lux."

A NEW BASIS FOR SUPPOSITORIES AND PESSARIES.*

BY WILLIAM MARTINDALE, F.C.S.,
Dispenser and Teacher of Pharmacy to the University College Hospital.

At our evening meeting in February, Dr. Redwood stated that "some medical men took exception to the present suppositories on account of their greasy basis,"† and at our last meeting several vehicles were suggested in place of the official one. Among others, Dr. Redwood suggested soap—animal soap. The use of this substance for the purpose is by no means novel, in fact, until comparatively recent years, the only suppository in general use was one made of the compound pill of soap. The great disadvantage in using soap as a basis, from a pharmaceutical point of view, is the difficulty in forming the suppositories containing it into a proper shape. It cannot be melted and poured into moulds in the way that we are accustomed to, each suppository would require separate manipulation with the hand and palette-knife, and this could never be done in the quantities in which they are used in our hospitals and sold wholesale by some manufacturers. There is also a therapeutical disadvantage. Soap, even curd soap, is not a pure stearate of soda; it is apt to contain some free alkali and always contains a little chloride of sodium, which has been used to separate it from the excess of water and glycerine formed during its manufacture. I think, therefore, the use of soap ought to be discarded.

We use some quantity of suppositories at University College Hospital; they answer the purpose of both pessary and suppository. The pessary weighing one or two drachms seems to be going out of use, especially if made of a fatty basis,—in liquefying these are apt to discharge and be a source of great inconvenience to the patient. Such is not so much the case, I believe, with suppositories where they are firmly grasped by the sphincter, and little or no inconvenience, from inquiries I have made, is felt by persons who have used those made of oil of theobroma alone, as a basis. Nevertheless, the use of oil of theobroma has its disadvantages. It solidifies very slowly, especially in the summer, it is somewhat difficult to remove from the mould, and being a fatty substance, it impedes the absorption of the medicament the suppositories are impregnated with.

From Professor Marshall's experiments with oleic acid, I was led to try making suppositories of morphia with pure morphia, and a sufficient quantity of this as a solvent, the solution being added to a certain quantity of oil of theobroma and moulded into suppositories in the usual way. The results were so far successful; the suppositories were obtained uniform in strength, as the morphia was dissolved in the basis, not merely suspended in it. Still, I did not consider this was all that was desirable. I, therefore, thought of other fatty acids, the solid ones—stearic acid more particularly, and tried it, but the melting point of this I found much too high—pure stearic acid melts at 69° C. (154° F.). I next tried a mixture of the two, equal parts by weight of oleic and stearic acids, melted together, and with this I was successful beyond my expectations. I have tried it with several substances, and find such a mixture very superior to those in general use, for the following reasons:—

1. *This mixture has a very low fusing point, and readily melts at the temperature of the body.*—It is a curious fact—I quote from Watts' 'Dictionary,'*—that "when stearic acid is melted with more fusible fatty acids, the mixture fuses, not at the medium fusing-point, but mostly at a temperature, even below that of the most fusible acid of the mixture." Thus equal parts of stearic and palmitic acids melt at 56·6° C., stearic acid, as I have said, fuses at 69° C. Equal parts of stearic and oleic acids melt much lower still. I have not had the opportunity of testing the melting-point of the mixture, but it must be below 100° F., the temperature of the blood, as they readily melt when placed in their position; they even do this in the warm hand. This low melting point is of advantage in their manufacture; the heat of a warm composition mortar being all that is required to liquefy the basis, and also to dissolve the medicament when this is soluble, the suppositories can thus be extemporized in a few minutes and prepared for a customer while he waits, as such a basis possesses the advantage of solidifying almost directly.

2. *The suppositories leave the mould without any difficulty.*—Pure stearic acid has another peculiar property, and one which many of you may have noticed in the beautiful crystalline samples of it which are sometimes exhibited by candle manufacturers. It is, that it expands very strongly when heated, especially at the moment of fusion (about 11 per cent.), and contracts the same on solidifying, so much so that cast lumps of it appear porous. This porosity does not appear to such an extent in a mixture of stearic and oleic acids, but the contraction which takes place is even more than 11 per cent. Care therefore must be taken to pour the melted liquid into the mould just before it begins to solidify, and also to fill up the cavity with more fluid immediately after the first contraction has taken place in the mould; it is better then to pour in a little excess and scrape this off with a knife when the suppositories have become solid. This, as I have said, they do very quickly, the mould may then be opened, and owing to the contraction that has taken place, the suppositories are almost quite loose in their cavities, and may be removed with a touch of the finger.

3. *This basis has the advantage besides of being a solvent of such alkaloids as pure morphia and atropia, and of being itself readily absorbed by the epidermis and mucous membrane, at least so far as the oleic acid is concerned.* This may readily be tested by rubbing a little oleic acid upon the back of the hand; it is absorbed in a short time, where an oily layer would have remained for hours unabsorbed.

4. *On account of the partial crystallization of some of the stearic acid, the suppositories are firm and can be placed in their position without difficulty, not being elastic, brittle, or yielding in any way.* This is an advantage, especially for a suppository, not so much for a pessary. Their elasticity is a disadvantage to those made of a solution of gelatine in glycerine for use as a suppository. By pounding in a mortar suppositories made of the basis I suggest, they soon form a soft pasty mass; they cannot, therefore, be made except by liquefying and pouring into moulds in which the stearic acid can partially crystallize and make a firm mass.

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, April 2, 1873.

† PHARMACEUTICAL JOURNAL, 3rd Ser., Vol. III. p. 639.

* Vol. v. p. 414.

5. *The proportions of stearic and oleic acids can be varied to suit the temperature of summer or winter, and also the other ingredients prescribed with them.* The low melting-point is a disadvantage pertaining to oil of theobroma in the summer, as the suppositories made of it sometimes liquefy spontaneously.

I have had some made of the proposed basis used at the hospital as pessaries, and requested the sister of the ward and the obstetric assistant to make inquiry of the patients if they observed any of the inconveniences and objections raised against those having a fatty basis, and have received replies in the negative—they require a little longer time to dissolve than those made of oil of theobroma I was informed.

I exhibit samples containing three grains of tannic acid in each, and some containing $\frac{3}{4}$-grain precipitated peroxide of mercury dissolved in each; the latter are made by adding to melted stearic acid an equal quantity of 10 per cent. oleate of mercury, care being taken to use as little heat to this as possible, to prevent reduction of the mercury to the metallic state. There are also some containing $\frac{3}{8}$-grain pure morphia, equal to $\frac{1}{2}$-grain of the hydrochlorate. These are semi-transparent, the morphia being in solution in the basis. They all have a neat appearance, and I think are an improvement upon those at present in use.

Official formulæ for suppositories in the Pharmacopœia appear to me to be superfluous. They are rarely, if ever, ordered according to them; *e.g.*, we have of morphia $\frac{1}{4}$, $\frac{1}{3}$, $\frac{2}{3}$, $\frac{3}{4}$, and 1 grain suppositories almost as often used as $\frac{1}{2}$ grain ones. The others also are not adhered to; if a formula for a basis were inserted it is all that is necessary.

At the Hospital for Women in Soho Square, the pessaries used are made by Messrs. Duncan, Flockhart, and Co., Edinburgh. The basis, according to their pharmacopœia, is 1 part of gelatine to 4 parts of glycerine, the gelatine being soaked in water first for a short time, to render it readily soluble in the glycerine on the application of heat. They are made of the ordinary size of suppositories. I exhibit some samples of them, kindly given to me by Mr. Johnson. I am informed by Dr. Squarey that both he and Dr. Meadows have observed them discharged in their original shape undissolved in the morning, when they have been administered as pessaries the night before. The gelatine and glycerine basis is therefore not a good one for a pessary even, besides having the disadvantage of being elastic and not possessing firmness sufficient for use as a suppository. Dr. Squarey thinks that for use as pessaries even these are unnecessarily large, if they were smaller they would have a much better chance of being more readily dissolved and absorbed.

In conclusion, I may state that both stearic and oleic acids can be obtained commercially sufficiently pure for our purpose at prices not above that of oil of theobroma, the basis now in general use for suppositories.

THE MUSTARD OF THE PHARMACOPŒIA.*

BY THOMAS GREENISH, F.C.S.

It might be thought by many persons that this subject is scarcely one suitable for a pharmaceutical meeting, but mustard holds a place in our materia medica, and enters into one of the preparations of the Pharmacopœia, the cataplasma sinapis. It is to mustard, in connection with this preparation, that I shall chiefly confine my remarks.

The mustard cataplasm is a therapeutic agent of great value, resorted to in a period of emergency, and frequently in the absence of medical aid; and if any further justification were necessary, I may add this fact also, that Dr. Redwood has mentioned 'Charta Sinapis' as likely to form part of the forthcoming Appendix to the British Pharmacopœia.

Mustard was first introduced into the Pharmacopœia of 1788, in the formula for cataplasma sinapis, the official mustard was the *Sinapis nigra.*

Cataplasma Sinapeos, 1788.

℞ Seminum Sinapeos pulverum tritorum
Medullæ Panis sing. p. libram dimid.
Aceti quantum satis sit.
Misce ut fiat cataplasma.

In the next Pharmacopœia, that of 1809, the official mustard being still *Sinapis nigra*, the formula was altered.

Cataplasma Sinapis, 1809.

℞ Sinapis Seminum
Lini usitatissimi Sem.
Singulorum contrit. libram dimid.
Aceti Calid. q. s.
Ft. Cataplasma.

It will be observed that linseed is substituted for the bread-crumb, and the vinegar is directed to be boiling.

In the Pharmacopœia of 1824, and the one following, 1836, there was no alteration made either in the official mustard or the formula for the cataplasm; but in the edition of 1851, black and white mustard became official, and the cataplasm was ordered to be made with boiling water instead of vinegar.

Cataplasma Sinapis, 1851.

℞ Aquæ Ferventis, uncias decem
Lini Semin. contrit.
Sinapis contrit. sing. uncias duas cum semisse vel quantum satis sit.
Pulveres prius inter se mixtos, aquæ paulatim adjice movens ut fiat cataplasma.

Mr. Phillips, in his translation of the Pharmacopœia of 1851, remarked, in reference to this preparation, "that the vinegar directed in the former Pharmacopœias was useless, if not injurious, to the excitant effect of the mustard." He also adds some caustic observations on mustard; he says that "both varieties of mustard, black and white, are extensively cultivated in this country for preparing that much used condiment 'flour of mustard,' which is at the best flour of the seed mixed with wheaten flour, powdered capsicums and turmeric, and at the worst wholly destitute of mustard flour, consisting of the damaged flour of the cereals, etc., coloured by turmeric and rendered stinging by capsicum."

I shall at this stage of the subject allude to a preparation introduced into the Pharmacopœia of 1809, and continued to that of 1851, in which mustard played an important part.

Infus. Armoraciæ Comp. 1809 *to* 1851.

℞ Armor. Rad. recent. concis.
Sinapis Sem. contus. sing. unciam
Aquæ Ferventis octavium.
Macera per horas duas in vase leviter clauso et cola, tum adjice
Spt. Armoraciæ Comp. unciam.

---

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, April 2, 1873.

This infusion was prescribed as a stimulant in paralysis.

In a paper read before this Society in 1845 (PHARM. JOURN. Vol. V. 1st series, p. 62), I directed attention to the fact that if this infusion be made with boiling water, care being taken that the vessel used is of the same temperature, the result will be quite devoid of pungency, and consequently without value as a therapeutic agent. I then stated that "it is of the utmost importance that the laws which govern the formation of this volatile oil should be well understood." This infusion has been omitted since the Pharmacopœia of 1851.

We now arrive at the British Pharmacopœia, and find that both black and white mustard continue official, and that there is a further slight alteration, not in the ingredients or their proportions, but in the directions for making the mustard cataplasm.

Cataplasma Sinapis.

Take of—

Mustard in powder	$2\frac{1}{2}$ oz.
Linseed Meal	$2\frac{1}{2}$ oz.
Boiling Water	10 fluid oz.

Mix the linseed meal gradually with the water, and add the mustard with constant stirring.

The alteration here is, that the linseed meal is first mixed with water and the mustard added afterwards, the temperature being thus reduced. This is another step in the right direction, and I shall have occasion by-and-bye to refer to it again.

Black mustard contains two proximate principles, myrosin and myronic acid, the latteri n combination with potash, and it is to their mutual reaction that the formation of the volatile oil is due. Myrosin is an albuminous substance, soluble in cold and in lukewarm water, but coagulated by heat, alcohol, and acids. Here we have a reason for the successive alterations in the mustard cataplasm.

If black mustard flour be mixed with cold water, or water at a temperature below 100° F., the whole of the volatile oil it is capable of yielding may be obtained from it. If the temperature of the water be 140° or thereabouts, it does not yield more than half the quantity, and at 180° very little oil can be distilled from it. These variations are due to the partial or entire coagulation of the myrosin present. In making the cataplasm of the British Pharmacopœia, I find that when the linseed meal is added to the boiling water the temperature is reduced to 180°, and after the addition of the mustard to 160°. Either of these temperatures is too high for the full development of the volatile oil.

I would suggest here an alteration in the directions. Let the mustard be first mixed with two or three ounces of water under 100° or lukewarm. Boil the remaining part of the water, with which mix the linseed meal, and add this to the mustard, which has had time to develop its pungency. The temperature of the cataplasm will then be about 120°. It will be found at once fully efficient and about double the strength of that made by the present formula; and this, in many instances, may be of the utmost importance.

It is the speedy action which gives to a mustard poultice an advantage over a blister.

Mustard flour has never, I believe, been prepared by the pharmacist for medicinal use, and I may assume that this is never likely to be done in the pharmacy. Its preparation will be left to the manufacturer, who has special appliances for the purpose. In reference to this part of the subject, I cannot do better than quote the concise description of Dr. Pereira:—"The seeds of both black and white mustard are first crushed between rolls, and then pounded in mortars. The pounded seeds are then sifted. The residue in the sieve is called *dressings* or *siftings;* what passes through is *impure flour of mustard.* The latter by a second sifting yields *pure flour of mustard* and a second quantity of dressings. By pressure, the dressings or siftings yield a fixed oil (fixed oil of mustard), which is used for mixing with rape and other oils."

The black and white mustard seeds are crushed separately, and then mixed in definite proportions. There is a special object in this to which I shall have occasion again to allude. The fixed oil has some reputation as an external remedy in rheumatism, due probably to a little volatile oil developed in it; but the demand is very limited, the bulk of it melts away into the rape oils of commerce, and the marc, as a solid cake, is sold for manure, and report says that it sometimes finds its way accidentally (?) into linseed cake. Formerly, when black pepper paid a duty, this mustard bran or dressings was extensively used in its adulteration. Through the courtesy of Messrs. Dewar and Sons, mustard manufacturers, of Newcastle-on-Tyne, I am enabled to place on the table samples of genuine mustard flour. I have here black mustard flour, white mustard flour, brown and white mixed, and another sample of the same from which a further portion of the husk has been sifted,* and also husks to which the name of dressings has been applied, and from which the fixed oil is expressed; a sample of the fixed oil and of the mustard cake are likewise on the table.

The question will naturally occur, why mix white with black seeds? The explanation is this. The quantity of myrosin in the black mustard seed is not sufficient for the decomposition of all the myronate of potassium present, and as the white mustard seed contains a large quantity of myrosin and no myronate of potassium, it is added with advantage and economy. If water be added to pure flour of black mustard seed, the essential oil allowed to form and then removed, a further addition of flour of white mustard seed will again give rise to more essential oil, and thus prove that all the myronate has not been decomposed by the quantity of myrosin naturally present in the black seed; and I believe that by decomposing this excess of myronate of

* In a letter received from Mr. Frazer respecting this latter article he says:—

"It must now be some twenty or twenty-five years since we adopted Dewar of Newcastle's pure brown mustard as the sole article of mustard kept by my firm in Glasgow. For two or three years we had to fight against a widespread prejudice in the public mind against its deeper colour than that of the article commonly in use, as also against the dark specks present in it.

"Finding this prejudice to be so strong as practically to render the sale of it almost impossible, I suggested to Mr. Dewar so to modify, if practicable, his process of manufacture, as to reduce the amount of dark specks to a minimum.

"Mr. Dewar did so, and the result was the production of a mustard at once absolutely genuine, and yet so near to the colour of that in ordinary use, that at length we were able to induce the public to give it a fair trial.

"Since then we have kept nothing but the pure article, and the results are such as amply to compensate us for the patience we had to exercise in its introduction."

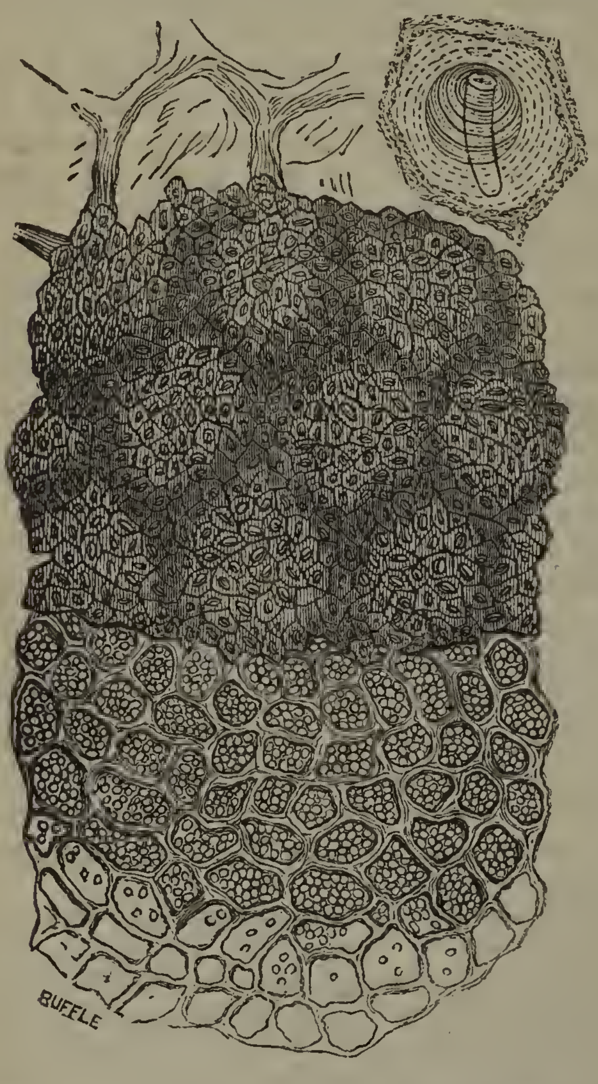
potassium, the bitter taste in the black mustard can be entirely removed, making it more agreeable for table use.

I think it would be an advantage if some certain proportions of the two seeds were given in our materia medica, so as to define absolutely what is to be understood as the official mustard.

Having considered mustard from a pharmaceutical point of view, I will now add a few remarks on the mustards of commerce, neither of which can be called the mustard of the Pharmacopœia.

I have examined a large number of commercial mustards, and find that they are all more or less mixed compounds. I am indebted to Mr. Martindale for several samples obtained in various parts of the metropolis, in one of which there is from 30-50 per cent. of a mixture of wheat and pea flour, the colour of the latter admirably adapting it for this purpose.

I do not know a better or more interesting subject than mustard for the "'prentice hand" of the student using his microscope for the advancement of pharmacy. Let him take a black mustard seed; soak it an hour in cold water, then boil it in a dilute solution of caustic potash (about 1 pt. of Liq. potassæ to 20 of water). He will then be able to separate the three coats of which the integument is composed, and study them under his microscope. I have here several slides of these three coats which may be examined presently, and from which the accompany-



ing woodcut has been made. The middle coat is the characteristic coat of the black mustard seed, and contains the colouring matter; an intimate acquaintance with these coats will teach him what is black mustard when he meets with it under the microscope. In the top right-hand corner is a drawing of the characteristic cell of the white mustard. Then let him take a sample of commercial mustard, place a little of it with a drop of water on his slide, and cover it with a glass, and with a power of 250 to 300 linear he will see starch grains. If his eye has not been accustomed to recognize starch-grains under the microscope let him touch the contents of the slide with a drop of a solution of six drops of tincture of iodine to an ounce of water, when the granule of starch will assume a faint violet colour. And I would here caution him against a mistake he may be likely to commit. If he mixes the mustard with water in a watch-glass, adding a small quantity of this very dilute solution of iodine, the development of the volatile oil will decolorize any starch that may be present before it is examined.

I would recommend to the careful consideration of the student some remarks of Mr. Stoddart on this subject in "Bristol Pharmacology" (PH. JOURNAL, Vol. I., 3rd Series, p. 661).

I am indebted to Mr. Rochfort Connor, of Somerset House, for these very beautiful and accurate drawings which are now exhibited, showing the several coats of the black and white mustard seed, and I am happy to see him amongst us this evening.

It is not my intention on this occasion to consider the dietetic uses of mustard; but I would express this opinion, that there is no necessity for the admixture of any foreign ingredient, such as wheat-flour, turmeric, or capsicum.

Black mustard-flour mixed with one-sixth of its weight of white, will make a condiment acceptable for table use, and at the same time suitable for the Cataplasma sinapis.

The consideration of the Charta sinapis of the future would occupy too much of our time this evening; but I hope on a future occasion to bring this subject specially under your notice.

THE EXTINCTION OF MERCURY IN FATTY BODIES.*

BY M. MAGNES-LAHENS.

Many fatty bodies have been successively vaunted as having a special action upon the extinction of mercury, and this action has been often attributed to their chemical composition; but the author is of opinion that the consistence of these fats exercises a much greater influence upon the extinction of the mercury than their composition. He has, in fact, found,—

(1.) That fats naturally liquid, employed in small quantity, reduce the mercury to a homogeneous and permanent paste with considerable and nearly equal rapidity; the advantage, however, being in favour of those liquid fats which have the most fluidity.

(2.) That fats naturally solid, employed in the same proportions, extinguish the mercury with a difficulty and slowness proportional to their hardness; but that when liquefied completely by heat, they accomplish the extinction nearly as quickly as the naturally liquid fats. This extinction, however, is not permanent, and the mercury reappears in large drops, as, in cooling, the mass hardens and cracks in a thousand places.

M. Lahens therefore concludes from these experiments that the extinction of the mercury is due to a slight layer of fat which envelopes the imperceptible globules of mercury, keeping them separated one from another, and that the extinction continues or

* Abstracted from paper in the *Journal de Pharmacie et de Chimie* [4], vol. xvii. p. 220.

ceases according as this coating preserves its integrity or is broken. The extinction of the mercury would then be the result of a purely mechanical force and not in any way of chemical action. The small quantity of oxide of mercury said to be found in mercurial ointment obtained by long rubbing and prolonged exposure to the air proves nothing contrary to this opinion.

The aptitude which lard acquires by liquefaction for the extinction of mercury, and the revivification of the metal in the mass as it cools, explain why the Paris Codex prescribes that the lard shall be half melted during the preparation of mercurial ointment. But the operation so conducted is very slow, and only accomplished after long manipulation, which predisposes the ointment to rancidity and weakens its consistence, and for this reason apparently the Codex orders the addition of a large proportion of wax.

Led by these considerations, the author has for some time been in the habit of adding a small quantity of oil of sweet almonds, the use of which in the following manner gives satisfactory results:—

Mercury	1000 grams
Oil of Sweet Almonds .	20 "
Lard	980 "

Mix intimately the mercury with the oil in a mortar, or preferably in a wide shallow vessel, by means of a large-headed wooden pestle. After twelve or fifteen minutes the mercury is reduced to a kind of homogeneous paste, in which scarcely any globules are perceptible to the naked eye. Mix this paste with 200 grams of melted lard until the mercury has completely disappeared,—less than an hour will usually obtain this result,—and then incorporate the rest of the lard cold by a few minutes' rubbing. Not more than 200 grams of lard should be added first, as a greater quantity retards a successful result.

Since the adoption in the Codex of benzoated lard for the preparation of mercurial ointment, the author has modified this process in the following manner:—

Mercury	1000 grains
Oil of Sweet Almonds .	20 "
Balsam of Peru. . . .	20 "
Lard	960 "

The mercury disappears with surprising rapidity in the mixture of oil of sweet almonds and balsam of Peru; when a homogeneous paste has been formed, the process should be continued as before.

This method M. Lahens considers preferable to the former. The mercurial ointment so produced he states to be smooth, beautifully bright and of a good colour, having an agreeable odour and easily preserved. The consistence also is good if lard of good quality be used.

THE PREPARATION OF PURE OLEIC ACID.

Some difficulty having been met with in obtaining commercial oleic acid uncontaminated by oxyoleic and stearic acids, the presence of which is detrimental to the preparation of oleates of mercury and morphia, a correspondent of the *American Journal of Pharmacy* publishes the following method of producing a pure oleic acid, from which oleates have been prepared that have not in any instance recipitated, and that are unobjectionable in colour and ppearance.

Any given quantity of almond oil* is taken and saponified by means of potash, care being taken to insure the entire saponification of the oil, which may be easily tested by means of strong alcohol. The soap is then decomposed by means of tartaric acid, carefully washed to free it from bitartrate of potash, etc.; then placed on a water-bath, and heated for several hours with half its weight of finely-powdered oxide of lead; the resulting combination, after cooling, is mixed with about three times its volume of ether, and allowed to settle; the clear ethereal solution is decanted and the residue treated by a fresh portion of ether, and decanted as before. The mixed ethereal solutions are then briskly agitated with an excess of dilute hydrochloric acid, to eliminate the oleic acid, which rises dissolved in the ether to the surface of the water. The solution is next washed with water and distilled to recover the ether, which may be used for a subsequent operation.

The portion remaining in the still consists of oleic acid $C_{36}H_{33}O_3,HO$ contaminated with a certain quantity of oxyoleic acid $C_{36}H_{32}O_4HO+HO$. In order to free it from the latter, the mixture is saturated with solution of ammonia, and the resulting compound, decomposed by means of chloride of barium, which throws down a precipitate of oleate and oxyoleate of baryta. The precipitate is then dried and treated with boiling alcohol, which deposits, on cooling, crystals of oleate of baryta, without any trace of oxyoleate. The oleate is then decomposed by a solution of tartaric acid in *boiled* distilled water, which sets free the pure oleic acid. Care must be taken in washing this acid for the last time, and also in decomposing the oleate of baryta, to avoid contact with the atmosphere.

When thus prepared, oleic acid is nearly colourless and slightly thinner than almond oil; it dissolves readily the binoxides both of mercury and morphia, forming with them solutions varying from almost white (5 per cent.) to the colour of linseed oil (10 and 20 per cent.) without giving rise to precipitates.

In preparing the oleates, the mixture should never be heated to more than 150° F., and the solution should be made in a closed vessel, in which the atmospheric air has been deprived of its oxygen or replaced by pure hydrogen; proper precautions being taken to allow for the expansion of the gas before entirely closing the apparatus.

COD-LIVER OIL AND LACTO-PHOSPHATE OF LIME

BY EDWARD CHILES.

This remedy is being quite extensively prescribed by physicians; and as considerable inquiry has been made as to an eligible mode of prescribing it, I will give my experience in the manufacture of the article.

For a long time I have had demand for a tasteless cod-liver oil, and have been in the habit of preparing it in the form of an emulsion with gum arabic and water, and covering the odour with a few drops of essential oil of bitter almonds.

Over a year ago I found physicians were prescribing cod-liver oil and lacto-phosphate of lime, and I devised a formula for it, based on my experience with the simple emulsion and the syrup of lacto-phosphate of lime, for which a considerable demand had sprung up. The formula I then devised has been followed by me up to the present time, and has invariably given satisfaction, and produces an article which does not separate or become rancid.

I think, however, it should be prepared extemporaneously as prescribed by physicians, and I have not kept it on hand, but prepare it as wanted, thus always giving a perfectly sweet article.

* Preference is given to this oil on account of its lesser liability to sophistication.

† From the *American Journal of Pharmacy*.

Take of	Gum arabic	℥ij ʒij
	Water	f℥ij
	Syr. lacto-phosphate of lime	f℥vi
	Cod-liver oil	f℥viij
	Essential oil bitter almonds	6 drops.

Rub the gum, water, and syrup together, until a smooth mucilage is made, then add the oil gradually with constant stirring, and, lastly, the oil of bitter almonds.

Thus made, each tablespoonful of cod-liver oil and lacto-phosphate of lime contains four (4) grains lacto-phosphate of lime and 50 per cent. of cod-liver oil. The gum in the above should be selected, ground, and passed through a sieve of 60 meshes to the inch. Cod-liver oil and lacto-phosphate of lime prepared in this manner forms a preparation free from unpleasant taste and odour, and enables the practitioner to administer these valuable remedies without repugnance on the part of the patient.

COMPETITIVE EXAMINATIONS IN CHINA.

The following description of the method of conducting the grand examination in China, is from the special correspondent of the *Illustrated London News*:—

"Mr. Simpson, while at Pekin, visited the Wen-Miao, or Temple of the ethical religion bequeathed to the Chinese nation by their great philosopher Confucius, or Kung-Fu-Tzse, who lived five centuries before Jesus Christ. In this temple is the place for the grand examinations. There are other Examination Courts in every provincial capital, where the first two degrees can be given; but the two higher degrees can only be competed for at Pekin. The Chwang-Yuen is the fourth degree, and is equivalent to our Senior Wrangler. He who gains this degree is also called 'One of the Ten Thousand.' The place where the examination is held contains ten thousand, and hence the name, for there is only one man out of that number who can receive the honour once in three years. Examination after examination, men come up to compete, till they grow old and grey; such is the desire to achieve this high distinction. It is told of one man that he competed every three years till he was eighty. When men persevere till this great age the Emperor generally confers some honour upon them. The competition at Pekin is a hard trial. It lasts nine days, and is divided into three 'goes.' For three days and three nights the 'ten thousand' are confined in pens, each man being imprisoned, so that he is totally separated from his neighbours, and there he has to write his essay or paper on the subject given out by the judges, which he does not know till he is in his cell. Paper, with an official stamp, is given out for him to write upon, and all depends upon his memory of the classics. Miniature copies have been produced, so that they could be smuggled in, but it is a crime to print or sell such copies now. 'I have read,' says Mr. Simpson, 'some of the efforts produced. They remind one much of early school essays, or essays for young men's associations for mental cultivation at home, but they are embellished with endless quotations from the classics, and the style may be described as the sign-board style; a flowery phraseology largely predominates."

"The examination court at Pekin is usually spoken of by the English residents there as a "hall of examination," but it is difficult to see how the word "hall" can be applied to it. A hundred and twenty rows of small, low, badly-built sheds, with a watch-tower in the centre, would not resemble what we should term a hall. For each student there is a small cell, little more than a yard square, and with height only for a man to stand up in. These cells are built in rows of about forty-five in the row, each row being separated from the next by a narrow passage just wide enough for a person to pass. There are about 120 of these rows, the whole number of cells being 9999. At the north-west corner a number of new cells are being constructed to afford more accommodation. There is a set of houses at the northern part for the examiners or judges to lodge in; for these persons are kept there the whole time, so that they cannot be communicated with by friends of the competitors. The tower in the centre is occupied during the whole time by watchers, to see that there is no communication between the students themselves or with anyone without the place. There are smaller towers at the corners for the same purpose, and guards walk along on the inside of the walls to prevent anything passing close by. There is a central passage up the middle of this place, and on each side of it are boilers for preparing food, and large earthen jars to keep a supply of water for drink.

"Each cell has two grooves in it, and boards are let into them—one for a seat, the other for a desk. The lower one, which serves as a seat, has to serve also as a bed. Each student is allowed to bring in some article of clothing to wrap himself in when he goes to sleep, which must be done in a sitting posture or doubled up on the board. Stamped paper is supplied to each man, as stated above, in order to prevent tricks; he has an ink-slab with pens, a teapot and teacup—such are the conditions under which a Chinese student has to compete for honours. It has been remarked that the competitiors here are not boys or all young men. Men of all ages come from every part of the country; but the Chinese student is seldom a lean, worn-out man, as our ideas of such a character might picture him. The degree of Sieu-Tsai is equivalent to Bachelor of Arts, Chü-Jen is equal to M.A., and Chin-Shü corresponds to our Doctor. Chang-Yuen, as was stated, is the highest honour, the degree exclusively conferred at Pekin, and is only awarded to one person every three years. All the other competitive examination courts in China may be understood from this one at Pekin. At Canton the court has 7500 cells, each 3 ft. by 4 ft. in dimensions. 'When a man,' says Mr. Simpson, 'gains any of the degrees of these examinations, his name is placed on the front of his father's house, and the village or town is proud of the distinction. Place and preferment are before him. He may rise to the highest dignities of the State. If he attains to great renown as a literary man, there are Confucian temples where tablets are erected to celebrities, and his name may be handed down to posterity.'"

PROFESSOR TYNDALL ON LIGHT.*

(*Continued from p.* 770.)

We shall study this subject of the polarization of light with great ease and profit by means of a crystal of tourmaline. And let us start with a clear conception of an ordinary beam of light. It has been already explained that the vibrations of the individual ether-particles are executed across the line of propagation. In the case of ordinary light we are to figure the ether-particles as vibrating in all directions, or azimuths, as it is sometimes expressed, across this line. Now, in a plate of tourmaline cut parallel to the axis of the crystal, the beam of incident light is divided into two, one vibrating parallel to the axis of the crystal, the other at right angles to the axis. The grouping of the molecules, and of the ether associated with the molecules, reduces all the vibrations incident upon the crystal to these two directions. One of these beams, namely, that one whose vibrations are perpendicular to the axis, is quenched with exceeding rapidity by the crystal, so that, after having passed through a very small thickness of the crystal, the light emerges with all its vibrations reduced to a single plane. In this condition it is what we call a beam of plane polarized light.

A moment's reflection will show, if what has been stated be correct, that, on placing a second plate of tourmaline with its axis parallel to the first, the light will pass through both; but that if the axes be crossed, the light that passes

* Abstract of a series of lectures delivered in the Cooper Institute, New York, and reported in the *New York Tribune*.

through the one plate will be quenched by the other, a total interception of the light being the consequence. The experiment is now before you: the image of a plate of tourmaline is upon the screen. I place parallel to it another plate: the green of the crystal is a little deepened, nothing more. By means of an endless screw, I now turn one of the crystals gradually round; as long as the two plates are oblique to each other a certain portion of light gets through; but when they are at right angles to each other the space common to both is a space of darkness.

It is on the green light which has been transmitted by the tourmaline that you are now to fix your attention, and now we may illustrate the two-sidedness of that green light. The light surrounding the green image being ordinary light is reflected in all directions; the green light, on the contrary, is not so reflected. The image of the tourmaline is now horizontal; I reflect it upward, and you see it still to be green. I reflect it sideways; the image is reduced to blackness because of the incompetency of the green light to be reflected in this direction. Making the plate vertical and reflecting it as before, in the upper image the light is quenched; in the side image you have now the green. Picture the thing clearly. In the one case the mirror receives the impact of the edges of the waves, and the green light is quenched. In the other case the sides of the waves strike the mirror, and the green light is reflected. To render the extinction complete, the light must be received upon the mirror at a special angle. What this angle is we shall learn presently.

The quality of two-sidedness conferred upon light by Iceland spar may also be conferred upon it by ordinary reflection. Malus made this discovery in 1808, while looking through Iceland spar at the light of the sun reflected from the windows of the Luxembourg Palace in Paris. I receive upon a plate of window-glass the beam from our lamp; a great portion of the light reflected from the glass is polarized; the vibrations of this beam are executed, for the most part, parallel to the surface of the glass, and if I hold the glass so that the beam shall make an angle of 58 degrees with the perpendicular to the glass, the whole of the reflected beam is polarized. It was at this angle that the image of the tourmaline was completely quenched in our former experiments. It is called the polarizing angle.

And now let us try to make substantially the experiment of Malus. I receive the beam from the lamp upon this plate of glass and reflect it through the spar. Instead of two images, you see but one. So that the light, when polarized as it now is, can only get through the spar in one direction, and consequently produce but one image. Why is this? In the Iceland spar, as in the tourmaline, all the vibrations of the ordinary light are reduced to two planes at right angles to each other; but, unlike the tourmaline, both beams are transmitted with equal facility by the spar. The two beams, in short, emergent from the spar, are polarized, their directions of vibration being at right angles to each other. When, therefore, the light was polarized by reflection, the direction of vibration in the spar which corresponded to the direction of vibration of the polarized beam transmitted it, and that direction only. But one image, therefore, was possible under the conditions.

And now you have it in your power to check many of my statements, and you will observe that such logic as connects our experiments is simply a transcript of the logic of Nature. On the screen before you are the two disks of light produced by the double refraction of the spar. They are, as you know, two images of the aperture through which the light issues from the camera. Placing the tourmaline in front of the aperture, two images of the crystal will be obtained; but now let us reason out what is to be expected from this experiment. The light emergent from the tourmaline is polarized. Placing the crystal with its axis horizontal, the vibrations of the transmitted light will be horizontal. Now the spar has two perpendicular directions of vibration, one of which at the present moment is vertical, the other horizontal. What are we to conclude? Why, that the green light will be transmitted along the latter, which is parallel to the tourmaline, and not along the former, which is perpendicular to it. Hence we infer that one image of the tourmaline will show the ordinary green light of the crystal, while the other image will be black. Let us test our reasoning. You see it is verified to the letter. By means of an endless screw I can turn the crystal 90 degrees round. The black image becomes gradually brighter, and the bright one gradually darker; at an angle of 45 degrees both images are equally bright; while, where 90 degrees have been obtained, the axis of the crystal being then vertical, the bright and black images have changed places.

Given, two beams transmitted through Iceland spar, it is perfectly manifest that we have it in our power to determine instantly, by means of a plate of tourmaline, the directions in which the ether-particles vibrate in the two beams. I might place the double-refracting spar in any position whatever. A minute's trial with the tourmaline would enable you to determine the position which yields a black and a bright image, and from these you would at once infer the directions of vibration.

Further, the two beams from the spar being thus polarized, if they be received upon a plate of glass at the polarizing angle, one of them will be reflected, the other not. This is the conclusion of reason from our previous knowledge.

I have said that the whole of the beam reflected from the glass at the polarizing angle is polarized; a word must now be added regarding the larger portion of the light which is *transmitted* by the glass. The transmitted beam contains a quantity of polarized light equal to that of the reflected beam; but this quantity is only a fraction of the whole transmitted light. By taking two plates of glass instead of one, we augment the quantity of the *transmitted* polarized light; and by taking a bundle of plates, we so increase the quantity as to render the transmitted beam, for all practical purposes, perfectly polarized. Indeed, bundles of glass plates are often employed as a means of furnishing polarized light.

Let us push our reasoning still further. When the tourmalines are crossed, the space where they cross each other is black. But we have seen that the least obliquity on the part of the crystals permits light to get through both. Now suppose, when the two plates are crossed, that we interpose a third plate of tourmaline between them, with its axis oblique to both. A portion of the light transmitted by the first plate will get through this intermediate one. But after it has got through, its plane of vibration is changed; it is no longer perpendicular to the axis of the crystal in front. Hence it will get through that crystal. Thus, by reasoning, we infer that the interposition of a third plate of tourmaline will in part abolish the darkness produced by the crossing of the other two plates. I have not a third plate of tourmaline; but the talc or mica which you employ in your stoves is a more convenient substance, which acts in the same way. Between the crossed tourmalines, I introduce a film of this crystal. You see the edge of the film slowly descending, and as it descends between the tourmalines, light takes the place of darkness. The darkness, in fact, seems scraped away as if it were something material.

We now stand upon the threshold of a new and splendid optical domain. We have to examine the chromatic phenomena produced by the action of crystals, and double-refracting bodies generally, upon polarized light. For a long time investigators were compelled to employ plates of tourmaline for this purpose, and the progress that they made with so defective a means of inquiry is astonishing. But these men had their hearts in their work, and were on this account enabled to extract great results from small instrumental appliances. But we have better apparatus now. You have seen the two beams emergent from Iceland spar, and have proved them to be polarized. If we could abolish one of these beams, we might employ the other for experiments on polarized lights. These beams, as you know, are refracted differently, and from this we are able to infer that under some circumstances the one may be totally reflected, and the other not. An optician, named Nicol, cut a crystal of Iceland spar in two in a certain direction. He polished the severed surfaces, and reunited them by Canada balsam, the surface of union being so inclined to the beam traversing the spar that the ordinary ray, which is the most highly refracted, was totally reflected by the balsam, while the extraordinary ray was permitted to pass on. The invention of the Nicol's prism was a great step in practical optics, and quite recently such prisms have been constructed of a size which enables audiences like the present to witness the chromatic phenomena of polarized light to a degree altogether unattainable a short time ago. The two prisms here before you belong to my excellent friend Mr. Wm. Spottiswoode, and they were manufactured by Mr. Ladd. I have with me another pair of very noble prisms, still larger than these, manufactured for me by Mr. Browning, who has gained so high and well-merited a reputation in the construction of spectroscopes.

These two Nicol's prisms play the same part as the crystals of tourmaline. Placed with their directions of vibration parallel, the light passes through both. When these directions are crossed, the light is quenched. Introducing a film of mica between the prisms, the light is in part restored. But notice, when the film of mica is thin, you have not only light, but coloured light. Our work for some time to come will be the examination of these colours. With this view, I will take a representative crystal, one easily dealt with; that is, the crystal gypsum, or selenite, which is crystallized sulphate of lime. Between the crossed Nicol's I place a thick plate of this crystal; like the mica, it restores the light, but it produces no colour. With my penknife I take a thin splinter from this crystal and place it between the prisms; its image on the screen glows with the richest colours. Turning the prism in front these colours gradually fade, disappear, but by continuing the rotation until the vibrating sections of the prisms are parallel, vivid colours again appear, but these colours are complementary to the former ones.

Some patches of the splinter appear of one colour, some of another; these differences being due to the different thicknesses of the film. If the thickness be uniform the colour is uniform. Here, for instance, is a stellar shape, every lozenge of the star being a film of gypsum of uniform thickness. Each lozenge, you observe, shows a brilliant uniform colour. Of course it is easy, by shaping our films so as to represent flowers or other objects, to exhibit such objects in colours unattainable by art. Here, for example, is a specimen of heartsease, the colours of which you might safely defy the artist to reproduce. By turning the front Nicol 90° round, we pass through a colourless phase to a series of colours complementary to the former ones. Here, for example, is a rose on a twig; a red flower and green leaves; turning the prism 90° round, we obtain a green flower and red leaves.

All these wonderful chromatic effects have definite mechanical causes in the motions of the ether; the principle of interference, duly applied and interpreted, explains them all; and if you give me your patience, we shall, as far as it is necessary, develop the causes of these effects in our next lecture.

THE DETERMINATION OF THE MELTING AND SOLIDIFYING POINTS OF FATS.*

BY F. RUEDORFF.

On testing all the usual methods for determining the melting points of fats, the author obtained the most concordant results by covering a thermometer-bulb with a layer of fat, about 3 mm. thick, immersing it in hot water, and observing the temperatures at which the fat began to separate from the bulb and to ascend through the water. Although some fats, and more particularly nutmeg-butter, did not rise from the thermometer even at temperatures considerably above those at which they are perfectly fluid, the author prefers his method to Wimmel's, to which the same cause of inaccuracy, namely, adhesion to the glass, attaches in a still greater degree.

The solidifying points of some fats were determined by observing the temperatures at which they became solid whilst they were violently agitated; but with the glycerides and some other fats which exhibit a rise of temperature during solidification, it was found best to take as solidifying point that temperature to which the thermometer rises during solidifying, as this maximum temperature appeared to be more constant than the turning-point, which has been determined and given as the natural solidifying point by Wimmel.

The following table exhibits the author's results:—

	Melts at	Solidifies at
	°C.	°C
Yellow bees-wax ...	63·4	61·5 62·6 62·3
White bees-wax......	61·8	61·6
Paraffin	49·6 52·5 to 54 53 52·7 to 53·2	49·6 53 52·9 52·7
Spermaceti	43·5 44·1 to 44·3	43·4 44·2
Stearic acid	55·3 56·2 to 56·6 56·0 to 54·4	55·2 55·8 55·7
Japan wax	50·4 to 51·0	...
Cacao butter	33·5	...
Nutmeg butter	70 to 80	...
Mutton suet	46·5 to 47·4	32 to 36
Beef suet	43·5 to 45·0	27 to 35

The remarkable phenomenon of a rise of temperature during solidification was also observed in artificial mixtures of fats; for instance, of spermaceti and stearic acid, and of paraffin and stearic acid, and is probably due to the constantly varying composition of the liquid remaining behind during partial solidification. A change in composition as solidification goes on, may possibly also explain the great interval of temperature during which beef and mutton suet pass from the liquid into the solid state.

DETECTION OF WATER IN ESSENTIAL OILS.*

BY G. LEUCHS.

All essential oils obtained by distillation with water contain water even when they appear quite clear. The author finds that when such oils are mixed with several times their volume of petroleum-ether (the so-called benzin), a turbidity is produced, owing to the separation of globules of water, the turbidity being the more marked the greater the quantity of water present. By this means he found water in the oils of lavender, cloves, spike, cinnamon, rosemary, sassafras, and juniper; the oils of lemon and bergamot likewise contained traces of water, as did also Portugal oil and the oil of *Gaultheria procumbens*: on the other hand, the oils of turpentine, cedar, lemon, rue, and amber were found free from water.

The Pharmaceutical Journal.

SATURDAY, APRIL 5, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

OUR ANNIVERSARY.

IT is now within six weeks of a year since it was our pleasing duty to record an event which then for the first time constituted a feature of the Society's annual gathering, though novelty was far from having been the only attraction it presented. We refer to the dinner at the Crystal Palace. At the time we ventured to apply to it the name "annual," on account of the very great satisfaction it gave to those who were present, and the generally expressed desire that it should be kept up as a periodical reunion of all those engaged in the drug trade who are able to be in London at the Society's Anniversary Meeting.

We are induced to draw attention to this matter now, since the time is close at hand, and also because we have recently heard many inquiries as to what is being done in arranging for the annual dinner. We think, therefore, that it would be opportune to suggest that those who entertain the desire to see the annual dinner successfully carried out this year should at once enter into communication on the subject and take decisive action to that end. A considerable amount of work is involved in making the arrangements necessary for the purpose, and it will doubtless be in the memory of those who shared in last year's festivity, that this work was on that occasion generously undertaken single-handed. To that circumstance, indeed, is to be ascribed, not only the success then achieved, but also the inauguration of the annual dinner; and, remembering this, the thought may naturally occur to many, that this year's arrangements cannot be left in better hands than those of the HONORARY SECRETARY of last year. But a second thought will as surely suggest that such an opinion can only be regarded as an instinctive compliment, and that it would be unreasonable, as well as ungrateful, to expect a repetition of the services rendered on that occasion by Mr. CARTEIGHE.

Probably the most convenient course would be for those desirous of co-operating in the matter, to communicate with Mr. BREMRIDGE, with the view of holding a meeting for the appointment of a committee, and we would especially urge upon the London members of the trade to embrace this opportunity of reciprocating the cordiality, so universally shown by their provincial brethren, at the various meetings of the Pharmaceutical Conference.

THE GENERAL MEDICAL COUNCIL.

THE medical parliament has met, and has occupied a whole week with discussion rather than business. We shall try and estimate the results of its deliberations presently, but we cannot help drawing attention to the extreme verbosity and wanton interruption indulged in by its speakers. To read the reports of its meetings in our medical contemporaries one would almost fancy oneself perusing the rhetorical encounters of a debating society, so crude is the language, so confused the tenor of debate, so petulant the recrimination. Some three-quarters of an hour, for instance, were wasted over Sir WILLIAM GULL'S expression of astonishment "at the course taken by Dr. ALEXANDER WOOD and Dr. ANDREW WOOD who, he thought, must have some *arrière pensée*." The unfortunate imputation at once brought the Drs. WOOD to their feet; indignant reclamations followed. Sir DOMINICK CORRIGAN, with a truly Milesian pugnacity, joined in the fray, which, by the time he sat down, had acquired the proportions of a regular "Donnybrook." Meanwhile the PRESIDENT sat as helpless as his counterpart in the French Chamber during an "interpellation" by GAMBETTA. Unless the "medical parliament" mend its ways, it will achieve an unenviable notoriety, and its meetings will have the same sort of attraction for the public as a Fenian demonstration in Hyde Park, or the Zoological Gardens at feeding time.

Sed haec hactenus. The subject of most interest to our readers in the Medical Council's transactions was its adoption of the report of the Pharmacopœia Committee, recommending, first, a reprint of the present Pharmacopœia, with such improvements as may be requisite; and, second, an Appendix embodying information as to medicines, whether newly-introduced or newly-prepared. We have already expressed our conviction that the Pharmacopœia should not be recast, or even modified, at too rapidly recurring intervals—a reprint, supplemented by an Appendix, being all that is required for the pharmacist and practitioner alike. Meanwhile the Committee might do worse than reconsider the doses of the more potent medicines as they are laid down in the present Pharmacopœia. A medical contemporary remarks, with apparent justice, that in the case of solution of strychnia and tincture of nux vomica, for instance, less than the largest doses prescribed by the Pharmacopœia do certainly produce decided physiological effects.

Of smaller interest to our readers, was the prolonged discussion on the so-called "Conjoint Scheme," by which a fusion of the various, and often competing, examining boards is sought to be effected. The Scotch members, it seems, consider their examining bodies as nearly perfect, and see no necessity for "levelling-down," to England and Ireland by passing under the roller of uniformity. They have no objection, however, to England and Ireland uniting on whatever basis of fusion they please, or for separately making conjoint Boards in either kingdom. Their policy is characteristically cunning. The higher standard of examination which such conjoint Boards would establish in England and Ireland, would scare all the less competent candidates into the hospitable arms of the northern schools, which would demand but half the diploma-fee of their rivals, and not quite so much preliminary and professional science. On petitioning the Government, however, to pass an enabling bill to bring about a conjoint scheme for England, the diplomacy of the northern contingent was frustrated,—the Government declining to introduce such an enabling bill. So while they gained in principle, they lost in profit. Cold water was thrown on conjoint schemes generally; but the sacrifice of England and Ireland to that principle was a pleasure that was denied them.

A tedious debate on the report of the Committee on the medical qualification of women, ended in the Committee being empowered to enter into communication with any public institution, in which provision is made for the education and examination of women, as midwives, as dispensers, and as superintendents of nurses or of medical institutions, as well as to consider and report on how a register of all persons obtaining qualifications from such bodies might be kept, on conditions similar to those for registering medical and surgical diplomas. The discussion embodied not a little that is of interest to pharmacists, and we shall return to the subject next week.

THE SURVIVAL OF THE FITTEST (?).

The struggle for existence which, according to the fashionable scientific theory of the day, has shaped the career of all creatures, from governments to gooseberries inclusive, has many evils to answer for. Not that the survival of the fittest is so much to be regretted, as that sometimes circumstances have been so untoward as to allow—at least in the human *mêlée*—that which is not fittest to survive. The weakest, but not always the worst, have gone to the wall; for in the struggle deceit, cunning, and impudence have always been appreciable powers, notwithstanding that the greatest intellects in all ages of the world have been bent to the task of modifying and counteracting their influence. In this country we have arrived at a stage when an efficient examination is looked upon theoretically as a panacea for all shams; but there exists considerable difference of opinion as to what constitutes an efficient examination. On the one hand prospective examinees remonstrate piteously against examinations lasting two or three hours; on the other a relentless examiner cries out, "I want days; I want weeks, before I should say that a man was fit to pass." Moreover, no more is required from the man who has enjoyed years of neglected opportunities, than from one who has made the most of as many months. Added to these elements of disturbance in the testing of shams is the introduction of the greatest sham of the whole, the system of studying a subject in order to meet the examiners' questions rather than for its own sake, known popularly as "cramming," or as it has been termed "getting up to the boiling point" in regard to the subjects of an examination. This phase of the competition between sham and anti-sham has recently been described by a writer in *All the Year Round* as follows:—

"The contest of the crammers and the examiners has been almost as interesting, and probably as arduous, as the perennial duel between ships and guns. Just as it is all but impossible to construct a lock which some other cunning artificer cannot pick, so it appears hopeless to devise a system of questions that shall test the sterling stuff of which competitors are made, without reference to the cut and-dried information with which they have been supplied. Change after change may be made, surprise after surprise attempted, but the ingenuity of the scholastic wire-pullers is equal to the occasion. The disgusted examiner, confident in his precautions, gradually recognizes the truth that he is not conversing with George Griffin, junior, but with Doctor or Mr. Varnish, M.A., who has a string of honorary capitals appended to the name that heads his prospectus, who speaks all languages, knows something of everything, and is growing rich apace by preparing young gentlemen for the civil and military service of their country. Mr. Griffin is there in the body, certainly, with his pink ears and heated forehead, and his preceptor is as undoubtedly absent, but, nevertheless, Mr. Examiner cannot but feel that all his well-meant efforts are as thoroughly baffled as if the young man were a medium, and Mr. Varnish held him under some as yet unknown mesmeric influence. There is no getting at the lad's real brain, no finding out what he will be when he shall at no distant date have forgotten Varnish and all his works. As it is, that subtle instructor of youth has armed him at all points. He is a pattern pupil, and has absorbed exactly such information—and no more—as will help him well through the ordeal that lies before him. If caught tripping on one subject, he is comfortably bolstered up on all the rest, and as the defeated examiner grudgingly sends in his name at the top of the list, he is forced to acknowledge with a sigh that Varnish is a very clever fellow. So he is, but services like his are very costly luxuries, and if any class of men derive direct benefits from competition, there is little doubt that Mr. Varnish and his compeers are of the number."

But *magna est veritas et prævalebit*, and with the lapse of time this difficulty may be overcome. In what way, it might be bootless to speculate; but there is a country which is reported to have had a thousand years or more start of us in civilization, and it is interesting to find that these examinations are still an institution. We are indebted to the *Illustrated London News* for an account from its special correspondent of how these things are managed in China; which has been printed on another page. Is this a foreshadowing of the finally surviving form of examination in this country? *Absit omen!*

THE CHALLENGER EXPEDITION.

THE first report of the proceedings on board H.M.S. "Challenger," from the pen of Professor WYVILLE THOMSON, has appeared in the pages of *Nature*, notwithstanding an intimation by Dr. CARPENTER that the narrative would see the light in *Good Words*. Rough weather appears to have been experienced during the first two or three weeks, which, if it were an unpromising commencement to a voyage round the world, also furnished a sharp test as to the stowing of the scientific apparatus. It is satisfactory to learn, therefore, that although the ship rolled considerably not a single instrument shifted, neither was there a glass broken either in the zoological workroom or the chemical laboratory.

On board the "Challenger" the more peaceful sciences appear to have the upper hand of the science of war; for sixteen out of the eighteen sixty-eight pounders which formed the ship's armament have been removed, and the main-deck has been almost entirely set aside for their rivals in the shape of dredging and sounding gear, hydraulic pump, aquarium, photometric and thermometric apparatus, zoological workroom, dark room for photographers, physical and chemical laboratory, etc.

Although the work done up to the date of the report must be regarded as tentative, successful soundings had been taken at great depths, and the trawl had been used at 2125 fathoms. Many interesting animal forms have been obtained, several of them new to science and others of extreme rarity and beauty. One especially, a molluscoid, a drawing of which is given in *Nature*, is extremely interesting; slender graceful branches, recurved at the extremity, springing from a transparent smooth quill-like stem between two and three inches high, and forming the outline of an elegant cup. Sea-peas and *Gorgoniæ*, always remarkable for their brilliant phosphorescence, have occurred frequently, and to these Captain MACLEAR is giving special attention in the hope of gaining fresh information respecting the beautiful though little understood phenomenon manifested by them. One, a *Mopsea*, which shone very brilliantly, gave a spectrum extending from the green well on into the red; another gave a very restricted spectrum sharply included between the lines *b* and D. All the fishes brought up presented a peculiar appearance from the expansion of the air contained in their bodies; their eyes, even when they were relieved from the extreme pressure, protruding considerably.

Further intelligence has since been received from St. Thomas, where the "Challenger" arrived on the 16th of March. The operations had been regularly continued, a dredging taking place every other day, or sometimes oftener; each dredging taking about twelve hours. At the deepest spots both on the east and west side of the Atlantic a quantity of dark red clay was brought up, containing just sufficient animal life to show that life existed at all depths. In depths of over two miles little has been found, but that little is new.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

April 2nd, 1873.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

Present—Messrs. Atherton, Baynes, Betty, Bottle, Fraser, Greenish, Hampson, Hills, Owen, Radley, Sandford, Savage, Schacht, Shaw, Sutton, Urwick, and Williams.

The minutes of the last meeting were read and confirmed.

BENEVOLENT FUND.

Legacy of £100 from the late Mr. George Waugh.

Mr. HILLS reported that he had had some correspondence with Mrs. Waugh, the executrix of the late Mr. George Waugh, of Regent Street. It had commenced, at the beginning of last month, by a letter of inquiry from Mrs. Waugh as to the usefulness and management of the fund. This information having been given, Mrs. Waugh wrote saying that, by a codicil to her late husband's will, the sum of £25 had been bequeathed to the Fund, but that in a private letter to her of much later date, the testator had suggested, that if convenient and in her judgment fit, the bequest should be raised to £100. In compliance with this suggestion, Mrs. Waugh generously enclosed a cheque for that amount.

It was then moved by the PRESIDENT, seconded by the TREASURER, and resolved:—

"That the President and Council of the Pharmaceutical Society beg to express their warmest thanks to Mrs. Waugh for the cheque for £100 sent by her, as executrix of their late much esteemed and respected friend, George Waugh, whose constant, generous, and large-hearted support of the Benevolent Fund was so conspicuous from its first establishment to the day of his lamented decease."

CONVERSAZIONE.

The SECRETARY reported that he had received a letter from the authorities of the South Kensington Museum, granting permission to hold the Society's Annual Conversazione at the Museum on the 21st of May.

A Committee was appointed to make and carry out the necessary arrangements.

NOMINATIONS FOR ELECTION TO THE COUNCIL IN MAY NEXT.

The Secretary reported that forty-two Members of the Society had been nominated for election on the Council in May next, and that the following twenty had declared their willingness to accept office, if elected:—

ATHERTON, JOHN HENRY, Long Row, Nottingham.
BALDOCK, JOHN HENRY, 3, High Street, South Norwood, Surrey.
BAYNES, JAMES, 24, Waterworks Street, Hull.
BETTY, SAMUEL CHAPMAN, 6, Park Street, Camden Town, N.W.
BOTTLE, ALEXANDER, 37, Townwall Street, Dover.
BROWN, WILLIAM SCOTT, 113, Market Street, Manchester.
GREENISH, THOMAS, 20, New Street, Dorset Square, N.W.
GUYER, JAMES BRETT, 11, Strand, Torquay.
HAMPSON, ROBERT, 205, St. John Street Road, E.C.
HILLS, THOMAS HYDE, 338, Oxford Street, W.
MACKAY, JOHN, 119, George Street, Edinburgh.
PALMER, ROBERT, 35, Ovington Square, S.W.
RADLEY, WILLIAM VALENTINE, 74, Market Place, Sheffield.

Robbins, John, 372, Oxford Street, W.
Sandford, George Webb, 47, Piccadilly, W.
Savage, William Dawson, 30, Upper Bedford Street, Brighton.
Turner, Charles Ernest, 63, Great Russell Street, W.C.
Whitfield, Henry, 45, High Street, Worcester.
Williams, John, 16, Cross Street, Hatton Garden, E.C.
Wright, George Henry, 103, Borough High Street, S.E.

The following twenty-two Members declined to accept office, if elected :—

Andrews, Frederick, 23, Leinster Terrace, W.
Burden, Edward, 38, Duke Street, Grosvenor Sq., W.
Bostock, William, 241, Stamford Street, Ashton-under-Lyne.
Carr, John, 171, High Holborn, W.C.
Churchill, John, New Street, Birmingham.
Darby, Stephen, 140, Leadenhall Street, E.C.
Deane, Henry, 17, Pavement, Clapham.
Dymond, George, Birmingham.
Groves, Thomas B., 80, St. Mary Street, Weymouth.
Haselden, Adolphus Frederick, 18, Conduit Street, Bond Street, W.
Hanbury, Cornelius, Plough Court, Lombard Street, E.C.
Hanbury, Daniel, Clapham Common, S.W.
Hodgkinson, William, 127, Aldersgate Street, E.C.
Huskisson, Henry Owen, 322, Gray's Inn Road, W.C.
Howden, Robert, 78, Gracechurch Street, E.C.
Morson, Thomas N. R., 38, Queen Square, Bloomsbury.
Randall, William B., 143, High Street, Southampton.
Reynolds, Richard, 13, Briggate, Leeds.
Savory, C. H., 143, New Bond Street, W.
Smith, Edward, 8, Strand, Torquay.
Stacey, Samuel, 300, High Holborn, W.C.
Vizer, Edward B., 63, Lupus Street, S.W.

Nomination of Auditors.

The Secretary reported that

Mr. Frederick Andrews, of Leinster Terrace, Hyde Park, W.,

had been nominated for election as an Auditor for the ensuing year.

The Council then nominated the following gentlemen for election as Auditors, in order to complete the list of five :—

Frederick Barron, Bush Lane, Cannon Street, E.C.
William Hodgkinson, 127, Aldersgate Street, E.C.
Edward Horner, 20, Bucklersbury, E.C.
William Squire, 5, Coleman Street, E.C.

The following, being duly registered as Pharmaceutical Chemists, were respectively granted a diploma stamped with the seal of the Society :—

Botterill, George Thomas ......Boston.
Colling, Robert ....Stockton-on-Tees.
Dunn, Henry...........................Shipley.

Two persons having paid arrears of subscriptions, together with the subscription for the current year, were restored to their original status in the Society.

Elections.

Honorary Member.

The following gentleman was nominated for election as an "Honorary and Corresponding Member of the Society :"—

Watts, Henry, B.A., F.R.S.

Members.

Pharmaceutical Chemists.

The following Pharmaceutical Chemists were elected Members :—

Barker, Matthew Mark ....Masham.
Barrett, Frederick John ....Wolverhampton.
Botterill, George Thomas.........Boston.
Churchyard, Robert Leman......London.
Colling, Robert ....Stockton-on-Tees.
Cotterill, Samuel ....London.
Dunn, Henry.............................Shipley.
Finlay, James ....Edinburgh.
Hardy, Samuel Croft ....London.
Holmes, Walter Murton ....London.
Jones, William ....Lyth Hill, Shrewsbury.
Little, Arthur Nicholas ....Upper Norwood.
Mason, Robert William ....Putney.
Nuthall, Edwin........................Norwich.
Overton, Charles Arthur ....Horncastle.
Paton, James...........................Edinburgh.
Wretts, John Robert ....London.

Associates.

The following, having passed their respective examinations, and being in business, were elected "Associates in Business of the Society :"—

Minor.

Loveless, Edward William ......Twerton.
Matthews, Ernest...................Royston.
Smith, Fuller..........................London.
Turner, Joseph Kitchin ....Cleator Moor.

Modified.

Morris, William Watkin ....Talgarth.
Parker, Alfred ....Uttoxeter.
Plaister, William James ....London.
Sansom, Henry ....Leamington.
Simms, Robert John...............Scarborough.
Thomson, William ....Exeter.

The following, having passed their respective examinations, were elected "Associates of the Society :"—

Minor.

Aris, George Henry ....Wellingborough.
Barnes, William James ....Dover.
Basker, John Anthony ....Grantham.
Cartwright, William Adam......Hyde.
Clement, Joseph ....Coleford.
Cooke, William Kendle ....Brighton.
Cox, William Dennis ....Grantham.
Dixon, Daniel ....Preston.
Elmitt, John Henry ....Horncastle.
Fingland, William ....Liverpool.
Gibbs, Henry..........................Aylesbury.
Gould, Robert George ....Poole.
Lawson, Edward James ....Whitstable.
Marin, Ferdinand Baptist ......London.
Marshall, Eli..........................London.
Mellor, John Gilbert ....Southport.
Prettejohn, Robert Froude ......Torquay.
Roach, Herbert William ....London.
Roberts, William ....London.
Short, William ....March.
Smith, Nathan ....King's Lynn.
Stephens, Henry Isaac............Bristol.
Symons, William Henry ....Barnstaple.
Taylor, George William ....Louth.
Thorp, John ....Manchester.
Tripp, Zeno ....Plymouth.
Walker, William ....Stockport.
Walton, Thomas ....Bishopswearmouth.

Modified.

Anderson, Charles William......Southampton.
Bratley, William ....Gainsborough.

Society of Great B[illegible]in,

17, Bloomsbury Square, W.C.

The Chemist's Annual, 1917.

Receipt
enclosed with
Compliments &
Thanks.

Hudson, Thomas Frederick......Birkenhead.
Jagg, John Henry ....New Cross.
Mayo, Robert William...........Chelmsford.
Strickland, Absalom Whitehouse.Bognor.
Westlake, John......................Brixton.

APPRENTICES OR STUDENTS.

The following, having passed their Preliminary examination, were elected "Apprentices or Students of the Society:"—

Agger, Joseph Edward...........King's Lynn.
Berry, John Bright ....Northampton.
Bond, Frederick John ....Tiverton.
Clarke, Herbert ....Lowestoft.
Cotterell, Edward..................Weymouth.
Crane, William Clifton ....Market Harborough.
Gregory, Walter ....Taunton.
Haworth, Edwin ....Oswaldtwistle.
Holt, George Alfred...............Douglas.
Jackson, Henry Lawson ....Crediton.
MacFarlane, Peter ....London.
Maynard, Henry Robert ....Brandon.
Munday, John ....Bridgnorth.
Paul, William Edmund ....Scarborough.
Thomas, Thomas Gratton ......Bagillt.
Wardle, William Stephens ......London.
Withycombe, George ....Hele, Tavistock.

FINANCE.

The Report of the Finance Committee was received and adopted; and sundry payments for accounts, salaries, etc., were ordered to be made.

ANNUAL STATEMENT.

The Financial Statement for the year 1872, with balance sheet and special statements, prepared, as suggested, by a professional accountant, was presented, and, after consideration, was adopted with a few alterations.

BENEVOLENT FUND.

On the report and recommendation of the Benevolent Fund Committee the following grants were made :—

To a Registered Chemist and Druggist, late of Torquay	£10
To the Widow of a late Member of the Society, residing at Nottingham	20
To the Widow of a Registered Chemist and Druggist, late of Louth	10
To a Registered Chemist and Druggist, late of Manchester	10
To a Registered Chemist and Druggist, late of Cardiff	10
To the Widow of a Chemist and Druggist, late of Wigan	10
To the Widow of a Chemist and Druggist, Member of the Society for three years, late of Dover	20
To a late Member of the Society, residing in London	10
To the Daughter of a late Member of the Society, late of Southampton	10

The Widow of the late John Beaton, London, a Member of the Society for twenty-one years, was placed upon the list of candidates for annuities.

The Widow of the late William Moss, London, a Member of the Society for twenty-three years, and late Local Secretary, was placed upon the list of approved candidates for annuities.

Other applications for aid were received, but were deferred for further consideration and inquiry.

The TREASURER suggested that the Secretary might be disposed to aid these cases from his private "Casual Fund" pending inquiries.

The SECRETARY said that he would be glad to assist as far as the circumstances of the individual cases would seem to warrant and the fund at his disposal would permit.

The Treasurer was requested to purchase £500 Consols on the Benevolent Fund account.

LIBRARY, MUSEUM, AND LABORATORY.

The Report of the Committee was received and adopted, and the Committee were authorized to purchase a balance for the use of the Students if necessary.

ANNUAL REPORT OF THE COUNCIL.

The preparation of the Annual Report was referred to the Library, Museum, and Laboratory Committee.

HOUSE.

The Report of the Committee was received and adopted.

PARLIAMENTARY.

The Report of the Committee was received and adopted.

BYE-LAWS.

It was moved by Mr. GREENISH, seconded by Mr. RADLEY :—

"That the bye-laws now read a second time be confirmed."

Mr. HAMPSON moved the following amendment :—

"That the Solicitor of the Society in the following explicit terms, having deliberately disapproved of the proposed amended bye-law, section 10, clause 16, as agreed to by the *Parliamentary Committee*—viz. 'this appears to us to vary from the intention that the examinations shall be freely open to all the world, and we recommend its erasure,' and Mr. Flux having likewise stated that the same was 'contrary to law,' and as the same amended bye-law, slightly modified, and now proposed to be confirmed a second time, contains the particular restrictions of time to which Mr. Flux took special legal exception, this Council, whilst accepting the other amended bye-laws, declines to accept the same—viz. section 10, clause 16, beginning at the word 'after the 31st of December, 1876, no person shall,' etc., to the end of the paragraph."

He felt some hesitation in bringing forward the question as to the legality or illegality of their proceeding with respect to the proposed bye-laws; but he felt it a matter of duty to fight out the question until it was fairly settled. Going back to Mr. Schacht's resolution, proposing the new regulations for the Board of Examiners, he considered it a very fair one, because it simply pledged the Council to the principle. But there was such a strong feeling prevailing at the Council in support of the amended regulations, that the question of legality was ignored. That was the first false step taken by the Council. Outside the Council there was a doubt as to the legality of the test proposed for candidates; and in the minds of many members of the Council there was a doubt existing as to the three years' test. He opposed the three years' test on principle. He maintained it was illegal. Therefore, he was not surprised to find the solicitor taking exception to the proposed bye-law. Before the parliamentary committee Mr. Flux expressed a strong opinion that the proposed bye-law was contrary to law. He would like to know whether Mr. Flux had changed his views upon that subject. He (Mr. Hampson) maintained that nothing would damage the Society so much as that a notion should get abroad that, for the sake of any particular purpose this year, or the next, an illegal step had been taken.

Mr. URWICK seconded the amendment. It seemed to him that they were going in a direction contrary to the spirit of the Act. They were stepping out of their sphere in an endeavour to make bye-laws inconsistent with the Acts of Parliament.

Mr. SHAW supported the original resolution. The matter had been discussed and affirmed over and over again. But Mr. Hampson had now raised the question of the legality or illegality of the course proposed; and from that point the matter must be decided. As far as he was capable of interpreting the law, he believed they were perfectly competent to make the suggested bye-law. It was not repugnant to the ordinary laws of the realm, and no doubt members of parliament, if individually canvassed, would say it was extremely desirable that every person who engaged in the dispensing of poisons should have three years' previous training. Moreover, it must not be forgotten that the Examiners supported the proposed bye-law; and much attention should be paid to their opinions.

Mr. Flux, who had been requested to attend, said the words "apprentice or student" had appeared in the bye-laws submitted to him, and his quoted memorandum had applied to them. Those words had been erased, and consequently his objection on that ground was removed. Then came the question whether the Council had, under the charter and statutes, power to test persons as to their competent skill and knowledge, and prescribe the mode of testing that. No doubt the Council were competent to prescribe reasonable regulations for testing skill and knowledge, and to prescribe that a test should be a proper period of actual experience; whether that period should be three years or a less period was a little out of his province. But if the Council in the *bonâ fide* exercise of their judgment thought three years a necessary period, it seemed to him that that was authorized by the Act, and a bye-law providing for it would be good.

Mr. Owen inquired whether it was necessary a person should be in one establishment three years.

Mr. Flux replied in the negative.

Mr. Urwick asked whether the Court of Chancery could, by injunction, compel the Examiners to examine a man who had not had three years' experience.

Mr. Flux replied that it was not a question for the Court of Chancery, but for *mandamus* in the Court of Queen's Bench. They had found the Court reasonable on each occasion when they had had recourse to it, and he believed he would only have to show the unanimity of opinion which prevailed at the Council and Board of Examiners, to carry the bye-law through.

Mr. Frazer would support the amendment, and wished he had Mr. Hampson's courage, in which case he would have moved a reduction of the fees.

Mr. Hampson, in reply, said the opinion of Mr. Flux as that day expressed, differed from his opinion as expressed before the parliamentary committee. He (Mr. Hampson) thought they should take counsel's opinion upon the subject. Mr. Flux seemed to think the difficulty had been removed by the alteration made in the bye-law; but he (Mr. Hampson) was not of that opinion.

The amendment was then put, with the following result:—

For (4) Messrs. Hampson, Urwick, Frazer, and Owen.

Against (14) Messrs. Atherton, Baynes, Betty, Bottle, Greenish, Haselden, Hills, Radley, Sandford, Savage, Schacht, Shaw, Sutton, and Williams.

The amendment was therefore lost, and the original motion was subsequently carried.

It was moved by Mr. Hills, and seconded by Mr. Sandford—

"That the bye-laws shall be altered in the Clause No. 7 of the Section numbered 10, by erasing therefrom the word 'twelve,' and substituting for the said word 'twelve' the word 'fourteen.'"

Mr. Williams suggested that the number should be sixteen, and an arrangement made for the payment of a fixed sum, to be distributed by the Examiners amongst themselves.

Mr. Hampson thought the proposition that there should be sixteen examiners a good one.

Mr. Bottle said the Council had power to appoint such number as they thought proper from time to time.

Mr. Sandford thought they had better fix upon such a number as they thought they could carry; and there was reason to believe that they would obtain the approval of the addition now proposed—fourteen.

Mr. Schacht considered the proposition so reasonable that those representing the Privy Council would not object to it.

Mr. Shaw said if they wished for sixteen, the President and Vice-President would make up eighteen.

Mr. Baynes said the Board of Examiners were overworked; and thought they should ask for eighteen at once.

Mr. Hampson said they must have a proper staff to do the work efficiently. He proposed that the number should be eighteen.

Mr. Urwick seconded the amendment, which was negatived.

Mr. Williams moved that the number be sixteen.

Mr. Baynes seconded the amendment, which was negatived.

The original motion was then put and carried.

Report of Examinations.

March, 1873.

ENGLAND AND WALES.

Examinations.	Candidates. Examined.	Passed.	Failed.
Major	4	3	1
Minor	60	39	21
	64	42	22

Certificates received in lieu of the Preliminary examination:—

College of Preceptors	1
Royal College of Surgeons	1
University of Cambridge	4
" " Durham	1
" " Oxford	4

BOTANICAL PRIZE FOR 1874.

A Silver Council Medal is offered for the best Herbarium, collected in any part of the United Kingdom between the first day of May, 1873, and the first day of June, 1874; and should there be more than one collection possessing such an amount of merit as to entitle the collector to reward, a second prize, consisting of a Bronze Medal, and also Certificates of Honour and Merit, will be given at the discretion of the Council. In the event of none of the collections possessing such an amount of merit as to warrant the Council in awarding Medals or Certificates, none will be given.

The collections to consist of Flowering Plants and Ferns, arranged according to the Natural System, and to be accompanied by lists, arranged according to the same system, with the species numbered.

The collector to follow some work on British Botany (such as that of Babington, Hooker, or Bentham), and to state the work which he adopts. The name of each plant, its habitat and the date of collection, to be stated on the paper on which it is preserved.

Each collection to be accompanied by a note, containing a declaration, signed by the collector, and certified by his employer, or a Pharmaceutical Chemist to whom the collector is known, to the following effect:—The plants which accompany this note were collected by myself, between the first day of May, 1873, and the first day of June, 1874, and were named and arranged without any assistance but that derived from books.

In estimating the merits of the collections, not only will the number of species be taken into account, but also their rarity or otherwise, and the manner in which they are preserved; and should a specimen be wrongly named, it will be erased from the list.

The collections to be forwarded to the Secretary of the Pharmaceutical Society, 17, Bloomsbury Square, on or before the first day of July, 1874, indorsed "Herbarium for Competition for the Botanical Prizes." After the announcement of the award, they will be retained one month, under the care of the Curator of the Museum, for the inspection of persons connected with the Society, and then returned to the collectors, if required.

No candidate will be allowed to compete, unless he be an Associate, Registered Apprentice, or Student of the Society, or if his age exceed twenty-one years.

PHARMACEUTICAL MEETING.

Wednesday, April 2, 1873.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

The minutes of the last meeting were read and approved.

The following donations to the library and museum were announced, and the thanks of the Society were voted to the donors:—

'London University Calendar,' 1873, from the University; 'Durham University Calendar,' 1873, from the University; 'Guy's Hospital Reports,' 1872–3, from the Hospital; 'Bulletin des travaux de la Société de Pharmacie de Bordeaux,' Janvier, 1873, from the Society; 'The Origin, Extension, and Prevention of Fires, and the relation of Mineral and Vegetable Oils, and other Materials to Fire,' from Professor Attfield; 'Grundlagen der Pharmaceutischen Waarenkunde,' 'Inventaire d'une Pharmacie de Dijon en 1439,' and 'Die Frankfurter Liste,' from Professor Flückiger; Obituary notice of Dr. Robert Wight, F.R.S., from Dr. Cleghorn; Notes on a new form of Percolator, the triplex Pill, Rhubarb, Aconite Root, Citrate of Bismuth and Ammonia, and Aloes, from Dr. Squibb. Specimen of African Ammoniacum; Dried specimens of the following plants:—*Richardsonia scabra*, *Lavandula spica*, *Coriandrum sativum*, and some Italian Cereals, from Mr. D. Hanbury; Specimens of Sulphate of Lanthanum, Niobic Acid, Titanic Acid, Bibromide of Mercury, Benzoate of Zinc, Bromide of Ammonium, Chloride of Zinc, Acetate of Calcium, Phosphide of Calcium, from Messrs. Hopkin and Williams; Fresh specimens of *Daphne laureola*, for the herbarium.

On the table were a fine specimen of Caffeine, exhibited by Messrs. Hopkin and Williams; various specimens of Pareira brava root, by Mr. Francis, jun.; some suppositories to illustrate Mr. Martindale's paper; and some beautiful Drawings, by Mr. Rochfort Connor, of Microscopic Sections of Mustard Seeds, lent to illustrate Mr. Greenish's paper by the Inland Revenue authorities.

THE PROPOSED APPENDIX TO THE PHARMACOPŒIA.

The CHAIRMAN then called upon Mr. Martindale to resume the discussion upon the proposed Appendix to the Pharmacopœia.

Mr. MARTINDALE prefaced his remarks on the general subject by reading a paper on a "New Basis for Suppositories and Pessaries," which is printed at p. 781. He then referred to the proposed insertion into the Appendix of the acetum ipecacuanhæ and the oxymel ipecacuanhæ. He said he could not think that these were preparations that had met with sufficient favour to be inserted in the Pharmacopœia. In using solvents for these drugs they should attempt to get such as were both therapeutically and chemically as inert as possible, and acetic acid was not so. There was the nitrite of amyl, too, about which Professor Redwood had made some remarks. At University Hospital they had used quantities of it, in doses of from one-sixth to half a minim. It was readily soluble in spirit, and also suspended by mucilage in a mixture. He could not think the aqua chloroformi which Professor Redwood suggested would be a useful preparation. The amount of chloroform it contained would vary according to the amount of shaking it received, and there would be a tendency towards indefiniteness which would be undesirable. The oxide of bismuth would be a good preparation. Professor Redwood had also suggested the admission of precipitated oxide of mercury, which, as most of them were aware, had been used to make the oleates of mercury of various strengths, and he thought Mr. Williams could verify to what extent they were used at the present time. The oleates were most worthy of insertion—much more so even than many of the preparations which Professor Redwood had named. With regard to phosphorated oil, the phosphorus could be made to dissolve in almond oil to the extent of 1 per cent. without much difficulty. He had some on the table so dissolved, and the almond oil was not treated in the manner Professor Redwood had thought necessary. The specimen was prepared some four months ago in the same bottle, and there had scarcely been any trace of deposit in it. The preparation of the almond oil in the manner which Professor Redwood had mentioned would be almost an unnecessary refinement. The almond oil would, he thought, be so decomposed that it would yield a worse preparation than that which could be obtained tolerably pure, commercially, in England. The phosphorus and oil required to be heated to about 180° F. or 200° F. in a water-bath to dissolve the phosphorous at all readily, and the mixture should not be exposed to the air whilst this was being done. The bottle should be kept tolerably closely corked, and shaken frequently during the process of making the solution. There was, too, the pulvis elaterii compositus, which, he thought, would be a good preparation The active substance was so difficult to divide into small doses: with the compound powder they obtained an accurate preparation for giving it in small doses. With regard to tincture of fresh orange peel, he believed he suggested that in the first instance at one of their meetings two years ago. But he thought they should wait until they had a new edition of the Pharmacopœia rather than have the two tinctures, which would create a good deal of confusion.

Mr. WILLIAMS said that with respect to the oleate of mercury, he certainly thought it had even now arrived at sufficient importance, and was in itself so scientifically correct that it might be introduced into the Supplement of the Pharmacopœia. He did not think they ought always to wait until a thing was ten years old before they should notice it. The oleate of mercury had been introduced by an eminent scientific man, who had taken quite two years to investigate it and verify the experiments. From his (Mr. Williams's) own knowledge, he could assert that when the materials used in its preparation were sufficiently pure and heat was avoided, the oleates of various strengths appeared to be very perfect and very permanent. It was an extraordinary thing that they should introduce the precipitated oxide of mercury into a new edition of the Pharmacopœia and not the oleate, which, he fancied, was the only preparation for which the precipitated oxide of mercury was at present actually required. It was therefore open to question whether it would not be wise to go a step further, and put in the oleates. With regard to phosphorated oil, to which Mr. Martindale had referred, he could only say there was an objection to the use of oil for medicinal purposes. Practically, he found that phosphorated ether was much more in demand, and seemed to be preferred by medical men. He quite admitted, however, that ether had many disadvantages, and that oil, if it were not objectionable as a medicine, was perhaps a better form. The preparations of bismuth also was a very important question, and he quite agreed that the Pharmacopœia ought to contain in its supplement the oxide of bismuth. But he ventured to suggest that there was even a better compound than the oxide of bismuth, and which would, he believed, practically be found to supersede it, and be even more valuable as a medicine, than the trisnitrate, so-called, or the carbonate, and that was the citrate. The citrate of bismuth was easily formed; the solution of nitrate of bismuth and citrate of soda mixed together in proper proportions—gave a precipitate, insoluble in water, which could be washed and dried, and was a permanent and beautiful body. It was a substance which would in the human system have all the effect of a carbonate or any other organic salt of bismuth,—that was to say, it would be decomposed by the action of the stomach; and there was also this great advantage that the ammoniacal solution could at once be produced, as the citrate of bismuth dissolved in ammonia solution as freely as sugar in water. It struck him that that would be a better form to have introduced into the Pharmacopœia than the oxide of bismuth, for it was a definite and beautiful salt deserving the attention of pharmacists generally.

Upon being asked to explain how he got the citrate of bismuth,—

Mr. WILLIAMS said he diluted the solution of nitrate of bismuth with as much water as it would bear, then added to that a solution of citrate of soda, taking care not to employ an excess as the precipitate would then be redissolved; the precipitate formed could be well washed, and any copper present was thus, together with free acid, got rid of entirely; so that although the bismuth might contain copper, that objectionable impurity could be entirely got rid of. He had for a long time made liquor bismuthi by taking five grains of the citrate, which represented, if he remembered rightly, three of oxide of bismuth, and about $\frac{1}{3}$ of liquor ammoniæ to each fluid dram of water. No citrate of ammonia was produced; the preparation never decomposed or grew mothery, and the solution was practically as perfect as it could be. Of course this preparation required the addition of a new substance into the Pharmacopœia, for citrate of bismuth must be an individual entity. But he thought that was not objectionable, and it would be, he considered, of great value as a medicine. He had made a note about compound powder of elaterium. It was a valuable suggestion that they should reduce the strength of a powerful medicine by means of sugar of milk; but would every pharmacist promise to make his own powder, and prepare it from the true English elaterium? If pharmacists would do that, he quite agreed that such a preparation would be an improvement upon the use of the crude drug.

Mr. GERRARD said that since the last meeting he had made a number of experiments with regard to suppositories, and the result of his investigations was to have been brought that evening before the Obstetrical Society by Dr. Phillips, but he was prevented from doing so through indisposition. The basis he (Mr. Gerrard) had decided upon for giving the best result was a mixture of oleic acid, lard, and paraffin. Paraffin had this advantage,—it had a melting point 20 degrees lower than stearin, and was much nearer the temperature of the human body. It was also possessed of much better keeping properties, and had not that rancid or unpleasant odour which stearin or oleic acid had. When combined in proper proportion with paraffin, it formed an unctuous substance, spreading itself over the surface of the body with which it was brought in contact, and was absorbed in that manner. He had some specimens of the paraffin there. It was a most harmless substance, remarkable for its want of chemical properties, and it was, moreover, only about one half the price of cacao butter, and formed an elegant suppository.

Professor BENTLEY presumed that this was not the time to refer to the general construction of the Pharmacopœia. At the same time perhaps he might be allowed to suggest that, in any future Pharmacopœia they should follow in some respects, the example furnished by the United States' Pharmacopœia, and have a secondary list of the materia medica. It would save a great deal of trouble and be advantageous in a variety of ways, if they had such a list compiled. He thought it must be evident to everyone that there were several substances in the present Pharmacopœia, which were to a certain extent, upon their trial, and which therefore should be placed in a secondary list. He would mention one substance particularly as being on its trial at the present time, and that was *guarana*. If a new Pharmacopœia were about to be published at the present moment, it would be difficult to exclude this substance, although it had not by any means yet had a sufficient trial in this country to warrant its insertion. Then, there was another substance, podophyllum, which, if twenty years ago they had had a Pharmacopœia with a secondary list, would never have been left till 1864 before it was put into the Pharmacopœia. This was a substance which had been in the United States' Pharmacopœia ever since the year 1820, and yet its use had been almost ignored in this country until lately, simply because it had not been sufficiently brought forward. He thought that in future Pharmacopœias it would be very desirable to omit all descriptions of materia medica,—all botanical descriptions, for instance,—unless they were perfect descriptions. The descriptions given of elder flower and aconite, for example, were no descriptions at all. A chemical test was a test, and on that account was extremely valuable; and in the same way a description of a flower or leaf that was not a test, or not one by which they could readily distinguish that flower or leaf, was better out of the Pharmacopœia altogether. The Pharmacopœia was not a materia medica book, but it was a book that ought to give descriptions of drugs, so far as those descriptions were requisite, in order to indicate adulterations. With regard to the proposed introduction of a compound elaterium powder into the proposed appendix, he should like to ask Professor Redwood what was the great objection to using in the composition of the powder, instead of the present uncertain elaterium, its active principle elaterin, it appeared to him that such a compound powder would be a very desirable introduction into the Pharmacopœia.

Professor REDWOOD could not conceive that it would be at all out of order to discuss the question of a secondary list in the Pharmacopœia on the present occasion. The proposed appendix was a sort of secondary list, and it was quite open to the consideration of the Pharmacopœia Committee of the Medical Council as to whether a secondary list, in addition to the appendix, might not be introduced at the present time.

Mr. WILLIAMS said that, if that were the case, he should like to suggest that some compounds which were now in great use, and which were of great value, might be added to such a secondary list, such, for instance, as the sulphocarbolates. These articles were largely consumed, and the consumption was constantly increasing. He had been told that the effect of both sulphocarbolate of zinc and of sodium was very beneficial medicinally. Another series of bodies which ought to receive the earnest attention of those drawing up a secondary list were the preparations adopted for hypodermic injection. That seemed to him to be the mode of administering medicines in the future; but at present there was a difficulty in making satisfactory hypodermic solutions. They must be quite neutral, or they would cause intense pain in their administration; and they must be very concentrated. He thought this matter was well worthy of the attention of the Pharmacopœia Committee and of the Medical Council, to see whether it were not possible to introduce preparations somewhat different from those now used for hypodermic injection. The sulphovinate of quinine, as lately mentioned in the PHARMACEUTICAL JOURNAL, was a very valuable salt for that purpose. He had prepared some and found it was soluble—although a di-salt, and therefore perfectly neutral—in its own weight of water. Such salts were evidently indicated as valuable for the purpose of hypodermic injection.

Mr. MARTINDALE remarked, with reference to the use of paraffin in pessaries and suppositories, that he could not conceive that it would be absorbed in such a ready manner as the preparation he had suggested, or even as the cacao butter. He thought that, when mixed with other fatty oil, it would have a tendency to separate, and would be apt to exude from the parts to which it was applied.

Mr. GERRARD said he had been trying the melting points of various mixtures of fatty oils, and he found in the case of stearin and oil, when heated to a certain temperature, that the oil separated out, leaving the solid substance in a mass. Supposing they had a mixture of paraffin, which melted at 110° F., and theobroma, which had a melting point at about 82° F., although the Pharmacopœia gave it at 122° F., when the thermometer reached 82° F. the oil of theobroma gradually melted out, and the paraffin floated about in small particles on the surface, and it was the same with stearin and oil. Stearin would not melt under 140° F. or 145° F., and therefore the same objection could not be urged against paraffin as against stearin, or, at least, not to the same extent.

Mr. MARTINDALE observed that a mixture of stearic acid with oleic acid had a melting point which was not the mean of the two, but lower than either of them.

Mr. BLAND wished to make a single observation with regard to tinctura aurantii recentis mentioned by Professor Redwood as proposed to be inserted in the appendix to the Pharmacopœia. The objection to that was the difficulty at certain times of getting the proper orange peel to make it with. When it was made with the proper "bigarade" orange peel, it was a most valuable preparation—not perhaps altogether in a pharmaceutical point of view, but for various purposes. If gentlemen wished to make this preparation, now was the time of year when they should try their experiments, because the oranges were tolerably plentiful, and were to be had at moderate prices. Without presuming to anticipate what Professor Redwood's formula would be, he would mention the method he had adopted, and that was to take a sharp knife and pare off the outer coating of the orange, so as to cut off the whole of the vessels containing the oil, putting it into a wide-mouthed bottle, and adding a sufficient quantity of rectified spirit to cover it; let it macerate a few days, then pour off the tincture and express in the usual way. That method furnished a tincture which he had found by experience to be most valuable.

The PRESIDENT then read the following letter which had been addressed to Professor Redwood by Professor Attfield:—

"MY DEAR REDWOOD,

"For almost the first time for eleven years I must be absent from the evening meeting. By letter, therefore, I will venture to ask you whether or not in the appendix, or in the preface of the forthcoming reprint of the Pharmacopœia, some reference can be made to the proposed slight alterations in the chemical nomenclature of the work. Similar alterations have already been made in the case of the American Pharmacopœia, and up to the present time have been cordially accepted by the medical and pharmaceutical practitioners of the United States. This method of bringing pharmacopœial names into harmony with the nomenclature of all the modern chemical text-books, and therefore with the present state of chemical science, has also been fully discussed in this country by the leading medical and pharmaceutical authorities, and the opinions of all seem united in its favour. Under these circumstances would it not be desirable to give a list (it is very short) of the proposed alterations, and thus prepare all parties for the change—slight though that change will be?

"Yours faithfully,

"JOHN ATTFIELD."

Professor REDWOOD asked Mr. Bland whether, in making the tincture of orange peel, it was not necessary to macerate the peel for an unusually long time? He had just stated that it was macerated for a few days.

Mr. BLAND believed a week was quite sufficient for the purpose, provided the peel was shaved off into small portions with a sharp knife, which was the way he had always done it.

Mr. GREENISH could not help thinking that it would be very embarrassing to have two tinctures of orange peel in the Pharmacopœia. Some medical gentlemen would prescribe the tincture, thinking the old form would be dispensed, and others would prescribe, thinking the new tincture would be dispensed. He hoped they might arrive at some definite conclusion on this subject. If the fresh orange peel was best, by all means let them have it, and omit the old tincture.

Professor REDWOOD thought it would be within the experience of most of those who had had anything to do with pharmacy, that many medical men would continue to prescribe the old tincture for many years after that made from fresh orange peel was introduced into the Pharmacopœia. It appeared to him that opinions were pretty equally balanced as to which of these tinctures was best. He, therefore, thought that the most simple plan was to have both introduced into the Pharmacopœia, with a difference in name that would enable the prescriber to indicate one from the other. They ought to be more cautious in striking articles out of the Pharmacopœia than in putting in new ones. The great difficulty experienced in reference to the B. P. of 1864, arose from a number of preparations having been struck out, which medical men were not at all prepared to relinquish the use of, and which had to be introduced again. The great object of the Pharmacopœia was to define preparations that were in use; and as long as they continued to be used to any appreciable extent, he could not see that any harm resulted from the definition being retained in the Pharmacopœia. If there were other preparations of similar descriptions which were thought to be, and by many were found to be, superior to them, let them be put in competition, and ultimately those which were proved to be the best would replace the others, and when that replacement had taken place in practice, the old preparation which it superseded might then be struck out. That was the principle which had been adopted in the United States' Pharmacopœia, which had just been published. The ground upon which he should propose to strike any article out of the Pharmacopœia, would be that of some serious objection attaching to it, or some grave defect in it. There were one or two preparations in the present Pharmacopœia which were subject to that objection. For instance the green iodide of mercury was a very defective and unstable preparation, and could not be administered because it could not be kept for administration in the state in which it was described in the Pharmacopœia; and that was a sufficient ground for discarding it. But a mere ordinary galenical preparation which might in some respects present similar but superior characters, ought not too hastily to displace the one that had been long established in use. He was not at all strong in the opinion that there was any great necessity or requirement for the introduction of the tincture of fresh orange peel, but he thought it would satisfy many who very strongly advocated its use. Mr. Martindale wished to know upon what ground the new preparations of ipecacuanha—namely, the vinegar and the oxymel—were introduced into the Pharmacopœia, leaving the present preparations of ipecacuanha as they existed. Now he thought the vinum ipecacuanhæ was not a preparation which was devoid of objection. Although it was an efficient preparation, it was very doubtful whether it was one that was constant in its efficacy, for it underwent changes in keeping. Moreover, wine was a questionable vehicle to use, because there were probably no two pharmacists making ipecacuanha wine who would use exactly the same wine in the preparation, and that of itself was an objection. Still ipecacuanha wine would continue to be used, and therefore he would leave it in the Pharmacopœia; but as ipecacuanha was such an important medical agent, it became a question whether they ought not to introduce some preparation that was more reliable, more constant, and which presented other characters which the vinegar did. The cheapness was an element that was not to be altogether overlooked. Acetic acid was one of the cheapest and at the same time one of the most efficient vehicles which could be used for the administration of the active principle of ipecacuanha, and the experience that they had hitherto had of this vinegar of ipecacuanha had proved it to be constant in its character. It did not change its colour, and threw down no precipitate, but retained permanently the whole active principle of ipecacuanha. Therefore taking into account the facility with which it was made, its cheapness, great constancy, and admitted efficacy, he thought nothing could be urged against its introduction into the Pharmacopœia. The oxymel again was a preparation made of the acetate, and would, he believed, prove to be a most acceptable addition to the preparations of the Pharmacopœia. Then with regard to the nitrite of amyl, he confessed he was not very strong as to the necessity of introducing it into the Pharmacopœia. But he must say that he considered it to be a very powerful and valuable therapeutical agent, possessing an action which no other preparation could replace. Being a very powerful as well as efficacious remedy, and being moreover a preparation which was not always, as met with in commerce, uniform in its characters and properties, it was just one of those substances which it was most desirable to have defined in the Pharmacopœia, because here again the object of the Pharmacopœia was definition. When nitrite of amyl was ordered there should be no question as to what the preparation was that should be used. If there were a secondary list in the Pharmacopœia, this would probably be one of the things that would in the first instance be put into it. He had heard a secondary list strongly advocated on many occasions, but he had never yet been a convert to the propriety of having such a list in the Pharmacopœia. The question that would be most difficult to solve was this: Who was to define what was to go into the secondary list, and what into the primary list? This led him to speak of the United States' Pharmacopœia, in which a secondary list had been inserted. He had been engaged in studying that work and in testing some of the formulæ for preparations which were introduced into it; and he must say that he had been struck with what appeared to him to be many inconsistencies in it. There was one other preparation to which he wished to refer, and to which reference had been made by Mr. Martindale, and that was the oleum phosphoratum. Mr. Martindale seemed to think that the instructions which he (Professor Redwood) proposed to give for its preparation, consisting of the purification of the oil of almonds before its use, was an unnecessary refinement. It might be so for some samples of oil; but he was quite certain that much, if not most, of the oil of almonds met with in commerce, if it be used simply as a solvent for the phosphorus, gave rise in a short time to a precipitate in the oil. The oleum phosphoratum as ordered in the Paris Codex, for instance, was found to undergo change. Some of the phosphorus seemed to be acted upon by some resinous or organic matter in the oil, and that was got rid of and decomposed by subjecting the oil to a high temperature; and if the temperature were carefully observed, no material alteration in the oil, so as to alter its general character, took place. The oil became colourless, but it did not acquire any disagreeable odour if heated up to 400° Fahr. He believed that the operation, although it might not be absolutely necessary, was a desirable precaution to take so as to ensure uniformity in the result, and to guard against defects which otherwise would be likely to occur. The object he had in view in introducing this discussion was to call forth the opinions of pharmacists, and he felt greatly indebted to those gentlemen who had come forward and favoured the Society with their opinions and experience. Referring, in conclusion, to the letter of Professor Attfield, as to the nomenclature which might be looked forward to in future Pharmacopœias, he (Professor Redwood) said he could not hold out much hope or expectation of anything being stated in the proposed appendix that would tie the authors of the Pharmacopœia to the nomenclature which they should adopt four or five years hence. He thought the prevailing opinion of the Pharmaceutical Committee and of the Medical Council would be "Sufficient unto the day is the evil thereof." When the time came for bringing out a new Pharmacopœia they would then consider what the nomenclature should be that it was advisable to adopt. At the same time he had no hesitation in saying he had every confidence that when that time came, the nomenclature which Professor Attfield would like to see adopted would be introduced.

The Mustard of the Pharmacopœia.

Mr. Greenish then read a paper on "The Mustard of the Pharmacopœia." The Paper is printed at p. 782, and gave rise to the following discussion:—

Mr. Martindale said he had tried at several places, but had failed to get the mustard of the Pharmacopœia, except at one establishment in London. Powdered white mustard seed alone, he thought, was generally supplied; this was very different from that which was used in the north of England, and supplied by Dewar, of Newcastle-on-Tyne.

Professor Bentley said that his experience did not accord with what Mr. Martindale had stated with reference to white mustard seed, for all the mustard he (Professor Bentley) had examined certainly contained a notable proportion of black mustard seed. He did not think that white mustard seed would in itself at all meet the desire of those who used mustard; and at the same time the use of black mustard by itself would be so powerful, so pungent, that unless a certain agreeable character was imparted to it the mass of the people would not use it; but if they mixed with it white mustard seed they got an agreeable flavour. It was for that reason especially that white mustard was used, and used advantageously. The admixture of other substances was a question which he would not go into at the present moment, as it would raise the whole inquiry with respect to what was commercial mustard, and the still further subject of its adulteration.

Mr. Bland believed that exaggerated notions prevailed with regard to the adulteration of mustard, and that the principal obstacle in the way of getting the genuine article had been the unwillingness to pay a decent price for it. For several years past he had been supplied with mustard which was stated by the manufacturer to be genuine, and he believed that that representation was perfectly correct. There was no starchy matter mixed with it, but it was purely a mixture of white and black mustard, and there was an entire absence of any foreign colouring matter. He was sorry to say that, generally speaking, the public were not good judges of mustard, preferring that which was sold by the oilmen and grocers at from 8*d*. to 1*s*. per lb. He had had some experience with regard to the fixed oil that had been recommended as a remedy for rheumatism, but he was not inclined to attribute to it any great value.

Parliamentary and Law Proceedings.

Alleged Death through the Use of Adulterated Vinegar.

In charging the grand jury at the Liverpool Spring Assizes, on the 27th March, Mr. Baron Pollock called attention to a charge of manslaughter against a woman named M'Grath, for causing the death of her infant child, eight weeks old, by negligence in administering an overdose of cough medicine. The child was delicate almost from its birth, and the prisoner applied to a medical man, who advised her to go to the union for medical aid. Instead of doing so, however, she bought a two ounce bottle of cough medicine from a chemist. The medicine was administered three times a day, according to directions, but on one occasion the remaining contents of the bottle, about an ounce and a half, were administered, and the child died. There was the evidence of the chemist to the effect that he made up as much as two gallons of this medicine at a time, and that he used laudanum, vinegar, and other ingredients. He sold large quantities of it, with directions upon the bottle. The chemist stated that the quantity of laudanum in the bottle would not amount to more than eight drops, and that if the whole contents of the bottle had been taken at once that would not have been sufficient to cause death. The vinegar was subsequently analysed, and it was then found that the vinegar was largely adulterated with hydrochloric acid. The chemist stated that he had bought the vinegar from a wholesale dealer, and that he was not aware of any adulteration. The bottle was examined, and instead of containing only a few drops of laudanum, it contained a much larger quantity of laudanum, and half the quantity would have been sufficient to cause death. The charge on the depositions was that the prisoner was guilty of negligence in administering an over-dose of the medicine, and that question involved to some extent the question of her knowledge. If the chemist who sold the medicine was under the impression that the ingredients were not adulterated, or that it did not contain more than eight drops of laudanum, one could hardly imagine how the prisoner could have had a greater knowledge, and therefore it was difficult to say how reckless negligence could be made out against her. However, if, after examining the witnesses, the grand jury should be of opinion that she intentionally administered a large dose of the mixture, so as in any way to affect the health of the child, then the offence would be *primâ facie* one of manslaughter. But some one was exceedingly culpable in adulterating the vinegar. He had not heard that any steps had been taken in reference to that matter.

When the grand jury had concluded their labours the foreman, addressing his lordship, said in the case of Mary M'Grath, charged with the manslaughter of her infant child on the 5th February, the grand jury had not been able to find a true bill. From the evidence which was placed before the jury, however, they felt that there was culpable negligence somewhere. There was a chemist who mixed a certain cough medicine, which on analysis, was found to be of the most dangerous and poisonous character. There was no doubt but death had resulted from the administration of the mixture. Vinegar had been used in its preparation, which was found to be highly adulterated and a most dangerous compound. The grand jury felt that they could not be discharged without first bringing these facts before the court in the hope that an investigation would take place. This vinegar had been sold to the chemist, and was in all probability being extensively sold elsewhere, and the grand jury felt it would be impossible to estimate the amount of injury which might be sustained through its use. They hoped, therefore, that some investigation would take place, and if culpable negligence was found some steps should be taken in the matter.

The judge remarked that he agreed with the jury in what they thought. Adulteration with hydrochloric acid was a most serious matter, and he hoped the opinion expressed by the grand jury would lead to an investigation. —*Liverpool Daily Post and Daily Albion.*

⁂ This case appears from the report to be somewhat obscure, for though the presence of hydrochloric acid in vinegar must be regarded as an aduleration, it could scarcely be poisonous or even dangerous.—Ed. Ph. Journ.

Action against a Druggist for a Mistake.

On Wednesday, March 26, an action to recover the sum of £200 was brought in the Record Court, Belfast, against Mr. Gibson a druggist, for selling the plaintiff a quantity of extract of belladonna in the place of extract of dandelion, whereby injury was caused to the plaintiff.

From the evidence, it appeared that Miss Doherty the plaintiff's sister, went to Mr. Gibson's shop to purchase some extract of dandelion, and was supplied with a box containing what was represented to be that substance. She and her brother having taken a portion of it were seized with illness, the man especially being delirious. A medical man was called in who pronounced the illness to be caused by belladonna poisoning, an opinion that was confirmed upon an examination of the residue in the box.

For the defendant it was urged that the drug had been supplied in his absence, and that there had been no negligence on his part, as the jar in his shop containing belladonna, was distinctly labelled "poison;" also that the plaintiff had suffered no permanent injury.

The jury, after some deliberation, returned a verdict for the plaintiff of £5 damages and 6*d.* costs.—*Belfast News-Letter and Telegraph.*

Prosecution under the Adulteration Act.

On Friday last, at the Clerkenwell Police Court, the case of prosecution for the sale of adulterated tea came on for hearing. As reported on p. 755, this case was adjourned for a fortnight, in order to allow the magistrate to consider an objection to a conviction on the ground that the analyst had not stated in his certificate whether the adulteration was injurious to health; Mr. Barker said he had come to the conclusion that he had the power to convict, and he imposed a fine of £10 and costs.

The Benevolent Fund.

Sir,—It is with great pleasure that I note the Benevolent Fund is at last exciting some attention. In common with some other chemists of this locality, I have long since resolved to withhold my mite, until the whole amount subscribed annually is at once devoted to charitable purposes. Whilst so many noble societies are calling out loudly for help, and are bravely casting their bread upon the waters, the Pharmaceutical Society, deaf to the voices around, is hoarding up money for the relief of the poor in some age that may never appear.

Pharmacists of past days doubted the generosity of the men of to-day, and we, forsooth, must needs copy them, fearful lest charity should be dead after the departure of her present patrons.

In conclusion, I would ask in the name of all that is right and charitable, that members in each town should unite their subscriptions, taken away from the Benevolent Fund, to relieve the destitute of their own neighbourhood; or that a different policy be pursued by our Council, when I doubt not that subscriptions would quickly be almost as numerous as members of the Society.

Walter B. Clark.

Leicester, March 29th, 1873.

Pharmacy Act, 1868.

Sir,—I quite agree with Mr. Beale in last week's Journal, that the Pharmacy Act has not proved to be of much benefit to chemists, inasmuch as the outside trade goes on much as usual, notwithstanding the prohibitory clauses. It is plain that if the public are not strictly protected against themselves by further legislation, the Act will be a positive injury to many of us; because, so long as the public can obtain drugs under certain names to which they have been accustomed, the quality will not be inquired into, the price being a more material question.

Tincture of rhubarb, made with English rhubarb and turmeric, is commonly vended in this locality, as well as the other things spoken of by Mr. Beale: and the result of the whole is, that though I have been established some thirty years here, and have two places of business amongst a population of 14,000, the profits afford but a moderate living. If a person can manage to get half a dozen red herrings, a few bits of pipeclay, and a bath brick, into the window, there is sure to be some wholesale (?) druggist to the fore, to provide everything that he can persuade the enterprising party to deal in. And I have about fifty or sixty of these to contend with, who treat the Poisons Act as a nullity, besides a considerable assortment of old women, who vend breast ointment, lotions, infallible embrocations, life pills, etc. Apart from the mere honour of the thing, there is nothing in the present regulations, so far as I can see, to prevent thoroughly incompetent persons from reaping, in such localities as mine, the principal benefit by a little ingenuity. I have a competitor who calls himself an "oilman," with a shop fitted up like a druggist's shop, who sells what he likes, and prepares prescriptions as if properly qualified. He has a better excuse than many, because he has been with a druggist; but there are numbers who take our legitimate trade, who can barely write their own names, and certainly cannot spell a sentence with a fair approach to correctness. Such persons as these are supplied with the veriest trash for sale, and unless I choose to compete with them, which I will not descend to do, I am undersold.

As regards prescriptions, this is not a neighbourhood for many, the local medical gentlemen being in the habit of making up their own, as well as making their blisters, lending clyster-pipes, etc. The consequence is that I am thrown back on prescribing for more than mere simple matters; whereas, if a proper Pharmacy Act protected me, I should find plenty to do in carrying out the ordinary branches that pertain to our business. I trust that now that the Council has gone so far as they have done, they will go a little further, and thoroughly detach us from the suckers who make it impossible for a great many of us to succeed, and who are standing examples of the superiority of impudence and cunning manœuvres to skill and education in obtaining a share of this world's goods.

Pudsey, near Leeds. Joseph Walker.

Early Closing.

Sir,—I am glad to notice that *one* at least of the Sunderland chemists (viz. John Aslin and Co.) has joined the early closing movement in that town, by adopting the practice of closing precisely at seven o'clock. This is a good example, and it might be advantageously followed.

A Registered Chemist and Druggist.

Sunderland, March 22nd, 1873.

Pharmaceutical Women.—Mr. H. J. Lutwyche writes that he would strongly advise those women who have an idea that they can become chemists to stay at home and learn to cook, for that not one out of twenty knows how to cook, and not one out of double that number knows how to boil a potato properly. His experience is that there are many occurrences which take place in a chemist and druggist's shop that render it an unfit place for a woman. He also states that out of eighty-three chemists and druggists who have been called upon by a friend of his, eighty-two have signed a "paper for women to be rejected," and most of them "expressed their regret that the Pharmaceutical Council did not reject female students long ago, which would have ended the matter at once." Whether or not it be desirable to exclude women from the practice of pharmacy, we do not think they are to be disposed of so readily as our correspondent seems to believe, and we think the better course would be to give them full opportunity to enter into any competition they please.

Mr. F. M. Bessant says that nearly all the correspondence on this topic has revolved itself round such questions as "the fitness of women for the work," "the fairness" as regards salary, competition, the advisability of exposing women to the chance of moral contamination, etc., and though he most heartily concurs with what "*H. L.*" says on the subject, and only thinks he has put the matter far too lightly in this respect, it seems to him that, until Mr. Saunders' letter appeared, no one had properly realized the full depth and importance of the question. The real question he considers to be—Was woman made for herself or for man? and that its bearing with regard to pharmacy is only one peculiar phase of it. He thinks that a branch of "trade," which is now endeavouring to show "the world" what a high place in "intellectual rank" it is entitled to, should not be one of the very first to give way to one of the most degrading innovations of these modern times. With reference to the fact mentioned in the Journal some little time back, as to female students being admitted into some French medical or chemical society, he is of opinion that we have not made such miserable progress in civilization in the last few years, that the French have now passed us, and stand as a pattern and example to us in anything.

"*Ignoratio.*"—The two quantities are mentioned to show the range of the doses. It is wrong to assume that it would be advisable or even safe to give an adult the higher dose in all cases.

J. Stather.—Your letter has been handed to the Secretary.

"*Verus.*"—We are unable to aid you; the two are completely incompatible.

J. F. Brown.—We believe this oil is to be met with in the London market. Try your wholesale druggist.

"*Look Out.*"—Your letter, which should have been accompanied by your address, has been handed to the Secretary, with whom you had better communicate on the subject.

"*Nemo.*"—We believe such a collection as you require is supplied by Mr. Siebold, of Manchester.

Communications, Letters, etc., have been received from Mr. Pocklington, Mr. Bennett, Mr. J. Abraham, Mr. Halawell, Mr. J. F. Brown, Dr. Fraser, Mr. Mackay, Mr. Anderson, Mr. Walker, Mr. Symes, Mr. Bladon, "Registered Student," "Jurisprudentia." W. A. C.

NOTES ON INDIAN SIMARUBEÆ.

BY ALFRED W. BENNETT, M.A., B.SC., F.L.S.,

Lecturer on Botany, St. Thomas's Hospital.

The Simarubeæ are an order of plants of considerable interest from a medicinal point of view, in consequence of the intensely bitter properties displayed by their bark and some other parts of the plant. The best known genus of the order, Quassia, belongs to the New World; but in Tropical Asia there are also a considerable number of species sharing in the same medicinal properties; and from the great and growing interest taken in the natural productions of our Indian possessions, I have thought it might be of interest to put together what is known about the species that are natives of those countries, which I am the better able to do from having had the opportunity recently of verifying, and in some cases correcting, the diagnoses of previous writers, while preparing a monograph of the order for Dr. Hooker's 'Flora of British India.'

The Simarubeæ are placed by Bentham and Hooker in their "cohort" Geraniales of Thalamifloræ; by Lindley in his "alliance" Rutales of Hypogynous Exogens: they are all trees or shrubs, often of a very great size, with usually inconspicuous, often very crowded and mostly unisexual flowers; the leaves often remarkably large and almost always compound; the fruit consisting, in nearly all the genera, of a number of distinct indehiscent drupes or samaræ, arranged, and often stalked, on a common receptacle. The species mostly inhabit the tropical and subtropical regions of both hemispheres, especially South America and Tropical Africa, and number about 120, arranged in 30 genera. The only representative of the order in Europe is the *Cneorum tricoccum* of the South of France; but it is well known in shrubberies, from its Asian representative *Ailanthus glandulosa*, extensively cultivated on account of its rapid growth, its magnificently large pinnate leaves, and as food for a species of silkworm, the *Bombyx Cynthia*. The diagnosis of the order may be stated as follows:—

Order SIMARUBEÆ, *Rich.*, *DC.*

Trees or shrubs, often with bitter bark. Leaves alternate, rarely opposite, pinnate or rarely simple, without stipules. Inflorescence axillary, racemose, or panicled, rarely spicate; flowers regular, usually unisexual, and generally small. Calyx 3-5-lobed. Petals 3–5, very rarely 0, valvate or imbricate. Disc annular, capsular, or elongated, simple or lobed, rarely absent. Stamens equalling or twice as many as petals, rarely indefinite, inserted at the base of the disc; filaments free, often scaly at the base; anthers oblong, usually introrse, bilocular, dehiscing longitudinally. Ovary free, 1–6-celled, usually deeply lobed, less often entire; styles 2–5, more or less united or free; stigmas capitate; ovules usually solitary in each cell, rarely more numerous, erect or pendulous. Fruit drupaceous, capsular, or frequently samaroid, of 1–6 distinct carpels, rarely syncarpous. Seeds usually pendulous; albumen present or absent; embryo straight or curved; radicle superior.

With regard to the general properties of the Order, and especially of those species which are not Indian, the following remarks are made by Lindley, Bentley, Royle, and others. The species are intensely bitter. A plant called "Paraiba" in Brazil, *Simaruba versicolor*, St. Hil., possesses such excessive bitterness that no insects will attack it. Specimens of it, placed among dried plants which were entirely devoured by the larvæ of a species of Ptinus, remained untouched. The Brazilians use an infusion in brandy as a specific against the bite of serpents, and also employ it with great success as a cure of maladies occasioned by parasitic insects. The wood of *Quassia amara*, a native of Surinam and the adjacent countries, is intensely bitter, and was the original Quassia of commerce, formerly much used as a febrifuge and tonic, and the flowers infused in wine or water, as a stomachic. It contains a principle called Quassin. The officinal Quassia-wood of the materia medica is now, however, yielded entirely by a Jamaican plant of the order, *Picræna* or *Picrasma excelsa.* It is much used as a tonic, febrifuge, and stomachic, and it also possesses anthelmintic properties. An infusion sweetened with sugar acts as a powerful narcotic poison on flies and other insects; its infusion may also be employed to preserve animal matters from decay. It is sometimes used by brewers as a substitute for hops, although prohibited under severe penalties. Quassin, the intensely bitter crystalline substance characteristic of the Order, is found here also. In Jamaica the plant is known under the name of Bitter Ash or Bitter Wood, and the wood was at one time used for the manufacture of small goblets, known as "bitter-cups." *Simaruba amara* is a native of South America and the West Indies, especially Jamaica, where it is known under the name of Mountain Damson. The bark acts as a tonic, and has been used in diarrhœa, dysentery, etc., and exported to Europe. In Cayenne the decoction, which is bitter, purgative, and even emetic, is used in fevers and diarrhœa. The timber is described by Sir R. Schomburgk as resembling white pine, both in colour and quality. The seeds of another species of the order, *Simaba Cedron*, or "Cedron," are highly esteemed throughout Central America, where they are used as a febrifuge, and are thought to be a specific against the bites of venomous snakes and other noxious animals. The active principle of this plant has been termed Cedrin. Purdie states that the tree grows in profusion on the Magdalena, near the village of San Pablo. In the Isthmus it is generally found on the outskirts of forests in almost every part of the country, but in greater abundance in Darien and Veraguas than in Panama. According to Dr. Seemann the natives hold it in high esteem, and always carry a piece of the seed about with them. When a person is bitten, a little mixed with water is applied to the wound, and about two grains, scraped into brandy, or, in the absence of it, into water, are administered internally. By following this treatment, the bites of the most venomous snakes, scorpions, centipedes, and other noxious animals have been unattended by dangerous consequences. Doses of it have also proved highly beneficial in cases of intermittent fever. Dr. Royle has no doubt that, from the similarity of the climate to that of their native country, all the Quassias and Simarubas would succeed well in Bengal. *Brucea antidysenterica* of Tropical Africa possesses similar properties to the species already named.

A. and Th. Husemann, in their 'Pflanzenstoffe in chemischer, physiologischer, und toxicologischer Hinsicht,' give the following account of the preparation and properties of these two substances:—Quassin is an indifferent substance, with the composition $C_{10}H_{12}O_3$, and was discovered by Winckler in 1835;

it occurs in the wood and bark of *Quassia amara*, L., and *Picræna excelsa*, Lindl., and perhaps also in the bark of *Simaruba amara*, Heyne. Winckler extracted the wood with alcohol of 80 per cent., evaporated, dissolved the residue in water, filtered, again evaporated, and extracted with a small quantity of absolute alcohol, again evaporated the extract almost to dryness, dissolved it in hot water, and decolorized the filtered solution by animal charcoal at a gentle temperature. Wiggers extracted the wood with boiling water, agitated the concentrated solution with lime, filtered, evaporated almost to dryness, boiled the residue with alcohol of 80 to 90 per cent., again dried, dissolved in a small quantity of absolute alcohol, precipitated the brown colouring substance from the solution by ether, repeated this treatment until, on drying, an almost colourless residue remained, and poured the alcohol-ether solution into water, when the quassin immediately crystallized out. When crystallized according to Wiggers's method from alcohol-ether, or from hot water or hot weak alcohol, quassin forms white, semitransparent, shining columns, persistent in air, without any smell, with an extremely bitter taste, and neutral reaction. It melts with a little more difficulty than colophonium, and hardens into a transparent yellow mass. At 12°C. it requires for solution 222 parts of water, dissolves readily in alcohol, but very slowly in ether. When strongly heated in air, quassin burns like a resin. Cold moderately concentrated nitric acid changes it, on heating, into oxalic acid; cold concentrated sulphuric acid dissolves it without colour, and water precipitates it apparently unchanged; tannic acid precipitates it from solution in alcohol in thick, white flakes. We still want a series of exact physiological experiments on the poisonous action of this substance on other animals besides flies and other insects. The usual statement with reference to quassin is, that Härtl observed that an application of ·06 to ·12 gram to a wound in the case of a rabbit caused faintness and want of appetite, and death ultimately in 30–36 hours; an alcoholic solution was here employed. With other experimenters, palsy resulted, but ultimate recovery. If the seeds of *Simaba Cedron*, Planch., which are used on the Magdalena river in South America as a remedy against intermittent fever, rheumatism, and poison, are heated with ether so as to remove the fat, and then extracted with alcohol, there shoot out of the solution on evaporation silky glancing needles of cedrin (composition not given), with a taste as bitter as strychnine. In large doses, this substance is poisonous.

(*To be continued.*)

SOLUTIONS FOR HYPODERMIC INJECTIONS.*

BY M. CONSTANTIN PAUL.

In the early period of the employment of the subcutaneous method of administering medicines, the substances most ordinarily so used were morphia and atropia,—or rather the hydrochlorate of morphia and the sulphate of atropia,—which were dissolved simply in water. These solutions, once prepared, sometimes remained on hand a considerable time, in consequence of the small quantity used at each operation, but it was soon noticed that they easily underwent change. Dr. Bourdon found that a solution of hydrochlorate of morphia, which had been kept for some time, had lost so much of its activity that he was able to inject equal to four centigrams of the hydrochlorate without producing the physiological effects to be expected from such a dose. The solution was therefore analysed by M. Delpech who found that it had lost one half of its proportion of morphia. In point of fact, the solution had become turbid through a confervoid growth, necessitating filtration. In a solution of sulphate of quinine also the growth had appeared, and M. Delpech found that a portion of the salt had disappeared. Dr. Bourdon attributed the weakening of the solutions to two causes:—(1) that the confervoid filaments act a similar part to threads placed in supersaturated solutions in influencing the formation of crystals, and this especially, as these solutions are usually concentrated and so predisposed to crystallization; (2) that the confervoid growth has the property of decomposing to a certain extent the medicaments under such circumstances. M. Gubler has recognized the confervæ present in a sulphate of atropia solution as belonging to the genera *Leptomitus* and *Hygrococis*.

Since water, distilled and undistilled, proved a bad medium for preserving solutions intended for hypodermic injection, it became necessary to seek a liquid less liable to change, and Messrs. Gubler and Delpech tried the distilled eucalyptus water. This preparation could be preserved much longer, but did not give complete satisfaction. The author has employed a liquid prepared by M. Adrian, consisting of—

Water	85 parts
Alcohol	10 „
Glycerine	5 „

This liquid he has found to be not more irritating than simple water, and capable of being kept for a moderate time, but still it permits the development of the confervæ. It is also necessary to remark that this vegetation shows itself with a variable intensity, according to the salt used, even when the vehicle is the same.

The solution which changes most readily is that containing hydrochlorate of narceia; a layer of confervæ develops on the surface, causing the formation of very small crystals appearing like a powder. The same solution acidified by hydrochloric acid precipitates fine crystalline needles, but the confervæ are not developed. The solution next in order of stability is that of bisulphate of quinine, in the lower part of which float large flocks of mould. Then follow the solutions of sulphate of atropia and hydrochlorate of morphia, which only develop a small proportion. Acetate of aconitia is scarcely altered. Solutions of hydrochlorate of quinine, sulphovinate of quinine, sulphate of strychnia, and nitrate of veratria remain without change.

Digitaline dissolved in alcohol is perfectly preserved, as is also sulphate of morphia dissolved in glycerine. The author, therefore, adopts by preference glycerine as a solvent, as being a neutral liquid and easily preserved without change. He also considers it to be of all the liquids that which approaches nearest in composition to the subcutaneous cellular tissue.

Experience has proved to M. Paul that it is necessary to use great precision in apportioning the

* Abstracted from papers in 'L'Union Pharmaceutique,' vol. xiv. p. 48, and the 'Répertoire de Pharmacie [N.S.],' vol. i. p. 91.

quantities for subcutaneous injections; neglect of this precaution he has known to lead to several accidents calculated to bring discredit upon this method of administering medicines. One difficulty occurs in the varying sizes of the syringes used. The plan adopted by him for securing his object is to weigh the syringe when full of the solvent and again when empty, the difference showing the capacity of the syringe. The number of half-turns of the piston necessary to empty the syringe is then counted, and the same number of milligrams, or other definite quantity, of the drug added to the quantity of solvent representing the capacity of the syringe. Each half-turn of the piston will then represent a definite quantity, only limited by the solubility, of the drug. For instance, suppose that the syringe contains 1·17 grams of water, and the piston requires twenty-one half-turns. If twenty-one milligrams of the drug be added to 1·17 grams of water, each half-turn will represent one milligram of the medicament. The formula will then be to put into the quantity of solvent representing the capacity of the syringe as many milligrams or other definite quantity of the drug as there are half-turns of the piston.

The strengths of the solutions used by M. Constantin Paul are as follows:—

Sulphate of atropia .	½ millgr.	to the half-turn.
Hydrochlorate of narceia	1 ,,	,,
Hydrochlorate of codeia .	1 ,,	,,
Sulphate of strychnia . .	1 ,,	,,
Hydrochlorate of morphia	2 ,,	,,

PERFUMES PHYSIOLOGICALLY AND COMMERCIALLY CONSIDERED.*

BY JAMES PATON.

The art of the perfumer is to the human nose what the art of the sculptor or the painter is to the eye, or the art of the composer to the ear. The perfumer's function is more purely æsthetic than that of the cook, whose art is inseparably combined with the most purely utilitarian and necessary of all offices. The eye, the ear, and the nose, besides all having the most important functions of direct utility to discharge, have each a separate æsthetic side, and although we cannot lay claim to the same lofty, wide, and ennobling range of influence on behalf of the nose as are fairly due to the other two organs, still, in its humble and limited way, it contributes to the pure sensuous pleasures of mankind. And just as the function of the nose as a minister of pleasurable sensation is thus comparatively humble, so the perfumer, as artist, must be regarded as very low in the scale of nobility compared with a Titian or a Canova, a Handel or a Rossini. Nevertheless, the æsthetic functions of the nose deserve something better than the contempt with which that much-abused organ and its functions are generally treated, and it is about as unreasonable to call a young gentleman who smells very sweetly the hard names which are usually directed against him, as it is to scoff at the old lady whose soul delights in the mechanical strains of a musical-box. The taste in both cases is simple in its nature; it requires little cultivation for its development, and it affords a real if not very profound gratification.

The art of the perfumer can lay claim to the most venerable antiquity. In a certain sense, of course, the enjoyment of perfume is coeval with the existence of the human race, as the flowers which bloomed in Eden must have ministered to the gratification of the senses of the progenitors of our race. But beyond this the collection and preparation of substances, on account of their odoriferous properties, must have existed almost from the dawn of human time. Perfumes occupied a prominent place in all religious services from the earliest ages, and to the present day the burning of incense forms a feature in the devotional exercises of nearly every system of worship under the sun. It would be an endless and useless task to quote authorities for such usages from our own Scriptures, or from the writings of the pagan authors, as they all teem with allusions to the habit, and are perfectly familiar to every one of us. The source of the word "perfume"—*per fumum*, by or through smoke,—at once points to the origin of the practice, and tells us that the art which combines the delicate and refreshing odours of the fashionable perfumer had its remote springs in the incense burnt on the altars of the patriarchs of mankind.

To trace the development of the art from these rude beginnings, the strange part it has played among the usages and superstitious practices of mankind, the important place that odoriferous substances have occupied in the commerce of nations, and the progress and extension of the art till it has arrived at the dimensions it possesses at the present day, would be a task of much interest and importance. But at present we content ourselves with some preliminary observations on the nature of the sensation we term an odour, the organs concerned in its experience, and the relation of perfumes or pleasing odours to pungent and other disagreeable smells; and having thus arrived at a conception of the position and relations of perfumes, I propose to make a few remarks on the chief sources from which the perfumer draws his scent-yielding substances.

It may be doubted whether anything is really known regarding the actual composition and nature of the substance of most of the pleasing odours. We know perfectly well the bodies which yield odours, and chemists can tell with absolute precision what is their chemical structure; but although they can further tell the conditions essential to the sensation of smell, the subtle essence which gives rise to it appears to be too ethereal for human detection or manipulation. A grain of musk will perfume millions of cubic feet of atmospheric air, and still it continues apparently a grain of musk. The following minute quantities of different substances spread out on the surface of smell cause a distinct sensation:

Phosphoretted hydrogen . .	$\frac{1}{3000}$ grain.
Sulphuretted ,, . .	$\frac{1}{30000}$,,
Bromine	$\frac{1}{40000}$,,
Oil of resin	$\frac{1}{1300000}$,,

A still smaller quantity of musk than the last given smells strongly, but the actual measure has not been ascertained.

It is assumed that, for the perception of an odour, it is necessary that the body to be smelt must be in a gaseous condition, just as it is required that before we experience a taste, the substance must be dissolved, and for the sensation of touch a resisting solid is necessary. Odorous gases are such as are readily and energetically acted on by oxygen, and the presence of oxygen is therefore a necessary condition of smell. Such gases as mix freely without uniting with oxygen—as hydrogen and nitrogen—are inodorous. In order also to experience the sensation of smell it is necessary that the odoriferous particles impinge with some violence upon the surface of the sensitive membrane in the nose which corresponds with the olfactory nerve, therefore, when we wish to experience a strong sensation of smell we sniff strongly, and when a disagreeable odour is to be avoided we hold our breath, and breathe out when we think we are beyond its influence.

Odours, we all know, are divided into two great and most easily distinguished classes, the pleasant—which usually monopolize the term odours—and the unpleasant, to which we give the brief but expressive name stinks. The mental phenomena, however, to which the excitement of the olfactory organ gives rise, admit of a more detailed classification; and I quote from Professor Bain's work on the 'Senses and the Intellect' the classes into which that philosopher arranges the sensations or peculiar states

* Read at a meeting of the North British Branch of the Pharmaceutical Society, March 28, 1873.

of consciousness which come to us through the nose. One class of odours, according to Bain, owe their character to sympathy of the nose with the lungs, or other vital organs connected with the nose; a second class appeals to the purely olfactory sensibility, that is the influence of the substances which come into this class goes directly from the olfactory nerve to our consciousness, and a third class involves an excitation of the nerves of touch. Under the first head,—smells which owe their character to sympathy between nose and lungs or other vital organs,—he places:

1st. *Fresh Odours.*—These are such as have a restorative action, and act chiefly on the respiratory organs, stimulating them to increased action. Fresh odours are, therefore, essentially the refreshing odours, and are comparable in their influence to the exhilarating effect of the pure cool air after exposure to the stifling effect of a close heated room. 2nd. The converse of fresh odours, or *close* or *suffocating* smells, such as those of overcrowded and ill-ventilated rooms, etc. The third class of such odours are the *nauseous* or *disgusting* smells, of which sulphuretted hydrogen is the type, and which depend for their influence on some antipathetic action on the stomach, which tends to cause nausea and vomiting. In these three are comprised the odours which depend for their character on a sympathetic action between the nose and other vital organs. Under the second head,—odours which depend for their character on an influence exerted on the olfactory nerves alone,—are odours which are classed as *sweet* or *fragrant*, and which convey to the mind purely pleasurable sensations. The odour of violets is quoted as an instance; but it is the art of the perfumer so to combine his materials, that this sensation is usually mixed up with the fresh odours to which we have alluded, and thus pure pleasure and refreshing stimulus are combined. The opposite of the pure, sweet, or fragrant odours are described as the *mal-odours* or *stinks*, of which the smell of assafœtida is a perfect if not pure example. These two—the fragrant odours and stinks—are thus, even according to Professor Bain, the only two real divisions of odours uncomplicated with other effects which do not belong to the functions of the nose. Regarding them he says, "As sweetness is the proper pleasure of smell, the effect of a stink is the proper pain of the organ, the influence originating the peculiar form of misery that we are adapted to receive by means of this sense. The sensation may be specified as the nose pain. Of an intense rather than a massive character, we are stunned and discomposed, but not necessarily depressed by it. It resembles in this respect a bitter taste, and is contrasted with the massive pains of chillness, indigestion, or disgust. The expression is in accordance with the acuteness of the sensation, being an intense contortion of the features chiefly about the nose." Of the third class of odours—those that excite the organs of touch, the sensation of *pungency* is the type, and is produced by the taking of snuff, the inhaling of ammoniacal vapours, or of vinegar, and it is sometimes experienced in an excessive degree by an unfortunate miscalculation of the amount of mustard it is safe and pleasant to trust into the mouth. It is properly independent of the sense of smell, the effect arising through an influence on nerves leading from near the nasal orifices, which, besides being excited by pungency, also are affected by cold, etc. *Ethereal* odours, such as the odour of alcohol and ether, are a combination of pungency with fragrance, and *acrid* odours are regarded as being compounds of pungency and stinks. Under the head of *appetizing* smells are included those with which hungry people are familiar during the *mauvais quart-d'heure* which precedes dinner, and also those to which are referable the sexual feeling excited in animals, and to the possession of which, in the case of two animals, we owe the existence of our most highly valued perfumes, musk and civet. Finally, under the head of *flavours* are included these odours which are developed through the process of mastication, of which cinnamon gives an example, it being a substance having little taste, and depending for its relish on the odour developed in the nostrils in the process of breathing during the swallowing of the fragrant bark.

Of all these varieties of smells, the perfumer has properly only to deal with the sweet or fragrant class which appeal directly from the nose to the mind, and yield unmixed pleasure. Other influences such as restorative or refreshing action may be mixed up with them, but these are the accidents of the classes; the perfumer having to do solely with the nose and its sensations. The series of substances which chiefly minister to the pure gratification of the olfactory sense are hydrocarbons of the terbene or turpentine series, or very slightly oxygenated volatile oils, of which the oil of cinnamon may be taken as an example. The converse series which the perfumer has to avoid, are usually found to owe their bad smell to the presence of sulphur in their composition; and the worst of all smelling substances owe their evil odour to the presence of arsenic.

For the elaboration of powerful odours in the great laboratory of nature bright light and strong heat are required. Therefore it is that to tropical countries which possess both these requisites we must look for our chief supplies of the materials of perfumery. The faint odours which are begotten among us children of the cold grey north, effectually prevent our cultivation of the materials of perfumery, and the only two substances of native growth in which our island excels—lavender and peppermint—owe their superiority to the fact of the less rank growth of these plants with us; which in warmer climates yield odours more powerful than pleasant. And as it is in warmer climates that the perfume-yielding substances are most freely produced, so it is in the same regions that their influence is most beneficially felt, and their pleasures most eagerly sought. Evil odours are of course as pronounced in hot climates as are the fragrant influences of sweet-smelling flowers, and with smells it is as with deeds, the best way to avoid the evil is to cultivate the good.

The sources from which the perfumer draws his raw materials are very numerous and varied. Besides several substances drawn from the animal kingdom which are staples of his art, he ranges over the entire limits of the vegetable world, and lays nearly all orders of plants under contribution to him; and of the individual plants he makes use of every part in turn. It may be the entire plant which serves his purpose, as in the case of many labiates, or it may be the roots, as in the khus-khus, the root-stocks in ginger, the bark in the cinnamon series, etc.; the wood, as in the Virginian cedar or in sandal-wood; the leaves, as in the case of patchouli, or the various parts of the flower, as is most commonly the case. Besides these, there are the numerous instances of fragrant balsams, gum-resins, and resins which exude from the plants, as balsam of tolu, myrrh, and a great variety of similar substances. The laboratory of the chemist is also laid under contribution for the benefit of the art of the perfumer; and some of the most wonderful triumphs of modern chemistry are found in the synthetical elaboration of odours and fruit essences, which, however, are more valued by the cook and confectioner than the perfumer.

The list of raw materials of perfumery, which includes only three substances from the animal kingdom,—ambergris, civet, and musk,—contains between 60 and 70 separate substances from the vegetable kingdom, and is capable of classification in various ways according to the natural affinities of the animals or plants yielding them, the form and condition under which they are presented in commerce, or the nature and similarity of the odours they yield. Thus the materials could be arranged zoologically and botanically, or separated into resins, balsams, roots, wood, barks, leaves, flowers, and fruits; or, taking as a basis of classification the nature of the odours, we should have so many possessed of the rose odour, the violet odour, the citrine or orange odour, or the balsamic odour, etc. Only one substance the perfumer places in his list as produced in the laboratory of the chemist, and that, under the name of mirbane, is the artificial oil of almonds, which is very largely employed in the preparation of almond soap.

It is now upwards of twenty years since Professor Hofmann and Mr. Warren De La Rue, in reporting upon the chemical section of the Great Exhibition of 1851, called public attention prominently to the artificial preparation of fruit essences and perfumes by the skill of the chemist; and it is to Hofmann himself that we owe the discovery of one of the chief sources of the body benzol, which is the basis from which artificial essential oil of almonds is prepared. Nitrobenzol, which in the hands of the perfumer is re-baptized with the sweet-sounding and meaningless name Essence de Mirbane, was discovered by the chemist Misterlich in 1834, and at that time described by him as strongly resembling in odour the essential oil of bitter almonds; but as it could then only be prepared from benzoic acid, there was no hope of manufacturing it at a cost which would enable the artificial to compete with the natural product in the market. In 1845, Hofmann discovered that benzol could be easily prepared in enormous quantities at a cheap rate from coal tar; and the series of investigations this eminent chemist then carried out gave us, in the first place, the artificial oil of almonds as a commercial product, and later, the infinitely more valuable series of coal-tar colours which have now revolutionized the art of the dyer and the industries concerned in supplying the raw materials of the dye-vat. Regarding these artificial odours and perfumes, Dr. Lyon Playfair, in his lecture on the results of the Great Exhibition of 1851, says:—

"An ingenious application of the science of chemistry has of late years been made in the manufacture of artificial essences of pears, pine-apples, and other fruits. In the concentrated form the smell is rather acrid, but when diluted, the resemblance to the fruit is recognized. The best imitations are the pine-apple and the Jargonelle pear; the green-gage, apricot, black currant, and mulberry, when properly mixed, are fair imitations. They are quite innocuous in the proportions used, namely, a drop and a half to the ounce; the cheap ices are flavoured with these essences. Their introduction originated in the discovery of the fact, that the peculiar flavour of "pine-apple rum" was due to butyric ether, which has since been obtained from the fruit itself.

"The jury in the Great Exhibition of 1851, or rather two distinguished chemists of that jury, Dr. Hofmann and Mr. De La Rue, ascertained that some of the most delicate perfumes were made by chemical artifice, and not, as of old, by distilling them from flowers. The perfume of flowers often consists of oils and ethers, which the chemist can compound artificially in his laboratory. Commercial enterprise availed itself of this fact, and sent to the Exhibition, in the form of essences, perfumes thus prepared. Singularly enough, they are generally derived from substances of intensely disgusting odour. A peculiar fetid oil, termed "fusel oil," is formed in making brandy and whisky. This fusel oil, distilled with sulphuric acid and acetate of potash, gives the oil of pears. The oil of apples is made from the same fusel oil by distillation with sulphuric acid and bichromate of potash. The oil of pine-apples is obtained from a product of the action of putrid cheese on sugar, or by making a soap with butter and distilling it with alcohol and sulphuric acid, and is now largely employed in England in the preparation of pine-apple ale. Oil of grapes and oil of cognac, used to impart the flavour of French cognac to British brandy, are little else than fusel oil. The artificial oil of bitter almonds, now so largely employed in perfuming soap and for flavouring confectionery, is prepared by the action of nitric acid on the fetid oil of gas tar. Many a fair forehead is damped with eau de millefleurs without knowing that its essential ingredient is derived from the draining of cow-houses."

(To be continued.)

PROFESSOR TYNDALL ON LIGHT.*

(Continued from p. 788.)

You have already learned that the word "light" may be used in two different senses: it may mean the impression made upon consciousness, or it may mean the physical agent which makes the impression. It is with the agent solely that we have to occupy ourselves at present. That agent is the motion of a substance which fills all space, and surrounds the atoms and molecules of bodies. The phenomena to be explained suggest the assumption, and the next process is to ascertain whether the assumption is competent to explain the phenomena. To this interstellar and interatomic medium certain definite mechanical properties are ascribed, and we deal with it as a body possessed of these properties. In mechanics we have the composition and resolution of forces, and of motions, extending to the composition and resolution of vibrations. We deal with the luminiferous ether in accordance with the rigid laws of mechanics, and from the composition, resolution, and interference of its vibrations, deduce all the phenomena displayed by crystals or polarized light.

Take, as an example, the crystal of tourmaline. Let a vibration cross this crystal oblique to its axis; we have seen by experiment that a portion of the light will pass through. How much we determine in this way: Draw a straight line representing the amplitude of the vibration before it reaches the tourmaline, and from the two ends of this line draw two perpendiculars to the axis of the crystal, the distance between the feet of these two perpendiculars will represent the amplitude of the transmitted vibration.

Follow me now while I endeavour to make clear to you what occurs when a film of gypsum is placed between the Nicol prisms. But at the outset, let us establish still further the analogy between the action of the prisms and that of two plates of tourmaline. The plates are now crossed, and you see that, by turning the film round, I place it in a position where it has no power to abolish the darkness. Why is this? The answer is, that in the gypsum there are two directions at right angles to each other which the waves of light are constrained to follow, and that now one of these directions is parallel to one of the axes of the tourmaline and the other parallel to the other axis. When this is the case the film exercises no sensible action upon the light. But now I turn the film so as to render its direction of vibration oblique to the axis; then you see it has the power demonstrated in the last lecture of partially restoring the light.

Let us now mount our Nicol prisms, and cross them as we crossed the tourmaline. Introducing our film of gypsum between them, you notice that in one particular position the film has no power whatever over the light. But turn the film a little way round, you notice instantly that the light passes. We have now to understand the mechanism by which this is effected.

First, then, we have this prism which receives the light emergent from the electric lamp, and which is called the polarizer. Then we have the plate of gypsum, and then the prism in front, which is called the analyzer. On its emergence from the first prism, the light is polarized; and, in this particular case, its vibrations are executed in a horizontal plane. The two directions of vibration of the gypsum are now oblique to the horizon. Draw a rectangular cross upon paper to represent the two directions of vibration within the gypsum. Draw a line to represent the amplitude of the vibration where it reaches the gypsum. Let fall from the two ends of this line two perpendiculars on each of the arms of the cross; then the distance between the feet of these perpendiculars represents the amplitudes of two rectangular vibrations which are the exact equivalents of the first single vibration. The polar-

* Abstract of a series of lectures delivered in the Cooper Institute, New York, and reported in the *New York Tribune*.

ized ray where it enters the gypsum, is resolved into two ethers, vibrating at right angles to each other.

In one of those directions of vibration the ether is more sluggish than in the other; and, as a consequence, the waves that follow this direction are more retarded than the others. You can readily imagine that in this way the system of waves may get half a wave-length, or indeed any number of half wave-lengths, in advance of the other. The possibility of interference here flashes upon the mind. A little consideration, however, renders it evident that, as long as the vibrations are executed at right angles to each other, they cannot quench each other, no matter what the retardation may be. This brings us at once to the part played by the analyzer. Its sole function is to recompound the two vibrations emergent from the gypsum. It reduces them to a single plane, where, if one of them be retarded by the proper amount, extinction can occur. But here, as in the case of their films, the different lengths of the waves of light come into play. Red will require a greater thickness to produce the retardation necessary for extinction than blue; consequently, when the longer waves have been withdrawn by interference, the shorter ones remain and confer their colours on the film of gypsum. Conversely, when the shorter waves have been withdrawn, the thickness is such that the longer waves remain. An elementary consideration suffices to show that where the direction of vibration of prisms and gypsum incloses an angle of 45 degrees, the colours are at their maximum brilliancy. When the film is turned from this direction, the colours gradually fade, until at the point where the directions of vibration of prisms and plate are parallel, they disappear altogether.

A knowledge of these phenomena is best obtained by means of a model of wood or pasteboard representing the planes of vibration of the polarizer and analyzer, and the plane of vibration of the plate of gypsum between them. On these planes the waves may be drawn, showing the resolution of the first polarized ray into two others, and then the reduction of the two vibrations to a common plane. Following out rigidly the interaction of the two systems of waves, we are taught by such a model that all the phenomena of colours obtained when the planes of vibration of the two Nicols are parallel, are displaced by the complementary phenomena when the Nicols are perpendicular to each other.

In considering the next point, for the sake of simplicity, we will operate with monocromatic light—with red light, for example. Supposing that a certain thickness of the gypsum produces a retardation of half a wave-length, twice this thickness will produce a retardation of two half wave-lengths; three times this thickness a retardation of three half wave-lengths, and so on. Now, where the Nicols are parallel, the retardation of half a wave-length, or of any odd number of half wave-lengths, with it produces extinction; in all thicknesses, on the other hand, which correspond to a retardation of an even number of half wave-lengths, the two beams support each other when they are brought to a common plane by the analyzer. Supposing, then, that we take a plate of dark ones. Here is a wedge-shaped film of crystal that shows these bands; but they are far better shown by this circular film, which is so worked as to be thinnest at the centre, and gradually increases in thickness from the centre outward. These splendid rings of light and darkness are thus produced.

Some of the chromatic effects of an irregular crystallization are beautiful in the extreme. Could I introduce between our Nicols a pane of glass covered by those frost-ferns, which the cold weather renders now so frequent, rich colours would be the result. The cases of irregular crystallization on glass plates, now to be presented to you, illustrate what you might expect from the frosted window-pane. And not only do crystalline bodies act thus upon light, but almost all bodies that possess a definite structure do the same. As a general rule, organic bodies act in this way; for this architecture involves an arrangement of the ether which involves double refraction. A film of horn, or the section of a shell, for example, yields very beautiful colours in polarized light. In a tree, the ether certainly possesses different degrees of elasticity, along and across the fibre; and were wood transparent, this peculiarity of molecular structure would infallibly reveal itself by chromatic phenomena like those that you have seen. But not only do bodies built permanent by nature behave in this way, but it is possible to confer, by strain or by pressure, a temporary double-refracting structure upon non-crystalline bodies, such as common glass.

When I place this bar of wood across my knee and seek to break it, what is the mechanical condition of the bar? It bends, and its convex surface is strained longitudinally; its concave surface, that next my knee, is longitudinally pressed. Both in the strained portion and in the pressed portion the ether is thrown into a condition which would render the wood, were it transparent, double-refracting. Let us repeat the experiment with a bar of glass. Between the crossed Nicols I introduce such a bar. By the dim residue of light lingering upon the screen, you see the image of the glass, but it has no effect upon the light. I simply bend the glass bar with my finger and thumb, keeping its length oblique to the direction of vibration in the Nicols. Instantly light flashes out upon the screen. The two sides of the bar are illuminated, the edges most, for here the strain and pressure are greatest. In passing from strain to pressure, we cross a portion of the glass where neither is exerted. This is the so called neutral axis of the bar of glass, and along it you see a dark band, indicating that the glass along this axis exercises no action upon the light. By employing the force of a press, instead of the force of my finger and thumb, the brilliancy of the light is augmented.

Again, I have here a square of glass which can be inserted into a press of another kind. Introducing the square between the prisms, its neutrality is declared; but I can hardly hold it sufficiently loosely to prevent its action from manifesting itself. Already, though the pressure is infinitesimal, you see spots of light at the points where the press is in contact with the glass. I now turn this screen. Instantly the image of the square of glass flashes out upon the screen. You see luminous spaces separated from each other by dark bands. Every pair of adjacent luminous spaces is in opposite mechanical conditions. On one side of the dark band we have strain, on the other side pressure; while the dark band marks the neutral axis between both. I now tighten the vice, and you see colour; tighten still more, and the colours appear as rich as those presented by crystals. Releasing the vice suddenly the colours vanish; tightening suddenly, they reappear. From the colours of a soap-bubble Newton was able to infer the thickness of the bubble; thus uniting by the bond of thought apparently incongruous things. From the colours here presented to you, the magnitude of the pressure employed might be inferred. Indeed, the late M. Wertheim of Paris invented an instrument for the determination of strains and pressures by the colours of polarized light, which exceeded in accuracy all other instruments of the kind.

You know that bodies are expanded by heat and contracted by cold. If the heat be applied with perfect uniformity, no local strains or pressures come into play; but, if one portion of a solid be heated and others not, the expansion of the heated portion introduces strains and pressures which reveal themselves under the scrutiny of polarized light. I place this square of common window-glass between the Nicols; you see its dim outline, but it exerts no action on the polarized light. I hold it for a moment over the flame of a spirit-lamp; on reintroducing it between the Nicols, light flashes out upon the screen. Here, as in the case of mechanical action, you have spaces of strains divided by neutral axes from spaces of pressure. Let us apply the heat more symmetrically. This small square of glass is perforated at the centre, and into the orifice a bit of copper wire is introduced. Placing the square between the prisms and heating the copper, the heat passes by conduction along the wire to the glass, through which it spreads from the centre outwards. You see a beautiful black cross inclosing four luminous quadrants growing up and becoming gradually black by comparison upon the screen. And, as in the case of pressure, we produced colours, so here also, by the proper application of heat, gorgeous chromatic effects may be produced. And they may be rendered permanent by first heating the glass sufficiently, and then cooling it, so that the chilled mass shall remain in a state of strain and pressure. Two or three examples will illustrate this point. The colours, you observe, are quite as rich as those obtained in the case of crystals.

(*To be continued.*)

THE USE OF GELATIN IN NUTRITION.*

BY CARL VOIT.

The author begins this paper by a discussion of the experiments made by previous observers on the use of gelatin as food. He considers that those of Edwards and Balzac and of Magendie were vitiated by the fact that they allowed the animals on which they experimented to eat their food instead of administering it to them by force. Disgust at the gelatin prevented the dogs from eating it, and they preferred to die of hunger. Voit, however, has noticed some dogs do the same with raw meat, and others with bread. His own experiments were made by feeding dogs on gelatin and flesh, or gelatin alone, on gelatin and fat, on flesh and fat, or flesh, gelatin and fat, and observing how much flesh underwent transformation in the organism as indicated by the nitrogen excreted, and how much was lost or gained by the body. The results showed that gelatin always saves albumin, and does so to a much greater extent than fat or carbohydrates. In a large dog 168 parts of dry gelatin supplied 84 of dry flesh or albumin. An increase in the quantity of gelatin in the food was followed by a greater saving of albumin; but the saving cannot be carried beyond a certain limit, for even when the greatest possible quantity of gelatin is administered and much fat in addition, some albumin from the body or the food still undergoes decomposition. The saving effect of gelatin is greater when fat is given along with it. No permanent deposition of gelatin in the organism takes place; but the whole of it undergoes rapid decomposition. The nitrogen of all the gelatin given could be found in the urine and fæces within twenty-four hours, and only in one large dog were there indications that a small portion of the gelatin remained after this time, but was decomposed on the following day. This is possibly connected with the simultaneous administration of much fat, which may perhaps hinder the rapid decomposition of large quantities of gelatin. It cannot be that gelatin spares albumin by supplying the waste of gelatigenous tissues instead of letting this be done by albumin, because we must then assume that the gelatin is not completely decomposed; and if this be the case, the amount of nitrogen excreted would show that there is no saving of albumin, and no advantage would be gained. Gelatigenous tissues cannot be formed from gelatin, but, as their development shows, only from albuminous bodies. The author then gives a full account of his opinions regarding albumin in the organism. When a dog is allowed to fast for several days, the amount of albumin daily destroyed in the body will be *e.g.*, 0·8 per cent. of that contained in it. When well fed with albumin, the same dog will daily decompose 9 per cent. of albumin. This clearly shows that the relations of the albumin in the body to decomposing agencies are very different. Voit therefore divides it into (1) *circulating albumin*, or albumin in the circulating plasma or lymph; (2) *organ-albumin*. The first sort undergoes rapid decomposition. It might have been called *plasma-albumin*, but the name of circulating albumin was chosen in order to indicate that it is during circulation through the tissues that this albumin comes under the conditions of decomposition. The albumin of blood-plasma is plasma-albumin; but only a small part of it is decomposed, because the greater part of it is in a state of firmer combination as organ-albumin of the blood. Organ-albumin is not decomposed as such, for it is not subjected to the conditions of decomposition until it has undergone conversion into circulating albumin. When the equilibrium between the organ-albumin and circulating albumin is suddenly disturbed, so that the proportion of the former is increased *e.g.*, by venesection, the excess of organ-albumin is not retained by the organism, but is converted into circulating albumin and decomposed. The author does not agree with Fick in his supposition that it is not albumin but peptones that are rapidly decomposed in the organism. Fick compares the rapid decomposition in the body which occurs after albuminous food has been taken to the blaze which occurs when a rapidly combustible body like gunpowder (to which he compares peptones) is mixed with a slowly combustible one like charcoal (which would represent albumin). Voit would rather compare it to a blaze on the addition of fine chips of wood to a burning log of the same kind. He considers the notion to be an unfortunate one that absorption in the intestine takes place by osmosis, and that albuminous bodies must, therefore, be converted into peptones before they can be absorbed. He is unable to see why it should be supposed that albuminous substances cannot pass through the intestinal walls when they readily do so through every possible membrane and organ. The albumin in the food is chiefly decomposed in the plasma current, but part of it serves to replace organ-albumin which has been destroyed, or as a deposit. According to the doctrine of luxus-consumption also, a small quantity only of albumin is decomposed in the organs, but the replacement of this only is necessary, and any additional supply is luxus, and undergoes combustion in the blood as a surplus. According to Voit, very little albumin is decomposed during fasting, but every supply of albumin in the food increases the stream of plasma to the organs, and so much albumin is thereby subjected to the conditions of decomposition. The rich supply is not luxury (luxus), but a necessity if the body is to retain a definite amount of albumin.

The simplest explanation of the fact that gelatin, like fat and carbo-hydrates, cannot entirely arrest the transformation of albumin in the body is, that it cannot replace the decomposed organ-albumin or construct new organs or tissues, not even gelatigenous tissues. In this respect it behaves exactly like peptones. It lessens the conversion of organ-albumin into circulating albumin; when given alone it diminishes the loss of albumin from the organism; and when given along with albumin in food, it lessens the proportion of albumin which undergoes decomposition, so that a much smaller quantity suffices to supply the needs of the body.

Gelatin differs from other nutriments inasmuch as it cannot replace any of them; fat and carbohydrates can completely prevent the loss of fat from the body, and each inorganic constituent the loss of a similar one, but gelatin does not totally prevent the loss of albumin, but only of a part of it. Gelatin does not lessen the loss of fat from the body to the same extent as carbohydrates, the amount of carbonic acid excreted remaining nearly the same.

When gelatin is given along with meat, it not only lessens the consumption of albumin, but also diminishes that of fat, though only to a small extent; it does not economise fat by taking up the oxygen which would otherwise oxidize it, since 200 parts of gelatin do not economise 74 parts of fat which on this supposition it ought to do, since these proportions of gelatin and fat require the same amount of oxygen for their complete oxidation.

Voit criticizes Liebig's division of food into plastic and respiratory, which he considers to be quite erroneous.

* Zeitschrift für Biologie, viii. 297—388, and from the *Journal of the Chemical Society.*

There is no more reason to regard albumin as plastic than water, fat and salts, for these are quite as indispensable as albumin to the constitution of a cell. Moreover, the greater part of the albumin taken into the body undergoes decomposition without even having formed part of any organ. Fat and carbohydrates, too, are not specially destined to produce heat, and they undergo decomposition quite independently of the thermal necessities of the body. It is quite a mistake to suppose that the oxygen taken in during respiration is the cause of the decomposition of the tissues, for it is in reality a consequence. The tissues split up into simple compounds quite independently of oxygen, and it is these compounds which take up the oxygen. A proper division of food can only be based on a consideration of the constituents of the body, and of what is necessary to replace the waste of these.

The constituents are water, inorganic materials, fats and albumin and its derivatives. Of water there is generally no lack, and inorganic constituents are generally found in abundance in any diet which contains a sufficient quantity of albuminous and non-nitrogenous materials, and therefore they do not require any special consideration. Fat can be supplied by giving it directly in the food. Animals in general, and especially herbivora, cannot take a sufficient quantity in this way, and it is therefore necessary to give carbohydrates in addition, which probably do not themselves form fat, but economize it. It can also be supplied by a diet of flesh, which by decomposition in the organism yields fat.

To replace the waste of albumin, a certain quantity of it must under any circumstances be contained in the food; at least as much as will replace the waste of organ-albumin. Generally much more than this is necessary, in order to keep up the stock of circulating albumin. A large quantity of albumin is required for this purpose when it is given alone, but much less suffices when fats and carbohydrates are given along with it, although they can never become transformed into albumin. This most important use of these articles of food was not sufficiently noticed under the old classification into plastic and respiratory. It is impossible to give gelatin a place in this classification at all, for it cannot assist in the formation of tissues, and is therefore not plastic, nor has it any greater value as respiratory food than albumin, and consequently cannot be ranked as such. Under Voit's new classification, it falls into its place at once. It economizes circulating albumin, like fats and carbohydrates, but much more powerfully, in this respect resembling peptones, which are not again converted into albumin. Besides this, it economizes fat to a slight extent.

THE ACTION OF HEAT ON SOLUTIONS OF HYDRATED SALTS.*

BY C. R. C. TICHBORNE, F.C.S., M.R.I.A.

While investigating the dissociative action of heat upon water of hydration, the author's attention was naturally turned to salts,—such as those of cobalt, copper, and nickel,—which present a change of colour when passing from the dry to the hydrated state. It is a general characteristic of neutral solutions of the chlorides of such bodies that they do not change colour on boiling at ordinary atmospheric pressure, neither does dilution affect their tint except by attenuating it; but Mr. Tichborne has never failed in their obtaining dehydration in solution by using extraordinary pressure. The laws of such chromatic change were found to differ from those produced by a basic condition of the salt.

For instance, the dehydration of the salts of cobalt is evinced by change of colour from light rose to dark pure blue. But no amount of boiling at ordinary pressure will convert a pink solution of cobalt into a blue one, unless the solution be extremely concentrated. Prout stated many years ago, that by concentrating a strongly acid solution of a cobalt salt by evaporation, he got a permanently blue solution, a result which he attributed to the abstraction of the water of hydration by the acid. He also reported that he had obtained from such a solution blue crystals, supposed to be the anhydrous salt. This experiment of Prout showed that the introduction into a neutral solution of any substance capable of exerting an affinity for the water of hydration—such as sulphuric and other acids, chloride of calcium, and other hygroscopic salts, or even sugar—has the effect of lowering the thermanalytic point of the salt. The quantity, however, of these dehydrants required to affect the cobalt solution being considerable, pure absolute alcohol was used to lower the thermanalytic point.

A solution of chloride of cobalt,† which has dried at 100° C. in pure absolute alcohol, is of a magnificent pure blue colour, free from any tinge of purple. If such a solution be placed in a deep beaker, and water poured cautiously down the side of the vessel, two layers are formed, the upper of which is blue, and contains the anhydrous salt; the lower pink, containing the salt hydrated by the direct action of the water. These layers will retain their positions a considerable time, by virtue of their different specific gravities.

Alcoholic solution which has been thus hydrated is peculiarly sensitive to heat, passing, as the temperature rises, through all the shades of pink and purple to a pure blue, giving the same absorption spectrum as that obtained from the anhydrous salt. The thermanalytic point is so lowered by the alcohol present that the water of hydration of the cobalt salt is gradually but perfectly dissociated. If the vessel containing it be now submerged halfway into a freezing mixture, the two differently coloured layers are again formed, the upper one, as before, being blue, and containing the anhydrous salt in the presence of the dissociated water of hydration.

Such is the result when, through the addition of another body, the thermanalytic point is brought below 100° C. at ordinary pressure. Similar effects are obtained when a weak solution of cobalt is boiled in a sealed glass tube one-third full of the liquid, the colour passing gradually through all shades of purple to a pure blue. Thus, by extraordinary pressure, the temperature necessary for the separation of the water may be obtained in an aqueous solution.

Aqueous solution of chloride of copper, heated in a sealed tube, from a beautiful blue, the colour of the hydrate, becomes gradually green, yellow, and ultimately a dark brown nearly opaque liquid. As it cools and gradually re-associates the water of hydration, it passes again through all these shades, becoming slightly opalescent through the formation of a bluish white basic precipitate. The addition of a little acid to this solution prevents this precipitation, makes the solution even more sensitive to heat, and allows the experiment to be made *ad infinitum*. Solution of sulphate of copper gives similar results as to dehydration, but a basic precipitate is determined even in an acidulated solution.

Caution should be used in these experiments, as explosions frequently occur. The plan recommended by the author is to take a strong white glass tube, draw it out until it has a diameter of $\frac{1}{50}$ or $\frac{1}{25}$ of an inch, and enclose this, when sealed, inside another much larger one before heating it.

The author points out that the effect of dilution on colour changes attending dehydration is, as might be expected, the reverse of that upon colour changes attending the basic condition due to the basic action of the water. In the first case, the increase of the relative volume of water retards the dissociation of water of hydration; in the second, the increase in the volume of water will assist the dissociation.

* Abstract of a paper read before the Royal Irish Academy.

† According to Marignac, the composition of the hydrated salt is $CoCl_2, 6H_2O$.

The Pharmaceutical Journal.

SATURDAY, APRIL 12, 1873.

Communications for this Journal, and books for review, etc. should be addressed to the EDITOR, 17, *Bloomsbury Square*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

DR. MACDONNELL ON DISINFECTANTS.

ON Saturday the 5th inst., Dr. ROBERT MACDONNELL, F.R.S., delivered before the Dublin Royal Society an able and instructive lecture on "Antiseptics and Disinfectants." There was a large attendance—many of the audience being public officers of health, *in esse* or *in posse*, anxious to be informed as to the most effective means of preventing such terrible epidemics as that of the small-pox, which ravaged the city in 1870-71. Dr. MACDONNELL passed in review the various causes of epidemic disease, dividing them into a perceptible and a non-perceptible class—the former being those which could be detected by any of the organs of special sense, the latter including such as were discoverable only by analysis. The next stage in his lecture was a rapid survey of the great controversy which has for some years been waged between M. PASTEUR of Paris and the late Dr. F. A. POUCHET of Rouen. M. PASTEUR, as our readers are aware, is a staunch adherent of HARVEY'S doctrine, *omne vivum ex ovo;* while Dr. POUCHET is equally strenuous in maintaining the thesis of "spontaneous generation." This controversy, so important to the investigation of the genesis of epidemic disease, whether its source be animal or vegetable, found an impartial critic in Dr. MACDONNELL, who, though deprecating a premature summing-up, inclined on the whole to the view of PASTEUR. Professor TYNDALL'S mode of testing the existence of germs in a given atmospheric area was next exemplified and estimated—more favourably than we should be inclined to do; and the lecturer concluded by a high tribute of praise to Mr. JOSEPH LISTER, Professor of Surgery in the University of Edinburgh, not only for the antiseptic ligature which had superseded the traditional modes of arresting hæmorrage, and such new devices as acupressure, but also for the application of the antiseptic treatment to tumours and exposed surfaces in the human subject generally. The discourse was in all respects worthy of the Dublin school; and taken in connexion with the lectures of STOKES, the Regius Professor of Medicine, and Dr. E. D. MAPOTHER, Professor of Physiology and Public Hygiène, it affords ample proof of the vigour and intelligence with which the u bject of sanitary reform is being prosecuted in the Irish metropolis. We hope Dr. MACDONNELL will be prevailed upon to make his lecture *publici juris.*

ANNUAL DINNER.

WE are gratified to learn that there is already a very cordial response to the suggestion put forward last week in reference to the Annual Dinner at the Crystal Palace. We understand that a number of gentlemen have already expressed their willingness to act as stewards, and we hope next week to be able to publish a complete list, together with other particulars. Meanwhile we would state that gentlemen who are desirous of having their names placed on this list should apply at once to Mr. CARTEIGHE, 172, New Bond Street, or to Mr. RICHARD BREMRIDGE, 17 Bloomsbury Square, who are acting as joint honorary secretaries.

NEW DICTIONARY OF MEDICO-SCIENTIFIC TERMS.

OUR readers will be happy to learn that a desideratum long felt by every student of the medical sciences,—that of a dictionary in which the terminology of these sciences is explained and illustrated,—will shortly be supplied. The New Sydenham Society has purchased the copyright of the well-known but extremely inaccurate and imperfect work of MAYNE, and is about to re-issue it, under competent editorship, in a new if not in an absolutely re-written form. The plan adopted will be, first, to give the etymology of the words met with in the literature of medicine and the cognate sciences; next, to supply an intelligible and complete definition of the same, with an illustrative extract or extracts from the authors who employ them in a special or restricted sense; third, to give the French and German equivalents of the English; and, lastly, to mark the quantity of the words, as a guide to the pronunciation. We hope that the work will be worthy of English medicine, and that the student will be able to find at home and in the vernacular what he has hitherto either done without or made shift to glean from such dictionaries as those of LITTRÉ and ROBIN, or the later editions of the 'Conversazions-Lexicon.' The Society, very properly as we think, invites the co-operation of the medical or scientific *savant* in suggesting, criticizing, or otherwise contributing to the speedy and effective completion of its onerous undertaking.

THE CHALLENGER EXPEDITION.

One of the lions of the cruise is a new species of lobster, perfectly transparent. Besides obtaining animals with eyes so fully developed that the body may be said to be an appendage to the eyes rather than the eyes to the body, the "Challenger" has dredged up a new crustacean in which the body has cut itself clear of the eyes altogether; the animal being totally blind, and not even having the trace of an eye. To make up this deficiency it is supplied with the most delicate beautifully developed claws it is possible to conceive. Near the West Indies, in a depth of only half a mile, some similar creatures were brought up, having claws longer than the body armed throughout with a multitude of spike-like teeth. At a short distance from Teneriffe, in a depth of a mile and a half, a rich and extremely interesting haul of sponges and coral was obtained, but the latter was unfortunately dead. It is a white species, as large and heavy as the pink coral of the Mediterranean.

A NEW POTATO DISEASE.

PROFESSOR HALLIER, in the *Zeitschrift für Parasitenkunde* for 1873 (vol. iv. heft 1), describes a new potato disease as having made its appearance at Apolda, near Jena, in the course of last autumn, the preceding summer having been remarkably dry in that locality. The disease differs from the one which has been so fatal during recent years, in attacking at once the tuber and not the leaves. The tuber in the diseased plants is found to be covered beneath the skin by a purple felt, composed of the mycelium of a fungus, which, on close microscopical examination, is found to perforate the skin, on the surface of which are a number of black spots having the appearance of the perithecia of a pyrenomycetous fungus. Soon after these spots make their appearance the potato becomes completely destroyed by a cancerous disease, the disease being always accompanied by the production of the fungus, which probably belongs to the genus Sclerotium. Professor HALLIER thinks that the same remedies or preventatives may be applied as in the case of the more prevalent disease, the selection of early varieties and of suitable soils, and the use of mineral to the exclusion of animal or vegetable manures. The geological formation at Apolda is the keuper.

JUST as we are going to press, to our great regret we hear of the death of another of the Founders of the Pharmaceutical Society, Mr. JOHN GARLE, who has so long been associated with its Board of Examiners.

WE are requested to state that the name of Mr. HENRY WHITFIELD, of Worcester, should not have been included in the list of names of gentlemen who, having been nominated for election to the Council of the Pharmaceutical Society in May next, have expressed their willingness to serve if elected. Mr. WHITFIELD has declined to accept office, if elected.

WE are informed that the old and well-known establishment of BUTLER, McCULLOCH, and Co., Covent Garden Market, has lately changed hands, and is now conducted (in partnership) by Messrs. FREDERICK McCULLOCH, A. MACDONALD, and SYDNEY G. HART.

Legacy of the late George Waugh, £25 (supplemented by the executrix, Mrs. Waugh, £75) ... 100 0 0

NORTH BRITISH BRANCH, EDINBURGH.

The North British Branch held their fifth meeting of the present Session, in the Society's rooms, on Friday evening, 28th March, at half-past 8 o'clock; Mr. Baildon, President, in the chair. Mr. John Mackay, in presenting a copy of the Proceedings of the American Pharmaceutical Conference held in Ohio, and a copy of the recent publication of the United States' Pharmacopœia, both of which volumes had been sent to the Society here by their friends on the other side of the Atlantic, proceeded to make some remarks on the general scope of the latter. While the arrangement was in many respects similar to that carried out in the British Pharmacopœia, he remarked that the materia medica substances were classed in two divisions, primary and secondary. The preparations were all arranged in alphabetical order, but he thought the omission of the dose attached to each compound a mistake, as much benefit had resulted from the authorities who compiled our own work having distinctly added the dose to all the preparations. He also mentioned the fact, that the troy ounce had been adopted throughout the work, and that therefore all formulæ were entered by the ounce, the pound having been discarded; so that no mistake could be made by comfounding the avoirdupois ounce or pound with the one intended. This was almost a necessity, as the troy ounce represented 480 grains, while the avoirdupois contained only 437½ grains. The drachm and scruple had also been discarded and grains used instead. The liquid measure indicated throughout is the old wine gallon. This contains 8 pints, each measuring 16 fluid ounces; and in order to prevent confusion, the term gallon is never employed, but that of pint constantly used.

He then noticed the various additions which had been made to the new edition of the work, and referred to the appointment of the Committee to whom had been delegated the revision, compilation, and publication of the work, by the Convention which had met in the summer of 1870 at Washington. This Committee had full power, on till 1880, to publish a new edition of this national work if at any time it was thought necessary to do so.

After going over the various additions and removals of the different substances in this edition of the book, he referred to the new mustard paper resembling Rigollot's leaves, and especially to suppositories and to the fluid extracts. In speaking of the former, he stated that a preference was given to theobroma oil as the excipient, and that nine different kinds were ordered as against only four which were officinal in the B. P.

One, he observed, was made with aloes, which reminded him of a suppository ordered some time ago by the late Sir James Simpson, containing gamboge.

Mr. Mackay then noticed the twenty-two liquid extracts in the new work. He remarked particularly upon the novelty of the menstruum proposed, namely, in a mixture of glycerine and diluted alcohol. In every case percolation and evaporation were ordered in the preparation of these extracts. He gave the precise directions as printed, and submitted liquid ext. gentian and extract of ergot made exactly as recommended. The cost he had found to be about 3*d.* per ounce; but if made on the large scale, and some of the alcohol perhaps saved in the evaporation, the cost might be much lessened. Both preparations were clear and looked uncommonly well, and evidently were possessed of great strength. One house in London had already made some experiments with similar preparations, while specimens of a few were shown at the last meeting of the Society in London; so that he had no doubt whatever in believing that it would, ere long, be determined whether such concentrations, made as directed, were suited for use in medical practice, and if so, the compilers of the supplement already proposed to be added to the existing B. P. would have their attention directed to the new mode of preparation, and probably suggest additions to the list of pharmaceutical preparations.

The liquid extracts submitted gave much satisfaction, the ext. gentian especially appearing to be a very superior preparation.

Mr. Mackay further noticed, that while the new chemical nomenclature had not been introduced, there had been a slight modification, to the extent that salts of alkaline metals were now recognized as compounds, not of the oxides, but of the base itself,—as, for example, carbonate of baryta was now called carbonate of barium; carbonate of lime, carbonate of calcium; citrate of potass, citrate of potassium: and so on.

In concluding his remarks, Mr. Mackay referred to the excellent manner in which the work was printed and published. The price was moderate, and he thought the volume well worthy perusal. While the Convention had invested the Committee with full powers, there was a caution apparently exercised by them which gave a guarantee that nothing whatever would be inserted by them in any future edition of this national work without full verification and testing as to the preparation and adoption of new formulæ.

Mr. Baildon proposed a vote of thanks to Mr. Mackay for having brought before the Society, in the full and clear manner he had done, the various features and constitution of this new edition of the American Pharmacopœia. This was carried with acclamation; and Mr. Paton then read a Paper on "Perfumes Physiologically and Commercially Considered." (See p. 803.)

After remarks from various members present, a very cordial vote of thanks was proposed by the Chairman to Mr. Paton for his interesting paper. This was seconded by Mr. Young, and carried unanimously.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The eleventh general meeting of this Association was held at the Royal Institution, Thursday evening, March 27th. The President, E. Davies, Esq., F.C.S., in the chair. The minutes of the previous meeting were read and confirmed.

Mr. R. L. Wood was elected a member, and Mr. W. Croskell an associate; and several donations were announced.

Mr. Alfred H. Mason, F.C.S., then read a paper on "The Manufacture of Glycerine: its Properties, Various Applications, and Quality, as it exists in Commerce." The paper was experimentally illustrated, and specimens of products taken in the various stages of manufacture of pure glycerine, by different processes, were exhibited and explained; also specimens illustrating its application in pharmacy, and as a constituent in toilet requisites, etc.

The Manufacture of Glycerine: its Properties, Various Applications, and Quality, as it exists in Commerce.

BY A. H. MASON, F.C.S.

Glycerine ($C_3H_8O_3$) was discovered by Scheele in 1779, who obtained it in the preparation of lead plaister. He named it "Sweet principle of Oils," from its sweet taste. Subsequently its properties were more accurately studied by Chevreul, in his classical investigations on the chemical history of bodies of fatty origin, and by Pelouze.

Most of the fats and oils of the animal and vegetable kingdoms have a constitution analogous to that of the compound ethers,—acetic ether, for example. When acetic ether is treated with alkalies it assimilates the elements of water, forming an alkaline acetate and alcohol. Oils and fats in like manner undergo, by the same treatment, a similar change. They assimilate the elements of water, glycerine is set free, and a salt of the acid, previously in combination with glycerine, is formed.

Glycerine is present in combination with solid and fluid fatty acids, in the shape of glycerides, to an amount of eight to nine per cent., and may be separated by treatment with bases (potash, soda, lime, baryta, oxide of lead), or with acids (sulphuric acid), and certain chlorides (chloride of zinc), also by means of superheated steam, or very hot water without the formation of steam in closed vessels. Glycerine is also formed as a constant product by the alcoholic fermentation of dextrose, levulose, and lactose. According to Pasteur's researches, the quantity of glycerine thus formed amounts to about three per cent. of the weight of the sugar.

Glycerine may be manufactured—(1) By saponifying oils with oxide of lead; *sic*, five parts of finely triturated litharge are heated with nine parts of olive oil or any other glyceride, and a small quantity of water, the mixture being constantly stirred and the water renewed, until the oxide of lead is converted into a plaister (Emplastrum Plumbi, B. Ph.).

$$\underset{\text{Oxide of Lead.}}{3\,PbO} + \underset{\text{Water.}}{3\,H_2O} + \underset{\text{Oleate of Glyceryl (Olive Oil or Oleine).}}{2(C_3H_5, 3\,C_{18}H_{33}O_2)}$$

$$= \underset{\text{Oleate of Lead (Lead Plaister).}}{3(Pb, 2\,C_{18}H_{33}O_2)} + \underset{\text{Hydrate of Glyceryl (Glycerine).}}{2(C_3H_5, 3\,HO)}$$

Insoluble lead salts (in this case, the oleate and stearate of lead) are formed; warm water is then added, and the aqueous liquid decanted, filtered, and sulphuretted hydrogen passed through the filtrate, in order to precipitate a small quantity of plumbous oxide, which dissolves. The liquid is then digested with animal charcoal, and evaporated *in vacuo*, or over a water-bath, until of the required specific gravity.

(2) From the alkaline mother-liquor of the soap-works (from which the soap has been separated by means of common salt), by neutralizing with sulphuric acid, removing the excess of that acid by carbonate of barium, evaporating the filtrate to a syrup, digesting it for several days with alcohol, separating the alcoholic liquid from the sulphate of sodium, which crystallizes out, decolourizing with animal charcoal, again evaporating to a syrup, exhausting the residue with strong alcohol, and finally evaporating the filtered solution over the water-bath. This process is, however, too troublesome and expensive for use on the large scale; besides, it is found that, by adding great excess of alkali, the glycerine is taken up and the soap produced is found to absorb and hold a much larger percentage of water,—a desideratum to the manufacturer of cheap soaps.

(3) From the residue of the manufacture of stearic acid for candles, by lime saponification. When this process is used, the glycerine remains dissolved in the water after the separation of the insoluble lime-soap. The lime also dissolved having been eliminated by either sulphuric acid, or, preferably, oxalic acid, the evaporation of the liquid to the consistency of a syrup will yield a glycerine pure enough for many technical purposes. This method, when properly carried out, yields a very pure product, and is the one principally used by continental manufacturers, but it is somewhat complicated, and unless great attention is paid to every part of it, small quantities of lime are apt to remain in the glycerine, rendering it unfit for use in medicine and pharmacy.

(4) By decomposing or rather dissociating neutral fats by means of water, or of superheated steam. This is the best and only unobjectionable method of obtaining glycerine, and is the process brought to a successful issue by Mr. W. F. Wilson, F.R.S.* It consists in injecting superheated steam at a temperature of between 500° and 600° into heated fat. The fats assimilate the elements of water, and are decomposed into their constituents—the fatty acids (oleic, stearic, or palmitic, as the case may be),—and glycerine; both distil over and form in the recipient two layers of liquid, of which the lower is tolerably pure aqueous glycerine. Supposing palmatine to have been the material employed,

$$\underset{\text{Palmitine}}{C_3H_5,3C_{16}H_{31}O_2} + \underset{\text{Water}}{3H_2O} = \underset{\text{Glycerine}}{C_3H_5,3HO} + \underset{\text{Palmitic Acid}}{3HC_{16}H_{31}O''}$$

First, we get a weak solution of glycerine containing from twenty to thirty per cent.; then by concentration rough glycerine. Brown glycerine is the product of a first distillation—pale glycerine, white glycerine, produced by further distillation, show the successive stages of advance to pure glycerine.

Properties.—Pure glycerine is a colourless, viscous, neutral, inodorous liquid, with a sweet taste, from whence it derives its name—γλυκὺς, sweet. Concentrated as far as possible *in vacuo* over sulphuric acid, it has the sp. gr. 1·28 at 59° (15°C). The glycerine of the British Pharmacopœia has the sp. gr. 125, and contains five per cent. of water. Glycerine is difficultly volatile, and only begins to distil unchanged at 518° Fahr. in a current of superheated steam, or in a partial vacuum, but it cannot be distilled in the ordinary way without much decomposition, intensely irritating vapours of acrolein being evolved. The vapour of glycerine is inflammable. Glycerine is uncrystallizable; at 408 Fahr. it becomes gummy and almost solid. It is miscible with water and alcohol in all proportions, and is a powerful solvent. Glycerine* is insoluble in ether, chloroform, etc. It does not evaporate, but on the other hand is hygroscopic, attracting moisture from the atmosphere and becoming more limpid; like sugar, it possesses strong antiseptic powers.

By gradually adding glycerine to a mixture of sulphuric and fuming nitric acids, carefully cooled, glonoin $C_3H_5N_3O_9$ (nitro-glycerine) is prepared; on adding water to the solution nitro-glycerine is precipitated as a heavy yellowish oil, soluble in alcohol and ether. It is a very unstable compound, and explodes when struck violently; it is largely used for various purposes, the preparation of dualine, and dynamite, etc.

Glycerine treated with iodide of phosphorus, whereby iodide of allyl is formed on being dissolved in alcohol, and distilled with sulphocyanide of potassium, yields sulphocyan-allyl, or artificial oil of mustard.

$$C_3H_5I + KNCS = KI + \underset{\text{Mustard Oil.}}{(C_2H_5)N(CS)''}:$$

or if sulphide of potash is substituted, sulphide of allyl $(C_3H_5)_2S$, essential oil of garlic is yielded.

Various applications.—As may be imagined, glycerine being a production in which so many wonderful properties are combined, its applications and uses are now manifold, and it appears remarkable that whilst so many sources of impure glycerine have long been known to exist, hundreds of tons being thrown away annually, it is but of late years that it has been utilized, and now the demand for use in pharmacy, arts, etc., is with difficulty supplied.

In the beginning of 1844 Mr. Thomas De La Rue, being engaged in some experiments requiring the use of syrupy substances, procured from the Apothecaries' Hall, London, some glycerine, some of which he applied to a burn and an irritation of the skin. The experience thus obtained of its properties of soothing and keeping moist, led to its introduction into the Hospital for Skin Diseases, where it soon came into extensive use, and from this time it gained considerable favour with the medical profession, being even suggested as a substitute for cod liver oil, or at any rate a vehicle to render that medicine more palatable. But the question of purity arose, most of the samples at that time being found contaminated with lead, even in those samples which were sold as "pure and free from lead;" but since the introduction of Mr. Wilson's process these contaminations need not be, and are rarely met with, so that now glycerine daily becomes more and more made use of in pharmacy and in the surgery.

It must be borne in mind that in applying glycerine externally and internally it should be previously diluted. Glycerine has a strong affinity for moisture, it takes it from the skin and thus gives rise to a sense of burning. Dilution with water will mitigate this, and in most cases prevent it. In pharmaceutical preparations glycerine may be used as a preservative agent, and to economize the use of alcohol; its more important medicinal value is as a vehicle for the preparation of a great variety of remedies for both internal and external use. The therapeutic effects of some medicines are considerably modified by its use. Solutions in glycerine are practically found in the case of astringents to be much less active than solutions in water. Its usefulness as an application to the surface of the skin when dry and irritable, is testified by the fact that almost every pharmacist now-a-days has his speciality in the shape of glycerine lotion, glycerine cream, etc., and in the demand for the various manufactures of glycerine soaps. Mr. F. A. Sarg of Vienna claims to be the introducer of these things,† and he deserves praise for the perfection to which he has brought his glycerine toilet requisites; they really contain glycerine in very fair proportions.

* We believe the originator of this method was Mr. Tilghman, of the United States.—Ed. Pharm. Journ.

* An interesting table of the solubility of various salts in glycerine, by Klever, will be found in the first volume of the present series of the Pharmaceutical Journal.

† Die Urtheile der 'Allgemeinen Weiner medizinischen Zeitung' uber Glycerin. Jahrgange, 1869-70.

Glycerine is largely used for cosmetics and perfumery, for keeping clay moist for modelling purposes, for preventing mustard from drying up; it is also useful as a lubricating material for some kinds of machinery, more especially watch and chronometer works, because it is not altered by contact with air, does not become thick at a low temperature, and does not attack such metals as copper, brass, etc. It is used in making copying inks. It is an excellent solvent for many substances, including the tar-colours (aniline blue, cyanine, aniline violet) and alizarine. In order to render paper soft and pliable glycerine is added to the pulp; it enters largely into the manufacture of weavers' glue or dressing (which is composed of dextrine 5 parts, glycerine 12 parts, sulphate of alumina 1 part, and water 30 parts), by the use of this mixture the weaving of muslins need not be, as was formerly the case, carried on in damp darkened cellars, but may be performed in well-aired and well-lighted rooms. Santi uses glycerine for the compasses on board screw-steamers, in order to protect the inner compass box against the vibrations caused by the motion of the propeller. A mixture of finely powdered litharge and *anhydrous* glycerine, made into paste, forms a rapidly hardening cement, especially useful as a cover for the corks or bungs of vessels containing such fluids as benzol, essential oils, etc., the cement being impermeable to these liquids. Glycerine, on account of its strong antiseptic powers, has been used successfully as an agent for preserving animal and vegetable substances. For mounting botanical and zoological specimens, as a substitute for alcohol, glycerine has been found preferable, as not being liable to evaporation, not combustible, and preserving the natural colours of the preparations more perfectly. Glycerine is largely used in the process of calico-printing; it is also used under patent process in preparing paper for dry printing; when added to confectioners' wares, preserved fruits, and chocolates, it serves to preserve them from becoming dry—it serves a similar purpose in the manufacture of tobacco and snuff. The water in gas-meters is liable to freeze in winter, or to evaporate too rapidly in summer—the addition of glycerine prevents these evils. Dr. Pohl and Pasteur have made many experiments with glycerine to apply it for sweetening certain wines which had become sour; and it has been successfully established that glycerine gives the wine a certain mildness and reviving flavour, so that it may be of great service in time of a bad year's growth.

Quality, as it exists in commerce.—Many impurities are necessarily found in crude glycerine, according to the process of manufacture, or the quality of water used in manufacturing. For industrial purposes, these impurities are not objectionable or disadvantageous if only present in moderate proportions; for medicinal use of course it is absolutely necessary that pure glycerine should be used, and the glycerine purified by Wilson's process manufactured by Price's Patent Candle Company is undoubtedly superior to any other I have examined. The fact that continental manufacturers now offer medicinal glycerine *à la* Price, inodorous, etc., would tend to substantiate this statement; and it occurred to me that it might be interesting to know how these various manufactures compare with Price's,—hence the ultimate object of this paper.

I have selected nine samples to report upon, and these represent English and continental manufactures.

The various chemical reagents shown, with the results, in the tabular form below, have been applied in the usual way, standard solutions being added to the specimen of glycerine (the glycerine previously diluted with an equal bulk of water), excepting the argentic nitrate. One part of solution was added to four parts of undiluted glycerine, and the mixture allowed to stand twenty-four hours. The specific gravity was taken at 60° F. with Baumé's hydrometer; and several were taken by weight, and found to correspond. The odour is easily ascertained by rubbing a little on the back of the hand: the peculiar mousey smell with some samples is easily detected, and this becomes more intense by heating a little of the glycerine in a test-tube.

Glycerine mixed with an equal volume of rectified sulphuric acid, should not produce effervescence or colouration if sufficiently pure for medicinal use.

By adding absolute alcohol and concentrated sulphuric acid to glycerine, on heating a fruity smell is set free, more or less intense owing to the presence of butyric or formic acid; the peculiar pine-apple odour is very strong in some samples, showing the formation of butyric ether.

For detecting sugar and glucose in glycerine.—To five drops of the glycerine to be tested, add 100 to 120 drops of water, one drop of pure nitric acid, and three or four centigrammes of ammonium molybdate; boil the mixture, and in less than two minutes it will assume an intense bluish-green colour if any sugar or glucose is present.

Sample.	Specific Gravity. Hydrometer.	Colour.	Odour.	Odour when treated.	Sulphuric Acid.	Argentic Nitrate.	Ammonium Oxalate.	Potass. Ferrocyanid.	Ammon. Hydrosulph.	Barium Chloride.	Litmus.	For Butyric Acid.	For Sugar.
A	31 °B.	None.	None.	Very faint.	No change.	No change.	No change.	No change.	No change.	No change.	No change.	Slight smell.	None.
B	30° B.	None.	Do.	Slight mousey smell.	Slight discoloration.	Do.	Do.	Do.	Do.	Do.	Do.	Present.	Do
C	30° B.	Do.	Slight.	Do.	Do.	Slight tinge.	Slightly turbid.	Do.	Do.	Do.	Do.	Do.	Do.
D	30° B.	Do.	Do.	Do.	No change.	Do.	Do.	Do.	Do.	Do.	Do.	Do.	Do.
E	31° B.	Do.	Very faint.	Do.	Slight tinge.	Faint opalescence.	No change.	Do.	Do.	Do.	Do.	Do.	Do.
F	29° B.	Do.	Fatty.	Do.	Do.	Slightly tinged.	Slightly turbid.	Do.	Do.	Do.	Do.	Do.	Do.
G	28° B.	Slightly tinged.	Do.	Disagreeable fatty.	Do.	More tinged.	Do.	Do.	Do.	Do.	Do.	Do.	Do.
H	28½° B.	None.	Mousey.	More mousey.	Discoloration.	No change.	No change.	Do.	Do.	Do.	Do.	Do.	Do.
I	28° B.	Brown.	Strong and fatty.	Strong and fatty, very offensive.	Intense discoloration and disagreeable odour.	Flocculent deposit.	Great deposit.	Do.	Discoloration and black deposit.	Deposit.	Red.	Plenty, and disagreeable fatty smell.	Do.

In the foregoing table, A represents Price's patent glycerine; B, C, D, E, F, were sold by continental manufacturers as double distilled white glycerine, *à la* Price, inodorous, guaranteed to stand the nitrate of silver test (sp. gr. 30° to 31° B); G and H as refined glycerine (28° B sp. gr.); and I a sample of concentrated *crude* glycerine from Hamburg, as exported for manufacturing purposes. A, B, and H have been exposed to strong sunlight in closed vessels for two days. A was unchanged, but B and H had the mousey odour developed very fully, but without discoloration.

It will be observed that there are *slight* impurities in

B, C, D, E, F, but I think none to prevent their being used in pharmacy and medicine when not intended for internal administration.

I consider that pure medicinal glycerine should not be affected by nitrate of silver, sulphuric acid, oxalate of ammonia, or exposure to sunlight, and should be perfectly free from smell after this treatment.

A long and interesting discussion followed. The President alluded to several experiments he had made to ascertain if glycerine and water would freeze, and thought it a singular fact that they would not, and hoped for some explanation of the phenomenon.

Dr. Cook, of Edinburgh, ably criticized the paper, alluding to a specimen of solid glycerine which Dr. Gladstone exhibited before the Chemical Society, which had come from Vienna, supposed to be frozen by excessive cold and the motion of the train. Dr. Cook thought the fruity smell produced by treating glycerine with absolute alcohol and rectified sulphuric acid was due to the presence of formic acid rather than butyric. The mousey smell from some samples he thought was due to acrolein.

Messrs. Armstrong, Tanner, Rigby, and Williams continued the discussion, after which Mr. Mason replied to the various questions which had been raised.

On the motion of the President, supported by Dr. Cook, an unanimous vote of thanks was accorded to Mr. Mason for his interesting communication, and the meeting terminated.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, 3rd April, 1873. Dr. Odling, F.R.S., etc., President, in the chair.

After the formal business of the Society was transacted, a paper on "A method of Determining with great exactness the Specific Gravity of Liquids," was read by the author, Dr. Sprengel. The instrument, consisting of a U-shaped glass tube, terminating in capillary tubes bent at right angles, is very delicate when proper precautions are taken. The second paper, entitled "Researches on the Action of the Copper-zinc Couple on Organic Bodies, No. II. on the Iodides of Methyl and Amyl," by J. H. Gladstone, F.R.S., and A. Tribe, is a continuation of the authors' researches on this subject, an account of which they communicated to the Society some short time ago. Dr. C. R. A. Wright then read a memoir "On Cymene from various Sources," in which he gives the results of his examination of cymene prepared from eight different sources, showing them to be identical. The last paper was by Dr. H. E. Armstrong, being No. XI. of "Communications from the Laboratory of the London Institution, Action of the Acid Chlorides on Nitrates and Nitrites, Part I. Acetic Chloride."

The meeting finally adjourned until Thursday, 17th April, when a lecture "On the Heat produced by Chemical Action," will be delivered by Dr. Debus, F.R.S.

PARIS SOCIÉTÉ DE PHARMACIE.

A meeting of this Society was held on Wednesday, March 5, under the presidency of M. Bussy. In the course of the preliminary business a letter was read asking the advice of the Society, under the following circumstances:—A pharmacien having died without leaving either widow or children, his brothers and sisters had provisionally carried on the business under the superintendence of a qualified pharmacien, assisted by a pupil approved by the medical jury of the department. This state of things had been denounced as illegal by another pharmacien, who had entered an action against the heirs, which being in the first instance decided in their favour, was now carried on appeal to the court at Caen. It was stated in the discussion which followed the reading of the letter that the custom in the Paris Circumscription was to allow to children, brothers, or sisters inheriting, the same delay as to a widow, putting them under the same obligations. This authorization was usually accorded by the Prefect of Police, on the advice of the School of Pharmacy.

M. Poggiale presented a note by M. Pollacci on the preparation of the hydrates of potash and soda by heating the nitrates of the alkalies with iron filings.

Commercial Propylamine.

M. Wurtz read the report of the commission appointed to investigate the subject of the propylamine of commerce. The report, pointed out that it was no part of their duty to answer the question as to what was the therapeutic value of propylamine, but that since that substance was prescribed by medical men the duty of pharmacists was to furnish it pure, and always identical in physical and chemical characters and medical properties.

Propalymine was stated to have been first discovered in 1850 by Wertheim, while treating narcotine with a caustic alkali, and to have been afterwards noticed by Winckler in ergotine and herring brine; by Wicke in the flowers of *Cratægus oxyacantha*; by Dessaignes in the *Chenopodium vulvaria*, in the blood of veal and in human urine. But in 1863, Wicke arrived at the conclusion that this ammonia compound, which he had also obtained from the flowers of the pear and mountain-ash, was trimethylamine. The method adopted by all these authors was to mix the substance from which it was wished to obtain the propylamine with potash or lime and submit the mixture to distillation. The gases disengaged (a mixture of ammonia, "propylamine," etc.) were collected in water acidulated with hydrochloric acid. The solution being evaporated, the residue was treated with absolute alcohol, which dissolved only the chloride of "propylamine;" this was afterwards decomposed by lime and the "propylamine" collected in water. The "propylamine" used by Dr. Dujardin-Beaumetz, and which has been obtained from herring brine, is a colourless liquid having an odour *sui generis* of herring brine and ammonia. But the reporters do not think this substance is really propylamine, and consider that nearly all the authors who have treated of this subject have mistaken an aqueous solution of trimethylamine for that substance.

The propylamine obtained by means of propylic alcohol by Sylva, in 1869, was a liquid having a strong ammoniacal odour, very alkaline, inflammable, colouring cupric solutions blue, precipitating alumina from its solutions and re-dissolving the precipitate, characters which belong also to its isomer isopropylamine, discovered by Gautier, which he obtained by means of isopropylcarbilamine:—

$$NC_4H_7 + 2H_2O = C_3H_9N + CH_2O_2.$$

But these three ammonias, although isomeric, differ from each other in their boiling points and the crystalline forms of their salts. Thus trimethylamine boils at between 4° and 5° C.; propylamine at from 49° to 50° C.; and isopropylamine at from 31° to 32° C. Winckler has established the identity of trimethylamine obtained from herring brine with that prepared synthetically, not only by direct comparison of the two bodies, but also by the characteristic reaction with iodide of methyl in the production of a crystalline magma of rectangular prisms of iodide of trimethylammonium.

The reporters consider that the commercial "propylamine" is but a complex product containing trimethylamine and ammonia in a greater or less degree of concentration; that medical men are using a substance of variable composition and consequently the results cannot always be the same. They therefore suggest that a uniform method of preparation should be adopted, such as to distil herring brine and collect the product in acidulated water, as before described; or that as it is trimethylamine which is contained in herring brine, it would be more simple to prepare that ammonia direct by means of methylic alcohol. The method proposed is to transform the methylic alcohol into iodide of methyl; to heat the ether so obtained under pressure with ammonia which would give crystals of iodide of tetramethylammonium, nearly insoluble in cold water. These crystals are then to be washed with distilled water to carry off any iodide of ammonia which may have formed, afterwards decomposed by lime, and the gas collected in water. The solution so obtained could be titrated in the same way as an ordinary ammoniacal solution, and therapeutics would have at its disposal a product of constant composition.

But the reporters consider it would be better to replace the alkaline solution, which from its disagreeable odour is repugnant to a patient, by the hydrochlorate of the base, which is nearly inodorous and has a saline taste, if it should prove that the effects of the salt are the same as those of the pure alkali. So far the experience of M. Beaumetz with this salt is satisfactory, and it is probable that such a substitution will be possible.

M. Petit said that he had examined various specimens of commercial "propylamine," containing from 2 to 52 centigrams of alkaloids or ammonia per cubic centimetre, and he had come to the conclusion that the greater part of them were much richer in ammonia than in propylamine, monoethylamine or diethylamine.

M. Lefort read a paper upon the preparation of pure protoiodide of mercury.

Sulphovinate of Soda.

M. Bussy said that he had recently had occasion to examine various specimens of sulphovinate of soda and that a certain proportion of them were mixtures in various proportions of sulphovinate of soda and bisulphate of soda. The presence of the latter salt, sometimes in large quantity, was not, in his opinion, the result of a fraud, but of a defect in its preparation, probably the prolonged action of a high temperature, especially in the presence of water.

M. Limousin remarked that the sulphovinate of soda is a very hygroscopic salt, and that when in order to drive off the humidity taken up from the air it is dried at a temperature exceeding 100° C. or 120° C., it is partially decomposed into bisulphate of soda and alcohol.

M. Jungfleisch said that in evaporating large quantities of sulphovinate of soda, water favoured the decomposition of the salt. The liquor became more acid as the temperature rose and the operation was prolonged. This decomposition could only be prevented by employing an excess of alcohol.

In the discussion which followed it was agreed that sulphovinate of soda is decomposed by simple prolonged contact with water, especially when heated. It then becomes acid and precipitable by chloride of barium. Such a decomposition is to be feared in lemonade or draughts prepared with it and kept for some time.

M. Boudet remarked that the danger would be the greater because sulphovinate of soda is usually prescribed in considerable doses.

The Society decided that these observations upon the ready decomposition of sulphovinate of soda during its preparation, or when kept in solution or in a humid state, merit the attention of pharmacists because of the danger that might result from the presence of bisulphate of soda both to the patient and the pharmacist.

Parliamentary and Law Proceedings.

Serious Charge against a Chemist.

At the Chester Assizes on Tuesday, April 1, Edwin Eastwood, described in the calendar as a druggist, of Dukinfield, was arraigned on the charge of administering to Ann Jones a certain noxious drug, with intent to procure a miscarriage. A bill charging the prisoner with wilful murder had been previously ignored by the grand jury. The nature of the evidence has already been described in this journal (pp. 338 and 355). The jury returned a verdict of "Guilty," and the judge, after commenting on the gravity of the offence, sentenced the prisoner to ten years' penal servitude.—*Stalybridge Reporter.*

Prosecutions of an Unqualified Practitioner.

At the Lanchester Petty Sessions on Thursday, March 27, Mr. Percival Hall, of Holmside, near Lanchester, was charged with wilfully and falsely using the name or title of surgeon, contrary to the provisions of the Medical Act. It was stated that the defendant had practised for many years, and the men of a neighbouring colliery paid 6*d.* a fortnight to him. His name was not on the Medical Register, but he had signed a certificate of death as a surgeon. Several technical objections were taken. The Bench considered the offence proved, and imposed a penalty of 5*s.* and costs.

On Thursday, April 3, a similar charge against the same defendant was heard at the Chester-le-Street Police Court. The Bench again decided against the defendant, and fined him 20*s.* and costs.—*Durham County Advertiser and Durham Chronicle.*

Reviews.

Half-yearly Abstract of the Medical Sciences; being a Digest of British and Continental Medicine, and of the Progress of Medicine and the Collateral Sciences. Edited by William Domett Stone, M.D., etc. Vol. LVI. London: Churchill, 1872.

Progress in legal or theological science is as slow as that of a glacier;—in medicine it is as rapid as the stream to which the glacier gives birth. To keep pace with it the student or the practitioner must either devote himself entirely to reading, or must rely on some such periodical abstract as Dr. Domett Stone endeavours to supply. If well done, a half-yearly summary of the progress of medical science would be invaluable; but, on the other hand, if imperfect, it is of rather less worth than a weekly periodical like the *British Medical Journal*, or the *Lancet.* Dr. Domett Stone's performance comes within neither of these extremes. It cannot honestly be called satisfactory; neither is it so perfunctory as to deserve absolute condemnation. It is a tolerable bit of compilation, corresponding to Homer's description of the drugs with which it so largely deals:—

Πολλὰ μὲν ἐσθλὰ μεμιγμένα, πολλὰ δὲ λυγρά.

Much of his volume is occupied with matters for which no competent medical man would thank the purveyor. There is a tone of mediocrity over a considerable part of the extracts, which implies little "progress" in the science which they are adduced to illustrate. Far too much space is devoted to native and colonial research; far too little to continental; while in the latter the French are laid under contribution nearly three times as often as the German *savants*—a ratio which, if science be held to guide the selection, should simply be reversed. Again, even in the English or colonial part of the volume, credit is given to the wrong person as the originator of this or that method or preparation or suggestion. For instance, in the mode of distinguishing creosote from carbolic acid the *Canada Medical Journal* is quoted as the first source of the innovation, whereas it was primarily suggested in our own columns. Moreover, the sins of omission are as flagrant as those of commission. The signal success of Leube in sustaining the nutrition of invalids by injections of minced pancreas *per anum*, when the ordinary channels of food-ingestion were closed, receives not a word of notice, although it has solved the *quæstio vexata* of forcible feeding in mania; while the occasional production of *erythema fugax* by the excessive use of hydrate of chloral receives ample illustration.

On the whole the volume before us cannot be recommended as a perfect mirror of the half-year's progress in medicine. It contains much that the general practitioner will find acceptable; but the competent physician or surgeon will glean but small sustenance from it. He may ask for bread only to be offered a STONE.

Obituary.

Notice has been received of the deaths of the following:—

On the 21st of March, 1873, Mr. Francis William Joy, Pharmaceutical Chemist, of Cardiff. Mr. Joy joined the Pharmaceutical Society in 1857, and during the greater part of the intervening time actively and efficiently served the Society as its Local Secretary. He died of bronchitis at the age of 42 years.

On the 21st of March, 1873, Mr. Josiah Steward, Pharmaceutical Chemist, of Trimpley, near Bewdley. Aged 69 years. Mr. Steward was a Member of the Pharmaceutical Society, having been one of its Founders.

On the 7th of December, Mr. Thomas Garnett, Chemist and Druggist, of Kendal. Aged 33 years.

On the 4th of April, 1873, Mr. William Maudsley, Chemist and Druggist, of 260, Tottenham Court Road. Aged 36 years.

Notes and Queries.

[334].—BLEACHING FERNS.—*Mr. George Delves* and *C. W.* wish to be informed of a good process for bleaching ferns and rendering them transparent.

DIARRHŒA AND CHOLERA MIXTURE.—"*A. B. C.*," asks for the formula prescribed by Sir John Fisher, late Chief Surgeon to the Metropolitan Police. The following is taken from a letter forwarded by that gentleman to the *Times*, of August 3, 1866:—

Aromatic Confection	6 drachm.
Tincture of Opium	1 "
Tincture of Catechu	2 oz.
Aromatic Spirit of Ammonia . . .	1 "
Chloric Ether	2 drachm.
Peppermint Water	13 oz.

Mix. Three tablespoonfuls to be taken every three or four hours until the diarrhœa ceases.

The following journals have been received:—The 'British Medical Journal,' April 5; the 'Medical Times and Gazette,' April 5; the 'Lancet,' April 5; the 'London Medical Record,' April 2; 'Medical Press and Circular,' April 4; 'Nature,' April 5; 'Chemical News,' April 5; 'Gardener's Chronicle,' April 5; the 'Grocer,' April 5; 'Journal of the Society of Arts,' April 5; 'Grocery News,' April 5; 'Produce Markets Review,' April 5; 'Scientific American,' April 5; 'Brewers' Guardian,' April 8; 'Journal de Pharmacie et de Chimie' for April; 'Moniteur Scientifique-Quesneville' for April; 'Practitioner' for April; 'Journal of Applied Science' for April; 'British Journal of Dental Science' for April; 'Educational Times' for April; Food, Water, and Air, for April.

Correspondence.

BENEVOLENT FUND.

Sir,—I cannot help expressing my surprise at the letter from Mr. Walter B. Clark, of Leicester, which appeared in your Journal last week; he thinks "the Benevolent Fund is *at last* exciting some attention."

I do not know what has so suddenly brought about this discovery, but it does seem strange that when we have elected annually two annuitants, until we have now thirteen such on the list, each receiving thirty pounds per annum, and when every deserving applicant has received relief, I say it does seem strange that the vitality of the Benevolent Fund should only now present itself to Mr. Clark. Happily other members of our Society held sounder views on the foundation of a charitable trust, and did not withhold their contributions lest men of the future only should benefit by them. But for this, and the proper investing of the unexpended subscriptions and donations at the end of each year, no unfortunate brother chemist or destitute widow would have had the assurance of a certain income to solace the remainder of his or her declining years; and what, perhaps, would be worse than that, even those who have been elected as annuitants might be suddenly bereft of their annuities if the Trustees of the Fund adopted Mr. Clark's view. It must surely be apparent that, when the money is capitalized, it is "at once devoted to charitable purposes." Where casual relief only is granted by an association, it may be justifiable to expend all the subscriptions received, but it is a well-known rule in societies granting pensions, to keep those pensions within the limit of the income arising from capital; and I trust that wholesome regulation will never be neglected by us.

When genuine cases are refused assistance (and Mr. Clark does not cite one such), it will be time to ask the Council to pursue a different policy; but when month after month grants are made, and in the common course of things demands on the Fund multiply, it seems to me that those who have the power to give are scarcely justified in withholding their assistance.

Few men in our ranks have possessed a more active spirit of benevolence than our late friend George Waugh; few men had better means of knowing how much was done, how much left undone by the Council in this matter; no man gave more liberally from first to last. Let his judgment as to the usefulness and proper appropriation, as well as his example in support of our Benevolent Fund, be a guide and example to us all!

Piccadilly, April 8th, 1873. GEORGE W. SANDFORD.

LEGALITY *v.* ILLEGALITY.—AN EXPLANATION.

Sir,—I am so inadequately and unfavourably reported in the two last Journal reports of the meetings of the Pharmaceutical Council, that in simple self-defence, as well as in the interest of the question I have had in hand, I must claim from you a little space that I may fairly state my position.

Without an intention to garble a report, the sins of omission may be so flagrant as to render it worthless, misleading, and mischievous. These remarks apply to the reports of the observations made in support of the amendments which I moved at the March and April meetings of the Council.

At the March meeting I read and commented upon the annotations of Mr. Flux on the draft of the proposed amended bye-laws, and I also referred to Mr. Flux's remarks made before the Parliamentary Committee. The annotations and remarks were in direct opposition to the views of the majority of the Council. The whole of this is withheld from the report.

At the last meeting of the Council I again moved an amendment, which I based upon Mr. Flux's opinion so deliberately given. I thought it was scarcely possible to withhold the publication of the amendment. I stated at the same time that I moved in this manner, because Mr. Flux's opinions, as cited by me at the previous meeting, were withheld in the report. This statement which justified me in again moving in opposition is also withheld.

No doubt all these omissions may be purely accidental. The consequences are, however, the same. I am misreported, and possibly to some degree damaged, and what is more important, the members fail to receive the fair and full report to which they are entitled.

Perhaps the imperfection of the reports arises from the system under which they are obtained. It would be well, therefore, to adopt some other plan better suited for the purpose, than to permit the evils of the present system to continue.

In December last, when Mr. Schacht proposed the amended regulations of the Board of Examiners, he first moved "that the question as to the Council possessing the legal powers to carry the proposed alterations into effect be referred to the Parliamentary Committee," and immediately afterwards, with needless precipitation, and without having solved the legal doubt, a majority of the Council voted their enactment.

In due time amended bye-laws are sought for to empower the Board of Examiners to carry out the amended regulations, and the proposed altered bye-laws are submitted to Mr. Flux, the Society's solicitor, for his approval.

To the following portion of the first draft of the amended bye-law, section 10, clause 16, Mr. Flux made the following marginal note:—

Part of Proposed Bye-law.	*Mr. Flux's Marginal Note.*
After the 31st day of December, 1876, no person shall be admitted to the Minor examination who has not been registered or employed as an apprentice or student at least three years previously.	This appears to us to vary from the intention that the examinations shall be freely open to all the world, and we recommend its erasure.

Mr. Flux also makes the following note to another proposed amendment of bye-law, what is equally applicable to section 10, clause 16. "The Statutes contemplate that each examination shall be complete in itself and open to all the world, but proper regulations may be made for the *conduct* of the examinations."

Before the *Parliamentary Committee* Mr. Flux also maintained with great force and clearness that the charter and statutes gave no power to exact a three years' interval between the Preliminary and Minor examinations. He averred that a reasonable time might be exacted—say a few days,—but he maintained that a period of three years was, in his opinion, unreasonable and illegal.

Having read and re-read the Acts and charter, with a view to discover the powers necessary to enforce the term and interval between the Preliminary and Minor examinations fixed by the amended bye-law as accepted by the Council, I was not unprepared to find that Mr. Flux, in his capacity of legal adviser to the Society, recommended its erasure, and that he so far independently justified the position of opposition I had taken up.

I was, however, filled with wondering amazement when I discovered at the last meeting of the Council that Mr. Flux had completely altered his views, because the words "apprentice or student" had been removed from the proposed bye-law. The words, about which there surely must hang a spell, still remain, although not precisely in the same position.

To facilitate a comparison of the proposed amended bye-law submitted to Mr. Flux, and which he pronounced to be illegal, and the amended bye-law he now pronounces to be in conformity to law, I place them side by side.

The Illegal Bye-law.	*The Legal Bye-law.*
After the 31st day of December, 1876, no person shall be admitted to the Minor examination who has not been registered or employed as an apprentice or student at least three years previously.	After the 31st day of December, 1876, no person shall be allowed to pass the Major or the Minor examinations, unless he shall satisfy the examiners that for three years he has been registered and employed as an apprentice or student, or has otherwise for three years been practically engaged in the translation and dispensing of prescriptions.

Perhaps my obtuseness and want of legal training incapacitate me from comprehending the subtle distinction which may exist between the two formulæ.

I can only congratulate myself under these circumstances, that I compound physic as a vocation, and not expound law.

The question of legality is a very grave one, and as I honestly believed that the Council was over-stepping its powers, I have done my best in an open manner to oppose the progress of the bye-law in its various stages.

If the Council be competent to stretch the law in one direction, why not in another?

The plea of advantage to the Society is urged on behalf of the illegal test. This is dangerous ground on which to move. Rather let fresh power be sought from Parliament if it can be shown that it is necessary and advisable to institute such a change.

I have tried in vain to procure, from all likely quarters, evidence that an appreciable number of persons pass the examinations who have not been previously subjected to a term of apprenticeship.

If proof of this kind had been adduced, there would have been a show of reason to justify a compulsory term if *legally obtained and exacted.* Not a tittle of evidence,—which evidence should have been the ground-work for the proposed alterations,—has been offered.

It is not yet too late to halt in the illegal course, and I trust that the members will, at the special general meeting, refuse to sanction the objectionable bye-law, which if passed, will remain a precedent of illegality.

205, *St. John's Road, E.C.,* Robert Hampson.
April 8th, 1873.

P.S.—I am reported—in the report of the April meeting of Council—to have proposed eighteen members for the Board of Examiners. This is a mistake, Mr. Schacht made this proposition.

[*⁎* We publish Mr. Hampson's letter *in extenso*, though it appears to contain matter which is not subject to reporting. In justice to ourselves we may add, that nothing was cut out or withheld from the draft of Mr. Hampson's speech handed to us by the reporter appointed to take down the Council proceedings, and likewise that Mr. Hampson had full opportunity to make any requisite correction in the proof-sheets.—Ed. Ph. Journ.]

Pharmacy in Ireland.

Sir,—A great amount of misunderstanding seems to exist in the minds of English chemists regarding the state of pharmacy in Ireland, especially with regard to the position occupied by chemists and druggists there.

The Irish chemists and druggists must not be confounded with those bearing the same name in England and Scotland. They are merely retailers of drugs, and have never been trained to dispense physicians' prescriptions. In fact, such a class may exist in England and Scotland in a few years, especially if the standard of pharmaceutical education be raised much higher. The Irish apothecaries are the Irish pharmacists proper, and in the larger towns, where they have given up the practice of medicine, and have devoted themselves to the retailing of drugs and the dispensing of prescriptions, pharmacy is in as flourishing a condition as it is either in England or Scotland. But the very fact of so many apothecaries having recognized that the practice of medicine and the practice of pharmacy ought to be vested in separate individuals, proves that a change in the existing state of things is required. Either the apothecaries must give up the medical part of their examination, or a new class must be instituted, having equal privileges with them in the practice of pharmacy.

At a meeting of the United Society of Chemists and Druggists of Ireland held recently, it was proposed that the Pharmaceutical Society be requested to extend their operations to Ireland. It would certainly be an advantage to have all the pharmacists of the United Kingdom subject to the same examinations; but it would be a great mistake to lower the examination—permitting pharmacists to commence business—to our Minor, where an examination equal to our Major might be easily enforced.

The draft bill drawn up by the Court of Apothecaries (a copy of which was printed in the first volume of the present series of the Pharmaceutical Journal, page 405) would meet all the requirements of the case. When this bill was formerly discussed in the pages of the Journal, the chemists and druggists (of Ireland) claimed a right to a modified examination, upon what grounds I cannot conceive. It would be a great misfortune to allow any class of men to become pharmacists who have never received the necessary training which would enable them to discharge such responsible duties, without their first giving ample proof of their abilities.

The apothecaries seem quite alive to the necessity for some change; and in place of crying out about vested interests, as they might have done, will evidently give their support to any good measure; but those who know the chemists and druggists of Ireland could never advocate their being admitted, as a body, to the privilege of dispensing.

The influence of the Pharmaceutical Society might be exerted in procuring a mutual recognition of examinations; our Major being held equal to the examination proposed in the draft bill for pharmacists commencing business, and our Minor equal to the proposed examination for assistants. The Modified examination we could scarcely expect to be recognized.

ALEX. ANDERSON.

277, *Oxford Street, W., March* 31*st*, 1873.

SUBJECTS FOR EXAMINATION.

Sir,—Among the many proposals regarding the examinations which have appeared in the Journal lately, there have been, as far as I have seen, none urging the advisability of including a knowledge of pharmaceutic jurisprudence in the list of subjects required for the Major or Minor. Nevertheless it is, in my humble opinion, a subject which yields in importance to scarcely any. And if the Council were to require a knowledge of the Arsenic Act, the Pharmacy Act, etc., we should not hear of so many unfortunate pharmacists being censured for contravening any of the legal enactments concerning the business as we do at present. A knowledge of medical jurisprudence is required from candidates for a medical degree, and if a knowledge of pharmaceutic jurisprudence were insisted on for the Major or Minor, it would, I think, do something towards raising the business towards that professional status which many seem to desire.

I hope that this may induce those who are more fully qualified to discuss this subject than I am, to enter the lists.

JURISPRUDENTIA.

Edinburgh, March 29*th*, 1873.

CHEAP DISPENSING.

Sir,—The subject of cheap dispensing has been the burthen of so many letters in the Journal, that its readers may be excused if they consider the subject rather threadbare. However, sometimes a specimen crops up, so glaringly inconsistent, that it seems best, when found, to make a note of it. The following prescription was handed me for dispensing, and two shillings charged as being a fair remuneration:—

℞ Acid. Nit. Mur. Dil. . . . . ʒij
Tinct. Scillæ . . . . ℥ss
Syrupi . . . . ℥j
Ext. Cinchon. Liq. Flavæ . . ʒiij
Aquæ ad . . . . ℥vj
℥ss ter in die ex aqua. M. ft. mist.

Judge of my surprise when the customer informed me that it had been made up for sixteenpence at a first-class establishment in a neighbouring fashionable resort, and that at Bristol tenpence was considered an honest price; while, to crown all, the medical man who wrote the prescription, gave advice and medicine for a shilling. Now, Sir, I have not the slightest reason for doubting the statement, but how is it done? I take it that the prime cost of ingredients and bottle, etc., would be hard upon fourteenpence (and say nothing about time), so that even at sixteenpence, with bottle brought, what a pitiful profit it would leave the man who has spent months in studying to qualify.

Of course, if legitimately dispensed, there could not be a profit either at tenpence or a shilling, and they cannot live upon the loss; so the only conclusion one can arrive at is that the ext. cinchon. liq. must be very much below the B. P. standard. Mr. Gerrard last week clearly showed how utterly dishonest such a system of dispensing is, and a glance at the figures representing his analysis of various samples of citrate of iron and quinine will perhaps reveal the real secret of cheap physic.

W. GEORGE BLADON.

Malvern Wells, April 1*st*, 1873.

METHYLATED SPIRIT AND THE ADULTERATION ACT.

Sir,—I have, like many others, been accustomed to keep two kinds of soap—liniment and spirit of camphor, made from methylated spirit—where a poor class of customers require such for *outward application*. Now, as one likes to know and do what is legal, can you inform me whether, under the new Adulterated Drug Act, such can be sold over the counter; and if so, will *one be compelled* to print *methylated* soap liniment and *methylated* spirit of camphor? Of course the pure I always use in prescriptions.

W. DALE.

Queen Street, Portsea, April 2*nd*, 1873.

PHARMACY IN QUEENSLAND.

Sir,—Will you kindly give insertion to this letter, as it may induce enterprising young men to go out to a colony that is fast rising in importance.

Several of our correspondents in Queensland have complained of the great want of Chemists' Assistants in that colony, and we know of one instance in which a good branch establishment had to be closed simply from the want of a competent assistant to carry it on.

We would beg to suggest this colony as an admirable field of labour for young men who have passed their examinations, and have not secured an engagement in this country.

BURGOYNE, BURBIDGES, AND CO.

16, *Coleman Street, London, E.C.,*
April 4*th*, 1873.

"*Lux.*"—You would probably obtain an explanation of the words in question at the office from whence the advertisement issued. Our correspondent writes that a dispensary appointment, for which it was specified that a legal qualification should be possessed by the candidates, was given to a person who had passed what is known as the "Assistants' Examination" of the Apothecaries' Company. Our correspondent further states that the fee for the above examination is two guineas, and he is of opinion, "seeing that a person passing so cheap and easy an examination can compete with those who go through the expensive ordeal of the Pharmaceutical Society and obtain one of the best paid situations that now offer," there exists a strong argument in favour of lowering the examination fees. As the law at present stands, no legal qualification at all is necessary for holding a dispensary appointment, such as that mentioned by our correspondent, any more than legal qualification is necessary for a dispensing chemist's assistant. This, no doubt, is a grave deficiency, but we are unable to perceive that it affords any argument in favour of lowering the examination fees of the Pharmaceutical Society.

W. A. C.—Several recipes for the removal of dandriff have appeared in the present series of the Journal. See Vol. I., p. 557; Vol. II., pp. 637, 878.

J. W.—The medal you refer to is a thing not at all countenanced by the Pharmaceutical Society, and we should expect those making use of the fact of possessing it would be classed among quacks and other exhibitors of spurious credentials.

W. K. H.—It is not necessary to rub the subnitrate down in a mortar before mixing it with any considerable bulk of an aqueous vehicle. The carbonate, on account of its somewhat granular condition, should first be triturated with a little of the vehicle.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. W. Brierly, Mr. Delves, Mr. Bennett, Mr. Clowes, Mr. Hanbury, Mr. Butler, X. Y. Z.

THE EMBRYO APPENDIX.

BY CHARLES SYMES, PH.D.

The report of the discussion under this head at the pharmaceutical meeting forms an interesting portion of this Journal for April 5th. Professor Redwood appears to adhere as tenaciously as Paul himself to the good old maxim, "Prove all things, hold fast that which is good;" and I quite agree with him that it is time tinct. aurantii recentis should be put on trial. It is of much older date than Mr. Martindale supposes. I have prepared it in quantities of two or three gallons at a time for a period of twelve years, and during the first half of that time made various experiments as to the best proportions of peel, spirit, and water calculated to produce a good tincture. For the last five or six years I have uniformly adhered to the formula given a few months since in this Journal with very satisfactory results, but using a tincture containing a larger proportion of spirit for preparing tinct. quinæ comp. Seeing it desirable, however, to have one uniform tincture for all purposes, I have recently prepared one gallon from the following formula:—

Thin fresh peel of Bitter Oranges . . .	5 oz.
Distilled Water	3 oz.
Rectified Spirit	17 oz.

Macerate the peel in the water with occasional agitation for forty-eight hours, then add the spirit, and continue the maceration and occasional agitation for a week. This makes an excellent tincture, and I suggest it as a suitable one for the Appendix. The *rationale* of the process is this: rectified spirit is the best solvent of the volatile oil, but it tends to harden the texture of the peel, and thus to seal up from its action that oil in the containing vesicles.

Water has just the opposite effect; it tends to soften and break up the organization of the peel, so that the previous maceration with it, and afterwards with the addition of the spirit, enables the operator to produce in nine days a tincture which could not be so well prepared with rectified spirit alone in a month.

I cannot imagine that any complication would arise from the introduction of a second tincture: that prepared from the fresh peel is not quite so dark as from the dry,—the chief difference is in point of flavour.

I have used it in dispensing for the above-mentioned period, and my experience has been that no one has complained of any difference as regards colour; but occasionally a customer has remarked that "a mixture possessed a much finer flavour of orange than when previously dispensed elsewhere." A simple explanation of the difference has always been satisfactory, has left the reputation of the previous dispenser unscathed, and has not diminished my own. Then comes the question of supply. Bitter Seville oranges are abundant in the markets from January till the end of April or beginning of May; and a chemist can very nearly estimate his consumption of the tincture during the season in which they cannot well be procured; he has only to act accordingly. Should his supply run short, I have no doubt but his wholesale friends would be glad to help him out of the difficulty.

Tincture of lemon peel is best prepared in the manner I have suggested to adopt for tincture of orange peel; but of course at the present time no material alteration in the B. P. existing formulæ can be made.

I think there would be an advantage in introducing into the proposed Appendix, a new syrup of lemons—"a syrup of lemon peel," made by adding 1 part tincture to 7 simple syrup—to correspond with the syrup of orange peel. Syrup of lemons is often prescribed as a flavouring agent in alkaline mixtures, where it is evidently not desired to exercise any neutralizing effect; the proposed syrup could be designated syr. cort. limonis; and if on the publication of a new edition of the Pharmacopœia it was found desirable to retain the acid syrup, it would be best prepared by adding 20 grains of citric acid to each fluid ounce of the above.

Extractum belladonnæ alcoholicum, prepared by treating the inspissated juice with alcohol, is a therapeutic agent by no means new, but one which should find its way into the Appendix. The only Pharmacopœia preparation (according to that authority), into which the present extract enters, is emplastrum belladonnæ, in the formula for which instructions are given for more or less imperfectly exhausting the extract with spirit.

If, however, we turn to unguentum belladonnæ we find the extract there in the proportion of 80 grains to one ounce of lard—"a most unnatural admixture," the instructions for preparing which should be—"rub with untiring perseverance, and do not scrutinize with microscopic eye when finished."

With *one fourth the quantity* of alcoholic extract we can prepare an ointment with which the B.P. preparation cannot compare either in elegance or efficiency.

The same remark applies to the preparation of pessaries, suppositories, and bougies of belladonna with cacao-butter or other fatty substances. The retention of the present extract would be convenient, perhaps, for dispensing in the form of pills, but for mixtures, the succus belladonnæ is well calculated to replace it.

A SOLUTION OF CHLORIDE OF IRON.

BY EDWARD BUTLER.

If a quantity of Liquor Ferri Alkalini, P.L. 1824, be kept until it has deposited a part of its iron as hydrated peroxide, this deposit, if filtered off, washed frequently, and added while moist to a weak solution of hydrochloric acid, about f℥i strong acid to f℥xv of water, and the solution filtered, presents the following peculiarities:—

It is a deep garnet red colour instead of yellow.

It has scarcely any taste, either acid or ferrous, but is very astringent.

This preparation seems to answer to the article mentioned by Mr. Squire, in his last edition of the Companion to the Pharmacopœia, as liq. ferri chloroxidi.

THE BOTANICAL ORIGIN AND COUNTRY OF MYRRH.*

BY D. HANBURY, F.R.S.

The remarks relative to myrrh in the 'Admiralty Manual of Scientific Inquiry, 1859 and 1871,'† having

* Reprinted from *Ocean Highways* for April, 1873, the loan of the woodcuts being kindly permitted.

† *Vide* PHARM. JOURN., I. (1860), 217; II. (1871), 205.

elicited no information, it may tend to stimulate those who are located in positions favourable for research if the state of our knowledge on the subject is briefly explained. The direction in which investigations should be made will thus become more apparent.

Myrrh is a gum-resin exuding from the stem of a small tree or shrub which is a native of the hot and dry countries around the southern extremity of the Red Sea. Though the substance itself has been known to mankind from the remotest period of history, and though it has been among the most precious articles of ancient commerce, the tree which affords it is almost—perhaps altogether—unknown to botanists. Whether the myrrh-tree belongs to a single species is doubtful; it is more probable that the drug is furnished by two or three distinct but allied species.

Let us now consider what has been ascertained on the subject. In 1820–26, the German traveller Ehrenberg visited the countries bordering the Red Sea, and among other places, Ghizan (Jhizan or Jezan), a town or village lying on the Arabian coast in latitude 16° 40′ N., opposite to the group of islands called the Farsan Archipelago,—that is to say, about 300 miles north of the straits of Bab-el-Mandeb

Balsamodendron Myrrha (after N. v. Esenbeck).

Here, and on the neighbouring mountains of Djara and Kara (which I do not find on any map I have been able to consult), he discovered myrrh-trees, forming, as he says, the underwood of a forest of *Acacia, Moringa,* and *Euphorbia.* From these myrrh-trees, he states, he picked some very fine myrrh. He also obtained herbarium specimens which the botanist Nees von Esenbeck described and figured under the name of *Balsamodendron Myrrha,*—thus, as it would seem, completely settling the question.

A few years ago Ehrenberg's herbarium was incorporated in the Royal Herbarium of Berlin, and these myrrh-tree specimens were re-examined by Dr. Otto Berg, with results which doubtless occasioned him some surprise. He found in fact, that Ehrenberg's Arabian myrrh-tree comprised two very distinct plants, namely, that figured by Von Esenbeck, and another to which was attached (*correctly,* let us hope) Ehrenberg's own tickets, stating that from it he had got myrrh. Berg gave the new myrrh-tree the name of *B. Ehrenbergianum.*

Whether myrrh is collected *from both* we do not know. Ehrenberg himself does not assert that the natives about Ghizan collect myrrh at all; and the myrrh of commerce is certainly not brought from that neighbourhood.

Whence, then, is myrrh brought? Vaughan, who was port-surgeon at Aden in 1852, says that a little is obtained on the south coast of Arabia, about 40 miles to the east of Aden. But this Arabian myrrh, of which I have seen samples, has not (although pure and clean) exactly the characters of true myrrh, and there is good reason to believe it the produce of another species than that affording the latter. However this may be, the Aden myrrh-tree is wholly unknown to botanists. Vaughan further pointed out that

B. Ehrenbergianum (after Berg).

myrrh, which is more commonly known at Aden by its Indian name of *Hera-bôl* than by its Arabic designation of *Mur,* is collected in great quantities by the Somali tribes occupying the country between Zeila and Cape Gardafui; and that it is also brought from Harar (otherwise called Hurrur or Adari), a commercial town of the interior, about 175 miles south-west of Zeila. Harar was visited in 1855 by Burton, who describes it as the "great half-way house" for the produce of Efát, Gurague, and the Galla countries. The drug arrives at the great fair of Berbera held in November, December, and January, and is bought up by the Banians of India for shipment to Aden and Bombay.

Cruttenden, who visited the Somali coast in 1843, and was afterwards assistant political agent at Aden, says myrrh is brought from the Wadi Nogál, a valley debouching into the Indian Ocean, south of Cape Gardafui, in about latitude 8° N., and from its bordering districts of Ogahden, Murreyhan, and Agahora. He says further that the mountains at the back of

Bender Mirayeh (a town about 20 miles south-west of Ras Filek, on the Somali coast) afford it, and that the drug is brought to Bender Mirayeh for sale.*

Whether it is *true myrrh* which is produced in these districts of the Somali country, or whether it is another kind of myrrh called by the Arabs *Bisa-ból*, and which is chiefly consumed in India and China, is an open question.

Again, it has been stated on very good authority, that myrrh is produced in the country lying between Tajúra and Shoa. Sir W. Cornwallis Harris, who was chief of a mission to the latter country in 1841, found the myrrh-tree between Waramilli and Nága Koomi, that is, about 200 miles from Tajúra, on the road to Ankober, the capital of Shoa. In an appendix to his narrative, he names as localities for the plant, the Adal desert, the jungle of the Háwash, and the borders of Efát.

It will thus be seen that four districts are asserted to produce myrrh, namely—1. the country about Ghizan, on the eastern shore of the Red Sea; 2. the southern Arabian coast eastward of Aden; 3. the Somali country south and west of Cape Gardafui; and 4. the region lying between Tajúra and Shoa, including Harar to the south-east.

Furthermore, there are certainly three varieties of myrrh which may well be derived from as many distinct species of myrrh-tree.

What are required for the botanical elucidation of the origin of myrrh are numerous, well-preserved, pressed and dried specimens of the tree, which ought to include, in addition to foliage, the flowers and fruits; specimens of the exudation of the tree should also be collected, in order that competent persons may pronounce whether it is true myrrh or not. Information as to the collection of the drug in any one of the localities named could not fail to be of interest.

The myrrh-trees appear to be of low stature and unattractive aspect, rigid, often spiny, with scanty foliage, minute flowers, and small, oval, dry berries.

* 'Journal of Royal Geographical Society,' xix. (1849), 65, 66.

GREEN IODIDE OF MERCURY.*

BY JULES LEFORT.

The green iodide of mercury, as hitherto prepared, is one of the most unsatisfactory mercurial salts in respect to stability. On this point the medical man and the pharmacist have long been in accord; for many therapeutists, M. Devergie† in particular, who have specially studied the action of this compound, consider it to be a medicament of doubtful value, and in any case to be very inferior to the red iodide. Indeed, it cannot well be otherwise, as it is known that the green iodide prepared by the direct action of iodine upon mercury, is always a mixture of the true mercurous iodide, a variable proportion of metallic mercury and sometimes of the red iodide, the colour varying from a dark green to a yellowish green, according to the care taken in its preparation.

Some chemists have been so convinced of the im-

* Paper read before the Paris Society of Pharmacy, March 5. 1873. From 'L'Union Pharmaceutique,' vol. xiv. p. 75.

† 'Bull. Thér. Méd. et Chirurg.,' Nov. 30, 1871.

perfection of the present mode of preparing this compound, that they have sought to obtain a better preparation by the double decomposition of a mercurous salt—such as the acetate or the nitrate—and an alkaline iodide, such as iodide of potassium. But, as is well known, these mercurous salts are not soluble in water except in presence of excess of acid; and if such solutions be treated with iodide of potassium, the free acid displacing a small quantity of iodine produces a mixture of red iodide of mercury and metallic mercury, which contaminates the precipitate. Of course the mercuric iodide is always easily separated from such a mixture; but such is not the case with respect to the metallic mercury which accompanies the green iodide through all the reactions to which it may be submitted.

In order to prepare the green iodide by double decomposition, the problem consists in finding a mercurous salt very soluble in water and neutral to test-paper. This I believe I have met with in the double pyrophosphate of soda and mercurous acetate, a salt which is included in the catalogue of double pyrophosphates which have been described by Persoz* and Pahl.† It is known, in fact, that the pyrophosphate of soda possesses the property of forming, with many salts and metallic oxides, definite compounds generally very soluble in water. Now I have found that with *chemically pure* pyrophosphate of soda mercurous acetate forms a compound which crystallizes in fine needles, changing after long exposure to air, but very soluble, without decomposition, in water. This salt, dissolved in a sufficient quantity of water, mixed with an equally dilute solution of iodide of potassium, yields a fine yellowish green precipitate, having exactly the composition HgI. As to the pyrophosphate of soda, it appears to take no part in the reaction unless it be to present the mercurous acetate to the iodide of potassium in a state of solution.

To prepare the pyrophosphate of soda and mercurous acetate, 60 grams of pure crystallized pyrophosphate of soda are dissolved in 300 grams of warm distilled water. After the solution becomes cool, 30 grams of mercurous acetate are added, and the mixture is left to react during several hours at ordinary temperature, assisted by occasional shakings. If the pyrophosphate of soda is chemically pure, the mercurous acetate is entirely dissolved, without the slightest decomposition; but such is not usually the case. During the action of the red heat upon the neutral phosphate of soda, to convert it into pyrophosphate, there appears to be a partial separation of the phosphoric acid from the soda, or a temperature too high and too long-continued eliminates a little phosphoric acid, so as to leave in the product of calcination a little free alkali. Practically, the pyrophosphate of soda usually reduces a small quantity of the mercurous acetate to a mercuric salt and metallic mercury. This fact has no other importance than slightly diminishing the yield of green iodide, and may be avoided in great part by care in choosing pyrophosphate of soda as pure as possible.

The solution of pyrophosphate of soda and mercurous acetate is filtered and added to another volume of distilled water. A solution of 30 grams of iodide of potassium in a litre of water is then poured in a little at a time, shaking after each addition. When the salts are perfectly pure, the precipitate produced is at first brownish green, then green, in which state it much resembles green oxide of chromium; but when it settles at the bottom of the vessel it has a yellowish green tint, which would lead to the presumption that it is a polychromatic salt. Neither in the first nor in the last phase of the precipitation is there any iodine or mercury set free, as is the case when mercurous nitrate and iodide of potassium is used. But should the solution of pyrophosphate of soda and mercurous acetate contain, as is usually the case, a little mercuric acetate, then towards the end of the operation a small quantity of red iodide is seen colouring the liquid a pale red; but it is easy to get rid of this by means of a slight excess of solution of iodide of potassium, which, thus diluted, does not decompose the green iodide of mercury. As a further precaution, the absence of mercuric iodide may be ensured by washing the precipitate with warm concentrated alcohol. The green iodide, washed sufficiently by decantation and afterwards collected upon a filter, should be dried at a moderate heat, and sheltered from the light.

The process described above is much more costly than that usually followed, but I consider the quality of the product obtained so superior as to remove any such objection.

THE MICROSCOPE IN PHARMACY.

BY HENRY POCKLINGTON.

(*Continued from p.* 762.)

Simarubæ Cortex.—Not in the B.P., but sufficiently generally used to be admitted here. General structure loose and spongy; medullary rays narrow and sinuous, or wider and straight; liber cells small, not numerous, and with thin walls; stellate cells numerous, large, porous, isolated, and aggregated in groups of three to six, sometimes more. Such is a brief general description of the structure of this bark, and with a few remarks on the more important points will suffice.

The first point that strikes one is the exceeding thinness of the walls of the whole of the cells excepting the stellates, and the thickness and solidity of the walls of the stellate cells. The whole structure, apart from these latter cells, is that of an endogenous water plant, so far as regards shape and delicacy of the cells. The liber cells themselves are almost wholly unthickened, and short tubular cells with relatively large central cavities. With these are associated almost perfectly globose, thin cells, containing prismatic, doubly refractive crystals, minute, and easily mistaken for small air-bubbles. Exceptionally long liber cells occasionally occur, and are apparently very minutely porous. The existence of pores can only be inferred from certain dispersive optical phenomena; they are entirely invisible under as high a power as can be used upon these tissues with success.

The stellate cells have generally very large central cavities, the smaller cells being nearly filled; they are very hard, minutely porous, and the successive depositions of sclerogen can only be seen with difficulty, in many instances, after the prolonged use of powerful reagents.

It is not an easy bark to examine, and cannot be properly examined when dried. An investigation of a fresh specimen would be interesting. A dried specimen affords a good subject wherewith to test the progress of a student. Magenta-stained sections are the most useful. Transverse sections unstained show but little. Radial sections are at once the most difficult to make and the most valuable. The absence of the bark from the Pharmacopœia, and the impossibility of studying it in dried specimens, are sufficient excuses for treating it with greater brevity than its interest structurally warrants.

The Cinchonas and a new candidate or two for pharmaceutical favour now only remain of the barks. Of the Cinchonas Mr. Howard has written so exhaustively that little remains to be said, save only from the microspectroscopic point of view. I shall therefore restrict myself to saying just enough to place before my readers the salient features of Cinchona structure, and to noting a few points of interest arising out of a spectroscopic examination of the colouring-matters of the bark, this latter serving as an introduction to the more serious microspectroscopic investigation of the coloriferous woods that will shortly engage our attention. Before touching the Cinchonas, however, I will say a little about the new candidate, and perhaps their some-day rival, *Eucalyptus globulus,* for very fine specimens of the bark and leaves of which plant I am indebted to the liberality of Messrs. Savory and Moore.

PERFUMES PHYSIOLOGICALLY AND COMMERCIALLY CONSIDERED.*

BY JAMES PATON.

Assistant Keeper, Museum of Science and Art, Edinburgh.

(*Concluded from p.* 805.)

Among animal perfumes, which are limited to three, musk deserves, from its importance, the first notice. Musk is secreted in a small follicle or pouch, termed in commerce a pod, which is found between the navel and the preputial orifice of the adult male alone of a small species of deer, *Moschus moschiferus.* The creature is nocturnal in its habits, exceedingly timid and fleet of foot, and therefore very difficult to stalk, if we may use such an expression. The animal is about the size of a greyhound, is hornless, and has two projecting canine tusk-like teeth developed in the upper jaw. The musk deer is very widely distributed in the mountainous regions of Central Asia, going northward from the slopes of the Himalayas, over the new kingdom of Kashgaria, and stretching even into Asiatic Russia, the length of Lake Baikal, and the course of the Yeniseisk. To the east it is found in the hilly regions of Assam and in the Chinese province of Sechuen, from which the finest qualities of musk are imported. Col. Markham, in his 'Journal of Sporting Adventure and Travels in Chinese Tartary and Thibet,' says:—"The musk, which is much better known than the deer itself, is only found in adult males; the females having none, neither has any portion of their bodies the slightest odour of musk. The dung of the males smells nearly as strong as musk; but, singularly enough, neither in the contents of the stomach nor bladder, nor in any other part of the body, is there any perceptible scent of musk. The pod which is placed near the navel, and between the flesh and skin, is composed of several layers of thin skin, in which the musk is confined, and has much the appearance of the craw or stomach of a partridge when full of food. There is an orifice outward through the skin, into which, by a slight pressure, the little finger will pass; but it has no connection whatever with the body. It is probable that musk is at times discharged through this orifice, as the pod is often found not half full, and sometimes even nearly void. The musk itself is in grains from the size of a small bullet to small shot. In autumn and winter the grains are firm, hard, and nearly dry; but in summer they become damp and soft. For two years after the birth of the animal the contents of the pod remain a soft milky substance, with a disagreeable smell. When it first becomes musk there is not much more than the eighth of an ounce. Though not so strong, the musk of young animals has a much pleasanter smell than that of old ones; but difference of food, climate, and situation, as far as my experience goes, does not at all affect the quality. . . . In many respects they are not unlike hares in their habits and economy. Each individual selects some particular spot for its favourite retreat, about which it remains still and at rest throughout the day, leaving it in the evening to search for food or to wander about, returning soon after daylight. They will occasionally rest for the day in any place where they may happen to be in the morning, but in general they return to near the same spot almost every day, making forms in different quarters of their retreat a little from each other, and visiting them in turn. . . . They seldom, if ever, lie in the sun, even in the coldest weather, and their forms are always made where there is something to shelter them from its rays. Towards evening they begin to move, and during the night they appear to wander about a good deal from top to bottom of the hill, or from one side to another. Their nocturnal rambles are apparently as much for recreation as in search of food, as they often visit regularly some steep ledge of rock or precipice, where there is little or no vegetation. The Puharries believe that they come to such places to play and dance with each other, and often set their snares along the edge of such a ledge or precipice in preference to the forest. In most of the hill states the musk deer is considered as royal property. In some the Rajahs keep men purposely to hunt it, and in Gurwhal a fine is imposed upon any Puharrie who is known to have sold a musk-pod to a stranger. In some districts they are hunted down with dogs, but snaring is by far the most common method practised for their capture; a few are occasionally shot by the village shikarries when in pursuit of other animals, but the match-lock is seldom taken out purposely to hunt musk deer, for a hill shikarrie does not carry the match lighted, and the deer being generally come upon face to face, almost every one would get away before he could strike a light and apply it to the match."

Three kinds of musk find their way into the English market, the first of which, Kabardeen, or Russian musk, comes to us from Siberia through Russia. It is of a very inferior quality, being poor in odour, and is said to be the produce of a different species from the Himalayan musk deer, called *Moschus Sibiricus.* The pods are large, and usually are to be depended on as to genuineness, which is much more than can be said for the pods we import in caddies from China. The Chinese musk generally is valued at from four to six times as much as the Russian, and in buying this very dear substance the purchaser would require to beware of bargaining for a pig in a poke. It is frequently adulterated with baked blood, dried liver, bark, pellets of lead, etc., to such an extent that only the smell of the orginal tenant remains in the pod. The perfumers further distinguish Assam musk from the Chinese or Tonquin musk, by its possession of a much more rank smell than that imported from China. Regarding the musk of the Western Himalayas, I find the following note in the catalogue of the Agra Exhibition of 1867:—"The Simla musk balls, which are presented as complimentary nazars by hill chiefs, are an inferior kind, and do not command anything like the price of the genuine Thibet balls. About 100 musk bags are imported from Changthan *viâ* Yarkand, of which about forty go to Yarkand; the rest

* Read at a meeting of the North British Branch of the Pharmaceutical Society, March 28, 1873.

go to Kashmir and Jammu, and are taken by Yarkand pilgrims to Mecca, for sale in India or other Asiatic countries. They are produced in the north-west of Rodokh and Nepal, and valued at Le (in Kashmir) from seven to fifteen rupees, at Yarkand from twenty-one to twenty-six rupees. In former times, musk bags of the Dasht-i-Khuttan, or great Tartar Desert, were in high repute, and fetched at the least forty-two rupees; but all supply from that quarter has long ceased."

Among animal perfumes musk not only stands pre-eminent, but in many respects it is the most wonderful material nature places at the disposal of the perfumer, and it has in all times been the most highly prized among the oriental peoples who possessed or could purchase it. According to the author and prophet of the Mussulman faith, the floor of the seventh heaven, or paradise of the faithful, is composed of pure wheaten flour mixed with musk and saffron, and the black-eyed houris who will welcome the immortal braves to these realms of odoriferous bliss are themselves fashioned out of pure musk. So enchanting to the senses of the followers of the prophet is the odour of musk, that it is said there exist two mosques in the mortar of which an enormous quantity of pure musk was mixed up; and such is the penetrating and enduring odour of this substance, that probably the perfume will continue powerful and persistent as long as the finger of time permits the walls to hold together.

Besides the *Moschus moschiferus*, which is practically the only source of musk in commerce, many other animals and even plants are possessed of a powerful musk odour. Among the creatures possessing the scent are the musk ox, *Ovibos moschatus*, of the northern regions; the musk rat of India, *Sorex myosurus;* the European musk rat, *Mygale moschata;* and of all other sources, the alligators and crocodiles of both hemispheres. This source of musk is well-known and utilized in India, as an extract from the catalogue of the Madras Exhibition of 1855, speaking of the alligator in Travancore, will show. "Musk," it says, "is taken from the glands of the jaw, which is very fine if well prepared, and separated from the flesh, otherwise it will give a very bad smell." Among the articles exhibited by Egypt in the Paris Exhibition of 1867, there occurred the musk of the crocodile as one of the ingredients in Egyptian perfumery. Many insects are also powerfully pervaded with an odour of musk. Among plants possessing the odour there may be named the seeds of *Abelmoschus moschata*, and the *Mimulus moschatus*, an American importation common in nearly all gardens, and which has taken so kindly to many of our water-courses that the whole reach of many of our streams is yellow with them in July. The most powerful odour of musk is, however, contained in the Sumbul or musk-root, *Hyalolena Siverzovii*, an umbelliferous root which comes to us from Afghanistan.

Civet must have been in the days of Shakespeare a very fashionable perfume, judging from the frequency of his allusions to that substance; and coming down even to the time of Cowper, we find the substance singled out for mention, though perhaps not what Exhibition juries term "honourable mention."

> "I cannot talk with civet in the room,
> A fine puss gentleman, that's all perfume."

It does not appear that the fine puss is here put in with any special purpose, but it occurs quite appropriately when we know that civet is yielded by several species of animals of the cat tribe, chiefly by *Viverra civetta*, or the civet, which occurs in the hottest regions of North Africa and Abyssinia, and *Viverra zibetha*, or the zibeth, a native of the Philippine Islands. Besides these animals there are various allied species of *Viverra* and *Viverrula*, which occur throughout India, all possessed of a civet pouch. The civet apparatus is present in both the male and female, and consists of two glands or sacs, placed in the neighbourhood of the genital organs, the inner surface of the sacs being pierced with a number of apertures communicating with the glandular follicles which secrete the material. Civets used to be kept in confinement in Dutch towns for the purpose of growing the scent; and at the present day the animal is reared in some parts of Africa in a semi-domesticated condition, and has its civet apparatus cleaned out with a long wooden spoon twice or thrice a week. Civet has in its natural condition anything but a pleasant odour, but in a highly dilute condition it combines most effectively with other odours and imparts to them both permanence and pleasing floral fragrance.

The source of ambergris was for a very long time a profound mystery, and the guesses hazarded about its origin were about as numerous as they were ridiculous. It was found sometimes floating on the surface of the open ocean, and most frequently cast up upon shores so far apart that it can scarcely be said ambergris belongs to one part of the sea more than another. From the coasts of Greenland, Iceland, both sides of America, the islands of the Indian seas, China and Japan, it has been brought. It was supposed at one time to be a balm which grew on sea cliffs just as fungi do on trees; then the dried saliva of whales, the excrement of birds, condensed froth of the sea, etc., etc. It is really formed, whether as a morbid secretion or not is not quite evident, in the alimentary canal of the sperm whale, from specimens of which it has frequently been extracted. Though it is usually obtained in pieces of from 2 oz. to 1 lb. it has been found in enormous masses. In 1691 a piece was found on the beach in county Sligo weighing 62 lbs. which sold in London for above £100. In 1695 the East India Company had a mass weighing 160 lbs. and it is said that pieces of as much even as 860 lbs. have been found, which is rather too much for the whale to contain, or for us to swallow comfortably. Ambergris has a mild sweet odour, not of much value by itself, but it mixes effectively with other perfumes, giving them ethereal odour and some amount of permanence. It is in great favour among oriental nations, where musk, ambergris, sandalwood and rose may be said to be the basis of the system of perfumery.

The time at our disposal will not permit of any extended notice of the most important series of perfumery materials, which are derived from the vegetable world, and to only one or two of the chief substances can any allusion be made. A very important series of substances which enter largely into the art of the perfumer, I have already had the pleasure of noticing in some detail in a paper on oriental spices formerly contributed to this society. Among vegetable sources of perfume the rose stands preeminent, as it has ever been the favourite flower in all regions of the globe, and as such sung by the poets. The first preparation of rose water is attributed to Avicenna in the tenth century, and there is an Indian story of a somewhat romantic air, which assigns to Noor Mahal, the wife of the famous Emperor Shah Jehan, the first discovery of the otto or Attar of roses. Doubtless otto of roses has for some centuries been prepared in India, and to the present day the finest and by far the most precious otto is prepared there. The otto, however, which supplies our markets comes from nearer home, a part of it being produced on the flower farms of Nice, on the Mediterranean coast of France; and the chief supply, not only of England but of all commerce being derived from the province of Adrianople in Turkey. The rose farms which thus supply the world with this prized odour, are chiefly situated on the southern slopes of the Balkan range, where the species cultivated are chiefly *Rosa damascena*, *R. sempervirens* and *R. mo chata;* this last, the musk rose, being that from which Indian otto is prepared. The roses, which are planted in rows, like vines in a vineyard, and are frequently interspersed with vine stocks, produce light red blossoms in the month of May, when the rose harvest takes place. The harvest is a somewhat precarious one, depending for its success on many influences of the atmosphere and weather, such as sudden frosts, the amount of heat, and moisture, etc., besides which the plants are subject to the attack of caterpillars. The entire flower is plucked and submitted to distillation, with its calyx attached. The distilling apparatus consists of a copper boiler tinned externally as well as internally, into which the roses are introduced with water, in the proportion of 50 measures of water to from 10 to 20 of roses. From the distilling apparatus a tube leads into a condensing vat of a primitive description, and the distillate is thence delivered into vasiform bottles of earthenware. It takes two hours boiling to complete the distillation of one charge, and the combined otto and water which come over, are separated by a long spoon funnel which has an aperture so small that it allows the water to escape, but retains the thicker otto. The best qualities of otto freeze at the lowest temperature, the freezing point ranging from 50 to 68° F. On an average 5000 lbs. of roses yield 1 lb. of otto. A substance of so much value of course presents too great temptation to adulteration to be resisted by the conscience of those who deal in it; and it is believed that adulteration is more the rule than the exception; purity in all cases being only a question of degree, and never becoming absolute. The adulterating medium is chiefly the varieties of oil yielded by the Andropogon grasses, and which go by the names of geranium, lemon grass, citronelle, verbena, etc. The oil is prepared for exportation by being put up in tinned copper flasks, which when filled are soldered up, or in gilt glass stoppered bottles, which generally contain inferior qualities. An average year's crop of Adrianople roses yields about 800,000 drams of otto, but for several years the produce, owing to unfortunate circumstances, has fallen off. The produce of 1871 amounted only to 540,000 drams, which was purchasable at 2*s.* 9*d.* per dram, f. o. b. at Gallipoli, equal to £10 10*s.* per lb. In 1867 the price f. o. b. at Gallipoli was 3*s.* 7½*d.* per dram, in 1868, 2*s.* 11*d.*, in 1869, 3*s.* 2*d.*, and in 1870, 2*s.* 11*d.*, and in each year the Turkish customs duties were being reduced 1 per cent., so that the duty, which amounted in 1867 to 5 per cent., was in 1870 only 2 per cent.

The lecturer subsequently noticed various other vegetable sources of perfumery, among which were sandalwood vanilla, the *Andropogon* grasses, Tonquin beans, and patchouli. Specimens of all these substances were exhibited to the meeting, besides stuffed specimens of various species of civets and the musk deer, and the substances which too frequently occupy the pod which should be filled with musk. The lecture concluded as follows—

In the department of the Alpes Maritimes, on the Mediterranean coast of France, flower farming is the staple occupation, and has attained an enormous expansion, and there the extraction of their odoriferous principles has become the leading manufacture. In the French reports on the Exhibition of 1867, it is stated that the trade in flowers and perfumery therefrom in the department amounted to 14,000,000 of francs, and that the yearly produce was 50,000 kilos. of essences, 450,000 kilos. of pomades or scented fats, 225,000 kilos. of perfumed oils, 3,000,000 kilos. of perfumed waters, and 35,000 kilos. of extracts. The flower trade has also become an important feature in the French Colony of Algeria, and some portions of Turkey are devoted to the cultivation of the rose, while in the East the rose, sandalwood, andropogons, patchouli, and the spices, are cultivated for our commerce. At Mitcham, near London, there exist considerable flower farms, chiefly for the cultivation of lavender and peppermint, the two substances, in which alone, as I have already mentioned, we excel. As far as can be made out from the Board of Trade returns, our perfumery trade in 1871 consisted of—Imports

Perfumery, 673,661 lbs., value . . .	£66,710
Essential or perfumed oils, 530,410 lbs., value	174,916
Perfumed spirits, including Eau de Cologne, 31,708 gals., value . . .	58,044
Giving a total value of . . .	£299,660

This of course represents only a small portion of an actual trade in perfumery and its materials which either escape classification, or are placed under other heads. In the same year we exported of perfumery of all sorts to the declared value of £135,444, besides of essential oils in which medicinal are confounded with the perfumes to the value of £226,389. These Board of Trade returns, however, can scarcely possess the value of a rough approximation to the extent of the perfumery trade, for besides the imperfect manner in which they are made up, the system of classification is so mysterious, and the heads under which the returns are made are so vague and general, that they possess only a significance of an uncomplimentary nature, and can lay claim to no higher utility than satisfying the not very exacting official conscience.

GENERATION OF SULPHURETTED HYDROGEN FOR LABORATORY OPERATIONS.*

BY W. SKEY.

In a paper read before the Wellington (New Zealand) Philosophical Society, the author stated that sulphuretted hydrogen was evolved from the surface of the sulphide, in the reaction of sulphides with zinc in acidified water, the zinc being oxidized and the sulphur of the sulphide hydrized. This reaction he now proposes to utilize in the generation of sulphuretted hydrogen for use in laboratory operations, by mixing well together equal proportions of fragments of galena and granulated zinc in a small apparatus of the kind generally in use for the preparation of this gas and adding dilute hydrochloric acid (1 to 20). Sulphuretted hydrogen is instantly given off, and its evolution proceeds energetically and regularly for a great length of time. A little hydrogen accompanies the sulphuretted hydrogen, which would not be objectionable in ordinary operations, together with traces of hydrochloric acid, which may be easily removed by passing it through a little carbonate of lime.

A better method is to use the zinc and the sulphide in mass, connecting them electrically by means of wires passing through the cork of the apparatus, which are only allowed contact with each other by means of proper connecting screws. The evolution of gas commences immediately upon making connection of the wires, and if care be taken to keep the zinc and sulphide from direct contact instantly ceases upon their disconnection. For this last method it is necessary to amalgamate the zinc.

THE TESTING OF FLOUR AND BREAD.†

BY J. ALFRED WANKLYN.

In the course of my work for the chemical section of a Manual, which Messrs. Smith and Elder are publishing, for the guidance of Medical Officers of Health and Public Analysts, I have had occasion to make some original observations on the subject of flour and bread, which appear to be called for at the present time. Notoriously, the detection of alum in bread is beset with difficulties, and is in a very unsatisfactory condition. This depends partly on the excessively small proportion of alum which is put into bread, and partly on the difficulty in dealing with alumina in presence of the ash of bread, which, as is well known, contains phosphoric acid, along with magnesia and lime, as well as silica. It has already been insisted upon by various authorities, that the testing for alum should not be on too small a scale: 100 grams of flour or 200 grams of bread appear to me to be proper quantities to operate upon; and I find that similar quantities have been recommended before. The novelties that I am introducing are, first, the acceleration of the incineration by the use of a jet of oxygen gas directed on the ignited mass. This is by no means unimportant, inasmuch as otherwise the task of incinerating 100 grams of flour might last for a few days. Secondly, instead of using nitric or hydrochloric acid for the attack of the ash, I use

* Abstracted from a paper in the *Chemical News*.
† From the *British Medical Journal*.

sulphuric acid; and, thirdly, I use weighed quantities of reagents, and as little as possible of them, and at the same time avoid all unnecessary dilution. Attention to these particulars renders the detection of alum in bread a certainty. I will give an outline of the process.

The ash from 100 grams of flour weighs 700 milligrams, and, in a case of aluminized flour, may contain some 30 milligrams of alumina in addition. I moisten this ash with a measured 0·5 cubic centimetre of oil of vitriol, then heat up until the oil of vitriol begins to volatilize, whereby the silica is rendered insoluble and the attack of the alumina in the ash is insured. Having done this, and allowed the ash to cool, I dilute with a little water and filter. The filtrate is then treated with 1½ gram of pure caustic potash, which renders it alkaline and redissolves the alumina. The solution is then filtered, and the filtrate treated with 1½ gram of chloride of ammonium, and boiled and allowed to stand, whereupon the alumina is precipitated as phosphate of alumina, which admits of being got on a filter, washed, ignited, and weighed.

The advantage gained in this instance by using weighed quantities of reagents, and by avoiding dilution, will commend itself to chemists, who will not fail to recognize that, though there be difficulty in insuring that an indefinite quantity of acid and alkali shall be quite free from alumina and silica, there is not much difficulty in getting 1 gram of sulphuric acid, 1½ gram of potash or soda, and 1½ gram of chloride of ammonium, so as collectively not to contain a couple of milligrams of alumina or of silica.

The testing whether flour be sound or not by the strength of the aqueous extract is not new, but has been developed and rendered easily practicable in the course of my experiments. The basis of the method is, that in sound flour there is very little sugar and dextrine, but that in unsound flour there is either much sugar and dextrine, or else that a short exposure to the action of water converts much of the starch of the flour into dextrine and sugar. In the space of an hour and a half, I can by a little management make a determination of the quantity of extractive given by a sample of flour. I take 100 grams of the flour, mix it well with some water, and then dilute the whole mass with water until it occupies exactly half a litre. I then pour it on a dry paper filter in a dry funnel, whereupon the liquid runs through tolerably rapidly at first; by and by, as is known, such a filter will become clogged up, but not until at least some 50 cubic centimetres of filtrate have run through. These may be measured and evaporated down to dryness in the water-bath, and the residue weighed. Ten times the residue yielded by the 50 cubic centimetres is equal to the amount of extractive yielded by 100 grams of the flour. The extractive furnished by 100 grams of sound flour is 4·69 grams. Of this, 0·44 gram is ash and 0·92 gram vegetable albumen, leaving 3·33 grams of dextrine, sugar, and gum. If sound flour be left for twenty hours in contact with cold water, and then the aqueous extract be taken, it will be found to be increased somewhat: I found it to be 6·01 grams. In unsound flour, Odling has found 12 and 18·2 grams of extractive per 100 grams of flour. I believe that Odling first proposed the determination of the amount of extractive yielded by flour to cold water as a test of the soundness of flour. I am inclined to the belief that this test may be made very practicable and valuable.

THE VAPOUR-DENSITY OF POTASSIUM.*

BY JAMES DEWAR AND WILLIAM DITTMAR.

Since the elaborate experiments of Deville and Troost on the vapour-densities of substances at high temperatures, little has been added to chemical science in this field of research. Doubtless this is in great part owing to the difficulty of any *one* student manipulating the complex apparatus necessary for the execution of the experiments. But the operations are greatly increased in difficulty when we select bodies that are readily inflammable in air and attack with facility glass and porcelain at the high temperatures to which they are exposed. This is the reason why the molecular weights of a most important class of elementary bodies, viz. the *alkali metals* (although these are volatile at moderate temperatures), have remained to the present time undetermined. It was with the view of adding something to our knowledge in this department, that we recently undertook some experiments with potassium, the results of which we now beg leave to lay before the Society. The special difficulties we had to overcome are involved in the endeavour to answer the following questions:—

1. Is it possible to convert potassium into a gas of one atmosphere's pressure at any of the *constant* temperatures we can at present command?

2. Is it possible to generate *pure* potassium-vapour and to keep it from getting oxidized?

3. Supposing a definite volume of such vapour to have been procured, how can its *weight* be ascertained?

After a succession of failures, which we shall not detail, we at last succeeded in devising a workable process, which may be briefly described as follows:—

A cylindrical iron bottle of at least 200 cub. centims. capacity, of a thickness in the body ensuring sufficient rigidity at even a bright red heat, and provided with a well-ground inbent neck, pierced with a canal of about 2 millims. in diameter, is employed as a generator and receptacle of the vapour.

A mass of about 20 kilogrs. of zinc contained in a plumbago crucible, which, being placed in a forge-fire, can be readily heated up to the boiling-point, serves as a bath.

The experiment begins by first deoxidizing the inside of the receptacle at a red heat by means of a current of dry hydrogen, which is continuously maintained until the bottle has cooled down below redness. At this stage about 200 grms. of pure mercury are introduced into the bottle, which is then inserted into the red-hot zinc, without, however, covering the upper extremity of the bottle. After ¾ of the mercury is distilled off (which is accomplished in a very short time), the neck is withdrawn, and while the mercury-vapours are still streaming out, an iron test-tube, previously prepared with great care and charged with 4–5 grms. of potassium, is dropped into the bottle, the neck reinserted, and after the *whole* of the bottle has been immersed into the zinc, the blast of the forge is forcibly increased so as, in the shortest possible time, to bring the zinc into the state of boiling, proper arrangements being made for keeping the neck of the bottle red-hot. The potassium in a short time begins to volatilize, issuing in jets into the air, and depositing caustic potash at the nozzle, which must be kept clear by means of an iron wire. As soon as the distillation of the potassium ceases, the nozzle is closed by means of a ground-in wire plug, at once immersed into a mass of mercury contained in a test-tube, and the bottle withdrawn to a proper support, on which it is allowed to cool.

After it has reached a manageable temperature, the bottle is inserted into a mass of recently boiled water, the wire plug withdrawn, and the hydrogen formed by the action of the water on the potassium pumped out, by means of a "Sprengel," into a eudiometer, to be measured.

In the experiments we have hitherto carried out, we have satisfied ourselves that the amount of mercury-vapour *not* swept out by the potassium is quite inappreciable; and as our object has been in the meantime to merely arrive at approximate results and to perfect our methods of manipulation, we have neglected the minute correction, which, on account of that small remnant of mercury, ought, strictly speaking, to have been applied to the volume of the vapour as calculated from the capacity of the bottle in the cold, the coefficient of expansion of iron, and the temperature (1040° Deville) at which the vapour was measured.

* Paper read before the Royal Society, March 6, 1873.

The results of our observations conclusively show that the density of potassium-vapour, as produced in the process described, cannot exceed 45 times that of hydrogen, and that therefore the molecule of potassium consists of *two atoms* (K_2).

We intend to prosecute our research in other directions, proposing to ascertain, if possible, the densities of the *iodides* of cæsium, rubidium, and potassium, these being, according to Bunsen's experiments, the most volatile of the haloids of the alkali metals.

PROFESSOR TYNDALL ON LIGHT.*

(*Continued from p.* 807.)

And now we have to push these considerations to a final illustration. Polarized light may be turned to account in various ways as an analyser of molecular condition. I hold in my hand a strip of glass six feet long, two inches wide, and a quarter of an inch thick. Holding it by the centre between my finger and thumb, I sweep over one of its halves a wet woollen rag; you hear an acute sound, due to the vibrations of the glass. What is the condition of that glass while the sound is heard? This: its two halves lengthen and shorten in quick succession. Its two ends, therefore, are in a state of quick vibration; but what is the condition of the centre? Here the pulses from the two ends alternately meet and retreat. Between their opposing actions the glass at the centre is kept motionless; but on the other hand it is here alternately strained and compressed. The state of the glass may be illustrated by spots of light, as the propagation of a sonorous pulse was illustrated in a former lecture. Here is a row of spots, which by a simple mechanical contrivance are made to vibrate to and fro. You notice the terminal dots have the largest amplitude of vibration, while those at the centre are alternately crowded together and drawn apart. The condition of this sounding strip of glass is here correctly represented.

Now, supposing we introduce the glass between the crossed Nicols, taking care to keep the strip oblique to the direction of vibration of the Nicols; and that we sweep our wet rubber over the glass, what will occur? At every moment of compression the light will flash through; at every moment of strain the light will flash through; and these states of strain and pressure will follow each other so rapidly that we may expect a permanent luminous impression upon the eye. By pure reasoning, therefore, we reach the conclusion that the light will be revived upon the screen whenever the glass is sounded. That it is so, experiment testifies: at every sweep of the rubber a fine luminous disk flashes out upon the screen. The experiment may be varied in this way: Placing in front of the polarizer a plate of ornamented glass, you have those beautiful coloured rings, intersected by a black cross; every sweep of the rubber not only abolishes the rings, but introduces complementary ones, the black cross being for the moment supplanted by a white one. This is Biot's experiment, though his apparatus confined the observation of it to a single person at a time. But we have to follow the ether still further. Suspended before you is a pendulum, which, when drawn aside and then liberated, oscillates to and fro. If, when the pendulum is passing the middle point of its excursion, I impart a shock to it tending to drive it at right angles to its present course, what occurs? The two impulses compound themselves to a vibration oblique in direction to the former one. But the pendulum, as you see oscillates, in a plane. But if the rectangular shock be imparted to the pendulum when it is at the limit of its swing, then the compounding of the two impulses causes the suspended ball to describe, not a straight line, but an ellipse; and if my shock be competent of itself to produce a vibration of the same amplitude as the first one, the ellipse becomes a circle. But why do I dwell upon these things? Simply to make known to you the exact resemblance of these gross mechanical vibrations to the vibrations of light. I hold in my hand a plate of quartz cut from the crystal perpendicular to its axis. This crystal thus cut, possesses the extraordinary power of twisting the plane of vibration or a polarized ray to an extent dependent on the thickness of the crystal. And the more refrangible the light, the greater is the amount of twisting, so that where white light is employed its constituent colours are thus drawn asunder. Placing the quartz between the polarizer and the analyser you see this splendid colour, and turning the analyser in front, from right to left, the other colours appear in succession. Specimens of quartz have been found which require the analyser to be turned from left to right, to obtain the same succession of colours. Crystals of the first class are therefore called right-handed, and of the second class, left-handed crystals.

With profound sagacity Fresnel, to whose genius we mainly owe the expansion and final triumph of the undulatory theory of light, reproduced mentally the mechanism of these crystals, and showed their action to be due to the circumstance, that in them the waves of ether so act upon each other as to produce the condition represented by our rotating pendulum. Instead of being plane polarized the light in rock crystal is circularly polarized. Two such rays transmitted along the axis of the crystal, and rotating in opposite directions, when brought to interference by the analyser, are demonstrably competent to produce the observed phenomena.

I now abandon the analyser and put in its place the piece of Iceland spar, with which we have already illustrated double refraction. The two images of the carbon points are now before you. Introducing a plate of quartz between the polarizer and the spar, the two images glow with complementary colours. Employing the image of an aperture instead of that of the carbon points, we have two complementary coloured circles. As the analyser is caused to rotate, the colours pass through various changes: but they are always complementary to each other. If the one be red, the other will be green; if the one be yellow, the other will be blue. And here we have it in our power to demonstrate a statement made in a former lecture, on the authority of Helmholtz, that, although the mixture of blue and yellow pigments produces green, the mixture of blue and yellow lights produces white. By enlarging our aperture, the two images produced by the spar are caused to approach each other, and finally to overlap. The one is now a vivid yellow, the other a vivid blue, and you notice that where the colours are superposed we have a pure white.

This brings us to a point of our inquiries which though not capable of brilliant illustration, is nevertheless, so likely to affect profoundly the future course of scientific thought that I am unwilling to pass it over without reference. I refer to the experiment which Faraday, its discoverer, called the magnetization of light. The arrangement for this celebrated experiment is now before you. We have put our electric lamp, then a Nicol's prism to polarize the beam emergent from the lamp; then an electro-magnet, then a second Nicol's prism, and finally our screen. At the present moment the prisms are crossed and the screen is dark. I place from pole to pole of the electro-magnet a cylinder of a peculiar kind of glass, first made by Faraday, and called Faraday's heavy glass. Through this glass the beam from the polarizer now passes, being intercepted by the Nicol's in front. I now excite the magnet, and instantly light appears upon the screen. On examination we find that by the action of the magnet upon the ether contained within the heavy glass the plane of vibration is caused to rotate, and thus get through the analyser.

I have already mentioned the two classes into which

---

* Abstract of a series of lectures delivered in the Cooper Institute, New York, and reported in the *New York Tribune.*

quartz crystals are divided. In my hand I hold a plate, one-half of which consists of a right-handed and the other half of a left-handed crystal. Placing the plate in front of the polarizer, and turning one of the Nicols until the two halves of the plate show a common puce-colour, we have an exceedingly sensitive means of rendering the action of a magnet upon light visible. You observe that by turning either the polarizer or the analyser through the smallest angle, the uniformity of the colour disappears, and the two halves of the quartz show different colours. The magnet also produces this effect. The puce-coloured circle is now before you on the screen. Exciting the magnet, one-half of the image becomes suddenly red, the other half green. Interrupting the current, the two colours fade away and the primitive puce is restored. And now observe that the action depends upon the polarity of the magnet, or in other words, on the direction of the current which surrounds the magnet. Reversing the current the red and green reappear, but they have changed places. The red was formerly to the right and the green to the left; the green is now to the right and the red to the left. With the most exquisite ingenuity Faraday analysed all these actions and stated their laws. This experiment, however, long remained rather as a scientific curiosity than as a fruitful germ. That it would bear fruit of the highest importance, Faraday felt profoundly convinced, and recent researches are on the way to verify his conviction.

(*To be continued.*)

SECRETIONS IN PLANTS.

M. Van Tieghem has lately published a series of observations on the glands and reservoirs for secretions in plants, which it may be remembered were carefully studied, as far as circumstances would allow, two centuries ago, by our countryman, Nehemiah Grew. M. Van Tieghem shows that there are special cells set apart for the formation of special secretions. These cells may be isolated or aggregated. If on the surface or epidermis, they constitute the glandular hairs so common in plants; if in the interior of a plant they may —1, retain their original form; or, 2, they may be developed into branching tubes which are insinuated between the other cells, as in the branched laticiferous tubes of Euphorbias. If grouped they may form, 3, a special layer, as in Acorus; or, 4, they may be grouped into compact masses, as in the glands of the Orange and Myrtle; or, 5, they may be superposed in vertical ranks, may be simple or branched, and with or without obliteration of the party-walls or partitions, as in the true laticiferous vessels of Arads and Poppies; or, lastly, they may be arranged in a series of longitudinal threads ranged around an air canal or lacuna, the walls of which they line with a sort of epithelium of secreting cells.—*Gardeners' Chronicle.*

CHILBLAINS.

The *British Medical Journal* quotes a paragraph from the *Apotheker Zeitung* describing a solution of iodine and tannin, which F. Rhien has found to be a very efficient remedy for chilblains. About an ounce of tannin is dissolved in a pint of water, and 74 grains of iodine in $1\frac{3}{4}$ oz. of spirit of wine; the solutions are then mixed and enough water added to make the whole up to $2\frac{1}{2}$ pints. In applying it, which is best done at bed-time, the mixture is gently warmed over a slow fire, the affected part is dipped into it while still cold, and retained in it until the liquid on being stirred feels uncomfortably hot. The vessel is then withdrawn from the fire and the affected part dried over it. The vessel must be of earthenware or porcelain, and care must be taken not to use too much iodine, especially when abrasions are present.

THE JOHN CARGILL BROUGH FUND.

ADDITIONAL SUBSCRIPTION.

Watson, Cleave, and Co., Shanghai £5 0 0

A meeting of the General Committee, Mr. Daniel Hanbury, F.R.S., presiding, was held, by permission, at the London Institution on Tuesday, the 8th of April, when the Hon. Secretaries, Mr. Michael Carteighe, Mr. Alfred Marks, and Mr. W. Chandler Roberts, submitted their report and accounts, as also a scheme for administering the fund. In the report, it was stated that an appeal on behalf of the children had been made to the proprietors of the London Institution, the fellows of the Royal and Chemical Societies, and the members of the Royal Institution, and to others. The subscriptions received, including a grant from the Royal Bounty Fund of £150, in reply to a memorial drawn up by Mr. Roberts, and submitted by the Deputy-Master of the Mint, amount to about £1,500. In addition, subscriptions amounting to £200 are promised by the Savage Club, of which Mr. Brough was a member, and the sum of about £400 will be contributed by the Committee of Chemists and Druggists. After deducting expenses the net aggregate amount will be nearly £2,000.

A deed of trust of the usual kind was approved by the Committee, and the first trustees were appointed—Mr. Daniel Hanbury, F.R.S., Mr. Thomas Hyde Hills, and Mr. Michael Carteighe. It provides for the appointment of three trustees, in whose names investments in the ordinary trust securities are to be made. Power is given to the trustees to apply the interest, and such part of the capital as they may consider necessary, to the support, etc., of the children; the trust to terminate on the attainment of the age of twenty-one by the youngest child, when the unapplied portion of the fund to be paid to such one or more as the trustees may think proper. Vacancies in the number of trustees to be filled, if practicable, from members of the Committee, if not, from the subscribers.

The report further stated that two presentations to Christ's Hospital had been placed at the disposal of the family—one by a friend, the other by Mr. Alderman McArthur, M.P., the case having been investigated and recommended to him by Mr. Deputy Webster.

The Secretaries expressed their full confidence in the ability and judgment of Miss Brough, the aunt of the children, who has undertaken their guardianship, finding in her devotion the best reason for regarding with hopefulness the children's future. After a warm acknowledgement of the valuable assistance rendered by the members of the various committees, and especially by Mr. Thomas Piper, the Hon. Secretary of the London Institution, the report terminated as follows:—"The Honorary Secretaries feel that they would not be justified in concluding this report without assuring the General Committee that the generous sympathy and aid extended to the children have deeply touched the family, who regard the list of the several committees, comprising as it does so many honoured and distinguished names, as affording enduring testimony to the respect and affection in which Mr. Brough's memory is held."

The resolutions required to carry out the scheme having been passed unanimously, votes of thanks were accorded to the Treasurer of the Fund, Sir John Lubbock, Bart., M.P., F.R.S, Mr. Alderman McArthur, M.P., Mr. Deputy Webster, and the Chairman of the meeting.

Belladonna as an Antidote in Opium Poisoning.—In the Shanghai Hospital Reports for 1872 Dr. Johnston states that he has successfully employed atropia in cases of opium poisoning, a large number of which have come under his care. He has administered it hypodermically in quantities varying from one quarter to one-half a grain, repeating the injection if necessary after two hours. He did not find that injury resulted from the use of atropia in any of these cases.—*Medical Record.*

THE BENEVOLENT FUND.

THE art of spending money satisfactorily is perhaps, all things considered, at least as difficult as that of getting it together; and it is therefore not surprising that the disbursements in connection with the Benevolent Fund should evoke criticism, or that such criticism should sometimes be unfavourable. In calling attention to the subject in these columns a fortnight since, it was with the hope that there would be a free expression of opinion on both sides of the question; and it is with satisfaction that our "Correspondence" columns have been opened to the discussion. Nothing but good can result from such an interchange of views; for while, on the one hand, the Council will doubtless be glad to adopt any wise suggestion made, or to carry out any clearly expressed wish of a majority of the subscribers, on the other it affords an opportunity of disabusing some minds of the idea that a varying body of gentlemen, selected for their fitness and placed in the best position for estimating this among other matters, should have persistently acted contrary to the true interests of the Fund.

So much depends upon the manner in which the relief is given that it will not be out of place to recall the fact that the Society has now engaged to pay the sum of thirty pounds yearly to each of thirteen persons as long as they live. It has also been decided to elect two more annuitants upon the same terms in October next. Now, considering there is little probability that the number of annuitants will ever be allowed to fall below that number, many subscribers will agree with Mr. SANDFORD, that the "well-known rule in societies in granting pensions, to keep those pensions within the limit of the income arising from capital," is a wholesome regulation which should not be neglected by the Pharmaceutical Society. Nevertheless, in the latest official statement respecting the Benevolent Fund it was shown that the interest on the £13,200 invested moneys was insufficient to pay the then existing annuities.

Another point worthy of observation is that this sum of money does not consist entirely of the accretion of surplus from ordinary subscriptions and donations. On four separate occasions the sum of £500 has been voted from the General Fund of the Society; about £2500 was the result of public dinners in 1848 and 1867; and another £500 came in the shape of a legacy. Many will remember the vigorous efforts that were made for the special purpose of raising the funded property to £10,000, at a time when it was necessary that applicants for relief from the fund should be connected with the Society; but since then, by the operation of the Pharmacy Act, its benefits have been thrown open to all persons on the register and their widows and children.

So much being said upon the past policy of the Council in reference to the permanent charges on the Benevolent Fund, a few words may be devoted to the question of temporary relief. The small amount of money so spent has been animadverted upon; though, notwithstanding the surprise of our correspondent, J. B. B., it is undoubtedly true that hitherto "no genuine case of necessity presented to the Council has been left unaided by temporary assistance." But he is right in supposing that there are more than thirteen needy druggists or druggists' widows; for last year special grants, amounting to £148, were made to various persons,—a fact of which he does not appear to be aware,—and doubtless there are many others who have not applied for assistance. This department of the Fund will, however, have to be considerably developed; of this there can be no question. With the immensely increased number of persons interested in the Fund, there will certainly be a corresponding increase in the number of applicants, and a large number will probably have to be relieved by special grants from the current subscriptions. Upon this point the numerous grants made at the last meeting of the Council, amounting to £110, are very significant, as is also the intimation that several cases stand over, pending inquiry.

The opportunities afforded for discussion at the annual meetings and in the Journal are such that there should be no excuse for the withdrawal of subscriptions. The subscribers can easily make their wishes known, and we are confident that the Council will be found not only willing but anxious to carry them out. But to imagine that relief can be administered satisfactorily by a series of local clubs is a great mistake, and we are glad that a correspondent has been able to show that the gentleman making the proposition has, like many good-natured people, proved to be worse in his bark than in his bite.

BARON LIEBIG.

SCIENCE, we fear, is about to lose one of her most distinguished votaries. Baron LIEBIG is so ill that his life is despaired of. For some years his health has been gradually declining; while the repeated fracture of a badly-set lower limb has precluded his taking that amount of walking exercise which the maintenance of bodily vigour demands. His physicians are in vigilant attendance on him, and we would fain indulge the hope that, septuagenarian as he is, his life may yet be spared to his country and to science.

APPOINTMENTS UNDER THE ADULTERATION ACT.

Mr. Francis Sutton, of Norwich, Pharmaceutical Chemist, and author of the well-known standard work on Volumetric Analysis, has been appointed analyst for the entire county of Norfolk. The fees to be paid by the public are to range from 2*s.* 6*d.* to 10*s.* 6*d.*; and these are to be supplemented so that in cases where 2*s.* 6*d.* is paid, the analyst will receive 10*s.*; 5*s.* will be increased to £1; and 10*s.* 6*d.* to £2. Mr. Sutton also holds the official appointments of Gas Examiner to the City of Norwich and Analyst to the Norfolk Chamber of Agriculture.

At Sheffield, the Town Council have elected Mr. Alfred H. Allen, F.C.S., as analyst for the borough, at a salary of £100 a year. Mr. Allen is Lecturer on Chemistry to the Sheffield School of Medicine and the Sheffield Pharmaceutical and Chemical Association, and is the author of several contributions on the methods of detecting adulterations.

We are glad to be able to record these two fresh appointments of analysts to discharge the duties required by the Adulteration of Food Act, 1872, since they show a disposition to construe the words in the Act relating to qualification in the sense for which we have contended.

CONVERSAZIONE AT ST. STEEVEN'S HOSPITAL, DUBLIN.

The healing art owes much to St. Steeven's Hospital, Dublin. The Medical Committee of the Institution entertained on Saturday, the 5th inst., a large number of its students and friends, who found much to interest them in the admirable assortment of chemical, botanical, and pharmaceutical preparations, as well as of surgical and philosophical instruments, exhibited on the occasion. The Lord Mayor at the close of the evening distributed the Cusack Prizes and Certificates to the successful competitors, and, addressing his audience, remarked on the satisfaction it must afford to every well-wisher of the Dublin school to find the St. Steeven's Hospital retaining and extending its attractions for the students of medicine, whether in its theoretical or practical departments. Centralization is unfavourable to science as well as to commercial or political life; and it is therefore with peculiar gratification that we see such provincial schools as that of Dublin keeping its ground against the powerful rivalry of the English and Scotch metropolitan seats of learning.

THE ANNUAL DINNER.

We understand that a large number of gentlemen have already authorized the placing of their names on the List of Stewards. But since the holidays have probably prevented many others from doing so, we are requested to say that the publication of the complete list is deferred until next week. Communications on the subject should be addressed to the Honorary Secretaries, Messrs. Richard Bremridge and Michael Carteighe, 17, Bloomsbury Square.

Provincial Transactions.

BRIGHTON ASSOCIATION OF PHARMACY.

THE EARLY CLOSING MOVEMENT.

A meeting in connection with the Brighton Association of Pharmacy was held at the Hanover Lecture Hall, North Road, Brighton, on Friday evening, April 11, to consider the question of early closing. Mr. Cornish, in the absence of Mr. Savage, the President of the Association, occupied the chair.

The Chairman announced that a paper would be read, supplied by one of their body, after the reading of which he hoped that some of the gentlemen present would give the meeting the benefit of their opinions, so that a general understanding to shorten the hours might take place.

Mr. Smith then read a paper written by Mr. Padwick, of Preston Street, the effect of which may be briefly given. Speaking of the cause of their present position, he thought they should not ignore the fact that they had worn and were still wearing chains of their own forging, and from which other business men have for some time past freed themselves; how galling they were none knew better than they who had to wear them. The principals were debarred from many home comforts and relaxations by continuous interruptions, the majority of which were needless, and assistants were compelled to be in attendance, thus preventing attention to the studies now so necessary to their obtaining the necessary qualifications in pharmacy. He alluded to many poisoning cases caused by inadvertence, some of which occurred when (the more active duties of the day being done) business discipline was in a degree relaxed, and hence the blunder, and he concluded his arguments in favour of early closing by suggesting that a committee be formed to carry out the matter; that circulars be sent to each of the principals, proposing eight o'clock as the time for shutters to be put up, and the doors to be finally closed at nine o'clock—the requirements of visitors during the four summer months to be met by the extension of the time by half-an-hour—and requesting each gentleman's aid and co-operation, and asking him, if the hour named be not considered practical in his case, to state the time at which he would be prepared to close his establishment.

The Chairman remarked that the peculiarity of their calling was that it was different from any other tradesman's business. But it should be understood that if they did shorten the hours of business, in all cases of emergency the public would be able to get all necessary things. It was for the meeting to consider whether they should act upon Mr. Padwick's suggestion.

Mr. Smith said that druggists work their minds and bodies as hard as those in other trades and professions, and therefore need the same amount of leisure; but in addition to ordinary work, the young men have to study for their examinations, while the older members of the profession are continually refreshing their memories, and adding to their stock of knowledge in order to keep up with the pharmacy of the day.

Mr. Armitage argued against the early closing movement on principle. He had closed his shops in Trafalgar Street early, and had experienced a loss in consequence. He thought the druggists should be able to close earlier, but how was it to be done? In his neighbourhood he did the most trade from a quarter past eight to ten o'clock. He, therefore, could not view the movement with much favour in his neighbourhood. Referring to the assistants, he remarked that where the shop closed late, they had the opportunity of going out in the daytime, and he did not think that if the shop closed earlier that they would use the time for educational purposes.

Mr. Smith: They must study at some time, or they will not pass their examinations.

Mr. Haffenden argued that so long as the shop was open, people would come in. His practice was to close on the Sunday, and he found he did not lose any of the real trade. In cases of emergency, people came to the side door. Acting upon Mr. Padwick's suggestion, he moved that a committee be appointed for the purpose of eliciting the views of the chemists, of whom it was said there were sixty-five in the town.

Mr. Cox, jun., in seconding the resolution, said that certain neighbourhoods must have certain times for closing.

Mr. Barton supported the resolution, remarking that they ought to have sufficient *esprit de corps* to arrange among themselves a more reasonable time for closing. Fourteen and fifteen hours a day was too long a time to be engaged in active business.

Mr. Glaisyer, of North Street, remarked that at his establishment the shutters were put up at 8 P.M., and the shop was entirely closed at 9.30 P.M., but probably that course could not be made a rule for every establishment. With regard to the arguments which had been advanced that assistants wanted time to study for their examinations, the principals expected that they had already passed, and that they came to work, not to study. It was arranged that they had time for recreation, and not to have any particular time set apart for study as if they were apprentices.

Mr. Colby, jun., did not advocate early closing, observing that assistants had recreation in the day time.

The resolution was then carried unanimously, and the following were elected as the committee to carry it out:—Mr. Savage, Mr. Cornish, Mr. Barton, and Mr. Haffenden, and the officers of the Association.

A vote of thanks having been accorded to Mr. Padwick for his paper,

The Chairman, replying to Mr. Glaisyer, said his remarks were strictly right in principle, but they had to keep themselves up to the mark, as new discoveries in chemical science were being constantly made. If they could shorten the hours it would confer a benefit upon the principals and their assistants, whose interests it was right they should have at heart.

A vote of thanks was then accorded to the Chairman, and the meeting separated.

CARLISLE CHEMISTS' ASSOCIATION.

On Wednesday evening, April 2nd, the Carlisle Chemists' Association held their monthly meeting, when a very pleasant, interesting, and amusing evening was spent. Mr. J. D. Walker, chemist, kindly exhibited an excellent microscope, and a collection of mounted objects, many of them being of pharmaceutical interest. He also explained the various parts of the microscope and their uses. A present of "Indian barks and their alkaloids" from Messrs. Howards and Sons was placed upon the table and much admired. The thanks of the Association were given to Messrs. Howards and Sons for their interesting donation, as also a vote of thanks to Mr. Walker for his instructive and interesting exhibition.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL ASSOCIATION.

A monthly meeting of this Association was held on April 9th, Mr. W. Ward, F.C.S., President, in the chair, on which occasion a lecture was delivered by E. Birks, Esq., Lecturer on Botany to the Sheffield School of Medicine, on "The Microscope, and how to use it." The lecturer commenced with a description of the various parts of the microscope, and explained how each was used in the investigation of any subject to which the instrument is applicable.

He then proceeded to illustrate the way in which the microscope should be worked in the study of vegetable histology, or the investigation of the elementary structure of plants and plant life; a full description being given of the vegetable cell and its contents, also of the manner in which cells are propagated and increased. The lecturer took occasion to state the views of those authors who maintain the hypothesis of the physical basis of life, as opposed to those who consider that life or vitality is essentially different from any known physical force, concluding a very able lecture by giving some practical hints as to the manner of working with and manipulating the microscope.

On the motion of Mr. Maleham, seconded by Mr. Ellinor, a vote of thanks was unanimously tendered to Mr. Birks for his interesting and instructive lecture. Some general announcements concluded the business of the meeting.

ASSOCIATION OF CHEMISTS AND DRUGGISTS OF IRELAND.

The usual monthly meeting of the above Society was held on Monday evening, at 12, Grafton Street. There was a very large attendance. W. Wells, Esq., was elected chairman.

The principal business was to discuss a bill promoted by the Apothecaries' Company for forming a Pharmaceutical Society in Ireland. The bill was generally approved by the meeting, and with a few amendments, will be submitted to the Apothecaries' Hall for approval.

It is expected that a bill will be introduced as soon as possible, as there is a perfect understanding between the Hall and the trade.

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

At the meeting of the Society of Arts on the 26th March, Mr. P. L. Simmonds read a paper on the Starches of Commerce. The chair was taken by Mr. Thomas Greenish, F.C.S., F.R.M.S. The following is a full abstract of the paper:—

The Edible Starches of Commerce, their Production and Consumption.

BY P. L. SIMMONDS.

The production and consumption of edible starches have now attained very large proportions. Unlike the French, who have two words which they apply, with different meanings—fecula and amidon, or starch,—we are, in a great degree, limited to one, all being essentially starches in commerce, even with the minor classifications of arrowroots, sagos, tapiocas, corn-flours, etc.

The French confine the term fecula to the starch obtained from roots, such as manioc; of stems, as the sago; and fruits or seeds, as of the horse-chestnut, acorns, etc.; while the amylaceous product obtained from the cereals, which crystallizes, on drying, into needle-like forms, they define as amidon, or starch.

Very little has been published on this extensive and important branch of commerce,—at least in a collected form, for occasional papers have appeared, from time to time, in various scientific journals. Perhaps, however, the best and most carefully conducted investigation into all the tropical starch-producing plants, their characteristics, and properties, was that carried out, about a quarter of a century ago, by Dr. Shiers, in British Guiana, and published locally in a pamphlet.

It is not my intention to trouble you with scientific and chemical descriptions of the special characters of the starches from various plants, or to treat upon the mooted question of how far they furnish nutritive food,—subjects which fall more properly within the scope of Societies like the Microscopical, the Chemical, the Pharmaceutical, the Medical, etc. I shall restrict myself to the commercial aspect of the question. I may, however, state that I have placed on the table a very large and varied collection of edible starches, which have all been carefully identified and referred to their proper sources, by my friend in the chair, for in commercial circles there is too much confusion on this point. A few figures will serve to prove that the commerce in these articles is of considerable aggregate importance.

In 1850 we imported about one million pounds of arrowroot; in 1860 these imports had increased to more than 2,383,000 lbs. In 1860 the value of the edible starches, etc., imported was £206,438. In 1870 it had increased to £366,550.

In 1871, the last year for which we have the complete official detailed returns of imports, the aggregate value of the farinaceous substances and manufactures therefrom imported is stated at £274,281; sago and sago flour, £197,381; total, £471,662. But as the article "maizena" is thrown in with Indian-corn meal, and much maize, rice, and even potatoes are converted into edible starches here, I may as well add the figures given for Indian-corn meal (£13,944) to the above, which would bring up the total to £485,706 for the year.

Our imports of arrowroot from the West Indies, in the last ten years, have fluctuated between 12,000 cwts. and 22,000 cwts. a year; from South Africa we now get from 3,000 to 4,000 cwts. annually.

Having thus given you an outline of the extent of our imports, I proceed to treat of the production and consumption in the several localities, preferring to arrange the information under these divisions, as more generally recognizable and more easily followed.

European Starches.

But few plants are utilized for edible starches in Europe. We are mainly dependant for our supplies of these on tropical and sub-tropical countries. Occasionally small quantities of Portland arrowroot have been made from *Arum maculatum.* In Italy the fecula of *Arum italicum* and of *Pancratium maritimum* is manufactured to some extent, and sold at 3½d. per lb. About two tons are made annually by one maker at Cava.

Starch is manufactured in the south of France and the neighbourhood of Paris from the horse-chestnut. It yields about 16 or 17 per cent. of starch. If it is to be used as food, it must be treated with water containing carbonate of soda, to remove all bitterness, and then washed repeatedly with pure water. Only small quantities of it have been imported into this country, more for curiosity than for commercial purposes.

Rice starch has, within the last few years, been prepared as a beautiful food product, under the name of corn-flour, by an eminent firm, and the care with which it is manufactured, and its nutritive qualities, have commanded for it a large sale. As much as 80 or 90 per cent. of starch has been obtained from some kinds of dry rice, but the average may be taken at 73. Imported maize or Indian-corn is also converted in this country into a starchy food product, sold as corn-flour.

Under the name of farina, without the prefix of "potato," a large quantity of potato starch is imported and sold here. The process by which potato starch is now so largely made on the Continent by improved machinery is very perfect. Its hygroscopic properties are however great; even when sold in the shops in the form of dry powder, as a substitute for arrowroot, it contains 18 per cent. of water, and if placed in a damp atmosphere, it will rapidly absorb double that amount of water. The percentage of starch in the potato ranges from 9 to 26 per cent. Sago, vermicelli, and various other food products are made on the Continent with potato starch. The famed gravies, sauces, and soups of France are largely indebted for their excellence to the so-called farina from potatoes.

As Professor Owen observed as far back as 1856, in his official report on the alimentary substances shown at the Paris Exhibition of 1855—"The French at present appear to excel in the art of preparing and modifying the starch principle of the potato, so as to simulate the product of the *Maranta arundinacea,* called under one form arrowroot, and under another, or granular form, 'tapioca;' as also to simulate the starch principle of the *Cycas circinalis,* called 'sago,' and that of certain Asiatic species of *Orchis,* called 'salep.' It must be added that the conscientious fabricators of these imitations vend them as 'French, or indigenous arrowroots, sagos,' etc., and at a lower price than that for which the genuine exotic article can be obtained. I am afraid that there is little conscientious principle manifested among vendors here, for European arrowroots and sagos sell as readily and promiscuously as Indian and American."

West Indian Arrowroot.

Maranta arundinacea furnishes most of the genuine West Indian Arrowroot, although other species, such as *M. nobilis, M. Allouya, M. ramosissima,* are also cultivated for a similar starch from their tubers, and several species of *Canna* are utilised for the starch in their tubers.

The Bermuda arrowroot was long considered the purest quality made, its superiority either arising from the nature of the water or soil, or from greater care in the manufacture, but the production has been declining, and has now given way to other more profitable crops. The general export from the colony was, in 1870, 45,675 lbs.; in 1871, 30,276 lbs.; and in 1872, 26,710 lbs.; valued at £1,323.

When made by the labourers in the West Indies on a small scale, arrowroot is prepared much in the same manner as potato starch in this country for domestic use; the only implements required are a grater and wooden troughs and trays; when made on a larger scale, as on the estates of the proprietors, the crushing of the root and the reducing it to a pulp are effected by simple and cheap machinery (a wheel and rollers) worked by water. The arrowroot is dried under sheds. Little or no use is at present made of the pulp after the extraction of the starch by lixiviation, but probably a serviceable paper might be made of it at a trifling cost.

In 1869 there were 65½ acres under culture in Jamaica, and in 1870, but 49¼ acres. The exports have declined year by year from 70,204 lb. to 6,343 lbs. In the Island of St. Kitts, arrowroot and *tous les mois* (from Canna) are produced to some extent.

The amount of arrowroot exported from St. Vincent is now about two millions of pounds; in 1847, the quantity shipped was only 297,587 lbs.; and in 1851, 490,837 lbs. Many circumstances have promoted this increased culture. When it began the price of the article was high, and the grower obtained a largely remunerative profit; its culture was not laborious; it was subject to few risks; it did not for its success require rich land or much manure; there was a constant and increasing demand for it; and in consequence of the abundance of pure water, great facilities were afforded for the manufacture, and that by a process so simple, easy, and cheap, as to require little skill in conducting it, and scarcely any capital. St. Vincent is the only arrowroot-producing colony that has kept steadily progressive.

I have not any recent statistics of the production of arrowroot in Barbados, but I believe little is made or shipped from the island now.

In Antigua there has been considerable decline in the production. From 1850 to 1854 the exports were from 300 to 500 boxes and barrels, and from Montserrat, in some years, 250 barrels. In 1870 our imports of arrowroot from Antigua had dwindled to 30 cwt., value £28.

Tortola used to export arrowroot and *tous les mois* of the value of £500 to £1,500 a-year, but has dropped out of the production.

North American Starches.

The enormous production of Indian corn in the United States, and the fact of its containing a less proportion of gluten than wheat, have led to its extensive utilization for starch manufacture, and also as a food product, under the names of maizena and corn flour. As an alimentary product this starch is gradually working its way in Europe, and has been rewarded with silver medals at several of the Industrial Exhibitions. Maize contains about 75 per cent. of starch. A considerable quantity of Maranta starch is produced on the coasts of Georgia and Florida. The yield of roots of all sizes is from 100 to 150 bushels per acre. From a bushel of roots weighing 43 lbs., about $5\frac{3}{4}$ lbs. of clear, dry fecula is obtained.

South American Starches.

In British Guiana a good deal of edible starch is made from the various tropical roots, but the starchy products do not form an article of export from the colony now, the arrowroots, cassavas, etc., being locally used. Palatable starch can be obtained from the root of the *Alstrœmeria pallida*, Graham, and the starch from the various Chilian *Alstrœmerias* was suggested to be sought for and shown at the Exhibition of 1851. The tubers of many of these could doubtless be utilised in a similar manner. In Brazil considerable attention is given to the production and manufacture of edible starches. A most interesting and varied collection of these was shown at the Paris Exhibition in 1867; it comprised among others the following products, many of which I have not been able to identify, in the absence of either scientific name or other clue to the plants:—

Yellow pumpkin starch.
Pine starch, and pine farina.
Fecula of Itua.
Maizena—Indian corn fecula.
Meal and tapioca of seeds of gergelim (*Sesame*).
Fecula and tapioca di forno.
Jacatupé starch.
Mango starch.
Potato starch.
Bread fruit starch.
Carnauba starch from the trunk of *Copernicia cernifera.*
Shushu or xuxu starch (from a bulb).
Fecula of bananas.
Meal of yam (*Dioscorea sp.*).
Arrowroot fecula (*Maranta*).
Starch of bitter potato.
Starch of Brazil potato.
Meal of Demerara potato.
Fecula of Maira potato.
Water farina of manioc.
Dry farina of manioc.
Beiju of manioc (dried slices).
Flour of manioc gratings.
Puba manioc.
Dry meal of white manioc.
Dry meal of yellow manioc.
Dry meal of white manioc, sold at three milreis the alquiere.
Coarse manioc meal.
Starch of manioc.
Tapioca of manioc.
Carima of manioc in small balls.
Dried meal of Macacheira or Aipim (*Manihot Aipi*), sells at two and a-half milreis the alquiere.
Carima of macacheira in small balls.

Feculas from other roots and bulbs than the manioc are rarely manufactured. The *Maranta arundinacea* is grown in Para; there are two varieties, one with a large long root, which produces the most fecula, the other, named "ounce's paw," from the resemblance it bears to the forefoot of that animal.

The arrowroot, after being subjected to the action of running water, is sometimes buried in the mud until it ferments and becomes a plastic mass, to which they give the name *puba*, as they do in like manner to the manioc, when it undergoes a similar process.

Jacatupé starch is extracted from the bulbous root of a climber whose leaf is poisonous. The starch is used in soups, puddings, gruels, and other food preparations, and is said to possess important medicinal qualities, in dysentery, nephritic and other diseases.

The manioc or cassava is, however, the plant chiefly cultivated for food purposes in Brazil. No species of plants have been more changed in scientific nomenclature by botanists than these, for they have been classed as *Jatrophas*, *Janiphas*, *Manihots*, *Curcas*, etc. I will adopt the names given by Pohl to the two principal species (most of the others seem to be but mere varieties) the bitter or poisonous species, *Manihot utilissima*, and the sweet species, *M. Aipi.*

The manioc would seem to be a native of Brazil; it has been introduced into India, and is grown about Calcutta, Madras, the Straits Settlements, and other quarters. It flourishes better on the borders of the sea and on islands than in the interior of the continent. On the coast of Coromandel the roots are more fibrous, and therefore inferior to those raised in Malabar. It is extensively grown in Guiana, the West Indies, and various parts of Africa.
