Mr. Dimmock, who is an enthusiastic member of the Accountants' Association, has certainly worked out the most complete system of monthly report we have yet seen, and has done so as the result of years of careful study. While it covers minute details which at first thought might appear as costing more than they were worth, a study of the report will show that every item provided for is useful and enables the manager to make an analysis of expenses such as every road will have to make in the near future if further reductions in expenses are expected. The report is comprehensive without running into red tape, and although it includes 29 pages, only one day is required in drawing off the statements from the account books.

AKRON CONSOLIDATION.

Mr. Will Christy, of Akron, O., has taken control of the new corporation resulting from the amalgamation of the reorganized Akron Street Railway & Illuminating Co. and the Akron, Bedford & Cleveland line. Joseph R. Nutt, treasurer of the Central Savings Bank of Akron, is also identified with the Everett syndicate. The bonds and most of the stock of the old company have been transferred to the syndicate. The contract called for the delivery of two-thirds of these securities or the whole deal would have fallen through, but everything has now been arranged and the syndicate is in charge.

It is also believed the Everett people are negotiating for the purchase of the Akron & Cuyahoga Falls Transit Co. In the event that this is the case it is more than propable the tracks of this company will be torn up and those of the new company used entirely.

PUNISHED FOR OBSTRUCTING TRACK.

Ulrich Noa, 18 years old, was recently sentenced to one year's imprisonment in the Green Bay, Wis., state reformatory for obstructing the track of the Fox River Valley Electric Ry. at Menasha, Wis. Noa's home is near Menasha. He placed a stone weighing about 50 pounds on the track, claiming he was drunk and that he did it for a joke; one car was nearly wrecked, but fortunately no lives were lost.

The Syracuse, N. Y., street car lines have lately been suffering from theives of the most persistent character. A gang has been at work for some time past cutting and stealing the trolley wires and track bonds; the police have been unable to get a clew.

CHARLES FITZGERALD.

Mr. Charles Fitzgerald was last month appointed general superintendent of the Consolidated Traction Co. of Pittsburg, Pa., succeeding G. F. Greenwood. Mr. Fitzgerald is widely known among street railway men throughout the country, but is better known in engineering circles. He is a native of Orange County, N. Y. His abilities as a mechanical engineer were first prominently recognized in 1881 by John Roach & Co., the Philadelphia ship builders, at whose works he held a responsible position when only 21 years of age. Three years later he accepted the position of erecting engineer at Robert Wetherill & Co.'s Corliss Engine Works at Chester, Pa., and when that company sent him to erect a power plant for the Citizens' Traction Co. at Pittsburg, in 1889, he was so well pleased with the bustling Iron City that he remained there, accepting the position of superintendent of the mechanical department of the Citizens' Company. Mr. J. E. Rugg, the veteran manager of the West

CHARLES FITZGERALD.

End Street Railway Co., of Boston, was at that time superintendent of operation of the Citizens' and with such a past master for a preceptor, Mr. Fitzgerald made rapid progress in the acquirement of the art of operative management, so rapid, indeed, that when Mr. Rugg resigned in 1895 Mr. Fitzgerald was made general superintendent of the Citizens' and the Fort Pitt Traction Cos. In 1896 these companies were consolidated with the Pittsburg, Duquesne, Central and Allegheny Traction Cos. into the present corporation embracing over 150 miles of track and an equipment equaled by few companies in this country. Mr. Fitzgerald continued as superintendent of three of the included lines and ably assisted in the management of the company until his recent appointment as its general superintendent. The appointment meets with popular approval in Pittsburg, the new chief being held in high esteem by all. He is a prominent member of the Engineers' Society of Western Pennsylvania, probably the most progressive body of its character in the country, and he is regarded as one of the best mechanical engineers in that end of the Keystone state.

Under the possibilities of his now greatly enlarged field of operation his friends are confident of the record he will make, and one and all earnestly wish him success.

The voters of Boston will ballot on the question of replacing the street railway tracks on Tremont St.

MAINTENANCE AND REPAIR OF ROLLING STOCK.

BY J. W. GREER.

A tendency toward extravagance is the besetting sin of the mechanical department of nearly all street railways, and is caused largely by the misapprehension on the part of the master mechanic and his employes as to the net earnings of the property. The mechanic of the present day is an intelligent, reasoning being, and the relationship between him and his fellow employes of the operating department is such that, "in strictest confidence," the conductor will give him the exact amount of the daily receipts of his car. One or two of the confidential statements from each division is all he needs to approximate very closely the gross earnings, as the conductors invariably keep a memorandum of the daily receipts, and these being pooled give the total. The operating expenses are not known outside the office, but the mechanic grabs up his ready pencil and proceeds to plot off an expense sheet to his own entire satisfaction. Of course he never gets beyond a correct estimate of the labor account, a rough estimate of the cost of material, a poor guess as to the cost of the fuel, and an absolute certainty of what the salaries of the president, general manager and secretary ought to be—measured by the amount he is being paid for his own services.

Depreciation, taxes, insurance, sinking fund, interest, printing, stationery, attractions, damages, donations, paving and other city expenses, attorney's fees, and the host of other accounts which make up the legitimate operating expenses of a street railway, are rarely if ever thought of by the mechanic. Consequently, when he strikes a balance between his estimated operating expense and the known gross receipts, he is not much to blame for believing that you are operating a bonanza, and treating the employes unfairly in the matter of wages. He is not slow in disseminating his eye-opening statement among the other employes, and discontent results therefrom. "A little knowledge is a dangerous thing." Where discontent and trouble are not bred by this state of affairs, extravagance is. Feeling that the company is rich and the road making money beyond measure, everything should be kept at the top notch of perfection; so half-worn bearings, pinions, gears, and other supplies are thrown out in a reckless way, because your first-class mechanic always takes a pride in his work, and, believing that the company is able to stand it, desires to have the cars when they leave the shop as good as new.

To remedy the state of affairs above described, it is not necessary to familiarize your employes with the details of your business, or to show them the balance sheet each month; but, as it is impossible to keep the gross earnings from them, why not at least obtain justice for yourself and your methods by allowing them to see that there is more on the expense side of the ledger than they ever dream of? I am aware that there are many successful managers who rigidly live up to the scriptural injunction, "Let not your right hand know what your left hand doeth." But they would, perhaps, have been much more successful had their method been such as to inspire sympathy and interest on the part of their employes, instead of trying to make military automatons of them. Make your master mechanic a member of your "cabinet," and you will find that he will drink in eagerly the business problems that arise; and, in

exchange for every point in business affairs he picks up, he will give you a dozen practical suggestions which will redound to your glory and the good of the company."

If you cannot trust the head of the mechanical department with a general knowledge of your business, then he is not fit to have entire control of the department, which, by its economical or extravagent management, can make or break the road more quickly than anything else except, possibly, accidents.

One of the simplest and most effectual methods of impressing the employes and the public with the fact that a street railway is not a mint, and that there is a side to the business unthought of and unseen by them, is to use strictly the voucher system in making all payments. Have the voucher blank made long and broad enough to contain on its back a distribution sheet showing a complete list of all the accounts pertaining to the operation of every department of the business from office to construction. Pay only with checks attached to one of these formidable documents, and you will find the effect magical. The simple reading of the list of accounts (usually ranging from 60 to 100) that pertain to the operating expenses of a street railway is calculated to surprise the layman or the employe, and often produces a genuine case of sympathy for the much abused and overburdened corporation. Invariably will a perusal of this sheet counteract a tendency toward extravagance and make the thoughtful employe glad that the company has enough left in its treasury every week to make the ghost walk.

I have dwelt at length on a phase of the mechanical department not usually considered in treating the subject in hand, because many years of my life have been spent at the bench and among the men as one of the hands, and, therefore, must perforce know more of the thoughts and feelings that actuate the mechanic than those who have been educated and employed only in connection with the business side of street railroading. Having passed successively through all stages of the business, I am prepared to assert that oftentimes the mechanic, in the faithful discharge of his duties, uses more real brainwork than the whole office force put together. My friend, Sam Jones, says, "It's always the hit dog that howls." Do not howl at the foregoing very unpopular, but nevertheless true, assertion unless you have tried both departments. The intelligent mechanic bears the same relation to the labor problem of street railroading that the farmer does to the body politic of our government.

Treat him as an intelligent, reasoning man should be treated, and he is the conservative element that will preserve the equilibrium of the whole through thick and thin; try to hoodwink him and you gain his dislike and distrust. He then becomes one of the Populist party, with whiskers on and a knife up his sleeve, and it is 16 to 1 that there will be trouble in camp.

Having organized the mechanical department on proper lines, you naturally look for proper results. As a stitch in time saves nine, we can apply the maxim practically by appointing one or more of the best, all-round mechanics as daylight inspectors. One man can properly inspect 40 cars a day, with an average of 10 cars to a division, and having to take station alternately at the end of four divisions; or he can inspect 60 cars, all in one division. The inspector should wear a belt containing a 14-in. combination wrench, a pair of pliers, a screw-driver and a few carbons. He should not be expected to make repairs on cars beyond tightening a loose nut or set-screw, and tightening screws in a connecting-sleeve, window-spring, grab handle, or bell pull. Occasionally a carbon will have to be replaced which has been overlooked by the night inspector.

While the foregoing matters are important and often save serious trouble and expense, yet they are merely side issues with the inspector. His real business is to ride back and forth from the last meeting point to the end of the line, catching each car in turn and closely observing everything about it or connected with it, and nothing on a blank provided for the purpose the needed repairs. These blanks should be of a size convenient for slipping into a pocket, when they are made up in pads, and should be so complete that a word will specify what is needed. The following form is suggested:

(Card 3⅝ x 6½ in.)
X, Y & Z Railway.
Car Inspector's Report.

Car No.... Date.....1899.

Repairs needed.

Wheels .....
Axles .....
Journals .....
Truck .....
Brake .....
Car body .....
Platform .....
Controllers .....
Doors .....
Sash .....
Blinds .....
Signs .....
Glass .....
Seats .....
Paint .....
Cleaning .....
Trolley .....
Motors .....
.....
.....
.....

(Signed).....Inspector.

It will be observed that after the word Wheels, "flat," "loose," "out of gage," "racked," or "not mates" would express all that would be needed, as the case might be. A chalk-mark on the particular wheel would indicate the one alluded to. A rubber stamp on the end of a pencil, bearing the name or number of the inspector would serve admirably for quickly signing the report.

A car in motion and a car standing still are radically different things. Therefore the inspector who rides on a car while he inspects it sees the actual condition of the rolling stock under service, and can grasp many needed improvements which the motorman would never discover; or if he did know something was wrong, he would be unable to locate or express the trouble. Not only the inspectors, but also everyone connected with the mechanical department should be broken in as motormen, so that, in addition to mechanical skill, they can bring to bear that intuitive knowledge which comes of practice in managing a car and the trained senses of touch and sound which guide the motor-

man largely in making up his mind that it is not running right.

The proper regulation of brakes, the tension of truss-rods, the working of joints in the car body, the rattle of glass in the sash, and many other things can be determined only by actually riding on the car under service conditions. It goes without saying that if the inspector takes the controller handle and brake and runs the car a short distance himself, he can discover more of the condition of his car in a minute than the average motorman could tell him in an hour. The writer believes in a riding inspection by daylight, and in work on motors and cars done wholly by daylight. Nothing should be done to the cars at night except to sweep and oil them, to replace carbons, examine and tighten connections, or change trolley poles or wheels. A night gang will usually scrape off enough paint, overlook enough points that need attention, and soldier away enough time to pay over and over again the interest charge on the extra equipment necessary to have the work done wholly in the daytime.

After finding out through the inspector just what needs to be done to each car, the next thing is to do it. In the next of these articles, we shall "take up the white man's burden" by commencing at the beginning, and giving a few ideas on cleaning cars and motors and keeping them clean.

STRIKE AT WHEELING.

On April 8th the motormen and conductors of the Wheeling (W. Va.) Railway Co., 81 in number, struck for an advance of wages from 16 cents to 20 cents per hour. The company attempted to operate some of its cars with non-union men but was obliged to desist because of the riots and disturbances which followed. The car house just outside the city limits where the non-union men were housed was stoned, and several of the cars in the city stoned by crowds of men and boys. It was again attempted to operate cars on the 11th with more success, but no cars were run at night.

On the 11th the company filed a bill in the United States District Court, and Judge Jackson issued an injunction restraining all persons from interfering with the cars or the mails they carry.

In the next few days abuse and intimidation of the new men resulted in the arrest of four men by the deputy marshals sent to enforce the injunction order. These men were tried before Judge Jackson on the 18th and each was sentenced to 30 days' imprisonment and $50 fine.

Before passing sentence the court said:

Before passing upon the cases that have been submitted to the court for its action, I think, under all circumstances, that I should talk to the community at large with reference to the strike, known now as the street car strike, and the first remark that I want to make is, that it seems to me remarkable, in a city as large as the city of Wheeling, with its mayor and police authorities, that that mayor, with all his policemen, has found it impossible to deal to any extent with the obstructions that have been placed upon the tracks of the street railway company.

No evidence has been presented to this court to show any interposition upon the part of the mayor, the chief of police or the policemen under them to protect this property. I have inquired, in reference to that, of the officers of this court, and it is something I cannot well understand. In a city as large as the city of Wheeling, with such a local police force as it necessarily must have for the protection of the interests of every citizen and of every species of property within the limits of the city, I repeat that I cannot well understand why the city authorities have not taken some action in regard to this matter.

Authorities who regulate the welfare and prosperity of a city are supposed to be indifferent as between parties connected with any violations of the law in reference to the rights of citizens, either of liberty or property.

I understand that the state authorities and municipal authorities are just as much bound to protect the rights of the street railway company as the United States is bound to enforce the laws regulating the transmission of its mails over railway property of any kind or character whatsoever.

It is to be regretted that there is a want of action upon the part of the local authorities and that the street railway company has been compelled to appeal to the United States Court to do that which it was the duty of the local authorities to do.

In the administration of the laws of the land, either federal, state or municipal, sympathy is not to be considered. The question of legal right is the question that it is the duty of the officers of either of those three branches of authority to consider and to enforce.

I have been told since my arrival in the city that the reason there seems to be no desire upon the part of the local authorities to enforce the law in protecting the property of the street railway company is, that they sympathize with the strikers. I have also been informed that these men who have struck for higher wages do not appear in the front of this trouble. But they are behind it and they incite and excite a class of the population of the community who have a small stakehold in its interest and welfare, to present themselves in the front to obstruct the operations of this street railway company and thus, to some extent, diminish the value of the company's property.

Let me ask the strikers who have left the service of the company if it would not be more manly upon their part to come forward and present themselves in the breach, instead of getting a lawless and irresponsible element in this community to stand in front as a bulwark to protect them against the execution and enforcement of the laws? Is it manly to incite women, and through them their children, to appear upon the scene and try to obstruct this street railway company in running its cars over its own property?

It seems to me if there is any manhood among those engaged in this strike that they would come out themselves and make their fight, and not ask these poor, unfortunate, infatuated people along the line of this railway to hoot and hollow and excite a mob for the purpose of interfering with the running of the cars of the company.

The court is not here to sympathize. Those who administer the law are not expected to sympathize. Their only sympathy is with justice and right under the laws of the land. That is the proper sympathy.

I am told—just as it appeared before me in the prosecution by the Government of the United States upon an information filed in this court some six years ago, against parties who were prosecuted for obstructing this same railway—that children, and small children at that, are used in piling rocks upon the tracks of the railway company. It appears from the evidence here that rocks are piled on the track in the absence of the officers, and spikes have been driven into the track to derail the cars. Of course, parties who do these things are not going to take witnesses with them, as it might result in their arrest. They do it at a time when the officers of the government who are there for the protection of the property, are absent. Every time a crowd gathers along this railway and hoots and yells at the officers of the government in the exercise of their legitimate duties in enforcing the processes of this court, it is aiding and abetting this strike and those who engage in it are just as bad as the principals who go and drive spikes in the track or tear up the rails to derail a car.

It is the fomenting of a public sentiment that is unhealthful—a sentiment in opposition to the enforcement of the laws of the land—that your people who are under arrest today are engaged in. Why do not all of you think and reflect about this matter? Why cannot you remember that the welfare of society is involved every time there is an effort upon the part of dissatisfied citizens in regard to any matter they are interested in and they produce a strike?

The society of this country has many grades and elements in it. There is the rich man; there is the man who has a comfortable liv-

ing; there is the man who is struggling for existence, and there is the man who can never "make both ends meet." Now, whose fault is it? This is a free country. No man is compelled to work except to save himself and his family from starvation. There is no law, except the law of the Almighty, that compels a man to work. By the sweat of your brow you shall earn what you possess. No railroad company, no corporation or co-partnership of any character and no citizen can compel other people to work for them.

You who are engaged in obstructing the running of cars on this railway are destroying the rights of the people who constructed a road quite as much for your convenience and benefit as for their own profit. Without this railway running through your streets from Bridgeport and Martin's Ferry, in Ohio, to Benwood in our own state, what inconvenience would you be subjected to? Think a moment, what a matter of public benefit this street railway is to you. Suppose the railroad should be obliterated and you had nothing but the trucks and express wagons that are now passing over your streets, for the accommodation of the public, what would be the effect upon your city? You would be retrograding from the condition of an electric street railway back to the old omnibus instead of progressing from the omnibus and old horse car line to the electric railway, and from the electric railway to the next advanced means of transportation that may happen in the future.

This country is a country of progress; it is a country in which all citizens enjoy equal rights; it is a country where every man has a right to labor for himself and be protected in the acquisitions that result from his labor. Now, think of that! No man is compelled to work. He may starve if he chooses to. Neither is any man compelled to work for inadequate wages. But in connection with that there is another thing to consider: If you cannot get what you think is right and fair for your services stop—quit—and let your neighbor come in who is willing to work for the same compensation. He has a right to do it. Why should you interfere with men who are engaged by this company and who are willing to work for wages that you do not wish to labor for? You should not interfere with them.

I am not here, gentlemen, to sympathize with either side in this matter. I am here to enforce the law. It may be that the railroad company is paying more compensation for labor now than the revenues of the road justify. The railway company certainly is the judge of that. It may be that the laborer who is employed is not getting what he thinks he ought to receive. He is the judge of that. If the railway company says: "We are paying you too much and shall have to reduce your wages," you have a right to quit. They cannot compel you to work. If the laborer says to the railway company: "You are not paying me enough; you ought to give me more," and they refuse to do it, you have a right to quit. Nobody interferes with you. That is your right—your inalienable right—under our institutions. But there the thing stops. You have no right to organize a communistic club or a communistic society for the purpose of enforcing that, which, under the law, you are not entitled to enforce.

What are the results of strikes? They demoralize labor. What else do they do? They interfere with values. The property of a city may have a value today, and the property of a railroad company may have a value today, but repeated strikes by labor organizations or communistic associations, or by people who have anarchistic views, reduces what?—the value of property. And when you reduce the value of property you reduce the ability of those engaged in business to pay a fair, remunerative price for labor.

Labor and capital must go hand in hand together. Capital should not be too exacting, nor should labor be too exacting. Capital and labor should deal with each other in a spirit of fairness, but neither should claim the right to dictate terms to the other. You go to your groceryman, and ask him what tea is worth, or what coffee is worth, and he tells you. "Well," you say, "I will go to another place: I think I can do better." That groceryman to whom you went cannot compel you to take his tea or his coffee at the prices he fixed, but you go to the other man, thinking you can do better, and you buy of him. Now, that is the underlying principle between man and man in all the negotiations of life. You ask a man what anything you want to purchase is worth and he gives you the price. You can buy of him or go elsewhere. You have the right to elect whether you will take it or not. You go to a railway company and ask what wages they pay and they will tell you. You can either accept their terms or go elsewhere. Now, you people who have been engaged in running cars on this line and have been receiving 16 cents an hour, or possibly $2 a day, have struck for 20 cents an hour. Your combined efforts cannot force that railway company to pay the advance asked for. This railway company can go out in this great nation of ours and get men from any source. It has been shown that they have already been able to get men from other places—from Philadelphia and Chicago—to take your places.

Now, act with some wisdom; be prudent; go home and think and reflect over this matter, and see if you have not made a mistake. Appeal, always, to your employer, when you think you are not paid a fair price, and consult and reason with him in reference to it. Then, if you and he don't agree in your views, and you can afford to do so, quit him. But don't undertake to take his property out of his hands by strikes; don't undertake to destroy his property by the same means, when you are dissatisfied with the field in which you are employed. That is the way to do it.

The law does not give you any right to go into the courts of the country and say to this railway company, "We are working today for 16 cents an hour, but you must give us 20 cents." You cannot make them do it. The law does not give the railway company any right to go into the courts of the country and say to the laborer, "We have been paying you 16 cents an hour, but you must come down to 12," and force them to do it. The courts cannot do that. Now, there is the whole thing in a nutshell.

If any of the new men engaged in this strike are within the sound of the court's voice (and I have no feeling in this matter except the feeling that I always have for those who feel that they are oppressed), I want to ask them to weigh well what I have said to you here today. This is the same character of talk that I made upon a former occasion in reference to a strike on this road. I have made it for the benefit of the community.

While coming up on the train yesterday afternoon from Parkersburg, I dictated to my stenographer what I consider the pith of this whole matter, and I will read it to you:

"The court is here for the purpose of administering the law relating to this case. It is not here for the purpose of administering sympathy to either the street railway company or to those who have been employed by that company, known now as strikers, who are insisting upon the company increasing the wages for their services.

"This is a free country. The constitution and laws of the country guarantee to every citizen the right to engage in any business that he is disposed to enter into. No limitations or restrictions are imposed upon the individual action of any citizen in regard to this right. In a free country like ours competition in every department of life is open to every citizen. He who by diligent and continuous effort acquires not only a competency but a fortune, has a perfect right to be protected in it. On the other hand, a laborer of the country who maintains and supports himself and family by his daily toil, has an equal right to be protected. Labor cannot, by individual action, or by united action, deprive the employer of his right to fix the price of labor any more than the employer can compel the laborer to work for him for a price less than the laborer feels is remunerative.

"The trouble in this case seems to be that there is an effort upon the part of the employes of this street railway company to force the employer, the railway company, to advance their wages without knowing whether such action upon their part is justified in any respect whatever. Every employer has a right to look into the question as to what he can afford to give for services rendered to him, the matter to be determined and decided by the revenues derived from the business in which he is engaged. No employe can determine that, for the employer alone is possessed of all the facts upon which he must base his decision and action. In this case it must be remembered by the employe that the employer is just as much interested in maintaining the operation of the road and in obtaining revenues from it, as the employe is interested in obtaining a just and fair compensation for his labor.

"Suppose we reverse the situation upon this occasion, and the employer determines to reduce the wages of the employes in the service of the company. The employer cannot compel his employe to serve for a reduced rate of wages. If he cannot, is it right and proper that the employe, who seeks to have his wages and compen-

sation increased, should take such steps as to coerce the employer to comply with his request without knowing whether or not the employer can afford to do so? Even if he could afford to do so, what legal right—what just right—has an employe to undertake to coerce his employer? The employe has the privilege of remaining with his employer or quitting his service. Why don't he elect to do that which the laws of his country justify him in doing? Whenever there is not a sufficient remuneration upon the part of the employer for the services of the employe, let the employe leave the services of the employer and seek other employment.

"I understand from the public press that this community is in sympathy with what are now known as the strikers. Let me say now that this is a mistaken sympathy upon their part. No community can decide, as such, between the rights of the employer and the employe. They cannot be familiar with the circumstances that have influenced the employer to refuse to accede to the demands of the employe on this occasion. This misguided sympathy is often a wrongful sympathy, and operates not only to the prejudice of the parties for whom the sympathy is expressed, but to the injury and detriment of the public at large. In this country the relation of capital and labor is not to be determined by sympathy. Labor will always command capital when capital can afford to pay for it. Capital will always command labor when it feels that it is justified in doing so. The effect of this public sympathy is unfortunate. It serves to stimulate parties who, while they may have some rights, have taken the wrong position in the assertion of them. A legal or an equitable or a just right cannot be enforced in this country of law and order except through the forms of the laws of the country. Whenever any community undertakes to set up for itself a standard, and to enforce that standard by mob violence, by communistic orders or by efforts upon their part which are conceived in a spirit of anarchy, and which lead to and end in anarchy, then the time has come when the laws of the land must be enforced to control that spirit of anarchy. Such is the duty of the court here today. The court is here to enforce law and order. It is here to restrain mob violence and to prevent interference with the movements of the mails of the United States, and to protect the rights of citizens of the United States under the interstate commerce act.

"Every good citizen of the state is interested in the suppression of this violence and in the enforcement of the law. A precedent of this character which defies law and order will result in disaster to the community. If such a thing is countenanced by the community at this time, it is only an inducement for other persons, who may conceive that they have a just grievance, to take the same course, and the time is not far distant when a repetition of similar acts of disorder will end in violence. And I say to the good people of this city that such violence will result in disaster to the community, to its business, to its enterprises, and will drive capital from its borders, which will seek investment elsewhere, and the grass may grow in the streets of your now prosperous and thriving city."

I have talked to you today, gentlemen, from no limited experience. I have passed the notch of three score years and ten. I have dealt with strikes before, and have never found any good results from them. I have dealt with them on the Baltimore & Ohio R. R., on the Norfolk & Western R. R., with that most notable strike of the employes of the Monongah Coal Co., and of the employes of this same company, six years ago, as the records of the court will disclose. I believe I have had one or two smaller affairs to deal with, but those I have mentioned were notable in their character. In every instance where I have been called upon to interfere as a judge of the United States court for the protection of the rights of property, I have found those, who, in their misguided judgment, organized the strike, and those who aided and abetted it, did that which did them no good, and only resulted in some injury to the owners of the property against which the strike was raised.

Take my advice. I feel kindly toward all of you. Born in Virginia, raised in the mother state as well as in the state of my adoption—the state of West Virginia—all my sympathies are with West Virginia. My feelings of sympathy are always with the oppressed and downtrodden. I have been poor myself. I am not rich now. Indeed, I may consider myself a poor man, after devoting nearly twenty-eight years of my life to the public service, on a salary that has barely supported myself and family. Notwithstanding all this, my observations and experiences have been that it is better to endure the ills you have than to fly to those you know not of.

Go home to your families. Be peaceable; be quiet; observe the law; then when you lie down upon your pillow at night you will feel the conscious conviction that you have done well. I have to dispose of these cases I have here today. I regret that I am compelled to enforce the law against these parties. God knows I wish it were otherwise. This court does not like to punish anybody, although he has had a great deal of it to do in his life, but as an example to you all, he must do it.

The marshal and his deputies are going to remain here until peace and order are restored. It is useless to undertake to fight a great government like the United States. Those officers represent the emblem of authority of this great sovereign government. This court today is only administering its laws. Now, think of that, and then say how long you will continue this course. Stop before you get into the clutches of the law, and let order and peace once more prevail in your community.

By the 20th the company had its regular complement of cars running in charge of new men and later reports state that no more attempts at obstructing the cars were made.

BELLOWS FALLS VOTES $1,000 TO ELECTRIC LINE.

In the construction of interurban lines it is frequently necessary to make radical changes in street grades, and such alterations are often of as much benefit to the town as to the road. The action of the Bellows Falls, Vt., town authorities in such a case will be of interest and value as a precedent to quote in other similar cases. The railway had been granted a right of way along a public street, with permission to cut the grade down seven feet. A survey, however, revealed the necessity of a deeper cut, and the town authorities thereupon voted to cut the entire roadway down 12 ft., making a 5 per cent grade, and voting for the work the sum of $1,000 from the city funds. That the action of the town was reasonable and fair is evident, but there are places where the citizens are not aware of the benefits resulting from electric lines, to lead them to as broad gaged a view of the situation.

CONSOLIDATION IN TENNESSEE.

What is known as the Hambleton syndicate of Knoxville, Tenn., at the head of which is Mr. Frank Hambleton, president of the Knoxville Traction Co., is engaged in some extensive negotiations in Nashville. Press dispatches state on the authority of Mr. C. C. Howell, vice-president of the Traction Company, the syndicate has purchased the entire plant of the Cumberland Electric Light & Power Co. It has also bought the majority of the street railway stocks and bonds of the Nashville companies and has options on other properties. One part of the new corporation's plans will be, when it is fully organized, to put up a gas plant both for fuel and illumination. It is stated that there will be from $5,000,000 to $6,000,000 expended in the various enterprises contemplated in Nashville by this big syndicate.

All of the properties controlled by the Brooklyn Rapid Transit Co. show increased earnings for April as compared with the same month of previous years. The total of passenger earnings for April, 1899, is $864,332; April, 1898, $758,353; April, 1897, $707,837. For the 10 months ending April 30th, the gross passenger recipts of the system were: 1899, $8,279,663; 1898, $7,350,538; 1897, $6,870,995.

NEW CAR HOUSE OF THE OMAHA STREET RAILWAY CO.

The Omaha Street Railway Co. has recently completed a new car house which involves a number of novel and interesting features. While the building is practically completed and the company began to use it Feb. 27, 1899, there are yet some finishing touches, such as pointing the interior walls and painting the roof trusses with asbestos paint, yet to be given, the early winter having interrupted the work. The building was constructed after the plans of Messrs. Fisher & Lawrie, architects, of Omaha, and is 124 ft. wide by 380 ft. long, covering over an acre.

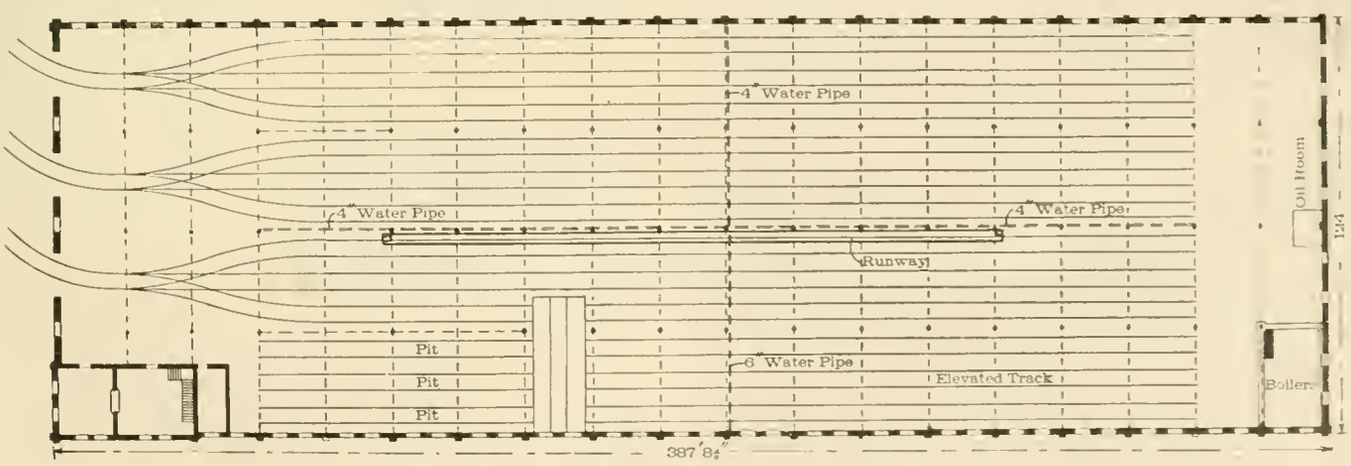
In each of the bays are laid three tracks as shown in the plan, which in the aggregate give 3,300 ft. of track storage. It will be remarked from the plan that to three of the bays access is given by an entrance track and two switches. The tracks of the fourth bay are reached by means of a transfer table. The three tracks to the north of the transfer table in the west bay have the only track pits in the barn; the middle track south of the transfer table is elevated 2 ft. above the general floor level and is the track where most of the work on trucks is done, the elevated track being generally more convenient than a pit. The first bay west of the center line has a cement floor for 60 ft. at the rear end, and the cars are washed at this point.

NEW CAR HOUSE, OMAHA STREET RAILWAY CO.

The walls are of brick, faced with red pressed brick, and trimmed with sand stone, 17 in. thick at the sides and rear end, and 25 in. thick at the front end; the side walls have 13-in. pilasters 19 ft. 8½ in. center to center. In each wall panel between pilasters are two windows so that the building has a light interior even when filled with cars. The front is finished with terra cotta and the general appearance may be seen from the photographic view of the exterior. Three rows of posts divide the car house into four bays. The posts are of pine 12 x 12 in. and are spaced 19 ft. 8½ in. center to center longitudinally. The roof trusses are of timber with iron rods and are shown in the sectional view of the building; from the bottom of the truss to the rail is 16 ft. 6 in. The roof is of matched 2-in. sheating covered with five layers of building felt and gravel.

The work of washing cars and cleaning and adjusting trucks has to be done in winter as well as in summer and an effective heating system was necessary for a portion of the car house. Accordingly two tubular boilers, 54 in. by 16 ft. are installed in a pit at the southwest corner of the building to furnish steam for heating purposes. The radiating surface provided consists of 1,500 sq. ft. arranged in manifolds along the west wall just below the windows and along the west row of posts, the bottom pipes being about 8 ft. from the ground. Last winter was particularly severe and during the coldest weather the men were able to work about the cars with their coats off.

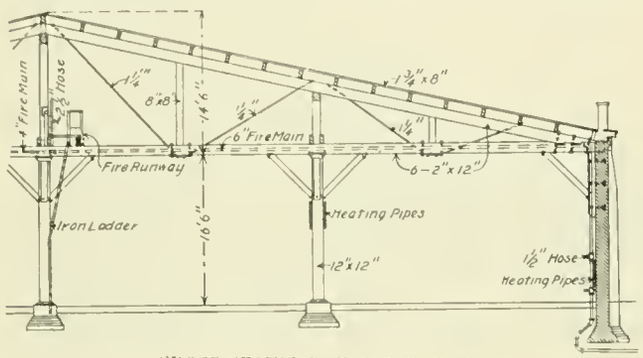
At the south end of the building an oil room is provided which is 8 x 10 ft. and will hold 12 barrels. The walls of this room are of brick and the roof of old rails and cement con-



PLAN OF NEW CAR HOUSE, OMAHA STREET RAILWAY CO.

crete; it is excavated to the depth of several feet below the general floor level so that in event of fire the oil cannot run over the rest of the building.

To provide an efficient system of fire protection for a building of this kind is quite a problem and the very satisfactory solution in this case was worked out by the general manager of the company, Mr. W. A. Smith, after consultation with the fire marshal of the city. A 6-in. water-main enters the building at the middle point of the west wall and is carried up the wall to the roof truss and thence across to the center line of the building; a 1½-in. hose connection is provided on the west wall. Along the center of the building just west of the center line, a runway 4 ft. wide is laid on the chords of the roof trusses; the runway extends to within 100 ft. of each end of the building, and at each end of it is an iron ladder down to the floor. The sides of the runway are pro-



CROSS SECTION OF CAR HOUSE.

tected by substantial wooden railings. At the point where the 6-in. water main intersects the runway is a 2½-in. fire hose connection and a section of hose long enough to reach to the end of the runway. Thus in event of a fire in any part of the barn it may quickly be reached by a stream of water from the bridge, whereas it would be extremely difficult to carry a line of hose in and out among the cars on the floor to reach a car on an inner track.

From the terminal of the 6-in. water main three 4-in. pipes are laid; one is carried to the east wall and terminates in a 1½-in. hose connection and the others along the center line of the building to within 60 ft. of the end walls where 1½-in. fire connections are provided.

The office of the car house foreman and the trainmen's waiting room and a lavatory occupy a space about 20 x 40 ft. on the ground floor at the northwest corner of the building. Immediately above these rooms, and reached by a stairway leading from the waiting room are two rooms, 16 x 20 ft. and 24 x 20 ft., which are provided for the "Street Railway Library and Amusement Club," which is a club of the company's employes. As the company provides the quarters and lights and heats them, the expenses are light; the initiation fee is 50 cents and the dues are 5 cents per month. The club rooms are neatly furnished with chairs, table book cases, etc., and the walls adorned with pictures; the club subscribes to all the leading periodicals and already has the nucleus of a library though organized only a few months ago. The membership is now about 160; employes who are not members are excluded from the clubroom by the company.

A steam locomotive is being used in the construction of the Sandusky & Interurban Electric Ry.

SCHOOL FOR MOTORMEN.

How to best examine an applicant for a position in the train service, and afterwards how to best teach him his duties, are questions which the managers of electric roads, and particularly on the large ones have found difficult of solution. Every manager has probably found that the best and most careful motorman does not necessarily make the best instructor of new men, and that it is quite important to have good instructors as to have good motormen and good conductors. President Vreeland, of the Metropolitan Street Railway Co., of New York, has decided that for a large road, such as his, the best method is to institute a school under the direction of men thoroughly fitted for their duties as instructors, and this plan has been fully developed so as to comprise instruction by lectures, recitations and laboratory practice, given in conjunction with actual practice of the men on cars. It is not the idea of the company to give theoretical instruction in electricty or mechanics, but merely to teach the motormen certain of their duties. Such instruction is ordinarily left for the motorman on the car who breaks in the new man to impart, and in many cases he does not give it.

In order to secure a position as motorman with the Metropolitan Co. the candidate must fill out an application blank, giving age, height, weight, address and references, which is transmitted to Mr. J. J. Swan, who has charge of this matter. Mr. Swan's assistants then look up the man's record,

J. F. Kane. J. J. Swan. J. J. Cahill.
SCHOOL ROOM.

and if his references are satisfactory, he is asked to call and submit to a physical examination by the company's surgeon. The physical examination is particularly rigid with regard to sight and hearing. Having successfully passed the examining surgeon the applicant is given a card to Mr. J. F. Kane, the instructor and superintendent of the motorman's school. On reporting to Mr. Kane, the applicant has his name entered on the application books and receives a book, which contains 88 rules, and enters on his student course.

The man gets a knowledge of rules and is required to know certain of them, particularly those pertaining to his duties, which knowledge he acquires along with the general practice.

On Wednesday, Thursday and Friday afternoons Mr. Kane conducts oral examinations on the rules. Particular stress is from the first laid on the rules concerning bell signals, how to reverse, how to insert fuses, and how to manage the controller. If after examination on the book of rules it is evident that the applicant cannot learn this part of his duties he is dismissed and surrenders his rule book.

The students spend 10 hours per day for two days on the rules and working with the controllers. Laboratory instruction on controllers is given by Mr. J. F. Kent, assistant instructor. Each man is given a number corresponding with the number of a controller with which he is to work.

About 50 controller and brake equipments are arranged in the room and the men operate these according to bell signals given by the instructors. The instructor has the students under his eye and can direct them, point out their errors and observe the progress made. For the laboratory practice, there are no electrical connections to the controllers, but the brake staffs are connected to springs giving the same resistance to setting up as is in practice given by the "Sterling" brakes with which all the company's standard cars are equipped. On a board back of each controller are a switch and a fuse box, which are manipulated in accordance with bell signals.

One bell. This is to stop, and the student turns off his controller and applies the brake.

Two bells. This means go ahead, and the brake is released and the controller handle turned from point to point as directed in the book of rules.

Three bells. This means an emergency stop.

Four bells. Reverse.

Five bells. "Follow Truck," that is, manipulate the controller and brake so as to accommodate the motion of a car to that of a truck which is supposed to be on the track in front of it and have the car so under control that the motorman will avoid a collision in case the truck shall suddenly stop.

The correct position of the motorman is with the right hand on the knob of the brake handle and the left hand on the knob of the controller handle.

After the student has progressed to this point he spends a good portion of the time, this is the time allotted for each class in controllers, on this exercise for three days. It is found that a great many students who pass the oral examinations on rules with ease cannot do the work on the controllers and brakes. They are awkward, are easily confused and cannot remember which way to turn the handle nor to which point to turn it. When the laboratory practice on controllers develops the fact that the student has missed his calling he is dismissed.

After the practice in controller and brake manipulation the student is instructed in the clerical work incident to the position of motorman. He is given a run card and learns how to properly fill it out and to read the time tables intelligently. He returns the run card after filling the blanks just as if he had a car in service, and if errors are made the instructor sets the matter right at the next school session.

Graduates of this school are then placed on a car in service with a sub-instructor for two or three weeks, depending on the proficiency shown, after which, if they prove to be competent to handle a car alone, they are given a position and receive badges and buttons.

CLASS IN CONTROLLERS.

SKELETON CAR.

Mr. Kane states that by means of this school the company is enabled to secure better men, and when given charge of cars they are known to be thoroughly instructed in their duties, and also it is pretty well known how they will conduct themselves in an emergency. When a new man is placed on a regular car to learn his duties from the motorman it is impossible to know how well he has succeeded, and the chances are that all his instruction has been under the most favorable conditions. The company is satisfied that the school gives it better men and saves it thousands of dollars in the accident account to say nothing of the saving of the motors and controllers.

Each Friday night there is a lecture in the school room for all motormen, especially the students, on the general subject of running cars. A skeleton car so arranged as to show the motor equipment and wiring, models of the plow, etc., greatly aid the men in understanding the apparatus with which they work. The skeleton car, shown in one of the illustrations, is fitted with motors, controllers and brakes, and is connected with the trolley circuit so that the instructors can give practical lessons in operating the car, replacing fuses, and a motorman's work in general.

Saturday night lectures are given once or twice per month; these are not especially for new men, but are for

men in all departments of the service, who may be interested in the electrical and mechanical workings of cars. These lectures include talks on electrical and mechanical matters; also talks on general subjects of railroading, talks on discipline and on how a man may become advanced in the railroad service, all by men of high standing in their lines

It should also be mentioned that there is a club room for the use of employes of the company, which contains current weekly and monthly papers and magazines with many special papers on electric and railroad subjects, together with a library of about 1,500 volumes, containing works on electrical and mechanical subjects together with works of fiction. This library is free for employes of the company and the men may take the books home and read them.

Seated at the table in the foreground of one of our illustrations are, beginning at the left, J. F. Kane, instructor; J. J. Swan, paymaster, and J. J. Cahill, assistant superintendent.

THE OMAHA STREET RAILWAY AND THE EXPOSITION.

The fact that a number of cities are to hold expositions and world's fairs within the next year or two will make the following notes concerning the passenger traffic of the Omaha Street Railway Co. during the Trans-Mississippi and International Exposition of interests at the present time. The Exposition was open from June 1 to Nov. 1, 1898, and every day the lines of this company were taxed to carry visitors to the Exposition grounds; the conditions were successfully met and the service rendered gave the greatest satisfaction.

The pasenger traffic on three of the big days was as follows:

Oct. 12, 1898: Running direct to Exposition, 106 motor cars and 40 trailers. Total in service 150 motor cars and 40 trailers. Cash fares collected, 193,760; transfer passengers, 77,504; total, passes and mail carriers not counted, 271,264.

Oct. 11, 1898: Same cars in service as on October 12th. Cash fares collected 183,700; transfer passengers, 73,480; total, 257,180.

Sept. 22, 1898: Running direct to Exposition, 102 motor cars and 36 trailers. Total in service, 145 motor cars and 30 trailers. Cash fares collected, 142,434; transfer passengers, 56,973. Total, 199,407.

The rolling stock with which these immense crowds were so successfully handled comprised:

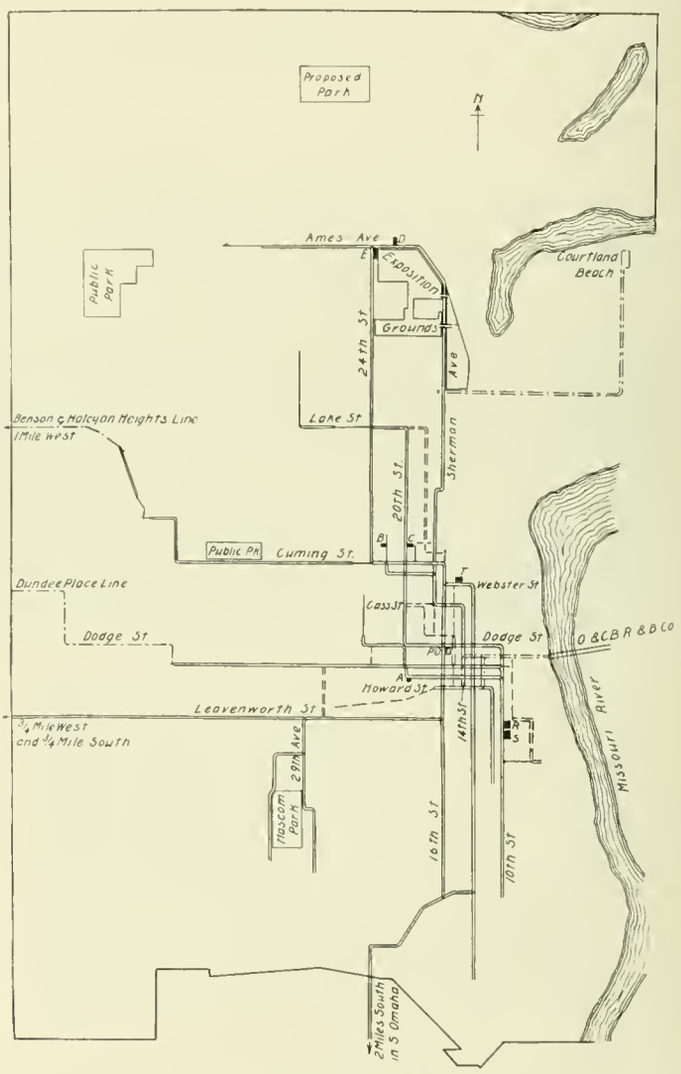
44 10-bench open cars seating 50 persons.
70 7-bench open cars seating 35 persons.
27 20-ft. closed cars seating 30 persons.
49 16-ft. closed cars seating 22 persons.

190

Since the Exposition closed the company has purchased 20 new 20 ft. box cars from J. M. Jones Sons, 37 Peckham extra long trucks and 37 G. E. 52 motors.

To enable the reader to understand the arrangement of various routes the accompanying map has been prepared, showing all the street railway lines of Omaha and the location of the railroad station and the exposition. The Omaha Street Railway Co. is a consolidation of the old Omaha Horse Railway Co. with other companies organized in the 80's to build cable and electric lines, and it now owns all of the street railways in Omaha, except three short suburban lines, the East Omaha with 5½ miles of track, the Dundee line with 1½ miles, and the Benson & Halcyon Heights line with 4 miles, and it furnishes electric power for operating these lines. The Dundee line is owned by the Metropolitan Cable Railway Co., but is an electric road. The Omaha Street Railway Co. operates 80 miles of electric lines, and has a number of old horse lines shown in the map by dotted lines which are not now used.

Referring to the map, R is the terminal station of the Chicago, Burlington & Quincy, the Burlington & Missouri



MAP OF OMAHA LINES.

and the Kansas City, St. Joseph & Council Bluffs Railroads; S, the terminal of the Union Pacific, the Chicago & Northwestern, the Chicago, Milwaukee & St. Paul, the Chicago, Rock Island & Pacific, The Wabash and the Kansas City, Pittsburg & Gulf; T, the terminal of the Missouri Pacific, the Freemont, Elkhorn & Missouri Valley, the Sioux City & Pacific, the Chicago, Minneapolis, St. Paul & Omaha, and the Belt Line.

The four through street railway lines to the Exposition Grounds may be traced out and were as follows:

1. Hanscom Park & N. 24th St. line running to the west side of the Exposition Grounds. On 24th to Cuming; on

Cuming to 16th; on 16th to Leavenworth; on Leavenworth to 29th Ave. and to Hanscom Park. Passengers from the Webster St. station, T, were carried on this line.

2. Sherman Ave. & South Omaha line. On Ames Ave. (north of the Exposition) to Sherman Ave.; on Sherman (this avenue separates the Exposition Grounds into two portions, which are connected by two viaducts over the street) to Cass; on Cass to 14th; on 14th to Howard; on Howard to 16th; on 16th to South Omaha. Passengers were transferred to this line from the Park and the East Omaha lines.

3. Union Depot line. From the west side of the Exposition Grounds on 24th St. to Lake; on Lake to 20th; on 20th to Dodge; on Dodge to 10th; on 10th to the Union Depots, R and S.

4. Sherman Ave. & South Omaha line. From the Exposition to 14th and Howard via Sherman Ave.

Transfers were made from the less important lines to these through lines at junction points. Cars on all routes passing depots transferred passengers to the Exposition lines.

The Exposition Grounds are but two miles from the Post Office, and as these through lines all pass through the heart of the city, the company had the advantage of a short haul. The location of the Exposition so as to be bounded by two lines and cut by a third was also a particularly fortunate one as it gave a large loop terminal.

The business district is that portion of the map where the car lines form a net work.

The shops and power houses are designated on the map by the letters A, B, C, D and E.

A is the old cable power house now used for the general offices and as a car house and repair shop.

B is the power house built by the Omaha Motor Railway Co. in 1889; it is equipped with two simple corliss engines made by the E. P. Allis Co. and eight 80-h. p. T.-H. generators. It was used during the Exposition but is not operated save in emergencies.

C is the electric power house and car barn built by the Omaha Street Railway Co. in 1889 before its consolidation with the Motor Co. and is equipped with the following machinery: One simple engine (removed from the cable plant) belted to a 500-kw. generator. One compound non-condensing corliss engine driving seven 80-kw. and 100-kw. Edison machines. Two Westinghouse compound engines driving four 125-h. p. Edison machines. One cross-compound non-condensing corliss engine, built by the E. P. Allis Co., direct connected to an 850-kw. multipolar General Electric generator; this machine was started June 1, 1898. The boiler equipment of this station prior to last year was 10 60-in. by 16 ft. tubular boilers; when the new unit was installed 10 new tubular boilers 66 in. by 16 ft. were added and a new steel stack 8 ft. in diameter and 125 ft. above the grates built.

D is the shed used for storing cars out of season.

E is a new car house built last fall.

The officers of the company are: President, Frank Murphy; vice-president, Guy C. Barton; treasurer, W. W. Marsh; secretary, D. H. Goodrich; general manager, W. A. Smith; general superintendent, F. A. Tucker.

The North Kankake (Ill.) Street Railway Co., is erecting a new car house 44 x 112 ft. The building is of brick.

OPENING AT FT. WORTH, TEX.

Ft. Worth, Tex., is jubilant over the completion of a nine mile electric belt line which affords rapid transit for people living in the suburbs to the business center of the city. This belt line connects with all the other lines and makes it possible to go anywhere and quickly reach any point in Ft. Worth on well equipped electric roads.

And while the city is rejoicing over the event it is lavishing praise and honor upon Mr. J. T. Voss, the president and manager of the Glenwood & Polytechnic College Street Railway Co. To him is due all the credit for a perfect working and convenient system—something Ft. Worth never had until Mr. Voss went there to stir matters up. Before he arrived the Glenwood & Polytechnic line was but a little over two miles long and had one mule car. To-day this line is 18 miles in length, has 10 motor cars. Mr. Voss

COL. J. T. VOSS.

took the Glenwood & Polytechnic lines as the basis of his operations. He leased the Arlington Heights Electric lines, connected them with the Polytechnic and put the whole system under electrical operation. Mr. Voss' next move was to purchase the old Riverside line and to reconstruct the Mistletoe Heights line. When this had been accomplished and all was in good working order Mr. Voss turned his attention to the belt line. The completion of this recently gives Ft. Worth a street railway system to be proud of.

J. F. Voss has been identified with street railway building and management for more than 20 years. His first experience was driving a horse car in Nashville, Tenn., but though only a young man, he soon became the general manager of three lines in East Nashville. From Tennessee he went to Macon, Ga., and there constructed a steam dummy line which he later sold out at a good profit. His next venture was in Atlanta, where, after five months as general manager of the Atlanta Traction Co., he became president of the Electrical Equipment Co. of that city. It was while in this position business took him to Ft. Worth, and there he met Mr. R. Vickery with the result of giving up his Atlanta connection and going to Ft. Worth. What he has done there has been briefly outlined.

The opening of the nine-mile belt line was made the occasion of great festivity. It was a regular gala day. The city was decorated, the bands played, speeches were made and Col. Voss and his two sons, who have aided him greatly in his work, were warmly toasted.

WAGES INCREASED.

The Consolidated Traction Co., of Pittsburg, May 1st advanced the wages of employes 11 per cent.

The Des Moines (Ia.) City Railway Co. has advanced wages 10 per cent; the order took effect May 1st and affects 200 men.

The Parkersburg (W. Va.) Electric Light & Street Railroad Co. has advanced wages 20 per cent.

D. G. HAMILTON, NEW PRESIDENT CHICAGO CITY RAILWAY.

Mr. D. G. Hamilton, who held the office of second vice-president, was, at a meeting of the board of directors of the Chicago City Railway Co. on Thursday, April 16th, elected president to succeed the late M. K. Bowen. Mr. Hamilton has for many years been prominently identified with street railway management. He was born in Chicago in 1843 and has lived here nearly all his life. For several years he was president of the National Railway Co. of St. Louis. He has long been interested in the Chicago City Railway Co. and is now a heavy stockholder. On the first of the present year he succeeded Joseph Leiter as second vice-president but had been a director in the company for several years.

Mr. Hamilton was graduated from the old Chicago University and began the practice of law, meeting with more than ordinary success. He acquired considerable real estate in the city and has long been recognized as one of Chicago's most able financiers. He has of late years given much of his time to real estate matters and the loaning of money, handling, however, to a great extent his own property. But he has always taken a lively interest in the management of the Chicago City Ry. and was the unanimous choice of the directors for the office of president.

Mr. Hamilton is western director of the Union Mutual Insurance Co., of Maine. He is a member of the board of trustees of De Pauw University and of the University of Chicago. He is a member of several clubs in Chicago, the Union League, Washington Park, and the Chicago being among the number.

HOW INTERURBANS INCREASE BUSINESS.

BY E. E. DOWNS, MANAGER CITIZENS' TRACTION CO., OSHKOSH.

Everything to the contrary notwithstanding, it is not necessarily true that the building of interurban lines retards the progress of the smaller towns to the advantage of the larger ones. It had become almost an accepted adage that the smaller towns suffered from such experiences until effectually disputed by the history of interurban movements in this country. Interurban traffic builds up and does not tear down.

When the Valley line was extended from Appleton to Neenah it was opposed to some extent by the Neenah business men who were misled by the belief that they would suffer by reason of the construction of the road. They thought that it would place them into too active competition with the Appleton firms, and thus lessen their sales. The opposite, however, proved to be true, and the Neenah business men and merchants today are enjoying an increase in their business. When the line to Oshkosh is built the same experience will again be met with, and the merchants on both ends of the line will see an improvement in the volume of their business.

No other conclusion can be drawn for the reason that the new road will place the cities into immediate harmony and touch with the farming elements. Where before it took a long time to reach the cities, the farmer can enjoy the accommodations of a city life at least in one respect by a rapid means of transit.

Not only will the road be of vast importance to the commercial interests of cities in developing new fields upon which to expand, but the vast traveling public will receive accommodations in a quicker and more modern service. When the new road is in operation it will be possible for any traveling agent to step from the very door of his hotel onto a car in this city and equal accommodations will await him on the other end of the line.

Men versed in railway matters, and who are considered authorities on the subject, maintain that the time is not far distant when the interurban road will gradually absorb what is termed the local traffic, while the larger railway corporations will be confined almost exclusively to through travel. They base their claims upon late developments which tend in this direction. Interurban travel is gradually becoming more and more popular. When it is taken into consideration that one can step from his own house and board a car which will carry him to a distant point, it is no wonder that this mode of travel is gradually revolutionizing the railway business.

STRIKE AT BAY CITY, MICH.

On April 6th the employes of the Bay Cities Consolidated Railway Co. quit work and went on a strike. A new man had been employed and one of the old motormen, Kidd by name, was directed to instruct him, which Kidd refused to do without a written permit from the president of the employes union. Thereupon Kidd was discharged and the strike followed because the company refused to reinstate him.

The men invoked the assistance of the State Court of Mediation and Arbitration, of which Hon. Jerome W. Robbins is secretary, and Mr. Robbins at once went to Bay City to confer with the strikers and the company. Mr. Robbins met representatives of the company stating that he was authorized by the men to conclude an arrangement; the company agreed to receive back all the old employes save 11 whose places had been filled by new men, and arbitrate all differences as to wages, hours, etc., and the proposal was accepted by Mr. Robbins, but later was repudiated by the men.

The City Council appointed a committee to confer with the various parties, and the report of the proceedings at a meeting of committee on April 11th is quite interesting. Mr. J. G. Weadlock and Mr. Morrison, assistant general manager, represented the company, and Messrs. Haller and Hasty, the men. The men at first asked that Kidd be reinstated but the company refused to do so until the Court of Arbitration had decided that it should, and the men waived that point. The main point discussed was the keeping of the 11 new men.

A settlement was effected on April 15th, the men returning to work without the company recognizing the union as an organization or reinstating Kidd and other matters of difference being referred to the Court of Arbitration. During the eight days that the strike lasted the most friendly feelings and relations existed between all parties; the men were all of good character and most of them had been in the company's employ for a long time, and the company better than anyone else appreciated their worth, and regretted that they should have been misled by professional agitators into taking a position antagonistic to the legal and moral obligations of the company to the public.

CINCINNATI STREET RAILWAY'S SHOPS.

The large car shops of the Cincinnati Street Railway Co., at Chester Park, are to be enlarged to more than double the present size. The present shops cover an area of 12 acres and the additions now contemplated will increase the space covered to 26 acres. It is the intention of the company to build all the cars used on all its lines. This plan has been under consideraion for several years but was only recently fully decided upon. The absolute necessity for 30 new cars of the winter type has brought the matter to a focus and the work on the new shops will be begun at once and pushed forward with vigor.

President Kilgour states that the works are to be supplied with all the most modern machinery.

FENDER DECISION IN BROOKLYN.

An ordinance of New York City provides that every trolley car running within the limits of the borough of Brooklyn must be fitted with a fender which shall be not more than 3 in. above the tracks. The Nassau Electric Railroad Co. was fined $25 under the ordinance, and on appeal the Supreme Court held the ordinance unreasonable and therefore invalid so far as the 3-in. requirement was concerned.

THE PENALTY OF OVERWORK.

The sudden death of Mr. Bowen has caused more than one street railway official to pause and consider how long he can hold out under the high pressure under which street railway management seems to be necessarily conducted. The Chicago Tribune in commenting editorially on the sad event says:

"The sudden death of Menard K. Bowen, the efficient president of the Chicago City Railway Co., points a lesson and suggests a business truth. The lesson is the danger of overwork, for primarily this was the cause of Mr. Bowen's death. In one sense this may be called a vice of the times. In the hurry and restlessness of American business life, aggravated by the strenuousness of competition and the haste to be rich, business men give little attention to diet, exercise, and the ordinary requirements of hygiene. The lack of proper rest and recreation gives the physical man no opportunity to resume his natural elasticity. The unnatural strain superinduces disease, nature has no assistance in resisting it, and the debilitated body succumbs and not infrequently involves the brain power also, the two being in close sympathy.

"An important business truth is suggested by Mr. Bowen's death. Mr. Bowen rose to the presidency of this large corporation because he was a skilled workman in his chosen field. He had experience as a civil and mechanical engineer, surveyor, construction superintendent, and railroad superintendent; knew how to handle men, understood the laying of cables, the operation of cars, and all the mechanical details of street railroading, besides having the executive ability necessary to the position he held. In a word, he was an expert, and it is experts that are now required by the great corporations, whether banks, business houses, manufactories, electric light companies, telephone companies, or traction companies. The day of handing down the management of business from father to son, regardless of fitness, or of calling into important places men who have been successful in a wholly different kind of business, has passed away. Young men or men of middle life who have demonstrated their capacity and shown their skill in all the details of operation are in request as managers of large enterprises, and Mr. Bowen was one of this class."

* * *

The death of Mr. Bowen recalls an exciting incident which occurred when he was superintendent of the Ninth St. cable line in Kansas City. On Thursday, Oct. 12, 1887, the special car in which President and Mrs. Grover Cleveland were touring the West, reached the Kansas City Union Station. Carriages were in waiting to drive the distinguished guests down Broadway to the Coates House. The streets were packed with people, and several companies of militia were drawn up at "present arms" to keep a passage open along Broadway. Ninth St., on which the cable line runs, crosses Broadway and six cable trains were stopped on one side of Broadway to await the passage of the presidential party. Just as the Cleveland carriage was crossing the tracks a loose strand in the cable caught the grip of the rear car, and the six heavy trains were hurled forward like a battering ram into the almost solid mass of people. Hundreds were knocked down and some badly injured, the Cleveland carriage escaping by a few feet.

The crowds, thinking the trains had been started on purpose, chased the gripmen and conductors from the cars, and followed them down Ninth St. to the power house, crying, "Hang them! Hang them!"

The mob threw the offending cars from the tracks, and, breaking some of them into pieces, used the doors as battering rams against the power house. Superintendent Bowen came out and faced the angry mob of 1,000 people, but he was unable to calm them, and only by summoning a large body of police was serious trouble averted.

A weather report has been ordered placed on every street car on the Lancaster (O.) Traction Co.'s lines at 9:30 o'clock each morning.

There is considerable talk concerning some proposed extension and improvements by the Ogden (Utah) Street Railway Co. One of the extensions may run up to and through Ogden Canon, and there may be also some Hot Springs connections.

THE ELECTRICAL EXPOSITION.

The annual exposition of the Electrical Exposition Co., of New York, now in progress at Madison Square Garden, possesses even more features of interest than were to be found at either of the previous ones. General Manager Nathan has been able to carry out his plans almost as proposed, and has secured many exhibits which are proving exceedingly attractive. The automobiles are creating a good deal of a sensation, many new points of novelty and of special application being shown.

Wireless telegraphy is also attracting much attention, and the experiments are being watched closely not only by electricians but by the general public. The special department devoted to the application of electricity to medicine, surgery and dentistry has a tonic for the doctors. Herein is a field in which the whole world has a vital interest.

Mr. Nathan has drawn upon the Government of the United States with much success. From the War Department there are exhibits of the Signal Corps, the flying telegraph, the switchboard used at Ponce, Porto Rico, and the map of battle line and the kit used at Santiago. Exhibits are also given with the heliograph which is used when wires for flash telegraphic signals, cannot be strung.

Through courtesy of the Navy there are shown night signal systems, battle order indicators, explaining the method of communication between commanding officer and gun crews. Then there is an electric diving lamp used for deep sea diving and samples of the various electrical material used by all vessels of the Navy.

There are some especially interesting exhibits in connection with the late war. The search light which was captured from the "Vizcaya" at Santiago, and was put in operation on the U. S. S. Texas, is there. This is the search light which disclosed the Merrimac in the entrance to Santiago harbor and led to the capture of Lieutenant Hobson. There is also the search light rescued from the ill-fated Maine.

Last year many exhibitors complained of being compelled to locate in the basement. The management has this year arranged to give all principal exhibits space on the main floor and the basement has been used for a number of special and interesting features. There is an electrical theater, an electrical "Cave of the Winds," an electrical grotto and an exhibit of the uses of electricity under water.

FT. WAYNE ELECTRIC CO.

The General Electric Co. has purchased the Fort Wayne Electric Corporation's plant and the business will be continued at the present location. There is no idea of a removal and the Ft. Wayne people can rest easy on that score. The concern has been reorganized under the name of the Ft. Wayne Electric Co. and while it is a branch of the General Electric Co. the officers of the local company are all Ft. Wayne men. Mr. J. J. Wood is the general superintendent and Mr. Hunting, as before, will look after the sales. The works have started up again and 150 men are employed. But this number is simply for the beginning. Just as soon as everything is in complete working order more men will be put to work.

It is stated that the plant is in first rate shape now and there is no question about its paying. There is a prospect of the works being enlarged and it is reported that President Coffin intends to go into the manufacture of electric motors and telephone apparatus quite extensively.

The General Electric Co. did not purchase the Ft. Wayne plant as a speculation but was forced into buying it to protect a mortgage the company held on the plant. In all probability Ft. Wayne capitalists would have bid the property in at the sale had not Mr. Wood honestly come forward and stated frankly that he had some doubts in regard to his patents. This made some of them timid, and although the disposition was strong to have Ft. Wayne still retain the plant they let the sale go on and Mr. Coffin, for the General Electric, was the buyer. But now that it is certain the plant will be kept where it is the Ft. Wayne people are well satisfied.

A motorman on the Louisville (Ky.) Street Railway Co. has sued for $15,000 damages for injury received by reason of an electric shock on May 12, 1898.

In the Power House

This department is devoted to the construction and operation of electric railway power houses. Correspondence from practical men is specially invited. Both the users and makers of power house appliances are expected to give their views and experiences on subjects within the range of the department.

By the courtesy of the B. F. Sturtevant Co., of Boston, we have received data as to the coal consumption at the mills of the United States Cotton Co., Central Falls, R. I., for a period of 15 weeks.

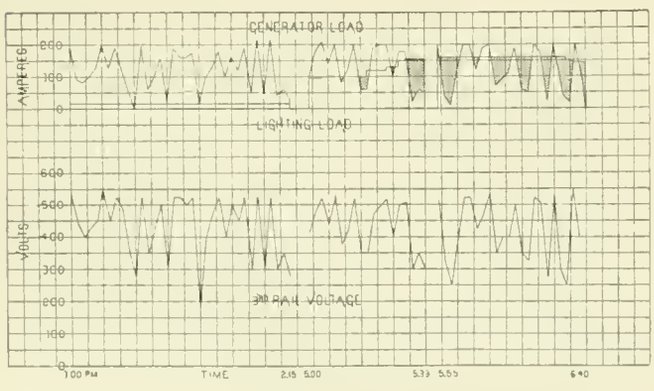
The plant consists of three Babcock & Wilcox boilers of 335-h. p. (rated) each. The engine is a cross-compound Harris-Corliss, developing an average of 1543.84 i. h. p. The remarkably low fuel cost of $5.80 per i. h. p. per year in a plant without economizers, is primarily due to the employment of a low grade mixture costing only $2.29 per ton, the burning of which has been rendered possible by the introduction of mechanical draft. The draft of the chimney, which was previously employed, was insufficient for the free combustion of this fuel, and as a consequence Cumberland semi-bituminous coal was used.

The installation of a Sturtevant fan, costing less than $600, is stated to have effected an annual saving of $6,500 in the fuel bill. The fan is driven by a direct connected engine, the speed of which is regulated by a device of the chief engineer, Mr. Thomas P. Burke, whereby a scarcely noticeable change of steam pressure immediately alters the speed of the fan, and consequently the intensity of the draft, and brings the pressure back to normal.

The fuel was a mixture of 78 per cent buckwheat coal, 15 per cent anthracite dust and 7 per cent Cumberland, the cost per short ton being $2.48, $1.38, and $2.95, respectively. Based on the 15 weeks' test the annual fuel consumption would be 3,907 tons, costing $8,953.23. Per i. h. p. per year this would be $5.80.

* * *

An interesting example of the value of a storage battery as a regulator for lighting circuits is to be found in the equipment of the Hartford station of the electrically operated section of the New York, New Haven & Hartford. The Hartford station is at the end of the third-rail section and its supply of current is taken wholly through the third rail. The voltage of this circuit as shown by the lower curve of the diagram varies from 175 volts to 550 volts. This wide fluctuation in voltage made it impossible to use an ordinary motor-generator set for lighting the station; accordingly a regulating battery was installed.



LOAD DIAGRAMS.

The generating unit consists of a 45-kw. shunt-wound generator direct connected on a common bedplate to a specially compound-wound motor, the compounding being so designed as to run the motor as nearly as possible at constant speed through large variations of voltage in the motor circuit which is derived from the third-rail system of the railroad.

The plant is installed in a small brick structure built against the company's right of way. The battery consists of 62 cells of chloride accumulator, made by the Electric Storage Battery Co., of Philadelphia. Each cell is a tank 23⅜ x 19¾ x 22⅞ in. and contains 11 type G plates 15½ x 15½ in., which fill but one-half the cell.

The battery is directly across the system as a regulator, receiving its charge through the hours of light load as may be seen from the left hand curves in the diagrams and only being required to furnish a small amount of current when the generator current drops, due to the fall of potential in the motor circuit, to a point below the lighting load indicated by the straight line in the diagram. On the right hand of the diagram it is seen that when the lighting load is at its maximum a very considerable portion of the current comes from the battery, the discharging periods being represented by section lining. When the lighting load is at its minimum the motor-generator is shut down and the lighting done from the battery alone, constant potential being maintained by the ordinary method of cutting in reserve cells.

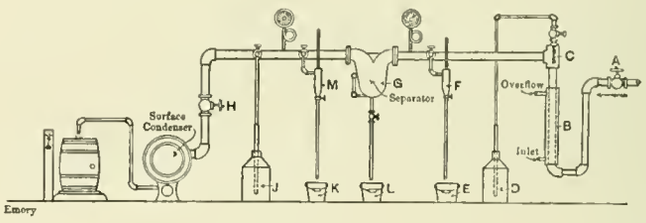
TESTS OF A STEAM SEPARATOR.

Mr. F. L. Emory presented a paper of this title before the American Society of Mechanical Engineers at its recent meeting in Washington in which were given the results of tests of a separator of the baffle-plate type designed to serve as a live steam separator, as an exhaust steam separator or trap and as an oil extractor. The external appearance of the separator may be seen from the diagram showing the arrangement of the apparatus; the



casting forms a depending bafile plate and has grooves and ridges along which the water flows after impinging on the plate or other walls of the chamber.

In the figure showing the apparatus A is the valve connecting the steam main with the boiler. At B is a cold-water jacket by means of which the steam to be used in the separator test was changed in quality. At C a steam nozzle took steam sample from the vertical pipe to a separating calorimeter D, and the steam's quality was thus known before passing into the separator. The steam gauge and throttling calorimeter F also checked this determination. The steam then passed through the separator G, and the drips were collected at L, the water level in the separator being kept constant. After passing the separator the steam was again sampled by the throttling calorimeter M and the separating calorimeter J, and passed through the valve H, by means of which the velocity was controlled and changed on different runs. The steam condensed by the surface condenser was pumped to the barrel on the platform scales and weighed. The throttling calorimeter on the right was not used with the very wet steam. By using the valves of the drips L and K, and also the steam used by the calorimeter J, the separator itself was used as a check calorimeter. All apparatus was carefully calibrated before the runs.

From the tests of the apparatus as a steam separator at pressure ranging from 1.3 lb. to 86.1 lb. gage pressure the conclusion is

**Price of Oil per Barrel.

drawn that if the separator is kept well drained it will deliver steam dry within 3 per cent. If the steam has less than 3 per cent of moisture initially the separator has little effect as such.

To test its efficiency as an oil extractor the calorimeters and other unnecessary apparatus were removed and steam allowed to flow through the separator to the atmosphere as would be the case in practice with a non-condensing engine.

A known amount of cylinder oil was pumped into the steam pipe slowly as it would be under working conditions, and the efficiency of the separator taken to be the ratio of the oil recovered to that injected. The oil was so intimately mixed with minute globules of water that the weight of oil recovered could be determined only from computations based on the weight and volume of the mixed oil and water and the known specific gravities of the two.

The results of three tests were as follows:

Oil put in.	Mixture taken out.	Per cent of oil regained.
lb.	lb.	
1.86	2.81	58.6
3.05	5.1	53.
1.4	1.82	42.

In round numbers an average of 52 per cent of the oil was recovered, although the mixture that might be used for lubrication again was a much larger amount.

TREND OF CENTRAL STATION DESIGN.

Abstract of an address before the Northwestern Electrical Association, By B. J. Arnold.

The problem which confronts the power-station designer is almost invariably that of the operation of arc lamps, incandescent lamps and motors for various purposes, with the greatest degree of economy, and with as little expenditure in first cost of plant as possible. This is strictly true of combined lighting and power stations, which present the most difficult cases to handle. When, however, the problem is simply one of the development of electrical energy for power purposes only, such as railway work or transmission work, it becomes much simplified. Since the question of the design of a station is interlinked with and dependent upon the system of distribution adopted, we find ourselves struggling with many of the old questions and some new ones, such as the alternating arc versus the series arc and the constant-potential arc, the polyphase transmission plant versus the direct current, the advisable voltage, either alternating or direct, to adopt for central-station work.

The old belted station we may consider obsolete and come at once to the general types which have been recently installed by competent engineers, and which may be considered as embodying the latest ideas of those skilled in this class of work. In all of these stations we find certain main parts which may be considered as accepted practice. Of course, there are many belted stations running and doing excellent service, which simply speaks well for the engineers and designers, and more especially the manufacturing companies who installed them in the earlier days, because at that time there were few engineers skilled in this branch of work, except those employed by the manufacturers.

The points in accepted practice may thus be summarized:

Water-tube boilers, capable of carrying high steam pressures. This probably will be disputed somewhat by the advocates of other types of boilers, and with some reason, but it nevertheless has become almost standard to use water-tube boilers in modern central stations.

Mechanical stokers, or improved furnaces or grates.

Self-supporting brick or steel stacks, usually steel. A steel stack can be put up for considerably less money than a brick stack, and for all practical purposes it is equally as good, and can be maintained a sufficient number of years to warrant its adoption in almost every case, if properly looked after.

High-pressure steam piping is not duplicated, as was thought necessary by engineers 8 or 10 years ago, practice having proven that one single steam header can be divided so as to make a plant reliable if the engines are properly located with reference to the boilers and the header. Steam piping costs excessively in a power station, and the less of it put in the better, because there is then less radiating surface to waste heat and fewer parts to keep up. The diameters of the steam heaters which are being placed nowadays are somewhat decreased, as compared with those installed four or five years ago.

Large compound condensing steam units. It has become accepted practice to install as large engines as practical, on account of the decreased cost per horse power and the increased economy of a large engine over a small one. They are almost invariably compound engines, where it is possible to condense, and in many cases where it is possible to condense or not. The tendency toward triple-expansion work is not as strong as it was five years ago. It has been determined that for almost all cases a compound engine will get nearly as good economy as a triple-expansion engine, and in many cases just as good; it requires less investment, is less costly to maintain, and the difference in economy of the triple expansion over the compound is so slight that it makes it inadvisable to install, except in exceptionally large sizes. On account of the excessive diameters of the low-pressure steam cylinders in large compound engines it is the practice to install triple-cylinder compound engines; that is, to divide the low-pressure cylinder into two smaller cylinders, the combined area of the two being equal to the area of the large cylinder of a single compound engine.

Direct-connected generators of large capacity. What has been said in general regarding large steam units applies equally to electrical generators, because the larger the unit the greater the economy of the combined unit.

To these chief features of design, which have become so generally accepted as to require little or no discussion, there may be added several features which may be justly called "tendencies" or "trends," which have not yet been universally adopted.

Economizers come under the first heading. There is no doubt, in my judgment, but that there is economy in the use of an economizer, ranging from 5 to 7 or 8 and sometimes as high as 10 per cent. In order to get the benfit of an economizer, ample draft must

be provided. Sometimes an economizer is installed where the draft is poor, the result being no economy and the annihilation of the draft. There is only one solution for this; to increase the height of the stack or introduce mechanical draft.

Mechanical draft. Under this head there are two types, induced draft and forced draft. Induced draft is a device which consists of a large fan or fans, driven by steam engines or electric motors, which are placed between the economizers and the smokestack, or, if economizers are not used, between the boiler flues and the smokestack, the object being to draw or suck the smoke from the boilers through the fan and deliver it into the stack. The advantages of the induced-draft scheme are, first, a lower and less expensive stack can be used; in fact, no stack at all is required except to get the gases above the buildings in the immediate neighborhood of the property; and, secondly, the fires can be handled under any and all conditions. We are all aware that the condition of the atmosphere changes our draft, and in case a stack is no larger than is required, there are days when it is difficult to hold steam, and it becomes necessary to put more boilers into service than would be necessary if a mechanical draft fan were used. Where the economizers can be installed in connection with induced draft an economy is always effected.

Then there is the forced draft, which consists in blowing air under the grates of the boiler and forcing it up through the fire and into the stack, which is supposed to perform the same function that the induced draft does. The objections to it are that inasmuch as it creates pressure in the firebox, the gases are liable to escape out into the room and make a distasteful fire room. Otherwise, the results accomplished are practically the same as with induced draft, and it is considerably less expensive to install, and this is its chief advantage.

Cooling devices. Under this head come cooling towers and cooling tables. During the last two years there has been a tendency to put in these cooling towers, and when properly put in there is always an economy effected, resulting in a net saving of at least 15 per cent in fuel. A tower consists of a series of vertical tubes or sheets, usually within a wrought iron frame, through which air is forced by blowers, driven by steam engines or electric motors, and down through which flows, or sprinkles, or is spread, the water delivered from the condensers. The water coming in contact with the air is cooled and accumulates at the bottom of the tower, and is then pumped into contact with the steam and condenses it. The same water is used over and over, so that only from 5 to 10 per cent will have to be renewed on account of the evaporation. The 5 per cent must be added from the city waterworks, or other outside source.

In place of the cooling tower, where real estate is cheap and available, a table can be erected, consisting of a series of boards laid gridiron-shape, upon which the water is delivered by the condenser pumps and is sprinkled down through the boards, and the air from the atmosphere penetrating through underneath the shelves comes in contact with the hot water and cools it. It then forms a pool at the base of the shelves and is taken from there and pumped back in contact with the steam in the same manner as in the cooling tower. This device can be installed for the same, or less, amount than a cooling tower, and it is advisable to install it where there is sufficient real estate to place it upon, because it requires no power to cool the water, and power is required to drive the fan of a cooling tower.

Motor-driven auxiliaries. Many of the most modern plants are equipped with electrically driven air pumps, boiler-feed pumps and cooling tower motors, if tower is used. There is a question as to whether this is the most economical thing to do or not. I incline toward the belief that there is economy in the use of electrically driven auxiliaries, on account of the non-wasting of heat by pipe radiation, if for no other reason, because the primary objects to be obtained in a power station are to generate the steam with as little fuel as possible, lead it as direct as possible to the steam cylinders, where it is to do its work, and exhaust it into the vacuum as quickly, with as little pipe to radiate heat, as possible; and electrically driven auxiliaries seem to me to accomplish this result better than any other.

Rotary converters. These devices are rapidly coming into use for transmission work, and a number of the most modern railways in Europe and in this country have been equipped in this way during the last year, and with excellent results.

What is known as a rectifier has been used extensively in Europe, and seems deserving of more attention than it has received in this country. This machine accomplishes the same result as a rotary converter without the use of field coils or any revolving parts except commutators.

Boosters have been adopted in a number of Edison central stations and railway plants.

Storage-battery auxiliary. The advantages of this feature have been so thoroughly discussed of late that it will be unnecessary for me to enter further into a discussion of its merits. While some engineers are not yet ready to consider its use established practice, its adoption by many of the leading direct-current stations of this country should prove its usefulness. I say this impartially, because I have no connection with any battery interests at the present time, although I have had until recently.

Having enumerated somewhat briefly the principal factors which are working to shape the design of the future central station, I will briefly describe two types of stations which have lately been built, and seem to represent the latest practice.

1. The composite station, consisting of two or more independent steam units, carrying upon the engine shaft a direct-connected generator suitable for giving light or power, and, in addition, a pulley or flywheel carrying a belt or rope driving a common shaft, to which the other engines similarly drive, and from which small direct-current arc machines or other old-style machines derive their power. This type is admirably adapted for utilizing out-of-date machinery. There have been several large plants of this style installed in the last two or three years by a leading firm of engineers, and the stations, I understand, are giving excellent satisfaction. I refer particularly to the stations at Toledo and Washington, and the solutions of the particular conditions of those cases seem happy ones, because they enable the owners of the properties to utilize all of their old machinery until such times as it may be deemed advisable to change.

2. The second consists of independent engines carrying direct-connected generators. This type is admirably adapted for plants where but one kind of current is delivered, but in case two kinds are required, it becomes necessary to have a generator of each type upon each engine shaft, or have double the number of reserve units that would be required if but one kind of current were desired from the plant. In either case the investment in plant becomes excessive to insure reliability. Two or more kinds of current can be obtained from such a plant by making all of the generating units alike, so far as kind of current is concerned, and driving secondary generators by means of motors running from the main generators.

While the stations first mentioned are good engineering, I believe this is better engineering to eliminate belts entirely, and if there are a number of different types of machines to drive, it is better to produce energy from standard machines of the same character and size, if possible; then drive the older type of high-speed machine, directly connected, from motors; and the efficiency of the combined plant will, I believe, be better than where the belted type is used.

3. There is one other method of construction, which I will not class as accepted, but mention it as a tendency in power-station design, known as the "Arnold system."

(In the discussion following his address Mr. Arnold was urged to say more concerning the Arnold system, and he then added a brief description of such a plant.)

There has recently been a plant installed under this system of 5,000 kw. ultimate capacity, 1,500 of which is now running, and I will describe it, and from the description you may get an idea of what the system is. One engine is installed with a shaft terminating in a flange. Then sufficient room is left for two generators, and then another engine is installed, having a flange on each end of its shaft to which to connect generators. Between the two engines are placed two generators having their shafts in line with the engine shafts. These generators are mounted on hollow shafts or quills carried in their own bearings. Beginning at the end of one engine shaft and extending through the quills, but not touching them, to the other engine shaft is an auxiliary shaft carried in two bearings near its center. With this auxiliary shaft, which is independent of either engine or generator shaft, either one or both the generators between the engines can be connected to either engine when in motion or standing still. This interior shaft does not revolve under normal conditions, but lies idle to be taken up in an emergency,

and under normal conditions you drive directly connected. You can add machines, generators and engines, in line, if you choose, and when you get another engine you have four generators available from each large or interior engine. By making the end engine extra strong, so that it will carry 100 per cent overload, which can very easily be done with slight increased cost, in case the large engine lets down you can run two generators at full capacity from the small engine until the large engine is again ready for work. This requires much less investment in plant than would otherwise be necessary to meet this emergency with independent units of power.

STANDARDS FOR DIRECT CONNECTED GENERATING SETS.

A paper read before the American Society of Mechanical Engineers, by J. B. Stanwood, Cincinnati.

An important factor in America's industrial progress has been the extended application of standards. There are standard dimensions for materials; standard sizes, parts, and capacities of machines; standard gages for close measurements; standard systems of inspection and testing, etc.

These different forms or methods of standardization have usually originated or developed in commercial and manufacturing activities, independent of any governmental instigation or control. They are universally recognized and employed wherever industry and commerce exist throughout our land.

This principle, as carried out in our individual shops and factories, has developed the well-known "interchangeable system" of construction, which, by forcing attention and care upon little things, has further specialized operations, and has stimulated the development of special machines to perform these operations, to the end that the cost of production has been greatly reduced.

Such standardization inside and outside of the shops also aids rapidity of production, inasmuch as standard material can be kept in stock to form standard parts or to complete standard machines, apparatus, or goods, all before these are even ordered.

These results—cheap production and prompt delivery—in connection with a high grade of product (to which these methods contribute) are most powerful factors for securing and maintaining foreign trade. Such influences are particularly active in America today.

In the steam-engine industry these methods have been largely in use; but within the past few years they have been rendered partially inapplicable by a radical change in the environment, due to the introduction of electricity and the employment of high steam pressure.

Whenever new types are undergoing development, before that weeding-out process known as "survival of the fittest" determines what the new type is to be, then standards have to wait until the process is complete. As regards the steam engine, it seems as if in one direction this determination of a type was well nigh completed, and that the time for some standardization had arrived; and, the sooner that this is done, a source of great expense will be avoided, and opportunity for further development and progress extended.

By the introduction of an electrical generator attached to and directly driven by the main shaft of a steam engine a new machine has been evolved. But the introduction of this system has brought a world of complication and expense to both the engine and generator manufacturers, while, to some, serious financial loss has been the result.

The principal cause of these difficulties has been the lack of standard sizes, speeds, and important dimensions of electrical generators, so that the adaptation of the steam engine in each case has been made a special problem, frequently requiring special design and construction.

To complicate the matter, the determination of the sizes and speeds of such generators is usually in the hands of a third party, who is not in touch with either the engine or generator builder. He may be a consulting electrical or mechanical engineer, an architect, a salesman, an agent, or some person presumably skilled in deciding upon the necessary machinery to satisfy certain conditions.

If fortunately there had existed a list of capacities and speeds for electrical generators that was recommended by proper authorities, this list would gradually be used by such persons in securing and specifying the machine to be employed. As it now is, any odd size and speed may be selected by them; as, for instance, to my knowledge, a 45-kw. generator to be operated at 210 revolutions was once specified, almost at random.

If for such a generating "set" bids are taken, then the engine and dynamo contractors who are unlucky enough to secure the order must design a special outfit. Perhaps this is the first time that A's engine has ever been sold to drive one of B's generators, and a new size of engine may have to be built, or vice versa; at any rate a correspondence ensues with an interchange of drawings for a new pattern of sub-base which has to be made. It may happen that the engine shaft has to be enlarged to fit the armature, or the latter has to be changed to fit the shaft. Later the shaft has to be shipped to the dynamo shop to be pressed into the armature, or the armature sent 500 or 1,000 miles to be fitted to the shaft. In all this it is fortunate if mistakes or misfits do not occur.

When the combined plant is ready for erection the engine erector has to co-operate with the electrical erector; usually one waits for the other a few days, under expense, doing nothing. Then begins the adjustment of the engine's speed to suit the generator's speed, which may be slightly fast or slow as the case may be; the governor, too, may be out in a similar way.

All told, these operations form a complicated and cumbersome system, which would be greatly ameliorated if there existed recognized and approved standards for a very few and simple conditions.

What are the features that need standardization? First, for the use of the outside engineer there is a need for a standard series of capacities and speeds; and, second, those parts of the engine and generator which have to be connected or fastened together should be standardized for each different size to facilitate the assembling of the combined machine or "set."

1. (a) Relative to a standard series of capacities and speeds, the different capacities or sizes should be selected to satisfy the usual demands of the market. The number of different sizes should not be too large, in order that the cost of production may not be enhanced by too great a variety of both generators and engines.

In this connection, there might be a standard method of determining the capacity of a generator, which would designate, with a given load or percentage of overload, a given time limit within which a permissible increase of temperature of the field-coils, armature, and commutator can occur.

(b) Relative to speeds, there should be at least three classes of speeds for each size or capacity of generator, corresponding, in the main, to the three classes of engines now on the market. These are known respectively as slow, medium, and high speed engines. By arranging the generator speed in this manner most of the conditions arising in practice could be met. There would be slow speed for factory, manufacturing, or street-railway service, which would be expensive, but durable and easily tended. A medium speed could be used for lighting-plants or conditions where lower first cost and a more limited space exist, but which will require closer attention and will probably be less durable. Lastly, the high-speed "set" would be required for limited space, low first cost, but it will require close attention and will probably be subject to heavier repairs.

Perhaps a series of generators could be arranged so that, by a modification in windings only, a given size for a standard slow speed could be used for larger standard sizes, at standard medium and high speeds.

2. As to the standardization of the dimensions of those parts of the engine and dynamo which are connected together there are: (a) The shaft diameter and armature bore, which should both be expressed in thousandths of an inch; (b) the length of shaft outside of the engine, and the location thereon of the outboard bearing, should be given in inches and feet; (c) the distance from center of armature to sub-base, in inches; and (d) the length and width of generator base, and the size and location thereon of the bolts which attach it to the sub-base, are probably all that are required.

Such a system would materially reduce the complication of construction and erection. A fewer number of engines with their sub-bases and generators would be required. These, in the marketable sizes, could be carried in stock ready for any combination

thereby permitting manufacturers to avail themselves of multiple production, so great a factor in reducing costs, improving quality, and facilitating delivery.

An American system of standards well introduced abroad and at home might give to us a large share of the electrical and engine business of the world.

In this connection, it seems to me that our society and the American Institute of Electrical Engineers are the proper authorities to undertake such an investigation as will, by their recommendation, bring about such a result.

To initiate a movement for this purpose, I do move that the Council be requested to communicate with the American Institute of Electrical Engineers to ascertain if that Institute will agree to appoint a committee to co-operate with a similar committee to be appointed by the American Society of Mechanical Engineers, to determine upon and recommend a standard series of capacities, speeds, and necessary dimensions for electrical generators for direct connection to steam engines.

And, furthermore, if a favorable response be received, then the president be requested, with the concurrence of the Council, to appoint a committee of the proper size to co-operate with the committee to be appointed by the American Institute of Electrical Engineers for the purpose herewith set forth.

ROOM FOR IMPROVEMENT.

When the successful man meets an abnormal condition of affairs he treats it in an abnormal way, and this we presume, is what Mr. E. T. Birdsall did with the abnormal power plant which he described in the course of discussing Mr. Lloyd's paper on "Storage Batteries" before the American Institute of Electrical Engineers.

Mr. Birdsall thus describes his experience:

"In these days when we are struggling to get the last cent out of everything and the last watt out of every pound of coal, it is quite discouraging to run across a peculiar plant, and I did it about a month ago. I was called upon to make a test of a plant to see if it could not be improved, as they thought that there was room for improvement. The plant was in a town of, I think, about 110,000 people. It consisted of two sheds; one contained the boilers and the other the engines and the dynamos. It was alongside of the railroad, so that they dumped the coal right from the cars into the boiler room. They had, I think, three or four horizontal tubular boilers and one Heine. Nothing of the boilers was covered, except by the brickwork at the side. The steam pipe was also bare. They had one cross-compound high-speed engine, non-condensing; two smaller high-speed engines, two Westinghouse standard engines, all belted to dynamos of various vintages. Everything that was a back-number and everything that was queer they had there. They had a wooden switchboard with the finest collection on it that I ever saw. They had one of everything. They evidently had called for samples and put them up. The man who owned two-thirds of the station, after taking me around it, said: 'What do you think of it?' Well, I did not dare tell him; I would have lost my job, as they say, right then and there if I had. I made notes of the machinery and then went back to the office. He said, 'I don't think that it is earning as much money as it should.' Well, that was my opinion, too; that is what I thought then. We went back to the office and went over the earnings. In the station everything was dirty. The boiler room was not fit to pile coal in. It was simply the worst I ever saw; and we went back and went over the books. The man that I was with was president and owned two-thirds of it. Another man was secretary and treasurer and owned the other third, except one or two shares, which somebody's wife owned, in order to make up the board of directors. That was the only station in the town. Upon going over the books we found that they had a capital of $25,000. They had machinery that must have cost them $40,000 at the time when they bought it, when the question was, 'How much has the man got?' not 'What is the machinery worth?' They had capital stock of $25,000 and no bonds. They also had a surplus of $25,000 in the treasury. I saw that with great gratification. Then I saw that they had paid no dividends whatever since the plant started; but they had paid the president an average salary of $20,000 a year, and the secretary and treasurer an average salary of $10,000 a year. He said, 'Where do you see any chance for improvement?' I confess I did not see as much as I did when in the station."

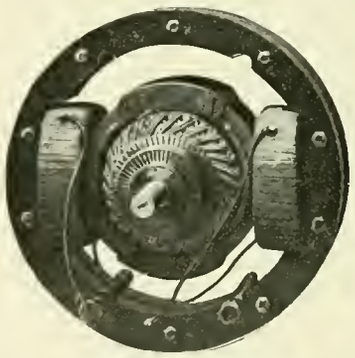
We are sorry Mr. Birdsall did not state what advice he gave in the premises.

A NEW TYPE OF ELECTRIC VENTILATING FAN.

Although the propeller or wing type of ventilating fan has been equipped with various types of electric motors, the design of these motors has hardly received the attention demanded by the importance of the work performed by such machines. The B. F. Sturtevant Co., of Boston, Mass., has of late been giving the entire subject very thorough investigation, and is now presenting a new type of fan wheel and of direct connected motor.

The wheel has been designed to secure the highest efficiency, and consists of blades secured to a light but stiff hub and held in their relative positions by a hoop at the periphery. The delivery edge of the fan wheel is helical, so that the air is picked up at the inlet edge at low velocity, and gradually accelerated to its maximum velocity with the least amount of slip.

The bi-polar type of enclosed motor illustrated in the accompanying engraving is manufactured both as a motor directly connected to a propeller fan and as an independent machine. For the former purpose it is used on all sizes of fans up to and including the 48-in. For larger sizes up to 120 in. four and eight-pole types are employed.



FIELDS AND ARMATURE.

The motor is entirely enclosed, and thereby protected from dust, a most important element in a machine used under these conditions. In order to avoid the excessive temperature which is incident to the operation of most enclosed motors, this type has been very carefully designed, so that a low temperature rise can be maintained without increasing the size and weight above that of the ordinary open type.

This machine is capable of continuous operation for ten hours, with a maximum temperature rise not exceeding 30° F. A practical efficiency of over 80 per cent is obtained even with the small-sized motors, and an excess load of 75 per cent above the rated capacity may be carried without sparking and without change of brushes. The brushes are of hard carbon, in holders of a modified reaction type, which allows of easy adjustment when it becomes necessary to reverse the direction of rotation of the motor. The bearings are self-oiling and self-aligning, and fitted with phosphor-bronze sleeves, which are removable from the outer ends of the boxes.

Officers of the American Air Power Co., of New York City, state that the recent experiments in running surface cars by air power have been entirely satisfactory, and that they will at once equip cars of the Metropolitan Street Railway Co. in 28th and 29th streets.

A decision of the Supreme Court of Massachusetts restrains the Commonwealth Avenue Street Railway Co. from erecting a car house on some of the company's ground in Auburn St., Newton, holding that there exists a restriction that no building other than a dwelling house shall be built there. This is a reversal of a Superior Court decision.

RECENT STREET RAILWAY DECISIONS.

EDITED BY J. L. ROSENBERGER, ATTORNEY AT LAW, CHICAGO.

JURY AND NOT WITNESS MUST DETERMINE ADEQUACY OF BLOCK SIGNALS.

Bergen County Traction Co. v. Bliss (N. J.), 41 Atl. Rep. 837. Nov. 23, 1898.

The opinion of a witness, that the kind of block signals used on a trolley road are not such as to insure reasonable safety to the employes operating the cars of that road, the Court of Errors and Appeals of New Jersey holds, is incompetent and irrelevant; that conclusion being a question for the jury alone to determine from all the evidence in the case.

NOT MINGLED WITH CARS.

General Electric Co. v. Transit Equipment Co. (N. J.), 42 Atl. Rep. 101. Dec. 19, 1898.

Motors, controllers and poles, sold to an equipment company, with the reservation that title thereto shall not pass until they are paid for, the Court of Chancery of New Jersey holds, are not so mingled with the cars to which they are attached that they cannot be separated therefrom and removed and title thus be reserved to them by the seller, as against judgment creditors of the street railway company owning the cars.

THROWING PASSENGER TO THE GROUND BY SUDDEN STOPPING OR STARTING.

Bourque v. New Orleans City & Lake Railroad Co. (La.), 24 So. Rep. 622. Dec. 5, 1898.

If a passenger in alighting from an electric car at point of destination, is thrown to the ground by the suddenness with which same is either stopped or started, and this result is caused or contributed to by those in charge of same, the Supreme Court of Louisiana holds, a case of negligence of the railroad company is made out, for which it must respond in damages.

ELEMENTS IN VALUING FRANCHISE FOR TAXATION.

St. Charles Street Railroad Co. v. Board of Assessors (La.), 25 So. Rep. 90. June 28, 1898. Rehearing, Feb. 20, 1899.

The Louisiana law requiring franchises to operate street railways to be taxed according to their value, makes the earning capacity of the corporation a basis for ascertaining the value at which the franchise shall be assessed, but, the Supreme Court of Louisiana holds, it does not exclude reference to other elements that bear directly on the question of that value.

ABUTTER CANNOT ENJOIN BOULEVARD COMPANY FROM LAYING TRACKS.

Redman v. Monongahela Boulevard Co. (Pa.), 42 Atl. Rev. 133. Jan. 3, 1899.

Abutting owners, the Supreme Court of Pennsylvania holds, cannot enjoin a boulevard company from putting down a double track street railway, laid with ordinary flat rails, in a boulevard which it is constructing under the Pennsylvania boulevard act of 1895, so long as the company disclaims any intention of permitting such track to be used for street railway purposes until permission so to do is granted by the complainants, though it expects the rails some time to be used by a railroad company, and its officers are the same as those of a traction company joined as a defendant.

TERM "RAILROADS" DOES NOT INCLUDE STREET RAILROADS IN OHIO.

Massillon Bridge Co. v. Cambria Iron Co. (O.), 52 N. E. Rep. 192. Nov. 29, 1898.

The Supreme Court of Ohio says that the statutes of that state relating to railroads are separate and distinct from those relating to street railroads, and holds that the word "railroad," in section 3208 of the Revised Statutes, giving a prior lien to laborers and furnishers of materials over mortgages, and in section 1 of the act of March 20, 1889, does not include street railroads.

MOTORMAN MUST LOOK ON SIDES OF TRACK.

City Railway Co. v. Thompson (Tex.), 47 S. W. Rep. 1038. Dec. 3, 1898.

It is the duty of a motorman in charge of a car to look, not only ahead on his track, to see that his way is clear, but, the Court of Civil Appeals of Texas holds, to look on each side of his track, to see that no one is about to get on it, and that no conditions or circumstances present themselves which will evidently compel persons then in his view, passing along the street, to go upon the track in front of his car, as by an ice wagon obstructing the passage on the side of the street.

ELECTRIC STREET RAILWAYS NOT ADDITIONAL SERVITUDES UPON STREETS.

Birmingham Traction Co. v. Birmingham Railway & Electric Co. (Ala.), 24 So. Rep. 502. Oct. 29, 1898.

Electric street railways, such as have now become so well known, the Supreme Court of Alabama falls in line with what it terms a most overwhelming volume of well-considered adjudged case and holds, do not impose any new or additional servitude upon the highway, or streets of towns or cities, for which the owner of the fee is entitled to conpensation, they being built upon street grade, doing no special injury to the fee, and to be regarded as within the implied contemplation of the dedicators at the time of the dedication or grant.

LANDOWNER CANNOT CONTEST LOCATION AFTER TIME ALLOWED.

Stillwater & Machaniesville Street Railway Co. v. Slade (N. Y.), 55 N. Y. Supp. 966. Jan. 11, 1899.

Under the New York Railroad law applicable to street surface railroads the third appellate division of the Supreme Court of New York holds that a landowner cannot contest the location of a street surface railroad, unless he takes the prescribed action therefor within the fifteen days allowed him after the service upon him of notice of the filing of the map and profile, the due process of law to which he is entitled in this respect consisting in affording him a reasonable opportunity to have his grievance redressed, if any he has, which the fifteen days give him.

SUIT CANNOT BE MAINTAINED "FOR THE USE OF" AN ASSIGNEE.

West and South Town Street Railway Co. v. Joseph Capek, for the use of Leo Roeder (Ill.), 31 Chicago Legal News 285. April 11, 1899.

In what is known as "Ackley Case," where the Supreme Court of Illinois decided against the assignability of actions for personal injuries, the suit was brought by and in the name of the assignee. But here is a case where suit was brought in the name of the party injured "for the use of" the assignee. Does the doctrine of the Ackley case apply? The branch Appellate Court, first district, of Illinois, holds that it does, and that an action for injuries cannot be maintained for the use of, when it could not be in the name of, an assignee of the claim in question.

WANTON NEGLIGENCE TO ATTEMPT TO CROSS BETWEEN CARS.

Meyer v. Pittsburg, Allegheny & Manchester Traction Co. (Pa.) 42 Atl. Rep. 41. Jan. 3. 1899.

The undisputed testimony given on behalf of the plaintiff in this

case proved that the plaintiff's husband, being at the side of the street, not at a crossing, and seeing two cars approaching each other from opposite directions, on the two tracks of the road, undertook to cross both tracks at a point between the cars. He was not successful in his attempt, but was struck and killed by one of the cars. After making this statement, the supreme court of Pennsylvania declares there is no possible reason why the defendant should be held liable to pay damages for such manifest and really wanton negligence; and that a nonsuit was therefore properly directed.

CARE REQUIRED OF PERSON PASSING CAR BARN.

Downs v. St. Paul Railway Co. (Minn.), 77 N. W. Rep. 408. Dec. 20, 1898.

Here a boy sixteen years old was struck by a car while he was trotting or running along the sidewalk in front of a car barn and power house; and the Supreme Court of Minnesota holds that a verdict for the defendant was properly directed, on the ground that the boy was guilty of contributory negligence. It holds that he was bound to exercise ordinary care. It may be conceded, it says, that he was not, as a matter of law, bound to stop and look through the doorway before crossing the tracks; but it insists that it was negligence for him to heedlessly trot along in front of the opening, and only two feet therefrom, without doing anything to ascertain whether a car was coming out—knowing that one might come out at any moment.

HANDSOME PLAINTIFFS HAVE SAME RIGHTS AS OTHERS.

Omaha Street Railway Co. v. Emminger (Neb.), 77 N. W. Rep. 675. Dec. 22, 1898.

While it was not insisted that ordinarily there would be error in exhibiting to a jury a limb injured as the one here in question had been, which had been run over between the knee and the ankle, yet it was contended that it was improper in this instance, for the reason that the party suing, a female, was young, handsome, and attractive, and, consequently, that the sympathies of a jury composed of men were unduly excited in her behalf. But the Supreme Court of Nebraska answers that the motto on the coat of arms in that state is, "Equality before the law." This young person, it continues, suffered injuries for which she sought compensation in damages, and she was entitled, in sustaining her claim, to resort to the same proofs that she might have resorted to if she had been aged, ugly, and repulsive. However, the Supreme Court thinks $5,000 sufficient compensation for her, and demands that $5,080 awarded over that sum be remitted.

CITY CANNOT CREATE CIVIL LIABILITY FROM COMPANY TO CITIZEN.

Sanders v. Southern Electric Railway Co. (Mo.), 48 S. W. Rep. 855. Dec. 23, 1898.

A city, to which a portion of the police powers of the state has been delegated, has a right to enact police regulations, and to punish their violation by fine and imprisonment; but the Supreme Court of Missouri, division No. 1 holds, it cannot, under the guise of its police powers, create a liability from one citizen to another, or create a civil duty, enforceable at common law, for this is the exercise of the power of sovereignty, belonging alone to the state. The Legislature may delegate a part of the police power of the state to a municipality, but it cannot delegate the legislative function of making laws that will be binding upon citizens, between themselves, in civil proceedings. And what it here says about creating a liability from a citizen it gives full benefit of to a street railway company.

PRIORITY OF RIGHT OF ERECTING TROLLEY WIRE AUTHORIZES CROSSING ANOTHER WIRE.

Birmingham Railway & Electric Co. v. Birmingham Traction Co. (Ala.), 25 Southern Reporter 102. Feb. 1, 1899.

A street railway company in undertaking to erect its trolley wire along its own right of way, and across the trolley wire of another street railway company, the Supreme Court of Alabama holds, is not violating that clause of the constitution guarantying to the latter company that its property shall not be taken until just compensation be first paid, when the former company acquired its right to erect a trolley wire along its right of way prior to the construction of the road by the company the wire of which it must cross. In other words, the court holds that the mere postponement by the one company of the exercise of its right to convert its system of steam power into that of electric power, which was known to the other company, would not preclude it from exercising it, and invest in the latter company such a superior interest in the use of the street, which it acquired subsequent to the acquisition by the first company of the right to use electricity, as would entitle it to demand compensation for such use.

SUMMER RESORTS DO NOT MAKE ELECTRIC ROADS PUBLIC NECESSITIES.

In re Auburn & Western Railway Co. (N. Y.), 55 N. Y. Supp. 895. Jan. 18, 1899.

A summer resort is, at the best, says the fourth appellate division of the Supreme Court of New York, too ephemeral to furnish a satisfactory basis for declaring a railroad which will accommodate its patrons, by reason of that fact, a public necessity, the patronage from this source necessarily being limited to a small portion of the year. Moreover, touching the relative rights of projected and established roads, the court says that, while it is the undoubted policy of the law to foster and encourage every legitimate enterprise which is at all likely to prove advantageous to the general public, it is, at the same time, the obvious duty of those upon whom the responsibility rests to issue certificates for new roads to exercise a wise discretion in these matters, to the end that one enterprise, however alluring it may seem, shall not be aided and encouraged at the expense of another, which is perhaps equally deserving.

DOUBTFUL CHANCES IN CROSSING IN FRONT OF CAR NOT TO BE TAKEN.

Harvey v. Nassau Electric Railroad Co. (N. Y.), 55 N. Y. Supp. 20. Dec. 6, 1898.

A person is not at liberty, the second appellate division of the Supreme Court of New York holds, to take even doubtful chances of the consequences of crossing the street in the face of danger, or of reliance upon a successful attempt of the motorman to stop the car. If he sees an approaching car, and does not take proper steps, in other words, use reasonable care to avoid it, he is chargeable with negligence. Moreover, the court holds, it is not a rule of law that a street car must be operated beyond the possibility of injury to pedestrians or vehicles. The obligation is to exercise reasonable care in operation, to be watchful and vigilant when approaching street crossings, and have the car well under control. Beyond this the obligation does not extend.

DERAILMENT OF CAR IMPLIES NEGLIGENCE.

Bergen County Traction Co. v. Demarest (N. J.), 42 Atl. Rep. 729. Mar. 8, 1899.

In a suit brought against a street railway company by a passenger for injuries caused by the derailment of the car, the Court of Errors and Appeals of New Jersey holds that proof of the happening of the accident is sufficient to charge the company with negligence, and to place upon it the burden of showing that the injuries were not received through any fault on its part. It is a matter of common knowledge, says the court, that the roadbed of a street railway is so built, and the cars so constructed, that, when there is no defect in either, and the cars are run with due care, the latter will remain upon the track; and, consequently, proof of the derailment of a car, in the absence of evidence to the contrary, justifies the conclusion that it resulted either from improper construction, failure to keep in proper repair, or negligence in operation, though, ordinarily, proof of the occurrence of an accident will not, of itself, support a conclusion of the defendant's carelessness.

RIGHT TO OPERATE CARS OF LEASED LINE ON JOINTLY USED TRACKS.

Coney Island & Gravesend Railway Co. v. Coney Island & Brooklyn Railroad Co. (N. Y.), 56 N. Y. Supp. 508. Mar. 7, 1899.

Under an agreement between two street railway companies, whereby the parties obtained an equal right to use a certain piece of track for all of the purposes for which they might find occasion, either in their business which then existed, or in their subsequent development and extension, there being no limitation, except that one may not be permitted to impair the right existing in the other, the second appellate division of the Supreme Court of New York holds that the operation of the cars of a leased line thereover will not be enjoined, it making a distinction, between such a case and one presenting the ordinary case of a trackage agreement, by which one street railway company obtains the right to the use of the tracks of another at an agreed compensation, wherein it has been held that the agreement does not operate to authorize the lessee to make use of the track for the operation of cars of other lines which it had subsequently leased.

MANAGER CANNOT GIVE OPINION OF COMPETENCY OF MOTORMAN.

Langston v. Southern Electric Railroad Co. (Mo.), 48 S. W. Rep. 835. Dec. 8, 1898.

To permit the defendant's manager, over the plaintiff's objection, to give to the jury his opinion that the motorman in charge of the car when the plaintiff was hurt was in every way competent, and one of the best on the road, the Supreme Court of Missouri, division No. 1, holds was reversible error, the purpose of this evidence being to rebut the charge of negligence made in the pleadings, and which the plaintiff's testimony tended to support, and to show that it was improbable that the car was suddenly jerked forward by any improper action of said motorman. If this competency was to be passed upon by the jury, the court says, they should have been furnished with facts upon that subject, and not the mere opinion of the witness. The experience of the motorman, his opportunity for familiarizing himself with the work, and learning the method of performing the same, and the length of time that he had been engaged in that position, it adds, would have been proper for that purpose.

RULE OF LOOK AND LISTEN INFLEXIBLE.

Cawley v. La Crosse City Railway Co. (Wis.), 77 N. W. Rep. 179. Nov. 1, 1898.

The supreme court of Wisconsin holds that the rule is inflexible and the duty is absolute to look and listen before going upon either a steam railroad track or an electric street railway track, and to see and hear an approaching car if within plain view and hearing, to a person exercising his senses of hearing and seeing with ordinary prudence, to detect it, having regard for the dangers reasonably to be apprehended, and that failure to perform that duty, or, after performing it, to keep out of the region of danger, is negligence per se (in itself); that it is not a mere rule of evidence which a jury may be permitted to consider, and say there was or was not negligence in a given case, according to their notions, but that it is a rule of law to be applied by the court when the facts are undisputed, and by the jury under the direction of the court, when the facts are disputed. The court further suggests that this rule is just as applicable to the crossing of a street railway track operated by a cable.

WHAT MOTORMAN MAY EXPECT WHERE TEAM IS DRIVEN TOWARDS TRACK.

Sanders v. Southern Electric Railway Co. (Mo.), 48 S. W. Rep. 855 Dec. 23, 1898.

A correct proposition of law, the Supreme Court of Missouri holds, is announced by an instruction, which the judge was asked to give the jury, in this case, that, if, from the evidence, they believed that the defendant's servants operating its cars saw the plaintiff driving towards the defendant's track, they had a right to presume that he would not attempt to cross immediately in front of the train; and that if the jury further believed from the evidence that the plaintiff, on approaching the track, saw the car coming, and halted his wagon, and that the defendant's motoneer saw this, then the motoneer had the right to presume that the plaintiff intended to remain halted until the cars had passed him; and that if the jury further believed from the evidence that the plaintiff started up again, and drove onto the track, and that the motoneer stopped the car within the shortest time and space practicable after the plaintiff started up again, then their verdict should be for the defendant company.

WHEN PERSON ATTEMPTING TO BOARD CAR IS INJURED.

Bachrach v. Nassau Electric Railroad Co. (N. Y.), 54 N. Y. Supp. 958. Dec. 13, 1898.

Before the servants of a street railway company can be charged with negligence, the second appellate division of the Supreme Court of New York holds, they should have been either fairly apprised that the person injured in attempting to board the car desired to board it, or that the situation was such that passengers might be naturally expected to get upon the car at the time. In this case, the court reverses a judgment given the plaintiff, for injuries sustained while attempting to board a car, because he failed to show either that the motorman recognized or should have recognized the signal made to him, or that the situation and movement of the car were such that the motorman should, in the exercise of ordinary care, have appreciated the fact that persons might be seeking to board the car as passengers, the reason for the slackening of the speed of the car at the time being entirely accounted for by another cause than anticipation of passengers, and might have been on account of the crossing of another railroad.

TAXPAYER CANNOT ATTACK CONTRACT FOR BUILDING STREET RAILWAY.

State (Randolph and others, Prosecutors) v. Board of Chosen Freeholders of Union County (N. J.), 41 Atl. Rep. 960. Dec. 6, 1898.

The fact that a street railroad company, with which a board of chosen freeholders has made a contract, under the New Jersey act of June 13, 1898, entitled "An act to authorize boards of chosen freeholders to widen, straighten, grade and otherwise improve highways under their control, and to provide for the construction of street railroads therein," to construct a street railroad upon a public highway under its control, has no franchise, apart from such contract, to construct or operate a street railroad upon such highway, the Supreme Court of New Jersey holds, does not give a taxpayer owning land upon the highway a standing to attack the contract. It also holds that the direction contained in said act that commissioners appointed on condemnation of lands taken for the purpose of widening, straightening, or changing the location of a highway in making their estimate and assessment of damages, "shall take into account the benefits conferred by the improvement on the remainder of any lot or tract of land partly taken," is not unconstitutional.

INJUNCTION REFUSED AFTER ROAD IS BUILT AND IN OPERATION.

Becker v. Lebanon & Myerstown Railway Co. (Pa.), 41 Atl. Rep. 612. Nov. 14, 1898.

After the work of location and construction of this railway was commenced, but before the workmen had arrived at the complainant's land, the latter filed a bill, in equity, to enjoin the railway company from constructing and operating the road in front of his premises. No application, however, was made for a preliminary injunction; and the road was in full operation before the company filed its answer, while it was nearly two years and a half later before the complainant took any further step to bring the suit to a hearing. Under these circumstances, and notwithstanding that the company had admitted that it had constructed its track on the turnpike in front of the complainant's premises with-

out legal authority, though not in intentional violation of law, the Supreme Court of Pennsylvania holds, in view of the loss to the company, the inconvenience to the public, the smallness of the injury to the complainant, and its easy compensability in money, that, however clear his right, no injunction should be granted, but he should be left to his remedy in damages.

"LOCATION" OF TRACKS DOES NOT INVOLVE PRIVATE RIGHTS.

State (Moore and others, Prosecutors) v. West Jersey Traction Co. (N. J.), 41 Atl. Rep. 946. Dec. 16, 1898.

A statute (3 General Statutes, of New Jersey, page 3237, section 126) authorized borough councils, upon public notice to all parties interested, to grant or to deny to a street railroad a location of its tracks confortably to its route; such grant, if made, to be upon such lawful restrictions as the interest of the public was deemed to require. Upon notice, consent to a location was given, upon the restriction, among others, "that the limit of this consent shall be twenty-five years from the acceptance of this ordinance." Subsequently, and without notice, a supplement to this ordinance was passed that eliminated the above restriction.

Under these circumstances, the Court of Errors and Appeals of New Jersey holds: That the municipal act of the "location" of a street railroad operated by the trolley system does not involve any private rights.

Such location is a legislative, and not a judicial, act.

Apart from express statutory requirement, notice is not requisite.

The notice required by the act is satisfied when it has been complied with.

Whether the action of council was in bad faith is not a judicial question.

Magie, Chief Justice, and Lippincott and Vredenburgh, Justices, dissent.

STARTING CAR WHILE PASSENGER IS GETTING OFF.

Morrison v. Charlotte Electric Railway, Light & Power Co. (N. C.), 31 S. E. Rep. 720. Dec. 13, 1898.

It was urged in this case that the car, an open one, stopped long enough for the plaintiff to get off, and that, if she got hurt by the car's starting before she got off, it was her own fault—negligence. The company also contended that she got off with her face turned the wrong way, and that this was her fault—negligence; that these contributed to her injury, and were the proximate cause of the same.

But even if it be admitted that 10 or 12 seconds is sufficient time to allow a woman to get off the car, and that she did not move as quickly as she might have done, still the Supreme Court of North Carolina maintains that the defendant was guilty of the grossest negligence in starting the car when she was getting off, in plain view of him. He must necessarily have seen her if he was paying attention to his duties; and if he was inattentive to these duties, and started the car without seeing her, he was guilty of gross negligence.

This being so, and it being shown—admitted—that the plaintiff's injury was caused by starting the car, over which she had no control, the court declares that it is difficult to see how the manner in which she was getting off contributed to, and was the proximate cause of, the injury, or that the length of time—10 or 12 seconds—could have contributed to, and have been the proximate cause of, the injury. Consequently, it affirms a judgment for the plaintiff.

PRESUMPTION FROM COLLISION OF CARS.

Falke v. Second Avenue Railroad Co. and Third Avenue Railroad Co. (N. Y.), 55 N. Y. Supp. 984. Feb. 7, 1899.

This action was brought to recover damages for personal injuries sustained through a collision between a Second Avenue horse car, on which the plaintiff was a passenger, and a Third Avenue cable car, at a point where the roads of the two companies intersect substantially at right angles. The plaintiff got judgment, but the Third Avenue Railroad Co. appealed, and the second appellate division of the Supreme Court of New York has reversed the judgment, ordering a new trial, on account of what it deems substantial error in the following charge to the jury:

"The accident which happened in this case—a collision between two cars running upon tracks which crossed each other—was one which, in the ordinary course of events, would not have happened unless some one had been guilty of negligence, and hence the mere fact that such an accident happened at all raised at once sufficient presumption of negligence upon the part of the defendants to make it incumbent upon them to produce evidence to show, as to each of them, that it, at least, had not been guilty of such negligence."

Doubtless, from the mere occurrence of the collision, the appellate division says, the presumption of negligence arises, and, had the action been against a defendant in the control and operation of both cars, such a defendant would be properly called upon for explanation. In such a case the charge of the trial judge would have been correct.

But in this case, the court goes on to point out, two different parties controlled the operation and management of the cars. There were two actors in the collision, the driver of the Second Avenue car and the gripman of the Third Avenue car. It was entirely possible, and also entirely probable, that the collision might have been due solely to the fault of one of the parties, and that the other might have been in no way to blame. Therefore, the court holds, the presumption of negligence arising from the accident did not tend to inculpate either party. Proof, it says, that one of two or more parties must have committed a tort, or became subject to a contract liability, does not establish the liability of any particular one of the parties, nor subject any party to the burden of explanation.

Of course, continues the court, this would not be applicable to the case of the Second Avenue Railroad Co., which assumed by contract the duty of transporting safely its passengers, so far as human care and foresight could accomplish that result, and of guarding and protecting them, even as against the negligence of other parties. But the Third Avenue Railroad Co. stood in no contractual relation to the plaintiff, and before it could be put on its defense, or called on for explanation, it was necessary for the plaintiff to present proof tending to establish that it was negligent; not merely that it or its co-defendant was negligent.

DUTIES OF STREET CARS AND VEHICLES COMPARED.

Wilson v. Minneapolis Street Railway Co. (Minn.), 77 N. W. Rep. 238. Dec. 5, 1898.

An instruction was given in this case that "street cars are, in the main, governed by the same rules as other vehicles on the street, and their owners have only equal right with the traveling public to use the street." This the Supreme Court of Minnesota holds, misleading and prejudicial. It pronounces it incomplete in that it omits the necessary modifications of the general rule, growing out of the difference in the nature of the two classes of vehicles, such as the construction, motive power, mode of operation, and speed of each.

It is true, as a general proposition, the court says, that a street railway company has no proprietary and superior right to the part of the street whereon its tracks are placed, and that the duty of exercising due care to avoid collisions rests upon it, as well as upon the owner or driver of other vehicles. But the duty, it insists, is relative, and in determining in a given case whether either has exercised ordinary care, attention must be paid to the differences above referred to.

Thus ordinary care and the law of the road require the driver of an ordinary vehicle passing another going in the same direction to drive to the left of the middle of the traveled part of the road. Of necessity, no such duty rests upon a street railway company. If the driver of such vehicle is on that part of the street occupied by the railway tracks, and ahead of the cars, but driving slower than the convenience and accommodation of the public demand that the cars should go, such driver has not an equal right with the railway company to keep along the track. His duty is to seasonably get off the tracks, and let the cars pass.

So, at a street crossing, whether the company has only an equal

right with the traveling public, or a greater or a less right, the court maintains, depends on the circumstances of each particular case—for example—which one acquired the right of way.

As already suggested, the court goes on to say, each must exercise ordinary care to avoid a collision, but it by no means follows that those in charge of the cars must exercise in all cases the same, or at least as much, vigilance as the drivers of other vehicles, in order to discharge the duty of exercising ordinary care. It may be greater or less, according to the circumstances of each case. The amount of vigilance to be exercised by the one in a given case cannot be determined by an arbitrary comparison with that required of the other.

UNREASONABLE FENDER REQUIREMENT.

City of Brooklyn v. Nassau Electric Railroad Co. (N. Y.), 56 N. Y. Supp. 609. Mar. 7, 1899.

While it appreciates the danger occasioned to pedestrians on the highway from the use of trolley cars, and sees the propriety of any regulations or requirements that the Common Council may impose upon the operation and management of such cars for the safety of the public, the second appellate division of the Supreme Court of New York insists that this is always subject to the qualification that such requirements must be reasonable; that is to say—practicable—not from the point of view of expense to the companies operating the cars, but practicable in the sense that they may not improperly interfere with the discharge of the public duty of such companies in transporting passengers.

It is a matter of common knowledge, the court goes on to say, that a trolley car has springs, and a platform, forming a solid part of the car body; that the weight of passengers will depress, more or less, the body of the car, including the platform; that a car in motion will oscillate longitudinally and laterally; that the surface of a city street is not perfectly flat or even over its entire breadth; that there are grades of different degrees, and curves of varying radii, in the city streets; and that the streets themselves have different degrees of convexity.

Bearing these facts in mind, the court holds that an ordinance directing that proper fenders shall be put on all cars is plainly both reasonable and practicable, but the requirement that such fenders shall be within three inches of the tracks is entirely impracticable and unreasonable, the court taking into account further that, while it not only may be possible, but is entirely probable, that in the future mechanical ingenuity will provide devices which will enable these fenders to be maintained at a somewhat uniform height above the street, automatically or otherwise, it is clear that no such device has been invented, or, if invented, its merits have not become so known as to require its adoption.

Therefor the court holds that at the present time, and in the present state of the manufacture of fenders, a direction in an ordinance that fenders shall be maintained three inches above the tracks is unreasonable and void; but, it adds, it is the duty of the railroad companies to comply with the other provisions of the ordinance, and maintain their fenders at the least elevation practicable, the ordinance which it pronounces in other respects valid being one requiring every railroad company operating cars by electricity, in the city, to equip, within 60 days, each car with a safety fender or safeguard attached to the front platform of said car, to be made and modeled in such a manner that it will be impossible for any person or persons to pass under the fender or the platform of said car or cars and come in contact with the wheels of said car.

MILWAUKEE FENDER WORKS WELL.

The Milwaukee Railway & Electric Co. some time since equipped a number of its cars with home-made fenders of the type illustrated in the "Review" for January last, page 45, and reports of a recent collision between a buggy and a car so equipped state that the fender worked admirably; it prevented any part of the wreck from getting beneath the car.

A street car service for collecting mail was put in operation April 1st in Hartford, Conn.

MONTREAL SHIRKED ITS SNOW BURDEN.

There is always an abundance of snow in Montreal during six months of the year, and what to do with it is frequently a serious problem. When in the old horse car days, the tracks were allowed to become buried and the car bodies were shifted onto runners, the question was a simple one; but with the advent of electricity it was necessary to clean the tracks, and the accumulations were of such size that something had to be done. The city, therefore, made an agreement with the company as to a division of labor in the matter. What the experience of the company has been is set forth as follows, by Mr. F. L. Wanklyn, manager of the Montreal Street Ry.:

Section 30, of By-Law 210, which regulates the operations of this company, sets forth:

"The company shall, under instructions from the city, keep their track free from ice and snow, and the city may, at its option, remove the whole or such part of ice and snow from curb to curb as it may see fit, from any street or part of street in which cars are running, including the snow from the roofs of houses, thrown or falling into the streets, and that removed from the sidewalks into the streets with the consent of the city, and the company shall be held to pay one-half of the cost thereof."

In the year 1894 the company entered into an agreement with the city, for five years, by which the amount to be paid by it, as contemplated by the above section, as its half of the cost of removing the snow from the streets occupied by its railway, was fixed at the sum of $1,650 per mile of street per annum, the total cost of clearing the snow on such streets being thus estimated at $3,300 per mile of street.

According to published figures prepared by the city comptroller, Mr. Dufresne, and presented to the Finance Committee, the cost of clearing the snow in these streets has been as follows:

Year.	Total cost.	Paid by Company.	Paid by City.
1893-4	$98,029.38	$57,101.18	$31,928.20
1894-5	75,532.35	46,200.00	31,332.35
1895-6	71,975.87	52,470.00	19,505.87
1896-7	52,361.98	49,557.87	2,904.11
1897-8	102,416.10	50,131.66	52,284.44
	$393,315.68	$255,360.71	$137,954.97

From the above figures it will be seen that upon the basis of equal expenditure the company should have paid the city the sum of $196,657.84, whereas it has paid the sum of $255,360.71, or an excess of $58,702.87; or, to state the matter in another way, the city, instead of expending an amount equivalent to one-half of the estimated cost, viz., $255,360.71, has expended only $137,954.97, thus saving an amount of $117,405.74. The figures for the current season, so far as at present known, show a still more striking disparity than do the above.

The company contends that the city has failed in its obligations in his matter; that it has not expended an amount of money sufficient to efficiently remove the snow, and that it has thereby caused the company great loss and damage, has very seriously prejudiced its car service and thereby caused immense annoyance and inconvenience to its patrons, the citizens of the city of Montreal.

WAGES INCREASED, AND WHY.

March 17th the Joliet (Ill.) Railway Co. posted a notice announcing an increase of 10 per cent in the wages of all regular employes. This is good for the men who get the increase, and good for the company because it is able to pay it. One reason why the company could do this is that it is one of the few which was able to take advantage of the long term franchise permitted by the Allen law. At the time that law was passed the present owners had just secured control of the company, and application for a 50-year franchise was made. As soon as the long time grant was made the company, by virtue of it, floated a bond issue and expended the proceeds in improving the road and putting it on an economical basis.

The Akron Street Railway & Illuminating Co. has been granted a 25-year extension of its franchise.

NEW KANSAS INTERURBAN.

Kansas City, Mo., and Kansas City, Kas., jointly have a population of 250,000 people. Leavenworth lies 26 miles north of Kansas City and has a population of 22,000. Fort Leavenworth, the largest army post in the West, is four miles north of Leavenworth and has a population generally of 3,000 people; between Kansas City and Leavenworth there is the National Soldiers' Home, with a population of 3,000, and Lansing with the Kansas State Penitentiary and a population of 2,000, and then there are all the small towns of Wallula, Conners, Piper and White Church.

For three years local men have been at work trying to secure a franchise between Kansas City and Leavenworth for an electric road. The Home-River Side Coal Co., of Leavenworth, has made a survey between the two cities with a view of building a double track road to carry both passengers and coal and are trying to interest eastern capitalists to take the bonds. State Senator J. C. Stone and Representative Keiffer took out a charter two years ago and tried to induce Chicago capitalists to build a road between the two towns. In 1897 W. E. Winner, of Kansas City, secured a franchise from the Leavenworth County Board to build a road from Leavenworth City to Lansing. This can be connected with the present Leavenworth Street Railway, and takes in the business of Fort Leavenworth. Mr. Winner's road is nearly completed, and it is expected that cars will be running on the same within the next sixty days. They will be operated by the Leavenworth electric road.

A. A. Penn, of Leavenworth, has secured a franchise from the Leavenworth County Board from Lansing, conecting with the Winner road, Wyandotte County line; and in Wyandotte County three franchises have been granted by the County Commissioners, one to the Leavenworth and Kansas City Traction Co., which is now owned by W. E. Winner, one to Mr. Carpenter, of Cleveland, O., and one to F. N. Wilcox, of Cleveland, O. During the last four months three deputations of capitalists from Cleveland have visited Leavenworth and Kansas City and have gone over the proposed road. During the latter part of March of this year they completed arrangements with W. E. Winner to take his present road and continue on to Kansas City, Kas., and connect with the Metropolitan Ave. line, which will give access into Kansas City, Mo. A charter was secured from the state of Kansas last month to operate a road to be known as the Kansas City & Leavenworth Electric Railroad Co.

The incorporators are D. H. Kimberly, C. O. Evarts, W. H. Gabriel, H. C. Ellison and Henry W. Wolcott, all of Cleveland; W. E. Winner, of Kansas City, Mo.; C. H. Chaplin and C. H. Mathews, of Kansas City, Kas.

As soon as the weather permits work will commence. It is not decided yet which of the franchises the new company will use. It is very probable that they will make a new survey between the two cities and perhaps use a part of all of the franchises. The road, when built, will be a direct communication between Fort Leavenworth and Kansas City, Mo., a distance of about 30 miles. The trains will run every half hour and make the run in one hour.

This is one of the most fertile valleys in the United States, and the promoters expect that the building of this road will open out this new territory to factories and new enterprises of every kind. The geological survey made under the supervision of the professors of the Kansas State University last year shows that the whole of this territory is underlaid with bituminous coal such as is now being mined at Leavenworth. The promoters not only contemplate the building of factories, but also the development of the coal industry. The Leavenworth coal mines at the present time give employment to 900 coal miners, but getting access to the Kansas City markets it is expected that this number will be doubled.

Capitalists from Chicago, New York and Cleveland for more than one year have had their agents at work trying to secure a right of way for this electric road. The Cleveland capitalists have been the most persistent. They are men who are also interested in seven roads in the east. It is believed that when completed this will be one of the best paying suburban roads in America.

Mr. F. N. Wilcox, of Cleveland, Ohio, brother of Senator Wilcox, of Colorado, has just completed all the legal matters in connection with the new road, and has returned to Cleveland. He is now waiting for the survey between the two cities which has been ordered.

HANDSOME PARLOR CARS.

The accompanying engraving shows he exterior and interior views of some new parlor cars recently built by the J. G. Brill Co., of Philadelphia, for the Baltimore Consolidated Railway Co., of Baltimore, which are among the handsomest which have yet been built. They are 25 ft. long, or about 37 ft. 8 in. long over all. They are 7 ft. 5 in. wide at the sills and 8 ft. wide at the posts, and the platforms are of unusual length, 5 ft. 6 in. to the dash. The height of the sills is 30 in.; this with the platforms dropped 7½ in. brings the step within 18 in. of the ground, with a 13 in. riser. The platforms have a large zinc lined box; this is furnished with a cushioned cover and is made useful for storage and for seats. The hood has the usual supports as well as a pair of brass brackets finished in grill work; the platforms have the usual angle iron bumpers with brake shaft outside of the dashers. There are no end windows, the space on the sides of the doors being fitted with panels. Each platform is furnished with an electric headlight. The cars were mounted on maximum traction trucks with 4-ft. wheel base. The driving wheels were 33 in. and the pony wheels 20 in. in diameter. The gage is 5 ft. 4½ in.; without motors these cars and trucks weighed 19,060 lb. The in-

PARLOR CAR—BALTIMORE CONSOLIDATED.

side finish of the cars was very handsome, as can be seen from the interior view. A couch and 16 chairs, all upholstered in red plush, form the furniture.

At each window a table was provided, and the tables when not in use are packed away behind the lining panels under the windows, these panels being hinged for the purpose. A buffet is placed in each corner of the car; one of these is provided with an electric heater for warming coffee. The large window in the center of the car has stationary sash; the upper parts of the two windows on each side of the central one are also stationary but the lower parts dropped into the side of the car in the usual manner. Each window post is provided with a push button. The transom lights are all of bevelled edge plate glass. The carpet or rug which covers the parquetry floor is red. This corresponds with the interior finish of mahogany. The roller curtains are of silk faille. The hanging curtains are of velour de Flanders and were lined with cream colored silk. The ornamentation is in gold with dead gold metal work.

The Citizens' Traction Co., of Oshkosh, Wis., has increased its capital stock from $225,000 to $500,000. The object of this increase is to permit the company to operate an interurban line between Oshkosh and Neenah. The name of the company will not be changed.

Pleasure Resorts in 1899.

The town which in these days cannot boast of some kind of an attraction in it or adjacent to it, is sure to be set down as an old fogy place and is considered unworthy of mention in any gazeteer or atlas, or, in fact, in any publication outside of a post office guide. It makes no difference what the attraction is, natural or artificial, it must be something if nothing more than a country graveyard, an old sawmill or a hole in the ground which can be designated as "The Cave." This is so certainly true that something is invariably "discovered" or manufactured which the citizen can point to with more or less pride as the "attraction." Fortunately the whole country is studded with lakes and rivers, and with the inherent desire of the human being to be near water, a town site is almost always chosen with one or the other in easy reach.

The utilizing of electricity as a cheap motive power has induced the construction of a vast number of street railways, and towns in which one can walk from one side to the other in a few minutes' time can boast of having electric roads. In many such cases it is the fact of a resort of some kind being near by which has been the incentive to the construction of such a road. Thus is there frequently a close connection between summer resorts and electric street railways and the hand of one is made to wash the hand of the other. It is a certain thing that the street railway companies of any town will make it a point to reach a resort of some kind, and to such an extent has this feature of the street railway business grown that many companies have bought and are buying available sites for parks and places of summer recreation and are improving them, erecting buildings, making or enlarging lakes and in every possible way are embellishing and beautifying the surroundings to induce visitors to come and thus patronize the road.

In the March and April issues of the "Review" considerable space has been given to the descriptions of these resorts and the attracions provided for the amusement of visitors, and we shall be glad to continue doing so and publish such views of scenery, walks, rustic bridges and pavilions as may be sent.

AUGUSTA, GA.

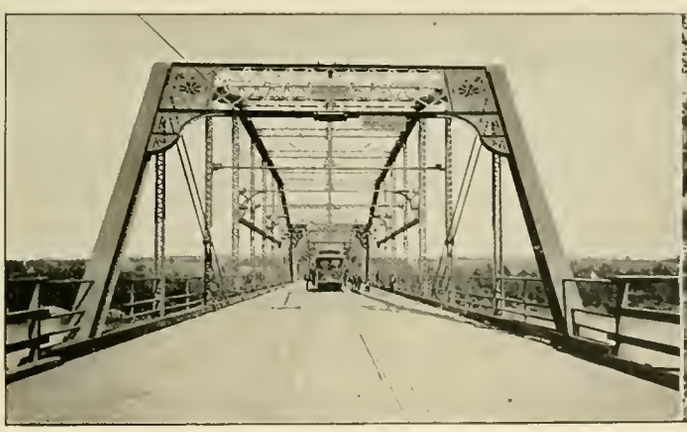
The NorthAugusta Street Railway Co. has built a line connecting the new suburb with Augusta, and when completed this spring it will be three miles long. The road is operated by the Augusta Railway & Electric Co. Connection is made with the North Augusta natatorium having 92 bath rooms. The ladies' side of the plunge is from 2 to 5 ft. deep and the men's reserve from 12 to 15 ft. deep. There are four springboards and other arrangements for enhancing the enjoyments of the bathers. The natatorium is liberally patronized, often 75 to 100 taking a swim at one time. The spring houses in Crescent Park are shown in another view, the largest spring yielding 800 gallons of clear, pure water per hour. The third view is of the iron bridge across the Savannah River connecting Augusta with North Augusta.

ST. THOMAS, ONT.

The St. Thomas (Ont.) Street Railway Co. has planned to give its patrons one of the most delightful pleasure resorts in the entire Dominion. Yarwood Farm has long been noted for its beautiful lakes and its natural and picturesque scenery. This farm lies six miles from the city of St. Thomas and is reached by the St. Thomas Street Ry. The company has recently purchased the farm and has had expert landscape gardeners at work laying out the grounds, and by the combination of art and nature has made a series of parks and amusement grounds rivalling anything in Canada.

NATATORIUM—NORTH AUGUSTA STREET RAILWAY.

At the very entrance to the resort is Yarwood Park. This is what constituted the handsome grounds around the old family residence. This needed no embellishing at the hands of the gardener; it had already been laid out as attractively as possible. The old farm house is a part of the purchase and from it such supplies as hot water and other aids to the comfort of the picnicker can be obtained. From this point, too, there is a splendid view of Lake Pinafore, a large body of clear, pure water which affords the most ample facilities for boating and bathing. The lake is large enough to make the use of steam launches and sailing yachts entirely convenient.



BRIDGE ON LINE OF NORTH AUGUSTA STREET RAILWAY.

SPRING HOUSE IN CRESCENT PARK.

Branching off from Lake Pinafore is a long, narrow body of water, almost a river, but which is in fact another lake and which, from its shape, has been called Long Lake. This also is used for boating, the smaller craft making this their particular location. Part way between Yarwood Park and Lake Pinafore is a natural spring. A fountain house has been constructed over it and here can be found a most delightful retreat, the water bubbling up from the depths of the earth cooling the atmosphere most refreshingly.

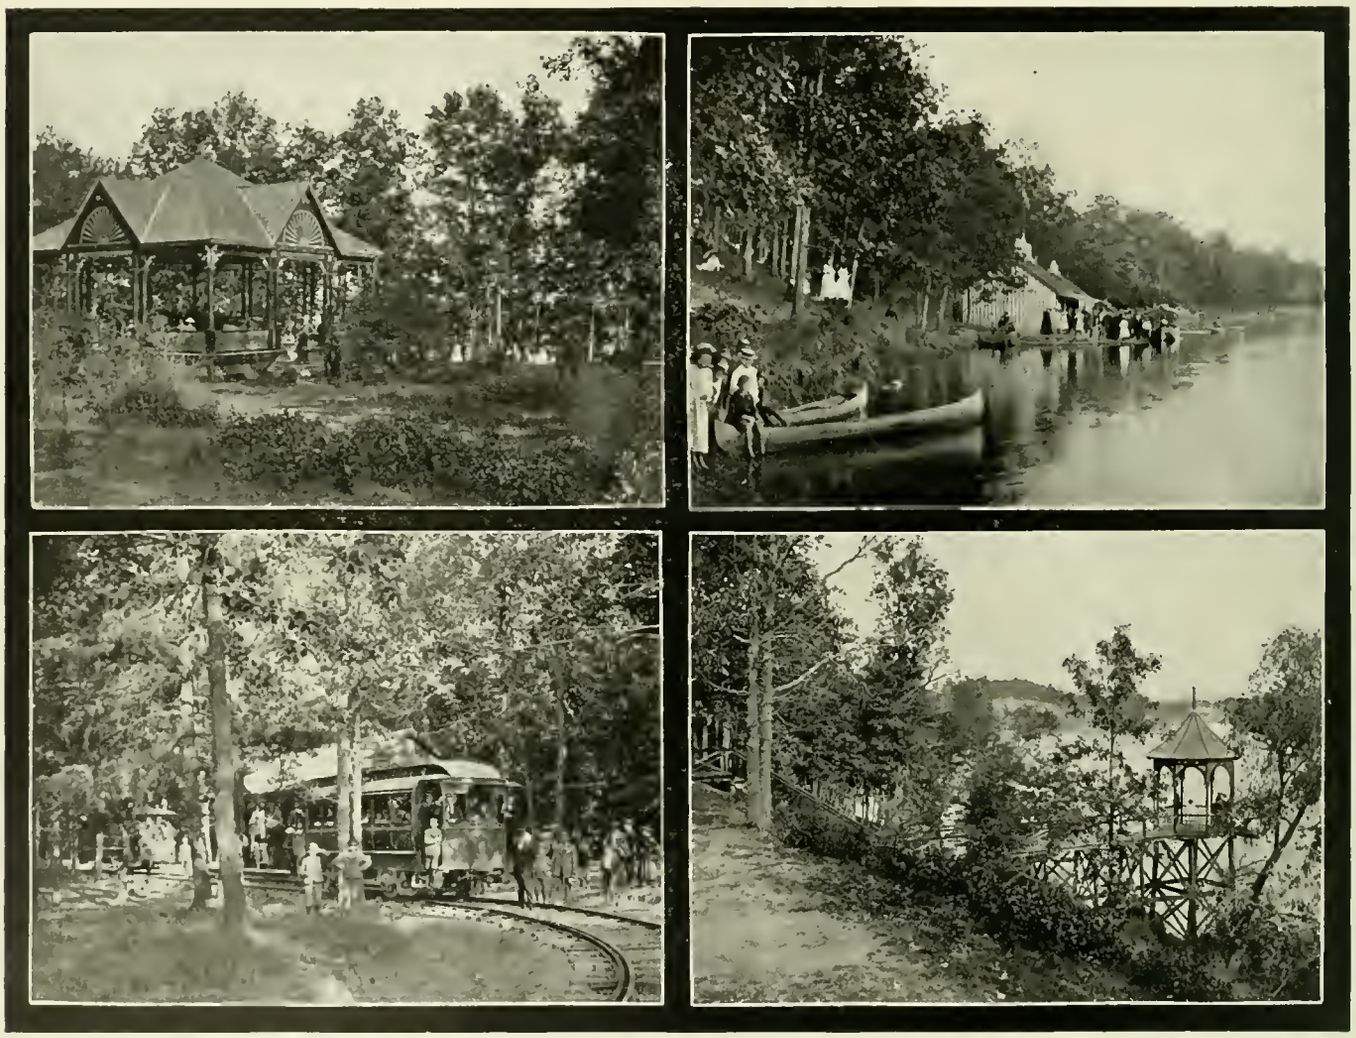
The street car line, after winding around and half encircling Yarwood Park, leads up to the pretty station the company has built at the entrance to Central Park. Here is where the artist has shown his skill. This park is one of the most delightful spots imaginable. Just enough trees have been left standing to afford shade, while the smooth walks are bordered on either side with the gayest and the choicest flowers. One end of this park reaches to the bank of Lake Pinafore and here has been built a large and airy pavilion which can be used as a lunching room for any who prefer it to eating out of doors. Over to the right from Central Park is the bicycle track and athletic grounds and close by are the golf links, the tennis court and the base ball grounds.

The whole section is indeed but a series of parks and playgrounds, the whole constituting one beautiful resort, the equal of which it would be hard to find. The St. Thomas Street Railway Co., J. E. Taylor, manager, owns and controls it all and takes its passengers there, a pleasant ride in comfortable cars for a 5-cent fare.

KANSAS CITY, MO.

In his paper before the A. S. R. A. at the Boston Convention, Mr. Walton H. Holmes, general manager of the Metropolitan Street Railway Co., of Kansas City, gave a short account of his experience with parks, and in conclusion stated that his company had ceased to maintain parks, but that two parks, one city and one suburban, were still operated by private corporations, to which the Metropolitan Co. paid a lump sum to secure the admission of its passengers free. One of these, Fairmount Park, is owned by the Fairmount Amusement Co., concerning which the general manager, Mr. V. W. Flowerree, says:

"Fairmont Park is situated on the Suburban road, between, Kansas City and Independence, at a distance of seven miles from the center of this city, and comprises a tract of ground of 150 acres of rolling land, well shaded and naturally adapted for park purposes. We have an artificial lake of 15 acres. On the grounds are all the usual park attractions, including boating, bathing, fishing,



MOWHAWK PARK, BRANTFORD STREET RAILWAY CO., BRANTFORD, ONT.

BRANTFORD, ONT.

The views in Mohawk Park, owned by Brantford Street Railway Co., shows that nature has contributed much towards making it a delightful resort. Here is the only water chute in Canada, which the company built at an expense of $1,200. The base ball grounds and bicycle track are drawing cards, two large meets having already been secured for this year. Last year there were 68 picnics held here, it being a favorite resort for Sunday schools. The refreshment privileges and those for merry-go-round, water toboggan, boats, etc., are rented. No theatricals are presented, but such attractions as tight-rope walking, tumbling and slack-wire performances drew fairly well last year.

merry-go-round, crystal maze, shooting gallery, etc. In addition to these are summer cottages and a summer hotel. The cottages, of which there are 13, have four rooms, and have always been full every summer. The hotel, which has 50 rooms, has also been well patronized during the park season. We also have a cafe, the privilege of which we lease to outside parties. Our summer theater, which has a seating capacity of 1,600, has been leased to the Walters "Orpheum" Circuit for the coming season—the arrangement being for them to play the same class of vaudeville attractions that they now play at their theater in Kansas City. We also have a very large band stand, with sounding boards and seats to accommodate 5,000 in front. It is left to the discretion of the Orpheum people whether they shall play their entire show inside or out. Under

either condition we are to have both out-door and in-door attractions, the out-door attractions including music, aerial acts and fireworks. The rate of admission to the theater is not to exceed 25 cents, with one-third of the seats free. The out-door seats in front of the band stand to be reserved at a price not to exceed 10 cents with one-third of them free. We charge no admission to the park, the fare on this division of the Metropolitan Street Railway Co. being 20 cents from Kansas City to the park and return. We feel that with the arrangement made with the Orpheum people for the coming season that we will more than double the attendance at the park and fully demonstrated that under such an arrangement the park will be made self-sustaining. In past years we have limited ourselves mostly to musical attractions, which have been quite successful, but as we were unable to follow up from week to week with such bands as we desired and at prices that would make them profitable, we did not think it advisable to depend on music alone this season. We believe with the low rate of admission charged to the theater (this rate with the car fare to the park included being no more than the rate of admission charged by the city theater) and with no competition, that this park ought to become very popular and profitable to both parties interested. Our season opens May 15th and closes September 15th.

"We have always found it profitable to encourage picnics and conventions, especially picnics, and make a special rate for them. We find that picnics are very attractive to children, and as it is necessary for their parents to accompany them such a distance, the traffic of the road is materially increased thereby."

CHARLESTON, S. C.

The Chaleston Consolidated Railway Co. opened the season of spring and summer concerts at Chicora Park on March 26th, the Fourth Brigade Band having been engaged. The concerts are from 3 to 6:30 p. m.

AUSTIN, TEX.

Austin, Tex., has its Hyde Park, an attractive resort reached by the Austin Rapid Transit Railway Co. The resort covers many acres of land and under the management of the railway company has been beautified and made exceedingly attractive. The grounds have been laid out with great skill and every advantage has been taken of nature to give the spot a charm. There is a natural body of water, which by dredging and enlarging has assumed all the proportions of a lake, which affords ample pleasure for any who are fond of the water and a sufficient number of boats have been provided to meet all demands. In the center of this lake is a picturesque island covered with banana and other fruit trees. Rustic bridges have been constructed at various points and in the season in the smaller and auxiliary lakes water lilies grow in great profusion. Especial attention has been given to the cultivation of these lovely flowers, the Victoria Regia growing to such size that the leaves spreading out over the water will support the weight of a six-year-old child. Many of these leaves are five and six feet across.

SCENES IN HYDE PARK, AUSTIN, TEX.

The grounds are about as attractive as it is possible to make them. Lovely walks and driveways wind in and out among the shade trees and the bicyclist there finds not only delightful roads for wheeling but must be enchanted at every step by the scenery which greets his eye. A number of deer and other animals have been added as attractions, and they receive a great deal of attention, notably from children, but from adults as well. The banana readily grows there, as may be seen in one of the accompanying illustrations.

The company has, among all the other improvements, built a handsome large pavilion and in this for about twelve weeks in the summer are given vaudeville and dramatic attractions of a light character such as are well calculated to please the general public and at the same time will never offend the most particular people. There is always, during the season, excellent music and nowhere

could a day be spent more enjoyably than at Hyde Park. The grounds are especially adapted for picnic parties and the company offers the most liberal terms for such concessions. Round trip tickets afford admission to the grounds and to all the varied and interesting attractions offered. We are indebted to Mr. Frank E. Scovill, superintendent of the Austin Rapid Transit Co., for the photographs from which our engraving was made.

BANGOR, ME.

The Lewiston (Me.), Brunswick & Bath Street Railway Co. is adding to the attractions it already has at Merrymeeting Park, on its line. Gen. Mgr. A. F. Gerald has been out West and has purchased a number of animals and birds which will be added to the already interesting menagerie at the park. He secured a monster ox, weighing over a ton. He also bought two rare specimens of the wolf species and two large buffalo. At one point Mr. Gerald was fortunate in finding a collection of wild geese. A flock happened to be flying over the town and hunters were sent out and captured a number of them. When all these attractions have been added to the collection, Merrymeeting Park will be able to make a fine show.

MANCHESTER, N. H.

The Manchester Street Railway Co. is looking forward to a big business this summer. On its line is a pleasant resort located at Lake Massabesic, which has grown very popular since the construction of the road to that point. The railway company owns the ground and the lake but doesn't control the resort excepting so far as seeing that it is conducted properly and is kept in first-class condition so that it may prove a pleasure to the patrons of the road. The company has built a handsome pavilion near the lake, but has rented it. One portion of this building is devoted to a theater which has proved to be so popular an attraction that it is the intention to erect a new and more commodious house of amusement, to be ready for occupancy as soon as the weather becomes warm. Some excellent attractions have already been booked and the management intends having a change of bill each week. A small fee will be charged for these performances.

The admission to the grounds is free to all passengers on the street car line, but those who go there on wheels or in any other manner than by the street car line are obliged to pay.

But the theater is by no means all that attracts people to Lake Massabesic. The bathing, boating, fishing and the merry-go-rounds and other features afford the visitors much delight, to say nothing of the bicycle riding about the grounds.

MARINETTE, WIS.

The people of Marinette are proud of their summer resort reached by the Marinette Gas, Electric Light & Street Railway Co. While the company owns the resort it has made leases to individuals of its various privileges. The resort boasts of a good hotel, a refreshment stand and has the ordinary boating and bathing features. During the summer there is always plenty of good music. The lake is a lovely body of water and all about the scenery is beautiful and attractive. To all passengers who go to this resort on the street railway the admission is free, but to others a charge of 10 cents is made.

POTTSTOWN, PA.

The Ringing Rocks Electric Railway Co. owns and controls its beautiful resort, Ringing Rocks Park, with the exception of the refreshment stands. These have been rented to other parties. The company has made this an exceedingly attractive place and the passenger traffic of the electric road during the summer months is large. There are ample boating facilities offered and the other features, such as the merry-go-round, the switchback railway, and the band music all contribute to make the park popular and a spot where one can find keen enjoyment and healthful recreation. The park is a popular place for picnickers, and the company is always ready to make liberal terms for such affairs. The admission to the park is free.

OWEN SOUND, ONT.

The matter of a summer resort at Balmy Beach, on the Georgia Bay, is being earnestly discussed. It is said that New Orleans and Cincinnati capitalists are looking into the matter and the people are very hopeful that by next year the plans at present outlined will be put into effect.

Property owners at the point named are active in their endeavors to interest outsiders and offer all the ground and help possible to further the enterprise.

One great feature of the culmination of this resort plan will be the construction of an electric railway to the proposed spot. The connection of Owen Sound and Balmy Beach has for a long time been talked of and if the resort plans go through there will be no question of the road being at once built.

MANISTEE, MICH.

The Manistee, Filer City & Eastlake Railway Co. is now improving a tract of 50 acres extending along the shore of Lake Michigan for ¾ mile, and is building boats, bath houses, theater, chutes, etc. There will be 20 swings about the grounds. Admission will be free only to passengers, and no provision is made for bicyclers, as there are few in that locality. Vaudeville performances and concerts will be given this summer.

NEW BRITAIN, CONN.

The Central Railway & Electric Co. owns White Oak Park, a pretty tract of 45 acres about three miles west of New Britain. Dancing and refreshment pavilions with broad verandas are most conveniently situated on the borders of a lake. An attractive bandstand has been added this year which overhangs the lake and faces an amphitheater seating from 300 to 500 persons. The mountain to the south of the park has been cleared this spring, attractive walks laid out, and the park extended in this direction. A number of rustic summer houses have been placed in various parts of the grounds and tables and benches under the oak and hemlock trees. Boating on the lake, swings, cages of birds and animals, a photograph gallery, merry-go-round, bowling alleys, pool tables and many other attractions afford amusement for all. During the afternoons and evenings a good band renders music for dancing. Theatrical performances will be given every afternoon and evening this summer except Sundays. More animals will soon be added to the collection. Admission is free except to bicyclers, who have to pay 5 cents.

MILWAUKEE.

Gen. Mgr. John I. Beggs, of the Milwaukee Railway & Light Co., expresses the following opinion in reference to street railway parks: "We do not believe that it pays street railway companies to run pleasure resorts, and do not engage in such business, our experience being that the same amount of time and energy expended in the care and betterment of the regular business of the company in the long run proves more permanently profitable. If crowds are unduly drawn to some special attraction other points on the lines are apt to be neglected, while it costs more to take care of the congested travel at one point."

TERRE HAUTE, IND.

The Terre Haute Electric Railway Co. rents its park with all concessions. Admission to the park is free to all, but an entrance fee is charged at the casino. The experience last year with theatricals was unsatisfactory.

BETHLEHEM STEEL CO.

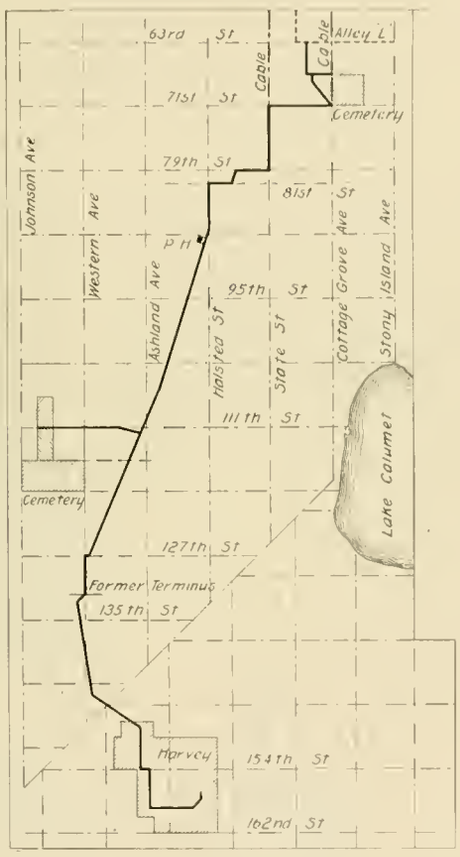
The Bethlehem Steel Co., Bethlehem, Pa., with capital stock of $15,000,000, has leased the property and franchises of the Bethlehem Iron Co. The capital stock of the latter company is $7,500,000, and the new organization guarantees 6 per cent per annum on that amount, to be paid quarterly and to be free from all taxes and deductions. The incorporators held a meeting and elected the following officers: Robt. P. Linderman, president; Abraham S. Schropp, secretary, and C. O. Brunner, treasurer. The directors elected are Robt. H. Sayre and Robt. P. Linderman of Bethlehem; Beauveau Borle, Edward T. Stotesbury, Joseph Wharton and John Lowler Welsh of Philadelphia.

CHICAGO ELECTRIC TRACTION CO.

The Chicago Electric Traction Co., the storage battery road which has heretofore had its terminus at Blue Island, operating between 63d St. and Blue Island (132d St.), is now building an extension south and east to Harvey, running nearly as far south as 160th St., 3½ miles, and nearly 1½ miles east of Blue Island. This extension is all single track; four miles are laid with 80-lb. 7-in. girder rails and one mile with 70-lb. T-rails, on white cedar ties, 6 x 8 in. by 8 ft., spaced 2 ft. between centers. Servis tie plates are used.

The Harvey terminus will be 13 miles from the power house of the company at 88th St. and Vincennes Road, and the round trip of 26 miles is more than the batteries should be required to make in regular service, though on a majority of trips they would probably be able to do it. Accordingly the company is now building a power house at Harvey for the purpose of partially charging the batteries there.

The building is of brick 26 x 70 ft. and one story high. The equipment comprises one 50-h. p. Nash gas engine, using gasoline as fuel, one 40-kw. Eddy generator, made by the Eddy Electric



LINES OF CHICAGO ELECTRIC TRACTION CO.

Manufacturing Co., Windsor, Conn., and a secondary battery of 95 400-ampere hour cells. The generator is shunt wound so that when the load decreases as the batteries become more fully charged the voltage of the generator rises to overcome the counter e. m. f. of the battery. The secondary battery is connected in parallel with the generator in order that abnormal loads may be taken care of.

The station is designed for charging four car batteries at one time. An elevator will be installed to lift a truck up to receive the battery from the car; when lowered the truck with the battery upon it is run over to the charging station and connected with the secondary battery.

Gen. Mgr. E. R. Gilbert advises us that this station will be in operation by June 1st.

The company is also building a new car house in the rear of its station at 88th St., which will give it much needed space for storing cars. The new building will be of iron and steel construction and be 100 x 160 ft. with space for 50 cars.

NEW YORK FRANCHISE TAX.

Every public service corporation in the state of New York is very much interested in the provisions of the Ford bill to tax franchises, which has been passed by the legislature, and is now in the hands of Governor Roosevelt. A hearing was granted on this bill by the governor on May 11th, and among those who were heard was Hon. W. Caryl Ely, president of the International Traction Co. The bill provides that the assessors shall determine the value of the franchises to be taxed.

Following is the full text of the law, the new amendments being in capitals:

Section 1. Subdivision three of section two of the tax law is hereby amended to read as follows:

3. The terms "land," "real estate" and "real property," as used in this chapter, include the land itself above and under water, all buildings and other articles and structures, substructures and superstructures, erected upon, under or above or affixed to the same; all wharves and piers, including the value of the right to collect wharfage, cranage or dockage thereon; all bridges, all telegraph lines, wires, poles and appurtenances; all supports and enclosures for electrical conductors and other appurtenances upon, above and under ground; all surface, under ground or elevated railroads, INCLUDING THE VALUE OF ALL FRANCHISES, RIGHTS OR PERMISSION TO CONSTRUCT, MAINTAIN OR OPERATE THE SAME IN, UNDER, ABOVE, ON, OR THROUGH STREETS, HIGHWAYS, OR PUBLIC PLACES; all railroads, structures, substructures and superstructures, tracks and the iron thereon; branches, switches and other fixtures permitted or authorized to be made, laid or placed in, above or under any public or private road, street or grounds; all mains, pipes and tanks laid or placed in, upon, above or under any public or private street or place for conducting steam, heat, water, oil, electricity, or any property, substance or product capable of transportation or conveyance therein or that is protected thereby, INCLUDING THE VALUE OF ALL FRANCHISES, RIGHTS, AUTHORITY, OR PERMISSION, TO CONSTRUCT, MAINTAIN, OR OPERATE, IN, UNDER, ABOVE, UPON, OR THROUGH, ANY STREETS, HIGHWAYS, OR PUBLIC PLACES, ANY MAINS, PIPES, TANKS, CONDUITS, OR WIRES, WITH THEIR APPURTENANCES, FOR CONDUCTING WATER, STEAM, HEAT, LIGHT, POWER, GAS, OIL, OR OTHER SUBSTANCE, OR ELECTRICITY FOR TELEGRAPHIC, TELEPHONIC OR OTHER PURPOSE; all trees and underwood, growing upon land, and all mines, minerals, quarries and fossiles in and under the same, except mines belonging to the state.

Section 2. This act shall take effect immediately.

Governor Roosevelt was very active in having the bill passed, and it is generally understood that he will sign it and that it will become a law. If so, it will go into effect next year.

HAVANA STREET RAILWAYS.

The Havana, Cuba, street railway system, now owned and controlled by three syndicates, the Internation Bank of Paris, the Harvey Syndicate, of New York, and one in Canada, is to be fully equipped with electricity. Capt. Hallet Allstop Borrowe, who won considerable reputation as a Rough Rider, is general manager of the system, having been placed in charge shortly after the purchase by the syndicates. He has been introducing American methods as far as possible, but it has been decided to wait until fall, after the rainy season, before beginning the work of equipping the road for electricity. The roads, even under the old methods, have been paying good dividends, and Capt. Borrowe believes that, with the adoption of electricity, the Havana street railways will be among the best paying investments in Cuba.

The Terre Haute (Ind.) Electric Railway Co. is improving its car equipment as rapidly as possible. The newer cars are rebuilt, and the older ones broken up as fast as they fall into a condition requiring heavy repairs. Portions of the cars thus broken up, which prove to be sufficiently good, are used again in rebuilding.

MECHANICAL DEPARTMENT

LIQUID AIR AND THE POWER REQUIRED TO PRODUCE IT.

BY A. H. NEUREUTHER.

Experiments in recent years have shown that there are no absolute or permanent gases, liquids or solids. All substances upon the earth would be vaporized if subjected to such a heat as prevails at the sun, and doubtless even the most refactory gases would become solid before reaching the temperature of absolute zero. Doubtless the water now upon the earth was once all vapor or a gas, and perhaps in some millions of years the temperature of the earth will have decreased until all the water will appear as a dry brittle mineral, and the atmosphere will liquefy forming new lakes and oceans.

If a gas be compressed its density is increased, but as long as the temperature is above a certain point it will not liquefy. If, however, the temperature be reduced to a certain point it will liquefy at a definite pressure and at a less pressure if the temperature is further lowered. The temperature above which a gas cannot be liquefied by pressure alone is known as its critical temperature, or point. Air at ordinary temperatures, has been compressed under fully 4,000 atmospheres (60,000 lb. per sq. in.) without liquefying. Oxygen gas, at 17° C., compressed to 4,000 atmospheres, reaches a density of 1.25, but is still in the form of a gas. Density of water taken as 1.00.

Table I from the London Engineer was prepared by Prof. Dewar and gives the density of some gases at temperature of 15° C. (59° F.) and at a pressure of 3,000 atmospheres (45,000 lb. per sq. in.), and also the densities of the liquids. It is seen that it is possible to have a gas denser than its liquid.

TABLE I.

Gas.	Density of gas at 15° C. and 3,000 atmospheres.	Density of liquid at boiling point.
Oxygen	1.1034	1.124
Nitrogen	0.8259	0.885
Air	0.8820	0.940
Hydrogen	0.0879	

Liquid air has a critical temperature of —140° C. (—220° F.) and a critical pressure of 39 atmospheres; at atmospheric pressure the temperature of the saturated vapor of liquid air is —191.4° C. (—312.6° F.); the density of the liquid at this latter temperature is 0.93; the color of the liquid is light blue. The specific heat and the latent heat of the liquid are unknown. Atmospheric air may be considered as the superheated vapor of this liquid.

The two elements of the air, oxygen and nitrogen, liquefy together and produce a nearly colorless fluid, with a slight bluish tinge, which may be kept in an open vessel for several hours before it will all evaporate, the length of time depending on the amount of insulation used to keep the heat of the atmosphere from it. The liquid must not be confined, as it develops an almost irresistible pressure. This remarkable slowness of evaporation is accounted for by the supposition that the evaporation produces such an intense refrigerating effect that it holds the process in check.

As evaporation takes place the nitrogen passes off first, while the oxygen evaporates more slowly, so that as the process goes on the remaining liquid becomes richer in oxygen. When first liquefied the air contains 23.1 per cent of oxygen; when 50 per cent of the mixture has evaporated the residue is 37.5 per cent oxygen; when 80 per cent, the residue is 60 per cent oxygen; 90 per cent, 77 per cent oxygen; 95 per cent, 88 per cent is oxygen.

The specific heats of air as calculated by Professor Linde are given in Table II which was taken from the London Engineer, Nov. 30, 1896.

TABLE II.

Pressure in atmospheres	1	10	20	40	70	100

METHODS OF PRODUCING LIQUID AIR.

The usual method employed before the present time in the liquefaction of gases has been as follows: Starting with a very easily liquefied gas, as carbon dioxide, the cold produced by the evaporation of its liquid, was used to refrigerate and liquefy a less easily liquefied gas, under a high pressure (such as ethylene, for example), and the evaporation of the liquid ethylene, was in turn used to refrigerate and liquefy one of the so-called permanent gases, such as oxygen or air. This was an elaborate and very expensive process. It is said that to produce the first ounce of liquid air cost $3,000, and later in the same laboratory a pint was made for $500.

The methods used by Mr. Tripler and by Professor Linde are quite simple as compared with the ethylene method, and are calculated to produce a commercial product.

The first apparatus made by Linde is shown in Fig. 1. The compressor P delivers air highly compressed to the water cooler, L J,

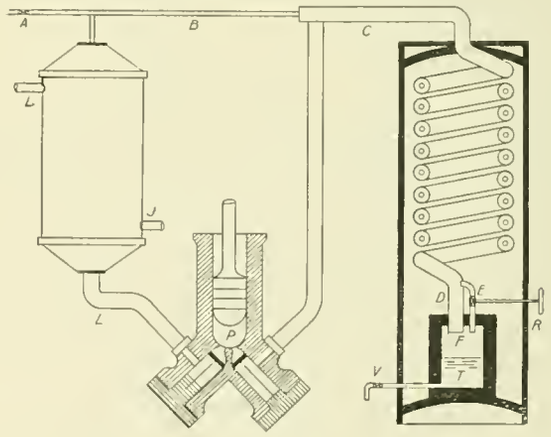

FIG. 1.

where the heat generated by compression is removed. The air then passes through the pipe B, which is inside of a larger pipe C (making a combination called a spiral interchanger, shown by D E) and escapes through the throttle valve R into the chamber T, and thus by expansion from a high to a low pressure, is much reduced in temperature. The air then returns by F through the outer pipe of the interchanger to the compressor, and being in contact with the inner pipe, cools the air as it comes from the intercooler L J on its way to the throttle valve.

Fifteen hours working with this apparatus results in such an accumulated cooling effect that liquid air begins to gather in the vessel T, and may be drawn off by a cock V. To compensate for leakage, or for that drawn off in liquid form, more air is forced in at A by a special compressor.

The latest form of the Linde apparatus is shown in Fig. 2. There are two throttle valves A and B. All the compressed air passes through A, but only about one-fifth passes also through B.

The passage through A causes a drop in pressure from 200 atmospheres to 16 atmospheres (from 3,000 lb. per sq. in. to 240 lb. per sq. in.) and four-fifths of the air in circulation passes back at that pressure through the middle one of the three tubes forming the interchanger to the compressor D. The remaining one-fifth passes through B, and about one-fourth of it gathers as liquid air in the vacuum jacketed vessel C at a pressure which is only enough above that of the atmosphere to allow the liquid to pass out where the

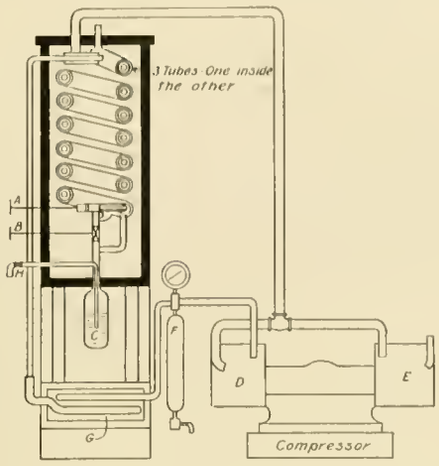

FIG. 2.

stop cock H is opened. The unliquefied or re-evaporated portion passing through B, escapes through the outermost tube of the interchanger. The compressor E takes in fresh air from the atmosphere, compresses it to 16 atmospheres, and delivers it so that it mixes with the air which is returning at that pressure from the middle tube of the interchanger to the compressor D.

The compressed air on leaving each compressor, passes through a coil in a water cooler which serves also to water-jacket the compressor cylinders. A small quantity of water is drawn in along with the air by the low pressure cylinder, and this, together with the natural moisture of the air, is extracted as completely as possible, first by means of a separator F, and then by passing the compressed air through the coil in G in a bath of ice and salt before it goes into the interchanger. It is absolutely necessary that the air be dry, for during the expansion from the high to the low pressure in the interchanger, and moisture in the air will freeze in the expansion valves and clog them, making them useless. The interchanger is inclosed in a case packed with sheep's wool.

Mr. Tripler's apparatus is shown in Fig. 3, and corresponds in principle and action with that of Linde. Mr. Tripler claims priority

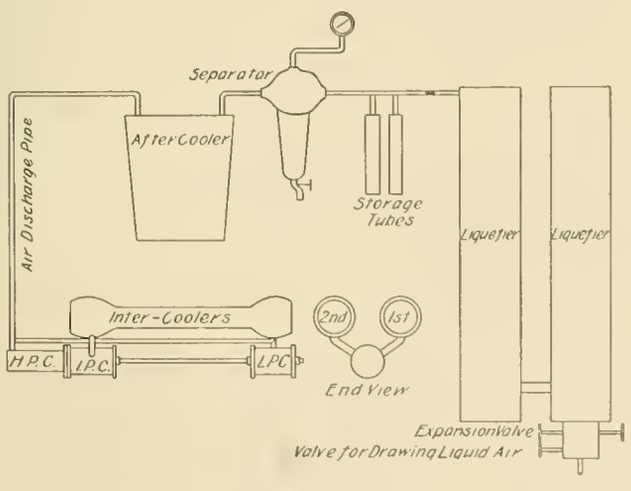

FIG. 3.

of invention, having discovered this method during 1889-90.

In Tripler's apparatus the air is compressed to 2,500 lb. per sq. in. in a three-stage air-compressor, cooling the air between each stage, and after the third stage by the after-cooler shown. Then the air is passed through a separator, then to the liquefying apparatus which consists of a series of coils of pipe arranged in several concentric cylindrical compartments in the two large liquefiers shown. The coils of pipe terminate in a specially designed expansion valve and orifice. The high pressure air entering the liquefier passes through the coils until it reaches the expansion valve. Here the air is expended in the chamber to very nearly atmospheric pressure, and in expanding from the high pressure of 2,500 lb. is reduced in temperature, and this cold expanded air in passing over the coils from which it has just issued reduces the air under the high pressure therein contained to so low a temperature that it is in part liquefied. With this apparatus, it is said, liquid air can be drawn off within fifteen minutes from the time of opening the expansion valve.

Tripler has a three-stage straight line Norwalk air compressor, with 16-in. steam cylinder, and with air cylinders of 10½, 6⅝ and 2⅝ in. in diameter and all of 16-in. stroke. The steam pressure used is from 85 to 90 lb. The capacity of the engine is about 75 h. p.

The cylinders are arranged in tandem, all on the same bed and in the following order: steam cylinder, intake cylinder, intermediate air cylinder and high pressure cylinder. The steam end is a simple steam engine, with adjustable Meyer cut-off valves.

The air is led to the compressor through a pipe, which extends above the roof of the building, in order to get clean air free from dust. Before entering the compressor, the air passes through a washer, which renders it free from dust and saturates it with water. It then enters the intake (low pressure) cylinder which is double acting, where it is compressed to 65 lb. per sq. in. From here it passes through an intercooler and is there reduced to the ordinary atmospheric temperature, it next enters the intermediate cylinder which is single acting, and is compressed to about 400 lb. pressure. From here the air is discharged into a second intercooler where it is again cooled to ordinary atmospheric temperature, and passes to the high pressure cylinder, where it is compressed to a discharge pressure of from 2,000 to 2,500 lb. per sq. in. After passing through an after-cooler, to bring its temperature to that of the atmosphere (or lower) again, the air flows through a separator where all moisture oil, dirt, etc., are removed, and thence it goes to the storage tubes and finally to the liquefier. This apparatus will produce three gallons of liquid air per hour.

POWER REQUIRED TO PRODUCE LIQUID AIR.

From the thermodynamic equations for isothermal compression we find the work required to compress 1 lb. of air from 14.7 lb. per sq. in. to 2,500 lb. per sq. in. is 135,899 ft. lb. For compression under actual conditions, such as are obtained in practice with three-stage compressors with water-jacketed cylinders, it is necessary to add about one-third more, giving the work for compressing as 181,100 ft. lb.

In such a compressor the air on leaving the high pressure cylinder will have a temperature of 352° F., and the volume of 1 lb. will be 0.12 cu. ft. The volume must be displaced against a pressure of 360,000 lb. per sq. ft. to deliver it to the storage tank and for this 43,200 ft. lb. more will be required, making a total of 224,400 ft. lb. If the mechanical efficiency of the engine and compressor be taken as 80 per cent the work developed in the steam cylinder to compress 1 lb. of air to 2,500 lb. per sq. in. is 280,500 ft. lb.

One horse-power-hour is 1,980,000 ft. lb. and will therefore compress 7.09 lb. of air to 2,500 lb. per sq. in.

As previously stated when describing Linde's apparatus, about 19 lb. of the highly compressed air must be expanded to liquefy 1 lb. This apparatus is similar in principle to Tripler's, so we may say that one horse-power-hour will give us 7.09 ÷ 20 = .355 lb. of liquid air.

To the foreging article we wish to add a short discussion of the amount of work which it is theoretically possible to get from liquid air when used in a boiler and engine as water is used in the steam engine. Some absurd claims have been made recently that liquid air, evaporated by the heat of the atmosphere, constitutes a source of power which is so superior to all others as to produce 3 1-3 times as much work as it costs.

Assume a mean temperature of the atmosphere, which is to boil our liquid air, of 60° F. Assuming a working cylin-

der capable of withstanding the high pressures, the liquid air may be vaporized and heated to atmospheric pressure without permitting change of volume (the pressure would then be about 11,200 lb. per sq. in.) and then expanded isothermally to atmospheric pressure. The theoretical work per pound of liquid air computed on this assumption will be in round numbers 156,000 ft. lb.

Another method of working would be to vaporize the air at 60° F., and at such a pressure that when the air is expanded without gain or loss of heat to atmospheric pressure the temperature has fallen to that of the boiling point of liquid air under atmospheric pressure. This would give in round numbers 66,000 ft. lb. per lb. of air. The upper limit of pressure in this case would be 1,120 lb. per sq. in.

A third method of working would be to expand isothermally at a temperature of 60° F., as in the first case, to a pressure of 1,120 lbs., and then adiabatically to atmospheric pressue as in the second case. The theoretical work per pound of air would in this case be about 104,000 ft. lb.

A fourth method would be to expand adiabatically from the pressure of 11,200 lbs. and 60° F. down to the temperature 313° F. (when the pressure would be 148 lbs.). The theoretical work would be about 48,000 ft. lb. in this case.

We are not concerned with the thermodynamic efficiency of these engines since there is an indefinite amount of energy available in the heat of the atmosphere which is serving us for fuel .

Mr. Neureuther has said that in the present state of the art 1 h. p. h. will produce .355 lb. of liquid air. The work to be got from .355 lb. of liquid under the conditions stated is in round numbers as follows:

Case I. 55,000 ft. lb.
Case II. 24,000 ft. lb.
Case III. 37,000 ft. lb.
Case IV. 17,000 ft. lb.

One h. p. h. is equivalent to 1,980,000 ft. lb., hence the portion of the power expended that we can theoretically get back is:

Case I. 2.8 per cent.
Case II. 1.2 per cent.
Case III. 1.9 per cent.
Case IV. .9 per cent.

The mechanical efficiency of the working engine would not be 100 per cent, and hence these small percentages would be still further reduced in practice, even could we get a working cylinder to withstand the pressure of over 11,200 lb. per sq. in., which would be the initial pressure in Cases I, III and IV.

A safe conclusion is that until liquid air can be made at a greatly reduced cost it will not compete with steam as a working fluid in power engines.

The claim made for Mr. Tripler that he can make 10 gallons of liquid air by expending 3 gallons in his engine, is groundless because a new supply of liquid air can be got only by compressing and cooling atmospheric air. The air in the engine will give out in isothermal expansion the work required to compress, isothermally, an equal quantity between the same pressure limits. But in practice the expansion is not isothermal and less than the theoretical amount of work is done by the engine. Also the compression is not isothermal and more than the theoretical amount of work is required. Thus even if all friction is neglected the operation is a losing one.

Liquid air weighs about 58.6 lb. per cu. ft.; compressed air at a pressure of 2,500 lbs. per sq. in. and 60° F. weighs about 13.7 lb. The available energy from the liquid is therefore between four and five times that of the compressed air. This advantage is lost if the air is to be stored for any considerable time; the liquid loses by evaporation, as it must be open to the atmosphere because of the high pressures resulting when it is heated.

OFFICIAL BRAKE TESTS IN NEW YORK.

March 29th the State Board of Railroad Commissioners of New York issued a notice to the owners of brakes for street surface cars inviting them to submit their brakes for test. Applications for permission to compete were received until May 2d. The substance of the notice was as follows:

"The Board of Railroad Commissioners of the State of New York will make a test of braking systems for street surface cars, on cars to be furnished for that purpose by the Metropolitan Street Railway Co., of New York City.

"Tests will be made of such braking systems offered as appear to the commmission to be practicable.

"Applications to have braking system tested, and for permits to equip cars for this purpose, must be made on the accompanying blank.

"All applications must be accompanied by a drawing, tracing, blue print or photograph showing the system complete; also a full description of the same setting forth the details of construction, application to car and method of operation.

"The cars to be furnished will be eight wheel cars with Brill maximum traction trucks fitted with G. E. 1.000 motors with nose suspension; driving wheels 30 in., trailer wheels 20 in. in diameter; length of car body over all 28 ft.; outside measurements of wheel base 17 ft. 6 in. The railway company will furnish space in its car house and pit room for the purpose of fitting up cars, but will not furnish any supplies, labor or machine shop facilities. The general master mechanic of the Metropolitan Street Railway Co. will designate the cars to be equipped and the car house at which the work shall be done.

"These tests will be made in any manner the Board of Railroad Commissioners may determine. While the tests are being made only one representative of the applicant will be allowed on the platform on which the brake is operated.

"All tests of braking systems for stopping a car will be from signal on a basis of W S ÷ D = E, where

E = Efficiency of braking system.
W = Weight of car.
D = Distance between point at which signal is given to point of stop.
S = Rate of speed at time of giving signal.

"The merits of braking system will be determined on the following points:

1. Emergency stop at —— miles per hour.
2. Stop at —— miles per hour, without skidding wheels.
3. Service stop at —— miles per hour.
4. Ease of manipulation.
5. Reliability of system.
6. Operation of the system by the ordinary motorman.
7. Simplicity of system.
8. Liability of brakes operating when they should not.
9. Safety devices in case of failure of any part of braking system.

"Distinctive emergency brakes will be tested on their merits and their non-interference with the ordinary brake."

The Commissioners do not specify in what units the quantities W, S and D will be measured, but for the purpose of discussion we may assume that W is in pounds, S in miles per hour and D in feet. The distance D, it is stated, is the distance between point at which signal to stop is given and the point where the car is stopped. It will consist of two parts: 1. The distance run between the time that the signal is given and the time when the brakes are applied. 2. The distance run while the brakes are stopping the car.

The first distance we may call D_1; it depends solely on speed of the car and the time required for the motorman to set the brakes after the signal is given, and is independent of the weight of the car.

The second distance we may call D_2; it depends upon the mass of the car, the square of the speed when the brakes are applied and upon the retarding force. The moving car has a kinetic energy equal to $\frac{1}{2}$ M v^2 which must be overcome; in the units we have assumed the kinetic energy of the car is .0334 W S^2. This energy is overcome by the average retarding force acting through the distance D_2. The retarding force evidently depends on the braking force, the coefficient of friction of the brake shoes and the friction of the car journals.

Assume a car weighing 30,000 lb. when empty and 40,000 when loaded. Assume that within two seconds after the signal is given the brakes are at once applied with full force; assume that the total braking pressure on the wheels is the maximum recommended in steam railroad passenger service, 90 per cent of the weight on the rails, all wheels being braked, and that the mean coefficient of friction of the brake shoes is 20 per cent. This gives for the retarding force .90 × .20 × 30,000 lb. = 5,400 lb.

Now let this car when empty and when loaded be signalled to stop when running at speeds of 5, 10 and 15 miles per hour, the motorman applying the brakes as quickly as possible, i. e., in two seconds, and with the full force allowable, i. e. ,5,400 lb. The journal friction is neglected. Under these conditions of applying the brake we would expect the braking system to have the same efficiency.

	Car Empty. W = 30,000 lb.		
Speed,	D_1	D_2	D
M. p. H.	Ft.	Ft.	Ft.
5	14.7	4.6	19.3
10	29.3	18.6	47.9
15	44.0	41.8	85.8
	Car Loaded. W = 40,000 lb.		
5	14.7	6.2	20.9
10	29.3	24.7	54.0
15	44.0	55.7	99.7

Now let us compute the "efficiency of braking system" by means of the formula W S ÷ D = E.

	E	
Speed.	Car Empty.	Car Loaded.
5	7,772	9,570
10	6,263	7,407
15	5,245	6,018

According to this the same braking system working with the same mechanical efficiency and applied in the same time will have nearly twice the "efficiency" in stopping a loaded car from 5 miles per hour that it has in stopping an empty car from 15 miles per hour.

The difficulty appears to be that D_1 which depends only on S, and D_2 which depends only on W and S^2 (other things being equal and journal friction neglected) are added together and combined with W and S to get E.

In the absence of a statement of the considerations which led the Commissioners to adopt this formula it appears to us to be but poorly adapted for the purpose of comparing different braking systems because the length of the stop will vary, as shown by the table, with the same mechanical efficiency of braking apparatus and the same skill in operation.

It has ben suggested that W S^2 ÷ D = E instead of W S ÷ D = E would be far preferable.

If the brakes were applied instantaneously the formula $WS^2 \div D = E$ would be correct, but this formula also fails to give comparable results if there is an appreciable time interval between the signal and the application of the brakes. Substituting our assumed values in the formula $WS^2 \div D$ we get:

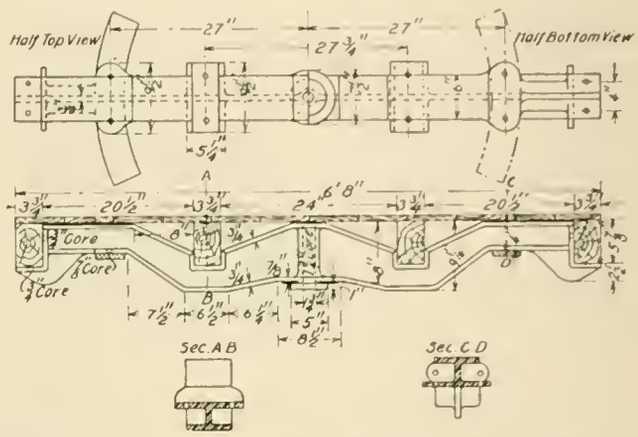
Speed.	Car Empty.	Car Loaded.
5	38,860	48,850
10	62,630	74,070
15	78,875	90,270

That is, $WS^2 \div D$ favors tests at high speed where $WS \div D$ favors low speeds. Both formulas favor loaded cars as against empty ones.

CAST STEEL BODY BOLSTER.

The accompanying illustration shows the cast steel body bolster designed for electric street cars by the Shickle, Harrison & Howard Iron Co., of St. Louis. The company has recently furnished some of these for cars for the Union Depot R. R., of St. Louis, and 100 for cars now building by the Stephenson Co.

One of the problems in designing street cars that are to be carried on double trucks is to keep the floor of the car as low as possible and at the same time allow clearance for the trucks on curves.



CAST STEEL BODY BOLSTER FOR STREET CARS.

This has been accomplished by dropping the bolster where it receives the sills and raising it over the wheels; such a bolster is easily made in cast steel when a similar shape would not be at all practicable if the bolster were built up. The bolster consists of a single casting only and therefore no parts can wear or rattle loose.

THE GRAF FENDER.

Mr. F. J. Graf, of New York, has recently perfected a novel and effective fender for cars, motor carriages and other vehicles, which is intended to embody features of construction designed to meet every possible requirement, and which has already been laid before the attention of the street railways. The device is covered by letters patent in the United States, Canada, Great Britain, France, Germany, Belgium, Austria and Hungary.

This fender has the advantage of being automatic in its operation, and, should the motorman fail to apply a releasing machanism by which it is projected from beneath the front portion of the car, its operation is equally certain and effective by the mere contact with the person struck. By the arrangement of the fender normally beneath the car platform so that it is projected only when needed, the unsightly appearance of some fenders is entirely absent, and, furthermore, such a fender as this cannot well be damaged through collisions, thereby saving to the company quite an item of expense in repairs.

Among the manifold advantages which are claimed for the invention is a certainty of action, impossibility of inflicting injury upon the person rescued, and the placing of the same beneath the body of the car, it being invisible except when operated, and the utilization of the car's momentum to assist in projecting the fender forward.

NEW IOWA ROAD.

Mr. W. F. Ryon advises us that the Spirit & Okoboji Lakes Rapid Transit Co. has been incorporated to build an electric road at Spirit Lake, Ia. The boom in copper and steel has prevented the company from placing contracts. The incorporators are A. N. Keith, Chas. E. Johnson, W. F. Ryon, August Portman and Robert L. Lovett, all of Peoria, Ill., where the office of the company is located, 301 Main St.; Mr. Ryon is secretary and manager of the company.

NEW TRANSFERS ON THE CHICAGO CITY.

By the courtesy of Mr. Geo. O. Nagle, superintendent, and Mr. Leon Jewell, superintendent of time tables, of the Chicago City Railway Co., we have been favored with a series of the new transfer slips recently adopted by that company and copies of the rules governing their use.

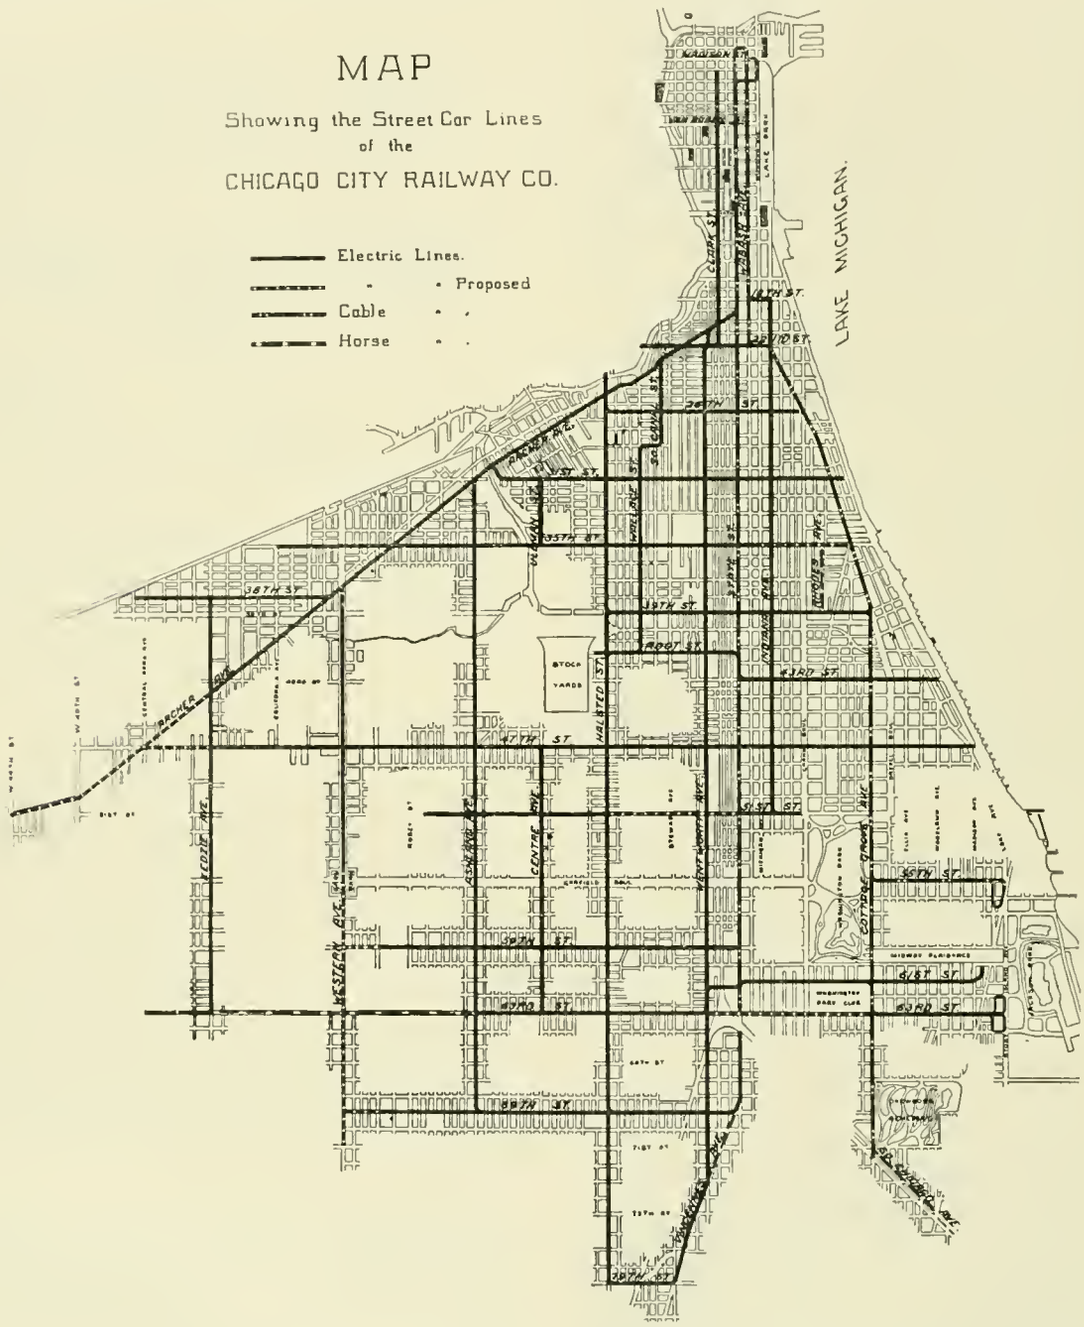
The network formed by the Chicago City lines makes a considerable number of different slips necessary to prevent gross abuse of the transfer privileges by the public, and the present series consists of 25. Each form is lettered and is used on one or more particular lines; the conditions on several lines are such as to require two slips and such second slips are designated by double letters. In some instances the two slips for one line are for use in different directions and in others they are used to distinguish cash and transfer passengers. We reproduce (D), (DD), (G), (GG), (O) and (P) with extracts from the company's bulletin to explain their use. All of the slips except (O) and (P) are 1½ x 4 in.; (O) is 2 x 4 in.; (P) is 1⅝ x 3⅜ in.

"On issuing transfer slips, punch in proper space for transfer point—in the light section to indicate a. m.—in dark section to indicate p. m.—also punch out the hour nearest the time due at terminus of line. Twelve (12) o'clock noon will be considered a. m. and twelve (12) o'clock night p. m."

"On issuing transfer slips to children give one slip for each half fare and punch in space "½ fare" in addition to hour and transfer point—will be honored only for children under twelve (12) years of age; two slips will be given when fares for two children are paid at the same time and registered as one full fare."

"Cash" fares include all kinds of tickets (except transfer slips) good for fare on Chicago City Railway Co. cars, whether "yearly," "monthly" or "registered" tickets.

"A. M. Following Date" to be used by conductors of cars running later than 12:30 a. m. and will be honored accordingly.



D AND DD WENTWORTH AVE.

Transfers "D" will be issued—only on north-bound trips—either for cash fares or transfers and to be punched, for transfer points, as follows:—

In space 1—from cars going north only to 60th.

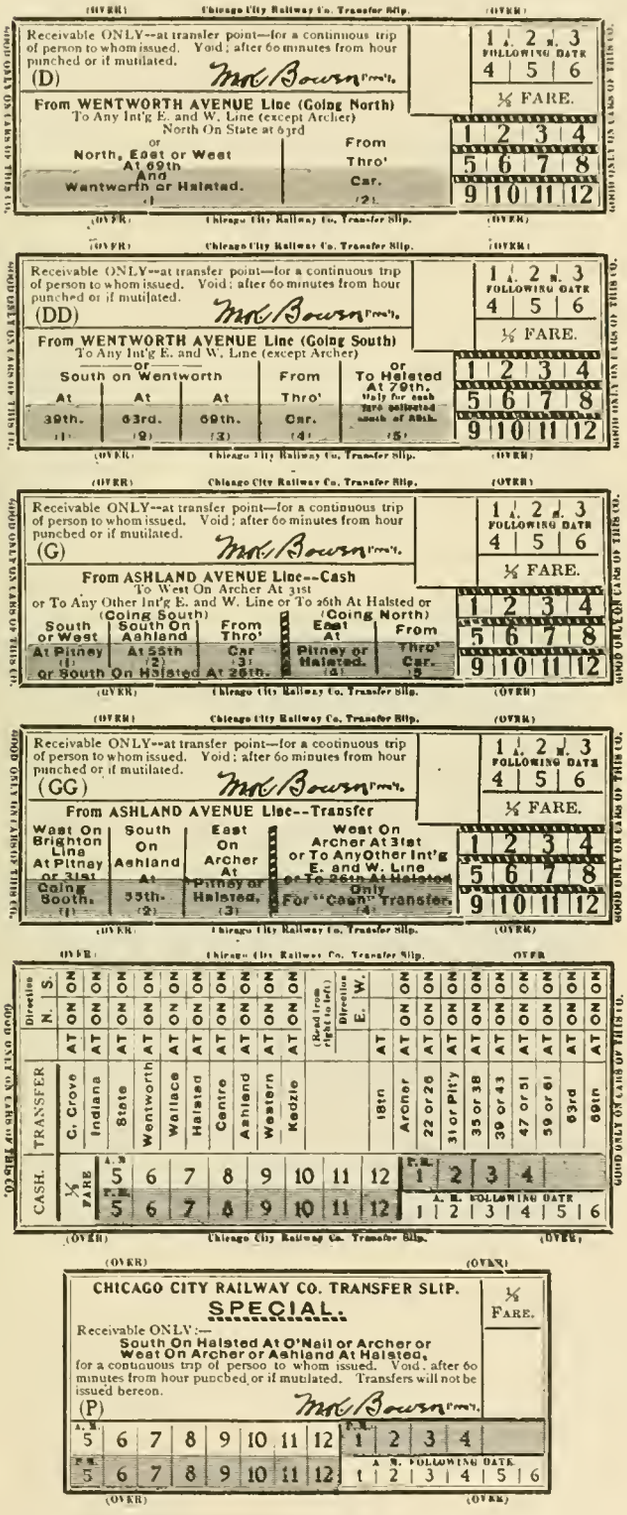
In space 2—from through cars.

Transfer "DD" will be issued—only on south-bound trips—either

for cash fares or transfers, except "To Halsted at 79th" to be issued only on cash fares collected south of 69th. Transfers "DD" to be punched, for transfer points, as follows:—

In space 1—from cars going south only to 39th St.
In space 2—from cars going south only to 63rd St.
In space 3—from cars going south only to 69th St.
In space 4—from through cars.
In space 5—for transferring passengers to Halsted at 79th St.

Transfers from short trip cars to through cars of the same line,



may, on request, be issued to passengers on arriving at transfer point.

G AND GG ASHLAND AVE.

Transfers "G" will be issued only for cash fares and for "Cash" transfers from short trip cars of the same line and to be punched, for transfer points, as follows:—

In Space 1—from cars going south only to Pitney Court.
In space 2—from cars going south only to 55th St.
In space 3—from through cars going south.
In sapce 4—from cars going north only to Pitney Court or Halsted St.
In space 5—from through cars going north.

Transfers "GG" will be issued on transfers and to be punched, for transfers points, as follows:

In space 1—for transferring "Transfer" passengers, to the Brighton line, going south.
In space 2—for transferring "Transfer" passengers, to the through cars, from cars going south only to 55th St.
In space 3—for transferring "Transfer" passengers, to the through cars, from cars going north only to Pitney Court or Halsted St.
In space 4—for transferring passengers, to intersecting "East and West" lines, on transfers (from intersecting lines) which were issued for cash fares.

Transfers "GG" punched in space 1, 2 or 3, may, on request, be issued to passengers (regardless of fare paid) on arriving at transfer point.

O, EMERGENCY.

Emergency transfers will be used only in cases that are not provided for on the regular slips (such as going to and from the depot via an intersecting line). They will be issued either for cash fares or transfers according to the general rules governing the line over which the car is passing.

Conductors will—punch "Cash" or "Transfer" according to fare paid—punch the word "On" (in column N., S., E. or W., as the case may require) opposite the line on which transfer is to be honored—punch the word "At" opposite the proper line to indicate transfer point. If punched "Cash" another transfer may be issued thereon the same as for cash fare.

These transfers will be honored when presented according to conditions printed on back of slip.

P, SPECIAL.

Transfers to the "West Side" will be issued only from north or east-bound cars of the Halsted, Ashland and Archer Ave. lines, for cash fares or on "Cash" transfers received from short trip cars of the same line.

Transfers from the "West Side" will be honored only on south or west-bound cars of the Archer, Ashland and Halsted St. lines, and transfers will be issued thereon only from short trip cars to the through cars of the same lines.

Passengers showing transfers to or from the "West Side" will be allowed to retain transfers and ride free on Halsted St. between Archer Ave. and O'Neil St.

In all cases before the transfer slips are issued to the conductors the date is printed upon them in the rectangle blank shown in our engravings.

TWO NEW WESTERN NEW YORK ROADS.

Two new companies have been organized in Buffalo for the construction of railways. The South Buffalo Railways Co. was incorporated with a capital stock of $500,000. This company proposes to build a road 18 miles long having a northern terminus at a point on the line of the Buffalo Creek Railway Co. and a southern terminus in the town of West Seneca. The road is to be standard gage and operated by steam. The directors are John J. Albright, Edmund Hayes, Geo. L. Williams, Wm. A. Rogers, Franklin D. Locke, John G. Milburn, Raymond Albright, Herbert H. Hewitt and Ralph H. Plumb.

The second company is the Ridge Road & Lake Shore Railway Co., capital $40,000, and the intent is to build an electric suriace railway from West Seneca to Hamburg. The road will be four miles long.

The directors of this company are Henry J. Pierce, Wm. B. Cutter, Clark L. Ingham, J. Henry Metcalf, Walter D. Ingham, Wm. H. Gratwick, jr., John H. Baker, John Otto, jr., and Geo. C. Riley.

The old Hamburg road has been stirred up by this new comer and has begun arrangements for an extension of its line almost alongside of the new route. It is expected to be a race between the two to see which will get the tracks laid first.

WHY MILWAUKEE SHOULD NOT REGULATE FARES.

Mr. H. C. Payne, vice-president of the Milwaukee Electric Railway & Light Co., appeared before a legislative committee in March last, and delivered an argument against a bill then pending to empower the city of Milwaukee to regulate the fare to be charged by his company. The points made by Mr. Payne are equally applicable to many other cities, and we present a portion of his argument.

"At the time of the purchase of the several street railways by the parties now owning the system in Milwaukee, say about the year 1890, there were five roads operating within the limits of the city of Milwaukee: The Milwaukee City Railroad Co., with 40.50 miles; the Cream City Railway Co., with 31.25 miles; the Milwaukee Electric Street Railway Co., with 12.75 miles; the West Side Railroad Co., with 20.75 miles, the Milwaukee & Whitefish Bay Railway Co., with 4.75 miles; total, 110 miles. These roads operated entirely independently of each other.

"There was no transfer system between the several roads, and if a passenger desired to go from a point on one of the lines to a point on any of the other lines, such passenger was compelled to pay two or more fares. The present company is the successor of all of the companies mentioned, and, in addition thereto, has increased the mileage so that at the present time it owns, controls and operates 175.03 miles of track.

"At the time of the purchase of these properties by us, transfers were issued only to a limited extent, there being but five points of transfer within the city, and less than 800,000 people availed themselves of the privilege in any one year. We have increased the transfer points to every place upon our road where the tracks intersect, there being 51 such points. During the year 1896, 7,913,593 people availed themselves of the use of transfers, thereby saving to them in that year $395,679.65. It costs the company just as much to transport a passenger upon a transfer as it does upon a cash fare, and, with no law or ordinance requiring us to do so, we have voluntarily made this great concession to the people of Milwaukee.

"Last year we transported 38,587,157 passengers, of which the number of passengers paying five cents was 30,673,564, and the transfer passengers 7,913,593. The total amount received for the transportation of these passengers in 1898 was $1,511,671.77, or an average fare per passenger carried in 1898 of 3.91 cents.

At the time of the purchase of these properties the total mileage was 110 miles. We have increased that mileage more than sixty per cent, and we now own and operate 175.03 miles of track. We have extended the street railway lines beyond the city limits to all the suburbs, and the electric cars now running to Whitefish Bay, Wauwatosa, North Greenfield, Soldiers' Home, State Fair Park, St. Francis, Cudahy, and South Milwaukee, and to Waukesha and Pewaukee Lake, as well as to Racine and Kenosha; and a line will be built by us this season to North Milwaukee.

"We have not only greatly increased the distance that a passenger can be carried for one fare, but we have voluntarily in many instances reduced the charges 25 per cent by the introduction of the sale of commutation tickets at 7½ cents, where the fare had previously been 10 cents, good for any point on our system inside the city limits of Milwaukee to the villages of Whitefish Bay, Wauwatosa, North Greenfield and Cudahy, and where formerly people desiring to go to West Park paid two fares, we now charge but one fare.

"Attention is often called to the city of Washington, where commutation tickets are sold, but what are the facts regarding the street railway situation in that city? There are but two companies of any importance in that city—the Capital Traction Co. (or the Pennsylvania Ave. line), with 35.96 miles of track, and the Metropolitan (or the F St. line,) with 22 miles of track, making altogether 57.96 miles. The earnings of the Capital Traction Co. in 1897 were $876,210.71; the earnings per mile of track $24,366. The earnings of the Metropolitan Co. for the same year were $737,819.69; the earnings per mile of track, $33,537. Consolidating the two gives 57.96 miles of track, with earnings of $1,614,030.40, or earnings per mile of track, $27,847.

"We have in the city of Milwaukee 141 miles of track, and the gross earnings of the road in 1897 were $1,409,017.04, or $9,994 per mile of track—$205,000 less than the 57.95 miles of railroad earn in the city of Washington, and earnings per mile of about one-third as great.

"Upon the two lines in Washington, upon investigation I found that over 72 per cent of the passengers carried by them rode upon commutation tickets. Assuming that the same results would follow in Milwaukee had we been compelled to sell commutation tickets at the rate of four cents, the loss to us in earnings for last year would have amounted to more than $230,000. Mr. Chairman, the net income of the company last year was but $38,108.67, which would have left us nearly $200,000 short of earning our interest and fixed charges.

"In the city of Washington there is no general system of transfers. Each company gives transfers to its own lines, but if a passenger desires to go to any part of the city reached by another line, such passenger must pay an additional fare, while in the city of Milwaukee there is a universal system of transfers in vogue, and a passenger can go from any part of the city for one fare of five cents."

A CONCRETE BREAKER.

The accompanying illustration shows a machine for breaking up hardened concrete on roads where paving is to be changed or repairs made. It is shown as it was used for breaking the old cable roadbed at Los Angeles. The machine is controlled by Skinner & Miller, engineers, of Los Angeles, Cal.

As may be seen it operates as does a pile driver. It is made just high enough to clear the trolley wires. The hammer weighs 2,500 lb. and the wedge, which cuts the concrete, weighs 200 lb. This wedge is of steel and is connected with the hammer by dowel pins.

CONCRETE BREAKER.

In size it is 10 x 12 in. on the face, next the hammer, and is 14 in. deep. The wedge has been patented and is owned by Messrs. J. A. Fairchild and Geo. R. Wilton, of the Alcatroz Asphalt Paving Co., of Los Angeles.

The hammer is run by an ordinary hoist, the power being a 10-h. p. motor which takes current from the trolley wire. It has a drop of from 8 to 10 feet. The motor, drum and hammer are supported by a frame, mounted upon rollers, and can be moved at will by is own power by attaching a rope to the yokes of the cable track. The hammer is moved laterally by the wheel shown at the left in the illustration.

Messrs. Skinner & Miller state that with this machine they have broken up from 320 to 350 ft. of single track per day of 10 hours; the roadbed was that of a cable railway and the concrete very hard.

THE SITUATION IN DETROIT.

(From Our Special Correspondent.)

Now it is a fight between the courts and the Detroit Street Railway Commission to see whether the municipality of this city has a right to buy and operate the street car system of this city. That is the one question being generally discussed in Detroit and almost all the business interests are united on the anti-ownership side. In the first place the Circuit Court has issued an injunction temporarily restraining the recently appointed Street Railway Commission from taking any action that will result in municipal ownership. Secondly, the commercial organizations of Detroit have employed the leading attorneys of Michigan and through the attorney-general of the state have started quo-warranto proceedings in the Supreme Court to contest the constitutionality of the McLeod law, under which the Street Railway Commission was appointed and by the powers of which municipal ownership was to be maintained in Detroit.

The attorneys on both sides completed their arguments before the Supreme Court on May 6th, but that body has stated that it will not be ready to hand down an opinion for several days, so with the pending injunction nothing definite can be accomplished towards municipal ownership in Detroit for some little time.

In the meantime but little has been accomplished during the past month towards the purchasing of the street railways by the city of Detroit. The experts appointed by the Street Railway Commission have completed their work and place a cash value on the real estate, tracks, power houses, rolling stock, overhead equipment and other properties of the four companies operating in Detroit at approximately $8,000,000. Just what value the experts and Commissioners have agreed upon as a price for the franchises has not been given out, but from the best information obtainable it is a good guess that unless the courts interfere Detroit will buy the street railway properties for about $12,000,000, paying therefor with low interest bonds.

In the street railway world at large it is probably a large mystery why the present owners of the street car systems in Detroit desire to sell out to the city. Today I had a talk with one of the leading street car officials in Detroit and received this explanation: "Some months ago the City Council Committee on Ordinances approached the street car management and requested many things, including better service on some of the light lines, an extension of the transfers, the construction of new lines in some of the suburbs, the lengthening of the hours of use of workingmen's 3-cent tickets and a number of other changes. Now the street car company was asked to make a proposition and leading councilmen stated that if the company did not care to make these improvements the city would buy the lines. As a consequence the company submitted an ordinance granting all the requests, provided a new franchise was given the present companies, with an alternative of municipal ownership. And thus started the present consideration."

Undoubtedly during the coming month the courts will render their decisions and following that the Commission and the street car owners will take final action. If the decision is favorable to the Commission it is almost certain that the city will buy the lines and properties in short order.

Detroit papers report that J. C. Shaffer, of Chicago, is negotiating with Tom L. Johnson for the Detroit street railways and has an option on the system at $9,000,000. Late information is to the effect that the Johnson deal with the city has fallen through entirely and this leads to the supposition that Mr. Shaffer could now buy the roads if he so desired. Mr. Shaffer, however, refuses to make any statement whatever regarding the matter.

The Ohio Central Traction Co., of which Israel A. Kelsey is president, and W. E. Haycox manager, is building 12½ miles new track between Galion and Bucyrus, and will have it completed about the middle of June. The company has bought eight new cars, four each closed and open, and is now building a new car barn with a capacity for 16 cars, and a new power house at Galion with a 400-h. p. capacity.

OPENING OF THE VICKSBURG ROAD.

Vicksburg is one of the oldest towns of the South, but until now has never had any better street car facilities than were provided by a few old rattle-trap boxes and a half dozen mules. But Vicksburg had a set of men who realized that she was capable of better things, and they determined to bring them about. The Society of Ben Bolians was formed, its object being the general upbuilding and

STREET RAILWAY ARCH.

improvement of the city. Through this society the Vicksburg Railroad & Manufacturing Co. was organized and developed so far as the furnishing of the city with electric light. Then it occurred to them that a city of 25,000 population was slow that did not have an electric street railway. Mr. S. F. Mordaunt, one of the enterprising business men, began looking for the right man to construct such a road, and found him in Mr. J. C. Shaffer, of Chicago. A company was formed, and Mr. Shaffer was made president; a

ILLINOIS CENTRAL ARCH.

charter was obtained Feb. 2, 1898. The electric light plant was purchased and the work of construction was begun last November, and on April 24th the road was finished and formally opened, the occasion being made the greatest event in the history of Vicksburg since Grant and Pemberton met there in 1863.

The Vicksburg Electric Street Ry. is eight miles in length. It begins at the city cemetery, runs through the center of the town with diverging lines both to the east and west, and then continuing on south out to Ken-Caryl Park, a 35-acre tract the company has

purchased, and which it is now converting into a handsome resort. There are now 10 open cars running, and the citizens are enthusiastic. They are crowded with passengers who delight in the novelty of street car service.

The company has built and fully equipped a large power house. It has two 250-h. p. Stirling and one 200-h. p. Heine boiler; one 300-h. p. Cooper and one 600-h. p. Russell engine and Westinghouse generators. The North American Railway Construction Co. built the track, the St. Louis Car Co. built the cars, and the Westinghouse Co. furnished the complete electric equipment. This power house was described in our issue of December, 1898.

President Shaffer and a party of friends went from Chicago to Vicksburg, in a special car over the Illinois Central, to attend the inaugural ceremonies. Everything was in perfect order on April 24th, and Vicksburg has never seen such a season of gayety and rejoicing. It was a whole week of festivity. Besides the street car line there was the opening of a new opera house and one day was devoted to decorating the graves of the confederate dead.

But the street car feature was the main one and attracted the most attention. On that day everybody had a free ride out to

VICKSBURG ARCH.

Ken-Caryl Park. The streets of the city were gorgeous with flags, bunting and elaborate arches, and all the bands in Vicksburg and the neighboring cities kept the crowds happy and the air full of music; the band from the U. S. S. Nashville had the place of honor.

While all the arches were handsome, the ones erected by the street car company, the city of Vicksburg and the Illinois Central Railroad Co., were the most attractive. The street car arch was crowned with an old mule car, which was in sharp contrast with the new cars on the streets.

At the Park there was some speech-making, Mr. M. J. Mulvehill, secretary of the company, and S. F. Mordaunt, general manager, being the principal speakers. President Shaffer was eulogized and in response to numberless calls made a few pleasant remarks.

After the speech-making all present were invited to partake of a feast, which had been provided. A gigantic barbecue had been in progress, and the meat with sundry accompaniments and unlimited lemonade was served on tables scattered through the Park. There was enough for all, and everybody enjoyed it.

The whole affair was a most happy one and one that will be long remembered not only by the people of Vicksburg, but by the thousands of visitors.

The Urbana & Champaign Railway, Gas & Electric Co., including the three properties named in the company's title, has been sold to parties in Portland, Me., represented by Mr. W. B. McKinley. The transfer took place May 1st. Under the able management of Mr. B. F. Harris, Jr., president of the properties sold, the plants have been brought to a high degree of efficiency and have become very attractice investments.

IMPROVEMENTS AT ALLENTOWN, PA.

The Allentown (Pa.) & Lehigh Valley Traction Co., of which A. F. Walter is manager, is rebuilding its entire track between Allentown and Bethlehem, and Allentown and Catasqua. It is replacing 45 and 50-lb. rails with 70-lb. and using 6 x 8-in. x 7-ft. ties. The company bought about 900 tons of the rails of the Lackawana Iron & Steel Co. John A. Roebling Sons Co. supplied ten miles of feed wire, 500,000 c. m. A great part of the special work is being furnished by the Loraine Steel Co., of Johnstown, Pa. Particular attention is being paid to the curves and all the steel for them is especially rolled and guarded, even on curves of long radius, in no case are straight rails bent into curves. From the J. G. Brill Co. were purchased 30 No. 21 E trucks, and from the Westinghouse Co. 30 equipments of type B 38 motors to use with them.

Manager Walter says the business of the road is in excellent condition, the receipts being largely in excess of last year at this time. An extra force of men is at work on the improvements, and it is expected all will be completed by July 1st.

APPOINTMENTS ON THE BROOKLYN RAPID TRANSIT ROAD.

President Rossiter has announced the following appointments: J. D. Barton, superintendent of Brooklyn bridge division, vice John Prince; George W. Edwards, superintendent of the Brooklyn "L"; W. W. Wheatley, assistant superintendent of all the lines under General Superintendent McCormack; George Goodwin, superintendent of the Ridgewood division; Charles E. Harris, superintendent of the southern division; Miller Robbins, Jr., superintendent of the central division; Richard K. Holdone, superintendent of Canarsie division; John C. Webb, superintendent of the eastern division; William F. Duncan, superintendent of the East New York division, and Newton W. Bolen, superintendent of the Greenwood division.

STRIKE AT DULUTH.

The employes of the Duluth Street Ry. went on strike on May 2nd, after the arrest of 10 discharged men, who are charged with cutting feeder wires. The company resumed service two days later with outside non-union men, and several attacks were made on the new men. Two attempts to dynamite cars were made in which one car was badly wrecked and several persons injured. The road is in the hands of a receiver who has secured an injunction against interference with the operation of the cars.

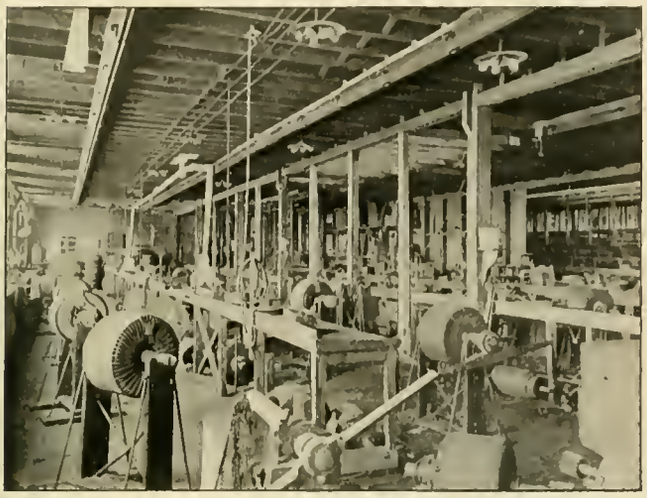
LUBRICATION OF GEARING.

It is a too prevalent idea that almost anything will answer as a lubricant for gear wheels; that the teeth will wear, the rate depending off how well the gearing is proportioned for its work. Gear teeth fail either through excessive wear of the contact faces or by breaking off because of the shocks made possible by the side clearance; the initial side clearance or backlash will vary from 1-64 in. to 1-16 in. in cut gears and from 1-16 in. to 3/8 in. in cast gears, increasing of course with wear of the contact faces.

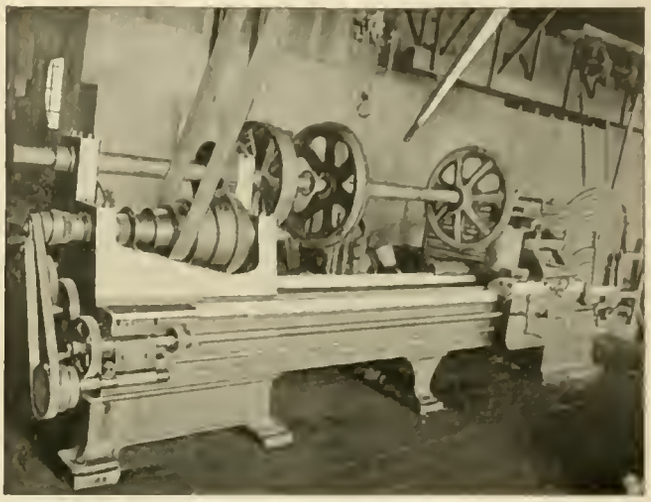
The Ironsides Co., of Columbus, O., has had great success with what it calls "Gear Shield." This compound has been perfected on the theory that the proper lubricant for gears is one which is tenacious and will build up a deposit on the tooth, which prevents metalic contact between the working surfaces and on the back side reduces the side clearance or backlash and provides a cushion which mitigates the effect of shocks due to varying loads. The company states that "Gear Shield" has proved to be equally well adapted for the fast-running gearing of street railway motors and for the slow-running and heavy gearing in rolling mills. In the accompanying illustration the heavy lines denote the "shield" formed on the surfaces of the teeth by this lubricant.

BROOKLYN RAPID TRANSIT SHOPS.

The main repair shops of the Brooklyn Rapid Transit Co. are located on 52d St., South Brooklyn, extending from Second to First Ave., a distance of 700 ft., with a width of 100 ft. The half nearest Second Ave., 350 x 100 ft., is two stories high, of brick. The main floor contains the mill room, part of general store room and the remainder is for car body work. On the second floor are the paint shop, paint stock room, general store room, draughting room and offices of the superintendent and time-keeper. The remainder of the building is of frame and one story high, except for a gallery over the armature room, where insulations, armature coils and fields are made, and another one over the machine shop used as a pattern loft and for putting the rope netting in fenders.



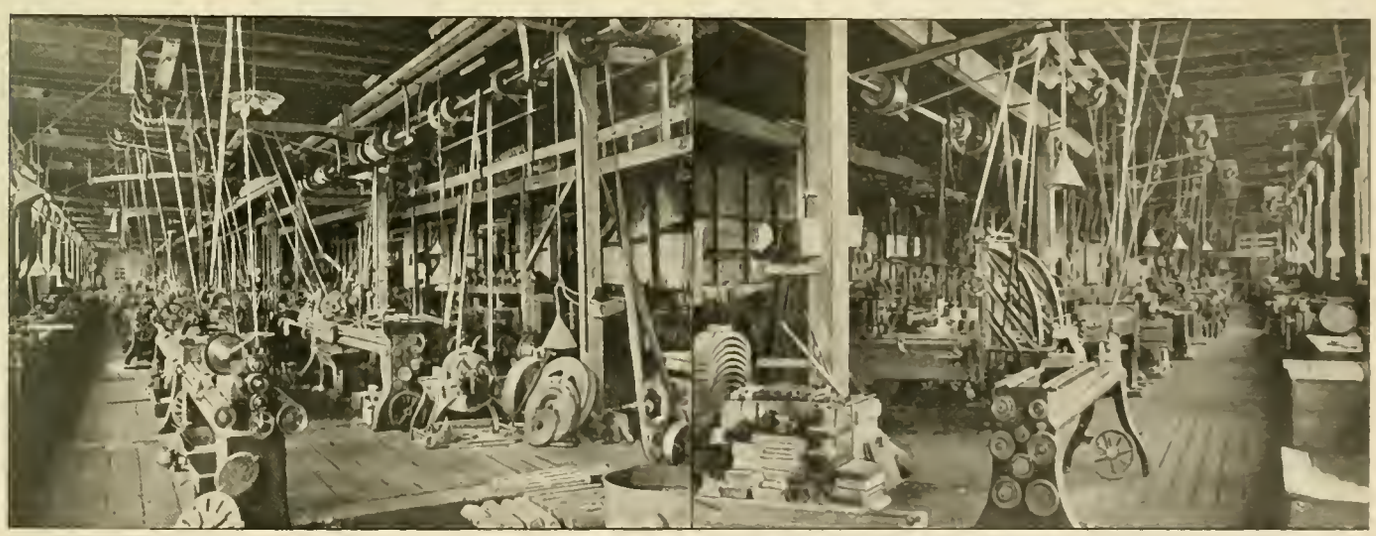
ARMATURE REPAIR SHOPS.



McCABE DOUBLE SPINDLE LATHE.

The armature room, occupying a space of 140 x 40 ft., is a very busy place at present owing to approach of the open car season. Some 300 W. P. 50 armatures are being changed from 13-turn to 9-turn machines with a heavier size wire. The shafts on these re-wound armatures are being changed on the commutator end so that the bearing surface is now 2⅝ x 6 in. in place of 3½ x 3 in. In connection with this alteration an iron sleeve babbitted bearing with a dust cap screwed on the end with a taper thread, is used. A number of Type B. Curtis armatures are being changed from four to six turns.

The machine shop and wheel fitting room are also in the frame building, the former occupying a space 110 x 40 ft., and the latter 50 x 30 ft. The machine shop is equipped with 11 lathes, 1 42 in. planer, 2 shapers, 1 milling machine, 1 horizontal mill, 9 drill presses and the necessary bolt cutters and emery wheels. The latest addition to the machine shop in the way of machinery is a double spindle lathe, made by J. J. McCabe, of 15 Dey St., New York, that swings 26 in. on the lower spindles and 44 in. on the upper. On the lower spindles all classes of small work are easily handled, while on the upper spindles an axle fitted with 33-in. wheels is readily swung and any work necessary to the axle or wheels is easily done without the necessity of removing the wheels. The upper spindles are very convenient for turning out the older types of motors for the large size axles that are now coming into use. Next to the machine shop is the wheel room, equipped with a vertical boring mill, hydraulic wheel press and axle straightener. This room also contains the electric furnace used for heating the 1¼-in. iron pipe that forms three sides of the standard fender. These pipes, 15 ft. long, are run into one end of the furnace, which is 16 ft. long, the proper sections heated, the pipe taken out of the opposite end of the heater, and laid on a suitable form, and then bent to shape with rollers connected by chains to a countershaft with tight and loose pulleys. This countershaft is set in suitable pillow blocks bolted to yellow pine timbers set in the concrete floor. Old motor brushes and electric light carbons are used in this furnace.



MACHINE SHOPS—BROOKLYN RAPID TRANSIT CO.

The law regarding the use of fenders and appliances for protecting life goes into effect in California July 1st.

LACONIA (N. H.) STREET RAILWAY.

The Laconia (N. H.) Street Railway Co., H. L. Pierce, of Leominster, Mass., president; L. S. Pierce, of Laconia, manager, is building five miles of new track to connect Lakeport and The Weirs. The company has recently bought four new 13-bench open cars and is remodeling its old barn, giving it a capacity for 16 cars and is building a power house of 500 h. p. capacity.

This company has a somewhat novel plant for street railway work. It has two Westinghouse gas engines and two generators run in connection with a Stetson storage battery. The new extension of the line is on a boulevard laid out along a small lake to The Weirs and further on to the shores of Lake Winnipesaukee. Previous to last fall the road used horses from Laconia to Lakeport. H. L. Pierce, president of the Pierce Construction Co., of Leominster, Mass., then bought into the company and changed the power to electricity. Mr. Pierce has built and operated a great number of roads, his range of territory reaching all the way from Maine to Texas. He is also the president of the Fitchburg & Leominster Ry., of Fitchburg, Mass.

L. S. Pierce, the manager of the Laconia Street Railway Co., was the electrician and superintendent of overhead construction of the Pierce Construction Co. until he took the position of manager of the Laconia.

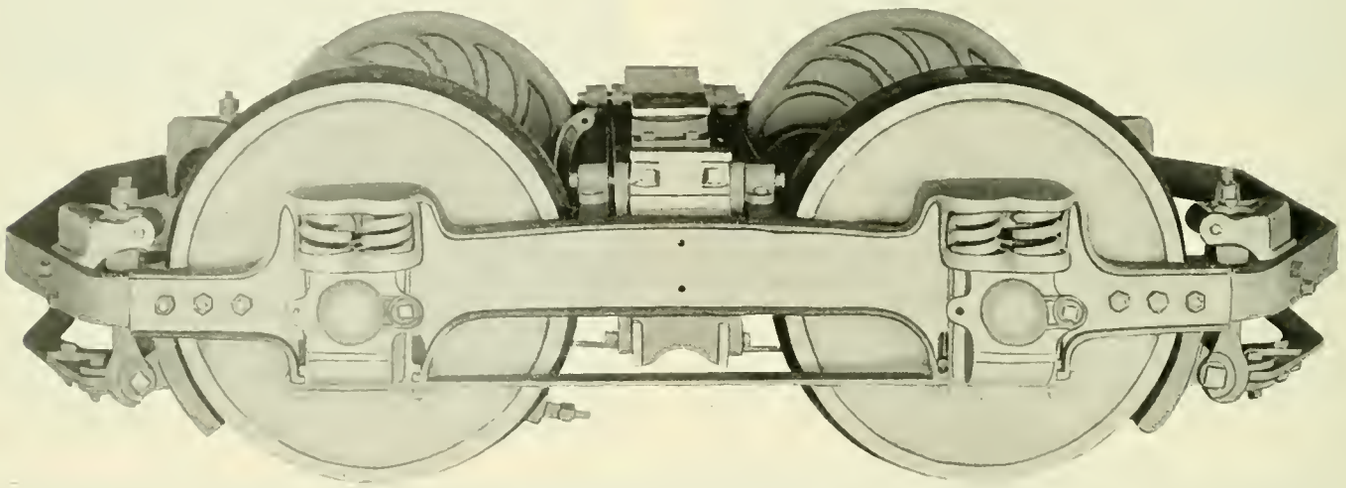
TROLLEY EXCURSIONS—A NEW FIELD.

The day of the tally-ho is pretty well over. Wherever it is possible to construct an electric road it is being done, and trolley rides have become the fad. Eastern Massachusetts is full of these electric transportation lines, and Robt. H. Derrah, of Boston, has been quick to take advantage of them and inaugurate trolley excursions. Mr. Derrah has had considerable experience in connection with transportation companies of this kind, and is entirely competent to promote and manage such excursions.

In planning the construction of electric surface roads, one aim, and a natural one, has been to reach or have on the right of way as many attractive features as possible. The roads throughout Eastern Massachusetts are especially favored in this regard, and a trip over almost any one of them affords a pleasant ride. Mr. Derrah will be glad to arrange with private parties, clubs, picnics, conventions, and any and all people wishing to get up a novel and interesting trolley excursion. He can show maps of routes, give full particulars as to attractions, and will provide any refreshments and entertainment desired. Mr. Derrah can be reached by mail or in person at Room 3, No. 113 Devonshire St. Boston, Mass.

Mr. Derrah entered the service of the West End Street Railway Co., May 3, 1889, when Henry M. Whitney was president, as office boy; when Mr. Little became president in 1893, Mr. Derrah was made chief clerk and held this position until the Boston Elevated Street Railway Co. took charge, when he became executive clerk for President Gaston. When Mr. Derrah resigned, President Gaston sent the following letter to the daily and weekly newspapers of Boston and vicinity:

"Mr. Robert H. Derrah, who has been for the last 10 years connected with the West End Street Ry. and the Boston Elevated Railway Cos., in the office of the president, leaves the service of the latter company today (April 29th) to enter upon business for himself. He has for several years made a special study of the growing electric railway system of New England, and as the publisher of Derrah's Street Railway Guide for Eastern Massachusetts has a wide acquaintance among street railway men. Mr. Derrah is to start upon a new enterprise in this part of the country, the management of electric car excursions for individuals or parties. In England the low price excursion is a popular form of entertainment, and in Boston and its vicinity more attractions of greater diversity can be found than in any other section of the country. While such a business is an experiment in New England, it has great possibilities, and Mr. Derrah leaves the Boston Elevated Railway Co., accompanied by the best wishes of its officials and employes to be first in the new field."



McGUIRE NO. 39 PIVOTAL TRUCK.

HIGH SPEED TRUCK.

We illustrate a type of truck which is the latest production of the McGuire Manufacturing Co., and which is one of a large order being sent to the South Bend (Ind.) Street Ry. These trucks are guaranteed to run 50 miles an hour under a car body of 50,000 lb. weight. The company states that the same load might be carried at a speed of 100 miles with safety.

The truck is built under the Cloud-McGuire patents, which feature it is claimed permits the frame to carry the car body lower than any other of the same strength.

The outlines show simplicity and strength. The only springs in sight are those over the journal box supporting the side frames, but there are elliptic springs housed under the bolster of sufficient capacity to carry the load and insure soft and easy motion. Altogether it is one of the most interesting trucks for electric railway purposes. While it has many desirable points, the three main ones are: First, short wheel base, to facilitate passing curves; second, allowing the car body to be carried as low as the motors will permit; third, motors hung outside of wheel base permits of quick repairs and better inspection. The Peoria & Pekin Ry. has just placed an order with the McGuire Manufacturing Co. for 20 double equipments of this same type truck. The McGuire Co. is running to the fullest capacity, night and day shifts.

The Milwaukee Electric Railway & Light Co. has announced that disabled wheels may be carried on its cars. This is a privilege bicycle riders will appreciate.

The contractors laying the underground trolley on the Boulevard, New York city, are disappointing a great many people, who expected nothing less than ruin to the grass plots adjacent to the track, and much delay to traffic. The work is progressing quickly and smoothly, and as yet no one has had a complaint to make.

ELECTRIC TRACTION AND ITS APPLICATION TO SUBURBAN AND METROPOLITAN LINES.

Abstract of a paper of Philip Dawson. Read before the Society of Arts, London, March 22, 1899.

There is no longer room for doubt that electricity is the one pre-eminently successful motive power for tramways. This is proved by the rapid growth of electric traction. The words "experimental line" have fallen out of use, yet it is only a few years ago that those who ventured to foretell that the trolley system would be generally introduced into this country were ridiculed. There is no country in which electric traction is advancing more rapidly, and in which finer plants are being installed than in Great Britain. The day is not far off when horses and steam will have disappeared from the streets as far as tramways are concerned, and when the horse 'bus as a competitor will be no longer known.

There are practically three methods of handling electrically the traffic on a railway, namely:

1. By locomotives or motor cars hauling a train of trailer cars.

2. By independent motor cars.

3. By a set of independent motor cars formed into a train and handled from the front car or from a so-called controller car. Each car, however, can be separated from the train, and it then becomes an independent motor car.

As regards the supply of the necessary current for the motors, there are three distinct methods:

Firstly. By accumulators or storage batteries which may be carried either on the motor car or locomotive, or on a tender.

Secondly. By having a car containing a stationary engine, dynamo, and boiler, which supplies the necessary current to the motors on the cars comprising the train of which it is part, and as proposed by W. Heilmann.

Thirdly. By continuous or multiphase current supplied directly from a generating station or from a sub-station which, in its turn, gets its supply of energy from the main station, the current being distributed either in the form of direct or polyphase to conductors running along the lines, and from which the power is supplied, through sliding contacts on the cars to the motors.

The two former methods, as far as this paper is concerned, will not be discussed, as sufficient data are not available to justly their being considered.

The system of transmission of energy to the motors by means of conductors laid along the track, will therefore alone be considered.

This method allows of several variations as far as the generation and distribution of power is concerned, amongst which the chief may be set down as follows:

(a) One continuous current generating station supplying current direct to contact rail. Where drop in pressue owing to distance becomes excessive, a negative "booster" may be used—it serves, so to speak, to pump back the current to the station, and is self-regulating, not taking at any period more power than is actually required to pump the current back. Should there be one or two lines too long to enable them to be worked this way, polyphase high tension generators should supply the power to one or more sub-stations along the line, as may be found necessary in which rotary converters are located, which transform the current back into continuous. The polyphase generators to be driven by continuous current motors in the generating station. As an example of such a station, the new Dublin tramway power house may be taken.

(b) One central station generating continuous current with sub-stations in which accumulators are located along the road, and which are charged by means of a booster and special cables. As an example of this system, the Leeds tramways may be taken as designed by, and carried out by, the late lamented Dr. John Hopkinson.

(c) A series of stations, as described under (a) and (b), situated at various distances and connected together one with the other. As an example of this, the tramways and light railways in and round Boston, Mass., may be taken, owned by the Boston Elevated Railway Co., which has absorbed the well-known West End Co.

Data of Boston Elevated Railway:

Track miles operated	305
Number of cars	2,648
Car miles run during 1898	20,787,000
Passengers carried during 1898	172,764,300
Number of power stations	5
Total capacity of power stations in kw.	16,100
Total rated i. h. p. of engines	24,000

(d) A power station generating polyphase currents, which, by means of static step-up transformers, are transmitted at tensions which run from 2,500 to 30,000 volts to sub-stations where static step-down transformers reduce them to pressures of 300 to 350 volts, the current at this pressure enters rotary transformers, which deliver direct current at 500 to 550 volts to the line. As an example of this later system, the Central London Ry., which is now under construction, may be mentioned

(e) A three-wire system with continuous current, the rails or return forming the neutral wire. This has been tried and found wanting, and the engineers of the Central London Ry. most carefully investigated its possibility and decided in favor of polyphase transmission and rotary converters, and rightly so.

From careful calculations and the investigation of what has been done both in Europe and America, there is no getting behind the fact that for any power station which will exceed 4,000 kw. in capacity, the polyphase system is nearly certain to prove commercially the only admissable one. This statement is upheld by such an authority as Mr. H. F. Parshall, M. I. C. E. It is evident that in the particular cases at present under consideration (suburban and metropolitan communication), more than 4,000 kw. will be under consideration; and therefore nothing, as far as the power station and transmission is concerned, but polyphase currents will be considered.

There are two distinct varieties of service to be catered for. One that on a system like the Metropolitan and District, where the stops are frequent and the runs short. The other the case of long distance lines with few stops. In the present paper it is only proposed to consider the first variety. In this case the use of polyphase motors need not be considered, as for work entailing frequent stopping and starting they have not up to date proved satisfactory.

A short examination of the importance of rapid acceleration on lines having stopping places at short intervals is interesting. Practical experience with electrically-driven motor cars, or locomotives on the experimental track of the General Electric Co., at Schenectady, has proved that it is perfectly feasible to attain a speed of 30 miles an hour 10 seconds after starting from a standstill. Assuming a level track, and that during 65 seconds the current is cut off, and the train allowed to coast, that the brakes are then put on, the train will be brought to a standstill 15 seconds later, and the total time from start to stop will be 90 seconds. Under these conditions it will be found that the average speed will have been 23.16 miles an hour, and that the total distance run will be about .55 of a mile. Assuming that instead of attaining the 30 miles an hour in 10 seconds, it took 30 seconds, and that this full speed of 30 miles an hour was kept up for 40 seconds longer, and the brakes then put on, the train would be brought to a standstill in 90 seconds, and the average speed would work out as 21.66 miles an hour, or an average speed of about 10 per cent less than in the previous case, the consumption of power, however, being much greater.

It is evident that the most important point is to attain a high average speed, and to keep the maximum speed attained as low as possible, as by so doing less power is required in braking the train, and also less power is required to run the train. The time between the moment when the maximum speed is attained, and when the brakes are put on, should be at least from four to six times that required for stopping the train, so as to allow for errors in judgment on the part of the driver, and also to enable him to make up lost time. On the Manhattan Elevated Ry., in New York, the trains which are drawn by steam locomotives take 20 seconds to attain a speed of 14 miles an hour, or less than half the speed in double the time as compared with electric traction just mentioned.

A much larger current will be required to attain a rapid acceleration than to attain a slow one, but the current will be required during a much shorter time, and the total energy supplied will be less in the case of rapid than of slow acceleration. This fact must not be lost sight of when calculating the feeders for such a system, and the train service should be arranged in such a way that as few trains

as possible start together. Furthermore, the more rapid the acceleration required the larger will the motors have to be, and therefore there will be a limit, above which it will not be advantageous to push the rapidity of acceleration. In new tunnel lines, such as are now being constructed all over London, it will be evident that it is an advantage to have the stations built with a down-grade for the trains to start, so as to help the motors and reduce the current required at starting, and that similarly it will be an advantage to have an up-grade when nearing a station, so as to reduce the amount of power required in braking. By properly choosing these gradients it is found that a total economy of from 40 to 50 per cent in the total power required by a train may be made. According to Mr. Potter's tests it was found that during acceleration an average power of 32 amperes per ton of weight of train was required.

With a complete train composed of one motor car and two passengers cars, weighing complete 148,000 lb., a maximum horizontal effort of 9,750 lb. was required in acceleration, the maximum current was 780 ampers at 500 volts, the maximum speed attained was 32 miles an hour, and the time taken to attain the speed was 34 seconds, the motor car being equipped with two 200-h. p. motors.

In another case, with a train composed of one motor car, equipped with two 125-h. p. motors and one trailer car, the total weight of train being 103,000 lb., a maximum speed of 31 miles an hour was attained in 37 seconds, the maximum current being 500 ampers, and the maximum horizontal effort required to attain acceleration 5,640 lb. In a series of tests made on the Nantasket Beach line it was found that with a heavy motor car, 51 ft. in length over all, carrying 100 passengers, weighing 31 tons, on an average distance of 2,980 ft., between stations, a maximum speed of 40 miles an hour was attained, the average speed being 18 miles per hour, and the power required was 0.098 Board of Trade units (i. e., kilowatt-hours) per ton mile.

In an experiment with a train composed of one motor car and one trailer car, weighing 57 tons, with an average distance between stations of 4,280 ft., a maximum speed of 37 miles was attained, the average speed being 17 miles an hour, the power required being 0.067 Board of Trade unit per ton mile.

From a comparison of the actual results obtained on the elevated electric railways of Chicago and on the Metropolitan and District line in London, we see that whereas the maximum speed of 25 miles an hour is obtained in 10 seconds with electric traction, it takes 33 seconds to do it with steam locomotives—and that whilst the electrically propelled train could do the distance of 1,880 ft. in 66 seconds, with steam it would take 93 seconds, or nearly half as much time again. If in the case of electric traction the power is cut off the moment the maximum speed of 25 miles an hour is obtained, and the train allowed to coast before the brakes are put on, the distance considered would be done in 76 seconds. The steam driven train even then would take more than 25 per cent more time to do the same distance.

Having tried to show the advantages which electric traction possesses as regards the possibility of increasing the frequency of the trains without decreasing the factor of safety, namely, the distance between two trains, it may be advantageous to see how, from an economical standpoint of generating power, electricity is a cheaper method of operation than steam locomotion. An electrically driven train only requires one man instead of two to drive it, and when the train is not running no power is consumed and no coal or water wasted. Steam locomotives, it is well known, use but very little less coal and water when they are standing still than when they are running, and are much less economical, consuming, as they do in America, from 5 to 6 pounds of coal per indicated h. p. h. On main line English roads it is stated that three to four pounds are consumed, and taking an average power of 400 h. p. per locomotive, and a train plus engine weighing 250 tons, at a speed of 40 miles an hour, we get at the most economical rate about 0.65 lb. of coal per ton mile, or compared to the electric power required by electric traction 13 lb. of coal per Board of Trade unit required, which is enormous—under favorable conditions it would not take much over 3 lb. of coal to give one Board of Trade unit at the switchboard. A properly-designed electric station with large units would probably never consume more than 2 lb. of coal per i. h. p. h., or 2.65 lb. per kw. h. at the switchboard, and engines of the size of 4,000 to 6,000 h. p. would be guaranteed to consume not more than 12 lb. of steam per i. h. p. h. A large station would fully justify a comparatively large initial expense in coal handling and stoking machinery, and the location of the station could be chosen so as to be most advantageously situated as regards both coal and water, the coal without being handled being taken from either the ship's-hold or the railway truck, conveyed automatically to the coal stores and from thence automatically to the fires, the ashes being conveyed away automatically as well. In such a station but very few men would be required, and the cost of power could be reduced below one half-penny per Board of Trade unit, including expenses of every kind.

Comparing again the coal consumption per train mile on large English main line railways, which varies from 35 to 58 lb. of coal per ton mile, corresponding to 28.12 to 46.4 lb. per Board of Trade unit, required to be generated at the power house. The following results actually obtained with slow-speed corliss type engines and standard American railway generators, may be of interest:

Total coal consumed, Brooklyn City Railway Co., per Board of Trade unit, 3 lb.

Total cost, everything included, of Board of Trade unit at switchboard, .5195 cent (about one farthing).

Cost of coal per unit, .2307 cent, about 0.166 of a penny; Union Traction Co., Philadelphia.

Poorest coal, 3½ lb. consumed, per Board of Trade unit at switchboard.

In another case cost of coal, 0.272 cent per Board of Trade unit at switchboard, about 0.186d.

Total cost of unit, all included, 0.591 cent, about 0.296d.

Coal consumption in another case with corliss engine, average for one year, per i. h. p. h., 1.65 to 1.76 lb.

What good slow-speed corliss engines, properly designed for railway work, compared to other engines mean are shown by the fact that by such a change in a large American station the coal consumption was reduced from an average of 8.3 to 4.9 lb. of coal per car-mile.

From a series of figures obtained from the various Chicago electric overhead lines, from 0.16 to 0.135 Board of Trade units are required at the switchboard to drive the trains, the average speed of the trains being 13½ miles an hour, and the maximum speed obtained varying from 28 to 35 miles an hour.

The coal and water consumption, per Board of Trade unit, must necessarily be very low, the losses in the step-up and step-down transformers and in the transmission and rotary converters would not be very great, and it would be perfectly feasible to attain an efficiency of 60 per cent at the motor terminals and of 50 per cent on the power applied to the car axles. Large engines and large gnerators and converters are dsigned so as to take an overload of 25 per cent for any period of time, and be capable of overloading 50 per cent for a short time without injury, and by a selection of proper units a very large economy could be attained.

The elevated railroads of New York and Brooklyn have been losing business during the last few years so rapidly that the financial conditions of the Brooklyn system is serious, and the return on investment of the New York system much reduced, and is still declining. The elevated railroads of Chicago have never been able to earn a satisfactory dividend. The general introduction of electricity in the Chicago system has greatly improved the Chicago situation, in spite of the competition of the surface trolley lines, which parallel the elevated lines in most cases. The elevated railroad problem is resolved into a discussion of speeds, station frequencies, and relative costs of service. Any railroad of this class which aims to maintain a high schedule must choose a motive power in which the possibilities of rapid acceleration are a maximum, and—all other conditions being equal—should choose that particular motive power which will bring about the quickest, acceleration, consistent with the economy.

The Manhattan system is a comparatively simple one, with four main through lines, without branches of importance, while the Brooklyn and Chicago systems are composed of trunk lines with branches, involving more or less complicated switching arrangements. Until about a year ago, the three Chicago companies, the Lake Street, the South Side, and the Metropolitan, had independent termini in the business heart of the city. Now, however, the "Loop," encircling the business district, is used as a terminus for all three lines and for a fourth, the North Western, now under construction, and all the elevated trains of the city pass round this loop on each trip. The Brooklyn elevated system has lately secured a

new terminus on the Manhattan Island side of the Brooklyn Bridge, and experiments are being made with a view to converting the entire Brooklyn system to electricity in the near future. The entire New York system, however, is at present operated by steam locomotives.

The little locomotives in use on the New York system weigh 47,000 lb., of which 31,500 are on the four 42-in. driving wheels, and 15,500 are on the four 30-in. truck wheels. The total wheel base is 193 in., of which 60 in. is rigid. The cylinders are 12 in. in diameter, and have a 16-in. stroke. The grate area is 16.5 sq. ft., and the total heating surface is 4,034 sq. ft. There are 154 flues 1½ in. in diameter and 75 in. long.

The standard Manhattan car weighs 29,088 lb., has seats for 48, and frequently carries 100 passengers. It is mounted on eight 30-in. wheels.

The total weight of a 5-car loaded Manhattan train is about 130 tons. The weight on the drivers is 12 per cent of the total train weight, and with 25 per cent adhesion, the maximum drawbar pull possible for the locomotive to exert is 7,875 lb.

The electric locomotive car of the Metropolitan Electric Railway Co., Chicago, weighs 53,200 lb. complete with motors, or 40,000 lb. exclusive of motors. It is a standard American passenger car with full seating capacity, about one-half of each platform being taken up with the cab and necessary controlling apparatus. The trail cars weigh 33,000 lb. The seating and standing capacity of both motor and trail cars is approximately 90 passengers. The average 4-car heavily-loaded train will weigh about 100 tons, of which 32.5 tons approximately are on the four wheels of the locomotive's motor truck, and 67.5 tons are in the trail cars. From 30 to 35 per cent of the entire train weight is available for traction under these conditions, and the maximum drawbar pull possible to exert without slipping of wheels is about 16,250 lb.

The South Side Elevated Railway Co., of Chicago, is equipped with the Sprague multiple unit system, by means of which two or more cars in a train are equipped with motors and may be operated in unison by a single controller from any point in the train. The company is now operating four-car trains on each of which is a motor truck carrying two motors. The cars weigh about twenty tons each without load, and about 60 per cent of the train weight is available for traction.

There are therefore three distinct types of elevated railway equipment, the steam locomotive using 10 to 15 per cent of the train weight for traction under heavy traffic conditions, the electric locomotive using 30 to 35 per cent, and the multiple unit system using any amount desired up to 60 per cent of the train weight.

The transportation expenses of the South Side Elevated Ry. in Chicago for July, August, and September, 1897, when steam locomotives were employed, were 2.8 cents per car mile, while in the same months of 1898 they were 1.9 cents per car mile, or a saving of nearly 0.9 cent, or about 33 per cent.

The characteristic difference between the acceleration curve of a train hauled by a steam locomotive and one driven electrically is that, whereas the acceleration where steam is used as a motive power increases at first, slowly following a curve which is nearly tangent to the horizontal or time axis, the acceleration curve in the case of electric propulsion is represented by a straight line rising very rapidly, and forming a very small angle with a vertical axis.

It may be interesting to mention a few details regarding the two large power stations which are now being equipped in New York, and which will operate the two large tramway systems of that city, namely, the Metropolitan and the Third Avenue. The Metropolitan Station is now under construction, and will contain eleven direct connected sets each 3,500 kw., room for extension being allowed, and a capacity having been foreseen of nearly double that amount. The following gives the particulars of the General Electric dynamos which will be used.

The machine will have a frequency of 25 cycles per second, at 6,600 volts. It will have 40 poles, and will run a speed of 75 r. p. m. It will be of the stationary armature type, the core being built up of laminations .014 in. thick. Each lamination has two dove-tail projections which fit in corresponding slots in a heavy cast-iron spider. Spaces are left between the laminations at intervals through which currents of air are driven by the rotating field and circulating by intimate contact with core and windings. The armature winding consists of form-wound coils placed in slots in the core and retained by wooden wedges, the edges of which fit into recesses in the teeth. The field frame consists of a cast steel ring supported upon a cast iron spider, to this are bolted laminated core of sheet iron, the pole pieces of which project over and support the copper field windings. The field winding consists of copper strips wound on edge with paper insulation between turns. The insulation is such as to stand a test of 4,000 volts alternating between the winding and the core. The exciting E. M. F. is 125 volts. The collecting rings are of copper, and carbon brushes are used. The armature winding is tested to 12,000 volts alternating. The temperature rise of the machine after ten hours' run at full load is well under 40° C. The efficiencies are as follows:

	Per cent.
1¼ load	96
Full load	95.5
¾ load	95
½ load	92.5
¼ load	88
Inherent Regulation	9

The steam engines which drive these dynamos are cross compound Allis vertical engines, 46-in. high and 86-in. low pressue cylinders, and 60-in. stroke. They will develop 4,500 i. h. p. at the rated economical load, and will be able to work continuously at 6,000 h. p. if required, and for a short space of time they are to be able to work at 7,000 h. p. The crank shaft is of solid steel, bored and forged, with a hole 16 in. diameter the entire length, and it is 37 in. in diameter where the wheel and armature are located. The diameter of the shaft in the bearings is 34 in., and the length of the bearings 60 inches. The fly-wheel will have cast steel centers, and the rim will be built up of steel plates riveted together. The rim will weigh 225,000 lb., and the engine itself, complete, about 600 tons, and it is believed that as good results as 12½ lb. of steam per i. h. p. will be easily obtained. There will be several sub-stations in which will be located step-down transformers of 300 kw. each, which will lower the voltage from 6,600 volts to 350 volts. At this pressue the current will enter rotary converters of 900 kw. each, and will be delivered in the shape of a continuous current of 500 volts to the tramway system.

This company operates some 250 miles of tracks and carries approximately 250 million passengers every year.

The Third Avenue Road is now engaged in equipping all existing horse and cable lines with electric traction, and for this purpose has just given out a contract for a power station which will eventually contain 16 3,000-kw. generators. The generators will be very similar to those described above, and are being built by the Westinghouse Co., who are the sole contractors for the whole work. The engines will be Marine type, vertical, and are being built by the Westinghouse Machine Co. Sub-stations with rotary transferers will be used, as in the case of the Metropolitan system.

To give an idea of what may be done as regards power transmission the following few figures may be useful. The first attempts at this class of work were made during the Frankfort Exhibition of 1891, 300 h. p. being satisfactorily transmitted a distance of 106 miles with a pressure of 30,000 volts. Since that time electrical power transmission has largely increased, and the results obtained have been very satisfactory. 4,000 h. p. at the present moment are regularly transmitted a distance of 85 miles to the city of Sacramento, Cal., at a pressure of 30,000 volts, where they are transformed into low pressure three-phase and continuous current for lighting, power, and traction purposes. At Telluride, Utah, 1,000 h. p. are transmitted 55 miles at a pressure of 40,000 volts; 4,500 h. p. are transmitted a distance of 40 miles to Salt Lake City at a pressure of 15,000 volts; 1,400 h. p. are being transmitted 35 miles to Fresno, Cal., at a pressure of 11,000 volts; 2,000 h. p. are being transmitted 30 miles to West Kootenay, British Columbia, at a pressure of 20,000 volts; 10,000 h. p. are being transmitted from Niagara to Buffalo, a distance of 22 miles, at a pressure of 10,000 volts. All the plants are working and giving satisfaction, and have nothing experimental about them and there are hundreds more such.

In the designing and carrying out of a large system, there are three points which are frequently overlooked and which may cause a disastrous failure. These are good and adequate bonding; thoroughly good insulation, both mechanically and electrically; and trucks suited for the work for which they are intended.

As regards the bonding, the bonds used should be flexible, but, at the same time, should contain no solder or brazed joint, and they should be expanded against the side of holes drilled in the web or foot of the rail, and held in place by pins. Bonds of this description, when properly applied, can be absolutely relied upon, the contact resistance of the bond with the rail not being greater than the resistance of the solid bond.

With regard to the third rail insulators, very good results are obtained by using insulating bolts screwed into base plates which are fixed to the sleepers, cast iron chairs being fixed to the head of the bolts to hold the rails.

THE PHILADELPHIA EXPOSITION.

Among all he expositions to be held during the next few years, either in this country or abroad, there is none which appears to be of more importance and to possess such vital interest for the American manufacturer as the one to be opened in Philadelphia on September 14th and to continue until November 30th. This exposition will have for its main feature the development of American goods made expressly for export, and to emphasize the importance of the event, it is the intention to secure exhibits of foreign products to be placed side by side with those of American make, in order that manufacturers of the United States may readily see just what competition they must meet abroad as well as to show the peculiarties in the demand of the foreign market. This is the first exposition of this character ever held in this country. Its importance from the standpoint of comparison alone must at once be manifest to every American manufacturer, whether he be a locomotive or a snowplow maker or the maker of the smallest novelties imaginable. So long as the products may or can be exported they will be given a place in this great Philadelphia exposition of 1899.

This enterprise has received the sanction of the National Government, and Congress has appropriated the sum of $350,000 in its aid. Philadelphia has given $200,000 and the state of Pennsylvania $50,000. At least $100,000 will be raised by private subscription, and if the bill now pending in the State Legislature to increase the state's appropriation to $250,000 is passed, there will be a total exposition fund of $900,000.

This important enterprise will be under the joint auspices of the Philadelphia Commercial Museum and the Franklin Institute. Nearly every Board of Trade and Chamber of Commerce in the United States has signified its willingness to co-operate and will send delegates to the Commercial Congress to be held in October.

The main buildings are now under construction and will cover eight acres of ground. The space available for the exhibition of products will be at least 200,000 sq. ft. Adjacent to the exposition grounds proper and the main buildings there is a tract of 56 acres which can be used for the erection of detached structures for special exhibits. There will be particular attention given to the amusement features and it is intended to make them as unique and interesting as possible.

The exposition grounds are located on the Schuylkill River within 15 minutes' ride of the City Hall.

W. R. GARTON CO.

This month is the first anniversary of the W. R. Garton Co., manufacturers' agent, which has now headquatrers in the Manhattan Building, Chicago. This company started in business a year ago, and has been phenomenally successful from the beginnings. The facts that only the best of lines were accepted and that both W. R. Garton, the president and treasurer of the company, and Ray P. Lee, the secretary, are men with a thorough knowledge of their business, will easily account for the success achieved. The company represents some 16 different concerns, among them being the Electric Railway Equipment Co., of Cincinnati, which makes a specialty of line material, steel and wrought iron poles, brackets, motor supplies and parts, etc. It also represents the Garton-Daniels Electric Co., the Keystone Electrical Co. and the Morris Arc Lamp Co.

The Keystone Co. is well known and popular in the East, and the W. R. Garton Co. is making its product equally well-known in the West. The Morris Arc Lamp Co. makes a thoroughly up-to-date line of lamps, prominent among them are the alternating and direct current enclosed arcs.

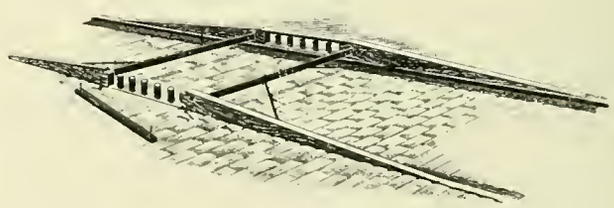
W. R. Garton is the inventor of the Garton lightning arrester, made by the Garton-Daniels Electric Co. Mr. Garton is also a stockholder in that company, and in the Raster Carbon Rheostat Co. He is from Iowa, and for over three years was manager of the railway department of the Central Electric Co. He has been identified with the electrical railway business for 15 years. He has been in Chicago for five years, and during that time has given his attention entirely to the commercial side of electrical matters.

Ray P. Lee, the secretary, is also from Iowa. He graduated from the electrical engineering department of the Iowa State University in 1894, and came to Chicago in 1895. He went into the company when it was organized in May, 1898.

The company also acts as consulting engineer, and in this branch of the business has met with the same success it has as a selling agent.

HOSE BRIDGE.

The Ohio Brass Co., of Mansfield, O., has in its emergency hose bridge a device which can hardly fail to appeal to every street car manager in the country. As the name suggests it is a contrivance to prevent the stoppage of cars in case of fire, where the firemen lay hose lines across the tracks. The accompanying illustration clearly shows the working of the device. The bridge is formed of two parallel trusses 16 ft. long, fastened together by two double hinged joints. When opened, the joints form a cross bar and become a rigid connection between the two trusses. The trusses are flat on the bottom and rest on top of the rail and are held in place by lugs. These lugs are made to fit either a T, a flat, or a



HOSE BRIDGE.

grooved rail. There are no fine adjustments to make and the bridge can be placed in position in 30 seconds.

This emergency hose bridge is no experiment as it has stood the test of practical service and proved entirely satisfactory wherever used. The total weight of the bridge is about 147 lb. and it can be contracted to a width of 9 in. Four of the bridges can be easily carried on the ordinary repair or tower wagon. There are six hose pockets each 4 in. square. The partitions are steel bolts, the lower ends being riveted to the bottom rail, and they form a support for the removable piece of the top rail. The bolts are covered with spindles of hard wood. The rail at the highest point, in the center, is only 5½ in. high.

The bridges have been used for more than two years by different roads and none has yet found the least fault with them. On the contrary the Ohio Brass Co. is able to furnish some exceedingly flattering and strong testimonials from companies that have used them.

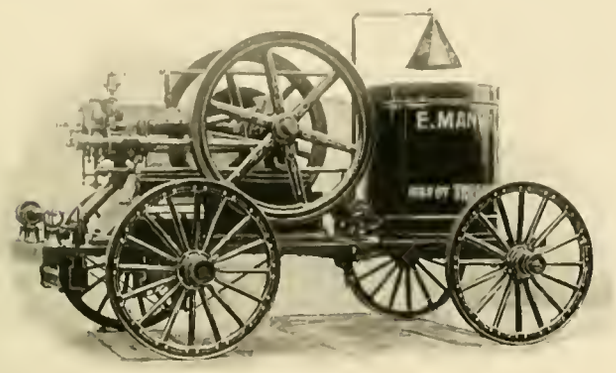
SALE OF TERRE HAUTE ROAD.

The Terre Haute (Ind.) Street Ry. has been purchased by Stone & Webster, of Boston. This firm held an option on the first and second mortgage bonds, and closed on May 5th. The firm took $450,000 worth of first mortgage bonds at face value, and about $300,000 out of $600,000 second mortgage at about a third their face. The property will be improved and be operated by the new owners.

New York city has her surface road trouble just like common cities. A broken stand on the Third avenue line caused a tie-up of 13 hours not long ago.

FALK COMPANY'S FOREIGN WORK.

Buenos Ayres seems as far away as Milolos, and the average street railway man would hardly expect to find the street railway interests of that city not only up to date, but even taking the lead over some of our American cities. However, the street railway interests there are very progressive, and determined that the company shall have the very best to be obtained. In order to perfect its track

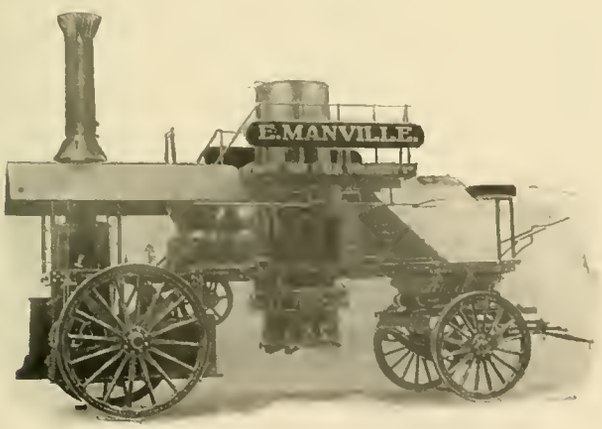


ENGINE.

construction it recently, at considerable expense, sent engineers to study the method of cast welding as introduced by the Falk Company, and the result, as might have been expected, was a decision to adopt the Falk cast-weld joint on all its lines.

To carry out its order speedily and in first-class manner the Falk Company built a special welding outfit which has been constructed in three machines, and equipped with air compressors and all the latest and best appliances for making the castings. Our illustrations in themselves give a good idea of this extremely interesting and complete portable foundry plant.

In its home work the company is busy, and at present is engaged in filling important contracts in Kansas City, for the Metropolitan road, and is also welding the interurban line from Oshkosh to



CUPOLA.

Neenah, Wis. Other welding contracts to be done this season include work in Washington, Hoboken and Canton, in addition to work in New York City which will require three welding outfits.

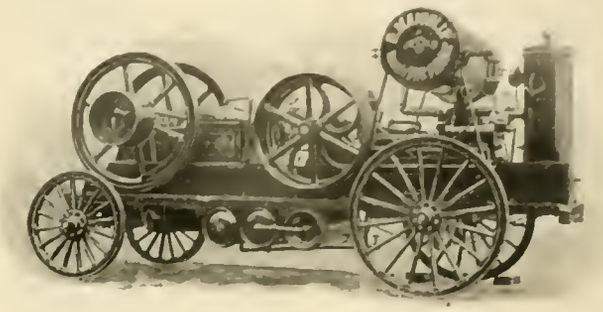
In its department of special work, and gears and pinions, the plant is extremely busy and has been running night and day for some time past.

The directors of the Union Traction Co., Philadelphia, Pa., have ordered a reduction of fare to Willow Grove by way of the Old York road. The reduction is from 15 to 10 cents.

Only one franchise is left in the city of Albany, N. Y., for street car companies, and the Municipal Street Railway Co. lately incorporated with a capital stock of $250,000, has bid for it on the basis of giving a 3-cent fare.

CHICAGO ELECTRICAL EXPOSITION.

The National Exposition of Electric Arts has been incorporated in Illinois with an authorized capital of $50,000. The officers are N. J. Heinbach, president; T. Carrabine, secretary, and W. E. Burnham, treasurer and manager. The company plans to hold an Electrical Exposition in Chicago this fall, at Tattersalls, to open on September 25th and close on October 9th. This exposition will, in a way, be an introduction to the annual convention of the American



AIR COMPRESSOR.

Street Railway Associations, which convenes in Chicago October 17th.

It is the hope to make the electrical exposition very complete, particular attention to be paid to the adaptability of electricity for household purposes. An effort will be made to give displays of writers' telegraphy and to demonstrate the uses of liquid air, the Nernst Electrolitic lamp and the X-ray phenomena.

The exhibition will be one of popular interest, and it is hoped the general public will attend in large numbers. Already a large number of concerns have applied for space.

ELECTRIC RAILWAYS IN GERMANY.

Mr. W. K. Anderson, U. S. consul at Hanover, reports the following statistics on electric railways in Germany:

Up to the end of the year 1891 the number of cities in the German Empire enjoying the advantages of electric street railways was 31; up to the end of 1892, 5; 1893, 11; 1894, 19; 1895, 32; 1896, 44; 1897, 61; and on Sept. 1, 1898, no less than 68. In 35 other cities or districts, railways are in the course of construction or finally determined upon. The entire length of electric lines in operation in Germany on Sept. 1, 1898, was 888 miles, and the total trackage was 1,205 miles. The number of motor cars was 3,190 and the number of trailers 2,128. The length of the new lines in course of construction or about to be begun at that date was 677 miles, and their total trackage 830 miles.

Most of the large industrial cities in Westphalia and the Rhine Province are connected by a network of electric roads, which serve not only for passengers, but for freight traffic.

"NO SEAT, NO FARE," NO GOOD.

One of the cases tried in the Chicago courts last month in which the city was the plaintiff and the West Chicago Street R. R. the defendent, and the cause "No seat, no fare," was decided in favor of the company. The crowding of the cars was clearly shown, and readily admitted by the counsel for the company. But the company proceeded to prove that this was not by any means its fault Counsel said it was the fault of the city itself in not permitting the use of electricity where the cable is now in operation and because it refused to grant more street franchises. Attorney Donahue, for the railway company, introduced a communication from Mr. Yerkes to the city council in which he stated he could not relieve the congestion on his lines until he was given these privileges. The company says the whole blame is on the ordinances which limit the size of the trains, the demands for safety which prevent running them closer together and the lack of privileges from the city.

REPORT OF MASSACHUSETTS STREET RAILWAYS.

The Massachusetts Railroad Commissioners' report giving the returns for 1898 shows that 103 companies reported—10 more than in 1897. At the end of the year 79 of these 103 companies were operating their railways; the lines of 13 companies were operated by other companies under lease or contract; six companies had organized and paid in a portion of their capital stock, but had not begun to build; and five companies had been consolidated with another during the year.

During the year 123.28 miles of main line, 1.03 miles of second main track, and 3.71 miles of side track, making 128.02 miles reckoned as single track, have been added to the street railway mileage reported; all of this was newly built. This makes the total mileage 1,644.66 miles, all of this except 21.71 miles, which are in Rhode Island, are in Massachusetts. Of the total, 13.15 miles were operated by horse and cable, and 7.50 by horse power only.

The average cost per mile of main track (including cost, but not length of side track) is shown by the books of the companies to be $22,537 for construction, $8,957 for equipment, and $11,735 for lands, buildings (including power plants) and other property—making the total $43,229 per mile of main track. These figures furnish but little clew to the cost of any particular railway which ranges from $10,000 in a country town to $97,000 in Boston and $111,000 for the Mt. Tom road.

The average capital investment per mile in 1898 was $44,958; the average for the last 10 years is $45,070. For the 10 companies that carry over 3,775,000 passengers a year, the average capital investment is $66,239 per mile; of these the lowest is $27,951 for the Holyoke Co., and the highest $103,658 for the West End, of Boston.

The gross assets were, $77,607,326, and the gross liabilities $75,889,625 leaving for surplus and special funds $1,023,320 which is an increase in the surplus of $691,199 as compared with 1897. The surplus for 1898 was 4.41 per cent of the capital; the average for 10 years is 3.42 per cent of the capital.

The gross earnings were 18,247,246, and the expense of operation $11,692,731; other expenditures were $6,096,736, leaving $457,769 for the surplus accounts.

The total amount of cash dividends declared last year was $2,076,233, an increase of $110,990 over the previous year. Eleven companies paid 8 per cent; 1 paid 8 per cent on preferred and 7.5 per cent on common stock; 1 paid 7 per cent; 1 paid 6¼ per cent; 19 paid 6 per cent; 4 paid 5 per cent; 1 paid 4.5 per cent; 3 paid 3 per cent; 1 paid 2.5 per cent; 1 paid 2¼ per cent, and 54 companies, new and old, paid no dividends.

The amount of dividend-paying capital was $33,649,950, of which

1898, . . .	1,538	121	9	330,889,629	22,205,405	7
Totals, .	–	783	101	–	136,717,687	70

the average rate was 6.17 per cent as against 6.91 for the previous year. The non-dividend paying capital was $5,283,967. Including this last the average rate for the state was 5.33 per cent, as against 6.02 for 1897. As seen from the table, which gives the dividends for the last 10 years, this is the lowest rate for the decade.

The total number of passengers carried during the year ending Sept. 30, 1898, was 330,889,629, an increase of 6.7 per cent over the previous year; the car miles run were 68,206,418, an increase of 9.7 per cent; the round trips were 6,887,976, an increase of 4.8 per cent; the average passengers per round trip were 48, as against 47 the previous year. Of the ten large roads the Union, of New Bedford, had the lowest number of passengers per round trip, 24; and the West End road the highest, 58; the average for the 10 roads was 50.

The tables give interesting data as to the percentage of operating expenses to gross earnings for the last 10 years, the operating expenses and net earnings of the 10 large companies for 1898, and the gross and net earnings per mile of main track owned, per round trip, per car-mile, and per passenger.

BUFFALO, HAMBURG & AURORA ROAD.

The Buffalo, Hamburg & Aurora Railway Co., Buffalo, N. Y., A. J. Benzing, president, and U. L. Upson, manager, is building 21 miles of new track between Buffalo, Hamburg and Aurora, and expects to complete the work this fall. The company will buy six new cars, straight sides, cross seats, center aisle, with capacity for 44 people. It has a car barn capable of holding 15 cars and a power house with a capacity of 1,400 h. p.

The road is being built by the Continental Construction Co., of Boston, Mass. The track is to be laid with 86-lb. girder rails through the villages, and a 60-lb. T-rails through the country. The cars are to be equipped with motors wound for a speed of 48 miles per hour. The work on this road was begun April 17th, and the contract provides that 13 miles shall be completed by August 1st.

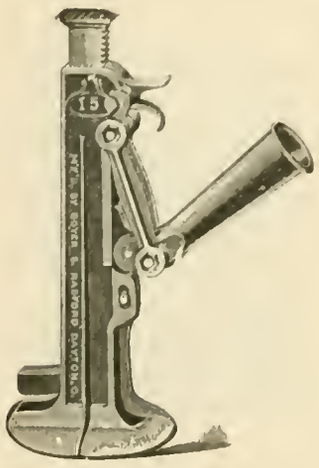
ARE THE CARS OVERCROWDED.

The Montreal Street Railway Co. is engaged in a controversy with the city as to the legal capacity of its cars; the difficulty is of long standing, but the city has only recently started to persecute the company. In January, 1894, the city surveyor prepared cards giving the number of the car, the number of passengers allowed inside and the number outside, and concluding with the sentence: "No one allowed on the front platform and side steps." The company objected to this last statement as not in accordance with the city by-law, and in May, 1894, posted similar capacity cards without the front platform and side step rule. These were only carried for a few days, however, and the matter has been permitted to rest until recently, when the city's representatives began preparations to prosecute the company for overcrowding its cars.

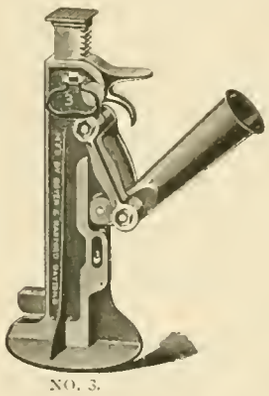
The pavilion at Cayuga Lake near Seneca Falls, N. Y., on the line of the Geneva, Waterloo, Seneca Falls & Cayuga Lake Traction Co., was destroyed by fire on April 18th. Manager W. C. Gray estimates the loss at $1,000, all of which falls on the insurance companies.

MAXON LIFTING JACKS.

Messrs. Boyer & Radford, of Dayton, O., makers of railway supplies, have for a leading specialty the Maxon patent lever and ratchet screw lifting jacks, of which we illustrate three types particularly designed for electric railways. No. 3 is a general purpose jack, well suited for replacing derailed cars, and may be used in track work work also; it is 19 in. high and has a lift of 11 in.; it weighs 60 lb., and has a capacity of 8 tons. No. 20 is a drop track jack with a capacity of 10 tons and a rise of 11¼ in.; the weight is 50 lb. This jack was designed by a practical roadmaster, and has been tested in every way with the most perfect satisfaction. No. 15 is for car barn service; it is 28 in. high, with a rise of 15 in.; the jack weighs 115 lb., and has a capacity of 15 tons. In this size the ratchet bar is reinforced the full length by a 1-in. bolt, to which the head is screwed, thus giving the bar more strength and rigidity.



No. 15.



No. 3.

No. 20.

The Boyer & Radford jacks are widely used, and the firm has received a number of very strong testimonials from companies using them.

NEW OFFICIALS AT INDIANAPOLIS.

Under the reorganization of the Indianapolis Street Ry. the new officers are as follows:

President—Hiram P. Wasson.
Vice-president and general manager—H. J. McGowan.
Second vice-president—Joseph S. Neff.
Secretary—Henry Jameson.
Treasurer—J. A. Lemcke.
Assistant secretary—C. Eldridge Morgan.

Counsel in Indianapolis are Ferdinand Winter and Chambers, Pickens & Moores. Counsel in Philadelphia are William Jay Turner and the firm of Jones & Carson.

LAWLESSNESS IN SYRACUSE, N. Y.

On April 21st, a mob of the citizens of Syracuse, N. Y., with the avowed approval of the mayor, tore up half a mile of the track of the Syracuse Rapid Transit Street Railway Co., stoning the cars which the company attempted to run in the street to protect its tracks. The reason alleged for this lawless action was that the track had been laid with T-rails in violation of the ordinance granting the franchise. Even were this true it would not justify mob law.

PERSONAL.

MR. L. P. BENNETT, of the Ohio Brass Co., Mansfield, O., was a visitor at our office recently on his way west.

MR. T. C. WHITE, of the Central Union Brass Co., Boston, was a caller at our office during his visit to Chicago, last week.

MR. C. K. KING, general manager of the Ohio Brass Co., Mansfield, O., was a caller a few days ago while on a Chicago trip.

MR. E. E. DOWNS, manager of the Citizens' Traction Co. of Oskosh, Wis., was last month called to Boston because of the death of his father, Loren Downs.

MR. ERNEST WOODRUFF was elected president of the Atlanta Railway Co., which is believed to be a step toward consolidation of the local lines.

MR. E. F. WICKWIRE, representing the Sterling Supply & Manufacturing Co., New York, will look after the western territory, and is rapidly making friends and acquaintances here.

MR. A. G. DAVIDS, superintendent of the Schuylkill Valley Traction Co., has been advanced to the position of general manager to fill the vacancy caused by the resignation of Mr. R. M. Douglass.

MR. A. L. WILKINSON, the genial representative of the Ohio Brass Co., of Mansfield, O., was recently married to Miss Laura Abraham, of Bryan, O. The wedding took place at the home of the bride.

MR. JOHN OLIPHANT is successfully representing the Ingersoll-Sargent Drill Co., and has charge of the Cleveland office. He will be remembered as superitendent of the Calumet Electric a few years ago.

MR. F. E. FISHER, who recently resigned as general passenger and freight agent of the Ohio Southern Ry. at Springfield, O., has been appointed to succeed the late Mr. Rush as superintendent of the Joliet (Ill.) Street Ry.

MR. JAMES R. LEDYARD, of Covington, Ky., has been appointed superintendent of the South Covington & Cincinnati Street Railway Co., to succeed Mr. T. M. Jenkins, resigned. The appointment took effect May 15th.

MR. Z. T. HERNDON, of Akron, O., who has been chief engineer of the Detroit & Lima Northern Railroad, has resigned to take a similar position on an electric line now being built between Kansas City and Leavenworth, Mo.

MR. HARVEY R. BOWEN has been appointed chief engineer of the Utica (N. Y.) Street Railway Co. Mr. Bowen has been holding a similar position with the Binghamton Railroad Co. He is now in Utica and will make that place his residence.

MR. ROBERT C. TAYLOR has been appointed chief engineer of the Twin City Rapid Transit Co. He fills the vacancy caused by the death of Wm. Kewely. Mr. Taylor has for several years been construction engineer for the Robinson & Carey Co., of St. Paul.

MR. M. B. RICHARDSON, of Oswego, N. Y., recently purchased at foreclosure sale the Lake Ontario & Riverside Ry., of that city. When the new company has been organized it will include Mr. Shepard, who will, it is said, have full control of the road.

MR. R. M. DOUGLASS has accepted the position of general superintendent of transportation of the Cleveland Electric Railway Co. He has been until recently general manager of the Schuylkill Valley Traction Co., of Norristown, Pa. Mr. Douglass has been in the street car business for about five years and has shown great aptitude for it. His first work was on the Syracuse & East Side Street Ry. He next became superintendent of the Brooklyn Heights Co. and left them to take the management of the Norristown road.

HON. W. S. FORMAN, of East St. Louis, Ill., was elected president and general manager of the St. Louis, Belleville & Suburban Electric Railroad Co. on April 28th. The new president contemplates some extensive improvements on the line, fenders being included in the list.

MR. LEONARD UNDERWOOD, who has been chief clerk to Gen. Supt. W. S. Dimmock, of the Omaha & Concil Bluffs Railway & Bridge Co. for the past year, has resigned to become private secretary to Congressman Geo. H. Burke, of Pierre, S. D., and will be located in Washington a part of his time.

MR. E. C. LONG, secretary of the Peckham Truck Co., was on April 26th married to Miss Cora Alice Phillips, of Poughkeepsie, N. Y. Miss Phillips was a favorite in Poughkeepsie society and the ceremony at the church and the reception afterward were brilliant functions, at which were present many out-of-town friends.

MR. IRA M. LUDINGTON has resigned the superintendency of the Rochester (N.Y.) & Irondequoit railway system. Mr. Ludington has for many years been identified with steam and electric roads in Rochester and only resigns now to give his full time to private interests. It is expected that Chas. L. Williams will succeed him as superintendent and assume the title of secretary and auditor as well.

MR. W. F. HAM, well known to our readers as one of the organizers of the Street Railway Accountants' association, has been made auditor of the entire Brooklyn Rapid Transit system. Mr. Ham was formerly secretary of the Nassau Electric Railway Co. He has entered upon his new duties. Mr. Ham has made street railway accounts his particular study and is recognized as an expert.

MR. JAMES RALEY CRAVATH, of Chicago, was married to Miss Ruth Myra Rew at the residence of the bride's mother, Mrs. Clara E. Rew, in Grinnell, Ia., on Wednesday, April 19th. Mr. Cravath was for several years electrical editor of the "Street Railway Review," and is at present with the Coleman Laboratory of Electrical Engineering as engineer. The newly married couple announce themselves "at home" after June 1st, at 5519 Monroe Ave., Chicago.

MR. WILLARD R. KIMBALL has resigned the vice-presidency of the Syracuse (N. Y.) Rapid Transit Railway Co. Mr. Kimball has for some time past been the controlling element of this corporation, but there has lately been a division among the directors and the anti-Kimball faction held the reins. A new executive committee has been formed and Mr. Kimball has accepted a position in that body. The company has decided to spend $350,000 in improvements on the road.

MR. H. A. REEVES, western representative of the H. W. Johns Manufacturing Co., of New York, returned to Chicago from California on Saturday, May 6th, in excellent health. Mr. Reeves left home sometime last December, a very sick man. He went direct to California, and though he spent the greater part of his time in the southern portion of the state, he has in various jaunts covered nearly every portion of it. He expresses himself as delighted with the country and the climate.

MR. S. FUJITA, a representative of the City Railway Co., of Tokio, Japan, was in Chicago recently. He has been visiting the larger cities of the United States making a study of the street railway system, particularly as regards motive power. He says the people of Tokio object to the overhead trolley on account of the narrow streets and that the underground system is too expensive and dangerous. He believes in the Hoadley-Knight air motor and expects to adopt it at home.

MR. W. M. BROWN, master mechanic of the Twin City Rapid Transit Co., was a caller at the "Review" office when in Chicago recently.

MR. ALEXANDER E. ORR has resigned the presidency of the Board of Rapid Transit Commissioners for New York City, a position he has occupied since 1894.

MR. FRANK X. CICOTT died recently in Detroit, Mich., at the home of his sister. A few months ago he returned from a foreign tour, having gone abroad to look into the chances for the investment of American and European money in tramway enterprises in other countries. He has contributed a number of articles to the press on the subject of tramways. Mr. Cicott was at one time director of the United States mint at San Francisco, Cal., and by reason of his extensive travels among street railway men in this country and abroad has secured an unusually large and pleasant acquaintance.

ELECTIONS.

THE NASSAU ELECTRIC RAILWAY CO., of Brooklyn N. Y., held an election for directors on April 11th. Col. T. F. Williams, Anthony N. Brady and Clinton L. Rossiter were chosen. The old directors did not favor the consolidation of the Nassau and the Rapid Transit systems and the newly elected ones do.

THE UNITED POWER & TRACTION CO., incorporated at Trenton, N. J., elected officers on April 24th. The following directors were chosen: Robt. N. Carson, Philadelphia; Jno. A. Rigg, Reading; T. C. Barr, Orange, N. J.; E. J. Moore, Theo. A. Royal, R. Nelson Buckley, Samuel F. Houston, Samuel Moore, and John T. Windrim, of Philadelphia; Richmond L. Jones and James A. O'Reilly, Reading; Samuel P. Light, Lebanon; Geo. H. B. Martin and F. R. Hansel, Camden, N. J. The board elected John A. Rigg, president; R. N. Carson, vice-president; E. J. Moore, secretary and treasurer, and Richmond L. Jones, general counsel. The new company has acquired control through purchase of stocks of the United Traction Co. of Reading, the Lebanon Valley Street Railway Co. and the Roxborough, Chestnut Hill & Norristown Railway Co.

NEW PUBLICATION.

STEAM ENGINE INDICATOR. Under this title the Power Publishing Co., World Building, New York, has published a book of over 200 pages on directions for the selection, care and use of steam engine indicators and the analysis and computation of indicator diagrams. The text has been largely compiled from the regular editions of Power and edited by Mr. F. R. Low, the able editor of that paper. Large additions have been made, however, and particularly in the matter of tables of convenient constants, of the properties of steam, hyperbolic logarithms, etc. A very useful diagram is a family of hyperbolas, printed on tracing cloth, with the position of the atmospheric line indicated for the usual spring scales, so that the expansion line of a diagram may be compared with theoretical line by slipping the card under the tracing cloth; the hyperbola may be transferred to the card by pricking through with a fine needle-point.

We recommend this book to all persons who seek information on the important subject of which it treats—the selection, use and care of indicators, and the computation and interpretation of diagrams, as a valuable work; we have already had occasion to make frequent references to it, and in every instance have found the desired information well and clearly put. Possibly those who have doubts experience in measuring the clearance of engines will have doubts as to whether the methods described will work as well in practice as on paper. It is to be regretted that the publishers did not cause more care to be exercised in the proof reading, and thus have prevented the numerous typographical errors and defective spacings which mar its appearance; these minor defects will doubtless be remedied in future editions, and should not blind one to the value of the book.

The price of this book is $1.50.

DEATH OF C. C. RUSH.

Mr. Clinton C. Rush, superintendent of the Joliet (Ill.) Street Ry., was struck by a Chicago & Alton passenger train at Lemont on May 3rd, and died two hours after from his injuries.

Mr. Rush had left Joliet early in the morning with the purpose of looking over the ground for the proposed extension of his road from Lockport to Lemont and Willow Springs. He had finished his inspection and was hurrying along the Chicago & Alton tracks toward the depot to catch the train due there at 10:50 a. m. In attempting to dodge an empty bucket left between the tracks by some workmen, Mr. Rush jumped directly in front of the on-coming engine, thinking probably he was getting on the clear track. The engine struck him full in the back and knocked him some distance. He was taken on board the train and carried to Joliet, where shortly after noon he died at St. Joseph's hospital.

C. C. RUSH.

Clinton C. Rush was popular in Joliet and much beloved by every officer and employe of the company by which he was employed. He had been connected with the street railway business nearly all his life. Still a young man, only 35 years of age, he had been in charge of the Champaign, Ill., system and had held the position of superintendent in Bay City, Mich., in Quincy, Ill., and latterly, through Mr. McKinley, secretary of the Joliet road, he was appointed superintendent of that system. He was a thoroughly efficient man. Though he had been in Joliet but comparatively a short time he had made a host of friends among the citizens and the employes of the road esteemed him highly.

Mr. Rush was born Sept. 10, 1864, in Champaign, and his remains were taken there for burial.

COMPRESSED AIR FOR NORTH CHICAGO.

The North Chicago Street Railroad Co. has for some time been desirous of improving its all-night service on the cable lines and is now making a trial of compressed air motor cars with the intention of using them for its owl cars and thus entirely supplant horses.

The Compressed Air Motor Co., of Illinois, in which the American Air Power Co., of New York, is a stockholder, is furnishing the apparatus for the test. The company has installed a compressing and storage plant in the North Clark St. power house of the North Chicago R. R. and provided an air motor car of the same type as those which have been in successful operation on 125th St. in New York City for over a year. This car had its reservoir charged with air before being shipped and when it arrived in Chicago it was run to the car house under its own power.

The machinery here was installed under the direction of Robert Hardie, who is well known as an authority on all that concerns air as a motive power. The work was done by the Fraser & Chalmers Manufacturing Co.

The experiments are being made on the North Clark St. line. The car starts from the "Limits" barns and runs over the cable track to the City Hall, but stops at the power house to be charged with air in order to demonstrate fully the practical workings of the system. The arrangements for charging are of course only temporary. The car used is 28 ft. long, with side seats; it weighs 18,200 lb. In these experiments it is charged to run 10 miles, but can be given air sufficient to run 25 miles and haul a trailer.

The offices of the Compressed Air Motor Co., of Illinois, are in the Monadnock Building and the officers are Henry D. Cooke, president; Alex. C. Soper, treasurer, and Robert Hardie, engineer. The directors are Messrs. Cooke and Soper and W. J. Chalmers, W. E. Selleck and W. Penn Smith.

REMOVAL OF THE STREET RAILWAY JOURNAL.

The New York office of the Street Railway Journal has been removed from 29 Cortlandt St. to 120 Liberty St. The new office is in the heart of the electric district in the lower end of the city where it is convenient to the Sixth and Ninth Avenue elevated roads, the surface lines and the ferries. The new offices are in the Beard Building, where the company occupies the entire half of the eleventh floor. A cordial invitation is extended to all its friends and patrons by the Journal to pay it a visit in its new quarters.

DINNER TO RICHARD McCULLOCH.

The friends of Mr. Richard McCulloch, of St. Louis, Mo., well-known to street railway men as engineer of the National Railway lines in St. Louis, gave him a farewell banquet at the Planter's Hotel, St. Louis, on Thursday evening, May 11th. The occasion was the departure of Mr. McCulloch for Geneva, Switzerland, where he has accepted a position with an electric street railway company.

RICHARD McCULLOCH.

The banquet was an extremely happy affair, the menu all that could be desired, and the menu card handsomely and appropriately designed. On the front cover was a fine portrait of the guest of honor, and at the bottom of each page were illustrations in tint of street cars, steamboats, railroad trains in which means of transportation electricity plays so great a part.

As special guests there were present Mr. and Mrs. Robert McCulloch and the Misses Roberta and Grace McCulloch. The friends tendering the banquet numbered 82, among them being Mr. and Mrs. C. N. Duffy, Mr. and Mrs. W. J. Orthwein, Mr. and Mrs. Arthur S. Partridge, Mr. and Mrs. Corwin H. Spencer, Mr. and Mrs. Frederick B. Brownell and Mr. D. G. Hamilton.

Mr. Richard McCulloch was born in St. Louis County in 1869. He was educated in the St. Louis public school, and in the Washington University of that city. At the latter institution he took the degree of mining engineer in 1891. Very early he became interested in street railway work, and much of his study while in college was in that direction. During his vacations he obtained practical experience on the St. Louis lines. He has filled positions in every department of street car work.

Mr. McCulloch was a member of the United States Geological Survey in Missouri, Arkansas, Indian Territory, Colorado and Montana, and in 1892 was connected with the Mexican National Smelting Co. In 1893 he took an expert course in the shops of the General Electric Co. at Schenectady. In the same year he was appointed engineer of the Cass Avenue & Fair Grounds Ry., St. Louis, and later became the civil and electrical engineer for the management of the National lines. In 1896 and in 1898 Mr. McCulloch presented reports to the American Street Railway Association.

COLOGNE TRAMWAYS IN 1898.

By the courtesy of the Cologne (Germany) Street Railway Co. we have received a copy of the annual report for 1898. This company has 62.8 km. of track, and owned Dec. 31, 1898, 696 horses, 117 open cars and 203 closed cars. During the year 5,317,006 car-km. (3,335,444 car-miles); the expense being 11.37 cents per car-mile; the receipts were 19 cents per car-mile. In round numbers the receipts for 1898 were $632,600 as against $559,000 for 1897.

The Sycamore Street Railway Co., of Pittsburg, Pa., has asked for a franchise to construct a road up Mt. Washington hill. There is a 15-per cent grade and it has been decided to use the "rack" system, such as is in operation on Pikes Peak in Colorado and on other mountain railways. Electricity is to be the motive power.

HALF FARES.

The Brooklyn Rapid Transit Co., has arranged with other Brooklyn lines for a system of transfers which will be of great benefit to the public.

There has been some friction between the Des Moines City Railway Co. and the Government over the mail service, but matters have been satisfactorily adjusted.

There is much earnest talk of a trunk trolley line from Detroit to Port Huron, Mich. If the project is carried out it will be the longest line of its kind in existence.

The Wichita (Kas.) city council has declared the $10,000 deposited with the city by the Church Street Railway Co., as forfeited, as the road was not completed by April 1st.

During the summer and fall the Omaha Street Railway Co. will rebuild about six miles of double track using 73-lb. 7-in. girder rails. Some of this is now under construction.

The Minneapolis Street Railway Co. has declared its determination not to continue the mail service at the price now paid by the Government. The existing contract expires July 1, 1899.

The Wisconsin Legislature has a bill before it providing for the conviction of persons guilty of fraudulently using transfer tickets. The Milwaukee road states that it loses heavily every year by the practice.

The Market Street Railway Co., of San Francisco, has moved its offices from 532 Market St., to the Wells, Fargo & Co. Express Building, 49 Second St. The new location gives the company pleasant and convenient offices.

The trailer system has been abandoned on the Joplin (Mo.) Electric Ry. The cars which have been used as trailers have been equipped with motors taken from the big cars and new ones put in place of those removed.

March 6th the city council of Des Moines, Ia., passed what is called the 7-ft. ordinance providing that hereafter street railway companies shall have pave the street for 7 ft. on each side of their tracks in all street occupied.

The Consolidated Street Railway Co., of Grand Rapids, Mich., has for the second time within a few months raised the wages of its men. The pay is now 15½ cents an hour. Good times and good business is said to be the cause of the increase.

The Columbus (O.) Street Railway Co., learning that the benefit fund of the Columbus Street Street Railway Employes' Beneficial Association was running low on account of extra sickness among members, has given the association a check for $500.

Conductors and motormen on the "White Line" running from Hoboken to Patterson, N. J., quit work April 19th. This is an electric line operated by the New Jersey Street Railway Co. Some change in the trip system was the cause of the strike.

According to a recent decision of the attorney general of New York the Manhattan Elevated Railway Co. is declared the road to be a "railroad" and not a "street railroad" company. This will greatly improve the securities of the company as investments.

The Elwood line of the Union Traction Co., of Anderson, Ind., is now completed and cars will be running in a few days. The Muncie line is hampered by the difficulty in procuring rails. The power house of this line will be at Doleville. Charles L. Henry, president of the company, was recently in Chicago and bought about $45,000 worth of modern machinery with which to equip the

Alexandria power house. It will, however, be several months before this material can be delivered.

An Elkhart (Ind.) judge has rendered a decision which may result in some interesting litigation. He declared that a city has the right at any time to remove a traction company's poles from the streets even if they had been placed there in exact accordance with the terms of the company's franchise.

Transfer tickets are not well adapted for love missives as a new conductor on a Terre Haute, Ind., line has discovered. He wrote something sweet on the back of a transfer which he gave to a young lady with whom he was epris. When she turned the transfer over to another conductor the story of course got out and the laugh was on him.

Mr. Henry Everett is evidenly meeting all the expectations of his friends as the manager of the Big Consolidated in Cleveland, O. It was said the road would greatly increase its earnings in his hands. The gross earnings of the company for the first quarter of 1899 were $425,796 against $407,376 for the same period last year. The operating expenses and taxes have been decreased $8,423, and the net earning for the quarter increased $26,843 over last year.

We are informed that the Freland Traction Co. has in course of construction a line from Lansdale, Montgomery County, Pa., to Perkasie, Bucks County, a distance of 11 miles. The power plant, car barn and offices of the company will be located at Souderton, and arrangements are being completed for the purchase of a six-acre tract at that place. Gleason & Kiely, Syracuse, N. Y., have secured the contract for the ballasting and track construction. The line will be completed by Oct. 1, 1899. John H. Pascal, president; F. J. Crilly, treasurer, and J. Balderfer, secretary.

The Cairo (Ill.) Electric Ry. has issued a new time card which might prove an excellent suggestion to the street car companies of other cities. The card gives a schedule of the leaving and arriving time of cars on the company's various lines, the "owl" car service being particularly emphasized, and on the back of the card is a time table of the arrival and departure of all the trains on the different lines of steam railroads entering the city. This cannot help being a good "ad" for the Cairo Electric Ry. as the card is useful enough to cause everyone to carry it constantly for reference.

FIRE IN BROOKLYN.

A power house of the Brooklyn (N. Y.) Rapid Transit Co., located at Division and Kent Sts., was partially destroyed by fire on the night of May 1st. This building was erected only a few years ago, and was large and complete in all its equipments. At the time of the fire there was about 5,000 tons of coal and 1,400 gallons of oil in the building. The origin of the fire is not known, but it is believed to have started in the oil room; one explanation is that it was caused by an explosion of gas in a coal chute. The damage was confined to the third floor and the roof.

YERKES STREET RAILWAY DEAL.

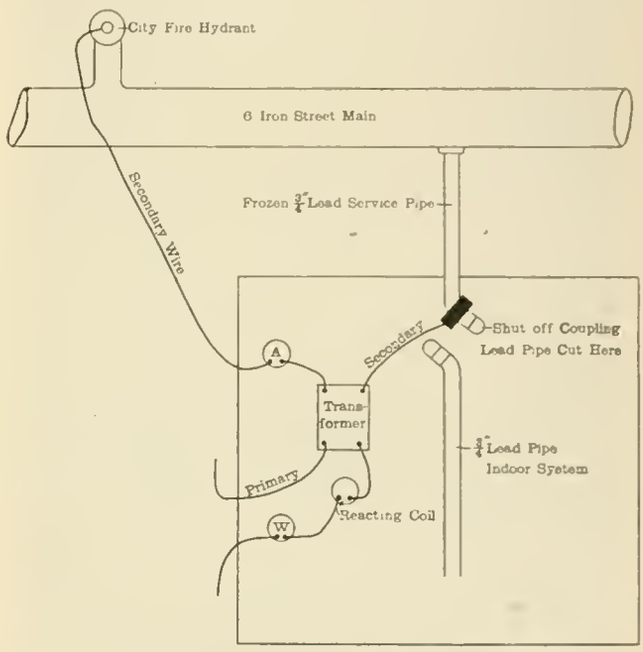
The plans for the purchase of a controlling interest in the Yerkes street railways of Chicago by eastern men, among whom are mentioned Messrs. Brady, Dolan, Elkins, Flower, Ryan, Whitney and Widener, have reached the point where only legal detail remain to be arranged. These gentlemen propose to guarantee 12 per cent to the minority holders of North Chicago stock, and 6 per cent on West Chicago. The old leases on these properties will probably prevent the organization of a new company.

So far as can be learned the elevated roads are not included in the negotiations.

THAWING WATER PIPES BY ELECTRICITY.

During the severe cold weather of last winter electricity was successfully used for thawing frozen water pipes in a number of cities in this country and Canada. Professors Jackson and Wood, of the University of Wisconsin, at Madison, for thawing service pipes made use of currents of from 200 to 300 amperes at 50 to 60 volts, and for 6-in. to 8-in. cast iron mains proposed currents as large as 1,000 amperes at 100 to 250 volts.

The Berlin (Can.) Gas & Electric Co. made use of alternating current of 2,080 volts primary and 104 volts secondary, the apparatus being arranged as shown by the accompanying diagram, which is taken from the Canadian Electrical News. The apparatus comprised a 200-light transformer, simple form of water rheostat, a portable switchboard and measuring instruments. Wires from the primary circuit were carried to the switchboard and thence to the transformer. The secondary wires from the transformer with the rheostat and an ammeter in circuit were then attached to the pipe to be thawed by means of clamps, the frozen portion of the pipe being, of course, made part of the circuit. A voltmeter is connected across the terminal and the rheostat adjusted to give 50 amperes



ARRANGEMENT OF APPARATUS.

for service pipes. Attachment to the pipes may be at any convenient point.

In Ottawa Messrs. Murphy and Bradley, of the Ottawa Electric Co., made use of a 1,000-volt primary current transformed down to 25 volts. Two transformers were used and worked in parallel. The reactive coil and rheostat were dispensed with; an ammeter was placed in the primary circuit because no portable instrument of sufficient range for the secondary was at hand.

Data for four trials were as follows:

1. Secondary, 17 volts; primary, 8 amperes. Connections through 25 ft. of ⅝-in. lead pipe. Water flowed in 3 minutes, full pressure in 6 minutes.

2. Secondary, 21 volts; primary, 5 amperes. Connections through 25 ft. of ⅝-in. lead pipe. Water flowed in 3 minutes, full Water flowed in 8 minutes, full pressure in 10 minutes.

3. Secondary, 22 volts; primary, 9 amperes. Connections through 25 ft. of ⅝-in. lead and 4 ft. of 5-in. iron pipe. Water flowed freely in 2 minutes.

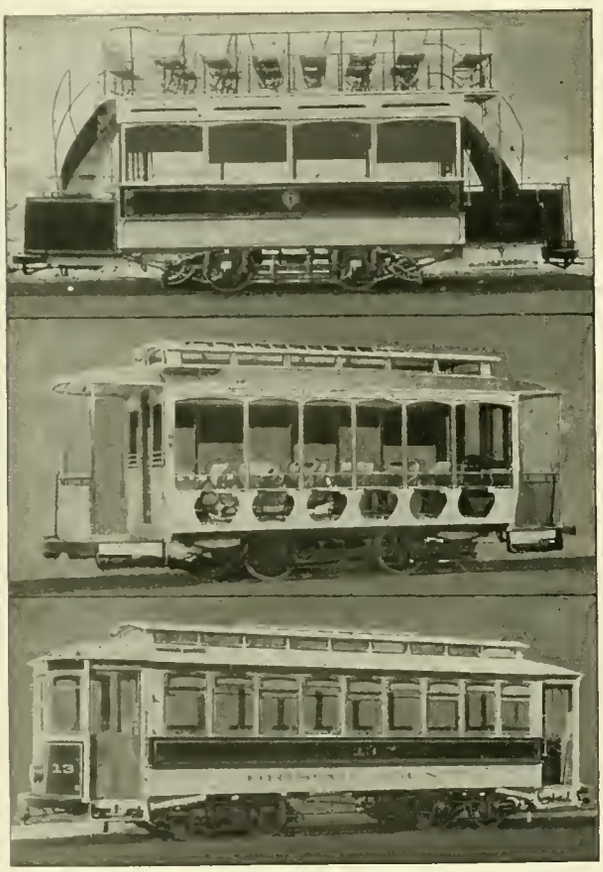
4. Secondary, 23 volts; primary, 7 amperes. Connections through 60 ft. of ⅝-in. lead and 24 ft. of 5-in. iron pipe. Water flowed in 1 minute, full pressure in 3 minutes.

The Des Moines City Railway Co. has advanced the wages of its men 10 per cent from and after May 1st.

RECENT BRILL CARS.

The accompanying engraving shows three cars recently built by the J. G. Brill Co. which are of interest as being of different types. The topmost car is one of a number built for the Hull (England) Electric Co. and has all the latest improvements in details.

The length of body is 16 ft.; the length over all about 28 ft.; width at sills, 6 ft. and the greatest permissable width but 7 ft.; the platforms are rather longer than usual, being 5 ft. 6 in. These cars differ from all those recently constructed in having fixed windows and on this account the glass is of a large size and of course set without separate sash. The inside seats are longitudinal with spring backs and the seats are sovered with carpet. Garden or "walkover" seats are used on the roof; the seats and backs are both of slats. On the lower deck the car seats 22 persons inside; on the upper deck, 29. The cars are finished inside with three-ply maple ceilings and



RECENT BRILL CARS.

cherry over the windows. Spring blinds are used with the usual fittings. It will be noticed that the railing at the sides of the stairs is made much higher than usual to give greater protection to persons ascending or descending the stairways. At the sides the rail is fitted with wire netting, giving the car a much lighter appearance than is usually found in English cars of this type. Galvanized gutters are fitted on each of the hoods. Red, green and white lights are arranged at the corners diagonally opposite the stairways. The trimmings are of bronze with bronze hand rail for the stairway. No. 90 Westinghouse controller is employed. By means of this the motors are turned into generators and form a brake by being short circuited through resistance. This brake is intended for emergency but ultimately more resistance may be added and the use of the electric brake become more frequent.

The car is mounted on Brill No. 21-E truck. With the delivery of this order there will be 57 of the 21-E trucks in operation in the city of Hull. There are two Westinghouse No. 46 motors for 500 volts and they are of the nose suspension style. The wheel base is 6 ft. and the diameter of the wheels 30 in. The Hull roads are of standard gage. One noticeable feature of this car is that of the unusual height which has been obtained in the center of the monitor deck, which is 6 ft. 8 in. from the floor. Angle iron bumpers are used with 6-in. projection in front of the dasher. The cars are to be fitted with electric headlights. The platforms are dropped 6 in. below the floor of the car, thus bringing the steps conveniently low.

The second car is of rather unusual type and was made for the Perth (Australia) Tramways Co. It is a 14-seat center-aisle open car without side entrances; 10 seats have reversible backs. The body is 26 ft. long, and the length over all 35 ft. 8 in. It is mounted on a 21-E truck. The height to the underside of the sill is 28 in., and over the trolley board 11 ft. 8 in. The gage is 3 ft. 6 in.; the wheel base 7 ft. Without motors the weight is 11,465 lb. The truck is equipped with two G. E. 58 motors. Round-corner seat-end panels are used and pantasote curtains are provided for closing the car in inclement weather. The plain appearance in the picture is due to the fact that these cars were shipped "in the white."

The third car is one built for the Mansfield & Easton (Pa.) Street Railway Co. for fast interurban service.

The body is 25 ft. 4 in. long and the car 36 ft. over all. The width at the sills is 7 ft. 5 in. and 8 ft. at the belt rails. The platforms are dropped and by using a 13-in. riser the step is brought within 16½ in. of the head of the rail. Both ends are completely vestibuled, having folding doors which close against the body of the car. The trucks are No. 27 D and have 4 ft. wheel base with 33 in. wheels There are two G. E. 1,000 motors. The interior of the car is finished in quartered oak with quartered oak headlinings and bronze trimmings throughout. The spring seats with reversible backs are covered with crimsom plush; the corner seats are placed longitudinally. The total seating capacity is 36 persons. The center of the car is supported by truss rods which are made of piping instead of solid rods, giving great stiffness and strength with light weight. The weight of these cars, with trucks and motors complete, is 27,825 lb. Brill radiating draw bars, electric headlights supplemented with one headlight for oil, are some of the remaining details. The complete enclosure of the car and its high speed, large seating capacity and steady riding, make it one of the most desirable types which has been turned out for the interurban service.

CHATTANOOGA RAPID TRANSIT CO.

The Chattanooga Rapid Transit Co. resumed operation of its lines May 1st. The question at issue with the Southern Railway Co. has been adjusted and that portion of the road which belongs to the Southern Railway Co. has been leased for 45 years.

The company is now pushing its extension rapidly. By June 1st the six miles of road to Sherman Heights will be equipped with electricity and by July 1st the new road into Chickamauga Park, 4½ miles in length, will be opened. Mr. Divine has secured a franchise to put in a line to the foot of Lookout Mountain, which will be constructed within a year. When this is completed the company will be operating 20 miles of road.

The officers of the company are: President and general manager, S. W. Divine; vice-president, G. M. Davenport; secretary and treasurer, W. D. Royster; auditor, E. D. Lilly; chief engineer, George Fitzwater.

ELECTRIC VEHICLE CO.

The Electric Vehicle Co. has purchased all the capital stock of the Siemens-Halske Electric Co. of America, and Charles E. Yerkes has resigned as president and director of the latter company. He is succeeded by Isaac L. Rice, president of the Electric Vehicle Co. and of the Electric Storage Battery Co., an allied company. The Siemens-Halske Co. was controlled by the Pennsylvania Iron Works, which owned practically all the stock, and in which Messrs. Widener, Elkins and Mahoney are largely interested. The Pope Bicycle Works is also controlled by the Vehicle Co.

The Illinois Vehicle & Transportation Co. has been organized to represent the Electric Vehicle Co. in the West; Samuel Insull will be president of the new company. The stock of the local company is said to be already in demand at 113.

ECHOES FROM THE TRADE

THE WESTERN ELECTRIC CO., of Chicago, has a contract to install a complete electric light plant in the Rose Building, Cleveland, O.

O. P. JOHNSON, of the Star Brass Works, Kalamazoo, Mich., manufacturer of street railway specialties, recently spent several days in Chicago, and was very successful in introducing his goods.

C. TOWNSEND BLAKE, of Philadelphia, dealer in railroad, municipal and gas bonds, is now installed in his new offices in the Girard Trust Building. Mr. Blake has recently added municipal bonds to his list.

A. O. SCHOONMAKER, of 158 William St., New York City, and prominently identified in the mica trade of the country, has appointed the W. R. Garton Co., Manhattan Building, Chicago, as his representative here.

THE E. P. ALLIS CO., of Milwaukee, is now building nine vertical compound engines of 6,600 h. p. each for the Metropolitan Street Railway Co., of New York, two of the 11 units ordered having been shipped in April.

THE PANCOAST VENTILATOR CO. has gone into a receiver's hands. From the showing of the company it would appear that it went on and incurred a large indebtedness when it must have known the accounts could not possibly be paid.

THE WESTON ELECTRICAL CO. is making contracts for its new factory at Waverly, N. J., a suburb of Newark. A railway switch is now being constructed to the spot and ground will be broken in a few days for the erection of what will probably be the most complete manufacturing establishment in the United States.

THE AMERICAN RAIL JOINT & MANUFACTURING CO., of Cleveland, O., has so far this season contracted to furnish different railway companies about 40,000 joints. Contracts have just been made with the Erie & Cambridgboro Electric Railway Co. for 25 miles, the New Orleans & Jefferson, 9 miles; the Kansas City & Leavenworth Railway Co., 20 miles, making a total of about 21,000 joints.

F. H. NEWCOMB, manufacturer of uniform caps, has recently received an order from the Brooklyn Rapid Transit Co. for 5,000 conductors' and motormen's caps. His caps have been adopted as standard. He has also received an order from the West Shore R. R. for a complete equipment of caps for the whole system, and also an order for all caps for the marine department of the New York, New Haven & Hartford R. R.

THE GARTON-DANIELS CO. states that since April 1st the sales of Garton lightning arresters have been over double what they have been in the same period of any previous year, and in order to keep up the stock it has recently doubled the force of employes. It will be able to meet any requirements for prompt shipments. The new kicking coils and lightning arresters for the protection of small motors, fans, etc., are meeting with a large demand.

THE WESTERN ELECTRIC CO. makes ceiling, desk and bracket fans for 500 to 550 volts; also fans for 120 and 220 volts, which can be placed on a 550 volt circuit. Bulletins 16 F, and 17 F, describe the "Standard" ceiling fan, and the desk and bracket fans made by this company. Bulletin 19 F describes the "Arctic" ceiling fan and accessories, and is the fourth of the series of bulletins. A 40-page fan motor catalog giving complete descriptions will be mailed to any person desiring one.

THE AJAX METAL CO., of Philadelphia, is not in any combine. There has been a bearing metal combination formed and the Ajax people were invited to enter, but respectfully declined. It is this concern's intention to run its own business in its own way and keep out of the combination. The company is satisfied it has a superior metal which it can sell at a fair price and prefers doing an independent business to being mixed up with other concerns.

THE ELECTRICAL INSTALLATION CO., of Chicago, has removed its offices from the 11th floor of the Monadnock Building to rooms 1516 and 1517. This company is well known in the field of electric railway construction and equipment. No change has been made in the personnel of the company. J. J. Case is president, A. M. Hewes secretary and treasurer, and J. A. Brett, general manager. They will be glad to see all old or new patrons in their new location.

THE CHICAGO PNEUMATIC TOOL CO. has purchased the patents formerly owned by the Consolidated Pneumatic Tool Co., now defunct. These patents include all the Keller & Wolstencroft types of tool construction and in addition several new applications which have not yet been taken out. These patents originally cost the Consolidated Pneumatic Tool Co. about $40,000, and in purchasing them the Chicago Pneumatic Tool Co. states that it acquires control of about all of the pneumatic tool patents of value in existence.

HAROLD P. BROWN, manager of the Edison-Brown plastic rail bond, has been notified that the United States Government will, for this season's work, use the Edison-Brown plastic bond. For two years the Government has been experimenting with these rail bonds and as a result they were put into practical service on the Indian Head tramways with a light rail and a ballasted track and this service has so thoroughly demonstrated the utility of the Edison-Brown bond that the decision has been made as stated, to use it exclusively.

ADAM COOK'S SONS, 313 West St., New York, announce that very particular engineers who are annoyed by using oil for lubricating purposes will find a welcome change in the engine room if they apply Albany grease to the crank pins. This firm makes a standing offer to furnish a sufficient quantity of the compound and an "Albany" grease cup free of charge to all engineers who desire to test the matter. Aside from the extra cleanliness obtained in the use of this standard lubricant the saving in dollars and cents in the oil bill is a substantial one and well worthy of investigation.

THE SPRAGUE ELECTRIC CO., of New York, has issued an exceedingly handsome catalog giving a number of fine half tone illustrations of the Lundell fan motors. The cooling device has almost ceased to be a luxury and become a necessity everywhere. It is a necessity in the factory or workshop, in the engine room and in all places where great heat is generated. It has become a necessity in the hospital and the sick room. It is a luxury in the theatre, the church, the business office and the home, but at the same time it has become a luxurious necessity. The Lundell fan motor has met with the greatest success in every field where it has been placed. The United States Government has adopted it for its vessels, its hospitals and its workshops.

THE DUPLEX CAR CO. has recently received orders that make it necessary to extend the factory arrangements. Many of the cars it is building for foreign delivery are arranged with a single seat on one side of the aisle and a double seat on the other. The

company informs us that most of the orders received for both foreign and domestic delivery are for finely finished and furnished cars. The prevailing demand is for the best cars as well as equipment. Many managers have believed that the "Duplex" car would prove to be popular when it was better known, and we congratulate the company on its excellent prospects for a large business.

THE WADHAM'S OIL & GREASE CO., of Milwaukee, is still meeting with most satisfactory success in the sale of its graphite curve grease, for use on street railways. This grease has been found to be exceptionally good for its purpose and is endorsed by all companies using it as the best article in the market. And added to the real excellence of the grease in itself, the low price at which it is sold is another reason for its great popularity. The company also makes a full line of motor and car greases and lubricating oils, but especial attention of street railway companies is called to its graphite curve grease.

THE AMERICAN STEEL & WIRE CO., of New Jersey, has purchased the business and manufacturing plants of the Washburn Moen Manufacturing Co., of Worcester, Mass. Mr. Geo. A. Cragin, who has been the manager of the latter company's office and warehouse at Houston, Tex., writes that he has connected himself with the new company and will make his headquarters at Chicago. The Houston agency will be closed as soon as the pending business matters can be settled. Mr. Cragin has for many years been identified with the Washburn & Moen Manufacturing Co. and will be a valuable man in the new company.

THE GOHEEN MANUFACTURING CO., in its new pamphlet, shows a number of photographic representations of iron work structures which have been protected by its "carbonizing coating." This material has become very popular and the demand has increased to such an extent that the company has been compelled to enlarge its plant. The demand during the four months of this year has been exceptionally heavy, eclipsing any similar period in any past year. The company claims to be the only maker of a chemically combined paint and on its "carbonizing coating" it has certainly earned a most excellent reputation, both in this and in foreign countries.

THE SIMONDS MANUFACTURING CO., of Pittsburg, Pa., of which J. C. Carry in the Fisher Building is the Chicago representative, is one of the big concerns in the country manufacturing electric railway supplies and builders of all kinds of special machinery racks, worms, worm wheels, gears and pinions. The company has recently issued an attractive booklet with an embossed silk cover, which says: "We'll Talk on Wheels and Railway Supplies." The little book does talk and shows a number of handsome cuts of wheels and gears and tells a story which must interest all who use these things. The letter copy is brief, sharp and right to the point and is well worth attention.

THE PEARSON JACK CO., 67 Federal St., Boston, has recently issued a small circular giving a brief description of its well known jacks and a few of the many strong testimonials received by it from roads using them. Mr. John Doyle, superintendent of track for the Chicago & West Michigan Ry. says, under date of Apr. 29, 1899: "A set of your jacks have been in use on the C. & W. M. wrecking car for the last year, and they have given the best of satisfaction. I consider them the best device on the market, and no wrecking cars should be without them. Our men became expert in the use of these jacks in a very short time, and can replace a car on the tracks in less time than with any other device." These jacks have a capacity of 50 tons per pair and weigh only 85 lb. each.

THE JOSEPH DIXON CRUCIBLE CO., of Jersey City, N. J., is issuing a neat little periodical, published once a month, called "Graphite." In each issue may be found much valuable and interesting information regarding this peculiar commodity now so commonly used in the arts and manufactures. Many people who have been bothered because their lead pencils were greasy would be surprised to learn that graphite, of which lead pencils are made, is also used very extensively as a lubricant. The little paper strongly emphasizes the advantages of using the "Dixon Graphite Axle Grease" on one page and on the next tells the reader what excellent pencils the "Dixon's American Graphite" are. There are nearly 40 different preparations made by the company, in all of which graphite is the prime feature.

THE MEAKER MANUFACTURING CO., of Chicago, is now shipping to the Omaha & Council Bluffs Railway & Bridge Co., Council Bluffs, Ia., a complete equipment of the new Meaker registers. These registers were illustrated and described in the "Review" for October, 1898, page 765. The Omaha & Council Bluffs road has long used the Meaker registers and while these have given the best of satisfaction the management was prompt to appreciate the superiority of the new type and placed an order with the Meaker Co. The objects accomplished by the new type of register are: An additional check is placed on the conductor, who is unable to read the grand total. Competitors or other interested persons are unable to keep a record of the business. The manager is able to easily check the bookkeeping of the office.

WESTINGHOUSE, CHURCH, KERR & CO., of New York, have received a contract from the Third Avenue Railroad Co., of New York, for a temporary plant to be built at once, to be in running order within a few weeks, for providing power until the permanent plant is completed. This temporary equipment consists of six 750-h. p. Westinghouse vertical steam engines, to be direct conected to six Westinghouse generators of 500 kw. each. It also comprises water tube boilers aggregating 4,000 h. p. fitted with Roney mechanical stokers. They also have a contract from the Laconia Street Railway Co., Laconia, N. H., for two Westinghouse gas engines—one of 85 brake h. p., and the other of 50 brake h. p., to be belted to generators; these engines are to be subjected to the severe loads of street railway service.

PURDUE UNIVERSITY, the technical and agricultural college of Indiana, has recently issued its register for the present year, which shows a considerable increase in the number of students and of the courses offered. Purdue is eminently a school of technology and its mechanical and electrical laboratories are among the most complete in the country. In railroad engineering especially it stands first; the work done here on steam locomotives is well known and the deposit at Purdue of the experimental apparatus of the Master Car Builders' Association offers opportunities for investigation in the field which cannot be equalled elsewhere. The electrical laboratory is well equipped and among the apparatus are street railway motors, controllers, etc., offering facilities for investigations in this branch of railroading also.

MANNING, MAXWELL & MOORE, of New York, with branch offices in Chicago and Pittsburg, have issued a very exhaustive catalog for 1899, illustrating the Shaw electric traveling cranes Mr. A. J. Shaw made the plans for the first electric crane ever constructed. This was more than ten years ago and since then all other kinds have been abandoned. Since then also great improvements have been made in this contrivance so indispensable to every power plant, locomotive and machine shop and foundry or wherever heavy carrying is necessary. The Shaw Electric Crane Co., the works of which are at Muskegon, Mich., makes two types of electric cranes, the single motor and the multi-motor and in these types this company has achieved the highest degree of excellence. These cranes combine all the features calculated to prove the most efficient for general work and it is also prepared to adopt special features desirable for special service. The catalog issued is fully illustrated with photographic views of various cranes in use in its own works and also many of those in operation in other large machine shops, foundries, locomotive works, and in a number of the United States arsenals and ship building shops.

THE WESTERN ELECTRIC CO., of Chicago, Ill., western agent for the S. K. C. system, Stanley Electric Manufacturing Co., of Pittsfield, Mass., has recently published a bulletin which should

prove vastly interesting to all users of lighting transformers. The Western Electric Co. claims to be first in having introduced high-grade transformers and although there has been at times a strong temptation to meet the competition of cheap types it has been resisted, the company believing it to be to its own interest and to the interest of all users of electrical appliances to make and sell only the best. That the best is the cheapest in the long run has often been proved and this company has found that policy to be the wisest. The bulletin, 101, just issued is full of information regrading transformers and should be in the hands of everyone interested.

WESTINGHOUSE, CHURCH, KERR & CO. are not only engineers and contract for the designing, furnishing and installing of complete plants of every description, but are also the selling agents of the popular Roney mechanical stoker. This stoker has been in use for over 15 years and its advantages over hand firing cannot be questioned. There are various stokers in use, but there is only one Roney. The success of this one, the satisfaction of all who have and are using it is a guarantee that it is one of the best in the world. The Roney stoker possesses all the following essential characteristics: Simplicity of construction and operation, accessibility, smokelessness, large excess capacity and the ability to burn all grades of hard and soft coals. The company has just issued a complete catalog giving in full all the advantages and by clear and carefully drawn illustrations, show its perfect working and construction.

THE BURT MANUFACTURING CO., of Akron, O., makes oil filters and in a catalog it has recently issued makes the startling statement that consumers of oil waste on an average from 50 to 75 per cent of all they buy. The company claims that this percentage of oil is wasted because of the dirt and grit which get into it and that by the use of a filter this waste can be saved and used over and over again until the last drop has been consumed in actual use. The company manufactures the "Cross" filter, which it is so certain will be approved that it agrees to send them on 30 days' trial and at no expense to the user. The company has been making the Cross filter for nine years and has from time to time improved it until today it is claimed to be the best, most perfect working filter on the market. It is in use in 23 countries and has been endorsed by many of the largest manufacturing concerns in the world. The offer of a 30 days' trial should be sufficient for any one interested.

THE WHEELER CONDENSER & ENGINEERING CO., at 120-122 Liberty St., New York City, will open a western office during the month of May at 1642 Monadnock Block, Chicago. It has always done a large business in the West, and has felt the need of headquarters in Chicago for some time. Mr. William S. Love, for several years connected with the Abendroth & Root Manufacturing Co., will have charge of the office. Mr. Love goes to his new position with the best wishes of the Abendroth & Root Co. It will interest the readers of the "Review" to know that the Wheeler Condenser & Engineering Co. has just closed a contract with the Alley "L" road in Chicago for three additional Barnard cooling towers, making eight in all. This installation will take care of all the condensing water for 12,000 h. p. of engines, and will be the largest installation of cooling towers of any design in the United States. The fact that the Alley "L" road installed towers of the same pattern it has been using for the last two years is evidence of what the management thinks of them. The new twine mill of the McCormick Harvesting Co., and the new wood department will be equipped with three Wheeler surface condensers of 2,500 h. p. each, contracts for which were let last week.

THE GENERAL ELECTRIC CO. has issued its report for the year ending Jan. 31, 1899. It shows that the total sales during the year were $15,679,430.86, with a calculated direct profit of $2,584,896.61. The increase in orders was 21 per cent over the year before. During the year large additions were made to the company's plants at Schnectady, N. Y.; Lynn, Mass., and Harrison, N. J., the total

cost of which was $897,739.58, and this entire amount was met out of current receipts and written off the books. A portion of the gross income for the year, amounting to $324,462.03, was acquired by the sale of certain securities which the company held on the books at $746,498.36, which brought $1,070,960.39, and this money, the report says, was not needed in the business, and was devoted to the purchase of $300,000 of the company's own debentures, to extensions to the factory plants, and to acquiring of stocks and bonds in subsidiary companies, amounting in face value to $814,221.

The unmatured and unsettled balances due to the company at the end of the year were $4,447,311.10, and the sum is but little in excess of the sales of the last three months of the year, which amounted to $4,151,904.62. The report says that in the settlement of old accounts during the year a net gain of $44,816.80 was realized over the sum at which they were carried on the books, and that of the $2,432,860.88 old notes and accounts receivable which were written off three years ago at a nominal value of $1 an account $1,374,703.69 remains, which stand on the books at $131. From settlements of this class of accounts the company received during the year $62,190.62.

EXHIBITION OF MAGANN AIR BRAKE.

One of the interesting features of the meeting of the Railroad Air Brake Men's Association at Detroit last month was a trip over the Detroit & Pontiac electric road arranged by William D. Ray, of the G. P. Magann Air Brake Co. A special car equipped with the Magann brakes was provided and the guests were given an opportunity to see the working of the system and to inspect the apparatus. On March 15th car No. 5 left Birmingham with a pressure of 230 lb. of air in the storage tank. After two round trips, making a total mileage of 104 miles and a total of 300 stops the pressure in the storage tank was 70 lb. On March 16th a run with 165 stops reduced the air pressure 88 lb.

SPECIAL CAR WITH THE MAGANN AIR BRAKE.

G. Fryberger, a motorman of the Toledo (O.) Traction Co., dropped dead from heart disease while on duty April 28th.

The Indianapolis lines have adopted a new ticket system. Besides the distinguishing feature of the color, blue and yellow, there is a complicated system of numbering to prevent counterfeiting.

MANHATTAN STATIONS WITH ELEVATORS.

A few months ago President Gould, of the Manhattan Elevated, New York, made inquiries of a number of the larger property holders along Sixth Ave. as to terms on which his company could install elevators in their buildings to furnish more convenient access to the elevated stations. One of the abutting owners, Mr. Morgenthau, said that if the Manhattan Railway Co. would arrange an exit on its platform from his second floor, he would install the elevators at his own expense; further, while he would prefer to place them near the rear of the building, he would consent to put them near the front if the railway company insisted upon that location. Mr. Morgenthau stated that such an arrangement would make his second floor as valuable as his first floor is now, and double the present value of the first floor.

The advantages of such elevators would be mutual. Ordinarily the traffic on the elevated is rather light during shopping hours and such a convenience to patrons as these elevators would be, enabling a person to get from one of the big stores to another without climbing stairs and without exposure, would bring to the elevated a large number of short haul passengers, which are a profitable class to handle. On the other hand, the elevated would bring people to the department stores and deliver them inside the building without cost, whereas the department stores gladly pay large sums to get people to enter their doors.

When an arrangement is so attractive that both parties are willing to pay for it, there can be no doubt as to its speedy accomplishment.

XENIA-DAYTON ROAD.

Mr. J. W. Neff, vice-president of the Rapid Transit Co., Xenia, O., advises us that his company has contracted with the Fairmount Construction Co., of Philadelphia, to build and equip the road between Xenia and Dayton. The road will be 15¾ miles long. The grading is completed for five miles and two miles of track laid. Contracts are all let for the power house and electrical equipment and it is hoped to have the road in operation by July 15th.

To secure an issue of $300,000 of 20-year, 5 per cent gold bonds the company has executed a mortgage to the Fidelity Insurance, Trust & Safe Deposit Co., of Philadelphia, trustee.

This paper is a member of the Chicago Trade Press Association.

Entered at the Post Office at Chicago as Second Class Matter.

VOL. IX. JUNE 15, 1899. NO. 6.

The importance of using a really effective method of destroying tickets which have been once used is shown by the experience of the Birmingham (Ala.) Railway & Electric Co. It found that its tickets were being sold on the street three for 10 cents, or even two for 5 cents; investigation showed that these were tickets that had been used and thrown away after being torn in pieces. Some enterprising person had picked the pieces out of the trash boxes and pasted them together.

So many committees from city councils of Great Britain have visited this country during the past few years in search of information on the best methods of operating street railways, it is somewhat surprising that our own American city fathers have allowed a good thing to go so long unworked. The city council of Chicago are about to vote $10,000 for the purpose of sending as many of its number to Europe as the appropriation will cover, to pay a visit to the old folks at home and incidentally to "study" trams and other subtle ways.

The improvement in prices of materials continues, iron and all its manufactured products being in especially strong demand. Special work of all kinds is being ordered in large quantities, and manufacturers are working night and day to fill orders. In this branch many delays are occurring in delivery on account of the inability of the shops to secure rail sections with which to work. The foreign demand for rails is large and increasing. There is every indication that a still further advance in prices of all kinds of iron and steel will be made.

The United States Circuit Court, which granted a temporary injunction in October, 1898, restraining the city of Cleveland from enforcing its 4 cent street car fare ordinances, on May 16th, continued the order in force till a hearing could be had on a petition to make the injunction perpetual. This decision was placed on the ground that the city had no authority to change the rates of fare until the present franchises of the company should expire. The right to so change fares had been reserved in the first ordinance passed by the city, but the court held that these earlier ordinances had been repealed by subsequent ones making no reservation. The question of the reasonableness of the 4-cent rate was not passed upon.

The trust craze has received a serious setback in the refusal of the banks to accept the truck stocks as collateral, and investors are not now as eager to subscribe as in the beginning. A notable example was the Carnegie syndicate, which probably is as meritorious as any of the combinations from a business standpoint, but which was unable to secure subscription to its $625,000,000 of consolidation stocks, and Mr. Frick and his associates were forced to make the subscription themselves.

There is invariably a day of grief ahead for hundreds of investors in the watered stocks which have been poured out on a gullible public during the past six months, and a check to these schemes is a matter of public congratulation.

The syndicate which has organized the Massachusetts Electric Companies has in so doing effected the amalgamation of more street railway companies than have ever before been consolidated at one time; the mileage is also the largest operated by any single company. Thirty-three railway and electric companies in New Hampshire, Eastern Massachusetts and Rhode Island are concerned in the consolidation, and the operation of all these properties, which are by local conditions very closely connected in interest, will be of like advantage to the public and the owners; the former will receive conveniences previously impossible, and the expense of administration will be decreased. It also insures a harmony of action in all matters pertaining to legislation.

At its last session the Wisconsin Legislature passed a very stringent anti-pass law, which will be found on another page of this issue. The law prohibits all parties, whether individuals or companies, from giving free passes of any description to state or city officials and employes, or to political committees, and prohibits these classes from accepting or making use of such free passes, all under heavy penalties. One of the first results has been that street railway companies are requiring policemen, firemen and other city employes, who have heretofore been carried free, to pay fares when they ride on the cars.

An interesting question has been raised at Superior where the street railway issues transfer tickets which bear the announcement: "This transfer ticket is a gratuity and is accepted as such by the passenger." The claim is made that public officers cannot accept such a ticket, because it comes within "any free pass, frank or privilege of any sort."

The franchise tax act has received the signature of Governor Roosevelt, and there appears to be a wide disparity of opinion as to the extent of the additional burden thus placed upon street railways of New York State. The amount of income from this source is widely estimated at from 14 million to 27 million dollars. The franchises are to be taxed on the same basis as real estate, which will therefore make the assessment 60 per cent of value. The law takes effect next October.

The attention of managers and claim agents is called to the latest news of that man of many names, whom the "Review" has for convenience christened the "grab-handle man," which appears on another page of this issue. After operating his swindle with success in many different cities he last winter fell in with the public spirited officials of some Massachusetts roads, who at considerable trouble and expense set about teaching him a lesson. He is now serving his second term in a Massachusetts house of correction, and we trust that the other charges against him may be prosecuted when he is again at liberty.

We print this month the names of several other companies which have voluntarily advanced the rate of wages to their men. It is not only an evidence of the better business which makes it possible to do this, but also of the disposition of the managers to pay as high a rate as the earnings of the companies will warrant. Contrary to a somewhat general impression there are few managers but would gladly pay just as high a wage scale as they can, for they not only appreciate a good quality of service, but are interested in the welfare of their men to an extent much greater than the men themselves often realizes. There are some roads, however, which have not as yet been able to lift themselves out of the difficulties into which they were forced during the protracted period in which the earnings were less than expenses and interest charges. Until these loans can be paid off and the properties put in former condition it will be hard for such roads to be as liberal as they would like.

Judge Marean, of the Supreme Court, of New York, has recently rendered a decision dismissing an action brought to prevent the running of express cars on the electric trolley lines on Long Island. The court says that the public "having discovered that the transportation of freight can be made more economically than by former methods, there is no meritorious reason why it should not enjoy that advantage.

The language of Judge Marean, is exactly in accord with the views concerning freight traffic in cities which we have repeatedly urged in these columns. There can be no more objection from an esthetic point of view to handling goods in a trolley car than in a wagon, and the wear and tear on the streets is vastly less. Wherever the experiment has been tried it has proved popular, and we predict that a great number of street railways will develop this branch of the business in the near future.

In this connection it is of interest to note that the Philadelphia & West Chester has a charter permitting it to carry certain classes of freight between Newton Square and Philadelphia. The company charges ¼ cent per quart for carrying milk, and has a revenue of $600 per month from this source.

The reports of the Railroad Commissioners of Massachusetts and Connecticut show that the total electric railway mileage (measured as single track) in the two states is nearly 2,100 miles, and though this fact is well known, probably few were aware that one can travel four-fifths of the way from Boston to New York on electric cars. The description on another page of this issue of the trip by trolley taken by a street railway man between these two cities is of more interest than as a mere recital of a novel pilgrimage. It is the longest trip ever made on electric lines, and yet if any one had suggested the possibility of such a thing only a few years ago he would have been laughed at. The development of the interurban electric railway is one of the most interesting and promising subjects of the day, both sociologically and physically. It is the bridge which connects the resident of city and country as the steam roads have never done, nor can do to an equal extent. By it farm life is deprived of many of its disadvantages which belong to isolation, and an interchange of people and ideas is obtained. The victim of an accident no longer need suffer for hours while some one struggles through impassible roads to call the doctor. Now the telephone does the calling and the electric car swiftly brings the needed aid to the sick and injured. The expansion and development of these lines during the next five years will be a subject of wonderful interest, and the result of untold benefit.

One of the points to be remarked is that the fare for 209 miles by electric cars averaged 1.34 cents per mile, while for the 43 miles by steam cars it was 2.12 cents per mile. For speed the statistics are more favorable to the steam roads; on the steam roads the average speed was 28.1 miles per hour, on the electric roads it was 12.3 miles per hour. This latter figure, however, is very creditable.

The present month marks the retirement of Mr. Charles T. Yerkes as president and director of the North and West Chicago Street Railroads and the controlling factor of the dozen or more street railway companies which go to make up the Yerkes System of Chicago. Mr. Yerkes' attention was first turned towards street railway investments in 1875, and he became associated with the men at the head of the street railways in Philadelphia, who were afterwards with him in the development of Chicago properties.

Mr. Yerkes located in Chicago in 1881, opening a branch of his Philadelphia bank, and was at once attracted by the great possibilities of the street railways. The North Side system appeared to him to be one whose improvement was easiest and most imperative, and in 1886 he succeeded in getting control of it. The era of reorganization and construction which has made the name of Mr. Yerkes famous was at once begun. First he arranged with the city for the tunnel under the Chicago River at LaSalle St., rebuilt this to conform to the requirements of the cable system, and built 17 miles of cable road, which included a loop in the business district. Two years later he secured control of the West Side system and securing the Washington St. tunnel, rebuilt it and installed the cable system on the West Side; later a new tunnel was built at Van Buren St. and a second cable route to the west division of Chicago was opened.

Mr. Yerkes was extremely desirous to equip all of his lines for mechanical traction and made extensive experiments with steam and gas motors in the endeavor to find a satisfactory substitute for horses on the feeder lines of his system. The overhead electric trolley finally solved the

problem, and in the five years since April, 1894, when a trolley ordinance was passed by the council the growth of the Yerkes System has been little less than marvelous. Today it comprises over 530 miles, of which 47 are operated by cable and 6 by horses. It is to be regretted that electricity as a motive power was not deemed practicable in 1886 when Mr. Yerkes first obtained control of the North Chicago lines, for then the enormous investment in the cable construction might have been avoided.

Mr. Yerkes has also been the moving spirit of the Lake Street and the Northwestern Elevated Railroads.

To no man is the city of Chicago more indebted for the transportation system which it today enjoys, to which rapid growth and prosperity are largely due, and yet no man has been subjected to more bitter vituperation by the press and people of Chicago than has Mr. Yerkes. Such treatment as this is undeserved, yet it is what a public benefactor usually receives as the reward of his labors. Mr. Yerkes takes a philosophical view of the matter; at the meeting of his stockholders called to ratify the lease to the Chicago Union Traction Co. he said in the course of an address reviewing the last 13 years:

> I never expect to have any appreciation for the things that I did. I have the feeling within myself that I am doing what is satisfactory to myself and therefore I do not ask for applause. I do not want it, for the men who applaud me today are likely to curse me tomorrow, if things do not go as they want them to go. But, as I say, the stockholders cannot help seeing these things with satisfaction, and if we had had better opportunities instead of having to literally fight for every step we made, we would have had many more improvements today than we have.

Mr. Yerkes' retirement marks the end of an era in the development of the urban transportation systems of Chicago and the city will be fortunate indeed if the succeeding years show an equal progress.

STREET RAILWAY ACCOUNTANTS' ASSOCIATION.

The whole of America is a pretty large field and when the Street Railway Accountants' Association of America was organized in the spring of 1897 the members had little doubt but that the name would be broad enough to include the membership. Not long since we noted that the Glasgow Municipal Tramways had joined the Association, and we have just been advised that the Central London Ry., London, Eng., has recently become a member. The Schenectady (N. Y.) Railway Co. has also joined.

CHANGES AT SEATTLE, WASH.

The plant of the Seattle (Wash.) Steam Heat & Power Co. has been purchased by parties interested in the Union Electric Co., and a large power plant is to be erected on recently acquired property, though it has not yet been determined whether it will be built by the Union Electric Co. or a new company. Negotiations are pending for the consolidation of the various street railway, electric light and power companies of Seattle.

The new management of the Nashville Street Railway, which recently bought the controlling interest in the Nashville & Suburban road, assumed control at midnight May 9th.

MUNICIPAL OWNERSHIP IN DETROIT PRACTICALLY SECURED.

$15,325,000 Is the Price to Which Both Sides Have Agreed Pingree's Neat Scheme to Get Around the Adverse Decision Which the Supreme Court May Render City Council Pledged to Carry Out Pingree's Plan Twelve Mile Haul for Three Cents.

Fifteen million, three hundred and twenty-five thousand dollars, cash, that is the price agreed upon which the municipality of Detroit is to pay for the street car properties located in her midst, and now every indication is that the deal will be closed in short order.

The Detroit Street Railway Commission, through its experts, after a thorough examination of the properties, decided that the actual value of the properties was $7,866,737.42, the same being divided as follows: Roadbed and tracks, $4,350,183.42; overhead construction, $760,939; power houses, $807,139.36, repair shops, tools and supplies, $83,994.08; rolling stock, $1,102,212.39; car houses and real estate, $523,248.30; other buildings and fixtures, $179,016.87. The owners of the street railway system did not exactly agree to these figures, claiming that the experts allowed too much for depreciation from the original cost, on account of operation and also that the real estate was worth more than it was valued at. Mr. T. L. Johnson, representing the bond and stock owners, by his invoice, placed the value of the real and personal properties at $8,062,737.

For the purpose of computing the value of the franchises and in making all negotiations, a compromise valuation of $8,000,000 was decided upon and at that figure the negotiations were carried on.

Prof. W. A. Bemis, of Kansas City, in making calculations on the value of the franchises, considering the years they have yet to run, used $8,000,000 as his valuation of the properties. An examination of the company books showed a net earning, except interest charges, for the year ending April 1st, 1899, of $805,833. Of this amount he calculates that it will require $55,000 per year for the next ten years to care for the increased traffic that will develop in the outlying districts of Detroit, leaving at the present income $750,883 to care for the interest charges and create a sinking fund for the retirement of the purchase bonds.

Regarding increased traffic, Prof. Bemis calculates that it will average 4 per cent per year and by taking the present earnings of each individual line, deducting therefrom the interest charges and adding thereto the annual increase of 4 per cent, by considering the number of years each franchise has to run, Prof. Bemis fixes their entire money value at the sum of $8,478,553, giving the properties a total valuation of $16,478,553.

With this approximate valuation of the street railway properties, the Detroit Street Railway Commission has carried on its negotiations with Mr. T. L. Johnson as the representative of Mr. R. T. Wilson, of New York, until a final agreement regarding price has been arrived at, as stated above.

Mr. Wilson has agreed to accept $15,325,000 cash, or the equivalent therof in bonds and if paid in bonds issued by the Detroit Street Railway Commission, same bearing 4 per cent interest, he claims that it will require at least $16,800,000 to represent the equivalent.

The municipal owernship commission of Detroit has agreed to this and with the proper ordinances, resolutions

and other data the entire matter was presented to the Detroit City Council on June 6th.

Owing to the fact that the Supreme Court of Michigan has failed to hand down a decision on the constitutionality of the McLeod law, by which municipal owernship was to be made possible, Governor Pingree has adopted a new method to bring about the trial of this pet idea. As the city of Detroit cannot legally now enter into the purchase of the street railways, the system proposed is for the three members of the Detroit Street Railway Commission, Messrs. Pingree, Schmit and Stevenson, to jointly form a corporation to be known as the Detroit Municipal Ry. As such a proposed organization these three commissioners have asked the council to grant them an ordinance to buy, build and operate street railways at 3-cent fares—5 tickets for 15 cents—and at any time the City Council may request the Detroit Municipal Ry., without compensation, shall transfer all of its property to the city, or commission representing the city.

Should the council approve of this move, and that is almost a foregone conclusion, then all of the street railways in Detroit will be transferred to the Detroit Metropolitan Ry. for the purpose of consolidation. The Metropolitan company will then issue 4 per cent bonds to the amount $17,500,000, which will cover all of the outstanding obligations of the three companies operating in Detroit. To further secure these bonds the Detroit Municipal Ry. will ask the city council to pass a security franchise calling for 5-cent fares; six tickets for a quarter except on the Detroit Railway, at present a 3-cent line; payment to the city of a tax of 2 per cent of the gross receipts, and with this as a consideration the Metropolitan Ry. will turn over to the Municipal Ry. all of the street railway properties in Detroit and suburbs and $700,000 in bonds besides, to make it a good bargain. These bonds are to be held by the Municipal Ry. for future improvements.

Should this plan meet the approval of the city council, then municipal ownership will have been accomplished without the consent of the Supreme Court of Michigan.

Should the time come in the future when the operating expenses will warrant, then the city council shall have the power to reduce the rates of fare below 3 cents. The Municipal Ry. must make quarterly reports to the council, giving a detailed statement of all monies received and from what source; of its expenditures and for what purpose made, as well as all other information required.

If the plan as outlined is carried out, it is the intention to convey the properties to a city commission as soon as one can secure a legal existence, but Governor Pingree figures that this will mean municipal ownership in fact if not in name, so he is satisfied with the arrangement.

Street railway men not acquainted in Detroit will be interested in some facts that this change in operating will bring about. Under the universal transfer plan, a number of lines will give a ride of twelve miles for 3 cents. Where now the three lines are operated separately, although under the same management, in the future they will interchange transfers and thereby greatly reduce the revenues of the individual lines.

Prof. Bemis, the "franchise expert" and political economist from a Kansas university, estimates that by reducing fares it will be five years before the receipts of the Detroit railways advance from what they today, and considering that there is but $105,833 difference between the present net earnings and the interest charges under the new heavy mortgage, many who have been warm supporters of the proposed municipal ownership plan are very much afraid that it will be a failure. The local opposition to municipal ownership among business men and the heavy tax payers, is as strong as ever, but the aldermen representing labor wards are afraid to oppose the plans of Governor Pingree.

Many a ward boss in the past few years has reached the political graveyard for opposing the supposed "reforms" of Pingree, and the present law-makers of Detroit as a rule will think of what might happen should they endeavor to prevent the passage of the necessary ordinances that will bring about municipal ownership under private operation, or any other method, a long time before much opposition can be concentrated.

The Citizens' Committee that has charge of the fight to prevent the purchasing of the street railway properties by any form of a municipal commission, is undecided just what to do to prevent the present plans being carried out successfully. The new move was a surprise, as it was generally supposed that all negotiations were off pending the Supreme Court decision; however, the attorneys that are employed by the business interests of Detroit state positively that the fight will be kept up vigorously as soon as the city council attempts to take any kind of action.

From the present outlook, June will show many developments in the attempt to secure municipal ownership in Detroit.

CLEVELAND 4-CENT FARE CASE.

In the "Review" for November, 1898, it was announced that the city council of Cleveland had passed ordinances limiting the street railway fare on the Big and Little Consolidated roads of that city to four cents, with tickets at the rate of seven for 25 cents. The ordinances were passed Oct. 17, 1898, and the companies at once petitioned the United States Circuit Court for an injunction restraining the city from enforcing the ordinances, thus preventing test cases being brought in the state courts. A temporary injunction was granted October 30th, and on May 16th this was continued until after the companies should have been heard or a petition to make the injunction perpetual.

The authority to regulate fares, which is claimed by the city, rests on a reservation made by it in some ordinances granting franchises in 1879. Since that date other franchises have been given to these companies by ordinances in which no right to regulate the fare was reserved.

The court said it was apparent that the reservation of the 1879 ordinance was inconsistent with grants made in 1885. If the ordinances passed since 1879 are to be construed as statutes they are so far inconsistent with that ordinance as to operate as an appeal. In every instance when additional rights were granted the companies agreed to carry passengers farther for the same fare and that this constituted valuable concessions to the people by the companies.

"The relations between the city of Cleveland and the complainant companies, as the successors of the various companies out of which they are formed, have been so far changed by the various contracts entered into since 1879 that the city is estopped from claiming that the reservation contained in the ordinance of 1879 can now be used to either increase or diminish the rate of fare upon a small portion of the lines."

The Street Railways of Washington, D. C.

Which Will Be Operated by the Washington Traction & Electric Co.

The street railways of Washington, D. C., which up to the present time have been operated by 10 independent companies, are about to be combined under the single ownership of what is locally known as the Crosby-Stevens syndicate. This company, which will be officially known as the Washington Traction & Electric Co., has already purchased most of the street railways in the city and suburbs of Washington, and will shortly purchase all the remaining roads with the single exception of the Capital Traction Co., which is to remain independent of the consolidation. In addition to its railway interests the new company also controls the United States Electric Light Co., of Washington, and the Potomac Electric Power Co. The property of the following railways has either already been acquired or arrangements for the purchase made by the new company: Metropolitan Railroad Co., the Columbia Railroad Co., Anacostia & Potomac River Railroad Co., Georgetown & Tenallytown Railway Co., Brightwood Railway Co., Washington & Great Falls Electric Railway Co., Washington & Rockville Railway Co., Washington Woodside & Forest Glen Railway Co., Capitol Railway Co., and the City & Suburban Ry. of Washington. The latter railway is not to be purchased immediately, but will eventually join the consolidation.

Through service from the suburbs to any part of the city of Washington for a single fare is one of the principal reforms to be inaugurated by the new company. To accomplish this the lines within the city will be all equipped with a uniform underground electric system and the lines outside the city limits will be run on the overhead trolley system. At the points where these two systems meet the suburban car will run over a pit in which an underground trolley will be adjusted to the bottom of the car, enabling it to continue in to the heart of the city over the underground lines. Much of the underground construction of several of the lines included in the consolidation has already been completed, although considerable still remains to be done. The condition of the suburban lines, however, is generally poor, many of them having been built in the comparatively early days of electric railways, and these are to be completely reconstructed and re-equipped. The contract for this work on the suburban roads has recently been awarded to the firm of J. G. White & Co., of New York and Baltimore.

The purchase of the consolidated roads has been made by the United States Mortgage & Trust Co., of New York, of which Geo. W. Young is president. Mr. Young has visited Washington frequently of late in the interests of the consolidated company. The general offices of the Washington Traction & Electric Co. are at 1417 G St., N. W., which is also the office of the Potomac Electric Power Co.

The reorganization and construction of these roads is in the hands of Oscar T. Crosby, F. C. Stevens, Charles H. Lieb and H. D. Mirick. While the members of the syndicate have been very reticent in regard to the future plans of the consolidated lines, it is apparent from the work now in progress that the Potomac Electric Power Co. will be the general supply station for all of the suburban lines, those in the neighborhood of the station receiving a direct 500-volt current, while those further away will receive a biphase high tension current, which will be transformed down to a 500-volt direct current at convenient distributing points. Whether the same plan will be adopted on all the roads of the consolidated company is not known at present.

THE METROPOLITAN RAILROAD CO.

One of the most important systems to be acquired by the new company is that of the Metropolitan Railroad Co., which was the first company in the city to equip its lines with the underground trolley system. The main line of the road, called the F St. division, starts at 15th and East Capitol Sts. and extends to 36th St. and Prospect Ave., a distance of 6½ miles. This line, running east and west, divides the city directly in the center. On the route of the F St. division are the National Library, the United States Capitol, the

FIG. 1—METROPOLITAN CAR BARN.

Baltimore & Ohio Depot, the Interior Department, the Postoffice Department, the Patent Office, the Treasury Department and all of the prominent hotels. This line also passes within two squares of the White House, Lafayette Park separating the line from the White House grounds. From this point the route runs through the most beautiful section of Washington, known as the West End.

The next longest division of the Metropolitan system is the Ninth St. line, which begins at 4½ and P. Sts., S. W. It passes the Arsenal grounds, runs along the entire Potomac River front, and returns to 4½ St. Passing the Baltimore & Potomac Depot and Central Market it turns into Ninth St. On this busy thoroughfare are situated the Interior Department, the Postoffice Department, the Masonic Temple and many other noted buildings. The line terminates opposite the National Baseball Park.

The third division of the Metropolitan road is called the Columbia Ave. extension. This line starts from the Capitol, and runs over the F St. division to Depot Circle. It branches off at this point, passing along Connecticut Ave. to Columbia Ave., and through the latter avenue to 18th St.

At the east terminus of the road, corner of 14th and East Capital Sts., is located the extensive car barn illustrated in Fig. 1, covering three acres of ground. This building,

which measures 433½ ft. in length by 280 ft. in width, is handsomely finished, being faced with red pressed brick, and contains in addition to the storage room for cars the company's executive offices, a paint shop, carpenter shop, machine shop, armature winding room, compressed air plant and testing room. Fig. 2 gives a general view of the interior of the car barn as seen from the east end of the building. The two extreme tracks at either side of the barn form a loop, the east bound cars running past the outside of the building and around through the building onto the west bound track. The remainder of the tracks inside the barn are all pit tracks for overhauling the machinery underneath the cars, and a transfer table at one end of the building is used to move the cars from one track to another. Figs. 3 and 4 show the carpenter shop and paint shop, respectively. These are equipped with all necessary tools, etc., for repairing and painting the cars. Over each track in these shops is a double overhead trolley line, carrying a trolley with flexible leads which can be attached to the car, thus enabling it to be moved about the shops or from the shops to the car barn without the use of horses or man power.

Two views of the machine shop are illustrated in Figs.

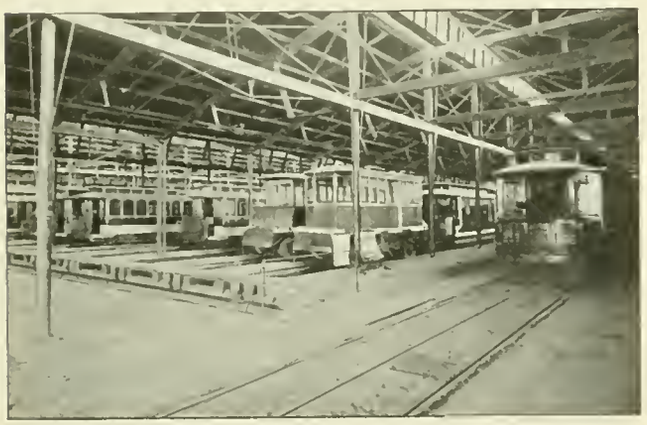

FIG. 2—INTERIOR OF CAR BARN.

5 and 6, which show different portions of the shop. This department is particularly well equipped for doing any kinds of machine work incident to a street railway. It contains 2 forges, 1 sawing machine, 1 standard emery machine, 1 drill press, 1 wheel boring machine, 1 32-in. Niles lathe with 9-ft. bed, 1 small 8-in. lathe, 1 Gould & Englehardt shaper, 1 hydraulic press, 1 Hartford grinder and 1 buffing wheel. These machines are run by a 20-h. p. General Electric motor. The armature and field winding room, which is situated directly over the machine shop, is shown in Fig. 7.

An important labor saving device in handling the machinery under the cars and transporting it between the repair pits and the machine shop is shown in Figs. 6 and 8. At the left of Fig. 8 a car is shown over the pit, in which armatures are removed. A track runs along the bottom of this pit on which a small truck runs, and this truck has a carrier upon it which moves vertically upon a threaded shaft. In operating this device the track is rolled directly beneath the motor and the vertical carrier is raised up against the armature. The armature bearings are then unfastened and the carrier with the armature upon it is lowered and the truck rolled out from under the car into the position shown in Fig. 8. The armature is then raised by a block and fall carried on a pair of wheels which run on an overhead track, and, as shown in Fig. 6, the armature is easily conveyed to any part of the machine shop upon this track. The car wheels are removed from the cars in a similar manner, and carried to the machine shop by the same device. Fig. 8 shows the method of lowering the car wheels into the pit by removing a section of the floor and track directly under the wheels after the car has been jacked up.

The machinery under the cars is cleaned by means of compressed air. The air plant is at one side of the car barn. This comprises an air compressor and a large tank, from which a supply of air under 60 lb. pressure is always available. The air from this tank is piped to different points in the repair pits to which a flexible hose and nozzle can be coupled. By turning the air through the nozzle on any part of the machinery, all dirt, copper dust, etc., is at once removed from even the smallest crevices, leaving the machinery much cleaner than any amount of wiping would accomplish, and in a small fraction of the time required to clean it by hand. The seats and cushions of the cars are thoroughly dusted in the same way by simply passing the compressed air nozzle over them.

These time and labor saving devices are made necessary by the company's rule to thoroughly overhaul every one of its cars twice a month, whether they show any need of repairs or not, and this means that about eight cars per day must be handled over the repair pits. This is accomplished by a comparatively small force of men, owing to the complete facilities which are provided for handling and repairing the machinery. Connected with the car-barn is a stable which contains an emergency wagon, horses and apparatus for making repairs along the line in case of trouble. Fig. 9 shows this wagon on which are seated the chief electrician, Mr. Chamberlain, and his crew. On the wagon is also shown a bridge, which is used to elevate a fire hose above the roofs of the cars, in case of a fire occurring along the route. At the starter's office is a transparent illuminated time table, which is easily visible in the darkest night, and at this point are also two Bristol recording voltmeters, which give records of the pressure on the line throughout the day.

Fig. 10 shows a view of the testing room situated on the second floor of the car barn. The board is supplied with current at 110 volts, 250 volts, and 500 volts, ammeter, voltmeters, wattmeters and other apparatus for testing incandescent lamps, insulation of cables, and other electrical supplies purchased by the company.

The company has in all 307 cars, including open and closed motor cars and trailers, 3 mail cars, 3 sweepers, 2 snow plows, and 1 sand car. The cars were built by the American Car Co. and the J. G. Brill Co. On the F St. division of the road there are 36 trains, composed of a motor car and a trailer, and 20 single cars in regular service. On the Ninth St. division 30 trains of two cars are operated, and on the Columbia Ave. extension 20 single motor cars are used, there being no loop at either end of the line for trailers.

The Metropolitan lines are operated from two generating stations, one of which is located at 2411 P St., N. W., and the other at 4½ and O Sts., S. W. The P St. station which supplies current to about one-half of the system, is a large brick building, faced with pressed brick, containing an engine room, boiler room and considerable extra space, which has not yet been utilized. The engine room, the di-

mensions of which are 60 x 80 ft., is illustrated in Fig. 11. It contains a 10-ton traveling crane, worked by hand power. The equipment of the engine room consists of three McIntosh & Seymour engines of the compound condensing type, which are directly connected to General Electric multipolar generators. Two of these engines have cylinder measurements of 22 and 42 x 42 in., and run at a speed of 90 r. p. m. These engines have a rated capacity of 750 h. p. and then come three generator panels. In the center is the station panel with a Weston ammeter and Thomson recording wattmeter, which measure the total station current. To the right of this are six feeder panels, and on the end of the board is an emergency panel. The latter is changeable with either of the feeder panels, and has a water rheostat in series with it, so that in case of a short circuit the feeder on which it occurs may be thrown onto the emergency panel

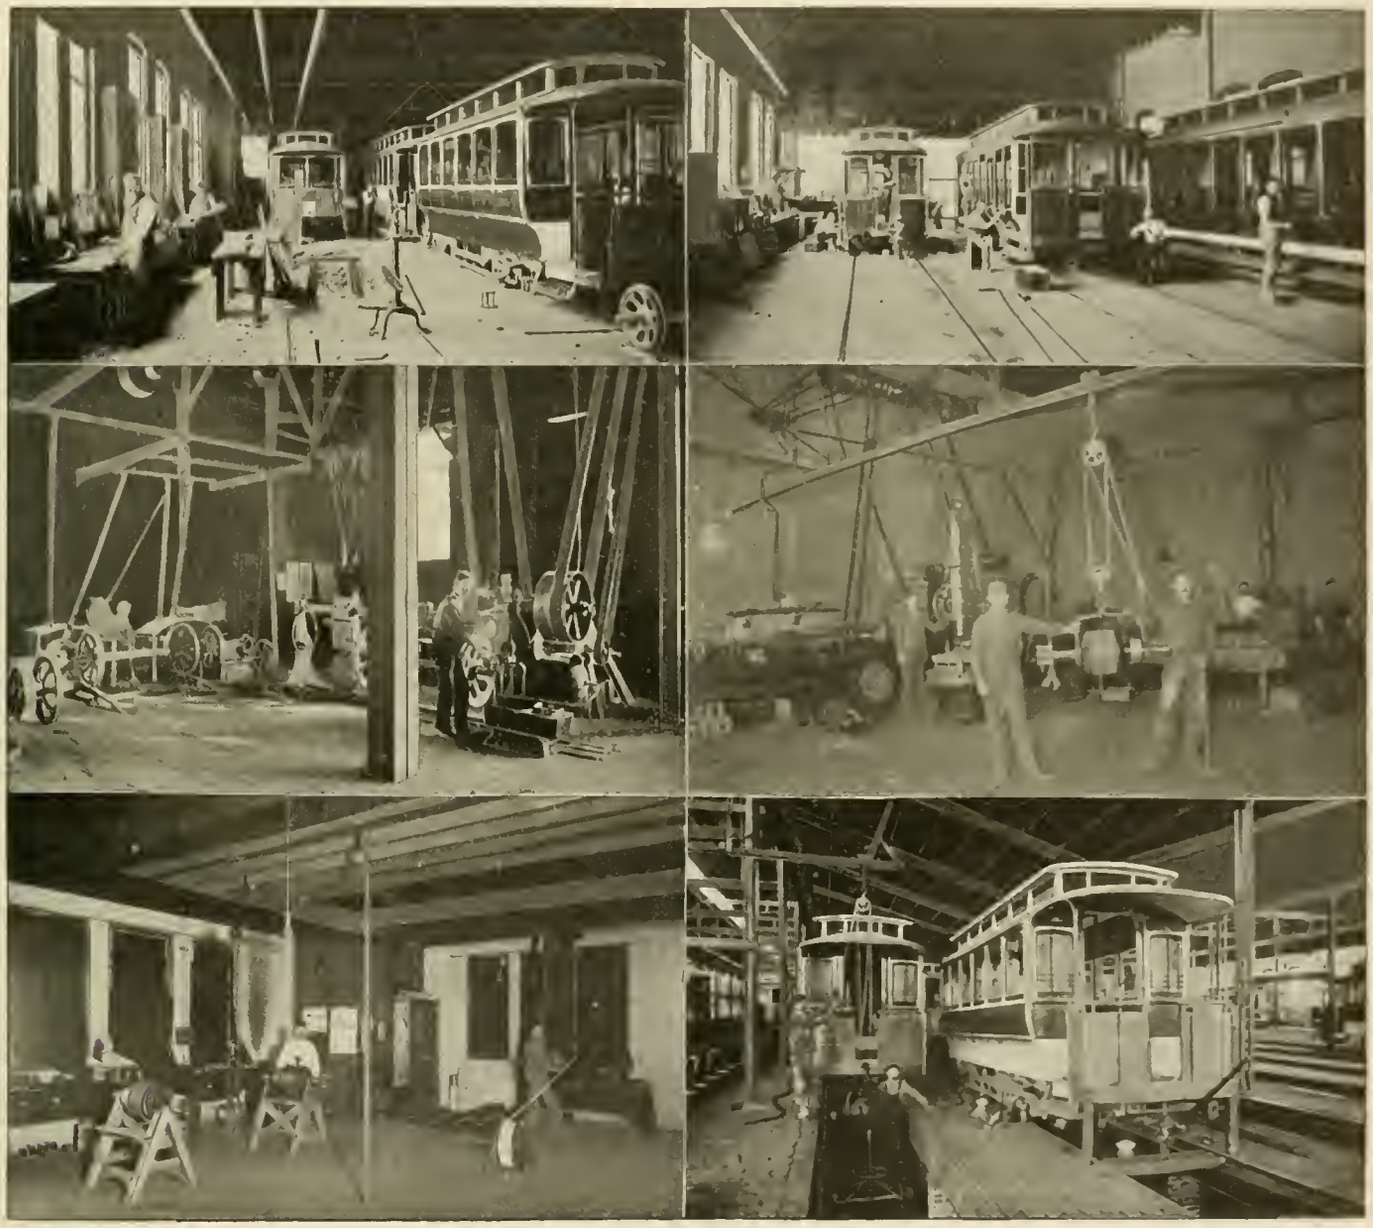

FIG. 3—CARPENTER SHOP.
FIG. 5—MACHINE SHOP.
FIG. 7—MOTOR WINDING ROOM.

FIG. 4—PAINT SHOP.
FIG. 6—MACHINE SHOP.
FIG. 8—CAR PITS.

and each is connected to a 500-k. w. 10-pole generator. The third engine measures 26 and 50 x 48 in., makes 90 r. p. m., and is rated at 1200 h. p. This engine is connected to an 800-k. w. 12-pole generator. The pressure at the station is 600 volts.

The switchboard is constructed of slate upon an iron frame, and is of the standard General Electric pattern. The first panel on the left hand end of the board is a negative panel, which is a common return for all the circuits. The next panel controls the lighting circuits for the building, and the resistence varied by raising or lowering an iron plunger into the water so that the short circuit, if not too heavy, may be burned out.

The engine room also contains three Worthington jet condensers, which, on account of there being no water in the neighborhood, are supplied from a Worthington cooling tower having a capacity of 30,000 lb. of steam per hour. The fans in the cooling tower are driven by a General Electric motor of special design, its chief feature of interest being a possible variation of 100 per cent in speed. It will also

operate on any intermediate speeds. It is of the 6-pole type, and is direct connected to the fan shaft.

The boiler room is situated directly behind the engine room and measures 60 x 80 ft. It contains 6 water tube boilers; 3 are rated at 200 h. p. and 3 at 300 h. p. each. Three are set with Murphy automatic smokeless furnaces, and three with plain furnaces. These are fed by two Worthington pumps, 9 x 5¼ x 10 in. in dimensions. They are

FIG. 9—EMERGENCY WAGON.

brass fitted throughout, and discharge their water through a Wainwright feed water heater.

The boilers are connected to a steel self-supporting stack 6 ft. in diameter and 125 ft. high. The piping is fitted throughout with Chapman valves; Blake atmospheric valves are used on the engines.

The lighting current of this station is from a 30-k. w. General Electric marine set. This plant is in charge of Mr. H. S. Bolten, chief engineer.

condensing engines, measuring 17 and 32 x 48 in., which run at 94 r. p. m. These are rated at 500 h. p. each, and each is direct connected to an 8-pole General Electric generator of 300 kw. capacity. In the adjoining room is a McIntosh & Seymour compound condensing engine with a 10-pole General Electric generator exactly similar to the two 750-h. p. units in the P St. station. The switchboard, Fig. 13, is exactly similar to the one previously described, with the exception of having one more generator panel.

There are four Nordberg jet condensers set in the basement below the engine room, one being directly behind each engine. These take water from the Potomac River, on the banks of which the station is situated. There are five water tube boilers, three of 250 h. p. each, and two of 300 h. p. capacity, all set with plain furnaces and connected to a brick stack. When the boiler plant was enlarged it was feared this stack would be too small, so it was fitted with a forced draft fan but up to the present its use has not been required.

There are two Snow pumps, 7 x 4 x 8 in., used for pumping water from the hot well to a tank, and these pumps are also piped so as to feed the boilers if necessary. Ordinarily the boilers are fed by a Dean pump, 10 x 6 x 12 in., and they are also fitted with two Metropolitan injectors, having a 2-in. discharge.

The building is lighted by means of a 6-pole, 110-volt General Electric generator direct connected to an Armington & Sims engine. The chief engineer of this station is Mr. C. S. Wilson.

The track and underground work of the Metropolitan Railroad Co. is very substantial as will be seen by reference to Fig. 14, which shows a cross section of the track and conduit through a manhole. The track rails are 7-in. girder rails weighing 83 lb., made by the Pennsylvania Steel Co., and these and the slot rails are laid on heavy cast iron yokes bedded in concrete. The manholes are built with

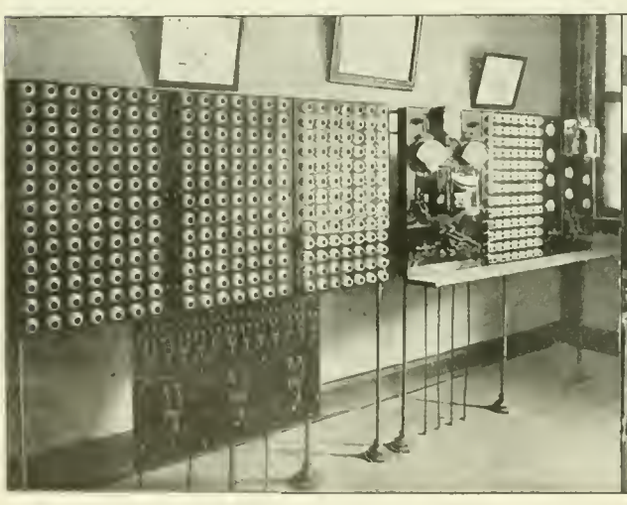

FIG. 10 TESTING ROOM.

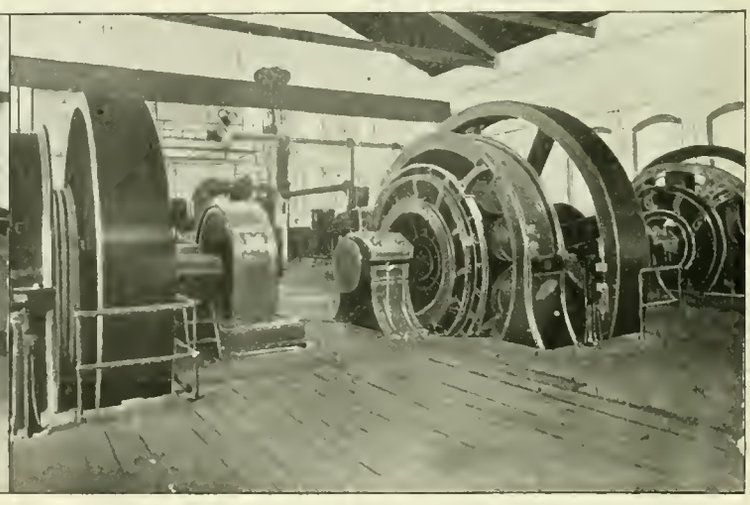

FIG. 11—McINTOSH & SEYMOUR ENGINES, P ST. STATION.

The other half of the Metropolitan lines are supplied from the 4½ St. station already mentioned, which is a brick building similar in general appearance to the P St. station, there being also considerable similarity in the equipments of both. The engine room of this station is divided by a series of brick arches into two district rooms. In the first room, Fig. 12, there are three Greene compound con-

either heavy brick or concrete walls 4 ft. square, surmounted with a heavy cap stone on which the iron manhole box is set. Fig. 14 also shows the method used for draining the conduits, and the manhole connection to the sewer, the drainage all being carried off through terra cotta pipes. The line of ducts is also shown entering the manhole. The ducts used in this construction are the single ducts made

by the H. B. Camp Co., and the four-tube ducts of the Potomac Terra Cotta Co. The cables are lead covered, varying in size from 300,000 cm. to 1,000,000 cm. Fig. 15 shows a section of the insulator used and the method of hanging the conductor rails. The insulators are heavy porcelain cylinders, with a coarse screw thread on both the inside and the outside. An iron cap with a flange that supports the weight of the insulator and conductor rail is screwed on the outside of the insulator and a bolt is screwed in the center hole of the insulator. Both the screw threads fit but roughly, and Portland cement is poured around each of the threads to make a solid joint. The lug to which the conductor rail is bolted is fastened on the insulator bolt between two nuts, which give it an opportunity to be raised or lowered and the hole in the lug through which the insulator bolt passes is made oblong so that the space between the conductor rails can be adjusted. The conductor rails are T-shaped, 22 ft. long, and are fastened to the insulators at the ends and in the center. The plow is about 2 ft. long, 8 in. wide, and just thick enough to pass along the slot. Two shoes at the bottom of the plow press out sideways between the conductor rails. The frame of the plow is made of thin steel bars and it is provided with two pairs of leads, one pair with fuses in circuit and the other pair without them. The fused leads are generally used, but in case the fuses blow the other pair of leads are connected to the car temporarily to bring it home to the barn.

The terminals which connect the feeder ends to the conductor rail are made in two parts, one of which is bolted and soldered to the rail, and the other bolted and soldered to the cable. The two connecting parts which are smoothly finished are clamped solidly together with bolts. With the old terminals formerly used much trouble was experienced by the burning of the metal due to the high resistance where the terminal was bolted to the rail without being soldered. With the new soldered terminal no trouble has been experienced.

FIG. 12—ENGINE ROOM, 4½ ST. STATION.

FIG. 13—SWITCHBOARD, 4½ ST. STATION.

The conduit and track construction was all done by Mr. E. Saxton who has laid all the underground conduit for the street railways of Washington. The character of Mr. Saxton's work is widely and favorably known, and ranks him among the best constructing engineers in the country. The success which has attended all of his work as a street railway contractor is very flattering indeed.

The Metropolitan road is the only one of the consolidated roads that is completely equipped and in full running order, all of the other roads being in various stages of reconstruction. During the National Peace Jubilee, celebrated in Washington for three days last month, the Metropolitan Co. decorated two trains of cars very handsomely in honor of the army and the navy. The ceilings of the cars were completely covered by rows of red, white and blue bunting, radiating out from clusters of incandescent lamps. The exterior decorations of these trains is shown in Fig. 16. On

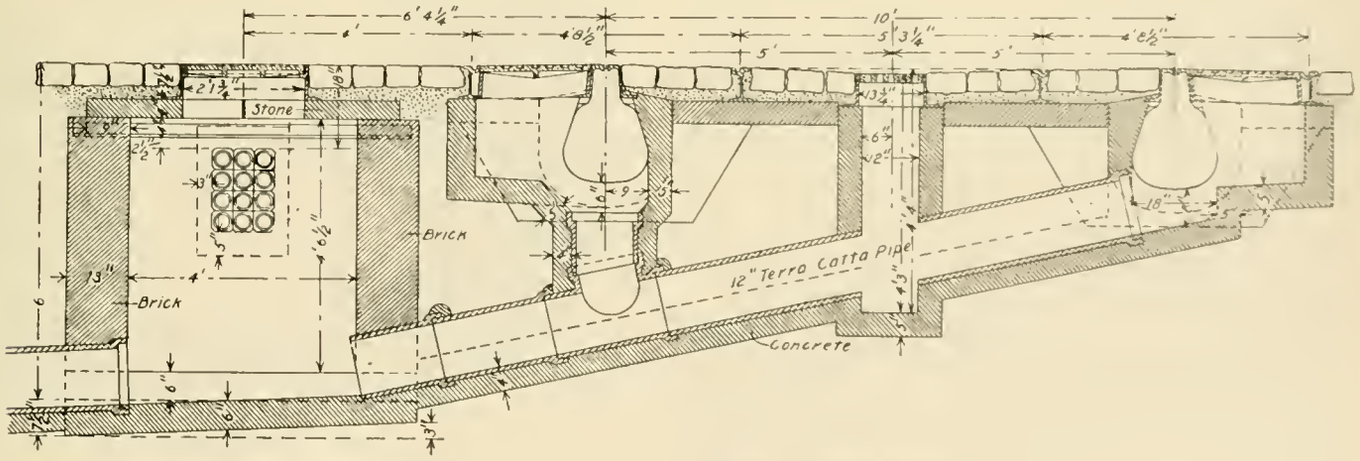

FIG. 14—CROSS SECTION OF METROPOLITAN ROADBED AT MAN HOLE.

the hoods of the front cars an American flag was set in a kind of transparency, the flag being kept unfurled by means of a fan motor revolving at one end of it. The army car bore the names of Miles, Shafter and Wheeler in illuminated letters, and the navy car the names Dewey, Sampson and Schley. The edge of the car roofs carried a solid row of red, white and blue lamps, and at the top of each side post was a cluster of white and colored lamps. The trains presented a very handsome and brilliant appearance and created much enthusiasm along the route.

The officers of the Metropolitan Railroad Co. are: R. D. Weaver, president; A. B. Grunwell, vice-president; G. B. Coleman, secretary, general manager and purchasing agent; Wm. J. Wilson, treasurer, and F. H. Chamberlain, chief electrician.

R. D. WEAVER.

G. B. COLEMAN.

Mr. Robert D. Weaver was elected president of the Metropolitan Railroad Co. July 14, 1897. Mr. Weaver is essentially a self-made man, having by his own energy and ability alone, climbed the ladder of success, and today stands at the top, one of the recognized solid and influential men of Washington. He left school at an early age and at once began his business career. For seven years he was associated with his father, and by the exercise of the best of business methods he rapidly accumulated a fortune. Later he became identified with street railway matters and has successively and successfully filled several offices with the Metropolitan. His policy has ever been a liberal one and through it he has made the Metropolitan one of the best street railway properties in the country.

Mr. G. B. Coleman has been connected with this company since he was a boy. He began as a bookkeeper, but soon showed as much ability as an executive officer as he did as the keeper of the company's accounts. He was gradually advanced from one position to another until he was elected as secretary. In October, 1896, Samuel L. Phillips resigned the presidency and Mr. Coleman was made general manager of the road in addition to the secretaryship. He was again elected to both positions in 1897.

Thoroughly efficient, energetic and progressive, Mr. Coleman has proved himself to be the right man in the right place. As manager of the road he has given the public a service that has pleased them, and in making it profitable he has pleased the stockholders. Added to his business qualifications, Mr. Coleman is personally a courteous and pleasant man. He is always ready to listen and his decisions are invariable wise and just. In business or in social circles it would be hard to find a more generally popular man than Mr. Coleman.

COLUMBIA RAILWAY CO.

The Columbia Railway Co., at present operating as a cable road, is now equipping its main line for the underground trolley system; considerable of the new construction work is already finished and the company expects to change over to the electric system by July 1st. This line starts at the Treasury Building on New York Ave, running to Ninth St., then on K St. to Seventh St., from Seventh St. to Fourth St. on Massachusetts Ave. and thence to 15th St. and Florida Ave., N. E. This line measures 2.8 miles, all double track. From the Florida Ave. terminus, where the power house is situated, a new suburban extension is being built, which extends to the east corner of the District, a distance of 4.2 miles. This is also a double track road and is being equipped with a double overhead trolley system, which was made necessary by the company's charter, which prohibits the use of a ground circuit. The new extension is being laid with 85-lb. T-rail of the American Society of Civil Engineer's section, on cross ties with stone ballast.

The power house, which is now undergoing a complete change, will contain two Allis tandem compound condensing engines, 22 and 42 x 42 in., running at a speed of 90 r. p. m., and rated at 750 h. p. each. These engines will be direct connected to two 525-kw. 10-pole General Electric generators. Two Worthington jet condensers will be used in this plant and six water tube boilers are being installed in three batteries of two boilers each. The Q. & C. oiling system will be used in this station.

The underground system of this company, and in fact, all the city lines, is in all essential points identical with that of the Metropolitan. In changing from the overhead to the underground system the company has procured a new device which will avoid all delay at this point. The device is a kind of automatic plow carriage which is fixed under the car. When the end of the overhead line is reached the overhead trolley is pulled down and the carriage automatically picks up an underground plow placed in the slot, without making any stop.

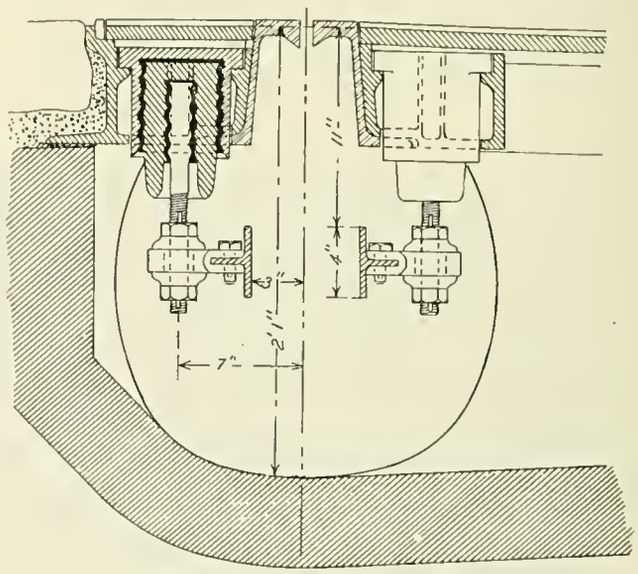

FIG. 15—INSULATOR AND RAILS.

The company has in all 52 cars for both lines. The new open cars for the suburban line, which have just been received, were built by the American Car Co., and are being

mounted on Brill double trucks. They are 42 ft. long over all and seat 44 passengers. They are built with leather cross seats and have a center aisle with twin doors. The cars are built without side steps and brass rails are fixed along the sides to compel the use of the platforms for entering and leaving the cars. These cars are each equipped with four G. E. 1,000 motors, and they all have Van Dorn couplers for running the cars in trains.

The officers of the Columbia Railway Co. are: Nathaniel Wilson, president; E. G. Davis, vice-president, and Theodore J. King, secretary, treasurer, superintendent and chief engineer of construction.

CITY & SUBURBAN RAILWAY OF WASHINGTON.

The City & Suburban lines, which will soon be a part of the Washington Traction & Electric, comprise four divisions, much of which is still in course of construction. First comes the East Washington division starting at 13th and D Sts., N. E., and running through the city east and west to the Treasury Department, at 15th and G Sts., N. W. Second is the New York Ave. division, which starts from the Pennsylvania Depot at Seventh and B Sts., passes through the city out New York Ave., to Brookland, running through Eckington, and is the only line in the city running to the Catholic University of America, and the Soldiers' Home. The third division is the North Capitol St. line which intersects the East Washington division at First and G Sts., N. W. It then runs out North Capitol St. to the Soldiers' Home and over the tracks of the New York Ave. division to Brookland. The fourth division, called the Maryland division, runs over the East Washington division from 15th and G Sts., N. W., to Fifth and G Sts., N. W., thence over the New York Ave. division to Rhode Island Ave. and out Rhode Island Ave. to the district line. From this point the line runs into Maryland, passing through Highlands, Hyattsville, Riverdale, College Park and Cakeland to Berwyn Heights, which is the present terminus of the road, although the company contemplates the early extension of this line to Laurel, a village situated half way between Washington and Baltimore. On the completion of its lines the company will have 36 miles of track in operation, that part within the city being on the underground trolley system, and the suburban lines on the overhead trolley system.

The underground construction of this company is essentially the same as that described above, except that some of the iron work is a little heavier. The track rails, made by the Lorain Steel Co., are 95-lb. girders, No. 216, and the conductor rails are stiffened by two webs on the back of the flange. The cables used are the lead covered, paper insulated cables of the National Conduit & Cable Co. The ducts are the iron cement lined ducts manufactured by the same company.

The suburban parts of the lines are particularly well built, as shown by the illustration, Fig. 17, which gives a view on the Maryland division just beyond the district line. On this division a speed of 40 miles per hour is attained in order to compete with the steam railroad service which it parallels. On this section a 95-lb. T-rail is used, laid on ties 8 in. square, with 8 in. of stone ballast below the ties and 8 in. between them. Center poles of iron are used, which carry a No. 0000 trolley wire. The rails are bonded with "Protected" rail bonds, the terminals of which were compressed in the rail webs under hydraulic pressure of 30 tons, which is the new method of the Protected Rail Bond Co.

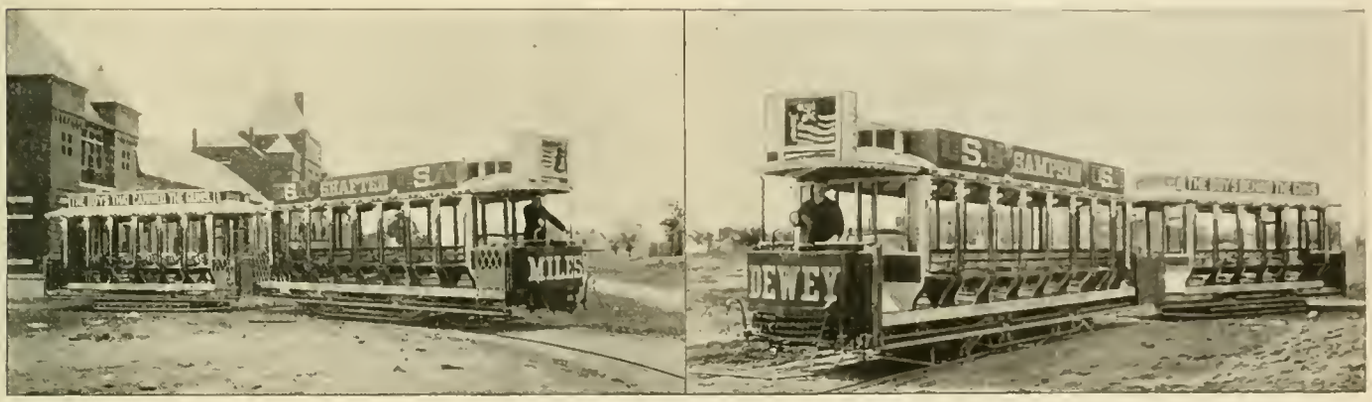

FIG. 16—METROPOLITAN TRAINS DECORATED FOR THE PEACE JUBILEE.

The company will operate 75 cars altogether. Of these 20 are short cars with single trucks and 10 are combination cars with Peckham maximum traction trucks. There are also 30 Laclede cars with 28-ft. bodies on Laclede double trucks as shown in Fig. 18. These have a center aisle with cross seats and are upholstered in plush. Ten closed vestibule cars have center aisles and cross seats and contain a separate smoking compartment, and the remaining five cars are open cars with 28 ft. bodies. The cars are all equipped with Westinghouse No. 49 motors, two on each city car and four on each suburban car; electric headlights, International double registers, Peckham trucks with 33-in. wheels and Parmenter fenders and wheel guards. Each car is also equipped with both an overhead trolley and an underground contact plow, and carries a changing switch used in changing form the metallic circuit to the grounded circuit or vice versa. On the City & Suburban the entire system is equipped with "International" registers which have given excellent satisfaction.

The City & Suburban Co. has no power house of its own, but purchases its current from the Potomac Electric Power Co., whose station is at 33d and K Sts., N. W. A two-phase current is delivered at a tension of 6,500 volts to three transformer station upon the line of the railway, one being located in the city in Washington St., one at Eckington

and one at Hyattsville. The Washington St. transformer station contains three 300-kw. rotary transformers of Westinghouse make, and the other two stations contain one each of the same units. At these points the 6,500-volt biphase current is transformed down to 600 volts direct current for use on the line. The transformer stations are not yet finished, although the machinery has been in operation for about three weeks under temporary wooden shelters. The first car on this road started on the East Washington division and the Maryland division on May 27th. The remainder of this company's lines are being rapidly pushed to completion. The officers of the company are:

FIG. 17—VIEW ON CITY & SUBURBAN LINE.

T. J. Hayward, president; W. Kelsey Schoepf, vice-president and engineer; R. I. Todd, superintendent and electrical engineer; S. C. Cooper, treasurer; Dana Stevens, secretary, and W. A. Heindle, principal assistant engineer.

BRIGHTWOOD RAILWAY CO. AND WASHINGTON, WOODSIDE & FOREST GLEN RAILWAY.

The Brightwood Ry. runs from the city line at Florida Ave. to the district line, a distance of 3.84 miles, and is a double track road with single overhead trolley construction. It has two short branches, one running to the Rock Creek Cemetery and the other, which is half a mile in length, runs to Tacoma. At the district line, where the Brightwood road ends, the Washington, Woodside & Forest Glen Ry. commences and runs out to Forest Glen, a distance of 4.11 miles. These two companies operate together 11 motor cars and 3 trailers, those on the Brightwood road running under 10-minute headway, and on the Forest Glen road under 15-minute headway. Since the purchase of these roads by the syndicate the old power plant has been discarded and they now run on a converting plant supplied with a 6,500-volt current from the Potomac Electric Power Co. This current is transformed down to 600 volts direct current by two General Electric rotary transformers of 150 kw. capacity each. Both of these roads are to be entirely reconstructed and equipped with new material and apparatus throughout.

GEORGETOWN & TENALLYTOWN RAILWAY CO. AND WASHINGTON & ROCKVILLE RY.

The Georgetown line, which is an old single overhead trolley line, starts at 32d and M Sts., N. W., and runs to the district line over 32d St., Wisconsin Ave. and the Tenallytown road, and continues to Bethseda Park; an extension of this line runs to Glen Echo and Cabin John Bridge. The road is about seven miles long to Bethseda Park, and the branch from the district line to Cabin John Bridge is five miles long. Both lines have double tracks throughout.

The Washington & Rockville road will extend from Bethseda Park to Rockville, a distance of seven miles. This road is not yet built, but its route is now being surveyed.

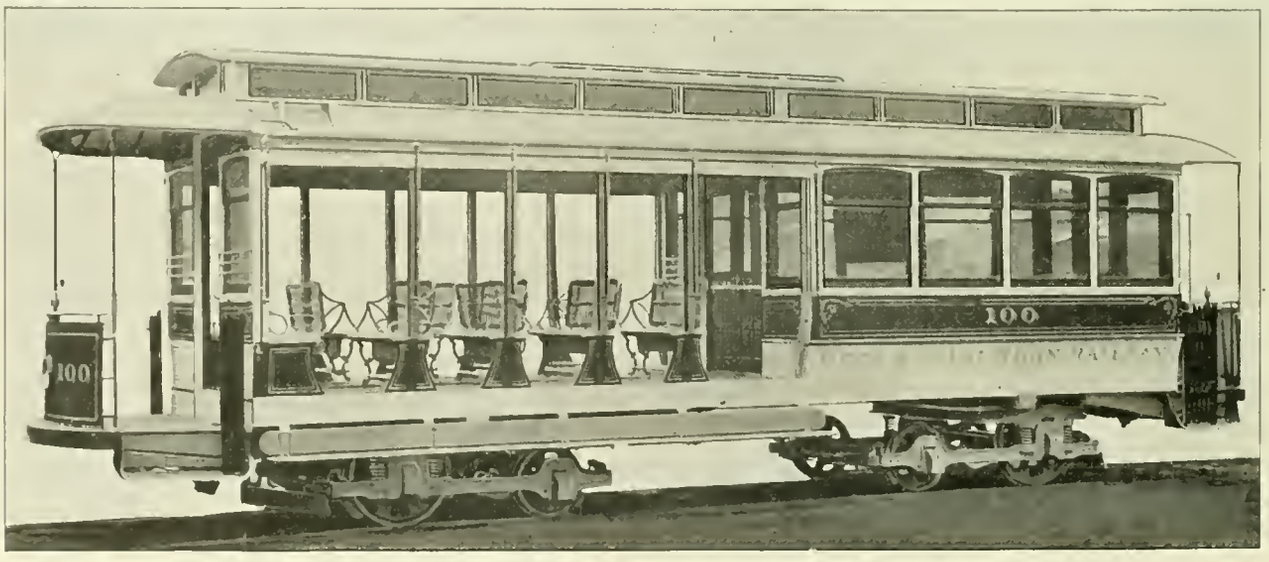

FIG. 18—LACLEDE CAR ON CITY & SUBURBAN LINE.

The Georgetown line has at present 21 motor cars, 15 with single trucks and 6 with double trucks. Part of the cars are equipped with G. E. 1000 motors and the others with Westinghouse 12 A motors. Six cars operate from 32d and M Sts. to the district line and three cars from this point to Bethseda Park. This road is supplied by a direct 500-volt current from the Potomac Co., whose station is very close to this line. On the Glen Echo branch of this road there is a small power house containing two Westing-

house 60-kw. dynamos driven by a Westinghouse upright compound engine of 100 h. p., and a 200-kw. General Electric generator run by a 350-h. p. Westinghouse upright compound engine. In case of a heavy load this station current is thrown onto the line in parallel with the Potomac current. This whole system, like all the suburban lines, is to be entirely discarded and rebuilt.

THE WASHINGTON & GREAT FALLS RAILWAY CO.

This line starts at the Union Depot, 36th and Prospect Sts., N. W., and runs to Cabin John Bridge, a distance of 8 miles, of which 5½ miles is a double track and 2½ miles a single track. This road does not pass through any streets as it owns its own private right of way over the whole route. It passes through Glen Echo and intersects the Georgetown & Tenallytown line about one mile from Cabin John Bridge. The road is to be entirely reconstructed and will be made a double track over its whole length. It operates at present 12 motor cars and 8 trailers, and it is supplied with a direct 500-volt current from the Potomac Electric Power Co.

THE CAPITOL RAILWAY CO.

The Capitol Ry. is a short road running from the Navy Yard to Congress Heights, a distance of about 2¾ miles, of which 1 mile is double track and 1¾ miles single track. This line, though short, has a large variety of motive powers. First comes a horse line and next an underground system, with surface contacts of iron raised a little above the pavements every 10 ft.; then comes a bridge with double overhead trolley wires carrying a trolley upon them from which a flexible cord depends to be attached to the cars, and finally a single overhead trolley completes the list. Only the horses and the single trolley system are now in use, there being three horse cars and three trolley cars now in operation. The trolley cars are equipped with Steel Motor Co. car motors on du Pont trucks.

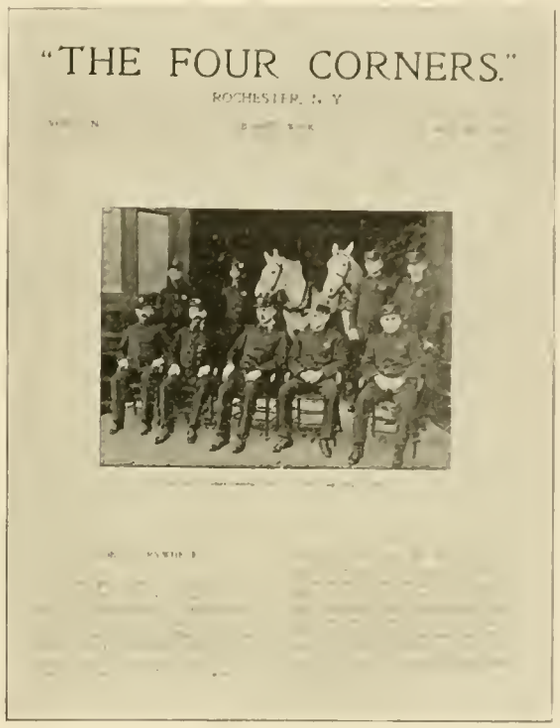
This company supplies its own current from a power house which is altogether out of proportion to the size of the road. It contains two engines of the Columbus Iron Works, one of 350 h. p. and one of 150 h. p. The large engine is coupled direct to a 200-kw. Siemens & Halske generator and the small engine is belted to a 100-kw. dynamo of the same make. Two Wickes Brothers return tubular boilers rated at 80 h. p. each and a Worthington feed pump complete the station equipment. The road is to be rebuilt and run from the plant of the Potomac Electric Power Co.

THE ANACOSTIA & POTOMAC RIVER RAILROAD CO.

The only remaining lines of the consolidated system are the Anacostia and Belt lines, these two companies having been consolidated some time previous to their purchase by the syndicate. The Belt line runs mainly in the city, while the Anacostia road is a suburban route. Both are old horse car lines and present no features of interest at present, as both lines are to be torn up and rebuilt with the underground trolley system inside the city limits and with the overhead system in the suburbs. Their power will be supplied from the Potomac Co.

ROCHESTER RAILWAY'S WEEKLY PUBLICATION.

The article in the April "Review" suggesting a plan by means of which the street railway company may effectually and cheaply reach its patrons, has already been adopted in Rochester, N. Y. Gen. Mgr. Nichols has been the first to put the scheme into effect, and the result is an extremely neat and inviting little sheet of four pages, which, by its miniature size, if nothing else, will instantly attract the attention of readers. The pages are each 7 x 9 in. with two columns to the page. The front page of the first issue is devoted to a sketch of one of the crack companies of the fire department, with a fine half tone of the men and horses.



"THE FOUR CORNERS."
ROCHESTER, N. Y.

ORGAN OF THE ROCHESTER N. Y. RAILWAY CO.

The remaining pages are devoted to announcements, time tables, and advertisements. An interesting feature is the "kickers' column." The publication is called "The Four Corners," and is published weekly and distributed on the cars.

Mr. Nichols writes us that the paper is a great success and that it must be increased in size or issued oftener.

ANOTHER FRAUD.

Last month a 16-year-old boy was arrested while selling tickets for the street car lines of the Birmingham (Ala.) Railway & Electric Co., at the rate of three for 10 cents. The tickets sold proved to be old tickets which had been pasted together. It had been the custom to destroy used tickets by tearing them in two and then throwing them into the trash box. There the pieces of tickets were rescued, pasted together and put on the market at bargain counter prices.

The employes of the Toledo (O.) Traction Co. were notified on May 20th of an increase in wages of 5 per cent.

THE GRAB-HANDLE MAN.

Mr. Benjamin J. Weeks, superintendent of the Quincy & Boston Street Railway Co., writes us from Quincy, Mass., under date of June 7th:

"Enclosed please find clipping from the Quincy Daily Ledger, of June 6, 1899, which will explain itself. This man is the original grab-handle man that was described in your paper September, 1897, and was identified from the cut in your paper. He has changed in appearance somewhat since that time and now wears glasses, and does not wear a beard."

The clipping is as follows:

Grabhandle man John Deitz, otherwise known as Shultz and Zimmerman, the grab-handle man who operated extensively among the street railways of the state and defrauded them out of various sums, was given a hearing before Judge Humphrey, in the District Court this morning, for obtaining $25 from the Quincy & Boston Street Ry. by false pretenses.

Superintendent Weeks testified that Deitz claimed to have fallen from a Houghs Neck car in October, 1898, by a grab handle coming off as he was about to alight from the car. He said he lived on Quincy Ave., and claimed to be badly injured.

Dr. Jones examined the man's injuries and was convinced that he was a fraud, but the company paid the fellow $25 rather than have a law suit, as there was some question as to the liability.

Conductor Dunham, Executive Clerk Gardner, of the company, and Claim Agent McAloon identified the fellow. Mr. McAloon also said he had examined the car after the accident, and he had gone to every house on Quincy Ave. but could find no one by that name.

Mr. Tarbox, of the Lynn & Boston, identified Dietz as the man to whom he had paid $40 to settle a claim for a similar accident. Mr. Snow, a conductor on the South Framingham road, also identified the fellow as having been the one who fell from his car last year by the grab handle coming off, and Mr. Sullivan, of the South Middlesex road, identified the fellow as the one who tried to work his road. He had identified him, however, by a photograph, and refused to pay, but had him arrested and sent to jail for six months for vagrancy.

Deitz remained mum during the hearing, and all he would say was that he did not understand. He evidently understood the sentence of nine months in the house of correction, for when it was pronounced by the clerk, Deitz murmured, "I am getting all my money's worth."

The method of Deitz, "or whatever his name may be," was to board a car and when the conductor was not looking to unscrew the nuts of the grab handle. He would then, when the conductor was forward, signal the car to stop, and as it slowed down would jump off with the grab handle in his hand and fall down. He would then claim damages, and in most cases the roads would settle rather than have a suit.

The "Review" has had occasion to make mention of the grab-handle man in four previous issues: September, 1897, page 559; August, 1898, page 583; December, 1898, page 852; January, 1899, page 3. In our issue of January last was noted the sentence of six months in the reformatory imposed upon this man for vagrancy at the prosecution of the South Middlesex Street Railway Co., of South Framingham, Mass. At that time it was stated that the Quincy & Boston would probably prosecute Dietz when his sentence had expired.

We trust that the Lynn & Boston will meet Dietz when his term has expired.

ANOTHER THEFT OF COPPER.

The Fair Haven & Westville Railroad Co., New Haven, Conn., recently suffered the loss of 700 ft. of insulated feeder wire. Current was on the line at the time, and the thieves were evidently sufficiently skilled in the art and well enough equipped with tools to escape injury.

CHICAGO UNION TRACTION CO.

The consolidation of the North and the West Chicago Street Railroad Cos., to which brief reference was made last month, is now so nearly completed that it is almost safe to speak of it as a fact. The Chicago Union Traction Co. has been organized with a capital stock of $32,000,000; of this $12,000,000 is preferred. This company has leased the property of the North Chicago and the West Chicago, the stockholders of these companies having approved the leases on June 2d. The rentals are to be equivalent to 12 per cent on North Chicago stock which is $237,600 each quarter, and to 6 per cent on West Chicago stock which is $197,835 each quarter.

To secure the payment of these rentals $10,000,000 of the stocks of the two companies which the Chicago Traction buys from Mr. Yerkes and $2,000,000 in cash will be deposited with the Illinois Trust & Savings Bank. Mr. Yerkes receives $9,000,000 cash, $1,000,000 preferred and $500,000 common stock of the Union Traction.

At the meeting of the North Chicago Street Railroad Co. Mr. Yerkes explained the situation; in substance he said:

The Chicago Union Traction Co. has made a proposition to the North Chicago Street Railroad Co. to lease its property for a long term of years and to pay the North Chicago stockholders a dividend of 12 per cent a year. The lease provides that there shall be placed in trust as security for this lease, and for that from the West Chicago Street Railroad Co., securities of those companies of the value of $10,000,000. The Traction company will also have $2,000,000 in cash, which will be used for improvements and extensions of the systems and whatever other matters are necessary for extending the street railroad properties. So there will be really $12,000,000 behind the leases. The Traction company will have a capital of $12,000,000 preferred and $20,000,000 common stock, and the preferred stock will be paid for at par, the proceeds being this $12,000,000 spoken of. It is provided that the $10,0000,000 of securities shall remain in trust for all time as security for these leases. The trust agreement provides that if there be default in the guaranteed dividend at any time so much of this deposited stock as necessary may be sold to make up the deficit. The leases to be authorized today will not be turned over to the Traction company until it deposits the $10,000,000 of securities, raise the $2,000,000 of cash and in all respects comply with the bargain.

The lease of the North Chicago is dated June 1, 1899, and is to be of force so long as the grantor company shall have any charter rights. An abstract of the lease is as follows:

First, that the North Chicago sells and transfers to the Traction a certain lease dated May, 1886, from the North Chicago City Railway Co. to the North Chicago Street Railroad Co., the Traction in all respects assuming the place of the North Chicago Street Railroad Co. under said lease. Second, that the North Chicago grants and leases to the Traction all its lines of street railroad, as the same now are or as they may be constructed, and all personal property, real estate, rights and privileges, for the term above mentioned, including the 2,501 shares of stock of the North Chicago City Railway Co., subject to the mortgage of $1,500,000 secured on same. The Traction has the right to vote this stock. The Traction may sell any real estate of the North Chicago Street Railroad Co. or of the North Chicago City Railway Co., the proceeds arising from such sale to be put in trust and to be expended for other real estate or to be applied to payment of the indebtedness of the corporation whose real estate is sold. Third, the Traction shall operate the street railroad lines and equipment and keep all property in good repair and condition, delivering the same at the end

of the lease in as good condition as when it was taken over, ordinary wear and tear excepted. Fourth, the personal and real property of the railroad company shall be appraised by two appraisers, one appointed by each party, and an inventory filed. The rental shall be $237,600, to be paid on the first days of July, October, January and April in each year, beginning July 1, 1899, also the cost of maintaining the corporate existence of the grantor, not to exceed $3,000 a year, and the payments to the North Chicago City Ry. under the old lease. The railroad company agrees to renew at maturity its outstanding indebtedness at request of the Traction. The West Chicago lease is in the same form. It transfers to the Traction the old Chicago West Division and Passenger Railway leases, and provides for a rental to the West Chicago of $197,835, to be paid the 20th day of each August, November, February and May, beginning Aug. 20, 1899.

The outstanding capital stock of the North Chicago is $7,920,000; outstanding bonds amount to $7,431,000; it guarantees bonds of the North Chicago Electric, Chicago Electric Transit, North Side Electric and Evanston Electric companies to the amount of $1,228,000 but as all these lines earn their interest the guarantee imposes no burden on the North Chicago. In 1898 the fixed charges of the North Chicago were $543,666. It owns and operates 94.33 miles of track of which 75.27 are electric and 18.12 cable. Gross receipts for 1898 were $3,015,323 and operating expenses $1,390,681; the surplus for the year was $210,019, after paying 12 per cent on the stock.

The outstanding stock of the West Chicago is $13,189,000; outstanding bonds, $18,168,000; the company guarantees $3,058,000 of the bonds of the Cicero & Proviso, Ogden Street, Chicago & Jefferson Urban Transit, Chicago Electric, Transit and North Chicago Electric, which however impose no burdens. In 1898 its fixed charges were $1,198,000. It owns and operates 202.70 miles of track, of which 165.68 are electric and 30.42 cable. Gross receipts for 1898 were $4,031,903 and operating expenses $2,017,946; the surplus for the year was $24,617 after paying 6 per cent dividend.

Notwithstanding the various statements current to the effect that Mr. Yerkes has disposed of all of his Chicago railway properties he still retains his interests in the Chicago Consolidated Traction Co. and in the Lake Street, the Union, and the Northwestern Elevated roads, which together with the holdings of his personal friends and business allies give him control of these properties. It is stated that the near future may see a combination including all the elevated and surface lines in Chicago and vicinity.

Such a complete consolidation was the ambition of Mr. Yerkes; that he was not able to accomplish it is for the most part due to the fact that he has had to fight the municipal authorities to secure every improvement he has made.

It is understood that the stockholders of the Chicago City Ry. placed so high a valuation on their holdings that the attempt to include the south side system in the Union Traction consolidation was abandoned for that reason.

April 26th W. F. Ryan, of Peoria, purchased the People's Street Ry., of Chillicothe, Ill., and on the same date sold the rails, etc., for scrap. The original cost of the property was $13,000; it sold for $800. The company had but two prosperous years, 1892 and 1893, and abandoned operations last fall.

W. F. KELLY GOES TO NEW YORK.

Mr. W. F. Kelly, who for seven years has been general superintendent of the Columbus (O.) Street Railway Co., resigned that position on May 19th to go with the Emerson McMillin Co., of New York. Mr. Kelly has long been associated with Mr. McMillin in his various street railway interests.

W. F. KELLY.

Mr. Kelly is an Ohio man by birth. He graduated from the Ohio Wesleyan University, and was a teacher for several years; he was admitted to the bar and has done considerable legal work. He learned the practical side of street railway operation as an employe of the Thomson-Houston Co., and went to Columbus in 1891 as electrical engineer for the Columbus Consolidated Street Railway Co.

At the time of the reorganization of the company in June, 1892, he became general superintendent of the whole system, a position which he has filled to the present time. He has always continued to discharge the duties of electrical engineer in addition to keeping a general supervision of the business interests of the road.

It is largely due to the efforts of Mr. Kelly that the employes of the road have been brought up to their present high standard of temperance, morality and efficiency. He has made the men feel that he is interested in their welfare and has been largely instrumental in bringing about the good discipline of the employes and their pleasant relations with their employers. He has already done away with the practice of securing positions for men for political reasons. The employes of the company are appointed and retained for their merit alone.

Mr. Kelly's business associates and his many friends in Columbus greatly regret that he is to leave them, but join in wishing him continued success in a larger field.

MUNICIPAL STREET RAILWAY FOR CONNECTICUT.

The very important question of the municipal ownership of the street railways has been agitating the citizens and the Aldermen of New Haven, Conn. The matter finally reached a stage where a vote was taken on the report of the council committee appointed to inquire "into the feasibility of the municipal ownership of public franchises," and the minority report favoring such ownership won the day.

This committee went into the subject extensively and the report was very exhaustive. One plan adopted by the committee had been the holding of public meetings to which the citizens were invited. The minority claimed that the meetings were largely attended and that the audiences were exceedingly enthusiastic in showing their preference for such a plan. The report of the majority was directly in opposition to this, but the Council, with only three dissenting votes, adopted the minority report.

The Montreal (Que.) Street Railway Co. is building 100 open cars of new and handsome design and new lines are being opened and old ones improved all over the city.

DEATH OF ROBERT GILLHAM.

Mr. Robert Gilham, general manager of the Kansas City, Pittsburg & Gulf R. R., died at Kansas City, Mo., May 19th. Mr. Gillham had been ill for only a short time with pneumonia.

While Mr. Gillham was connected with a steam road when he died, his energy, during his busy life, has been almost entirely directed toward street railway interests. He was born in New York City Sept. 25, 1854, and during his earlier school days showed a strong inclination for the profession of civil engineering. He completed his studies for this career at the Classical and Mathematical Institute at Hackensack, N. J., and in 1874 began practice in that city.

In 1876 he went to Kansas City, where he built the Kansas City Cable Ry., which included the steep incline up the bluff to the Union Depot. Mr. Gillham was not only the engineer of this system, but he was the financier as well, and secured all the money necessary to build the road. He

ROBERT GILLHAM.

also built the Kansas City Elevated Ry., was the chief engineer of the company and was elected its vice-president. He also raised the funds for and built the Eight St. tunnel, which was completed in May, 1888.

But Kansas City was not the only place which has had the benefit of Mr. Gillham's energy and abilities. He built the Omaha cable system, the 16th and Lorimer St. viaducts and the Denver Cable Ry., in Denver, Col. In the East he built the Montague Street Cable Ry., at Brooklyn, N. Y., and the Cleveland Cable Ry., at Cleveland, O.

In 1893 he returned to Missouri, and accepted the position of vice-president of the Kansas City Elevated Ry. and was instrumental in bringing about the consolidation of that system with the Metropolitan Street Railway Co. In 1894 he took the receivership of the Northeast Street Railway Co. and put the property on a paying basis in about two years.

In 1895 he began his connection with steam roads. He was appointed the chief engineer of the Kansas City, Pittsburg & Gulf, and had charge of the construction of this road from Kansas City to Port Arthur, Tex., 787 miles, and in 1897 was made general manager of the system, including the Omaha, Kansas City & Eastern, Omaha & St. Louis, Kansas City & Northern Connecting, Kansas City Suburban Belt and Kansas City & Independence Air Line. He was also chief engineer of all these roads. He constructed the Port Arthur ship canal and had charge of all the terminal and harbor improvements at Port Arthur.

When the Gulf road got into trouble, some time ago, Mr. Gillham stood by it and in April, 1899, was appointed receiver. He resigned this position, however, but still, at the request of the new receiver, retained the office of general manager.

Robert Gillham's has been a very active life. He became much interested in compressed air and at one time he was sent to Europe to make some extensive technical tests, one result of which has been a valuable addition to the literature on this interesting subject.

The funeral was held on Sunday, May 21st, and was observed in an unusual manner. When the casket was carried from Mr. Gillham's late residence an operator stationed there notified the chief dispatcher's office and orders were given to hold every train on the entire system from Illinois to the Gulf until the late general manager should have been laid in his grave. For an hour not a wheel turned on the Kansas City, Pittsburg & Gulf road. No greater mark of respect was ever paid to one of its officers by the owners of a railroad.

IMPROVEMENTS IN DAVENPORT.

General Manager Lardner, of the Tri-City Railway Co., Davenport, Ia., has been authorized to make some extensive improvements. He will make an addition to the present shop and car storage facilities in Davenport at a cost of $15,000. The new building will be two stories high and 65 x 150 ft. in area, and will give the company a frontage on Rock Island St. of 320 ft. with a depth of 150 ft.; this will afford ample room for all probable developments of the road for several years. New machinery will be put in the new shop.

The recent purchase of the rolling stock of the Moline Central lines made this addition imperative. Mr. Lardner will also buy a new engine and dynamo, so that the capacity of the power-house will be greatly increased. It is the purpose of the company to equip all its cars with electric heaters.

CHICAGO LAND DAMAGE CASE.

Judge Bishop, of the Cook County Circuit Court, Chicago, on May 8th rendered a decision in favor of the Lake Street "L" road and against the Chicago Office Building Co. which may prove to be of great importance. The Office Building Co. brought suit for damages it claimed resulted from the construction of the road alongside its building. The road demurred on the ground that where the fee to a street is in the city which permits a railway company to use that street and the use is not inconsistent with the purposes of such a street, an abutting property owner cannot recover damages. Judge Bishop sustained the demurrer, and if the decision is upheld by the Supreme Court it will defeat all pending suits for damages on account of the erection of elevated roads and all which are in contemplation.

NEW ROAD IN NEW JERSEY.

The Trenton, Lawrenceville & Princeton (N. J.) Railroad Co., J. L. Branson, of Langhorne, Pa., president, will, it is expected, be in running order by July 1st. Work has already commenced and will be pushed forward as rapidly as possible.

This new road bids fair to become very popular. It is ten miles from Trenton to Princeton and Lawrenceville lies half way between these towns. The company is incorporated under the general railroad laws of New Jersey, and not as a traction or street railway company. It owns its own right of way and can use either steam or electricity as its motive power. The tracks are to be the standard gage and if desirable, freight cars can be transferred from steam roads.

The population of Trenton is 70,000; of Lawrenceville 1,000, and of Princeton 6,000. Besides this there may be estimated as living along the line about 3,000 people. With Trenton as a great market and commercial point and Princeton, famous for its educational institutions, this road is much needed and cannot fail to receive paying patronage from the start.

A TROLLEY TRIP FROM BOSTON TO NEW YORK.

BY ROBERT H. DERRAH.

Not very long ago, stimulated by the rapid development of high power electric locomotives, some enthusiast predicted that the day would soon come when trains would run from Boston to New York, at high speed, over the hills and valleys, regardless of grades, carrying passengers between these points. That time has not yet come, but there are signs that the dream of the past may become a realization in the not remote future. The writer has proved that it is possible to go from Boston to New York, with the exception of a few gaps, all the way by electric car, and even now arrangements are under way for the filling of these gaps. The total distance is 261 miles, 209 of which are covered by trolley, and the time consumed in making the trip is less than twenty and one-half hours. In the trip I made, 9 miles were covered by carriage and 43 miles by steam train, and including $2 for the carriage and 91 cents for steam railroad fares, the total cost of transportation was $5.71.

CULVERT CROSSING, ST. CHARLES STREET R. R., NEW ORLEANS.

NOVEL CULVERT CROSSING.

The accompanying engraving from a photograph taken on the lines of the St. Charles Street Railroad Co., of New Orleans, is interesting as showing the wood paving used on all except the main streets, and also a novel culvert crossing. The drainage of New Orleans being on the surface the depth of crossings over the gutters has been limited to 5 in. in order not to interfere with the flow. The company is laying some 9-in. girder rails and at culverts it is necessary to cut away the lower flange and 4 in. of the web, and rivet angles to the web as shown in the illustration.

The United Railways & Electric Co., Baltimore, Md., has paid a dividend of one-half of one per cent on its income bonds and preferred stock for the three months ending May 31st. The amount paid out was $70,000.

Even to one familiar with the street railway developments in New England, the trip to New York by trolley was something of a revelation. Bearing in mind that of the 209 miles covered by trolley fully 180 miles are in the country, and less than 30 miles in city streets, the reader will come to a realization of how important a factor the electric railway has come to be in our New England country life. It has wrought a great change in the habits and life of the people. The country farms have been robbed of their isolation, the trip to the nearest large town is no longer a matter of taking a "day off" because of train connections, and the "pleasure traffic" of the people of the cities has been infinitely extended, making possible excursions into the country for people to whom such excursions had previously been a luxury.

There are only five breaks in the continuous trolley line to New York from Boston, and some of these are short.

The first is between West Warren and Indian Orchard, Mass., a distance of some 18 miles. Yet here the Palmer & Munson Street Railway Co. has obtained a franchise from its existing line at Forest Pond through to West Warren, via Ware. This company now operates a line through from Palmer to Three Rivers and Forest Pond, and when this new link is connected, it will bring the traveller from Boston some 10 miles nearer Springfield. Between Warehouse Point and East Windsor Hills, in Connecticut, is another gap of five miles and this gap is to be closed by a line now under construction. When this is completed, one may ride from Indian Orchard, through Springfield, Hartford, and New Britain to Berlin, Conn. The third break comes between Berlin and Meriden, a distance of about eight miles. Although a street railway between these points is not projected, the New York, New Haven & Hartford Co. probably will have its third rail electric system in operation

between these two points in the near future, with sufficient service to accommodate the general riding public. Petitions are now pending before the Legislature of Connecticut asking for the right to operate a line of electric cars from New Haven parallel to the tracks of the New York, New Haven & Hartford, to Wallingford, Conn. Should these petitions be granted, and the line built, there will be a continuous electric line from Meriden to Stamford, a distance of 65 miles, all connected. From Wallingford to Mount Carmel, Conn., is a break of about four miles, and in spite of the fact that this is the shortest gap in the whole line, it will probably be the last one filled, as the country traversed is one which would afford almost nothing in the way of revenue from local traffic. The last of the missing links is that between Stamford and New Rochelle, Conn., but an electric railway covering the 17 miles of this distance is likely to be constructed in the near future.

So much for what may happen. To come to actual facts, I left Park Street Station in the Boston Subway at 8.30 one Monday morning, boarding a Newton Boulevard car. After a run of 34 minutes through Boston and its aristocratic suburb of Brookline, I arrived at the city line between Newton and Boston, where connection was made with the car of the Commonwealth Avenue Street Railway Co., near at hand. After a fast ride to West Newton, a change was made to the line of the Wellesley & Boston Street Ry., which crosses the Commonwealth Avenue line without switch connection. This took me in a few minutes to Newton Lower Falls, where, at the other end of the bridge crossing the Charles River, connection was made with the Natick & Cochituate car to Natick. Thence over the line of the South Middlesex Street Railway Co. I went on to South Framingham, crossing over the steam railroad track. Thus far most of the country traversed had been urban or suburban in character, but after leaving South Framingham the car of the Framingham Union Street Railway Co. carried me into a region distinctly rural—a country of farms and small rural villages, all the way from here to the central city of Massachusetts. The car of the Framingham Union Street Ry. runs to Framingham Center, where connections are made with the Marlboro Street Railway Co. to Marlboro. A through line will be run from South Framingham to Marlboro this summer, shortening the journey somewhat. Here a change is made to the cars of the Worcester & Marlboro Street Ry. to Worcester, which city I reached at 1 o'clock, arriving in time for luncheon.

Resuming the journey on the 1:45 p. m. car of the Worcester & Suburban Street Ry., a run was made to the town of Spencer, where connections were made with the Warren, Brookfield & Spencer Street Ry. for West Warren. Here came the first break in the journey by trolley, but the electric car arrived in time to allow me to take the 5:24 train on the steam railway for Indian Orchard, a distance of 18 miles. Here another electric car was boarded, and I arrived in Springfield at 6:35 p. m. over the line of

the Springfield Railway Co. The journey from here might have been continued that night, but as my desire was not especially to make record time, I remained in Springfield over night.

At 6:35 on the following morning (Tuesday), I boarded a trolley car passing through Longmeadow to the dividing line between Massachusetts and Connecticut. Here the state boundary enforced a change to the line of the Enfield & Longmeadow Street Railway Co. to Warehouse Point, Conn., a little town, where a carriage ride is forced upon the traveller. A dollar conveyed me in a carriage to Windsor Hill, although from Warehouse Point to East Windsor Hill, some four miles, the rails and ties of a street railway were scattered along the roadside and the line connecting these two points will be in operation this summer, thus saving the passenger 90 cents. At East Windsor Hill the Hartford Street Railway line is taken to Hartford, where a change is made to another line which is operated jointly by the Hartford Street Ry. and the Central Railway & Electric Cos. As for some seven miles these companies operate over a private roadway, swift time is made, giving a glimpse of the possibilities of the future electric railway between Boston and New York. The line operated runs to New Britain, 10½ miles, and here a change was made to the line of the New Britain Street Railway Co., running to Berlin, and arriving at the electric terminus there in time to take the 12:43 o'clock train for a run of eight miles. Fifteen minutes later I stopped in Meriden for luncheon, after which I took the car of the Meriden Street Railway Co. to Wallingford, about nine miles, coming to another gap in the journey. At this point, in order to make as much as possible of the journey by electric car, I took another carriage as far as Mount Carmel, some four miles, connections being made there with the electric cars of the Fair Haven & Westville Street Railway Co. for New Haven.

The New Haven & Milford electric cars run every two hours, and as, owing to an unforseen delay, I had missed the 4:15 p. m. car by about five minutes, I was obliged to remain over until the departure of the 6:15 electric car, which took me through to Bridgeport that evening. The run over this portion of the journey was one of the most delightful of the entire trip, there being occasional glimpses of Long Island Sound, while the scenery of the Connecticut Valley is of the most charming character. The country landscapes are refreshing to the city traveller, and the succession of pretty villages and old colonial houses would delight an artist.

Remaining in Bridgeport over night, on Wednesday morning I took an early car for Westport, still following the coast, where connections were made with the cars of the Norwalk Tramway Co. (The trip from Westport to Stamford was made in a special car of the Norwalk Tramway Co., which met Mr. Derrah and his companion, who represented the Boston Globe; a number of Norwalk men were guests on the special.—Ed.) taking me through to South Norwalk, and there connecting with the Stamford Street Railway line. Arriving at Stamford, I was obliged to take the steam cars again for the final break in the line, to New Rochelle, a run of 17 miles. At New Rochelle a line runs out of the town to Mount Vernon, where a change was made to the car for West Farms. At West Farms another change was made for 129th St., New York City, the distance from New Rochelle to this point being 15 miles. One cash fare was taken, and two transfers furnished. At 129th St. the Metropolitan line was taken, running to the City Hall in New York, completing the journey.

It should be borne in mind that when I took this long trip by trolley the cars were not running on the summer schedule. In the summer time many of these lines run a greater number of cars, so that it would be possible for one to make this journey in a somewhat shorter time than I consumed. In September or October, when the country is seen at its best, with the forests colored by the frosts, no more delightful trip could be imagined. It is well worth taking at any time, and one who has been unacquainted with the conditions of electric railroading in the country can have no idea of the broadening influence of such a journey. As a rule, the rolling stock of all the companies is of a high class, and the time made is generally good. On many of these roads will be found center-aisle, vestibuled cars, and the latest improved motors, while the rolling stock and roadbed are far superior to that of the average city railway of a decade ago. Ten years hence may see an equally great improvement. At least it is likely to see a continuous trolley line between Boston and New York.

The table and sketch show the mileage, rates of fare, time consumed, and the route of this trolley journey. In the table the figures give the distance, fare, and time between the station opposite the figures and the station just above it.

BOSTON TO NEW YORK BY TROLLEY.

Total	261	$5.71	20 : 29

Average fare by electric cars, 1.34 cents per mile.
Average fare by steam cars, 2.12 cents per mile.

IN THE POWER HOUSE

This department is devoted to the construction and operation of electric railway power houses. Correspondence from practical men is specially invited. Both the users and makers of power house appliances are expected to give their views and experiences on subjects within the range of the department.

In the report of the committee on the revision of the American Society of Mechanical Engineers code of 1885, relative to a standard method of conducting steam boiler trials the method recommended for measuring tube heating surface was changed from that given in the committee's preliminary report. The report submitted at the Washington meeting in May, 1899, says:

"The area of heating surface is to be computed from the surface of shells, tubes, furnaces, and fireboxes in contact with the fire or hot gases. The outside diameter of water tubes and the inside diameter of fire-tubes are to be used in the computation."

The preliminary report recommended taking the outside diameter of the tubes in all cases. The rule adopted is to be commended because it is correct and accuracy is more important than uniformity.

CALCULATING HORSE-POWER FROM INDICATOR DIAGRAMS.

April 11th, Mr. Edward F. Miller presented a paper entitled "Some Uses of the Steam Engine Indicator" before the New England Railroad Club. An extract is as follows:

"Figure 2 represents what is called a stroke card. The indicator shows the pressure on one side of the piston for a revolution. (a) When we calculate the horse-power from a card, we are assuming that the back pressure and compression line on the other side of the piston are the same as shown on the card. This may, or may not, be the case. (b) In calculating the total horse-power for the two ends of the cylinder, any error from this cause affecting the calculation for one end of the cylinder will be nearly balanced by an opposite error in the calculations for the other end, so that the final result is practically right. (c) If it were not for the piston rod making the area of one side of the piston smaller than that on the other, there would be absolutely no error arising from this.

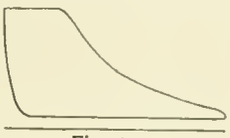

Fig. 1.

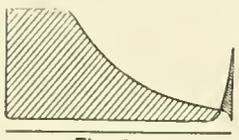

Fig. 2.

"(d) The stroke card shows the pressure on opposite sides of the piston at all points of the stroke. The difference between the lines at any point is the effective push per square inch. This card is constructed by using the steam and expansion lines of the card from one end, and the back pressure and compression lines for the same stroke from the card taken on the other end.

"In constructing this diagram for very accurate work, the ratio of the areas of the two sides of the piston have to be considered. The pressure above the atmosphere for one side being multiplied by this ratio. It will be seen that up to the point of cut-off, the difference of pressure or effective pressure is nearly constant; this difference grows less due to the drop along the expansion curve, till at the point where the two lines cross the pressure on the two sides balance. Beyond this point the pressure exerted to hold the piston back is greater than that exerted to push it ahead. The energy stored in the fly-wheel during the first part of the stroke is given out here near the end of the stroke to help the engine over the dead point."

Assuming the paper to have been correctly reported, it is surprising to find in a paper on this subject such erroneous ideas concerning one of the most common uses of the steam engine indicator. For convenience in discussion reference letters have been inserted in the extract quoted.

(a) The statement (a) is incorrect. The only assumption made when horse-power is calculated from an indicator diagram is that the diagram correctly represents the changes in pressure and volume which took place in the cylinder.

A few definitions may be of assistance here:

A horse-power is 33,000 ft. lb. of work done per minute.

Work when measured in foot-pounds is the product of force (pounds) and distance (feet), or it may be expressed as the product of the force per unit area and the volume displaced while that force is acting. From this latter conception of work we get the well-known expression: Work equals the integral (between the proper limits) of p.dv, where p is the force per unit of area acting during any short interval of time and dv the volume displaced while the force p is acting.

If the indicator diagram shows the changes in pressure and volume on one side of the piston during a revolution, then the area between the line traced during the working stroke, a line of zero pressure and two parallel straight lines joining these two, is proportional to the work done BY the steam during its working stroke, because it is proportional to the integral of p.dv. Similarly the area between the lower line traced by the indicator pencil, a line of zero pressure and two parallel end lines in proportional to the work done ON the steam during the exhaust stroke. The difference between these two areas is area of the diagram and is proportional to the net work done in that end of the cylinder during that revolution. When the area of the diagram is multiplied by the proper constants and by the number of revolutions per minute and the product divided by 33,000 ft. lb. the result is the horse-power developed in that end of the cylinder.

This result is exact, and the fact that the steam pressure on the opposite side of the piston is one of the opposing forces against which the work was done does not make the case different in principle from one where a friction brake furnishes all the resistance.

(b) Since the horse-power computed for each end is exact the statement (b) concerning compensation of errors is incorrect.

(c) For the same reasons the fact that the effective piston area is usually less on the crank end than on the head end does not introduce any error and the statement (c) is incorrect.

(d) The "stroke card," if properly drawn, shows the net force per unit area acting on the piston due to steam pressure. It gives no idea, however, of the net force or effective push on the cross-head or crank pin, because the "effective push" due to the steam together with the fly-wheel have in the early part of the stroke to accelerate, and in the latter part of the stroke to retard the reciprocating parts. While the "stroke card" is undoubtedly useful for some purposes, the calculation of horse-power is not one of them.

"KALOR."

Prof. R. C. Carpenter, of Cornell University, writes us concerning what purports to be a letter from him recommending a fuel saving compound known as "Kalor" and made by the National Fuel Compound Co., of Boston. Professor Carpenter writes in substance as follows:

"I find on referring to the testimonials that a letter of mine is published which has no reference to 'Kalor,' but did have reference to another compound, which at the time was called 'S. C. (394) Compound.' I was engaged by a disinterested third person to make a series of boiler tests in 1892 with and without the latter compound in such a manner as to determine its value, and was requested to write to a third person the results of the tests as made from time to time. The letter published is a copy of one written during the progress of the trials for information of said third person, and the tests to which it refers were those in progress at the time. It will be noted by referring to the letter that the trials quoted did show an apparent, although slight, advantage

due to using the compound. The compound was applied by putting it in solution and applying it to the coal. Mr. Wm. Kent suggested that the apparent gain might be due entirely to the dampening of the coal when applying the compound. Subsequently other trials were made, and it was found that equally as good results could be obtained by slightly dampening the coal without the use of 'S. C. (394) Compound' as with it. The final conclusions of our entire series of trials was that the compound S. C. (394) was absolutely worthless as a fuel; further, that all the gain which was caused by its use in some cases was due to the applied water or to the method of handling the fire. This final conclusion I see is not given in the testimonial.

"I know nothing in regard to 'Kalor,' nor know anything in relation to the National Fuel Compound Co., but do know that the letter in question was never written for the purpose for which it was used, and consequently that its use in such a manner must tend to deceive the public. If the compound is the same as the compound investigated in 1892 I do not hesitate to say that I believe it entirely worthless as a means of improving the calorific value of fuel."

SAFETY VALVES.

From a paper on "Steam Engineering" read before the Maritime Electrical Association by P. A. Freeman:

"Safety valves are the most delicate part of a boiler and demand constant care and watching if we wish them to work fairly accurately. My experience with spring safety valves has led me to adopt the rule that all our safety valves shall be lifted from off their seats once every 24 hours. If this is not done I find that a so-called skin forms on spring and seat, and if the valve is not lifted oftener than once a week it will take considerable more pressure to lift it than for which it was originally set. Another very serious trouble with safety valves which often occurs is the loosening of the check nut, and if this is not attended to immediately upon the indication of such troubles the steam pressure will drop and all steam escape into atmosphere, shutting down the plant. Although it at first appears difficult to the engineer or fireman to tighten the nut and set the valve properly, nevertheless if he understands his type of valve thoroughly he can accomplish it with his monkey wrench, hammer and chisel in very short space of time with perfect safety to himself and plant. If the valve should commence to blow off and steam pressure drop more than 5 lb., or if the steam pressure should at any time drop more than proper on account of the safety valve blowing off, the engineer or fireman should at once assume that the valve is out of order and must be attended to immediately. If the check nut is loose it can be remedied by turning the valve spindle to the right until the steam stops escaping, then the cap may be removed and the check nut tightened without further difficulty. The boiler pressure should be increased to the same point at which the valve blew off, and beyond, in order to make certain that the valve will blow off at the proper pressure. This point can be easily obtained by slightly turning the valve in the proper direction.

The above method of handling the safety valve is that commonly used in ordinary practice, but for close regulation the cushion seat should also be raised or lowered according to the range within which it is desired to have the safety valve act. Under no conditions should the safety valve spindle, or any of its parts be struck or hammered in order to make it close, as this is a very dangerous practice and is liable to cause more or less serious explosions. This latter precaution of mine may seem to be hardly necessary, yet in my own experience I have seen an engineer strike down on the spindle with a piece of wood 6 x 6 with the idea of causing the valve to close. Although at this time of which I speak no serious results occured, it might cause great danger the very next time it was tried.

CORNELIUS SMOKELESS FURNACE.

Mr. Frank H. Mason, U. S. consul-general at Berlin, has sent to the State Department an account of the operation of a process of burning low grade fuels without smoke patented by Mr. Paul Cornelius. Tests have been made in various plants which, it is stated, resulted in a great saving in fuel bills and the complete abatement of the smoke nuisance.

The plant at Berlin, which Mr. Mason inspected, is thus described:

The two boilers are of the ordinary flue pattern, placed side by side and their furnaces separated by a dividing wall, so that one can be thrown out of use or turned on, as occasion may require. The furnaces are about 10 by 4 ft. in area and the smoke passes by subterranean flues to a stack chimney standing in a central court and rising above the roof of the building. Near the furnaces is located an ordinary fan blower, driven by an electrical motor of ½ h. p., the speed of which is easily controlled and which drives the air through a 6-in. pipe into a hollow iron chamber about 10 in. deep, which forms the front section of the hearth of the furnaces. Into this air chamber is fitted one end of the hollow grate bars, which are about 2½ in. in diameter, extend backward the length of the furnace, and are supported by ordinary bearings at the farther end. These hollow grate bars are round on the bottom, but at the top are hexagonal, presenting three faces, each pierced with holes about 2 in. apart and beginning with a caliber of ⅛ in., which increases slightly throughout the length of the bar, to equalize the discharge of air from the gradually decreasing pressure within. The hollow grate bars are laid about 6 in. apart, and there is placed between each pair three solid triangular bars, which assist in sustaining the weight of the burning fuel. The air being forced by the fan blower into the hollow chamber, is there heated from the fire on its upper surface, then passes into the hollow grate bars and is injected upward in three rows of jets, one vertical and two inclined to right and left, so that the entire under surface of the burning mass resting on the grate is fed constantly by jets of fresh-heated air, which generate from the most ordinary grades of fuel an intense white heat, which can be perfectly controlled by regulating the speed of the fan blower and produce a combustion so natural and perfect that the smoke is entirely consumed.

PIPE FLANGES AND BOLTS.

Abstract of a paper presented before the American Society of Mechanical Engineers by A. F. Nagle, of Chicago.

There is probably no part of a steam plant which presents so untidy, so incongruous, an appearance as the exposed pipe flange joint. The engine itself is handsomely finished, and all its steam joints are steamtight and covered in a substantial manner with nonconducting material and sheet steel. But we do not get away from this finished and polished machine before we are offended by the sight of the rough, uncovered, and hot pipe flanges. Why is this unsightly practice continued? Why should not a simple little round pipe joint be made as steamtight as any part of the engine?

The pracical engineman will tell you that all these steam pipe

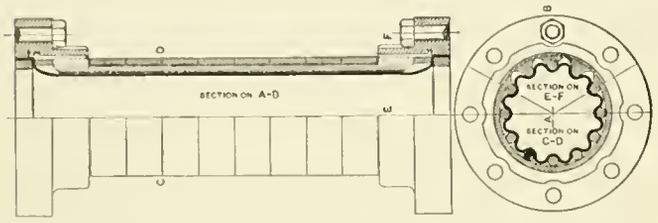

FIG. 1.

joints are liable to leak or blow out at any time, and hence he wants to have easy and quick access to them, which he would not have if they were covered. Here is a confession of a weak point in our steam engineering practice that should not be allowed to go on forever. I have given this subject considerable study of late years, and some of my conclusions I shall be glad to lay before this society.

It can scarcely be imagined that it is difficult to make a single flange joint steamtight when undisturbed by an extraneous force. The fact, however, is that in a modern large steam plant the elongations due to heat are irresistible, and provision must be made to take care of them. This is not always easy to do within the limted space at command, but it may be set down as a guiding principle that wherever possible it is better to let these expanding forces come upon torsional resistance rather than in the form of transverse stress upon the pipe and its flanges. Flexure produces a strain upon the bolted joint which it is not able to stand to any appreciable degree without opening up the joint, but torsion is easily resisted by a bolted joint to any degree even to the point of twisting the pipe to destruction, should it not possess sufficient flexibility to give the required amount of angular motion.

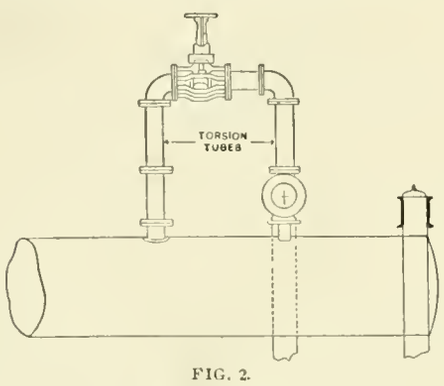

FIG. 2.

Assuming a permissible fiber stress of 10,000 lb. per sq. in. in the bolts and basing computations on the dimensions of standard Chapman fittings for steam pressures of 250 lb. it is found that the pressure which can be put on the gasket is from 168 lb. per sq. in. on a 16-in. pipe to 347 lb. per sq. in. on a 3½-in. pipe; these pressures are very small and it is quite apparent why a slight transverse stress on the piping causes plane faced flange joints to open. The pressure per square inch on the gasket is found by subtracting the steam pressure on the area of the pipe from the total permissible stress on the bolts and then dividing by the net bearing area of the full flange.

To get an increased unit pressure on the gasket the national recourse is to a tongue and groove. Similar calculations were made for the gasket pressures obtained with the dimensions of tongues and grooves now largely used which are ½ in. for 3-in. to 7-in. pipes; ⅝ in. for 8-in. and 9-in.; ¾ in. for 10-in. to 14-in.; ⅞ in. for 15-in. and 16-in.; 1 in. for 18-in. to 24-in. The gasket pressures vary from 600 lb. per sq. in. of tongue for 22-in. pipe to 2,500 lb. per sq. in. for 7-in. pipe.

The author shows that if the tongue is made 1 in. wide for all sizes of piping, the gasket pressure will vary from 755 lb. per sq. in. of tongue for 16-in. pipes to 1,360 lb. for 6-in. and 7-in. For other sizes between 3-in. and 24-in. the gasket pressure varies but little from 1,000 lb. per sq. in.

In order to carry out more completely the author's idea of relieving flange joints of all transverse stress, or flexure, and substituting, so far as possible, torsional strains therefor, he has designed a pipe construction which admits of torsional movement to a large degree without straining either the material of the tube or the flange joint to any appreciable extent. It is shown in Fig. 1 and consists of what might be termed stave construction instead of solid pipe. These staves are steel rods securely fastened to the flanges. Exterior to these staves are strong iron or steel enveloping rings. Interiorly is a thin, longitudinally corrugated copper tube also securely fastened to the end flanges. This makes a pipe which is strong in every direction but one, namely, that to resist torsion. With these flexible tubes put in in the proper manner all elongations of steam pipes should be easily taken care of and without straining any joint to a dangerous degree. See Fig. 2.

It is not intended to patent this form of pipe, and hence it can be made by any one who chooses to do so.

COST OF OPERATING ELEVATED ROADS.

Mr. B. H. Thwaite, writing on "The Influence of Electricity upon Railway Locomotion" in the current number of the Engineering Magazine, gives the following figures on the cost of operating the Liverpool Overhead Ry., the Manhattan Elevated, New York, and the Brooklyn Elevated. Though not stated, we presume the tons are long tons.

	Liverpool.	Manhattan.	Brooklyn.
Cost of coal per ton-mile.....	.020d.	.029d.	.038d
Cost of supervision per ton-mile	.014d.	.036d.	.021d.
Total operating expenses per ton-mile	.1245d.	.190d.	.152d.

UNION BOILER TUBE CLEANER.

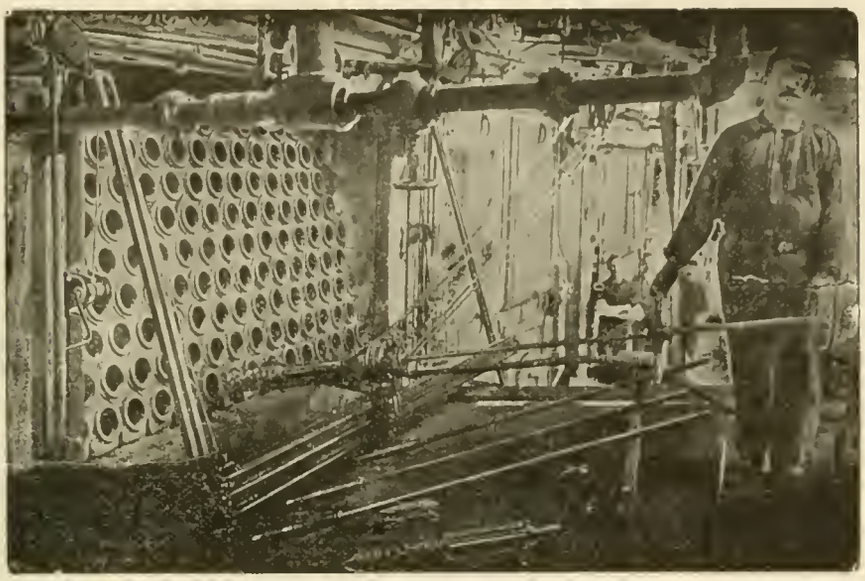
The accompanying illustration is from a photograph showing the method used by the Union Boiler Tube Cleaner Co., of Pittsburg, Pa., for cleaning horizontal straight tube boilers. A substantial platform is first erected in front of the tubes; this platform should be the full width of the boiler front and about 10 ft. long. The boiler tubes are uncapped at both ends and the doors removed; brackets are then bolted to the hinge lugs and to these is secured the cross bar that carries the driving head of the cleaning device. The power for driving is transmitted through ropes, suitable pulleys and counter weights being arranged to take up the slack. The cleaning head is rotated at from 1,200 to 2,000 r. p. m. depending on the diameter of the tube, and is kept cool by a stream of water under ordinary hydrant pressure.

The cleaning head, which is seen in the foreground, is formed of a series of discs, nine in number, one in front of another, five of which are in a progressively graduated series. One of these discs has a left-hand thread and forms a nut or binder, which, with the aid of the cone-shaped head, holds the other eight discs in place; to each of these eight discs are loosely pivoted, but restricted in motion, three arms; to each of these arms is loosely pivoted a wheel having 18 sharp points—both arms and wheels, 24 of each, are made of the best tool steel, finely tempered; the rapid rotary motion causes the arms to fly out, and consequently each successive set of cutters up to the sixth set operates in a path of larger diameter than the preceding set; the last three sets of cutters do the final cleaning out and polishing of the tube. There should be but one going through.

The feed rod is in sections fastened together with snap couplings; after each of the rods passes the driving head a movable bearing is fastened around the coupling, there being three of these bearings necessary with tubes of ordinary length.

For boilers having curved tubes a flexible shaft is used in conjunction with suitable straight shafts and gearing, the details of which depend on the design of the boiler to be cleaned. The company states that its device is applicable for cleaning all straight or curved metal tubes used in water tube boilers, economizers, condensers, etc., regardless of the nature of the incrustation.

It gives returns from horizontal straight tube boilers aggregating nearly 25,000 h. p. showing that from 5 to 61 tubes can be



UNION BOILER TUBE CLEANER.

cleaned per day of 10 hours, the average being 30 per day. The cost per tube, including repairs, labor and interest for one year on the cost of the device, was 26.3 cents; per horse-power it was 13.1 cents. These data are for the first cleaning of the boilers.

The extra fuel consumption because of the decreased conductivity of incrusted tubes is usually placed at 13 per cent for scale 1-16 in. thick, 38 per cent for ¼ in., and 60 per cent for ½-in. scale. The importance of keeping the tubes clean and the value of apparatus for doing so at small cost are therefore apparent.

THIRD AVENUE-MANHATTAN INTERCHANGE OF PASSENGERS.

The transfer ticket arrangement entered into not long ago between the Manhattan Elevated and the Third Avenue lines in New York City, has grown very popular, and as a natural consequence is a financial benefit to both roads. The officers of the Third Avenue line say that since the plan went into effect there has been an increase in the patronage of 25,000 passengers, and they figure that at the very least calculation 20,000 of that is new business. So popular has the plan become and so certain are the officials of its lasting benefits that the company intends buying 25 more cars for the route.

The officials of the elevated road are equally pleased at the result and can see an increase in business all over the city. Neither company has as yet had any official report, but it is a certainty that both roads are profiting by the arrangement.

The severe storms occurring in the vicinity of Chicago about the end of May caused much damage. The heavy rain of Sunday night, May 28th, washed out the roadbed on the Chicago & Milwaukee Electric Ry. in Wilmette, near Chicago.

The Pueblo (Col.) Electric Street Car Co. on June 1st made an advance in the wages of its employes, which means to most of them about $18 per month. This is the second increase since the consolidation of the Pueblo lines.

EVAPORATIVE CONDENSERS.

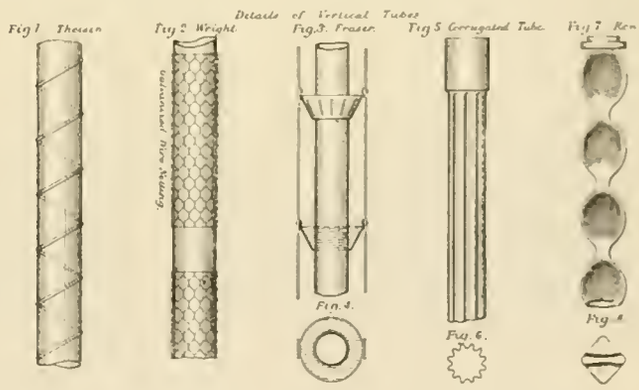
Abstract of a paper read before the Institution of Mechanical Engineers, England, by Harry G. V. Oldham.

The evaporative condenser, which is now being rapidly developed, has forced itself upon the users of large quantities of steam, and of necessity finds a place in the equipment of large generating stations for supplying light and power by electricity.

Jet and surface condensers are in many cases prohibited by reason of the large quantities of cooling water consumed, and the waste of the latter unless some method of cooling is adopted. This again, entails the apportioning of large ground space for the necessary cooling ponds and apparatus, and large steam installations have thus been compelled to work without a condenser. Inability to reduce the back pressure on the piston is also a drawback. Again, the actual amount of condensing water used when an evaporative condenser is employed may be from 25 to 30 per cent less than the amount of feed water used when the engines are non-condensing, and about one-fortieth the water supply when surface condensing.

The general principle of the condenser is simple; it consists of a large number of copper, brass, wrought or cast-iron tubes, arranged horizontally or vertically according to the type of condenser employed. The tubes are connected with chambers at each end. Through these tubes the exhaust steam is passed, and water is allowed to flow over the external surfaces. Part of the water on the external surface is being evaporated, and carried away with the heat taken from the steam. A more rapid and better result is obtained if a fan is used to remove the hot damp air.

It is well known that at such pressures as we have to deal with in the condenser the thermal units in 1 lb. of steam are about 1,000 more than in 1 lb. of water at the same temperature. Before any condensation takes place, therefore, it is necessary to withdraw this number of thermal units from the steam. The latter not only heats the circulating water as in a surface condenser, but evaporates a considerable portion of it. Each 1 lb. evaporated from the surface of the tubes takes with it about 1,000 thermal



units; and thus for each 1 lb. of steam condensed, only 1 lb. of cooling water should be required. It has, in fact, been shown by experiment that only two-thirds of this is required, a large amount of heat being dissipated by radiation, conduction, etc.

There is a tendency, when the tubes are of a large diameter and the steam passes through without taking a circuitous course, for a central core to pass through without being condensed. It is therefore desirable to stir up the steam, so that the condensation may be more rapid and effective. Internal steam distribution has been provided for by Mr. Row, who uses a design with interesting results in exhaust steam heaters, etc. The principle will be seen from the diagram in Figs. 7 and 8. The exhaust steam on its passage through the tube impinges against one indented surface and

is thrown off on to another, being thus split up so as to bring all parts of the steam in contact with the tubes. In providing for internal steam distribution, Mr. Wright places a tube of small diameter inside the one upon which the film of water flows. This does not break up the steam, but eliminates the uncondensed core and utilizes the largest surface of the tube area. Messrs. John Fraser & Son have devised a series of internal spiral distributors,

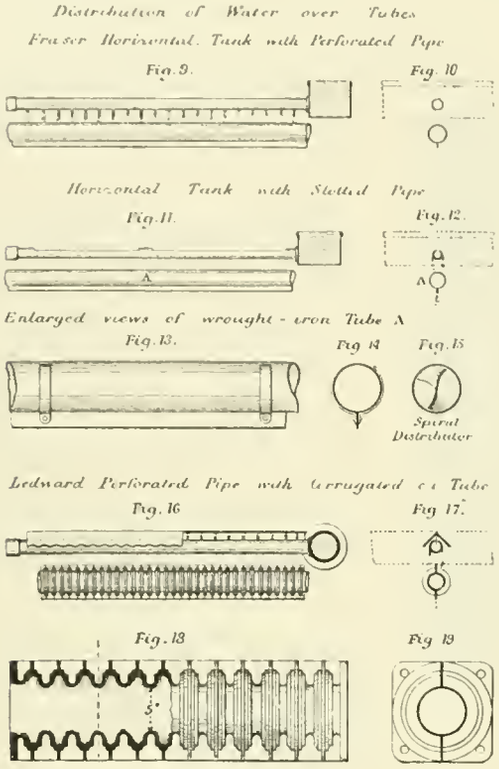


Fig. 15, which they place inside the tubes. These distributors, being very thin, do not in any way contract the area through the tubes or impede the flow of exhaust steam. The vapor on entering the tubes is split in two portions by the action of the spiral-shaped division, which gives the steam a spin as it passes through. The internal distribution in the Ledward tube is shown in Fig. 18 and 19. The exhaust steam follows the corrugations and is drawn to the surface where they are largest. Though space for a central core exists, it is maintained that the steam is sufficiently disturbed in this tube, from the fact of its having to pass in and out of the corrugations. These latter act as a trap to any solid matter, and particularly to oil, which may be carried over with the exhaust steam.

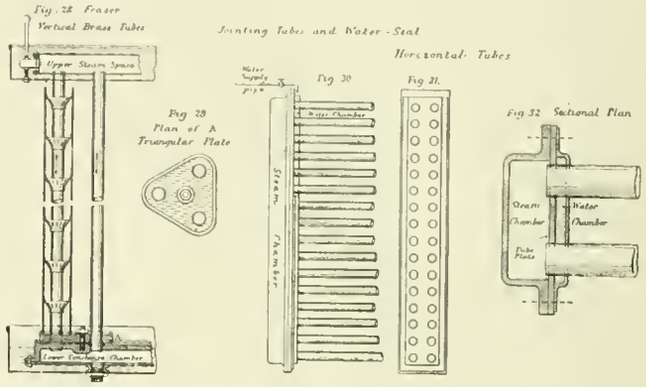
DISTRIBUTION OF WATER OVER TUBES.

In a great measure the success of the condenser is due to a proper distribution of the cooling water over the external surface of the tubes. In the case of a vertical tube condenser the water is delivered into a top receiving tank through which the tubes pass, the holes in these tanks having a larger diameter than the tubes. This leaves an annular space through which the circulating water passes on is way down each tube into a lower receiving tank.

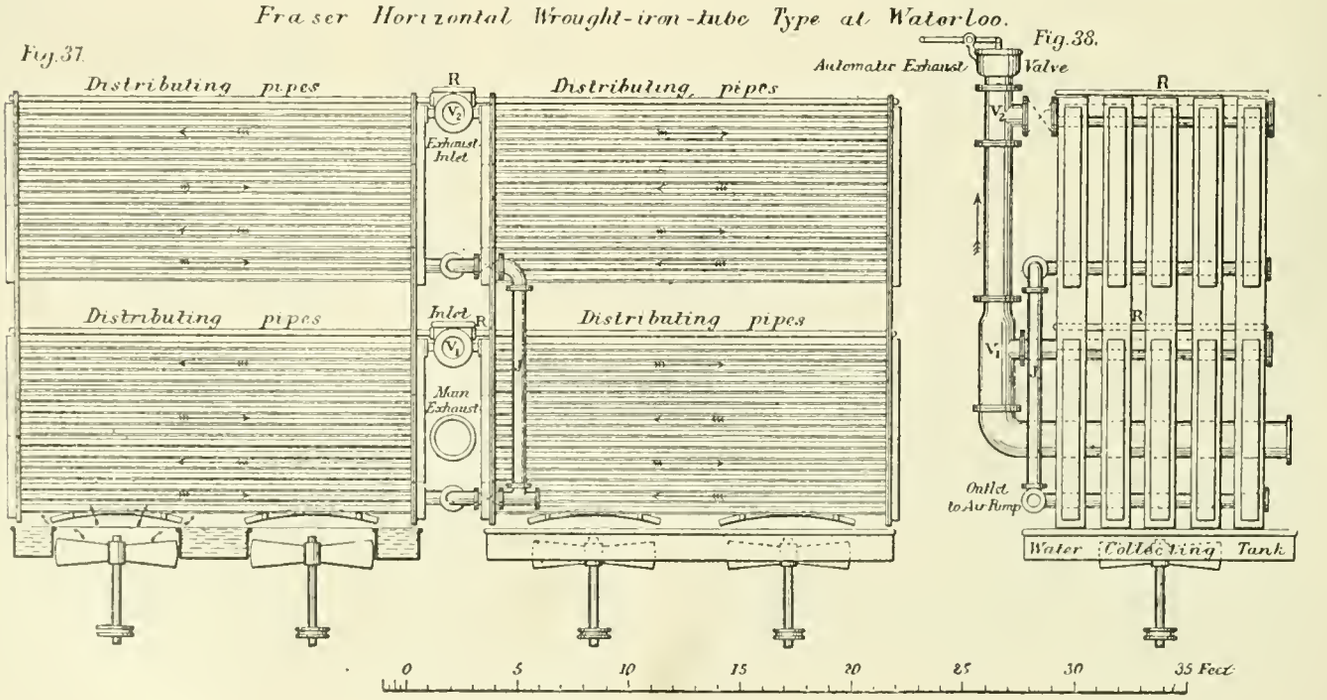


On the horizontal tube type the distribution is somewhat different. At the extremities of the rows of tubes, and at right angles to them, is placed a rectangular tank into which the circulating water is pumped. Into this tank galvanized iron pipes are led and carried vertically above each top tube in the condenser. Each pipe is perforated so as to allow the water to fall upon the whole length of each uppermost tube. The water passes round the circumference of the first tube, is collected underneath and distributed over the second, and so on until it has passed round each one and is finally collected in a receiving tank below.

The most important methods employed are those of Theisen, Wright, Fraser and Ledward.

Theisen uses vertical brass tubes of about 2 in. diameter, shown in Fig. 1. On each of these is wound in the form of a helix or

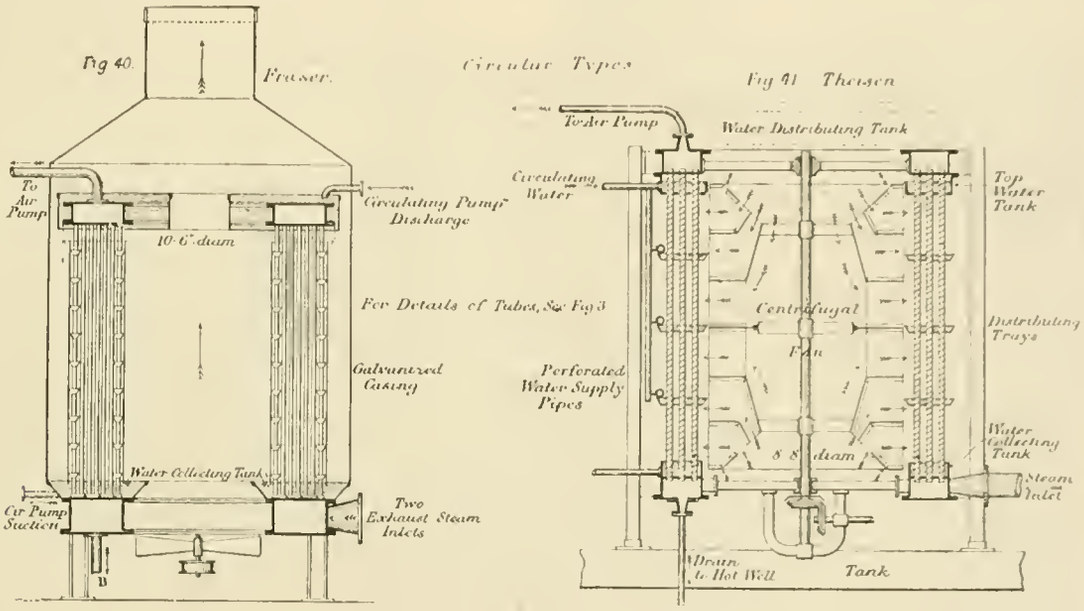
Fraser Horizontal Wrought-iron-tube Type at Waterloo.



screw thread a No. 9 galvanized steel wire, causing the water to follow this course round and round the tube until it reaches the bottom.

Wright places round the vertical brass tube brass plated wire in the form of ordinary galvanized wire netting. This appears to give a satisfactory distribution of the water. Later designs have spaces between the lengths of netting which allow of these being moved up and down for cleaning the tubes and removing scale, Fig. 2.

Fraser, in his vertical type, places round the brass tube perforated conical brass cups as shown in Figs. 3 and 4, about 12 in. apart, connected by a light rod on each side. It was found by experiment that the rupture of the film of water took place after falling about 12 in., and the action of these cups is to collect the water at distances of about 12 in., so that there is a steady film of water continually passing down the tubes. A small annular space is left between the lower edge of the cup and the tube to allow the water to pass through. Several slots are made in the side of the cups through which the water can still flow, even should the annular space become obstructed by sediment or dirt. The cups also act as tube scrapers by being moved up and down by hand. Figs. 5 and 6 show a brass tube which is now being



introduced for evaporative condensers of the vertical type. The tube has corrugations drawn into it for the greater part of its length, giving 25 to 30 per cent more surface than the plain tube. The ends are left plain for about 3 in. to allow for jointing and expansion. Fig. 7 shows an elevation and Fig. 8 a section of the Row tube as applied to evaporative condensers.

With the Fraser horizontal tube, Figs. 9 and 10, water is taken from a rectangular tank and passed along a perforated galvanized iron pipe immediately above the condenser tube. For further distribution on each of the lower tubes, strips of galvanized iron extending the whole length are fixed on the underside of each tube by means of iron straps or brass spring clips. Fig. 14. When fans are used with this type of condenser a curved trough is fixed under each tube on the lowest tube of each row, turning the water off into the side tanks. This prevents it from dropping on to the fan blades, and the disturbance of the water on the face of the tube.

The water distribution in the Ledward condenser is carried out as shown in Figs. 16 and 17.

Other arrangements for distributing the water over the tubes consist of open troughs perforated at the bottom, or with notches along the top edges. One form of wood trough that is used has a flat bottom and inwardly inclined sides; the water flows over the tops of the sides and drips from the two bottom edges into two condenser tubes.

It is very important that all joints be air tight, and in addition to rubber packed or expanded joints a water seal is generally provided. Figs. 28 to 32 show method of joining the tubes to the headers in vertical and in horizontal types.

The Kensington & Knightsbridge Electric Light Co. has an installation of the Ledward type at one of its stations which condenses the exhaust from engines using 20,000 lbs. of steam per hour and maintains a vacuum of 23 to 27 in., depending on the temperature of the circulating water. From 20,000 to 30,000 gallons of water is circulated per hour. The tubes are of the design shown in Fig. 18, and are in sections 5 ft. long. The amount of radiating surface is about 8 sq. ft. per 1 lb of steam per hour, and the condensation is about 8 lb. of steam per running foot of pipe. The maximum ground space is placed at .9 sq. ft. per h. p.

Condensers with cast iron tubes, plain, save for a fin on the lower side to collect the water for distribution on the next lower tube, have been used with success.

A Fraser condenser with horizontal wrought iron tubes for dealing with 40,000 lb. of steam per hour has been erected at the station of the Waterloo & City Electric Ry. This is arranged in two bays, Figs. 37 and 38. The tubes are 3 in. in diameter and 18 ft. long, made of galvanized iron. There are 640 tubes, giving a total tube surface of about 9,000 sq. ft. Figs. 30 to 32 show the arrangement of the tubes; steam passes first through the 10 upper tubes, returns through eight, goes back through the next eight and then passes through the bottom six. Four fans 5 ft. 6 in. in diameter, driven at 300 r. p. m. by an electric motor through a continuous rope, are used for circulating air. The ground space occupied is 1 sq. ft. per 5 h. p.

Condensers of the circular type are shown in Figs 40 and 41. In connection with these a supplementary condenser is sometimes used; this consists of a cast iron or steel vessel with brass tubes. The cold water necessary to replace the loss by evaporation in the main condenser is passed around the tubes and the discharge from the main condenser passes through them on its way to the air pump.

In condensers with Thiesen tubes a minimum of 1 sq. ft. of tube surface per 8 lb. of steam condensed per hour is usual; in the supplementary condenser it is 1 sq. ft. for 80 lb. of steam per hour. A Thiesen condensing plant at present working in connection with 11 separate engines, aggregating 3,000 h. p., requires 31 h. p. to operate circulating pump, fans and air pump.

The Wright evaporative condenser has vertical tubes and differs principally in the method of distributing water over the surface of the tubes.

To be continued.

Street car men in St. Louis estimate that last year the number of transfer tickets issued by the various lines amounted to 20,000,000. On this basis the consolidation of the roads will necessitate the granting of at least 40,000,000 transfers per annum.

NEW INDEMNITY COMPANY.

The Pennsylvania Mutual Indemnity Co., Drexel Building, Philadelphia, is the latest organization for undertaking an indemnity insurance, but has already written a promising line of policies and has every reason to expect a large business before the end of its first year. The lines carried are confined exclusively to electrical concerns,—railway and lighting, and the insurance is made to cover both employes, and passengers on the cars, as desired.

Among the members of the board of directors will be recognized some well known names in the street railway field: J. F. Porter, president, Alton Railway & Illuminating Co., Alton, Ill.; A. Demange, president Blomington (Ill.) Street Railway Co.; Cyrus See, president, Meadville (Pa.) Traction Co.; A. E. Maher, treasurer North River Electric Light Co., New York; E. C. Clay, president Jenkintown Electric Light Co., Philadelphia; A. C. Brister, claim agent Philadelphia & Reading R. R. The officers are W. W. Paterson, president; H. W. Rogers, secretary, and Newton Jackson, general manager. Mr. Jackson has had much experience in indemnity insurance and will undoubtedly secure for the company a large amount of desirable business. He will be glad to correspond with any manager and describe in detail the plan and evident advantages under which his company is working. A large guarantee fund for payment of leases has already been paid in.

the exhibit of goods made in this country for export, and that one very strong feature will be the showing of all kinds of foreign makes alongside of the American, in order that the manufacturer here can see just what he must compete with.

REORGANIZATION OF NEW ORLEANS CO.

The reorganization of the New Orleans Traction Co. which has been contemplated for some time was effected last month and the New Orleans City & Lake Railroad Co., the Crescent City Railroad Co. and the New Orleans Traction Co. are now combined in one company known as the New Orleans City Railroad Co. The officers of the new company are: President, R. M. Walmsley; vice-president, A. Baldwin; secretary and treasurer, A. H. Ford; general manager, C. D. Wyman.

The prospects of the company are quite good; there was an increase in receipts last year and a decrease in expenses, and at the present time the receipts are increasing as compared with last year. Payments of dividends on preferred stock will begin July 1st; the company's preferred stock is now selling at about par, while the common stock is quoted at between 21 and 22 and is rapidly appreciating.

The company has recently completed changing the last of its horse lines for electrical operation, and has recently received some new suburban cars and ordered 20 new urban cars for fall delivery. About 10 miles of new track will be laid during the year and much of the special work renewed; the building of new shops and a power station and other improvements are also contemplated.

AUTOMOBILE EMERGENCY WAGON, PITTSBURG.

PHILADELPHIA EXPOSITION.

Mr. P. A. B. Widener is the president of the National Export Exposition, to be held in the city of Philadelphia from September 14th to November 30th, and no stronger guarantee could be given of its success. Mr. Widener is an active man in many fields, but in nothing of late years has he taken a more assertive interest than in making this exposition a crowning glory, not only of Philadelphia, but of the whole nation.

The work of preparation is progressing rapidly and satisfactorily. The buildings will all be ready for the installation of the exhibits by August 15th, giving a full month for their proper arrangement before the exposition opens.

The value of this exposition to the small manufacturers of the country can hardly be estimated. Expositions as a general thing are dominated by the large concerns, but the management has in this case established such broad principles and propose to conduct the affair on such liberal lines that the small manufacturer will be put on an equal footing with the large one.

It should be borne in mind that this exposition is especially for

CHANGES IN ATLANTA, GA.

Now that the financial combination of the street railway lines of Atlanta, Ga., has been concluded, the management is busy arranging for a physical consolidation. Petitions are going into the council asking permission to connect the tracks in order to have it one system in fact as well as name. The Atlanta company has made the first move and when the permission asked for has been granted work will be at once begun. In this work of connection there will be an opportunity to correct many evils and make changes long recognized as desirable. When all is completed Atlanta will have a most satisfactory system of street railway.

AUTOMOBILE EMERGENCY WAGON.

The accompanying illustrations show an automobile emergency wagon built for the Consolidated Traction Co., of Pittsburg, Pa., by the Columbia Automobile Co., successor to the Pope Manufacturing Co., of Hartford, Conn. It was a part of the maker's display at the electrical exhibition in New York last month, and attracted a great deal of attention as the pioneer in this field. It was shipped to Pittsburg June 3d.

The wagon is equipped with all appliances and tools carried on wagons of this type, fire extinguishers, extension ladder, stretcher, lanterns and a complete kit of lineman's tools and apparatus. It is built to carry a crew of four or five men at a speed of 10 miles per hour for 18 miles, this distance being much in excess of the requirements in this class of work. The batteries, weighing 1,400 lb., are carried beneath the main body and are removable at the side. The total weight is 4,500 lb. Wooden wheels with solid

WAGON WITH LADDER RAISED.

rubber tires, 42 in. in diameter at the rear and 36 in. in the front, are used.

We are indebted to Mr. Fitzgerald, general superintendent of the Consolidated Traction Co., and to the maker of the wagon for the photographs and data.

COLLECTION OF PORTRAITS OF ELECTRICIANS.

L'Elettricita, published at Milan, Italy, will exhibit a collection of portraits of men connected with electricity at the International Exposition commemorating the centennial of the Voltaic cell, to be held at Como within a few weeks, and requests that everyone who has been identified with electricity as an author, professor or inventor will forward a photograph with autograph signature to the editor of l'Elettricita, Via Cusani 11, Milan.

The wages of the employes of the Indianapolis (Ind.) Street Ry. have been increased 10 cents a day.

VALENTINE SIGNAL STSTEM.

Mr. H. B. Rogers, general manager of the Brockton (Mass.) Street Railway Co., sends us a description of a signal system patented by Mr. Daniel Valentine, the company's chief engineer. Some time since the company installed a signal system which did not give satisfaction and the question was given to Mr. Valentine to investigate; he devised the system described here and Mr. Rogers states that he has found it simple and reliable.

The system comprises rail contacts and signal boxes with lamps and semaphores. There is a signal box for each direction of traffic and the two boxes are arranged as shown in Fig. 1. Fig. 2 is a diagram of the wiring and the apparatus for moving the semaphores. D is a solenoid and G a solenoid bar having at one end a contact piece H, and at the other the tell-tale or semaphore F. In the body of the solenoid bar is a helical or inclined groove which receives a stationary projecting tooth, so that as G

FIG. 1.

moves in or out of the solenoid it rotates and changes the position of F. T is a feeder supplying current to the apparatus. P is a cluster of lamps and Q the rail contact; L is a solenoid, the bar of which forms a catch to lock the bar G in "danger" position, and is released when a current passes through the coils of L. The meaning of the other letters and figures in Fig. 2 will appear from the detailed description of the method of action.

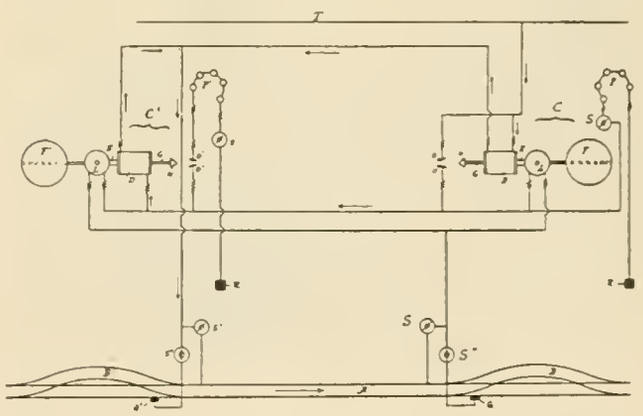


FIG. 2.

If a train or car should proceed on the track A in the direction of the arrow in Fig. 2, on passing the contact-plate Q', the circuit from the line T will be closed through the solenoid D, causing its solenoid-bar E to be moved forward and causing the semaphore F to be set for "danger" and locked in that position. During the forward motion of the solenoid-bar E, its contact-piece H is caused

to close the circuit through the circuit-closers O O, by which the circuit is closed through the lamps P as well as through the solenoid D', causing its solenoid-bar E', to be moved forward and causing its semaphore F' to be set accordingly and locked. During the forward motion of the solenoid-bar E' its contact-piece H' is caused to close the circuit through the lamp or lamps P', thus causing the semaphore F, either alone or in connection with the lighted lamp or lamps P, to indicate to a train approaching the turnout B in an

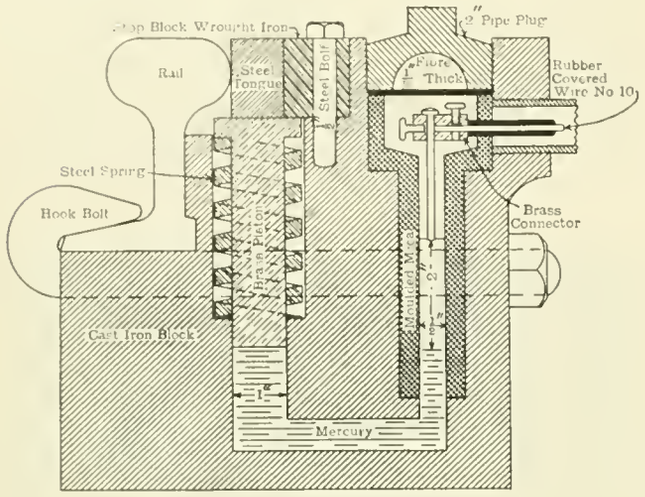

FIG. 3—CONTACT BLOCK.

opposite direction that the track in not clear. The position of the semaphore or telltale F', either alone or in connection with the lighted lamp or lamps P', will indicate to a train following the first train in the same direction that the track between the turnouts B' B is obstructed by a train or car. On passing Q' the moving of F' to "danger" shows that F has already been set to danger. As the train or car going in the direction of the arrow reaches the turnout B it causes the contact-plate Q to close the circuit through the solenoids L L', causing the locking levers on the solenoid-bars E E' to be released and the latter to be automatically returned to their normal positions by gravity, the solenoids D and D' being placed

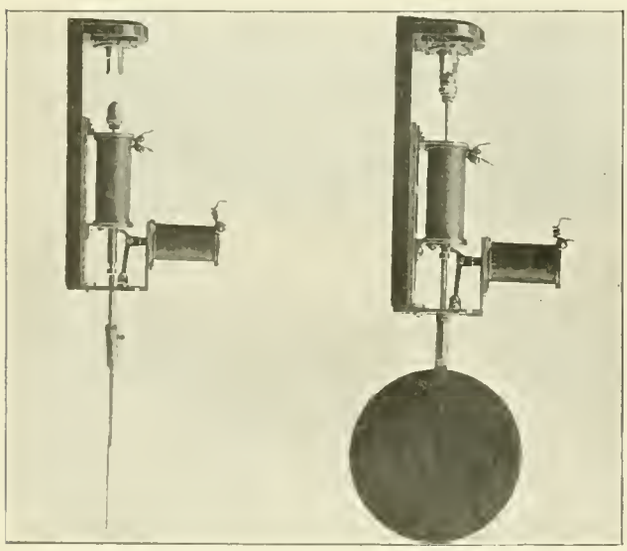

FIG. 4 -THE SOLENOIDS AND SEMAPHORE.

vertically, and the lamps are cut out and the semaphores turned to safety position.

In fig. 2, s, s', s", S, S', S" are switches for cutting out the rail contacts and lamps and operating the signals non-automatically.

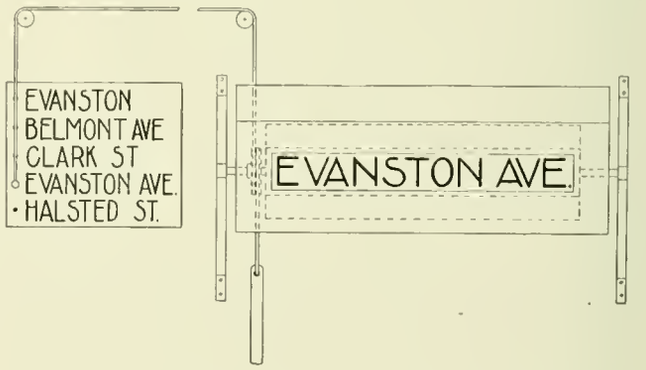
The rail contact box is shown in section in Fig. 3 and its construction will be readily understood. The tongue which is pressed down by the car wheel is 18 in. long by 1½ deep by 1 in. wide, and at one end is pivoted to the web of the rail. Mr. Valentine says concerning the contact: "The weight or pressure required to force down this spring sufficient to close the circuit is 1,500 lb. No road wheel, except that of a car, can get on the contact tongue and press it down, as it is too narrow for a heavy team. In fact, there is no wheel only 1 in. wide made for road work that will carry 1,500 lb., and we have had no trouble from that cause. The tongue is so arranged that the trackman can raise it up to clean underneath after a storm of rain, if needed, but up to the present this has not been necessary. The contacts alone were in operation all through the past winter, and were never once found to be frozen, after being filled with mercury. During heavy rain storms the rail contact boxes are covered with water, but as the water cannot get to the contact point without displacing the mercury, trouble from water is out of the question. It is advisable to fill the space under the steel tongue with salt during the winter months, or during those days when it is necessary to salt the frogs and switches."

INDICATING SIGN ON NORTH CHICAGO.

A simple but ingenious device to indicate the "next car" on the North Chicago Electric Ry. has been placed in the Arcade at the north side "Limits" barns, from which the cars start.

The device is simply an iron case about 3 ft. long, 18 in. high and 12 in. deep fastened to the wall with a pair of brackets. The lower portion of this case is rounded, and inside is a hexagonal prism constructed of a metal frame with glass sides. This prism is mounted on an axle having a grooved wheel on one end.

On five of the glass sides there are painted in bright colors



(corresponding with the color of the line) the names of the different lines of cars which pass through the arcade. A window is cut in the iron case and by means of five incandescent lamps inside the name of an approaching car shows clearly through the window.

At the rear of the arcade is a board with the names of the different car lines upon it, a hole is bored opposite each name. From a pin stuck in one of these holes a rope leads over pulleys to the sign cylinder, passes around the wheel on the cylinder axis, and is fastened to a weight moving vertically in a suitable box. An operator at the board moves the pin to the proper hole as he sees the car approaching and the cylinder size in front is set accordingly. When no car is on the track the blank space is exposed.

The arcade is rather dark and until the car has almost reached the front end it is difficult to distinguish the line, hence the advantage of this sign. The device is only used during the evening and on Sundays when the traffic is heavy.

The New York City street car companies are considering the idea of adopting the Baltimore system of watering the streets from tanks on trolley flat cars.

The Central Railway Co., Peoria, Ill., is making extensive improvements in its lines. New steel rails are being laid and the cars given a general overhauling. The Peoria & Pekin Railroad Co. is rebuilding its depot and when the work is completed it is expected the street cars will enter the depot to let off and take on passengers. The handsome fountain in Prospect Park is now finished.

MECHANICAL DEPARTMENT

SOME NEW CARS.

The Atlanta Consolidated Street Railway Co., of Atlanta, Ga., has recently completed eight cars, which are very elaborate, and at the same time, very serviceable for street railway purposes. These cars were built at the company's shops, where 12 more are now under construction. They were designed by Mr. Thomas Elliott, chief engineer of the company.

It was not with an idea that cars from the factory were not good enough that this company began building its own cars, but with the three-fold purpose of constructing a car to meet the special requirements, of saving the item of freight, and of spending the money at home.

The idea of durability seemed to be uppermost in the mind of the designer of these cars. The sills are made of the best heart pine 3 x 8 in. and steel angles are bolted in every corner of the framing. The sides of the cars are perfectly straight, making the sills wider than the trucks, and for this reason it is necessary to put in a sub-

NEW CAR, ATLANTA, GA.

sill to carry the trucks. The inside measurements are: Length, 20 ft.; width, 87 in. The platforms are 5 ft. long and 8 in. lower than the floor in the car. One side of the platform is completely closed up by extending the dasher around until it joins the car proper. The diagonally opposite side of the other platform is similarly closed, so that passengers alighting from the rear platform will step away from any paralleling track. The doors are not placed in the center of the car, but about 12 in. nearer the side where the step is. This makes it very much more convenient both for the alighting passenger and any who may be standing on the platform.

Beginning at the side of one door and extending around the car to the corresponding side of the opposite door is a sheet of No. 10 steel. This sheet is set flush with the bottom edge of the main sill, and extends upward 36 in. This presents an even surface, easy to screw to the window posts. On the inside of the car and separated from this steel by the window post, is a solid piece of ash and cherry panel-work extending from the floor up to the window, and from one end of the car to the other. The space between this panel-work and the outside steel sheet is just large enough to allow the window sash and blinds to drop. And this space being straight admits of much better workmanship than is ordinarily found.

All of the carlines are lined on each side with a piece of 3-16-in. steel, bolted through, thus adding great strength to the deck. There are no wooden look-outs under these cars, but instead a 4 x 6-in. steel angle is used, (See the illustration) and to this angle is bolted the floor, which is 1⅛ in. thick.

The doors are hung on ball bearings and a slight depression at each end of the bearing track keeps them in position when open or closed. These ball bearings have completely eliminated the constant trouble of hard running doors, so annoying to passengers. The bearing is entirely new, and a conception of the company's chief engineer.

These cars were built with a view of operating them both in winter and summer. To this end the doors and windows are very large, and when these are opened the cars are thoroughly comfortable on the warmest day. Should a sudden shower come up they can quickly be made rain tight in a jiffy.

Cross seats of the Hale & Kilburn walk-over pattern, finished in red plush, are used. Seven of these are placed on either side of a 19 in. aisle; thus giving the car a seating capacity of 28. Some objection was made to using red plush seats in a summer car. To meet this objection the seats were covered with linen, which gives them a very cool appearance.

The advisability of building cars with straight sides was questioned from a standpoint of appearance. To begin with, this question of appearance is a mere matter of opinion. And furthermore, with the width of car used, cross seats could never have been put in if the sides of the car had been curved. Then, too, the straight sided car is much more easily and durably constructed, and makes a better pocket for the window sash and blinds. The only real objection to the car with straight sides is that, with a standard gage truck, the side sills are wider than the truck; this is easily obviated by using a sub-sill, as has been done here.

The decks are 12 in. high, which adds materially to the comfort of the car during the summer season.

The cars are finished inside with ash and cherry, except the head lining, which is of quartered oak. The blinds are made with cherry stiles and white pine slats.

These are already the most popular cars on the company's lines; and the riding public has been loud in praising them, stating that it is easy to get one's "money's worth" in a ride on such comfortable cars.

DATA ON AXLES.

In the "Review" for April were published some notes concerning the experience of different street railway companies with axles. Herewith is additional information on the same subject furnished by other companies.

Road K operates 300 miles of track and has a total of nearly 6,000 cars in service. The rolling stock equipped with motors comprises that shown in the table.

EQUIPPED WITH MOTORS.

Type	16-ft. Box	20-ft. Box	25-ft. Box	7 & 8-B Open	9-B Open	14-B Open	Plows, Etc.
No.	60	330	884	568	667	47	171

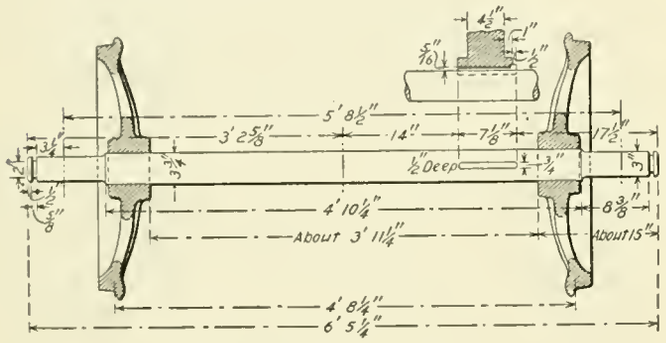
Wt. trucks, wheels, axles	4,530	4,530	6,740 8,240	3,370 4,530	4,530	7,200	
Wt. motors	About 2,300 lbs., varying somewhat with make						
No. of motors per car Summer	1	1	2	1	1	2	
Winter	2	2	2				2

The motors used are W. P. 50, G. E. 800, G. E. 58 and Westinghouse No. 12. Both sidebar and nose suspensions are used, one-half, or less, of the weight of the motor being carried directly on the driver axle.

For the last four years cold rolled steel axles of the dimensions shown in the accompanying drawing have been used. There are no specifications or tests for the axles. The keyway is cut on a milling machine and is ½ in. deep by ¾ in. wide by 7⅛ in. long. The same axle is used for non-driven as for motor-driven wheels.

The company has had no cold rolled steel axles break in service; in 1898 16 axles broke in service but they were either hammered iron or old style axles. The axles which have failed for the most part broke just outside the wheel; a few just inside the wheel. The fracture generally shows indication of an old crack which gradually increased until the section became too weak and failed.

There are no data at hand to show the relative number of broken motor axles and broken non-driven axles, nor whether rear axles break oftener than forward axles. Low temperature in winter has not noticeably increased the number of failures except with steel axles several winters ago; these were not of the material at present standard. The track is in good condition, but a larger amount of special work makes it severe on axles.



STANDARD AXLE, ROAD K.

The company finds that it never has to throw out axles because of journal wear, except when the journal has been cut, which is unusual.

Formerly 3⅜-in. axles were used on this road but the present standard is 3¾-in.; larger axles could not be used without making costly changes in the equipment.

The opinion is expressed that the method of suspending the motor affects the life of the axle, the life being longer with side bar suspension.

Road L operates about 150 miles of track and has 250 motor cars. The cars are 34 ft. long and mounted on double trucks. The car body weighs 8,000 lb., the trucks 1,000 lb. each without wheels or axles, and the motors (two per car) 3,200 lb. each; the total weight including maximum load is about 20,000 lb. The gage is 3 ft. 6 in.

The motor-driven axles are hammered iron, 3¾ in. in diameter with 3¼-in. journals; non-driven axles are hammered iron 3⅜ in. in diameter with 3-in. journals. The only specifications are that the material shall be first class and the axle free from seams and dirt. Hammered iron is used because flaws and cracks do not travel so rapidly as in steel.

The key-seat is made by drilling holes at the ends and planing out the center, and is ¾ in. wide by ½ in. deep.

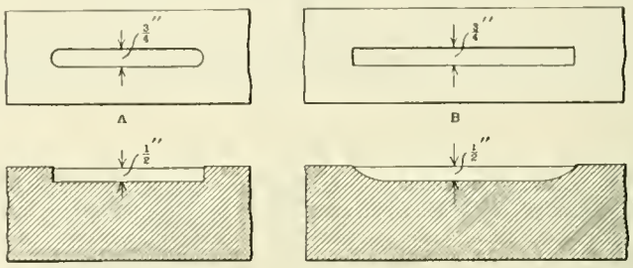
Quite a number of axles are said to break in service but the figures are not given. More axles fail in winter, and 99 per cent of the broken axles are motor-driven.

It is stated that the axles have been enlarged at the key-seat from 3¾ in. to 4⅛ in. with good results. Shallow keyways, ⅜ in., have been tried, but were not satisfactory, as the keys quickly become loose; for keys ¾ in. wide the seat should be at least ½ in. deep.

A yoke suspension is perferred as conducive to longer life of axles.

Road M has now in service about 940 axles under motor cars. Of these 800 are 3⅝-in. axles with 3¼-in. journals, which size has been standard for several years. Recently it was decided to make all renewals with 4-in. axles and about 140 of these are now in service. The 4-in. axles will be used with all motors having an axle bearing large enough. For the last three years this road has been buying wrought iron axles instead of steel which had been used previously.

During 1898 the number of steel axles which broke in service was 242, and the number of wrought iron axles 13. In drawing conclusions from these figures it must not be forgotten that the steel



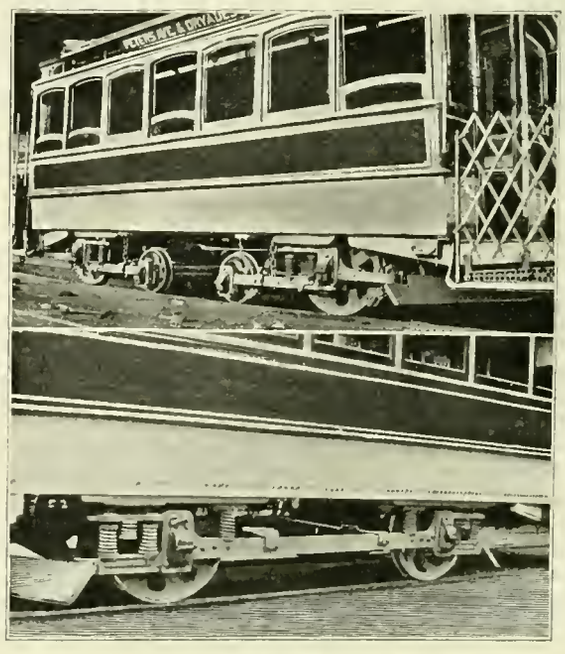
axles must have been in service at least three years longer than the others. Of the steel axles breaking in 1898 about half broke in the keyseat and half at the inner edge of the wheel seat.

The keyseats in all the axles which broke at that point were cut by boring and planing and had square bottom corners at the ends, as shown at A in the figure. Those that failed elsewhere had keyseats cut on a milling machine and were of the section shown at B. That this latter form of keyseat is greatly to be preferred is corroborated by a report made to a committee of the Railway Master Mechanics' Association in 1891; this was that steel locomotive driving axles having keyseats with a square bottom end corner broke, those having keyseats with end like that in B did not break.

REBUIDLING CARS AND TRUCKS.

The New Orleans Traction Co. has recently been rebuilding some of its cars and trucks and some of the details will doubtless prove of interest. The 28-ft. cars on the New Orleans City & Lake road were originally equipped with two "Eureka" maximum traction trucks each, which gave excellent service, but as they grew old the cost of maintenance increased and Mr. Rojo, the master mechanic, determined to make one single truck out of the two double ones, discarding the trailer wheels.

The only new material required was the steel for making connecting bars 3¼ x 4½ in. and 7 ft. 3¾ in. long. This made a single truck



OLD AND NEW TRUCK.

with a wheel base of 8 ft. From the illustration it will be noted that the old trucks, deprived of their pony wheels, are reversed so as to extend the spring base, making it about 11 ft. A slight alteration in the cross timbers of the car is necessary, but the total cost

of the change is not more than $50 per car. The results with the rebuilt truck are said to be very satisfactory.

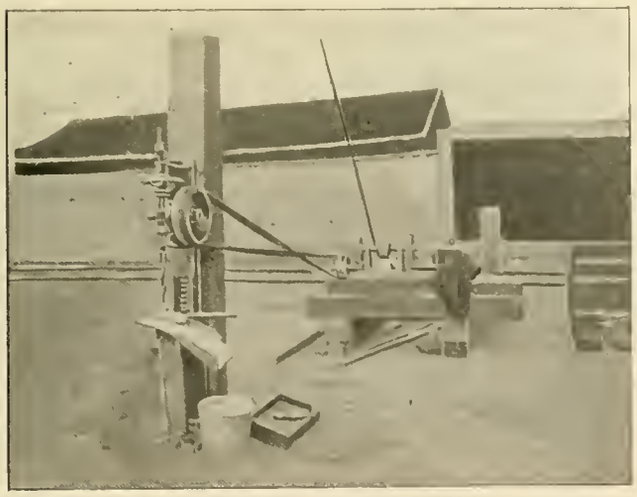
Side entrance summer cars have lost favor with General Manager Wyman, and he is transforming the equipment by placing wire screens at the sides of the open cars and cutting an aisle through the center. The smaller open cars formerly used as trailers in summer are being spliced to make large trailers for through traffic on

RECONSTRUCTED OPEN CAR.

the Lake line. Two 8-bench side entrance cars are spliced to make a car 45 ft. 4 in. over all. The joint is reinforced by a steel plate ½ x 6 in., and truss rods are used underneath; the remodeled car will seat 64 people. It will be noted that there are no side entrances on these cars.

DRILLING CONDUCTOR RAILS.

The Brooklyn Rapid Transit Co. is changing the Brooklyn & Brighton Beach R. R., recently acquired by it, for electric traction and is replacing the light T-rails with 9-in. girders. The T-rails taken up will be used for conductor rails on the elevated lines and in consequence have to be drilled for rail bonds. Near the elevated junction two posts have been set and drills mounted on



TEMPORARY PLANT FOR DRILLING RAILS.

them; the posts are set the proper distance apart so that both ends of the rails may be drilled at once.

Two motors taking current from the Bergen St. line drive the drills through jack-shafts; mounted on the jack-shafts are emery wheels for grinding the drills. A platform is arranged at the proper height with oiled rails for the rails to slide upon, so that they can be handled without difficulty.

SHOP FLOORS.

At the December, 1898, meeting of the American Society of Mechanical Engineers one of the topics discussed was that of machine-shop floors.

Mr. Charles T. Newcomb stated that for ground floors his practice for the last 17 years had been to use for joist floor timbers, 6 x 6 in. kyanized timbers placed 4 ft. on center, well bedded and laid crosswise of the shop, so as to put the plank lengthwise of the shop. On top of the timbers are placed 3 in. matched spruce planks, planed on one side. Before the planks are laid the earth fillings under plank are well puddled for about 2 ft. and left higher than floor timber, and struck off to light of floor timbers, leaving a solid surface under plank onto which machinery can be set without other foundations. This kind of floor will wear out on top in about five years, when it will be found to be rotted on bottom so as to need replacing, the kyanized timber lasting indefinitely.

Kyanized timber or treated lumber can now be obtained very readily on the market. This kind of floor costs laid 11 cents per square foot, and is easily replaced, and in view of the fact that the top of floors wear out, it is better to use this or similar cheap construction and have a new floor when needed.

For second-story floors for such work as is usually put on such floors, he used 3-in. matched spruce plank with paper laid over it to keep the dust and dirt from passing th[illegible]n, the top flooring being 1⅛ in. thick matched hard maple, bored and blind nailed, not wider than 3½ in. This kind of floor will last many years, wearing out in spots only. The spots can be easily and quickly patched.

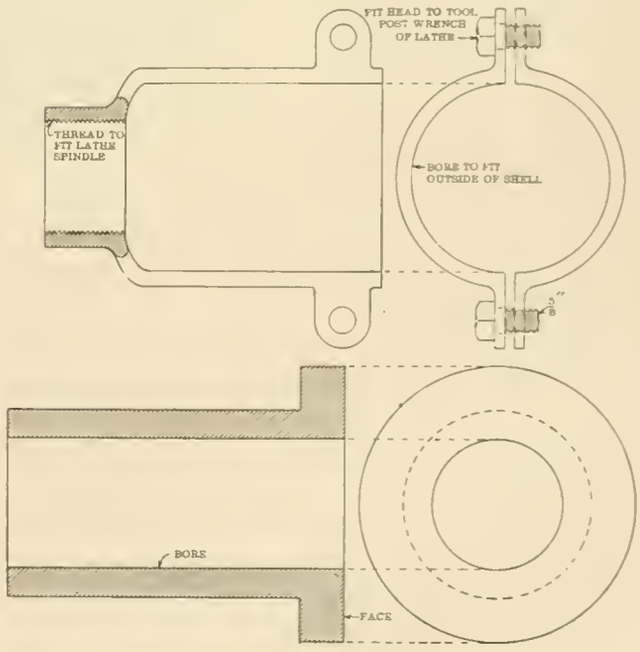
Mr. Albert A. Cary stated that the result of experiments he had made with different woods for top flooring in factories has led him to adopted maple as preferable to all others.

Mr. Durfee described the floor of a shop erected by him. After the ground was excavated to the proper depth it was covered with 10 in. of broken stone; on the stone were bedded chestnut sills and the space between sills filled with broken stone. On the sills were laid 4-in. planks and 5 in. wide. The planks were placed slightly open joints (not to exceed ⅛ in. wide) and were laid at an angle of 45° with the traffic. The galleries in the shop were laid with 4-in. spruce planks not over 8 in. wide with a top flooring of 1⅛-in. hard pine.

CHUCK FOR BORING ARMATURE BEARING SHELLS.

Council Bluffs, Ia., May 22, 1899.

Editor "Review": We have devised and are using in our shop a special chuck which makes possible a great saving of time in fitting up the heavy 25-lb. armature bearing shells for G. E. 57 motors; it can, of course, be used for any similar shell and may prove of interest to your readers.



CHUCK FOR ARMATURE SHELLS.

The shell for our motors is shown in Fig. 1. To bore these shells in the ordinary lathe chuck consumes too much time, as

every shell must be turned up when it is chucked. With our special chuck the shells are bored perfectly true and no time is required to center them in the chuck; the work can be accurately done by cheap labor.

The chuck is merely a casting, weighing about 50 lb., with two slots cored back to the thread which screws onto the lathe spindle, See Fig. 2. The top bolts are to tighten the two halves of the chuck on the shell, and the heads of these bolts should be fitted to the tool post wrench of the lathe on which the chuck is used. Our practice is to pour the shells on a plug smaller than the bearing, slip them into the chuck, bore and face them, and then spin the metal out as tightly as possible in the shell.

In fitting up the chuck the thread should be cut first and the casting screwed on the lathe spindle, after which it should be bored; this method insures a perfectly true bore. The dimensions of chuck to take a shell 4¾ in. diameter by 8½ long, are 6 in. diameter and 11 in. long.

We have just finished fitting 75 shells and found the chuck effected a great saving of time; also it was accurately done with labor costing 13 cents per hour. W. B. TARKINGTON,
Master Mechanic.

Omaha & Council Bluffs Railway & Bridge Co.

NEW YORK AIR BRAKE TESTS.

New York, May 29, 1899.

Editor "Review": Referring to your discussion in the May "Review," p. 336, of the formula chosen by the New York Railroad Commissioners for comparing the efficiency of different braking systems, it is evident that the Commissioners use the term "efficiency of braking system" in a broad practical sense, i. e., points 1, 2 and 3, will be judged upon the distance travelled beyond the point at which signal to stop is given. This signal should be given by a person on the car, as making a stop from a fixed point gives the motorman a chance to get ready, which would not be proper for an emergency test, and largely eliminates the factor which you call D_1 (the distance run between the time that the signal is given and the time when the brakes are applied,) a most important point in considering the practical efficiency. The coefficient of friction of brake shoes varies for different speeds, and evidently recognizing this fact the Commissioners propose to test the various brakes under the same conditions as to weight and type of car and speed, therefore the formula $W S \div D = E$ is as good as a more complicated one.

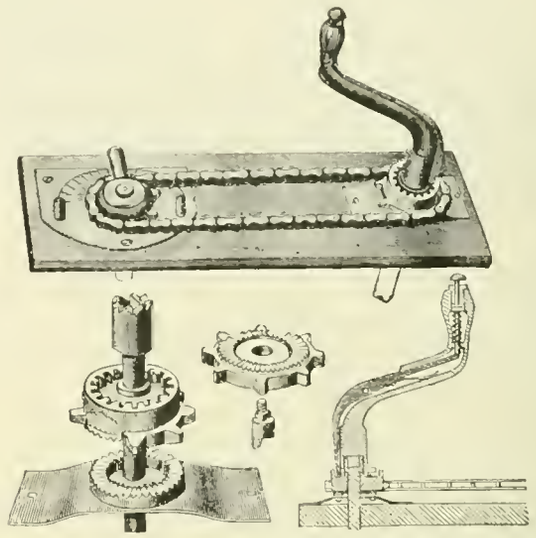
It is far simpler and more just to the contestants to eliminate the variables from the test, than to attempt to provide a complicated formula that will give each variable its due weight with respect to the value of the others.

Yours very truly,
STANDARD AIR BRAKE CO.,
Jas. R. Ellicott, Gen. Mgr.

GROSSMAN CONTROLLER ATTACHMENT.

Mr. Adolph Grossman, of New Orleans, has recently patented an ingenious device for use on electric cars for turning off the controller and applying the brakes by one operation. The accompanying drawings show the details of the brake handle and gears on the brake staff and the method of connecting the brake and controller shafts.

The upper end of the brake staff is provided with beveled teeth and the staff can be operated in the usual manner. To the brake staff a sprocket wheel is secured, provided at its under side with a clutch face engaging a corresponding face mounted on a spring plate. The sprocket wheel has an interiorly toothed flange, adapted to be engaged by a detent lever fulcrumbed on the crank and held out of engagement with the flange by a spring. In order to enable the motorman to place the detent lever in engagement with the flange, and thereby lock the sprocket wheel to the crank, a pusher pin is provided, normally held in the position shown by means of a coiled spring. When the pin is depressed the detent lever will be placed in engagement with the toothed flange; when the pin is released the lever is disengaged by its own spring. Loosely mounted on the rheostat shaft is a sprocket wheel connected by means of a chain with the brake staff sprocket wheel. The rheostat sprocket wheel has a clutch face designed to engage a similar face on the under side of a plate fixed to the shaft. The plate has an arm by means of which the current is turned on and off. When the motorman desires to stop his car he depresses the pin, in order to lock the brake staff sprocket to the crank and turn the crank to the right. By reason of the chain connection with the rheostat sprocket the motorman, in turning the brake staff, also causes the switch arm to rotate and shut off the current. When the current is cut off, the motorman releases the pin in order to disengage the sprocket wheel from the brake crank and continues to turn the crank until the car is stopped. By turning the crank to the left the brakes are released; by depressing the



GROSSMAN CONTROLLER ATTACHMENT.

pin, the two sprocket wheels will operate to cause the switch arm to turn on the current in order to start the car.

Should the motorman forget to release the plunger when the switch arm has turned the current on or off, the continued rotation of the crank can do no harm, because the clutch teeth of the rheostat sprocket will ride over those of the switch arm plate.

A trial of the device was recently made on cars of the New Orleans Traction Co., and it is reported to have worked very satisfactorily.

CHICAGO TO MILWAUKEE BY ELECTRICITY.

When two small gaps have been closed up, from Evanston to Highland Park and from Waukegan to Kenosha, Wis., it will be possible for a person to ride in electric cars all the way from Hammond, Ind., to Waukesha, Wis., and to go it quickly and cheaply.

The tendency of these electric roads to absorb local passenger traffic is not more clearly illustrated than round about Chicago. The electric line from the city to Hammond has been in operation for a long time. The North Side cable line and the North Shore electric to Evanston, with which it connects, have been carrying passengers for several years. The lines between Highland Park and Waukegan and between Kenosha and Milwaukee and from Milwaukee to Waukesha are now all old stories. Men are at work constructing the road from Evanston to Highland Park, and the right of way for a road between Waukegan and Kenosha has all been secured and the present summer will see these two gaps closed and a practically continuous line of about two hundred miles will be open. Besides this there is some strong talk of connecting Milwaukee and Green Bay.

In regard to time required, a passenger can start from Chicago now at 6 a. m. and reach Milwaukee at 12:30 and Waukesha at 2:30 p. m., the cost of the trip, including the two jumps on the steam cars, being only $2.45. This trip was taken recently by the representative of a Milwaukee newspaper.

A car on the line of the Suburban Traction Co., Pittsburg, Pa., jumped the track on the morning of May 30th and came near precipitating 12 people down a 60-ft. embankment. Everybody but the motorman left the car.

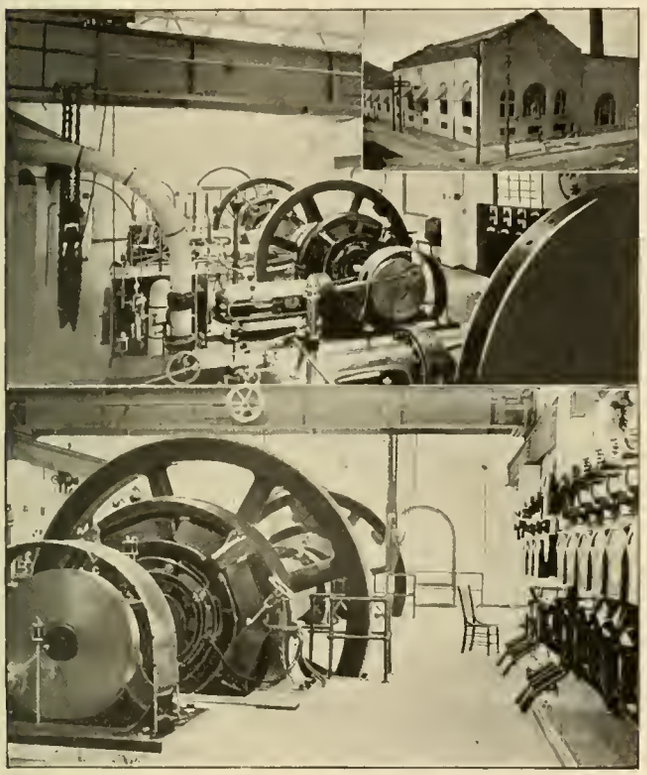
D. G. HAMILTON.

POWER STATION OF THE ST. CHARLES STREET R. R., NEW ORLEANS.

The power plant of the St. Charles Street Railroad Co., of New Orleans, has been in operation for several years, and has proved to be economical and durable. When built the general opinion was that the foundations for heavy engines must, in New Orleans, be built upon piling, but this plant has demonstrated that such is not the case.

The power plant occupies a portion of a building at Marigny and Peters Sts., within 100 ft. of the Mississippi River. The whole building is 190 x 127 ft. and includes the shops of the company. The portion containing the power plant is 88 x 109 ft.; the walls are of brick supported on piling. The roof is a steel frame with fire-tile filling and covered with galvanized iron. The engine room floor is 8 ft. above that of the boiler room and is made of brick arches, and covered with pine flooring.

The boiler room is 69 x 88 ft. and 28 ft. high to the cornice; it is lighted by skylights. There are three 250-h. p. Heine boilers



POWER HOUSE—ST. CHARLES STREET R. R.

equipped with Murphy furnaces; Alabama run of mine is used for fuel. The feed water is taken from artesian wells; condensing water for the engines from the river. The feed water comes from the wells at about 78° F., and is first heated at 200° in a 500-h. p. heater made by Warren, Webster & Co., and then taken to a Green economizer with 216 tubes, where the temperature is raised to 265°.

There are two Worthington pressure feed pumps, one pump used to lift water to a house tank mounted on a 20-ft. tower, and one small pump for returning all sewage to the river, besides two condenser pumps which draw from the river.

The stack is 6 ft. 6 in. in diameter and 125 ft. high, lined with fire brick for 85 ft. It rests on a foundation of 40 ft. piling capped with timber on which is 7 ft. of concrete.

The engine room is 40 x 88 ft. The entire area to be occupied by engines and generators was excavated to a depth of 3 ft below the street grade and the bottom covered with two layers of 6 x 6 in. cypress timbers; on the timber was laid 18 in. of concrete; then a layer of old 45-lb. steel rails placed 12 in. c. to c., and above these 18 in. of concrete, the top of this forming the basement floor. On the foundation so prepared were built the engine and generator foundations, which are of brick. These have proved to be perfectly satisfactory and the cost was very much less than if piling had been used.

There are three cross-compound Hamilton-Corliss engines built by the Hooven, Owens & Rentschler Co. These engines have cylinders 14 and 26 by 36 in. and run at 100 r. p. m.; the fly wheels are 14 ft. in diameter with 12-in. face, and weigh 25,000 lb. Jet condensers are used.

The steam piping is of an extra heavy wrought steel and is not in duplicate. The exhaust main is 12 in. in diameter and extends along the entire length of the engine room; it is connected to the three engines and the two condensers and in case of emergency connection to the atmosphere is made through an automatic valve. The station piping to the river includes one 12-in. flanged cast iron pipe for the condenser intake, one 5-in. main for feeding the boilers in case of emergency and one 6-in. discharge for the boiler blow-off.

There are three 8-pole 200-kw. Walker generators directly connected to the respective engines.

The switchboard is of enameled slate with nine panels; it is equipped with Weston ammeters and voltmeters and a Thomson recording wattmeter.

There is a 20-ton Morris crane traveling the ...e length of the engine room.

We are indebted to Mr. Alexander L. Black, electrical engineer of the company, for the photographs and data.

CHICAGO ELECTRICAL ASSOCIATION BANQUET.

The Chicago Electrical Assoeation held its annual banquet at the Technical Club on Friday evening, May 19th. Plates were laid for 47 and that number of members and their friends feasted and made merry.

This was 110th meeting of the Association and much credit is due Mr. J. M. Hollister, chairman of the banquet committee for the pleasant evening and the general success of the event.

Mr. E. E. Jewell acted as toast-master and suggested many interesting topics which were discussed in an informal manner. But the real enjoyment of the evening was that offered by the responses to the set toasts. Among the principal ones was "Electricity of Long Ago," responded to by Mr. C. J. Warner, the patriarch in electrical work. Mr. Warner's pratical experience in the field dates back to 1831. Prof. Carhart, of the Michigan University, responded to the topic "Education," Lieut. F. B. Badt to "Mathematics," and Mr. E. P. Warner to "The Construction of Electrical Generating Apparatus."

Altogether the banquet was a most happy event, proving both enjoyable and profitable to those present.

IMPROVEMENTS AT KNOXVILLE.

The Knoxville (Tenn.) Traction Co. is making extensive improvements in its roadbed and rolling stock. The track to Chilowie Park is double; in the business district 100-lb. 7-in. Lorain Sec. 338 rails are laid and elsewhere 55-lb. T-rails in 60-ft. lengths. Hewn white oak ties 6 x 8 in. x 7 ft. are spaced 2 ft. c. to c. In paved streets the ties are laid on a 6-in. macadam foundation and the spaces between the ties filled with concrete; the paving material is vitrified brick, 3 in. of sand being placed between the cement and brick. In unpaved roads the ballast is Tennessee marble.

The overhead work is the center pole construction with flexible bracket suspension; the material was furnished by the Creaghead Engineering Co.

The new cars were ordered from the Brownell Car Co., of St. Louis; they are 8-bench open cars, vestibuled; there is a box for the motorman at each end of the car and on either side of the box is a short seat for two persons. The cars are equipped with G. E. 1,000 motors and K-10 controllers and Van Dorn couplers; they are mounted on du Pont trucks.

At the power house a new boiler and a 200-kw. generator have been installed.

Mr. C. C. Howell, vice-president and manager of the Knoxville Traction Co., and also of the Knoxville Electric Light & Power Co., is exerting every effort to make his road second to none in the country.

The Southwestern Gas, Electric & Street Railway Association.

First Annual Convention of the Association at Austin, Tex., May 17 19, 1899—Officers' Reports—Papers Read by Street Railway Men.

The annual convention of the Southwestern Gas, Electric & Street Railway Association was held in Austin, Tex., May 17th to 19th. This association was organized at Laredo, Tex., in March, 1898, its membership comprising gas, electric and street railway men of Texas, Mexico, Louisiana, Arkansas and New Mexico.

The recent convention at Austin was to have been held one month earlier, but was postponed on account of the small-pox epidemic then raging at Laredo and other points in Texas and Mexico. This postponement was no doubt one of the main causes for a decreased attendance. The uncertainty as to whether the municipal power plant of Austin could furnish power was the cause of many manufacturers and supply houses failing to set up any exhibition of their machinery.

The convention convened at 10 a. m. on May 17th, being called to order by President Carl F. Drake, of Austin. Secretary E. L. Wells, of Marshall, Tex., recorded the proceedings. Mr. Drake made a few remarks welcoming the visitors to the city and expressing the hope that the session might be of pleasure and profit to all concerned. He then introduced Mayor John D. McCall, of Austin, who delivered the formal welcoming address. Mr. T. D. Miller, of Dallas, responded to Mayor McCall's address of welcome, on behalf of the association. This ended the proceedings of the first day's session. The visitors were then taken in charge by the local reception committee and shown about the city. They were escorted to Hyde Park and other suburban resorts and spent a very enjoyable afternoon. They also paid their respects to Governor Sayers, who made a brief address, in which he paid the members of the association high compliments. Major Ira H. Evans, of Austin, responded to the Governor in a brief but appropriate speech.

PRESIDENT'S REPORT.

The second day's session was devoted to the reading of the officers' reports. President Drake's annual report was as follows:

Gentlemen of the Convention:—It is my pleasant duty to make to you the first annual report of the President of the Southwestern Gas, Electric and Street Railway Association. A large number of our members were, previous to the joint meeting held at Larado in 1898, members of either the Texas Gas & Electric Association or the Texas Street Railway Association, but for the benefit of those who are not familiar with the reasons for the amalgamation of these two bodies it is perhaps wise that we make some slight explanation.

Those interested in the ownership and operation of gas, electric and street railway plants in Texas, some years ago realized the necessity of a concert of action. In its inception the Gas & Electric Association conceived that their interests were in a measure identical. The street railway people, not having been invited into the fold, and realizing the necessity of organized action, formed the Texas Street Railway Association. Owing to the large investment necessary to carry on the business of any one of these branches, the number of firms interested within the border lines of our state were necessarily small, and many of our best educators among the manufacturers and representatives of the great supply concerns were obliged to attend two meetings, both of which were limited in their scope and membership, but held for the same general interest. It was thought, therefore, that a combination of the two associations would be wise. Upon investigation we found that our sister republic of Mexico and the states and territories surrounding Texas were entirely without organizations of this nature. It therefore seemed that great benefits might be derived from the organization of an association whose interests were so thoroughly identical and whose territory embraced the southwestern portions of North America.

To this end your committee, appointed at Laredo, organized the present association, and it is proper that we should hold our first annual meeting in the capitol of the state whose organizations were the foundation and the corner stone of what we hope to see in the near future, a thoroughly international and so far as the southwest is concerned, interstate association, the value of whose work and the limit of whose membership shall only be exceeded by those great national meetings which are annually held in this country.

Of the work of the past year, in detail, your secretary and treasurer will doubtless advise you at length, they being more familiar with the routine affairs of the association. These will be supplemented by the reports of the various committees, and I shall therefore, after touching lightly upon those items with which I am familiar, deal more with generalities and confine my report to making such suggestions as I believe will be of benefit to us in enlarging our membership and widening our field of development. In accordance with your instructions at Laredo, the committee on permanent organization, to which was given the power to prepare a constitution and by-laws, prescribe such rules and appoint such committees as were necessary to the conducting of our business and including this meeting, met at the office of the president in this city, and formulated such rules as experience had taught us were necessary for our guidance, making them as brief, concise and clear as was possible. These have been submitted to you, and we trust that you have studied them carefully and come here prepared to so alter and amend that when a permanent organization is effected its laws shall be as nearly perfect as possible. We shall call upon some of the members of the committee to give their ideas and would suggest that before adjournment a committee on constitution and by-laws shall be appointed and that it, in conjunction with our past committee, submit for your consideration a permanent and lasting constitution and by-laws.

Your committee, appointed to select a silver cup, to be presented to President Diaz, owing to unforseen circumstances, met with some delay, but the plate has now, however, been properly engraved and is now with us and will be forwarded at once, together with a proper communication. We shall ask Mr. Miller, of Dallas, who is chairman of this committee, to report to you at length.

Such other committees as were appointed will be called upon to make reports. The associations that were the parents of the present association were organized, and very properly so, for a purely educational purpose. Their organizers did not at that time realize the limits to which we were likely to grow, and I concur with them in the belief that the chief aim of this association should be the distribution of knowledge among its members, and exchanging of experience and information. The rapid advancement and development is such that no one man engaged in active business can keep up with the new thoughts, the new ideas and the new facts that were heretofore only theories; therefore the necessity of our getting together to learn from each other that which is taught by experience.

There is also another field for us who are actively engaged in business and whose time is so occupied that we are unable to enter into the smaller details, which is of particular interest to us; this field embraces economy in construction, economy in maintainance, economy in operation, and under the latter head a thousand questions arise in every business man's daily experience. The assignment of papers and your question box furnished a solution of the problem of education; but the application of the knowledge so acquired, it seems to me, should be through permanent committees to be appointed at such meeting, to hold their offices for one year and to be at all times subject to the call of the chairman or the officers of the association, and ready at all times to take up any work that may be suggested by the members.

As an illustration, there is scarcely a doubt but that the rates of insurance, as they heretofore have been fixed by the state board of underwriters, have in many cases been exorbitant and in some cases almost prohibitive. This, we believe, with proper attention could be satisfactorily adjusted.

The members of various legislative committees, whose duty it is to investigate and pass upon many bills which are of direct in-

terest to us, doubtless use their best judgment, but they are neither practical electricians, manufacturers of gas, nor managers of street railway plants. In order to arrive at an honest and just verdict they must be educated. As a rule you will find that the instigator of the bill if aggressive and strongly in opposition to any of our interests is only too often a man who is governed by some personal or local following. He may have had cause on account of unfair treatment, or it may be an imaginary wrong that he strives to remedy. Had you a legislative committee, whose duty it was to get before these bodies and explain to them the conditions and the facts as they exist it would be the source of much benefit to us, and would in a great many cases prevent unwise legislation, which is passed often with no evil intent, but purely from lack of information. There is probably no one here who is more bitterly opposed to what is known as "lobbying" than I, but in the many years that I have lived in the capital I have seen many cases where the legislative body was as anxious to secure information as were the interested parties to give it. We therefore think that a committee on legislation would be wise. And so on a great many committees might be appointed on other lines which would be of great importance to us. We cannot come together daily or weekly, as the exigencies of the occasion may demand. We are all active business men and if we could be represented during the year by strong committees, having separate and individual work to perform, and which should meet with us once every year and give us an account of the stewardship, I believe that great practical benefit would result. There have been one or two questioning voices during the year; but only few have seemed to fear as to the result of our amalgamation. The past year, of course, has been no criterion as to what might be done. At Laredo we joined issues without any laws or any definite plan of action. We thought that as with other bodies of a similar nature it would take time necessarily and I sincerely believe that the basis we have adopted, together with the suggestions that will be offered at this meeting, will soon put us in a place where we will not only demand, but have a right to expect both national and international recognition. To my brother officers and to the standing committees, I wish to extend my sincere thanks for their untiring efforts.

Secretary Wells presented his report, as follows:

SECRETARY'S REPORT.

Gentlemen: The formation of the present Association from the Texas Gas & Electric Light and the Texas Street Railway Associations in Laredo, Texas, in March of last year was accomplished during the latter part of the joint session of the two associations, and a new Southwestern Gas, Electric & Street Railway Association was launched on its career with practically no rules and no precedent for the guidance of its officers. The committee appointed at Laredo to draft a constitution and by-laws for the new Association met in this city in May of last year and the result of their labors is herewith presented to you in their report.

The committee appointed to arrange for the 1899 convention selected Austin as the place and April 19th as the time of the meeting, owing, however, to the prevalence of small-pox in Southwest Texas and Mexico and to the inadequate and unprecedented condition of the water power of the city of Austin from which current for the purposes of exhibition and entertainment were to be drawn, it was deemed advisable to postpone the date of the meeting to May 17th. That this postponement has influenced the attendance unfavorably is probable, but it was considered that no other course was open under the circumstances. On May 21st, the following board of directors was appointed by the president to serve until their successors are elected at this meeting, or for such time as may seem proper to the association: J. F. Strickland, Waxahachie; E. Dysterud, Monterey, Mexico; W. E. Hamilton, Shreveport, La.; L. T. Fuller, Calvert, Tex.; W. E. Holmes, Austin; J. H. Fitzgerald, Houston; Thos. D. Miller, Dallas; W. H. Weiss, San Antonio; H. M. McGregor, Houston, and Harry L. Monroe, Dallas. On the same day the following finance committee was appointed: Messrs. Scovill, Lord and Yaeger.

On June 23, 1898, Messrs. Drake, Monroe, Miller and Wells met in Dallas and took steps looking to the reduction of insurance rates on gas and electric risks. As an outcome of this meeting the secretary issued a circular letter during July on this subject, attaching copy of a letter from President Drake, which read as follows:

Austin, Tex., June 27, 1898.

Mr. E. L. Wells, jr.,
Secretary, Marshall, Tex.

Dear Sir: The Lumbermen's Association of Texas, of which I am an officer, has made arrangements with insurance companies whereby our rates have been largely reduced in consideration of our giving them a large amount of insurance in bulk. You will please take up the matter at once with the members of the Southwestern Gas, Electric & Street Railway Association and ascertain how much insurance they will be willing to place through the Association, provided we can give them equally good insurance, with as good or better adjusters, at a considerably less price than what they are now paying. I am not prepared now to state just what this reduction will be or through whom we shall write our policies, but can assure you that if sufficient risks can be obtained considerable benefit can be derived.

Our Association heretofore has been of much benefit from an educational standpoint; but we believe that a practicable financial benefit will greatly strengthen us. We therefore hope that you will without delay communicate with our members and obtain from them a definite proposition as to the amount of insurance they would be willing to place through us, assuring you, however, that there will be no pecuniary remuneration to any officer of the Association, and the benefits, whatever they may be, will be equally divided amongst our members.

Trusting that you will give this your immediate consideration awaiting your commands, I am,

Yours truly,
(Signed) C. F. Drake,
President.

As a result of this circular a considerable amount of insurance was pledged, but not enough to justify the Association in taking the final steps necessary to secure the desired reduction. The good accruing to the Association and to its individual members through the accomplishment of such a plan is obvious and need not be enlarged upon. It is therefore hoped that steps will be taken at this meeting to bring the matter to a successful issue. During the past few weeks the committee has deemed it best to defer further action until pending legislation affecting insurance has taken definite shape. On Sept. 5, 1898, a meeting of the directors of the Association was held at the Minger Hotel, San Antonio. The program for the 1899 convention was arranged and subjects were assigned with the view of presenting to this body a series of papers that would be a credit to the Association. In these assignments, I am sure, you will find that the directory has been most fortunate. The constitution and by-laws as prepared by the committee were passed upon subject to the action of this convention. The following committee on insurance was appointed with authority to enter into negotiations with both the old line and mutual companies, looking to a reduction of the present rates: Messrs. Weiss, Holmes, Drake and Wells. Messrs. Scovill, Weiss and Drake were appointed a committee to meet with the representatives of the Street Railway Association at Austin on Sept. 20, 1898, to arrange for one or more summer amusement circuits for the season of 1899. On Oct. 17, 1898, President Drake appointed the following committee on membership. Messrs. Monroe, Johnston, Dutton, Dysterud, Brook and Hamilton. The secretary respectfully suggests that a more general interest in the acquisition of new members would be most proper. The life and growth of the Association depend on the constant infusion of new blood and too much attention cannot be paid to this feature. He would also be glad to see some plan adopted looking to an organized effort on the part of the Association as a whole and of the traveling members in particular whereby large and constant additions to our membership roll can be made. The Association has maintained during the year an electrical department in the Southwestern Industrial and Lumber Review, which has done much to keep the members in touch with one another as well as generally informed as to the light and railway news of this section. Mr. Chas. A. Newning, editor of the Review, has exerted every effort to make his journal useful to the association and that he has been eminently successful cannot be questioned. It is hoped that this unique feature of association work will receive much encouragement from members during the coming year, not only in a financial sense, but in the way of contributions, and open discussion between members that will be of interest and of benefit to the Association as a whole. In addition to the matter appearing in the Review the Association has

issued through its secretary several circular letters during the year to the entire territory embraced in its scope, calling attention to the advantages of associate work and soliciting applications for memberships. It is hoped that these efforts will redound to the benefit of the Association and that with others which will follow they will succeed in building up an organization that will be of credit to the section, and a source of much good to the profession. In conclusion the secretary begs to thank the officers of this Association, and all members who have helped him with their assistance and advice.

Summer Attractions for Street Railways.

BY T. H. STEWART, SECRETARY CITIZENS' RAILWAY CO., WACO, TEX.

Under ordinary conditions the way of the manager of a street railway system does not lead through shady avenues, lined with fragrant flowers, with downy couches here and there in pleasant nooks, on which he may at will recline and take his ease. But rather it is filled with stones and boulders, hedged in by jagged rows of thorns and thistles and yawning chasms ever threatening to engulf him.

But there came a time when the public would not ride and empty cars rattled back and forth and brought no fruit. Stockholders grew restless and fretful. Out of every 5 cents passenger receipts, there was required 7½ cents expenditure for maintenance, damage suits and franchise taxes. Expense accounts grew and kept growing and took the shape of spectres and goblins and haunted the manager at night, and in his waking hours were ever present.

But the street car man did not despair. He was made of different material. He set his mind to work to devise ways and means to coax the people to board his cars and contribute of their hoarded wealth to fill his coffers. He called to mind how in his younger days he had coaxed a stubborn calf to go by simply twisting its tail. He also remembered that he had once induced a terrapin to come out of his shell by the application of a red hot coal. But neither of these methods seemed practicable in the case of the public. Then he remembered how eagerly and with what untiring zeal he had pursued the elusive end of the rainbow for its traditional bag of gold. "Eureka, eureka," he said,—or words to that effect—"I will put a bag of gold at the end of my line in the shape of summer amusements, and the public will go after it."

I have given the subject of "Summer Amusements for Street Railways" some thought and consideration, and will very briefly present to you the result.

The first question to be considered will be the particular style of entertainment to be offered. This will depend entirely upon circumstances and conditions surrounding the street car system and the facilities at its command. If it has the use of a good-sized park, such amusements as base ball, picnic parties, bicycle races, balloon ascensions, fire works, trapeze performances, etc., can be made good drawing cards. But if the entertainment must be confined to an auditorium, it must take the form of theatrical performances, musicals, balls, etc. In any event, it is of the first importance that the opening attraction be well attended and a success. It is a singular fact that the people like to go wherever the crowd goes, and if the season can be opened with a large crowd in attendance the battle is more than half won. To this end great care should be exercised in selection a first-class attraction for the opening and getting it properly advertised. Newspaper advertising in the way of reading notices is one of the best methods of reaching the public, and such advertisements should be plain simple statements of facts in a dignified and straightforward manner. Remember that you are building a structure to last through a season, and your foundation must be solid, else your building will likely topple over before it is finished. It is well to begin, at least, by telling the truth, however awkward it may come. Later on, if the strain becomes too great we might depart therefrom, and give free reign to lurid imagination, but it ought to be done by degrees. When anything happens to mar your entertainment, or if the play has been tiresome, if you will admit its shortcomings in your newspaper notices and promise to do better the next time, it will go a long way toward securing the public confidence. It is not a good idea to try to fool the people.

After starting with a good entertainment and a good attendance, the street railway man must be ever watchful to keep his performances strictly respectable. Under no circumstances should he permit anything either in word or act bordering on the vulgar, for his success will depend entirely on the attendance of ladies and children, especially the ladies. Get the feminine approval of your entertainment, then you may rest satisfied.

The street railway man who undertakes to furnish an entertainment daily for an entire season, of such character as to please his audiences so that they will come again and again to see them, and outside of this give proper attention to his other duties, has taken upon his shoulders a task that is herculean, and he needs the brains of a Solomon to be forever planning, the eyes of Argus, that he may never sleep, and the legs of a centipede, that he may never tire. His ears should be large and commodious, that into them may be poured complaints innumerable and criticisms galore. In patience he must surpass the Job; his temper must never become ruffled; his smile under all circumstances must be childlike and bland. But above all and over all, his tongue should be well oiled.

And right here is a good place for me to air a pet scheme which has been nursed for some time by street railway managers in Texas, and which I hope to see in operation at least by the beginning of next season. It is to establish a circuit embracing a number of cities. We will say a half dozen cities combine together, those of us who depend upon theatrical companies for summer attractions, and before the opening of the season select and employ for the entire season a high-class entertainment company for each city in the circuit, these companies to play alternately for a week or longer in each city of the circuit, the object being to furnish as often as necessary in each place new faces and new attractions, and at the same time relieve the management of a great deal of worry and annoyance. I only touch upon this subject in a general way, as it will not admit of discussion in so short a paper. The luxuries of today are the necessities of tomorrow. The summer attraction started as a luxury to the people; it has developed into a necessity with them, and our patrons meet us early in the spring with clamors for our opening bill at the end of the line. We must be prepared to meet their tastes and wishes, and a summer theatrical circuit is now almost a necessity to fill this need. I hope this important question will be thoroughly discussed at this meeting.

There is a question about the entrance fee, as to whether a fee should be charged. There are two classes of people. One class are always looking for bargains. The things they get free, or at a great bargain are the things they prize most highly. The other class do not consider a thing of value unless they pay a high price for it. Inasmuch as you cannot charge a high entrance fee to your entertainments, I think it best to make the entrance entirely free, and charge a small sum for desirable seats. In this way you can catch both classes of people. The bargain hunter will have secured his bargain, for he can see the entertainment free, while the moneyed man will have been satisfied, at least in a measure, for he can pay his money and get the best there is to be had.

Then there is some revenue to be derived from letting of special privileges such as lemonade stands, candy stands, etc., and it is desirable on this account to have a large attendance—another reason for making the entrance free. While on this subject, the street car company should see to it that the venders of these refreshments should be gentlemanly in their behavior and always attired in neat and clean uniforms befitting their business.

The price to be paid by the street car company for any special entertainment will be governed, of course, by the benefits derived from the entertainments, and is a matter for the judgment of the person in charge.

The character of the entertainment should be changed as often as possible to keep up interest, and great care must be taken not to keep the audiences too long or they will become tired and bored. It is much better to send them away a little hungry than to send them away gorged.

In case you should make the entrance entirely free there will be a question about what to do with those who visit your place in other conveyances than your cars. In my opinion such visitors should be charged the same amount paid by those who use your cars. My experience is they will not object to this.

Speaking for the company with which I am connected as to its experiences with summer entertainments, I can say unreservedly that they have been a source of profit and success.

Means of Encouraging Diversified Use of Electric Current.

BY C. L. WAKEFIELD, DALLAS.

Several things are necessary in order to encourage a diversified use of electric current. In the first place, you must be able to furnish power at a figure less than the cost of equipping and operating a small steam plant. This is not so difficult a part of the problem as it might appear, as you must always take into consideration the employment of considerable labor in operating a small plant, and the further fact that an ordinary high speed engine takes much more steam per horse power than the cross-compound condensing engine, such as are now being installed in our newer plants.

In Texas few manufactures can be carried on successfully except those in which labor is the principal item of the cost of production; freight rates are so high both on the finished product and the raw material, that success cannot be reached unless the freight is but a small part of the total cost. There are a great many things that can be manufactured in this country from cotton and the by-products of cotton mills, but the necessary expert labor does not live in Texas, it must be imported or induced to locate here. It strikes me, therefore, that the first step necessary towards the encouragement of a diversified use of the electric current, is to thoroughly advertise the resources of your town with regard to raw material and power, and I know of no better way than through a commercial body or club, and if there is no such organization in your town, one should be organized, and by you if necessary.

The perfection of the alternating current motor has eliminated many disagreeable features in the use of the electric current, in that these small machines are not likely to get out of repair and need no expert to put them in shape, should they by chance get out of order. The time when electricity will be generally used for cooking and heating purposes is probably very far distant; the difference in the cost of gas or fuel for this purpose and electricity to get the same results cannot be bridged except by convincing the users of the current of the extreme nicety and cleanliness of this mode of cooking, and until our people are so far advanced financially that they can afford luxuries of this sort, very little can be hoped for in this line.

I suggest, therefore, that the first thing to do is to get our people or outsiders to install factories in the lofts and other unused portions of buildings in our cities for the purpose of making brooms, blank books, baskets, belts, paper boxes, etc.—or any small articles for which much power is not required. A cheap motor adapted for ready attachment to ordinary sewing machines would greatly increase the use of electricity.

One difficulty is that the work in a kilowatt-hour is so little known that people are not willing to be charged for just what they use. The flat rate is the most popular and the most iniquitous thing in the business. It is simply one of the plans by which the good citizen is made to pay the dead beat's bill. Time and experience will probably cure this evil and greatly alleviate the distress that the station man suffers by reason of it. Any one with a small manufacturing business in Texas can afford to pay from 2 cents to 3½ cents per kilowatt-hour for current, and whether or not, you can furnish the current at this price depends upon your equipment and somewhat upon your geographical position, as the latter influences the price of coal, although the cost of fuel is now being ruled more by the labor trust than any other thing that I know of.

There is a field already before you that has only been partly worked and is capable of much larger results than are now being obtained. I refer to fan motors for residences. In many smaller towns a day circuit is not operated and inasmuch as such a circuit will only cost you coal and a small outlay for day attendance, I would advise all station managers in towns of 5,000 or over to try the experiment, and at the same time not to try to get too much from the consumer for this kind of service.

A Model Plant Under Model Management: What Both Should be Like.

BY J. F. STRICKLAND, WAXAHACHIE.

This plant is located in a live and progressive city of eight to ten thousand inhabitants. The generating station is centrally located and 50 per cent of its business is within one-fourth mile of the station, 75 per cent within one mile, and at no point has this plant a customer more than one and one-half miles out. Hence, according to my views, the management wisely adopted the 220-volt direct current system. Some of my friends no doubt will take issue with me on this point, but as we are dealing with a plant where the conditions are as stated above, I will say that all they would need to reconcile them with this system would be practical experience in its operation.

STATION EQUIPMENT.

Buildings: The building is one story brick or stone with fireproof walls between boiler and engine rooms with two heavy metal covered doors within this wall, one each towards either end of the engine room. This building is divided up as follows: Engine and dynamo room 30 x 42 ft. Boiler and pump room 40 x 42 ft. Office, including hallway to storeroom, 20 x 20 ft. Storeroom 20 x 20 ft., and directly in the rear of the storeroom and across an open hallway or alley, we find a repair shop 20 x 22 ft well equipped for all repairing necessary around this plant. This building also has concrete floors throughout, except in the office and storeroom, and is supplied with all necessary openings for ventilation, ingress and egress, and the reception of machinery. It will be noticed that there is a minimum risk of fire about this building, hence a low rate for insurance.

Fuel: There is space inside of the boiler room on side next to the railroad track to store about fifty tons of coal.

Boilers: There are two in number, of the return tubular type made of the best material, with double strap, butt joints, treble riveted and well stayed for safety at a working pressure of 125 lb. They are set in masonry in the best workmanlike manner. They are 60 or 66 in. in diameter and are of the proper length and number of flues to make them 100 h. p., nominal. These boilers are connected to one common flue running above uptakes to a steel stack resting upon its own foundation and of proper area and heighth to carry away the gases for a battery of three boilers of 100 h. p. each. They are so spaced in the building as to allow for the setting of the third, and they are equipped with one steam and one electrically driven pump, each being of a capacity to supply a battery of three boilers. There is connected between the engine exhaust and the water supply system, a heater for the utilization of the exhaust steam in heating and extracting as near as practicable all impurities of the feed water. These boilers are also equipped with first-class mechanical surface skimmers and all steam connections are made in a practical workmanlike manner, and as flexible as conditions will allow; each has an independent safety valve. Each connection from boiler to steam main has places therein and near to the boiler a gate valve which enables the engineer to cut in or out either boiler as the load varies.

Engines and generators: There are two four valved, high grade, medium speed engines of 100 h. p. each, with gridiron admission valves and exhaust valves of the well known cylindrical, oscilating type. To each of these engines is direct coupled one 65-kw. 220-volt direct current generator capable of carrying 25 per cent overload from three to four hours. One of these units carries the load except on special occasions. At the peak of the load the other one is started up and both units are run in multiple over the peak. While the rated capacity of these two units is only 2,500 lights, they easily take care of 5,000 lights wired in, which are almost exclusively on meter basis. As stated, this plant is located in a live and progressive city, hence I will endeavor to show what provisions have been made to take care of the increased business. The demand is so great now that something must be done, and the matured plan is (presuming that the territory has increased with the business of this plant) to install the three wire system, work the two units now in the station in multiple series, which means 220 and 440 volts. At this time there is to be installed a unit of about 300 h. p. of the corliss compound type with a 200-kw. generator direct connected. This generator will deliver current at 220 and 440 volts. This type of generator is being discussed pro and con at present by able engineers, but my belief is that it will be practicable by the time the business of this plant demands it. If not, however, the next thing to it will be adopted.

Motors: From the date of the above mentioned addition all motors, say from 3 h. p. up, are to be 440 volts, and those already on the service should be changed as soon as convenient. This would simply balance the load.

Switchboards and interior wiring of station: Beginning at each generator there is a double line of conduit or 3-in. vitrified clay pipe leading to the switchboard; it is laid in cement and lined with paper saturated with good insulating paint. For these leads a good rubber covered cable is in use, and on each generator panel there is a main switch, ammeter, voltmeter, rheostat and a recording wattmeter, with capacity equal to its respective generator, besides the necessary equalizers, terminals and switches; connected across the buss bars there is a recording voltmeter. The instruments on the second board are one switch, an automatic current breaker, ammeter, and magnetic blow-out lightning arrestor on each circuit. Other instruments on this board are ground detectors, clock and some minor station instruments. The board is located in the center and near the front of the engine room. All circuits go out through a tower directly over the board and from there to the pole lines.

Meters: As stated, the business of this plant is largely done through meters. A feature that is growing in favor because an accurate meter is just to both the producer and the consumer. The management is also introducing the two rate meter as rapidly as possible, which will certainly be a winner.

MANAGEMENT.

The owners of this plant have in their wisdom employed a conservative, yet progressive man, and dividends or no dividends, for the time have been left entirely with him. He immediately employed an up-to-date electrician who is good in practice as well as in theory, as both are essential to success in our line. Certain authority was given the electrician and from this time he acted as both the superintendent and electrician. A first class mechanical engineer for a city of the size of this is in charge of the station, and given the day run. He is furnished such help as is necessary to enable him to keep everything in first class mechanical shape. All the other employes are a sober, reliable type of men and are educated to let the patrons of the plant do all the kicking (if any is to be done), and they to report the same to their superiors. The manager of this plant will not tolerate in any of his employes any discourtesy to his customers. The manager of this company looks after the supply business, wires, building, etc., which according to my views is proper as he is to be held responsible for the good or the bad lighting and all other complaints known to the business. It is necessary for the manager to know as nearly as possible all about the class and condition of the wiring through which he is to supply current. The manager is also of the type that believes first in good service, but especially in maintaining rates on a legitimate basis, which is easily done where the service is kept up. He is a progressive fellow, always looking out for business and encouraging every probable consumer of current; the day load is especially looked after, and reduced rates are made for this service. He stays as clear of politics as possible yet he maintains a fair contract with the city. He furnishes nothing free, neither does he rent anything to his customers, except in special cases. It is the opinion of the manager of this plant, as well as the writer, that it is a mistaken idea to rent fans, motors or meters as a rule; but the central station should supply them to its customers at just profit enough to make that branch of the business self sustaining.

Rates: The greater part of the business of this plant is done through meters and the established price is 20 cents per kilowatt, but at this point the two-rate meter does good work on long hour service, or day business. Meter bills are payable at the end of each month and all flat rate customers are required to pay their bills 30 days in advance. The point here is that a customer who invests his money in meters, fixtures, etc., is a safer risk than those who run on the flat rate business with less money invested in fixtures.

Quarterly dividends are the result of the operation and management of this plant.

A number of papers of interest only to gas men were read at the third day's session. The following officers were elected: President, Thomas D. Miller, of Dallas, Tex.; first vice-president, J. F. Strickland, Waxahachie, Tex.; second vice-president, C. A. Yeager, Laredo, Tex.; third vice-president, W. E. Hamilton, Shreveport, La.; directors, Carl F. Drake and F. E. Scovill, of Austin; E. Dysterud, Monterey, Mex.; Fred Fries, San Antonio; E. L. Wells, Marshall; J. C. Cullinane, Denison; secretary, T. H. Stuart, Waco; treasurer, Fred Fries, San Antonio.

It was voted to hold the next convention at Waco, Tex.

INTERURBANS HELP SMALL TOWNS.

One of the hardest things to combat in securing franchises for an interurban road through small towns, is the fear on the part of the local merchants that the building of their road will take their business away and send it to the larger places. Of course experienced railway men know the history of events to absolutely disprove the assertion. An interurban road helps all along the line. The following is good campaign literature and is a copy of a letter written by the editor of the Pontiac (Mich.) Gazette, to an old friend of his in Indiana, in a town "threatened" with the advent of a trolley line, which was expected to close up every store in the place. The Pontiac road is about 27 miles long, has been in operation several years, and connects that town with Detroit, to which everybody was expected to go for their trading. What did result is told as follows:

"Our people are now delighted with the road and so are the villages of Birmingham and Royal Oaks, between here and Detroit. It was naturally thought the big city of Detroit, only 27 miles away, would be largely benefited by the road to the detriment of the trade of smaller places, but this preliminary scare has entirely disappeared. Before the road was built our merchants were apprehensive that trade would go to Detroit more largely, but they are all pleased now as business has improved greatly and the road has been a blessing. The little towns along the route which were supposed to be doomed by the road, are now more prosperous than ever, so that all the arguments we at first advanced against the electric road were largely visionary, the phantoms of fright. Not only are the towns benefited, but every farm along the line has largely increased in value, and there are no happier people than the farmers over electric roads. We are building another line to Detroit by another route, so you see our people are not alarmed over having close connection with a city of 250,000 people. The talk that trade would all go to Detroit has proved to be moonshine."

COPPER IN 1898.

Commercial Agent Atwell, of Roubaix, transmits to the State Department a table of the copper production of the world for the last four years, which is from the Revue da la Semaine:

Country.	1898.	1897.	1896.	1895.
	Tons.	*Tons.*	*Tons.*	*Tons.*
Algeria	50	.....	.....	35
Argentine Republic	125	200	100	150
Australia	18,000	17,000	11,000	10,000
Austria	1,100	1,210	1,075	1,110
Bolivia	2,050	2,200	2,000	2,250
Canada	8,040	5,905	4,000	4,000
Chile	24,850	21,900	23,500	22,075
Cape of Good Hope	7,060	7,440	7,450	7,080
England	550	555	555	580
Germany	20,085	20,145	20,065	16,555
Hungary	430	445	210	200
Italy	3,435	3,480	3,400	2,500
Japan	25,175	23,000	21,000	18,430
Mexico	10,435	11,370	11,250	11,620
Newfoundland	2,100	1,800	1,800	1,800
Norway	3,615	3,450	2,500	2,685
Peru	3,040	1,000	740	450
Russia	6,000	6,025	5,100	5,280
Sweden	480	545	500	515
Spain and Portugal	53,225	54,060	53,325	54,950
United States	234,261	215,460	203,893	172,297
Total	424,126	397,190	373,363	334,562
Average price January 1 of each year	$250.08	$238.97	$229.85	$208.40

Consul Stearn, writing from Bamberg, gives the estimated copper consumption of various countries in 1898 as follows: Germany, 101,518 tons, an increase of 81 per cent since 1892; England, 106,000 tons, a decrease of 4,500 compared with 1897; France, 55,000 tons, 4,000 less than in 1897; East Asia, 20,000 tons; Russia, 6,600 tons.

Street car mail service is fast growing in popularity in Hartford, Conn. The cars were put on April 1st and on that day collected 399 letters. The increase was rapid, doubling in a few days. The service is being used for special delivery letters much to the satisfaction of the business men.

DETROIT, LAKE SHORE & MT. CLEMENS.

The Detroit, Lake Shore & Mt. Clemens Ry. has now been in operation for about eight months and has demonstrated the advantage of using cars which are not only handsome in appearance but in which the perfect comfort and convenience of passengers is made a first consideration. By the adoption of sleeping, parlor and buffet cars, which for the most part are simply luxurious palaces on wheels the steam railroads of the country have robbed traveling of nearly all its inconveniences and made it a pleasure instead of a trial. The Detroit, Lake Shore & Mt. Clemens Ry. seems to be the pioneer in regularly running palace cars on electric roads.

This road, which has proved very popular, now runs from Detroit to Mt. Clemens. The route lies along the beautiful Detroit River and along the shores of Lake St. Clair. It is 26 miles long, every foot of the way being through an attractive country, starting from one of the loveliest cities in the world and ending where are located some of the most famous mineral springs yet discovered.

The president of the road is Mr. M. B. Mills, a very wealthy Detroit capitalist. He is commonly called the "Commodore," being the owner of the "Cynthia," one of the finest appointed yachts in this country. Thos. N. Fordyce is the secretary; F. T. Ranney, treasurer, and W. J. Hart, general manager. Mr. Hart was interested in the Interurban road of Saginaw, Mich., but sold out there to become manager of this line. He had general charge of its entire construction and equipment.

The track is of 70-lb. T-rail laid on oak ties 6 x 8 in. x 8 ft.; the ballast is gravel. The cars were built by the Barney & Smith Co. and are particularly fine ones. They are 51 ft. long and are without any doubt the most comfortable, complete and handsome ever regularly used on an electric line. Each car contains a baggage and smoking room, the latter fitted with folding seats. There is a luxurious stateroom with four seats in which it costs 10 cents per passenger additional to ride. This stateroom is much used by parties desiring to play cards on the trip. There is also a complete toilet apartment and a water cooler.

The regular passenger compartment has a seating capacity of 50. The cars are each lighted with 25 16-c. p. lamps and have Wagenhals electric headlights. The cars all through are very handsomely fitted up.

The power house is located at Lakeside. It is built of brick and is 100 x 40 ft.; the roof is metal. The equipment comprises two Russell compound four-valve engines guaranteed to develop 450 h. p. with 125 lb. steam pressure. Each engine is direct connected to a 300-kw. Siemens & Halske generator. There is also a 200-h. p. Russell four-valve engine direct connected with a 100-kw. Siemens & Halske booster. The switchboard is of the ordinary type. There are two Stirling water tube boilers, each provided with the Jones' machanical stoker. There is also a Laidlaw-Dunn-Gordon single jet condenser for each engine, a Wainwright closed feed water heater and all the other usual appliances.

The cars on this line are fitted with two trolleys, one immediately behind the other, and both are used when the car is heavily loaded. The diameter of the trolley wheel is 6 in. and it has a groove 2 in. in width and flange 1¼ in. in height. The Wilson-Thompson trolley pole catchers have been adopted.

All the cars are provided with telephones and connections can be made with telephone wires at the turnouts by using junction boxes. If necessary, messages can be sent between turnouts by means of a flexible connection and jointed poles furnished with hooks which are thrown over the telephone wire. While this telephone service is especially provided for the use of the conductors and the train dispatchers the public can have the benefit of it in case of emergency.

The Detroit, Lake Shore & Mt. Clemens Ry. is an admirable road and its success from the start will doubtless give the palace street car a strong impetus.

DETROIT, LAKE SHORE & MT. CLEMENS RY.

COMMERCIAL ASPECT OF TRAMWAYS IN GREAT BRITAIN.

The commercial aspect of electric traction in Great Britian was discussed in the Engineering Magazine for April by Mr. Emile Garcke, who after an extensive experience with electrical enterprises in England is now managing director of the British Electric Traction Co. The difficulties of promoting an electric tramway in Great Britian are classified and their causes analyzed by Mr. Garcke. He states that the great developement of various industries by means of private enterprise in the early part of the century resulted in a reaction which for the last twenty or thirty years has greatly discouraged private undertakings in the nature of monopolies. One of the tentative and mischievous measures which has proved prejudicial to the public and to investors was the Tramways Act of 1870. Unfortunately capitalists did not at first fully appreciate what they were doing and the tramways after a pitiful existence of 21 years are being purchased by local authorities at the price of old rails and machinery.

When in 1882 an electric lighting act was passed, capitalists had learned their lesson and none of 62 provisional orders granted to companies in 1883 was carried out; very little was done until 1888 when the act of 1882 was amended making the period of purchase 42 instead of 21 years.

The limited tenure permitted by the Tramway Act of 1870 is not the only cause of the failure of many tramway companies in Great Britian. The capital expenditure per mile of track is much greater than in America and this Mr. Gracke states is due largely to the difficulties placed in the way of the company by municipalities.

"The whole tendency of late has been to regard commercial promotors of public works not as benefactors, or as people rendering a public service and therfore entitled to a fair reward for their labors and risks, but rather as people who have no interests in common with the public they serve. In theory and in law, the right of a tramway company to use the street is granted on the sole ground that it is for the interest of the public that they be allowed to do so. The grant of the powers is an accommodation to the public and not a privilege or gift to the company, and, therefore, the company should be fairly remunerated for rendering a public service; and the better the company does the service, the better it should be rewarded; but local authorities now generally take the view that the promotor of public works is an usurper who should be mulcted and discouraged rather than assisted.

"This view is not held by responsible legislators nor by representative institutions, but is forced upon them by the organizations

and influence which municipal corporations are able to bring to bear."

Typical cases showing the difficulties that private companies have to meet are as follows:

"(a) A tramway company sanctioned by Act of Parliament obtained statutory power to adopt electric traction. For the purpose of carrying this out, the angles of the loops or passing places on single lines had to be slightly eased so as to enable the electric car, which cannot—like the horse car—be pulled to one side to pass over them. The corporation objected to these alterations being made, unless the company agreed to widen the streets in other parts of the town. The result was that the introduction of electric traction was delayed until this legal point was settled, and the company has nothing to show for the unnecessary law costs it had to incur.

"(b) Upon the invitation of a corporation, a tramway was promoted. The corporation insisted upon the scheme being enlarged by lines being added which were not needed, except, perhaps, to increase the value of some building plots, and which lines, in the opinion of the company, would not pay to work for very many years. Many other serious conditions were imposed, and as the company declined to accede to these conditions the corporation opposed the confirmation of the order at every stage of its process; as there was no longer any prospect of the undertaking becoming remunerative, the order was withdrawn, and there is no electric traction in that town.

"(c) In the case of a tramway worked by steam without any profit, application was made for necessary powers to work the line by electricity. The corporation approved of the proposal, but made it a condition of their assent that the electrical energy should be purchased from an electric-light station which the corporation proposed to establish. The electric-light station by itself would probably not pay, as the town is a very small one; but the corporation hoped that, by obtaining the tramway as a customer, they would be able to make their proposed electricity-supply works remunerative; but so doubtful was this that they would not undertake to supply the electrical energy except at a price which would be higher than the cost of working the tramway by steam power."

In one instance, two cities no more than eight miles apart, each having municipal tramways, cannot agree on a common gage and therefore an interurban line is out of the question.

PROMPTNESS OF AMERICAN ENGINEERING.

Nothing daunts the American engineer, and the following story from The Tradesman partly accounts for the rapid progress being made in the introduction of American steel railway materials in Europe.

The British Government needed an iron bridge over Atbara River, near Phartown, and submitted tenders to several of the leading engineering works of England. Time was the essential consideration, rather than cost. The best any British firm would say was "seven months." The Pencoyd Iron Works, of Pittsburg, have completed the spans—seven of them, 1,029 ft. long in all—and loaded them for shipment, in six weeks. This reminds an eastern daily of a story:

Some years ago a landslide in Switzerland destroyed a section of railroad. It was rebuilt carefully and solidly, to last till the crack of doom. It had taken several years to complete. An American engineer was present at the ceremonies. "Could you beat that?" the Swiss engineer said to him, with pride. "No, we couldn't," the American replied, "but—" "But what?" the Swiss asked, as he hesitated. "Well," the American went on, "I doubt if we should have made as good a job of it as you; but instead of wating three years to finish it in this style, we'd have put up a temporary trestlework around the landslide and been running trains again in six weeks." The Swiss shook his head. "We never thought of that," he said. "P. D. Q." is an American expression which means, as Kipling says, "with speed." The British Government wanted that bridge over the Atbara River, and wanter it quickly for Kitchener's use. The Americans said they would have it done P. D. Q., and—to use another American expression—they got a hump on themselves and did.

There is some excuse for the English taking seven months to do a six weeks' job, in the fact that the great strike of 1898 resulted in overloading their capacity with home orders, so when a new order of magnitude comes in it is set down to be done when every one booked ahead of it is out of the way. But that isn't all, it doesn't account for all of the difference. An American house, the pay being enough to justify it, will run "double turn" twenty hours each twenty-four. Or it will temporarily extend the works. They will meet the demand if it be possible; and they are more fertile in expedients for the purpose, than any other people in the world. By virtue of this peculiarity our iron works, in various lines, are getting a good many large and—we hope—profitable orders, from Europe. Locomotives, electrical appliances, heavy enginery of the stationary kinds, are ordered on this side, because neither the German nor the British firms can do the work in the time limit allowed.

U. S. MAIL SIGNS ON STREET CARS.

May 13th Postmaster-General Smith promulgated an order regarding the use of "U. S. Mail" signs on street cars, which is as follows:

"Hereafter no street car company having a contract for transportation of United States mails shall display the words 'United States Mail' or their equivalent upon any cars except those in which the mail is actually carried. Such companies must provide portable signs bearing the words 'United States Mail,' which shall be displayed on cars only when the United States mail is being transported therein. The sign 'United States Mail' must not be painted on or displayed from cars having street letter boxes attached thereto, the boxes themselves being a sufficient indication that United States mail is being carried on the cars. This order does not in any way affect street cars used exclusively for the transportation of United States mail."

MILEAGE REPORTS AT TERRE HAUTE.

The accompanying diagrams show the two sides of the conductors' collection report recently designed and adopted by M. F.

Form D. 10M 12-98.

NOTICE

Conductors MUST POSITIVELY use station letters in making out these reports and familiarize themselves with the letter of station their car starts from and runs to. Negligence and Indifference on the part of conductors will be treated as it will merit.

M. F. Burke

General Manager.

SALE OF LEXINGTON (KY.) ROAD.

Mr. R. Lancaster Williams representing capitalists in Baltimore and Richmond, Va., last month purchased the property of the Lexington (Ky.) Railway Co.; the purchase price has not been made public, but parties who are well acquainted with the affairs of the company estimate it at $750,000. The property sold includes that of the Belt Electric Line Co., which operates the electric railway; the Central Electric Co., operating the lighting plant; the Hercules Ice Co. and the Passenger & Belt Co.

May 13th the board of directors, which consists of J. Williams Mittendrof, S. Davies Warfield, W. J. Loughridge, Geo. W. Doonall, J. R. Morton, R. P. Stoll and R. Lancaster Williams, chose officers as follows: President, R. Lancaster Williams; vice-president, Geo. W. Darnell; treasurer, R. P. Stoll; secretary, T. D Murray. R. T. Gunn, who was superintendent of Belt Electric Line, will continue to have the management of the concern under its new owners.

The company intends to at once begin an extension of the lines within the city and there is a strong probability that a belt around the city will be constructed. There is considerable talk looking toward the purchase of land in London for a park and if that is done a large summer hotel and places of amusement will be certain to follow. In the event of such a plan being carried out it goes without saying that the lines will be extended to the park and that will be but the opening wedge of a plan to extend the lines to connect with all surrounding towns.

SOUTHERN CALIFORNIA ELECTRIC POWER CO.

In the "Review" for April, 1897, we noted the plans of the Southern California Electric Power Co. to develop the water power of the Santa Ana River; this plant was completed about Jan. 1, 1899, and has been sufficiently tested to determine that it is fully equal to the work for which it was designed. This is the longest line for the commercial transmission of power that has ever been successfully operated; water is taken from streams in the San Bernardino Mountains and transmitted 2½ miles to the generating station, where it flows to the water wheels under a head of 700 ft., generating electrical energy which is transmitted to Los Angeles, 81 miles distant, at a pressure of 33,000 volts. The drop in this line is less than 3,000 volts.

H. H. Sinclair, Henry Fisher and other members of the Redlands Electric Light & Power Co., one of the pioneer companies in the development of power from the streams of Southern California, who formed a corporation known as the Southern California Power Co., for the purpose of developing the power of the Santa Ana River, secured O. H. Ensign as electrical engineer, and L. S. Boggs as civil and hydraulic engineer. Before the plant was completed it was sold to the Edison Electric Co., of Los Angeles, and the current is now being used in Los Angeles and Pasadena for lighting and power purposes, and will soon be utilized in propelling the street cars of Pasadena.

The Santa Ana River is comparatively a small river during the summer months and a very ugly stream after a heavy rain. The minimum flow of the river at the mouth of the canon, in an ordinary summer, is 4,500 in., but during the past summer it fell as low as 1,250 in. During winters of heavy rain it is a stream which runs high into the hundreds of thousands of inches, and as the canon has a grade of about 300 ft. to the mile, the water comes down with a force almost irresistible.

The point of the diversion of water from the river is at the junction of that stream with Bear Creek, where there is a natural reservoir site. The two streams come down from mountain heights through picturesque narrow canons, but just above the junction of the two streams the canons broaden out considerably, and then the united canon leads between two massive walls of rock 200 ft. high and but little more than that distance apart. Here there will be built, in the course of time, a dam, which will serve the purpose of a settling basin, a reservoir for increasing the minimum flow of the stream and adding to the irrigation system in the valley below, and as a means of diverting the water. This is not yet undertaken, the water at present being diverted by means of a temporary structure.

At this point the water is taken into a series of flumes and tunnels having a capacity of 15,000 miners' in. of water. The flumes in this system have an aggregate length of 4,150 ft., while the tunnels, which are arched and lined with Colton Portland cement, have an aggregate length of 11,850 ft. At the terminus of this system there is a pressure pipe, of which a twin will be built in the course of a few months, which leads down a precipitous hill side to the power house. This pipe is an important feature of the plant, being 2,210 ft. long and delivering the water at the Pelton wheels under a head

of 728 ft. The steel of which this pipe is made, at the top, is No. 10 gage, from which it increases to a thickness of 3-16 in., and then by sixteenths of an inch, until at the bottom it is 9-16 in. The twin of this pipe is designed to double the capacity of the plan and give it a dual character, an idea which is carried out throughout the whole design, making it possible to operate either half of the plant alone, or the two together.

This pressure pipe is joined to a steel, lap-welded 30-in. receiver, flanged and bolted and divided by a 30-in. gate valve. Where the pipe taps the receiver there is a 30-in. gate valve and by-pass.

The power house is 126.6 ft. by 36.6 ft., inside measurement, and is constructed of Portland cement concrete. The machines are arranged along one wall, with the shafts parallel to the long dimension of the building. The water wheels are mounted directly on the shafts of the revolving fields of the three-phase generators, each unit being independent of the other, the machine being combined as a water wheel and generator upon one base.

The outlets from the receiver to supply water to the wheels are tapered from 10 in. down to 6 in., where the nozzle connects. The largest nozzle is 3¾ in. in diameter. The wheels are of the well-known Pelton impulse type, and are 82 in. in diameter. Each wheel weighs 12,500 lb. The center of the wheel is made of cast steel, turned all over to give accurate balancing, the buckets or cups being held on by 1-in. bolts, driven into body-bound, reamed holes, the buckets themselves being of soft cast steel. The generators are of the revolving field type, with armature so mounted that they can be moved off the field for repairs without dismounting. The water wheels are governed with a special Lombard governor designed for impulse work, and the working of this appliance is one of the novel and most successful features of the power plant. The revolving portion of the combined water wheel and generator weighs 36,000 lb., and is driven at the rate of 300 r. p. m. The generators are of 750 kw. capacity, being operated at 750 volts. There are three General Electric exciters of 30 kw. capacity each, each driven by a separate Pelton water wheel and governed by a Replogle mechanical governor.

Each of the main Pelton wheels discharges its water through a separate tunnel under the floor into a separate tail-race and each tail-race discharges into a common reservoir 8 ft. wide, which in turn empties into the river through a sluice gate.

At a point farther down the stream, the water is again withdrawn from the river and used for irrigating purposes. It is claimed that the amount available is much greater than in the case of ordinary river flow, or an irrigating canal, as the careful construction of the power canal prevents the great loss from seepage or evaporation, incident to an ordinary open canal, and also the loss from underground flow, which happens when the water is carried in a mountain stream.

The current generated at 750 volts is transformed to 33,000 volts for the line. There are now installed four banks of three transformers each, wound for from 750 to 19,000 volts. Three of the transformers are grouped in Y to give the required 33,000 volts on a three-phase circuit. The transformers are of the General Electric air cooled type and mounted on a foundation of iron girders and concrete, which is 30 in. above the floor.

The low tension switchboard is composed of marble panels 90 in. high, 36 in. wide and 2 in. thick. There are six such panels for the generators, one for the three exciters and one for the total output, on the latter are mounted a recording voltmeter, a recording ammeter, and a recording wattmeter on each bus-bar. On each of the three transformer panels there are two sets of transformer switches, so arranged that the transformers can be connected to either set of bus-bars. The double set of bus-bars are arranged to run two complete and separate plants, or with all machines on one bus-bar, this arrangement being carried through the exciter bus-bars as well.

The high tension switch board stands on a gallery above the low tension, and consists of two line panels, a panel for each bank of transformers, there being arrangements for six banks of transformers. These panels are also equipped with double bus-bars. The line panels have an ammeter in each leg of the circuit.

All the panels in the building are composed of Tennessee marble, the currents being somewhat insulated from the marble by thick, hard rubber bushings, which extend five inches through on each side. The marble is all polished on both sides.

The transmission line from the power house is 81 miles long, and is composed of two circuits of three wires each, No. 1 B. & S. gage. In the canon the poles are 30 ft. high, 8 in. on top, 110 ft. apart, the canon being 5½ miles long from the power house. From the mouth of the canon to Los Angeles the poles are 120 ft. apart, 35 ft. high, 8 in. on top, except through cities and towns, where 50-ft. poles are used. The wires form triangles, are spaced from 17 to 28 in. apart, and are spiraled every 88 poles on the south side and every 41 poles on the north side. The two spiralings are so arranged that tney never come on the same poles. This method is reported to have successfully prevented any interference with the telephone circuit on the same poles.

As a whole, the system seems to meet every expectation of the company, and it is believed that it will be no great time until the additional pressure pipe is put in and the power generated thereby doubled. This is the worst time in the history of the state for the generation of electricity by water power, the rainfall having been so light as to reduce the flow of the river to the lowest point ever known. The water of the Santa Ana last summer touched the low point of 1,250 in., whereas the normal summer flow as stated is about 4,500 in. There is probably more snow on the mountains this year than there was last, though the continued comparative drought would seem to hold out little hope for a great increase, if any, over the flow of last summer. Thus the achievements of the present can be taken to be about the minimum expectations of the plant, while in a normal year the supply of water would certainly be many times that required by the plant.

In other respects, the conditions have been such as to thoroughly test the efficiency of the new plant, the canon having been the scene of a heavy fall of snow, which is by no means infrequent at that altitude, while on many nights the most dense fogs ever experienced in this section have prevailed, the fogs being considered the worst obstacles to the heavy-current transmission of electricity.

The plant to date has cost about $600,000, a large part of which has been expended in labor, especially in the long series of tunnels.

The current is received at Los Angeles at the main power station where it is transformed by three 250-kw. air-cooled transformers to 2,200 vols and sent to the switchboard, from which it is distributed for three distinct purposes.

A part of the current is put direct on the mains and feeders which supply the residence portion of the city, under a voltage of 2,200, small transformers being placed on the poles in front of the individual houses where used, to reduce the voltage for the houses to 100. Another portion of the current at the same voltage is taken to the sub-station, by means of a line part aerial and part underground. At this sub-station it is converted into a direct current at 110 volts, by means of two motor generator sets, each consisting of a 300-kw. three-phase synchronous motor, direct connected to two multipolar 110-volt generators of the same capacity. From these the current is distributed through a network of underground mains and feeders which supply the customers in the conduit district of the city. For the distribution of this current, the Edison three-wire system is used.

The Edison Co. is at present installing at the main station a 525-kw. synchronous motor direct connected to a 550-volt direct current generator. The current furnished by this will be used for supplying power at 500 volts in the conduit district and for railway purposes.

The Edison Co. is now utilizing this power in the operation of 49,000 incandescent lights, 300 arc lights and small motors aggregating about 700 h. p. in this city, besides owning and operating the Pasadena Electric Light & Power Co. plant, with 15,000 incandescent lights and 105 arc lights. The officers of the company are George H. Barker, president; Henry Fisher, vice-president; William R. Staats, secretary, and John B. Miller, treasurer.

CABLE STRAND CAUSES WRECK.

About 7 a. m. on May 22d an exciting street car wreck ocurred at the corner of Adams and Clark Sts., Chicago. A west-bound cable train, consisting of the grip car and two trailers, had been halted to permit a Wentworth Ave. electric car and trailer to pass, when it was struck from behind by a second cable train. A broken strand of the cable had caught in the grip of the rear train and it was beyond control. The eight cars were all more or less injured and also an express wagon; the only person hurt was the driver of the express wagon.

RECENT STREET RAILWAY DECISIONS.

EDITED BY J. L. ROSENBERGER, ATTORNEY AT LAW, CHICAGO.

CAR SHIFTER NOT A SUPERINTENDENT.

Whelton v. West End Street Railway Co. (Mass.), 52 N. E. Rep. 1072. Mar. 1, 1899.

A car shifter, whose sole duty it is to get cars ready for conductors and motormen, the supreme judicial court of Massachusetts holds, is not a superintendent, and neither is his starting of the transfer table, nor his failure to stop it when it has caught the foot of a conductor, an act of superintendency, within the purview of a statute making an employer liable for injuries caused by the negligence of a superintendent.

ALWAYS TO USE ORDINARY CARE IN ALIGHTING.

North Chicago Street Railroad Co. v. Brown (Ill.), 52 N. E. Rep. 864. Feb. 17, 1899.

If an instruction, which requires of the plaintiff reasonable care, is not technically accurate because it does not instruct the jury as to what is reasonable care, the supreme court of Illinois holds that the objection is obviated in another instruction that a person attempting to alight from a street car is bound, under any and all circumstances, to use ordinary care and caution to avoid injury to herself, and if she fails to use such care, and is injured by reason thereof, the owner of the car cannot be held liable for such injury.

KENTUCKY STATUTE AS TO VALUATION OF FRANCHISES CONSTITUTIONAL.

Paducah Street Railway Co. v. McCracken County (Ky.), 49 S. W. Rep. 178. Jan. 27, 1899.

The court of appeals of Kentucky holds constitutional sections 4077-4079 of the Kentucky Statutes, notwithstanding that the state board of valuation and assessment, created and provided for by the statute for the purpose of valuing of franchises, was claimed to be unconstitutional. Moreover, as to the contention that the board should have deducted the indebtedness of the company, and the cost of operating its business, from the value of its franchise, the court answers that no such rule of valuation is applied to any other property, and that the claim of double taxation is not tenable.

RIGHT TO MAKE A TEST CASE.

Adams v. Union Railroad Co. (R. I.), 42 Atl. Rep. 515. Jan. 9, 1899.

The point was taken by the defendant in this case, reported at some length under another heading, in this department, that, because the plaintiff boarded the cars for the purpose of making a test case, this was a moot case, which the court would not entertain. But the supreme court of Rhode Island answers that a moot case is one which seeks to determine an abstract question, which does not rest upon existing facts or rights. Where a concrete case of fact or right is shown, it says that it knows of no principle or policy of law which will deprive a party of a determination, simply because his motive in the assertion of such right is to secure such determination. It is a matter of common practice. Most of the cases of trespass to try title are of this sort. For which reasons it is of the opinion that the case was not objectionable on this ground.

NOT NEGLIGENCE TO RING GONG A DOZEN TIMES.

Henderson v. Greenfield & Turners Falls Street Railway Co. (Mass.), 52 N. E. Rep. 1080. Feb. 28, 1899.

This was an action to recover damages for personal injuries received by being thrown from a wagon on account of a horse being frightened by the noise and sparks from an electric car. The supreme judicial court of Massachusetts holds that a verdict was properly directed for the defendant. It says that up to the moment of the accident there was nothing in the behavior of the horse which rendered it negligent on the part of the motorman to ring the gong, and it declares that it cannot be said that to ring the gong on an electric car in a public street half a dozen or a dozen times, which it was charged was done, is of itself, without anything more, evidence of negligence. Beyond this, it contents itself with merely remarking that there was nothing to show that the noise and sparks were due to any defect in construction or negligence in operation.

CARE REQUIRED OF EMPLOYES WHILE PASSENGER IS ALIGHTING.

Lutz v. Louisville Railway Co. (Ky.), 48 S. W. Rep. 1080. Jan. 11, 1899.

In this case, wherein a judgment for the defendant is reversed, and which is "not to be officially reported," the court of appeals of Kentucky holds that this instruction, which was asked for, but not given, is a correct statement of the law, to wit: "The court instructs the jury that the law made it the duty of the defendant's agents and servants operating the cars upon which it is alleged plaintiff was a passenger to observe the utmost care and skill which a prudent man would exercise, under like circumstances, in the management and control thereof, while she was alighting therefrom, and to afford her reasonable opportunity to alight in safety; and if the jury shall believe from the evidence that the defendant's said agents or any of them, failed to observe such care, and that by reason of such failure plaintiff received the injuries by her alleged, then the law is for the plaintiff, and the jury should so find."

MOTORMAN NOT NEGLIGENT IN NOT SEEING BICYCLER.

Gould v. Union Traction Co. (Pa.), 42 Atl. Rep. 477. Feb. 27, 1899.

During the moment when a certain motorman's eyes were turned from one side of the street, a boy, 12 years old, riding a bicycle came rapidly and noiselessly upon that side of the street from behind a wagon, which was close to the track, with his bicycle turned so that he was facing the car, and then suddenly changed his direction, and struck the car, because he could neither go forward nor stop. The motorman was not, under the circumstances, the supreme court of Pennsylvania holds, negligent in not seeing the boy, he having just then turned his eyes momentarily towards the other side of the street in the performance of his duty to watch both sides of the street. And so it reverses a judgment obtained by the plaintiff. If the motorman had seen, or by the exercise of reasonable care could have seen, the boy in time to stop the car, the court says that it would of course have been his duty to do so.

CROSSING IN FRONT OF APPROACHING CARS.

Clark v. Bennett, Receiver of the San Francisco & San Mateo Railway Co. (Cal.), 55 Pac. Rep. 908. Jan. 13, 1899.

The supreme court of California holds that it cannot be said that a person is guilty of contributory negligence merely because he attempts to cross a street railway when a car is approaching. If that were so, it continues, he could never attempt to cross such a track in the crowded parts of a city, where there is practically always an approaching car; and in such case, as street cars go at a comparatively slow rate of speed, and are quickly stopped, it insists, the question of negligence would depend upon the proximity or remoteness of the car, and upon all the other circumstances surrounding the occurrence. In such a situation, it declares, the traveler cannot be held to exercise the very highest prudence and judgment; it is sufficient if he exercises that degree of care and prudence and good sense which men who possess those qualities in an ordinary or average degree exercise.

INDEPENDENT LINE CANNOT BE BUILT UNDER EXTENSION PROCEEDINGS.

McClean v. Westchester Electric Railway Co. (N. Y.), 55 N. Y. Supp. 556. December, 1898.

A separate and apparently independent line of street railway, a special term of the supreme court of New York holds, cannot be constructed under extension proceedings, the articles of association of the company and the provisions of law contemplating but a single line of road, carrying from end to end for a single fare.

Nor, while second extension proceedings had might cure defects in the first, does the court consider that they can relate back so as to make valid resolutions of the municipal authorities which were before inoperative and ineffectual.

And the court does not think that an owner of land, offering to prove that a street railway is unauthorized, and so is a nuisance, is called upon to prove that the probable, speculative, or actual benefits of the unauthorized structure will not offset the apparent disadvantage or injury, however small.

NOT REQUIRED TO INSTRUCT CONDUCTOR OF NINE YEARS' EXPERIENCE.

Fletcher v. Philadelphia Traction Co. (Pa.), 42 Atl. Rep. 527. Feb. 27, 1899

This was an action brought to recover for the death of a conductor of nine years' experience. He had run only closed cars. About 5 o'clock in the afternoon of the day of his death, he was instructed to take out an open summer car. He assumed charge of the car, and started on his trip. Soon after, a violent thunderstorm arose. He went out on the running board, and commenced pulling down the curtains at the sides. Just at that moment a closed car passed him on the other track, striking and killing him. Negligence on the part of the company was charged in its not warning him of the danger incident to the passage of an open and closed car on tracks only 37½ inches apart.

The court below submitted the question of the company's negligence to the jury; instructing them that if they found that there was special danger from the nearness of the tracks at that point, which was increased by the greater width and arrangement of the open car, and that this danger, because of the conductor's inexperience was unknown to him, then it was for them to say whether the company was negligent in not warning the conductor of the danger incident to his employment on an open instead of a closed car. The result was a verdict against the company.

The supreme court of Pennsylvania, however, thinks that no authority of the state sustains the ruling of the court below, and reverses its judgment, holding that it erred in not directing a verdict for the company. Many of the cases of the state hold that it is the duty of employers to warn young or inexperienced employes of dangers not obvious, but incident to their employment, and that a failure to do so is negligence for which the employer is answerable. But the supreme court declares that this conductor was neither young nor inexperienced. Concede that he had never conducted an open car that necessitated walking on the running board along the outside; yet, from his long experience, the court considers that he must have known the danger in passing another car on a wider one. The inexperienced conductor, it says, is one new to the business, and unaware of a danger not plainly noticeable.

CASE WHERE OPERATION OF PORTION OF LINE COULD BE ABANDONED.

State v. Helena Power & Light Co. (Mon.), 56 Pac. Rep. 685. Mar. 31, 1899.

Here a writ of mandamus was applied for to compel the above company to operate a portion of its system of street railway which it was alleged that it had abandoned.

A writ of mandamus may be issued, says the supreme court of Montana, to compel the performance of an act which the law specially enjoins as a duty resulting from an office, trust or station. But it holds that the operation of the line of street railway which had been here abandoned was not an act specially enjoined as a legal duty, and that the writ of mandamus could not be issued.

In explanation of this, the court says that it did not appear that the charter of the company, or the statute under which it was organized, required it to maintain or operate a line of railway; nor was it claimed that the state had delegated to it the power of eminent domain. Indeed, the court says that it did not appear whether the company owed its existence to a special act of the legislature, or to a compliance with the terms of some general act authorizing the formation of corporations thereunder. At the argument, it was stated that it was organized and exists under chapter 25, division 5, Compiled Statutes of 1887, entitled "Corporations for Industrial or Productive Purposes;" but nothing contained in that chapter, the court holds, may be so interpreted as to impose upon the company the obligation to continue the operation of any portion of its system of railways.

Moreover, the court pronounces the ordinances of the city barren of any language expressing or implying the intention of the council to impose such duty, the ordinances merely granting the right and privilege of constructing, operating, and maintaining railways in particular streets. That the ordinances provided that unless a designated portion of the line of railway should within a certain period of time be constructed and operated or the right and privilege granted would be forfeited as to the parts of the line where the failure occurred, and provided for the running of cars at such intervals as might from time to time be directed, the court apparently does not consider altered the case.

EVEN COURT KNOWS JERKS ARE UNAVOIDABLE ON CABLE LINES.

Bartley v. Metropolitan Street Railway Co. (Mo.), 49 S. W. Rep. 840. Feb. 15, 1899.

It is a matter of common knowledge, of which even a court is not ignorant, as well as a matter of physics, says the supreme court of Missouri, Division No. 1, that the rope of a cable railroad cannot be kept taut, and that the jerks which are common and unavoidable to such roads are caused by the slack in the rope being taken up.

In order to recover from a cable railroad, continues the court, it is not enough to show that there was a jerk, but it must affirmatively appear that the jerk was an extraordinary or unusual one, or attributable to a defect in the track, an imperfection in the car or apparatus, or to a dangerous rate of speed, or to unskilled handling of the car by the gripman.

This was an an action to recover $25,000 for personal injuries. The court says that the testimony did not show anything extraordinary or unusual in the jerk complained of. No defect in the track or car or apparatus was shown, and no negligence of the gripman was made to appear. Under such circumstances, the court holds, it was the duty of the trial judge to declare these facts, and to sustain a demurrer to the evidence at the close of the plaintiff's case, and it was error on the lower court's part not to do so.

Moreover, the court will not agree with the contention that negligence should have been imputed to the defendant, entitling the plaintiff to go to the jury, although his testimony fell short of making out a prima facie case. It says that the contention is not tenable, because it is not true that jerks do not usually occur in the running of cable cars, but, on the contrary, it is a fact that they are unavoidable. It is only in cases where the injury would not occur in the ordinary conduct of such affairs that negligence is imputed to the defendant. Where, as here, it affirmatively appears, and is proved by common experience, as well as by the laws of physics, that the particular thing complained of is unavoidable, it holds, there can be no negligence.

ASSESSABLE FOR LOCAL IMPROVEMENTS.

Cicero & Proviso Street Railway Co. v. City of Chicago (Ill.), 52 N. E. Rep. 866. Oct. 24, 1898. Rehearing denied Dec. 13, 1898.

Under its previous decisions, the supreme court of Illinois says that it regards the question settled that a street railway occupying a public street is liable to be assessed for a local improvement in the same manner as other property owners.

But reliance was placed, in this case, by the company, on the provision of the revenue law that "the personal property of street railroad, plank road, turnpike or bridge companies shall be listed and assessed in the country, town, district, village or city where the

principal place of business is located. The track, road or bridge shall be held to be personal property, and listed and assessed as such in the town, district, village or city where the same is located or laid."

The fact that the track of a street railroad company may be required to be assessed as personal property for general taxation, the court however holds, has no bearing on the question of taxation for local improvements. No question in regard to the assessement and collection of general taxes under the revenue law of the state, it maintains, is involved in a case of a special assessment for a local improvement.

The legislature, no doubt, had the right to provide, in the assessment of property for state, county, and city purposes, that the track of a street railroad company might be assessed as personal property, without changing the nature or character of the property when a proceeding might be instituted to make an assessment on contiguous property to pay for a local improvement, says the court. It perceives no reason why for one purpose it might not be treated as personal, and for the other as real, property. But, however, that may be, it adds that it is satisfied that the property of this company was within the meaning of the law, contiguous property, and, as such, was properly assessed for the construction of a vitrified tile-pipe sewer.

MOTORMAN SHOULD HAVE FULL USE OF BOTH EYES.

Rice v. Crescent City Railroad Co. (La.), 24 So. Rep. 791. Jan. 9, 1899.

No man should be in charge of an electric car as motoneer, running along populous thoroughfares of a city, the supreme court of Louisiana holds, who has not the full and complete use and sight of both eyes.

In this case, a motor inspector and repairer of cars, whose right eye had been injured in an accident, so that he was almost blind in that eye, who had boarded the car in question, had been asked by the regular motorman to take charge of the car, because the motorman felt sick from a blow he had received in the stomach by reason of the brake handle slipping from his hand.

A child was run over, and killed. If the temporarily acting motorman saw her, and failed to govern his car accordingly—running at such slow speed as to be able to check it immediately should the imminence of danger appear—the court says he was guilty of the grossest, if not criminal neglect. If he did not see her, it says that it was due to the fact that he was not performing his duty by keeping a sharp outlook, or to the fact of his blindness. In either event, it holds, the company would be liable.

The fact that the car ran 150 feet after the child and its nurse were struck, the court pronounces eloquent in refutation of the contention of the defense that there was neither negligence in the effort to stop the car nor want of skill on the part of motorman in diong so.

A child 3½ years of age is, of itself, the court holds, incapable of contributory negligence. But if its nurse, after reaching it on the street, started back with it across the track, and in consequence of this was run over, the court says that it would relieve the company of liability.

No doctrine or rule exists in Louisiana, the court says, that the negligence or imprudence of a plaintiff, while not of the proximate character to defeat his recovery, may yet be looked to by the jury or court in mitigation of damages.

Nevertheless, the supreme court goes on to say that it has constantly exercised its reasonable discretion of increasing or diminishing the sums awarded for damages, according as its judgment, operating on the facts, prompted in given cases.

But it denies that it has ever been the intention to fix by rule specific sums for different classes of injuries, or for varying grades and duration of anguish and suffering. In this respect, each case, it says, considered independently, on its merits, and on the state of facts peculiar to it, a due regard, however, being always had to the proper observance of a reasonable uniformity of jurisprudence on general lines.

Finally, the facts and circumstances of this case, it thinks justify the reduction of the verdict of the jury from $12,500 to $4,000, for the killing of the child mentioned.

RULES AS EVIDENCE IN PERSONAL INJURY CASES.

Cincinnati Street Railway Co. v. Altemeier (O.), 53 N. E. Rep. 300. Mar. 14, 1899.

Rules adopted by a street railway company for the government of its employes in operating such railway, the supreme court of Ohio holds, are competent evidence, when relevant, in the trial of a cause for damages for personal injury caused by the negligence of the servants of such company.

In discussing this subject, the court says that the rules by which a street railway company runs its cars are a part of what are termed the resgestae, or things inseparably connected with the accident as one of the circumstances surrounding the case, and which are often necessary to a proper understanding of the same. They are not so much in the nature of admission as a part of the transaction. The rules by which a railway is operated are as much a part of the transaction as the construction, and appliances of the cars, motors, machinery, and tracks.

If the rules require more care of the employes for the safety of the passengers than the law requires, the court goes on to say that it is easy for the court to say so to the jury, and point out what the law requires, and wherein the rules require more than the law, and that to the extent of the excess the company is more careful than is required by law. Such a showing, it thinks, would be an advantage to the company instead of a detriment.

If the rules require only what the law requires, the court maintains that no harm can come to the company from their introduction in evidence.

But if the rules require less than the law, or if there are no rules at all, then, the court says, the company might well be held to be negligent for such a state of affairs.

It seems, therefore, reasons the court, that the introduction of the rules of the company is not only proper, but would lead to the working out of just results in all cases, sometimes against the company and sometimes in its favor. The fear that the introduction of the rules of the company would discourage such companies from making strict rules for the safety of passengers, the court thinks, is more fanciful than real. The reason it gives, is that the company would suffer much more loss from absence of strict rules than from having the rules introduced in evidence, and self-preservation would induce such companies to adopt such rules as will reduce accidents to a minimum, whether such rules are received in evidence or not.

RIGHTS WHERE TELEPHONE AND ELECTRIC RAILWAY COMPANIES USE SAME STREETS.

Birmingham Traction Co. v. Southern Bell Telephone & Telegraph Co. (Ala.), 24 So. Rep. 731. Oct. 29, 1898.

In this case a bill was filed by the last named company praying that an injunction be issued restraining and enjoining the traction company, its officers and agents, from so constructing its line of poles and wires on and along certain streets as to interfere with, hurt, harm or injure the complainant's telephone property, service wires and poles; and an injunction was granted.

To begin with, in considering the case, the supreme court of Alabama says that it does not understand that it was insisted that the telephone company had the exclusive right to the city streets for the purpose of operating its telephone system. No company under ordinary circumstances, can assert and maintain a right to the exclusive enjoyment of a public street. Such a monopoly the law does not favor.

In the same vein, the court goes on to say, that, while it is probably true that two electric systems of the kind under consideration cannot be constructed in and operated along the same street—unless it be of uncommon width—without inflicting some incidental injury or damage, the one to the other, it may be safely stated as applicable to all conditions, that no one public corporation of the kind should be given a monopoly to the exclusion of the others in the use of the streets of a city. Ordinarily, it holds, such privileges should be granted, equal with and not superior to other like enterprises established for the use of the public; and when two are authorized by law to use the same street, it should be with the express or implied condition, that each shall respect the rights and

interests of the other, and occasion, no unnecessary harm the one to the other.

At the same time, while the court does not decide that prior occupancy of a street by a telephone company confers any superior privileges, it does insist that it may certainly be considered in denial of a street railway company's usurpation of superior rights in the street.

It also holds that where the unwarranted usurpation of a railway company amounts to a trespass upon a telephone company's rights, which is recurrent and continuous, a court of equity will interfere by injunction.

Besides this, it says that the authority of a court of equity to grant and maintain an injunction in such a case may be rested on that other ground of chancery jurisdiction, that such courts will interfere to control such corporations as these, to keep them within the line of their authority and subject to law, in order to prevent such usurpations as were here complained of.

EXEMPTION FROM OBLIGATION TO PAVE BETWEEN TRACKS.

Wood v. Common Council of City of Binghamton (N. Y.), 56 N. Y. Supp. 105. Feb. 4, 1899.

This was an action brought by certain taxpayers to restrain the collection of taxes for the expense of paving a street, between the rails of the track of the Binghamton Railroad Company and two feet in width outside such tracks, and to compel said company to pay such expense, less the cost of paying one foot in width between the rails, which it had already paid.

Now, while it concedes it to be true that this company became vested with all the rights of certain other companies at the time of their consolidation, and that the statutes under which the several companies were organized did not impose an obligation to pave streets, yet the trial term of the supreme court of New York holds that the omission in such statutes to require the companies to pave did not vest in them or their successor, the Binghamton Railroad Company, any right to be perpetually exempted from such obligation, if the legislature should impose it, the power to impose such obligation at any time being given the legislature by the state constitution.

The term "vested rights," the court holds further, relates to property rights, and does not embrace within its meaning the immunity or exemption created by an omission in the statute under which the incorporation was effected, to impose a liability for the paving of streets used and occupied by a street surface railroad.

And, if nothing further appeared in the case, the court says that the plaintiffs would be entitled to the relief sought, for the reason that, under the general railroad law as amended, it would be the duty of the defendant railroad company to pay the expense of paving between the rails and two feet in width outside thereof, and the city of Binghamton would have no power to assess such expense upon the abutting owners or the city at large.

But one of the defenses of the company was that it was exempt from the duty to pave required by section 98 of the provisions of the general railroad law by virtue of a contract or contracts made with the common council of the city, in 1892, which the legislature confirmed, ratified, or legalized in 1893, which contract required the company to pay one-fifth of the expense of paving and repairing between the rails of its tracks and to erect poles of a certain description which might be used by the city for the purpose of stringing electric light and fire-alarm wires, etc., and this legalizing act the court holds valid and of the effect contended for by the company, so that it was entitled to judgment dismissing the complaint on the merits, though the action of the common council alone would have no such effect, being unauthorized.

CONSTRUCTION OF CONTRACT WITH TOWN LIMITING FARE.

Adams v. Union Railroad Co. (R. I.), 42 Atl. Rep. 515. Jan. 9, 1899.

Under a statute giving authority to towns to pass ordinances or make contracts granting franchises to corporations for operating street railways, etc., the town of East Providence made such a contract with the defendant, in which it was agreed that, "during the continuance of said exclusive franchise, the fare from one point to any other point on the lines of the party of the second part in said town shall not exceed five cents." By entering into this contract, the supreme court of Rhode Island holds that the defendant waived its previous rights in respect to fare, including the rights it had as one of the successors of another company authorized by its charter to fix rates of fare not exceeding ten cents between any two points on said road. Under this view of the contract, the court pronounces the defendant's plea of justification for refusing to transfer and carry the plaintiff for one fare of five cents from a point on its main road to a point on the connecting road above mentioned of no avail, so far as it rested upon rights previously held.

There still remained the question, which was the one chiefly pressed in argument, whether the plaintiff could avail himself, as an individual, of the right to claim the benefit of the provisions of the contract in an action of trespass for assault and battery on account of being ejected from the car for refusal to pay an additional fare on the connecting line. This, the court answers in the affirmative.

The terms of the contract, that "the fare from one point to any other point on the lines of said party of the second part shall not exceed five cents," the court declares that it cannot vary by reason of the fact that, when the contract was made, two rides for five cents was not the established rate of fare.

The contract in question, the court goes on to say, was made for the benefit of passengers using the defendant's cars. The town could hardly show damages for its breach, and therefore, if the people for whose benefit it was made could not recover for its breach, no one could. True, the town might take steps to avoid the contract and stop the road for failure to perform conditions; but, in so doing, it would cut off the privileges of many to redress the wrong of one. This would neither be a reasonable nor an adequate remedy. It must have been intended to be a contract for the benefit of the public, made through the town as their corporate representative, upon which passengers could rely, and for breach of which they could seek redress; otherwise, it would be a contract of little obligation and force. Along this line of reasoning does the court reach the conclusion that the plaintiff, having paid the fare of five cents, had paid all that he could be required to pay under the contract, which, being for the benefit of passengers, a class of which he was one, was for his benefit, and of which he could take advantage.

The statute giving authority to a town to act by ordinance or contract, the court says that if it acted by contract, as in this case, the necessary implication was that it might stipulate for terms other than those expressed in the statute. Thus, the statute providing that the charge for service should not be greater than the price actually charged by the corporation at the time of granting the franchise, the court holds, would clearly imply that it might be less.

NO PRESCRIBED RATE OF SPEED.

Fullerton v. Metropolitan Street Railway Co. (N. Y.), 55 N. Y. Supp. 1068. Feb. 10, 1899.

There is no statute, says the first appellate division of the supreme court of New York, which prescribes the rate of speed at which one may run a car through the streets of the city of New York, and, therefore, except in extreme cases, it cannot be laid down that to run a car at any given rate of speed in any place constitutes negligence, as matter of law. It is not intended to say, it continues, that a rate of speed cannot be so great that, taken in connection with all the circumstances, the court would not be required to hold that it constituted negligence of itself; but circumstances which would warrant such a holding would be extreme. Ordinarily, the question whether the speed constituted negligence is a question of fact, to be determined by the jury in view of the surrounding conditions at the time. All these things are to be taken into consideration.

The duty of the driver of the car is to manage it in a reasonably prudent and careful manner, having in view all the conditions which surround him at the particular place where he is; and whether in this case he did so manage his car the court holds was to be determined by the situation as it was then exposed by the evidence presented in the case. More particularly, it hold that when it is made to appear that a heavy car, operated by machinery, running upon a steep down grade in a populous street of a city, is permitted to acquire such a rate of speed that it cannot be stopped in a distance of 40 feet, if necessity requires, the question of negligence is for the

jury, and should not be determined as a legal proposition by the court.

While there happened to be no one on the street at the time in question, yet, the court says, it was clearly the duty of the motorman to keep his car under reasonable control, so that he could manage it with sufficient promptness to stop it promptly, if occasion arose to do so.

While there must be conceded to vehicles of this kind a right to run at a considerable rate of speed, yet, continues the court, that rate of speed must in all cases be such as is reasonable and safe, in view of the correlative rights of other persons upon the streets. Those living upon the streets have the right to be upon them, not only to go backward and forward, but to cross them, as their necessities, business, and even pleasure, may require; and the cars running along the street must be managed so as to give such persons a reasonable opportunity to exercise their rights in the streets, if they use ordinary care in doing so. To that end, it is clearly the duty of the persons controlling the movements of such a vehicle to keep the car under such control as to be able to check its speed, or bring it to a standstill, in time to avoid injury to those persons who have occasion to be upon the street. To do this involves, not only the duty of regulating the speed of the car so that it may be stopped within a reasonable time, but of giving such a strict attention to the situation as to be able to use the appliances for bringing the car to a stop without unnecessary delay. What conditions must exist, to establish proper care, in view of those duties, in any given case, cannot be laid down as a matter of law. They must be questions of fact, to be determined by the jury.

It is safe to say, however, adds the court, that if the jury should find that a motorman permitted the speed of his car to be so accelerated upon a down grade, where it would be naturally difficult to control it, that he was not able to bring it to a stop in the time usually taken for that purpose, when the car was running at the ordinary rate of speed, he would be guilty of negligence, for which his employer would be responsible.

RISKS ASSUMED BY CONDUCTOR.

Pikesville, Reistertown & Emory Grove Railroad of Baltimore County v. State, to Use of Russell (Md.), 42 Atl. Rep. 214. Dec. 20, 1898.

In accepting the employment of an electric railway company as conductor, the court of appeals of Maryland holds, a person takes upon himself all such risks as are usually incident to the service, and also such other risks as are known to him or are discernible by ordinary care on his part. He is obliged to observe and guard himself against danger from the poles as properly or apparently located. On the other hand, where a pole has been negligently and improperly placed, so that thereby the usual risks of the service are increased, and if such misplacement is not apparent to the conductor with the exercise of reasonable care, and is not in fact known to him, the court holds, he is under no obligation to protect himself against such increased risk. In such case, the increased danger being hidden and secret, no rule of law demands that he shall look out for it.

Applying these principles to this case, where the poles along the road were apparently placed in line, as is usual with such poles, and at the apparent distance of about two feet, eight inches from the track, but one of the poles was seven inches closer, the court holds that for the increased risk consequent therefrom the conductor was not bound to look out, unless he knew of the location of the pole, or ought reasonably to have known it, or unless it was obvious.

Taking up next the contention that the conductor in question, as matter of law, was guilty of contributory negligence in attempting to collect fares on the side next to the poles, the court says that he was a new man, and knew of no rules on the subject, and was not informed there were any. His duty was to collect fares, and he was not directed on which side of the car he was to do it. If, therefore, he chose to collect the fares on the pole side, for any reason, the court continues, his obligations as to taking care of himself were not thereby enhanced. He was bound in any case to look out for the poles as they ought to have been and apparently were located but the use of the pole side of the car did not impose upon him the duty of knowing what he did not and could not reasonably know. If he did not know of the misplaced pole, and the increased risk growing out of its misplacement, there was no reason why he should not collect fares on the pole side, so long as he was careful to protect himself from all the apparent danger he incurred in so doing.

In all such cases, adds the court, the question of the negligence of the parties should be submitted to the jury, for them to determine from all the facts offered in evidence whether either or both of the parties had been guilty of negligence, in consequence of which the accident happened.

A PECULIAR ACCIDENT.

The accompanying cut is taken from a photograph of an accident that occurred at Watertown, N. Y., during the March blizzard, and accentuates the pretty well established fact that the street railway manager's couch is not necessarily a bed of roses. It might not be amiss at this juncture to invite the ardent advocates of municipal ownership to contemplate the above picture. They might possibly hesitate before thrusting their sickle with too prodigal a hand into the golden harvest the grasping monopolies are supposed to be reaping.

There were some peculiar features surrounding this accident that make it of interest. In the first place, it is a striking illustration of the old adage that it is the unexpected that happens, and that accidents do not as a rule occur at the so-called danger points, for the

WRECK AT WATERTOWN, N. Y.

car left the rails on a straight and level piece of track which was in perfect order, the car running at a moderate rate of speed. But it chanced to be raining and freezing hard at the same time, and the girder rail filled up rapidly with ice, causing the flanges of the forward wheels to mount the rail. The car ran some 13 ft. on the frozen ground and went over the abutment of the bridge, falling a distance of 30 ft., the forward part of the car being submerged in the water of the Black River. Nothing was saved of the wreck except the trucks and motors, there not being enough left of the wood-work "to make tooth-picks," as Superintendent Smith graphically expressed it.

Fortunately only three passengers were in the car when it took its fearful plunge; two of them saved themselves by jumping. The only person injured was a young man named Zimmerman, who was carried down with the wreck and pinioned under the front platform —all of his body being submerged in the water except his head, which he managed to hold up until he was rescued from his perilous position by neighbors, who were obliged to chop away a portion of the wreck before he could be extricated. He was taken to the hospital, where it was found that in addition to severe bruises he had sustained an injury to the spinal cord, causing partial paralysis, this company happily disappearing after a few weeks.

The company was insured with the American Mutual Indemnity Co., of Scranton, Pa., which sent its adjuster, Dr. H. B. Rockwell, to the scene, and succeeded in obtaining Mr. Zimmerman's release for $150. An enterprising attorney, even before the adjuster had left town, succeeded in persuading the man that he was "incompetent to sign a release," and instituted a suit against the company, which was afterwards withdrawn, however, when it was found that he could not enlist the co-operation of the doctors and nurses.

WISCONSIN ANTI-PASS LAW.

At the last session of the Wisconsin Legislature an anti-pass law was passed and it received the approval of the governor. It is as follows:

"Section 1. No person, association, co-partnership, or corporation shall offer, or give, for any purpose, to any political committee, or any member or employe thereof, to any candidate for, or incumbent of any office or position under the constitution or laws, or under any ordinance of any town or municipality, of this state, or to any person at the request or for the advantage of all or any of them, any free pass or frank, or any privilege withheld from any person, for the traveling accommodation or transportation of any person or property, or the transmission of any message or communication.

"Sec. 2. No political committee, and no member or employe thereof, no candidate for and no incumbent of any office or position under the constitution or laws, or under any ordinance of any town or municipality, of this state, shall ask for, or accept, from any person, association, co-partnership, or corporation or use in any manner or for any purpose, any free pass or frank, or any privilege withheld from any person, for the traveling accommodation or transportation, of any person or property, or the transmission of any message or communication.

"Sec. 3. Any violation of any of the above provisions shall be punished by imprisonment in the state prison not more than five years nor less than one year, or by fine not exceeding one thousand dollars, nor less than two hundred dollars.

"Sec. 4. No person, and no agent or officer of any corporation within the purview of this act shall be privileged from testifying in relation to anything therein prohibited; and no person having so testified shall be liable to any prosecution or punishment for any offense concerning which he was required to give his testimony or produce any documentary evidence.

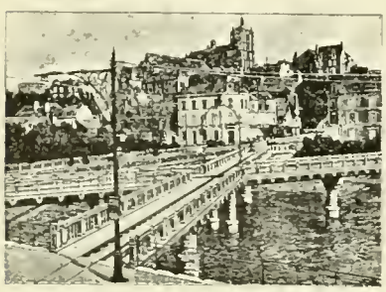
"Sec. 5. This act shall take effect and be in force from and after its passage and publication."

In compliance with this act a number of street railway companies have issued orders that henceforth policemen and firemen will not be carried free.

THE X BRIDGE AT LE MANS.

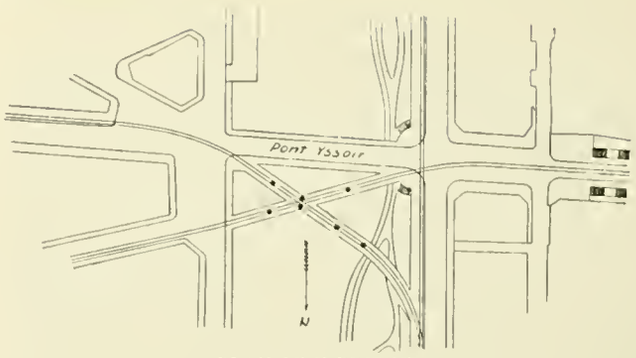
A bridge built not long since at Le Mans, France, has attracted a great deal of popular attention because of its peculiar form, which is that of an X, and is of interest to engineers because of the low cost. This bridge was destroyed by M. de la Noe, a chief engineer of bridges and roads, and has been described in recent issues of French technical papers, notably La Revue Technique.

It was desired to build a bridge across the Sarthe for the department railroad (steam) and at the same time provide another route for an electric tramway system which had previously crossed the river on a wagon bridge and made use of the department tracks in the neighboring streets. The existing bridge, built in 1888, was beginning to show signs of weakness under the electric tramway traffic and it was desirable to stop this, and quite out of the question to run the steam trains over this bridge. At the same time it was found that the single tracks were insufficient for the use of the two roads and the narrow streets did not admit of a second track. As a solution of all the problems it was proposed to build a new bridge adjacent to the existing Pont Yssoir. The city and the electric tramway together raised $7,000 for the purpose and the department $2,000 more, which was fixed as the maximum. The routes of the two roads decided the peculiar X-shape of the bridge.



THE X BRIDGE.

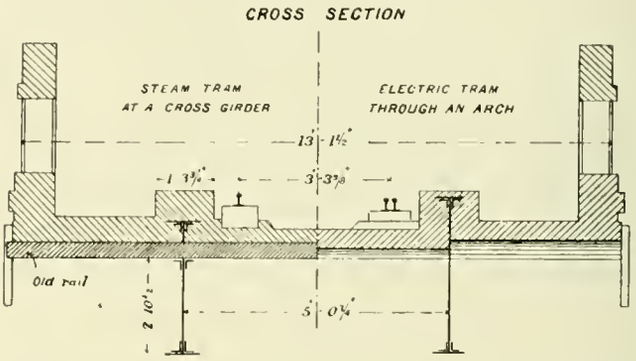
The necessary area was 5,382 sq. ft. As the old Pont Yssoir had cost $7.07 per sq. ft. with foundations and $5.18 per sq. ft. without foundations, the funds at hand seemed entirely inadequate, but the



PLAN OF X BRIDGE.

X bridge was built for $1.21 per sq. ft. including foundations, a total of $6,408.

The X bridge is supported on one double and five single piers; the piers are of concrete, 1 m. in diameter, and rest on wooden piles, the cost for the six being $858. Old rails are used in the piers to strengthen them. The main girders are continuous and placed 1.8



m. apart. The cross girders are old rails stuck through the webs of the main girders and resting on angles riveted to the latter. The arches between the cross girders are of hollow brick, and concrete is placed above so that it forms a part of the upper flange of the main girders.

The line drawings are from Indian Engineering and the general view from La Nature.

REPORT OF RECEIVER OF TERRE HAUTE ROAD.

Joshua Jump, receiver of the Terre Haute (Ind.) Electric Railway Co. retired from his office after a most excellent stewardship. Mr. Jump was appointed receiver in October 1897.

His first annual report to the court showed total receipts of $154,804.15 and disbursements $140,619.26, leaving a balance on hand of $14,184.89.

He has recently filed his last report which is from Oct. 18, 1898, to Apr. 17, 1899, inclusive and is as follows:

Cash on hand	$14,184.89
From passengers	47,816.05
From sundries	538.75
From light installations	479.48
From city lighting	12,916.21
From commercial arc lighting	2,721.81
From incandescent lighting	9,404.60
From power	2,416.91
From steam heat	2,125.59
From steam heat installations	75.55
Total	$92,679.84
Disbursements	88,934.01
Balance	$3,745.83

STREET RAILWAY TRACK CONSTRUCTION.

BY M. D. BURKE.

Read before the Engineers' Club of Cincinnati and published in the Journal of the Association of Engineering Societies.

In treating the subject, it appears to be desirable to describe briefly what was done in the days of the horse car, the transition to that which is now being done to provide tracks for the motors at present in use, and, finally, to suggest such forms of construction as would appear appropriate for the conditions which exist, or are likely to prevail in the near future.

More than 27 years ago the writer was employed to reconstruct certain portions of track in Cincinnati, and to replace some curves that were in unsatisfactory condition. He found that the curved rails were iron castings, and that the curved tracks had been constructed as shown by Fig. 1. Only the inside rail was provided with a guard, which was unnecessarily high, the groove was excessively wide, while the outer rail was merely a flat casting upon which the wheel was carried upon its flange. It was thought possible to better some of these conditions, so new patterns were made, and the curved tracks were built as shown by Fig. 2. It will be observed that the "knees," or castings which were intended to hold the timbers to gage were omitted, and the tie rod introduced, and that both rails were grooved. Prior to that time, these little cast brackets, fastened to the ties with 3-in. spikes, had been the sole dependence for holding the track to gage, and, since the loads were always carried upon the upper outer corners of the timbers, there was always a tendency to widen the gage. The tie rod was introduced to resist this pressure, and "knees" were afterwards used only where required for straightening crooked stringers, or where joints needed a special support.

This was the first track which the writer ever saw made of grooved rails. This form of rail, somewhat lighter in section, was, at about that time, or soon after, patented, made of rolled steel, bent to the desired radius, and, for many years, was manufactured and sold by the William Wharton jr., Co., Limited, of Philadelphia, as the Wharton patent curve. The form of rail head has not been essentially changed in the standard grooved rails of today, but the support is different.

In those days street railroad rails were essentially "strap rails," varying in weight from about 18 lb. to 50 lb. per yard. They were spiked to the tops of wooden stringers, which were in turn, fastened to cross-ties, generally with boat spikes, but sometimes with treenails or wooden pins. The earth or gravel was tamped under both the longitudinal stringers and the ties, which were placed four or five feet apart, so that the loads carried, at the speeds then attained, were fairly well supported, while the track was in good condition. But there was an abundance of elasticity, and the "wave motion" that theoretically precedes the locomotive, was generally visible to the naked eye. Each car was usually provided with a "frog," by the use of which the driver was expected to be able to pull his car onto the track, if it got off, or to pull it off and on again, if it became necessary to pass around some immovable obstacle on the track.

The municipal statesmen of those days, in protecting the rights of their constituents, found it necessary to provide a broad inside tram, so that the street car track became a tramway for the use of all vehicles that could travel upon it. The width of the express wagon, to the outside of wheel treads, was found to be about 5 ft. 2 in., so the gage of street car tracks was generally fixed at 5 ft. 2½ in. and ordinances provided that the rails should have an inside tram of 3 in. As a natural result, vehicular traffic was concentrated along the lines of street railroad tracks, and where double tracks existed was systematized by them to some extent, but vehicles going in the same direction did not travel at the same speed, and the pulling into and out from the tramways was destructive to pavements and tracks as well as to vehicles.

The rails were secured to the stringers by spikes having countersunk heads, driven through the tram of the rails into the wooden stringers, but the expansion and contraction of the rails, due to changes in temperature, either sheared the spike heads, enlarged the spike holes, or bruised away the wood, and the fastening became defective, but the rails were provided with lips coming down over the corners of the stringers which aided greatly in keeping them in place.

Pavements were generally of cobblestone, or the roads were made of broken stone or gravel. Between rails, where the car horses or mules traveled, the most satisfactory roadway was the cobblestone pavement. An eminent engineer of this city invented, and, I think, patented, the pavement made of round locust blocks paved on end. One of our prominent street railroad officials declared that the said engineer made that pavement all out of his own head, and had blocks left. In the tracks it was an utter abomination, as the heart of the locust block polished and became worn to a rounded point, while the residue of the stick disappeared, and animals' feet were destroyed in traveling on the slippery pegs. Where the wooden block is of about uniform density, as cedar, oak, or pine, it does for street car horses, it soon becomes worn and does not furnish as reliable and durable footing as the much-abused cobblestone.

A few forms of rails that were used are shown in Fig. 3. A shows the "crescent rail," which was laid on Elm St. It weighed about 18 lb. per yard, was spiked, or rather nailed to 3 x 6-in. stringers, had no inside tram, and was rather just criticised. B shows the Route 9 rail, which was laid on Vine St., it weighed about 30 lb. per yard, the rail head being rolled thin to fit over an oak strip, nailed to the top of the stringer. It had the required inside tram, and, if it did not fill all of the requirements, it rattled around in them effectually. C was the Mount Auburn, or Route 8 rail, laid on Main St. It was laid on 6 x 8-in. timbers placed flat. It made a very good tramway,

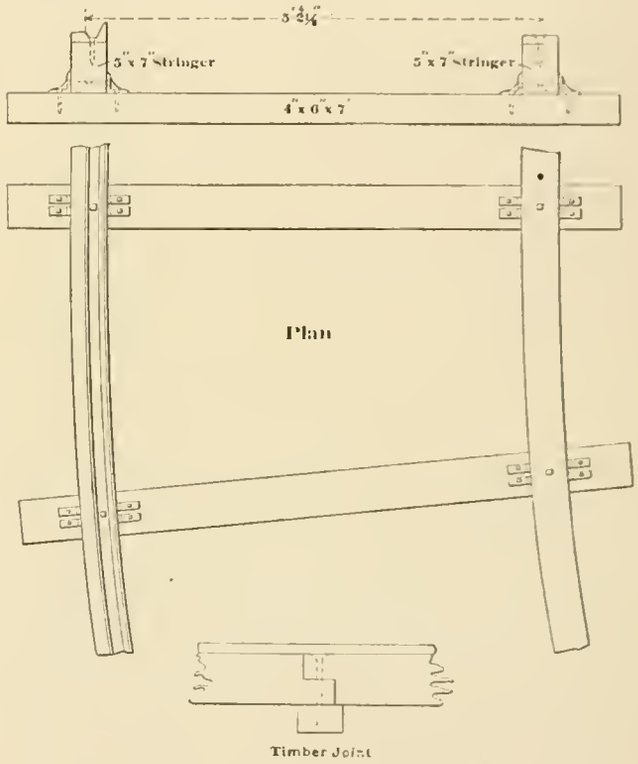


FIG. 1.—CURVED TRACK PRIOR TO 1871.

but a rather indifferent car track. There was but little rail head, and what there was rested upon the extreme outside of a broad timber, and was so soon pressed out of gage that the cars traveled upon the wheel flanges. D was used upon the same route, on the upper end of Main St. It was laid on 4 x 6-in. timbers, set on edge. There was much criticism because of the narrow inside tram, but the track, being held to gage by tie rods, was a fairly good one for street cars.

E is the center bearing or "saddlebags" rail, laid on the eastern part of Route 5, and on Route 7. It was the best of the strap rails, because it had sufficient weight to make it tolerably rigid, and, as it brought the weight upon the center of the timber, it avoided the tendency to tilt the stick over, and thus widen the gage, as did all of the forms having the inside tram. The lack of the tram brought upon it much censure from teamsters, but it was retained until the advent of the electric motor.

F is the standard T-rail of about 35 to 40 lb. per yard, always preferred by railroad companies, and very much used, but objected to

in pavements, because it provided no tram, but did provide a groove alongside of it in the road. Its defects, from the side of the railroad company, were lack of depth, lack of protection to wheel flanges, and weak joints; while, on the side of the public, it was claimed that no street surface could be maintained adjacent to it.

G is the standard tram rail, weighing from 42 to 50 lb. per yard, used upon what was regarded as first-class lines in cities requiring good service and well-maintained streets.

Where the rails met upon the timbers, the wood soon yielded, and the maintenance of the joints became troublesome. In original construction an iron plate about 4 x 6 x ¼ in. was used, but it was soon shown that something more rigid was necessary. The cast iron joint plate, shown in plan and section at H, Fig. 3, was devised by the writer, and was the most satisfactory that he has

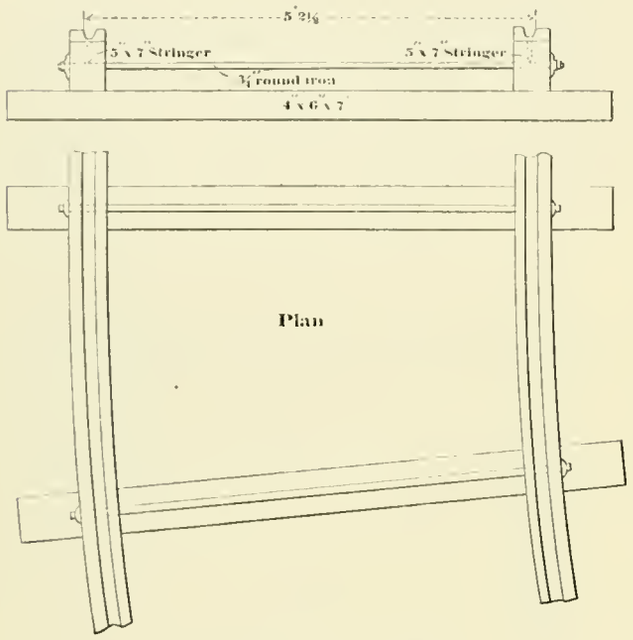

FIG. 2.—TRACK BUILT IN 1873.

seen, excepting a plate slightly lighter, but very similar in section, made of rolled iron.

The gage having been arbitrarily fixed at a width that suited street traffic, it became necessary to construct cars having a short wheel base in order to operate them on the curves necessary to turn the corners in city streets. A rigid wheel base of about 6 ft. was commonly adopted, and we could swing around a circle having a radius of 33 ft. to the center of the track. As might be expected, there was some friction connected with such proceedings, but these short curves never occurred upon heavy gradients, and the resistance due to curvature was not the most serious obstacle to be surmounted.

For the empty horse car, the load upon each wheel was about half a ton, seldom exceeding 1,200 lb. The live load was exceedingly variable, and generally, good-natured and accommodating. If it found itself off the track, and stuck in a chuck hole, it would often get off and assist in putting the dead load back upon the track. Of average passengers, it takes between 50 and 60 to make a load of four tons, but that load was often exceeded on crowded cars, making the weight on each wheel frequently greater than 3,000 lb. These heavy loads, on the yielding timbers, disturbed the pavements, and made street and track repairs continuously expensive. City officers learned that the maintenance of streets carrying car tracks was more expensive than that of other streets, and they began to lay additional burdens on the street car companies. Promoters, failing to realize the great expense incident to street maintenance, frequently accepted grants which involved such great expense for paving and maintenance, that the conditions of the grants could hardly be complied with. The stringers required such frequent renewals, and the rails were so constantly loose and out of gage, that some remedy must be devised.

Mr. Johnson had invented an automatic switch, so planned that the mule should turn it by stepping on the proper side of a tilting plate, and thus avoid interrupting the driver when engaged in his legitimate occupation of beating his team. In the few nights that the writer spent with the inventor in this city, setting two or three of those contrivances, Mr. Johnson saw the decayed timbers, and, bringing his inventive mind to bear, he produced the "girder rail." The iron or steel web and base of the T rail were placed beneath the head and tram of the strap rail, the base and stem taking the place of the wooden stringer. Being about right, it soon became popular, and the worst evil now connected with it arises from the fact that there are too many forms of it. If standard weights and heights were rolled, the cost of manufacture could be reduced, and better results would follow.

Street railroad companies had become accustomed to the use of light rail sections, the price per ton for iron rails was then about

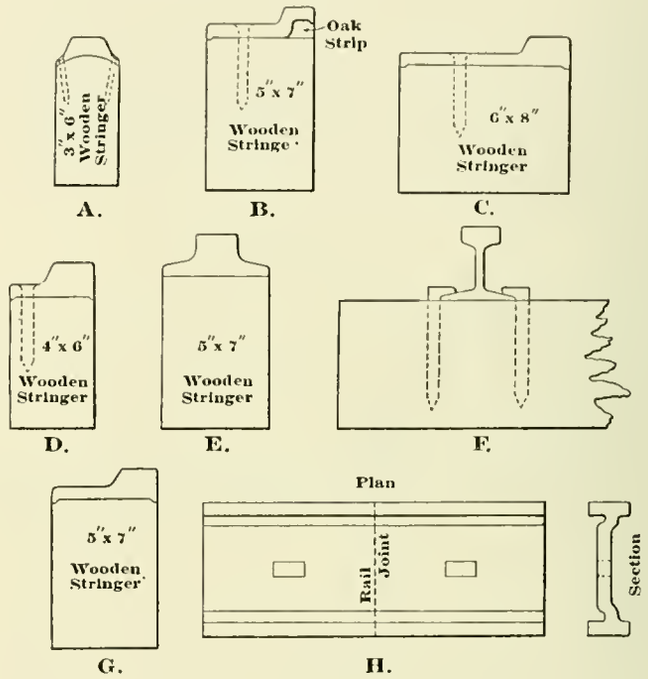

FIG. 3.

three times the present price for steel rails, the requirement for the inside tram was being rigidly enforced, and the sections produced were influenced by these conditions, so that all defects were not eliminated. In Fig. 4, A is a typical section of light girder rail, weighing about 32 lb. per yard, while B, would then, (say 15 years ago), have been regarded as a standard heavy section.

In these sections the lack of strength in the joints is at once apparent, and lack of depth became troublesome so soon as any proper form of street pavement was to be placed along the tracks. They have still another defect which people were slow to learn, and which, in fact, is still a mystery to some people who are struggling

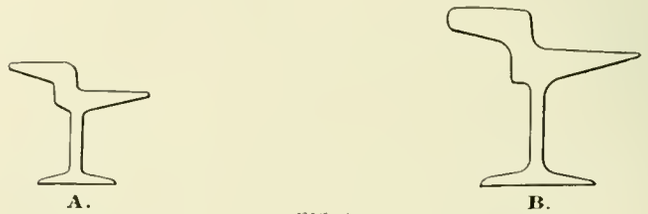

FIG. 4.

with low joints. In the girder, the rail head and tram constitute the upper chord, the base of the rail the lower chord, while the stem makes the connecting web. The distribution of the material is approximately as follows: 66 per cent in the upper chord, 21 per cent in the lower chord, and 13 per cent in the web. This is a bad disposition for a beam or girder, especially when the material in the upper chord is subject to much wider and more sudden variations in temperature, than that in the lower chord. The rail head and tram, being exposed to the direct rays of the sun, become much warmer than the base of the rail, and consequently longer;

there is sufficient material in the base to cause the rail to curve vertically, loosening it from the ties, and no fish plate or other fastening, and no trackmen, however skillful, can keep up the joints. This condition, with its consequent troubles, still exists with the forms of rails having the inside tram.

When cities began laying stone block pavements, and it became apparent that neither broken stone, gravel, nor asphalt, could be maintained where the top of the tie came within three or four inches of the surface, various devices were brought out for lowering the ties. The clamp chair, which was especially adapted to what is known as the bulb rail, in which the lower chord of the girder is given a rounded form, the box joint chair, the brace joint chair, and numerous rail clips and tie plates have been devised, and many are still in use; but those girder rails still keep on bowing up in the middle and down at the ends, and they still continue to loosen any and all of those fastenings, and they are not likely to stop, so long as metals continue to expand when heated.

To obviate these difficulties, and to provide for the greater weights and higher speeds of electric motors, deeper girders are being generally adopted, carrying the rail down on a broader base to a heavier tie, placed at a greater depth. Sixty-five and 70 lb. per yard, are now regarded as light rail sections, while 80, 90, 95, and even 100 lb. per yard, are now common weights of rails used in the tracks of electric roads in the streets of our larger cities. But nearly all of them are laid on wooden ties. It is true that the tie is generally imbedded in concrete, or placed upon a foundation of crushed stone compacted by rolling, but the fastening of the rail is to this perishable tie, and it is inaccessible, except by the digging up of costly pavements, and the interruption of congested traffic. The stringer has gone, now why not eliminate the perishable tie. Leave off that silly inside tram, and omit the wooden tie, and you may be able to make your track for electric roads reasonably permanent.

The maintenance of the street railroad track is essentially different from that of the steam railroad track; and in its construction this difference should be fully considered.

The steam railroad track is placed upon a right of way owned and controlled by the company which owns the track. Its construction, its drainage and its maintenance, are all in the hands of its owners, who supply the requisite material, and direct the workmen under skilled supervision. The joints, the drains, the ties, are visible, and are subject to daily inspection. When the requisitions have been made, and the materials and funds supplied, (it may be that these are sometimes administered in homeopathic doses), there is nobody to consult, no traffic to interrupt but that controlled by the company itself, and repairs are systematically made, without interference or delay.

With the street car track, these conditions are all reversed. The roads are built in public streets or highways, where everybody has a right of way, and each individual assumes and asserts that he has a little better right than any street car company, when he wants to drive on the street, and an absolute right to be carried on time, when he wants to ride on the cars, he preparing his own schedule.

The track construction is entirely buried from sight, excepting the tops of the rails, and frequently they are covered with mud. The drainage, when there is any, is under the control of municipal authority, and, unless provided when the tracks were laid, it cannot be either supplied or maintained by the street railroad company, unless it be under conditions which the municipality shall dictate. If bolts or spikes become loosened, or a tie requires better support, such facts cannot be known until a depression is visible in the track, and the adjacent pavement shows the effect of the movement that has been imparted to the rails. Then a permit must be obtained from the authority having control of street repairs, often involving the rights of contractors who have agreed to maintain the pavements, and in due time the street pavement can be taken up, the defect remedied, and the pavement replaced. The delays are so vexatious, and the conditions imposed are so onerous, that what might have been prevented at trifling cost by the tamping of a single tie, or the adjustment of a single joint, has involved numerous delays, and the expenditure of many dollars.

Because these conditions do exist, and for the further reason that street railroad companies should, as a matter of right, use every proper means to render their service as prompt and reliable as it can practically be made, and because the use and occupancy of streets and highways by the street car companies should be attended by the least disturbance of such roadways, and the least amount of interference with their use by the general public, it follows that the construction of street railroad tracks should be of the most durable materials, and the most permanent workmanship that is attainable at reasonable cost. Since the electric motor has taken the place of animal power in propelling cars, and since those cars have been given such weights and speeds that colliding with them is accompanied with great danger, it follows that no tramway should be provided to allure vehicles to their tracks, but that street surfaces should be so formed that wagons will pass over or along the rails without being impeded by the broad groove or rut that invariably accompanies the inside tram. That feature should, therefore, be eliminated from the rail. Where street surfaces are properly paved and maintained, the full grooved rail should be laid. Where they are composed of broken stone or gravel, the deep T-rail should be laid, having a low inside guard that will provide a space for wheel flanges, and a shoulder against which the road metal can be packed.

Possibly a digression may be permitted for a brief discussion of rail sections. It may be true that some of the sections of girder rails now in the market, have been designed by the men who make and sell steel by the ton, so that weight is fully as desirable as length of service. Then it may be true that electrical engineers have designed some sections, without having made a careful study of the matter of so disposing the material as to secure the greatest life of rail at the least cost. And then again it is possible that a few city engineers have interjected certain requirements and conditions, just because they could. At any rate, there is great variety, and many of the sections are not such as can be commended on the

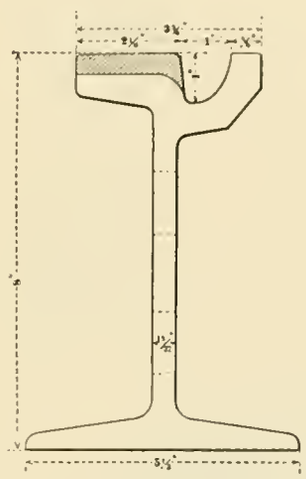

FIG. 5.

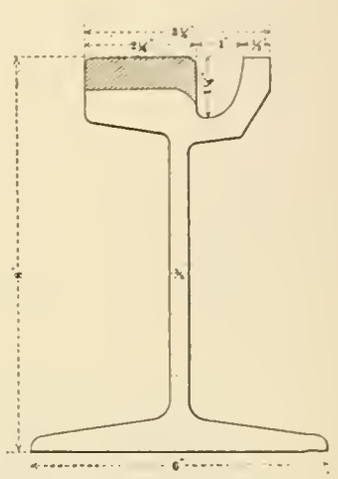

FIG. 6.

score of economy. It is not the purpose of the writer to design a rail, but he is willing to state a few of the principles that, in his judgment, should be considered in making such a design, and he desires to urge the advisability of adopting standard sections for certain heights and weights, so that the cost of manufacture can be reduced.

In track construction, it may be assumed that the rail is the essential feature, and that it should be so designed that it can be rigidly held in place, that it will resist, without deflecting perceptibly in any direction, the stresses to which it is subjected, and that it will continue to do so until it shall have lost, by actual wear in service, the greatest allowable percentage from that portion with which the wheels come in contact, before it shall be unfitted for service. The rail head upon which the wheels bear is the only portion subjected to actual wear, and when that shall have lost so much material in service as to cause it to fail to properly support the car wheels, the whole of the residue of the rail becomes scrap. The web and the base serve only to maintain the rail head in proper position. Width of base renders the rail laterally stiff and easy to support. Depth of rail makes it vertically rigid, and carries the rail fastenings down beneath the paving blocks. It also provides space for rigid joint fastenings.

When the rail acts as a girder, the material in the base is subjected to tensile stress, and that in the rail head to compression. To allow for reasonable wear, there should be at least one-third more material in the upper chord, or rail head, than there is in the lower chord or base. In the web there should be sufficient material to transmit the loads to the base. Inasmuch as the web must resist

lateral as well as vertical stresses, it is usual to make rather liberal allowances for that purpose, and also to give ample bearing surface for the bolts, but web material, beyond that which is required for these purposes, is wasted, and, adding to the thickness of the web, in high rails, increases the weight more rapidly than increasing any other dimension. It is here that waste occurs. Granite blocks constitute our heaviest pavements. They are 6 in. in depth. There cannot, therefore, be any valid reason for giving rails a greater depth than 8 in. In a rail having a depth of 8 in., there can be no possible use for a greater thickness of web than $\frac{3}{8}$ in. By no calculation or practical experiment can it be shown that a web of that thickness could be deformed by any force, or combination of forces, acting upon it in the track.

As an example, take Section 95, No. 216, as rolled by the Johnson Co., and very extensively used in this city. Fig. 5 shows the rail as used, the shaded portion of the head being that part subject to wear, and Fig. 6 shows a rail of the same weight and height, just as rigid and strong, the shaded portion of the head again representing the part subject to wear. When that part shall have been

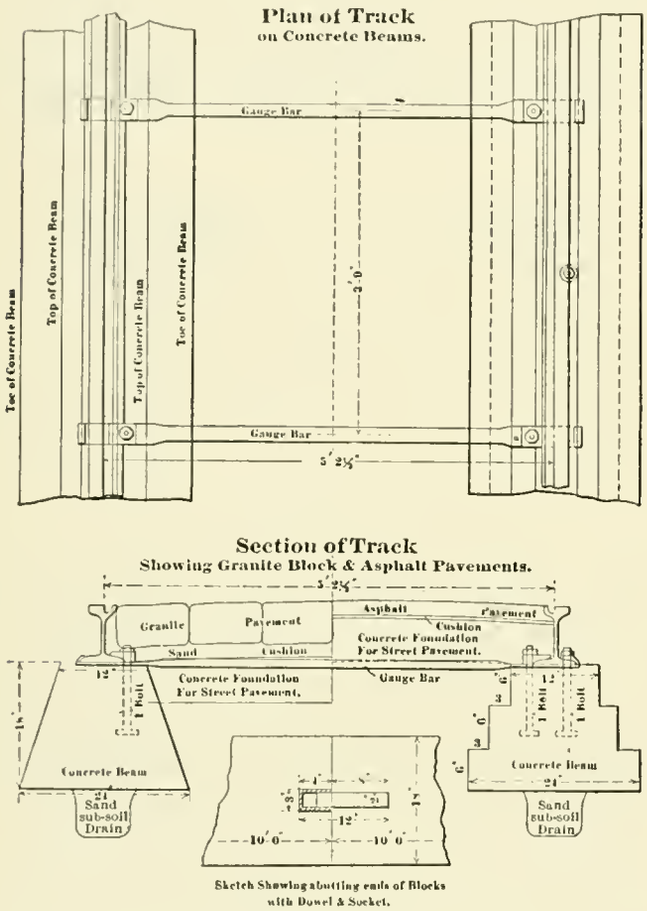

FIG. 7.

worn from either rail, as it will be by continued use, the residue will be scrap. A comparison of the areas of the shaded portions of the sections shows that, if the wear be uniform, the changes suggested would increase the life of the rail about 60 per cent. That is to say, if the rail shown in Fig. 5 has a life of 15 years, that shown in Fig. 6 will wear, under the same traffic, 24 years or more.

The essential differences consist in widening the base, deepening the groove by lowering the guard, squaring up the side of the rail head to lessen the flange friction, and taking material from the web and placing it where it will be subject to wear. But this is only a criticism, not a design. It is made upon a rail section which is very familiar to all of us, and is in fact on a section that is very much superior to many that are in use. The tonnage carried by some of the tracks where this rail is in use closely approximates, if indeed it does not exceed, that upon the main tracks of some first-class steam railroads. That use will wear down those rails, and, unless the joints fail, the wear will be quite uniform, and nearly as indicated upon the sections. It is certainly desirable to defer the day of renewal as long as possible. It is no more difficult to roll one of these forms than the other, and that form should be used which, at equal cost, has the longest life. But it is time to speak of the real subject of the paper, that is, how to lay the rails.

In Engineering News for Jan. 5, 1899, are two articles and two designs for "permanent ways" for steam railroads. The one written by a member of the editorial staff of that journal is so readily adaptable to the construction of electric street railway tracks that its author should have full credit for the invention, if there be one. With the modifications which the writer would suggest, to adapt it to street railroad tracks, it is shown in Fig. 7.

The plan consists essentially in placing the rails directly upon continuous concrete beams, placed centrally under each rail, fastening the rails to the concrete by holding-down bolts and rail clips, and holding the rails to gage by gage bars. There is nothing perishable in the construction, and, when properly built, there should be no expense for track repairs until the rails wear out. The dimensions of the beams that are necessary will depend upon the nature of the soil and upon the climate in which the tracks are laid. In the average clay or gravel soils of this vicinity, the dimensions shown on the drawing will be found ample to sustain the heaviest traffic, where the subsoil is properly drained. This form of construction should not be used upon newly constructed embankments subject to any considerable settlement.

The concrete can be made in its proper position in the street, or the blocks can be made at a factory, hauled to the work and placed in the tracks, being connected by iron dowels, as shown in the sketch. If made in position, the concrete would be placed in three layers, and the sides, instead of being sloping as shown on the left in the drawing, would exhibit offsets, as on the right. The sectional area and the bearing surfaces are the same in either case. The writer, having much more faith in the continuous beam than in either the tamping of the foundation or the dowel joint, would, wherever possible, build the beams in position; but where that process would be impracticable, the other method could be successfully used, and it would have some advantages. For instance, there could be no question about the quality of the concrete, and it could not be used until it had acquired sufficient strength to insure its preservation.

The base of the rail should be about 6 in. in width, and its depth should be sufficient to give to the rail joints as nearly the sustaining power of the body of the rail as is practicable. If made in position, a bearing plate should be placed under rail joints; if made at the factory, that would not be found practicable. By the plan shown in Engineering News, the holding-down bolts are all shown on the inside of the rails, but, for a street car track, the writer would place two bolts in each rail upon the outside, and bring those bolts through the base of the rail, for the reason that the paving may be all taken from one side of a rail, while it remains upon the opposite side, and the pressure might then be so great as to spring the rail inwards, unless the rail clips had very efficient bearings. While such motion would not be likely to be imparted to the rail, the method suggested would certainly prevent it. But there is still another reason,—viz, these two bolts, passing through the base of the rail, would prevent any creeping of the rails; and, as the holes need not be slotted, the expansion and contraction of each rail, whatever that might be, would be confined to that rail length, and its effects could not become cumulative. About one-half the usual allowance for expansion and contraction should be made in track laying, as that would prevent any objectionable openings at the joints, and at the same time avoid subjecting the track fastenings to the extreme stresses brought upon them by attempts to wholly resist such motion.

The quality of the concrete, used in these beams, is an essential feature. Its cost will vary, in different localities, with the cost of the materials which compose it. In this climate it is not essential that it be made with portland cement, because it will not be exposed to the direct action of the weather; but, if natural cement be used, it must be of good quality, and the ingredients must be so proportioned and manipulated that the resulting mass will be a dense artificial stone. In this locality, or wherever clean sand, crushed stone or clean gravel is obtainable at the prices prevailing here, it can be made, at a reasonable profit, at $5 per cubic yard. Upon this assumption, let us see what a mile of this kind of construction will cost, omitting the rails and street paving, as those items are common to each kind of track.

Estimated cost of one mile of permanent way for electric street railroad:

1,300 cu. yd. of excavation at $0.20 per yd.	$ 260.00
120 cu. yd. of sand for subsoil drain at $1.00 per yd.	120.00
880 cu. yd. of concrete at $5.00 per yd.	4,400.00
9,665 lb. of holding-down bolts, with heads and nuts, at $0.01½ per lb.	144.98
32,553 lb. of gage bars (6'-1" x 3" x ⅜") at $0.012 per lb.	390.64
2,816 rail clips at $0.04 each	112.64
7,089 lb. of joint plates at $0.012 per lb.	85.07
Total	$5,513.33

or $1.04 per lineal foot. If the blocks be made in 10-ft. sections and connected by dowels, the joint plates should be deducted, and $253 added for the cost of dowels and sockets, making the total cost per mile $5,681.26, or nearly $1.08 per lineal foot. The cost of the track laying may be assumed to be the same as that for the present form of construction. Since it would necessarily be done simultaneously with the placing of the concrete, the actual expense would probably be somewhat less.

Estimated cost of one mile of street railroad track on ties in concrete:

1,400 cu. yd. of excavation at $0.20 per yd.	$ 280.00
1,175 cu. yd. of concrete at $3.00 per yd.	3,525.00
2,640 ties at $0.45 each	1,188.00
7,920 lb. of spikes at $0.0125 per lb.	99.00
4,693 square yards of rolling at $0.03 per sq. yd.	130.79
Total	$5,222.79

or, about $0.99 per lineal foot. If the ties be laid on broken stone, the cost per mile will be about $3,850.00, or about $0.73 per lineal foot.

From these figures it will be seen that, if this form of track construction be desirable, its cost is not prohibitive, for in one case the saving, by methods now in common use, is but 5 cents per foot, or $264.00 per mile, and, in the other the saving is but 31 cents per foot, or $1,636.80 per mile. Now, is it desirable? If it be really permanent, there can be but one answer to the question, and it appears to be perfectly self-evident that a track, properly constructed upon the plan suggested, would cost practically nothing for repairs until the rails should fail from actual wear. Being continuously supported, the rails would not act as girders, but, if the foundation should yield, or be dug from under them, those concrete beams and the rails would carry any electric car now in use over spans of ten or twelve feet without perceptible deflection. The construction does not extend into the ground a sufficient depth to interfere with pipes or other conduits, and at the same time it does rest upon a part of the street that is not likely to be seriously disturbed by the plumber or the street repairer.

The question may be asked, why make the beams so heavy, when the loads upon them are so light? The answer is, that in view of the great amount and unknown position of the excavations that are almost constantly being made in the public streets, it is cheaper to provide a wide margin of safety than to repair the defects that might result from such causes. Then, as we know by recent experience, the frost penetrates to considerable depths in this climate, and would be likely to reach the bases of these beams, but not so as to affect their stability. Were they lighter and shallower, however, its effects might be seriously detrimental to the stability of the track.

The holding-down bolts are spaced 3 ft. 9 in. apart, making eight on the inside of each 30-ft. rail, and there are two upon the outside of each rail, making 10 1-in. bolts by which each 30-ft. rail is secured to its foundation. It is at once evident that this affords far greater security than is now obtained by about three times the number of spikes. The gage rods are made from flat steel bars 6 ft. 1 in. long for our Cincinnati gage, with rail bases 6 in. wide and ⅜ in. thick. "The ends are turned up to form claws, which engage the outer edge of the rail flange, and the central part is stamped into a semicircular trough shape, to stiffen it to resist compression. These bars are also punched to slip over the holding-down bolts. It will be seen at once that these gage bars would offer vastly more resistance to the spreading of the rails than the present spikes in wooden ties. The rails would, in fact, be solidly held to perfect gage. The security of this, as compared with the rail braces, tie plates and spikes which are now used, will be apparent." (From Engineering News.)

Regarding the subsoil drain, which is here shown as filled with coarse sand, the writer believes that to be the most effective material for the purpose, except in rare cases where the inflow of water would be quite considerable, when a tile should be bedded in the sand. It should be connected, by tile drains properly screened, with the sewers or other outlets for the water, at frequent intervals. In placing it in trenches, it should be well compacted, so as to aid in supporting the concrete beams. These trenches should not be filled with broken stone, especially in clay soils, as the clay will fill the interstices between the fragments of stone, and the drains will thus become entirely clogged. For the same reason gravel is inferior to sand. Where the subsoil is sand or gravel, the drains will not be required. The quantity of water to be carried by these drains is so small that it will seldom produce a running stream, but it is of the utmost importance that it be cared for, or its effects may be highly detrimental.

For suburban or interurban roads, a lighter form of construction may be used; but, even in such work, the form of track construction herein described would be found economical because of its permanency and the saving that would be effected in track repairs.

As heretofore stated, the writer does not claim much originality for the ideas of track construction advanced in this paper, but he does believe them to be in the nature of real betterments in the work, and therefore worthy of careful study, of elaboration, and, where found to be betterments over present practices, of adoption. The foundation should have the same ownership as the rail which it supports. As little reliance as possible should be placed upon street pavements for the stability of the tracks, and the latest possible quantity of detriment to street pavements caused by the presence of the tracks. It is believed that the plan here presented will be conducive to those ends.

LONDON AUTOCAR.

In a paper before the Liverpool Self-Propelled Traffic Association Mr. Thomas H. Parker treats of new features in the design of motor-vehicles, and among other cars describes the one designed by him for the London Electric Omnibus Co., which is shown in the accompanying illustration.

It is constructed on the double-bogie principle having the batteries under the seats. It has two motors, one on each bogie, driving all four wheels. To each of the four wheels has been attached a powerful hydraulic brake, working by means of a force pump near the driver's seat. It has only two handles to manipulate it. The vehicle has three speeds forward and one backward, it will turn in its own length, and will run over ordinary roads 25 miles with one charge at a mean speed of 10 miles an hour. The weight with 14 passengers, driver and conductor is about 7,800 lb.

LONDON AUTOCAR.

A car of the United Traction Co., Allegheny, Pa., suddenly started from the barns at 5 o'clock on May 20th and ran away. It dashed down the steep grade on Charles St., and on a curve below jumped the track and crashed into the front of the Valley House. There was no one on board. The car was wrecked and the damage to the bulding was about $800.

OMAHA EXPOSITION.

An organization has been perfected in Omaha, Neb., called the "Greater America Exposition," and the intention is to hold an exposition in which exhibits from the newly acquired possessions of the United States will be the main features. The buildings of the Omaha Exposition of 1898 have been purchased by the new company, and the work of publicity and promotion has begun. The show is to open July 1st and to continue for four months. The managers claim that already commissioners have been sent to the different islands to secure attractions and they promise to have native Cuban and Filipino villages, showing the people exactly as they are in their own homes.

But these colonial exhibits will form only one feature of the exposition. Space will be given free for American manufactures, and it is to be hoped there will be a good showing made. The grounds are now being handsomely laid out and a veritable tropical garden may be expected.

COLLAPSE OF CAR BARN AT CINCINNATI.

The framing of new car barn of the Cincinnati, Newport & Covington Railway Co., in process of construction at the corner of 11th and Brighton Sts., Newport, was blown down in the severe storm of Sunday, May 21st. The collapse occurred about noon. The damage is estimated at $5,000.

This car shed is 280 x 100 ft. and was being constructed of steel. About half of the trusses were in position upon the columns. Neither the trusses nor the uprights had been properly braced and the wind threw the entire roof frame to the ground.

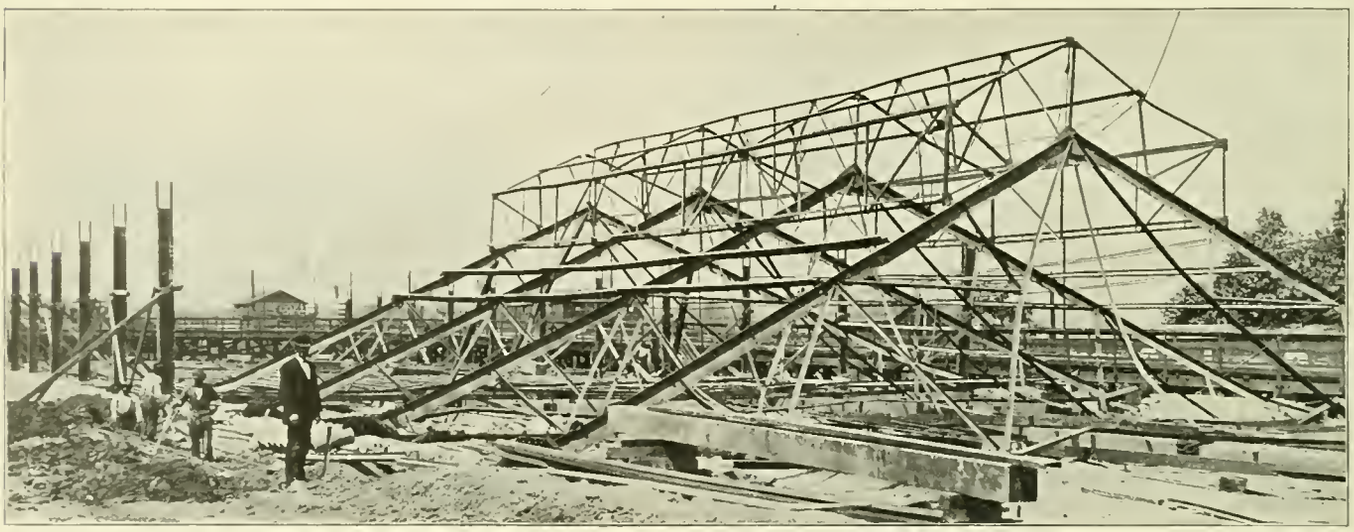
There will now be considerable delay in the erection of this barn, as it will take some time before material to replace badly twisted members can be obtained. The order for new material has been placed and as soon as possible the building will be erected.

NOTES FROM NIAGARA FALLS.

The Niagara Falls & Lewiston Electric Railroad Co., which built and for four years operated the electric railroad through the Niagara gorge along the New York bank, will pass out of existence and be succeeded in business by the Niagara Gorge Railroad Co. This change is the result of a sale of the road by the sheriff of Niagara County in Lockport on May 23d. The purchaser was Herbert P. Bissell, of Buffalo, who is the chief promoter of the new company, and who is the only one of the old company remaining in the new one. The capital of the new company will be $1,000,000, whereas the old company was capitalized at $1,400,000. During the month of May large forces of men were employed in the reconstruction of the roadbed, removing fallen rock, and putting in new trestles and bridges. New retaining walls were built at several points. The roadbed was reballasted and the overhead construction repaired. It is stated that steel bridges will replace all wooden structures.

The incorporators of the new company are: Gen. Francis V. Greene and Avery D. Andrews, of New York; Herbert P. Bissell, J. Henry Metcalf, Joseph T. Jones, William C. Cornwell, Clarence M. Bushnell, Edward W. Eames, John A. Kennedy, George A. Ricker, Arthur C. Coffey, Herbert H. Hewitt, George C. Riley, George V. Turner and Bert L. Jones, of Buffalo. The board of directors includes all of the incorporators mentioned excepting Messrs. Kennedy, Ricker, Coffey and Riley. The officers of the company are: President, Gen. Francis V. Greene; vice-president, Herbert P. Bissell; secretary, Herbert H. Hewitt; treasurer, Bert L. Jones; general manager, Godfrey Morgan; chief engineer, George A. Ricker.

Governor Roosevelt has signed the bill which will allow the commissioners of the New York state reservation at Niagara to construct, without expense to the state, street railroad tracks upon and along that part of the Riverway, so called, between Falls and Niagara Sts., Niagara Falls. The commissioners in their discretion may grant revocable licenses to street surface railroad companies to use such tracks upon such terms as the commissioners may prescribe. The Riverway is the street running along Prospect Park, and the new law makes it possible for the International Traction Co. to make connection between the Falls St. tracks and the tracks of the Niagara Falls Park & River Ry. on the upper steel arch bridge. The construction of this loop will thus make connection between the tracks used by the Buffalo & Niagara Falls cars and the tracks that run along the Canadian bank of the river to Queenstown, and in the future electric cars may be run from Buffalo, N. Y., to Queenstown, Ont., the steamer landing, direct.



WRECK OF CINCINNATI, NEWPORT & COVINGTON CAR SHED.

FIRE IN NEW JERSEY.

On May 24, 1899, about 3 a. m. the car house of the Atlantic Highlands, Red Bank & Long Branch Electric Railway Co., at Shrewsbury, N. J., and almost all the rolling stock were destroyed by fire. The origin of the fire is still in doubt, but the evidence thus far seems to stamp it as the work of an incendiary. The car house was large enough to hold 20 cars, and included work shops and a large supply of stores. It was built of brick, with an iron roof. Today only the two side walls are standing. There were 16 cars in the shed at the time, and these were totally destroyed. The loss is estimated to be about $35,000, and is fully covered by insurance.

A PROMINENT VIRGINIA MANAGER.

Mr. R. D. Apperson, general manager of the City Street Car Co., of Staunton, Va., and president of the Virginia Street Railway & Electric Association, has been practically identified with electric and railway work all his life. His career began at 11 years of age, when he was employed in the cashier's office of the Pullman Palace Car Co.

President Apperson was born at Mt. Sterling, Ky., on Aug. 16, 1863. When he was a year old his parents moved to New Orleans. He was with the Pullman company for about 18 months, when he went to Kansas City, Mo., and secured a place with the

R. D. APPERSON.

Bell Telephone Co., as switch boy. In a week he was promoted to the position of operator, and in course of time became the manager of the office. Resigning, he went to Little Rock, Ark., and was appointed assistant superintendent of the Little Rock Cotton Seed Oil Mills. He held that position for five years, when the same company made him superintendent of the cotton compress.

But street railway business began to attract Mr. Apperson and he left the Cotton Seed Oil Co., to become cashier of the Little Rock & Citizens Street Railway Co. In four months he was made superintendent, as well as cashier, holding both offices until the road was sold in April, 1890. Staunton, Va., was Mr. Apperson's next field of action. He went there to construct and equip the City Street Car line, and when that work was finished he was asked to take the full management, which he did. For six years the road was operated by horse power. He then changed the entire plant to electric traction, personally superintending the installation. At this time also he installed the electric lighting and gas plant for the street railway company and now holds the position of general manager of all three concerns.

Mr. Apperson has always been thoroughly practical, and in all his street railway and electric work has drawn his own plans and done his own engineering.

IMPROVEMENTS OF SOUTH CHICAGO CITY LINES.

There is great activity along all the lines of the South Chicago City and the Hammond, Whiting & East Chicago Electric roads. Improvements of all kinds are under way, all tending to put the roads in first-class condition. Grades are being raised, streets paved, sewers built and grade crossings placed.

Near the north end of the South Chicago City line the grade is being raised 3½ ft. on Buffalo Ave. and the street paved with granite blocks. The grading begins at about 87th St. and extends south to 92d and around the curve to where Indianapolis Ave. branches.

Another important piece of work is the putting in of 54 heavy solid grade crossings to replace "jump" crossings. The new crossings are the steam road standard, built of 80 and 85-lb. rails. The crossings are spiked to hardwood tie bedded in cement. As fast as may be necessary all the remaining crossings will be improved in the same way.

On the Hammond, Whiting & East Chicago line Indianapolis Ave. is being filled from where it begins at Buffalo Ave. to Hammond, Ind. This line passes down between Wolf Lake and Lake George, crosses the Calumet River and runs on to Homan Ave. The Lake County Commissioners are doing the filling and are macadamizing 13 ft. on each side of the street railway tracks. There are on this line four miles of double track and the company is paving its own right of way.

A similar improvement is being made on the other branch, the Whiting & East Chicago line. The grade will be raised and the road macadamized from the junction at Forsythe across the state line to Whiting and from Whiting to East Chicago.

A large sewer is being constructed in Homan St. and the grade is being raised about 20 in. from the Calumet River south. In the case of simply grading and paving the streets, Mr. Walmsley does not allow traffic to be interfered with but in this work on Homan St. the sewer building obliged the company to remove its tracks.

The company has plenty of cars of all kinds, but just now the great problem is to secure safety in operation. The long footboard for open cars has been abandoned. The open cars are being reconstructed so that it is possible to enter and leave them from the rear platform only, that in front always being guarded with gates. Wooden guards cover all the wheels and with the fenders it seems an impossibility for any one to fall or be dragged underneath the car. For a long time the general manager, Mr. Walmsley, recognized a danger in passengers putting their heads and arms out of the cars when crossing the bridge over the Calumet River. To avoid accidents he had rods fastened to the sides of all the cars, even the winter ones. He has adopted the same plan for the open cars and has three ½-in. round iron rods placed on each side of the cars. To prevent small children from falling out between the seats a strip of 1½-in. band iron is carried from the floor up to the lower rod.

In the matter of fenders, Mr. Walmsley has inaugurated a change which pleases him very much. He sees no use for such a contrivance on the rear of a car, which is both useless and unsightly. He has therefore devised a detachable fender which can be shifted very quickly. Each fender is numbered and belongs to a certain car.

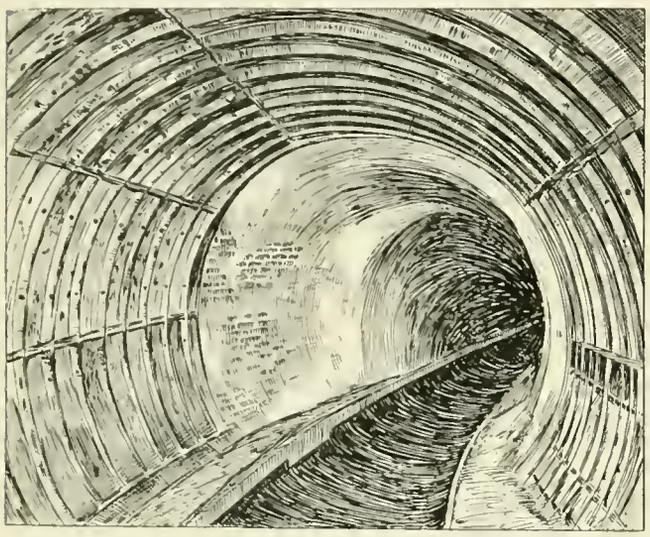
SECTION OF TIME TABLE.

Mr. Walmsley has also devised something unique in the way of a time card. Besides having a convenient map showing clearly the routes of the different lines and in foot notes affording all possible information regarding the time used in running from the north end starting point, Madison Ave. and 63d St., to any other main terminal and also noting the color of the signs in the daytime and the lights at night, the card gives the leaving time in minutes between each hour.

Inventors are busying themselves at present over the problem of wireless telegraphy. Reports come from the patent office that no less than ten applications a day are filed for patents in this field. The applications are mainly from experts engaged in the manufacture of electrical machinery and from scientists. Regular telegraph operators do not seem to interest themselves much in the new discovery, at least not to the extent of trying their hands at invention.

THE OLD NEW YORK TUNNEL ROAD.

If, while the New York Board of Rapid Transit Commissioners is discussing the question of tunnels as a means of rapid transit, they would stamp their feet on the Broadway pavement, they might hear a sound—a sort of hollow mocking sound—a ghostly sound—which might be the death knell of any such hopes or expectations. For underneath that great thoroughfare is a tunnel, or what was a tunnel, dug out nearly thirty years ago. The idea of the promoters of the scheme was to have rapid transit from the Battery all the way to the Park with air for the motive power. But that tunnel is now the grave of buried hopes and of over a quarter million of dollars in money, all wasted in a futile attempt to build a passenger railway on which danger or delays from obstructions would be entirely eliminated. It is true the conditions are different now. New tunneling appliances have been invented; pneumatic systems have been perfected, electricity has been made subservient as a motive power and an underground road could undoubtedly be constructed much cheaper than was possible 30 years ago. But with all these improvements and all these great advantages over the past, the fact remains that it is still easier to bore a hole through the yielding



INTERIOR OF OLD NEW YORK TUNNEL.

atmosphere, and to construct a railway upon a steel structure, than to tunnel through the ground.

The Beach Rapid Transit Ry. originated in the brain of one Alfred E. Beach, a newspaper man, with scientific inclinations. He was interested in the transmission of letters and packages through tubes by means of compressed air, a system of transit now in use in some of the large cities. Mr. Beach conceived the idea of constructing tubular street cars and shooting them through the tunnel on this principle. He raised some money and went secretly to work. The entrance to his tunnel was at 260 Broadway, where a building was rented. The earth and stones dug out during the day were carted off at night. For four months gangs of men were kept busy, and but few people knew that such work was going on. Several hundred feet of excavation had been made when the workmen ran against the walls of an old building. In removing this obstruction the pavement above settled and this gave the secret away. Protests were entered against the further prosecution of the work. Beach fought the opposition hard and to popularize his enterprise and prove the absence of any danger and the great benefits the system would provide, he inaugurated a reception to the great men of New York to be held in the tunnel itself. A car had been constructed and it was contemplated giving the guests a trip over the line as far as constructed, but unfortunately the power would not work and the reception was to a certain extent a failure. A successful trip was, however, made a few days later. This was in February, 1870. The car made regular trips and the people of the city were wild with enthusiasm.

Mr. Beach met with much opposition, but finally, after many failures, he secured a charter. Then came the railway panic and before the money could be raised the "L" system had grown in favor and for that time solved the rapid transit problem. The last effort made to do anything with the tunnel was in 1876. It died a natural death, but the yawning grave, empty but for the wreck of the pneumatic car, is still there.

THIRTY-THREE ROADS COMBINE.

A syndicate has effected the consolidation of 33 street railways in eastern Massachusetts and Rhode Island. The negotiations have been in progress for several months and were only concluded on May 9th, the Newport & Fall River being the last to come in. The new association known as the Massachusetts Electric Companies, will control the system of street railways from Nashua, N. H., through eastern Massachusetts and in Rhode Island to Newport, excepting the Boston Elevated; the consolidated mileage is about 625 miles.

The capital is $22,000,000. This is based on the actual cost of the properties, with enough added to provide for the payment of all the floating debts and for such improvements as expert reports may show to be advisable. One half of the capital stock will be common and the other half preferred 4 per cent cumulative. No bonds will be issued.

It is intended to reduce expenses wherever practicable without impairing the system. It is thought that a number of the now operating power houses can be dispensed with by enlarging those located so as to furnish the requisite power for all the sections.

The syndicate is composed of American capitalists, and will operate in the counties of Essex, Middlesex, Plymouth and Bristol. As showing the prices paid for the various properties the following may be interesting. The Lynn & Boston was secured for $2,600,000, the Lowell, Lawrence & Haverhill for $1,500,000 and the Brockton system for about $1,000,000.

The following is a list of the street railway and electric light companies concerned: Lowell, Lawrence & Haverhill; Reading & Lowell; Lowell & Suburban; Rockport; Nashua; Gloucester; Gloucester & Rockport; Gloucester, Essex & Beverly; Lynn & Boston; Beverly & Danvers; Salem & Wakefield; Wakefield & Stonham; Woburn & Reading; Mystic Valley; North Woburn; West Roxbury & Roslindale; Needham & Boston; Norfolk Central; Norfolk Suburban; Boston, Milton & Brockton; Braintree; Brockton; Brockton & East Bridgewater; Brockton, Bridgewater & Taunton; Quincy & Boston; Taunton; Dighton, Somerset & Swansea; Providence & Taunton; Globe St. (Fall River); Newport & Fall River, and Newport street railways, Newport Illuminating Co., and Hyde Park Electric Light Co.

Mr. P. F. Sullivan has been appointed manager of the consolidated system, and a better man could hardly have been chosen. He is well known among street railway men as one of the most efficient managers in the country, and is an accepted authority on street railway economics.

Mr. Sullivan began his street railway career in 1888 in the capacity of secretary of the Lowell & Dracut and the Lowell Horse Railway Cos. When these roads were consolidated in 1891 he was made the general manager and has held that position until now when he assumes charge of the Massachusetts Electric Cos.

Mr. Sullivan is president of the Massachusetts Street Railway Association and has ever been much interested in its growth and advancement. In 1896 the Association sent him to Europe to investigate the systems abroad and he gave particular attention to the laws governing street railways in Great Britain, France, Germany and Ireland and familiarized himself with the methods of legislation regarding them. On his return he made an exhaustive report of the information he had obtained which was submitted to the Association and has proved of much value.

Mr. Sullivan has been a resident of Lowell for over a quarter of a century and no one man has more friends. His nature is genial and he has the happy knack of making people like him even before they know him. In business he is always prudent, just and firm. He studies every matter thoroughly and when once he has taken a stand he is convinced is right he is immovable. And those with whom he comes in contact invariably find him correct in his judgment.

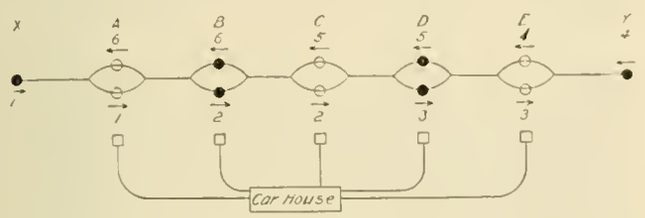
A man in Duluth, Minn., was recently arrested and given 60 days imprisonment for throwing stones at street cars.

SIX-MINUTE HEADWAY ON SINGLE TRACK.

Oakland, Cal., May 27, 1899.

Editor "Review": In regard to the inquiry concerning the operation of cars with a 6-minute on single track, appearing in the "Review" for May, I would say that I have had several years' experience in operating cars on $7\frac{1}{2}$, 8, 9, 10 and 15-minute headway and a plan for preventing unnecessary delays at turn-outs, which is used on my division, may be of interest.

With a single track and the headway fixed, it is first necessary to find the time required for a round trip of the car, and then the number of turn-outs, and the time between them may be determined. Thus if a round trip requires 30 minutes and the headway is 6 minutes, six cars and five turn-outs three minutes apart are necessary. Thirty-six minutes after the first car has started from one terminus the six cars are located on the line as shown by the solid circles in the diagram; three minutes later they are located as shown by the open circles. Time tables should then be prepared which give the time at which each one of the six cars should be at each of the turn-outs and termini.



Now if signal lamps be placed at each of the passing points and wired so that they can be manipulated from the car house or office, delays may be avoided. When a car is off time or turned into the car house for repairs, the signal lamp at each passing point is turned on at the time the disabled car is due there, and the conductor of the other car, seeing the light burning, proceeds to the next turn-out without delay.

My first suggestion is to avoid a single track if possible, because it is difficult to operate it successfully. But if the road can only build a single track the system of signal lamps described will prove convenient, and it is believed that it has one advantage not found in some more elaborate systems. That is, a failure of the signal light to operate holds the car on the turn-out.

We use this flash light system on our division and it has given satisfaction in avoiding delays at switches. Yours truly.

G. ROBERTSON.
Supt. Berkeley Division, Oakland Transit Co.

A CORRECTION.

Boston, June 3, 1899.

Editor "Review": Our attention has been called to an error on page 344 of your May issue wherein you refer to the storage battery in use at the power plant of the Laconia (N. H.) Street Railway Co. as being of the "Stetson" type. We beg to state that this is incorrect; it should have read "Chloride" type. Yours truly.

THE ELECTRIC STORAGE BATTERY CO.,
Frank J. Stone, New England Manager.

STRIKE AT CLEVELAND.

The employes of the Cleveland Electric Railway Co., known locally as the Big Consolidated, struck at 4 o'clock on the morning of Saturday, June 10th. The men demanded the recognition of the union and a board of arbitration to pass upon alleged violations of the company's rules; there were some minor questions concerning hours and schedules but the men and the company could easily agree concerning them.

No serious attempts were made to run cars until Monday morning when non-union men took out a number of cars. Strikers at first contented themselves with attempting to persuade the new crews to abandon their cars; later the cars were stopped by backing heavy drays and other vehicles onto the track and stones and eggs were thrown at the men, and the trolley ropes cut. The mobs were dispersed by the police and a number of persons slightly injured.

The company's board of directors adopted the following resolution at its meeting on May 12th:

"Resolved, That the differences between the Cleveland Electric Railway Co. and its former employes have substantially narrowed down to the proposition, upon which the company must stand that it must hire and discharge men without the dictation of anybody. As already stated, it does not attempt, nor will it attempt, to dictate to its employes whether they shall belong to a union or not. It will not require them to joint, nor will it discharge them for joining or refusing to join, at their pleasure. The company must reserve to itself the right to treat directly with its own men, to hire new ones as the needs of its service require, and to discharge inefficient men without accounting to anybody except to its director. Entertaining these views, it must respectfully decline to submit these questions to arbitration."

ELECTRIC LIGHT CONVENTION.

The annual convention of the National Electric Light Association began its sessions at Madison Square Garden, New York City, on May 23d. This was the 22d meeting of the association. The attendance was large and the sessions were interesting. President Alden M. Young, of Waterbury, Conn., was in the chair. President Young made a brief address of welcome, in which he called attention to the great number of electric light stations now within the limits of New York City and as illustrating the rapid advancement made in electrical science and its growing importance as a commercial factor he said that in Brooklyn the 10 street railway companies, in 1897, represented an investment of $55,000,000, and were operated as separate companies. They owned 678 miles of track and had carried 223,180,504 passengers during that year. In 1898 the entire system had been changed to electricity, the capitalization had been increased to $150,000,000, and the passengers carried had been 236,680,010.

A number of interesting papers were read. Mr. W. S. Barstow, of Brooklyn, followed the president with an article on "A Local Transmission System—Development and Operation." Mr. William Lispenard Robb, of Hartford, Conn., presented a paper on "Rotary Transformers and Storage Batteries as Related to Long Distance Transmission." The other papers read at the various sessions were: "Single Phase Distribution," by Mr. Herbert A. Wagner, of St. Louis; "Underground Electrical Construction," by Mr. Louis A. Ferguson, of Chicago; "Some Notes on Underground Distribution of Two-Phase Current in New York City," by E. A. Leslie, New York City; "Means of Affording Safety in Electrical Distribution," by W. L. R. Emmet, of Schenectady, N. Y.; "Alternating Current Generation and Distribution—Changes Contemplated in Atlanta, Ga.," by Mr. H. M. Atkinson, of that city, and "Transformers, Iron Loss—Its Increase—the Remedy," by Mr. G. Wilbur Hubley, of Louisville, Ky. All the papers elicited more or less discussion.

After other routine business had been transacted the association went into executive session and elected the following officers: President, W. W. Carns, Memphis, Tenn.; first vice-president, O. T. Crosby, Washington, D. C.; second vice-president, J. B. Cahoon, Elmira, N. Y.; secretary and treasurer, George F. Porter, New York City; master of transportation, C. O. Baker, Jr., executive committee, F. A. Copeland, W. W. Bean, W. McLea Walbank, Samuel Insull, Samuel Scovil, H. M. Atkinson, E. T. Peck, W. M. Brock and C. S. Scott.

During the convention the delegates were treated to an automobile ride, a sail around Manhattan Island and a trip to the works of the General Electric Co., at Schenectady, N. Y., the company providing a special train for that purpose.

PROPOSED IMPROVEMENT AT BAY CITY.

Mr. M. P. Heraty, president, and Mr. Lawrence Johnston, director, of the Bay City Consolidated Railway Co., of Bay City, Mich., were in that city recently looking over the property. They both expressed themselves as pleased with the prospects, and will advise the expenditure of at least $100,000 to put the road in first-class condition. It is Mr. Heraty's intention to call a meeting in Philadelphia of the Board of Directors and make an effort to have that sum appropriated. If it is done the work will be pushed through within a year; if not the road may pass into other hands.

THE DULUTH STRIKE.

The street railway employes union at Duluth, Minn., has ordered a boycott. The resolution is as follows:

"Whereas, we, the organized street railway employes of the city of Duluth have, through the obstinacy of the officials of the Duluth Street Railway Co., become involved in a controversy which we have so far been unable to settle, and

"Whereas, our city officials have so conducted themselves as to manage to keep astraddle of the fence in that they refused to take a decided stand in regard to this controversy, and

"Whereas, the agreement entered into between the two delegations that went to St. Paul has been broken by the representatives of the business element of our city, therefore, be it

"Resolved, that we, in defense of our rights as American citizens, having exhausted all other legitimate means to obtain an honorable settlement of our differences,

"We now declare a boycott upon the Pavilion at Seventh Ave. West and upon the Duluth-Superior Bridge, and that we also boycott any and all business men who patronize the same."

The history of this strike is quite interesting. Early in March the receiver and the manager of the Duluth (Minn.) Street Railway Co., found it desirable to reorganize the service and the employes were divided into three classes; the men in the first were those whose services had been satisfactory in every respect and an increase in wages was announced to take effect April 1st; the second class were kept on probation; the third class were dismissed. The men alleged that the discharge of 17 men during the first week in March was an attempt to break up their union and considerable talk of a strike was heard.

The executive committee of the union issued an address on March 9th in which Mr. Mendenhall, the receiver, and Mr. Warren, the general manager, each received his full share of abuse. A few days later other men were discharged and on March 21st, several of the ex employes petitioned the court having charge of the company to order their reinstatement.

When the petition came up for a final hearing on April 8th, affidavits were presented by General Manager Warren, containing definite charges against the men seeking reinstatement. These charges were for violating rules, and in one case dishonesty was alleged.

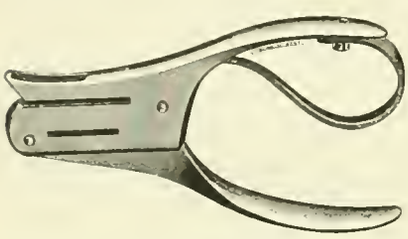
The court being called upon to decide between what it called two classes of the company's employes expressed a belief in the good faith of the management, and refused to order the reinstatement of the discharged men, but did not determine the truth of the charges.

In the "Review" for May we noted that a strike was ordered on May 2d, after the arrest of 10 men charged with cutting feeder wires. Attempts to assault non-union men who had been employed and to damage cars were made by the strikers, and also attempts to blow up cars by dynamite placed on the track.

Later announcements are to the effect that the strikers are applying for their old positions. The company states it will keep the non-union men, but will fill vacancies with the old employes if they so desire.

WOODMAN TICKET PUNCH.

The R. Woodman Manufacturing & Supply Co., of Boston, Mass., has achieved a big reputation on many special features among its railway supplies, but with no one article has it met with more success than its new transfer ticket punch. This punch has become vastly popular all over the country with street railway men. It is fitted with an elliptical spring which has been found to be a great improvement over any other kind used. The best of Jessop's tool steel is used in making the cutting dies and this gives the punch great durability.

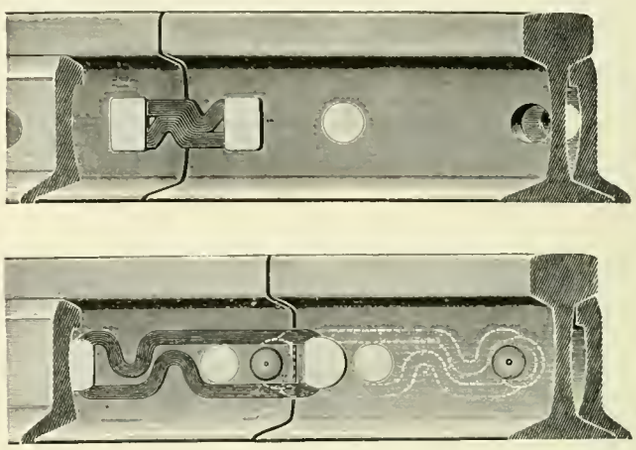


Air power cars began running regularly on the 23d St. cross-town line in New York on May 13th. The route is from North River to East River and the headway 16 minutes.

PROTECTED RAIL BONDS.

The Protected Rail Bond Co., located at 10 S. 10th St., Philadelphia, is the new company controlling the rail bond patents formerly owned by J. M. Atkinson & Co., and the Forest City Electric Co. The new company has just printed and is sending out its first catalog of the rail bonds and rail bonding tools. This catalog is a very handsome one and is perhaps the most complete ever issued on rail bonds. It contains 32 pages besides the cover which is embossed in gold and silver and has 30 illustrations. The company will be pleased to send one to any person interested in the subject.

The accompanying illustrations show types of the "Protected"



"PROTECTED" RAIL BONDS.

bond, which are so well known as to need no description. The company has excellent facilities for making its bonds and has made adequate provision for taking care of the business; the factory at Cleveland is working night and day, though the season has barely opened. Mayer & Englund, of Philadelphia, Pa., will have full charge of the company's business in the East and of the export trade. J. M. Atkinson & Co., of Chicago, will have full charge of all business in the West.

For the past year the company has been experimenting with hydraulic tools for bonding and punching; a number of orders have been placed for installation of "Protected" bonds with these tools and the company will shortly place complete outfits on the market.

NEW PENNSYLVANIA LINE.

Senator Gibson is the chief promoter of the Edinboro & Erie Electric Ry., the new trolley line between those two Pennsylvania towns, and he states the road is to be pushed rapidly through to completion. The financial arrangements have all been settled and no difficulty was experienced in disposing of the bonds. The company is capitalized at $500,000, but at the present time only $425,000 will be issued, the balance to be held in case improvements and extensions are needed to a greater extent than the earnings of the road will warrant.

The contract for 55,000 ties, 380,000,000 ft. of lumber and 200,000,000 ft. of planking has been let to R. B. Willis, of Erie. C. M. Stephens, the construction engineer, has already opened his office in Erie and has secured as his assistant W. H. Baxter, of that city. Senator Gibson says the law under which the charter was granted does not prohibit the carrying of express packages and baggage and in all probability this road will do that kind of business.

ANOTHER STREET RAILWAY BAND.

A brass band of 20 pieces has been organized by the employes of the Hartford (Conn.) Street Railway Co. Fred Phoenix, leader of the East Hartford band, and a member of the Colt's band, is directing the practice of the members of the new organization at every opportunity, in the Vernon street barns. The band is made up of conductors, motormen, car painters, electricians and utility men.

WORK ON THE A., B. & C.

The Akron, Bedford & Cleveland Electric Railway Co. has nearly completed the laying of 15 miles of double track between Akron and Bedford. The company has had a force of men at work since early in the spring. It is the intention to lay double track the entire length of the line, 23 miles, but the work on the remaining 10 miles will rest until next spring.

There are rumors to the effect that this company contemplates the purchase of the Canton and Massillon city railway, but President Everett of the A. B. & C., declares there is no foundation for the talk, so far as his company is concerned. Nor, according to President Everett, is there any plan on foot to build a connecting line between Akron and Massillon.

PROGRESS ON THIRD AVENUE, NEW YORK.

The main line of the Third Avenue Railroad Co., New York, is now nearly ready for the conduit cars and will be completed by the latter part of July. The electrical conductors have been placed in the conduit but are for the present set back so as to permit the temporary operation of the cable. The plan for making the change in operation is to shut down the line some Saturday night, withdraw the cable, and put a force of men at work to set out and adjust the electrical conductors. It is estimated that the necessary work can be done in 24 hours so that electric cars can be run the following Monday.

The old cable cars will be equipped with motors and used on the Third Avenue's cross-town lines. The new cars are to be 41 ft. over all, with 32-ft. body and will be mounted on double trucks.

MEETING OF OHIO STATE ASSOCIATION.

The annual meeting of the Ohio Street Railway Association was held at Springfield on June 14th, at the Lagonda Club. Among those present from out of town were: B. W. Peterson, Wheeling; C. Currie, Lima; H. C. Fogle, Canton; F. E. Grimm, Lancaster; C. E. Harrison, Steubenville; John Harris, Cincinnati; W. R. Morrison, Bay City, Mich; Reid Carpenter, Mansfield; C. R. King and A. L. Wilkinson, of the Ohio Brass Co.; Chas. Hodge, of the Westinghouse Co.; George A. Schroder, of the Multiplex Reflector Co., Cleveland; O. C. Evans, of the Johnson Co.; G. R. Scrugham, of the Creaghead Engineering Co.; C. S. Nolloth, of the Standard Electric Co.; and E. J. Wehrly, of Arbuckle Ryan Co., of Toledo.

The vistors were elegantly entertained by Gen. Mgr. S. L. Nelson, of the Springfield Railway Co., who placed a private car at the disposal of his guests.

All of the old officers were re-elected to serve during the coming year; no place for the next meeting was decided upon.

MR. H. C. BENAGH has tendered his resignation as superintendent of the Savannah (Ga.), Thunderbolt & Isle of Hope Ry. to take effect July 1st.

MR. SULLIVAN T. HOPKINS, superintendent of the Columbus (O.) Street Ry. was on June 7th married to Miss Mattie Lockett, daughter of Hon. John W. Lockett, of Henderson, Ky.

MR. FRANK WOODMAN, of Haverhill, Mass., has been appointed superintendent of the Merrimac Valley Division of the Massachusetts Electrical Companies which includes the roads at Nashua, Lawrence, Lowell and Haverhill.

MR. NELSON GRAHAM, assistant superintendent of the Montreal Street Ry., will shortly go to Glasgow to become superintendent of the Corporation Tramways.

MR. F. H. C. BOUTELLE, resident manager for an English railway syndicate in Buenos Ayres, was in Chicago recently inspecting car shops and electric railways.

JUDGE EGBERT JAMISON, who recently resigned as general counsel for the North and West Chicago Street Railroad Cos., has declined the presidency of the Chicago Union Traction Co.

FALK PLANT BURNED.

Just as we go to press we learn that the entire plant of the Falk Co., of Milwaukee, was destroyed by fire on the morning of June 13th; the loss included the office and all its contents were destroyed. The Falk Co. is building a new plant as noted on page 425 of this issue and while the fire at this time causes a very heavy loss indeed, the company will soon be in command of greater resources than before. Work on the new plant will be pushed as rapidly as possible and the company bespeaks the forbearance of customers until its completion.

MULTIPLEX REFLECTORS.

We illustrate herewith a new headlight that is now being placed on the market by the Multiplex Reflector Co., Cuyahoga Bldg., Cleveland, O. This reflector is claimed to be superior to any others on the market; they are corrugated and a single incandescent lamp makes a brilliant light. Fig. 1 shows a standard size headlight with

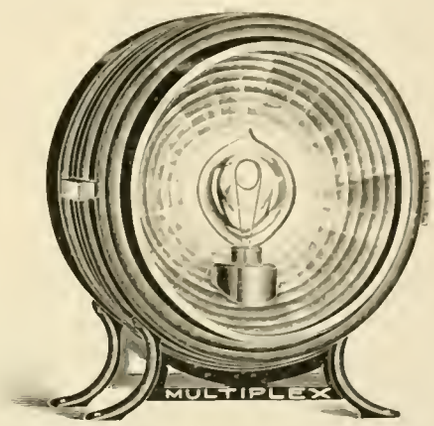


FIG. 1.

corrugated reflectors. The case is of polished steel with solid steel back which has four legs so that it can be fastened to the car hood very securely. The wires enter at the back of the bottom of the case and the connections are thoroughly insulated; the case itself is waterproof. It is reported that a 16-c. p. lamp throws a beam of

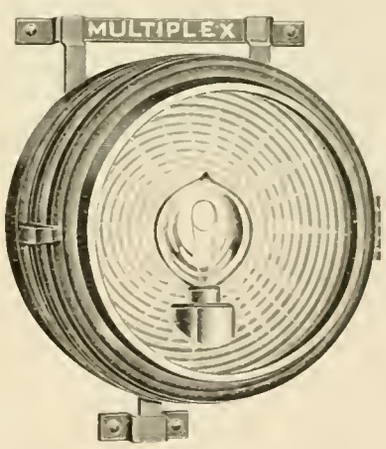

FIG. 2.

clear light 300 ft. Fig. 2 is the reflector as made for dash lamps; this lamp has direct connections.

These lamps are being adopted by both the Big and Little Consolidated roads of Cleveland, and by the Cleveland & Chagrin Falls road.

The International Register Co., Chicago, has just shipped 50 registers to the Twin City Rapid Transit Co., of Minneapolis, for immediate use.

The Marinette (Wis.) Electric Street Railway Co. proposes erecting a water toboggan at Lakeside. Manager H. C. Higgins thinks "shooting the chutes" will be a popular amusement.

HALF FARES.

The women of Sioux City, Ia., played street car conductors on May 13th and collected a neat sum for the benefit of Morning Side college.

The directors of the Brooklyn (N. Y.) Rapid Transit Co. held a meeting May 18th and passed resolutions on the death of Roswell P. Flower.

Burglars got into the safe of the Missouri Electric Railway Co. at Webb City on the night of May 4th and secured $605, the receipts for the day.

The North Jersey Street Railway Co., of Jersey City, has voluntarily increased the wages of its men. The advance ranges from 15 cents to 25 cents per day.

A company with a capital of $500,000 has been organized in Lima, O., for the purpose of building an electric railway from Toledo, O., to Dayton, a distance of 153 miles.

The Wisconsin Legislature adjourned without passing the bill to limit street railway fares; it passed an act, however, providing that street railways shall make reports to the state railroad commissioner.

The officials of the Atlanta (Ga.) Consolidated Street Railway Co. entertained visitors on May 16th. After a trolley ride there was a barbecue at the power house in the afternoon; about ninety guests were present.

An electric car containing 25 passengers was run into by a Northern Pacific train at Seattle, Wash., on May 20th. One man was killed and seven others were severely injured. The motorman saved his life by jumping into the bay.

The town board of West Seneca has granted the Hamburg Railway Co. a franchise to lay tracks and operate an electric road over the Ridge road and Hamburg turnpike, to connect with the Limestone Hill line, Erie County, N. Y.

An accident occurred on the River View branch of the Union Railway Co., of Baltimore, Md., on May 30th. A trolley slipped the wire and as the car stopped suddenly, a train following crashed into the rear end and injured several people.

Something like $70,000,000, which has been tied up pending the consolidation of the Baltimore, Md., street railways, is now released, the financial arrangements having been completed. The Consolidated company retains $21,000,000 in its treasury.

The Pittsburg, Pa., traction companies have invested very largely in new summer cars in anticipation of a heavy suburban traffic. It is stated that the total amount of money expended in improvements and for new cars will reach nearly half a million dollars.

The Alliance (O.) Street Ry. has been sold by order of court. Dudley B. Wick, of Cleveland, bought it for $15,334. The road consists of three miles of track running from the Union depot to a point near Mt. Union College. It is believed the line will be extended to connect with Canton.

It is announced that in all probability the Manhattan Elevated, of New York, will install inclined elevators at its stations when the change to electricity is completed. The Reno system, which is the only one in practical operation at this time, was illustrated and described in the "Review" for December, 1896, p. 750.

May 23d the breaking of a piston rod on a locomotive on the Brooklyn Elevated R. R. caused a blockade from 7 to 11 a. m. The rod broke just as the train was leaving a station, or the accident might have been more serious. The rod fell across the track and one car was derailed, one end being pushed off the structure, so that the truck fell into the street.

The Atlanta (Ga.) Consolidated Street Railway Co. has just issued a new transfer ticket which will cover about all the lines in the city. There is also a prospect that the line out to the barrack will be extended to College Park, a distance of about four miles.

The Nassau (N. Y.) Electric Railroad Co. has filed a report with the State Railroad Commissioners showing business for the quarter ending May 31st to have been: Gross earnings, $401,720; operating expenses, $390,101. Net earnings, $11,619. The same quarter of last year showed a deficit of $50,144.

The Market Street Railway Co. of San Francisco, Cal., went before the Board of Supervisors and declared its willingness to surrender its right in Geary St. if the Board would advertise for bids for its sale according to law. This surrender was offered for the purpose of securing new and more favorable franchises for a longer term. The Board referred the matter to a special committee.

It appears that the Indianapolis 3-cent fare litigation is not at an end, notwithstanding the new law and that the new company has made a contract with the city and purchased all the interest of the two old companies. One C. F. Smith has commenced suit for $5,000 damages because a tender of 3 cents was refused and he was ejected from the car.

The stockholders of the Brooklyn (N. Y.) Union Elevated Railroad Co. on May 3d elected the following directors: Frederic P. Olcott, Wm. Hours, jr., Frederick Uhlman, Wm. F. Sheehan, Nicholas F. Brady, Frederick S. Flower, John S. George, Ira A. Kipp, jr., John B. Taylor, John V. Clark, Henry Folger, Clinton Rossiter and T. S. Williams.

The Canton-Massilon Electric Railway Co. has increased the wages of its employes. Conductors and motormen who have been one full year in the service will receive $1.75 per day and 16½ cents an hour for extra time. Men who have been in the company's service for less than one year will receive $1.60 per day and 15 cents per hour for extra work.

The Eighth St. power house of the Cincinnati Street Railway Co. was recently damaged by fire to the extent of $5,000. A carriage factory across the way took fire and severely scorched the power house. The building was saved by the flood of water poured upon it by the firemen and the main damage was to the two dynamos and two engines from the effects of the drenching.

The order of the Postmaster General requiring street railways to paint out the letters "U. S. Mail" on their cars and provide portable signs to be displayed when the cars have mail on board, will be complied with by the Omaha Street Railway Co. so far as it relates to removing the permanent signs. Concerning the portable signs Gen. Mgr. W. A. Smith is reported to have said that his company is in the position of a man who is paying his own board and working for nothing, which he regards as an almighty independent position.

The Chattanooga (Tenn.) Rapid Transit Co. is pushing its lines to all the interesting points outside of the town. The Chickamauga Park extension is being rapidly constructed, and the line from the present terminus at Rossville will be extended to McFarland's Lake at once. The cut-off from Anderson Ave. to Orchard Knob has been entirely graded and some steel rail has been laid. The road to Orchard Knob will be in operation in a few days. A little later the road will be still farther extended from the Knob to Sherman Heights.

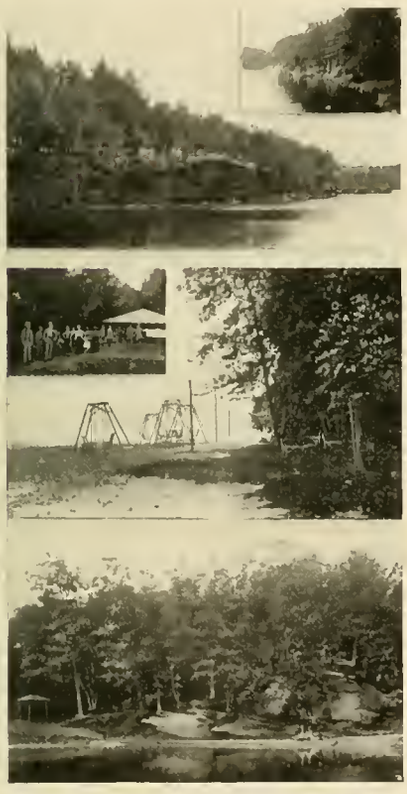
The U. S. Consular Reports advance sheet for June 3d states that the Wellington mines at Oyster Harbor, British Columbia, will be equipped for electric working, and the coal will be hauled from the mine to the depot by electric locomotives. The contract for this plant has already been let to a local firm. The electric tram line will be nearly five miles in length and operated by two 150 h. p. generators directly connected to automatic, high-speed, horizontal engines. This plant also includes two standard mining locomotives of 100 tons capacity.

Pleasure Resorts in 1899.

MIDDLETOWN, CONN.

The Lakeview Park, three and one half miles from Middletown, is easily reached by the South Main St. line of the Middletown Street Railway Co. This park comprises 20 acres, and is owned and controlled by the street car company. It has been fitted up as an attractive resort. The natural advantages are many. There is a large lake and on it the company has put steam launches, sailing yachts and a plentiful supply of small boats. A beautiful hardwood grove has been converted into a magnificent park and around it and through it are winding, shady walks encircling numerous grass plots, especially adapted for lunching and picnic parties. The natural beauties of the place are greatly enhanced by the presence of a deep ravine across which has been built a bridge 132 ft. long. The ravine is fully 50 ft. deep.

In one of the groves there has been constructed a large pavilion with a stage and seats for the accommodation of several hundred people. Entertainments of the high vaudeville class are given here



LAKE VIEW PARK, MIDDLETOWN, CONN.

daily. There is an excellent restaurant and all through the grounds are attractions of a varied order including shooting galleries, ball throwing, merry-go-rounds, and for the especial delight of the children a set of "flying horses" has been secured. There is always good music provided by the company. No intoxicating liquors are permitted on the grounds nor are teams or bicycles allowed inside. The latter can, however, be checked at the entrance.

Mr. E. W. Goss writes us as follows concerning the experience of his company last season:

"About May 15th last year we made up our minds to fix up a pleasure ground, and found this site about two miles from the end of one of our lines. We had to purchase land from some five or six different people, and build two miles of track, and put up such buildings as we wanted. At that time we had purchased no material such as rails, ties, etc., but succeeded in opening on the 1st of July, so that we got the best part of last year's business. We have located in the park an outdoor theatre, with a stage 30 x 50 ft., with dressing rooms on the sides. Fronting the stage is an incline on which we placed about 600 seats, which we sell at 5 and 10 cents. The theater and seats are in a hemlock grove, making it shady and comfortable there. There is a deep ravine running across the park which we found necessary to bridge. We also built a small restaurant building which we are enlarging this season. One section of our park runs along the side of a fair-sized lake, and there are several small groves running along side of it. We also have a large hardwood grove in another section of the grounds in which we placed tables and seats for picnic parties. I think the cuts show it up so that you can get a fair idea of the place. We run our main light wires from the station to a small building near the theater, and run out different lighting circuits from this house. In the house is a combined stereopticon and moving-picture machine. For lighting the grounds we did not think that taking lights from the regular railway feeder would be satisfactory, so we decided to run a No. 0 wire from the station direct to the park. This gives a very satisfactory service, and the lights are as steady as those in the city, although they are taken from the railway generator, using incandescent lamps in groups of five. Last season we ran shows on the stage from the week after we opened until the middle of September, and found that the better shows drew more patronage than when we happened to get an inferior one. We intend to commence booking earlier this season and expect to do more business than last season. We do not charge any admission to the park, but do not allow any bicycles

STREET RAILWAY PARK TERMINAL, MIDDLETOWN, CONN.

or teams to come on the grounds. Bicycles can be checked at the entrance, and owners of teams are provided with a place to hitch their horses outside. It would cost more to collect entrance fees than they would come to, as we are located some three miles from the center of the city. Charges of 10 cents and 5 cents are made for the seats fronting the stage; outside the railing people can look on if they wish. We have rented all the privileges this season to one party, giving him the privilege to sublet such as he does not care to run himself, and holding him responsible for everything in that line."

BIRMINGHAM, ALA.

In the "Review" for July, 1898, we published a number of views of East Lake Park, the attractive pleasure resort of the Birmingham (Ala.) Railway & Electric Co. This season colored electric incandescent lamps are to be placed in the trees for illumination at night. A large dancing pavilion is a feature of this park and music for dancing is provided every evening. This resort, like many others in the South is now under the control of the Southern Amusement Syndicate. This must not be construed to mean that the railway company has no right in the matter whatever. It purposes to see that nothing at all of an objectionable character will be permitted on the grounds, but so far as details are concerned, the syndicate has the management in its hands.

East Lake is a popular resort and the people are looking to the theatre there for that class of amusement. The Syndicate is in a position to furnish the best attractions and it has booked many first class shows for the season.

General Manager McClary of the Birmingham Railway & Electric Co. takes especial interest in this resort and is running special through trains for the benefit of his patrons.

PITTSBURG, PA.

Calhoun Park, on the Dravosburg division of the United Traction Co.'s line is a delightful resort of 51 acres. It is midway between Pittsburg and McKeesport in a bend in the Monongahela River and is about a 30-minute ride from each city. The ground is largely covered with forest trees and there are many fine springs. The park is lighted by electricity and a long distance telephone is at the service of pleasure seekers. A large pavilion has been built and furnished for dancing and dining purposes. There is a restaurant for serving meals and lunches at all hours, refreshments of all kinds

LAKE VIEW PARK, MIDDLETOWN, CONN.

to picnic parties and coffee and ice cream by the quart or gallon. In the kitchen, patrons of the park are furnished with fuel and cooking utensils free. A merry-go-round, roller coaster, bowling alleys, shooting gallery, race track and base ball fields afford athletic amusements. The booths and shelters of all kinds will accommodate 10,000 persons. Admission to the park is free and no concessions are let.

NEW ORLEANS, LA.

The New Orleans Traction Co. proposes to make its West End Park, on Lake Pontchartrain, the great resort, the Coney Island in fact, of the South. The company, under the management of C. D. Wyman, has already done much to make West End attractive, but the present season will effectually eclipse all its past glory. All the buildings, pavilions and band stands have been freshly painted and the park has been opened with the most flattering evidences of success. The best of music has been provided, the vaudeville shows will be exceptionally good; there are moving pictures, chutes and besides the botanical gardens, which have been added to extensively since last season, there is a perfect working scenic railway, such as they have at Coney Island, Boston, Philadelphia and Chicago.

General Manager Wyman has provided some magnificent electrical displays, which will be novelties to the Southern people and will be a delight to all visitors. But the scenic railway is the grand feature of all. This contrivance beats all the roller-coasters in the world. The capacity of the car is for eight persons. The highest point of rise is 80 ft., but at that elevation, in the evening, a magnificent scene is offered the passengers in the view of the thousands of electric lights scattered all over West End.

And the side of this resort is no small part of the pleasure to be obtained. They are handsome and comfortable and safe. In anticipation of very large patronage the rolling stock has been increased so that no one need fear crowding or delay in either going or returning home. Everything has been done to make West End a delightful spot, and the public which goes there and finds enjoyment can thank the New Orleans Traction Co. for the pleasure.

KNOXVILLE, TENN.

The Knoxville Traction Co. has greatly improved its park, known as Chilowie Park, for the present season. It has naturally a number of attractive features, among which may be numbered a lake covering five acres, half a dozen flowing springs and a prominent hill, Chestnut Hill, from which a good panoramic view of the city and surrounding country may be obtained. Last year this resort proved to be very popular.

A pavilion is located on Chestnut Hill and comprises a large dancing floor, a dining room and a well equipped kitchen. This building, together with four acres of ground, is fenced off from the rest of the park and is frequently rented for private parties; when not so rented it is open to the public and an orchestra furnishes music every afternoon and evening.

A theater with seating capacity for 1,500 has been recently completed; 800 of these seats are reserved, and a charge of 10 cents made for them. Among the other attractions are a Griffith gravity railway, an electrically operated merry-go-round, a large bowling alley, billiard and pool rooms, a shooting gallery, a cycle skating track and over 200 swings.

Water for the pavilion is pumped from the springs by windmills.

The park and all its buildings are brilliantly illuminated with arc and incandescent lamps.

SANS SOUCI PARK, CHICAGO.

Sans Souci Park, which was illustrated and described in our issue for March, last, was opened for the season on May 27th, and the patronage which it has drawn since that date corroborates the belief under which the park was built, that the South Side would appreciate a high-class pleasure resort fully as much as the other divisions of the city. Early in the evening of the opening the weather was very threatening and later it rained heavily; notwithstanding these unfavorable conditions there were over 18,000 people present and the management was obliged to close the gates at 8:35 p. m.

This park is a private enterprise under the management of Mr. W. H. Carter, but, to use the language of one of our Texas friends in a paper on summer resorts, the bag of gold has been so hung that the Chicago City Ry. will carry nearly all the people who wish to chase it.

The grounds and buildings are most brilliantly lighted; music by an excellent band, a temple of palmistry, booths of various kinds, vaudeville performances in the pavilion theater and the largest electric fountain ever built are among the attractions.

The accompanying engraving gives a view of the park from a point in the northwest corner. The building in the foreground at the right of the picture is the Japanese tea house, that at the left is the power house for the fountain, while directly in the center is the electric fountain. Immediately to the left of the tea house in the engraving is the theater and restaurant pavilion and in the background are seen the various smaller pavilions and booths visible from this point. The fountain has a capacity of 160,000 gallons of water per hour and the lamps have an aggregate candle power of 19,000; this is 50 per cent more water and 100 per cent more light than the rating of the fountain in Willow Grove Park, Philadelphia, which is the next in size to the Sans Souci fountain.

The fountain was designed by C. E. Moore, master mechanic, and C. J. Reilly, superintendent of motive power, of the Chicago City Ry., and they have substituted hydraulic and electrical control-

ling devices wherever practicable so that one man operates the pumps and controls both the water and light effects.

In the northeast corner of the park, near the bicycle sheds, is a large switchback merry-go-round, built by the American Merry-Go-Round & Novelty Co., of Lockport, N. Y.; it was designed by Mr. Wm. R. Inshaw, who has built two others of this type, one in Schenley Park, Pittsburg, and one at New Bedford, Mass.

Mr. Sturtevant is giving the theater much attention. Two performances are given each day, afternoon and evening. Some excellent attractions are engaged, and he intends, during the summer, to give all the popular comic operas, beginning June 25. A change of bill is made every week. Sans Souci Park affords every variety of amusement. Every taste and disposition can be suited, but it is safe to say that in the evening the electric fountain receives the most attention.

Last week the program was as follows: Band concert beginning at 1:30 p. m.; fountain at 3:00; vaudeville at 3:30; trained horses at 5:00; conclusion of band concert. In the evenings are the concert and theater performance and two exhibitions of the fountain, at 8:40 and 10:40.

SANS SOUCI PARK, CHICAGO.

THE NEW YORK FRANCHISE TAX.

The New York franchise tax law published in the "Review" for May, 1899, page 333, was amended at the special session of the Legislature called for that purpose last month. The changes made were substantially as follows: Authority to assess franchises is given to the State Board of Tax Commissioners, thus taking it out of the hands of the local assessors; but the State Board reports its valuations to the local boards, and the taxes are collected by each city or town for itself. The State Board, in making up the valuation is to include both the tangible property and the franchise connected with it, so that in the case, for instance, of a street railroad, local assessors will have nothing to say concerning the valuation either of the track or of the right to use it. The State Board is to give hearings at Albany after making a valuation, but before finally reporting it to the local assessors. An assessment may be reviewed by the courts. From the franchise tax as based on the valuation made by the State Board are to be deducted any and all taxes paid by the corporation to the city or town in the preceding year, such as license fees, gross earnings, taxes, etc., but not including money paid for paving or repairing streets. No deduction or credit shall be given for a greater sum than the amount of the special franchise tax. Other taxes are not to be affected by the new tax, and the tangible property shall not be taxable except on the assessment based on the State Board's valuation.

The new law goes into effect October 1st next. It is quite generally assumed that in administering this law the assessors will be guided by the market value of the stocks and bonds of a corporation.

There is a wide difference in the opinions expressed as to how the street railway properties will be affected by the new law. The estimates as to the amount of the tax vary in amount from $14,000,000 for the whole state to $25,000,000 for New York City alone; the estimate of the state comptroller's office is $27,000,000 for the state. The assessment is real estate.

There can be no doubt that the law will bear very hard on the small street railway companies throughout the state. In an argument before Governor Roosevelt on May 11th, Mr. G. Tracy Rogers, president of the New York Street Railway Association, presented the following data on this point:

"One hundred and three street surface railroads submit annual reports to the state, 49 of which show a surplus amounting to $1,102,855, and 54 show a deficit amounting to $471,878. Of the $1,102,855 surplus, $805,288 is shown by 12 companies in Greater New York, leaving but $297,567 to be divided among the 37 companies outside of that city. Of the 103 companies reporting, but 18 declared dividends (five of these being in Greater New York), the total dividends amounting to $3,069,465, of which the five Greater New York roads paid $2,512,374, leaving a balance of only $557,091 to be divided among the remaining 13 dividend-paying roads. Six of the dividend-paying roads showed a deficit after so doing. Eight of the 103 street surface railroads mentioned have gone into the hands of receivers during the past four years. In addition to these, at least 12 or 15 companies have gone out of business entirely or saved themselves from going into receivers' hands by making some arrangements with the bondholders. Briefly, the above report shows that the small and medium sized roads in New York state, and in fact all the roads with the exception of those in the very largest cities are struggling along under the most discouraging conditions, and cannot stand any additional burdens of taxation."

The larger companies in the state will probably be less affected.

When the law goes into effect its constitutionality will be tested, and a hard fight will doubtless be made against it. Mr. John Sabine Smith, an eminent corporation lawyer of New York, says concerning the law:

"The power to tax may be used as an indirect means of levying a burden not contemplated by the originators of the enterprise, and one which will strangle the operation of the work. This undoubtedly is not true of rich corporations, as a general rule, but all corporations must be placed on the same basis of fundamental principle of taxation, namely, that it shall be equal."

PERSONAL.

MR. J. MARSHALL ATKINSON will be married to Miss Elizabeth Amolia Weiland, daughter of Mrs. Annie Marie Weiland, of Lynchburg, Va., on Wednesday, June 21st. We join the many friends of Mr. Atkinson in the electrical and street railway world in extending congratulations.

MR. CLARENCE P. KING, president of the Schuylkill Electric Co., Philadelphia, and Mr. Duncan, his superintendent, were callers at our office when in Chicago last month.

MR. ALFRED OSKAMP, representing the Kisinger-Ison Co., of Cincinnati, called on the "Review" when in this city recently.

MR. ALBERT STANLEY, lately assistant superintendent of the Citizens' road at Detroit, has been appointed superintendent to succeed Mr. John Grant.

MR. JOHN A. WILSON, who was formerly with the Trenton Light & Power Co., was, in March last, appointed chief engineer of the Traction Passenger Railway Co.

MESSRS. HENRY M. WILLIAMS AND FRANZ BURGER, of the Ft. Wayne (Ind.) Consolidated Railway Co., called on the "Review" when in Chicago recently.

MR. JOHN GRANT, superintendent of the Detroit Citizens' road, has resigned that position to become assistant general manager of the Indianapolis (Ind.) Street Ry.

MR. WILL J. BROWNE, of Dubuque, Ia., has made an arrangement with the General Electric Co. and assumed control of the Dubuque Light & Traction Co., which has been in the hands of a receiver.

MR. CONWAY F. HOLMES, superintendent of the Metropolitan Street Railway Co., Kansas City, has been very ill for some weeks with congestion of the brain. At last account he was improving.

GEN. W. A. BANCROFT, general manager of the Boston Elevated Railway Co., last month declined an offer of the position of general manager of the new Chicago company, which is to take over the Yerkes lines.

MR. J. C. ROTHERY, superintendent of the Niagara Falls Park & River Ry., has been appointed superintendent of the upper steel arch bridge. The International Traction Co. now owns and controls both the railway and the bridge.

MR. G. F. GREENWOOD, consulting engineer, will go to Cuba this fall to reconstruct the street railways in Havana. Mr. Greenwood has, until recently, been the general manager of the Consolidated Traction Co., of Pittsburg.

MR. J. A. VANDERGRIFT, of Philadelphia, consulting engineer of the Chattanooga (Tenn.) Rapid Transit R. R., is at Chattanooga looking after the improvements now under way. He will remain there until all the work is completed.

MR. SAMUEL INSULL, president of the Chicago Edison Co., was on May 23d married to Miss Margaret Anna Bird, at the residence of the bride's mother, in New York. Miss Bird was better known to the public by her stage name of Gladys Wallis.

MAJ. E. C. LEWIS, at a meeting of the board of directors of the Nashville Street Railway Co., held May 18th, was elected vice-president to succeed Mr. J. C. Bradford, who had resigned. Mr. Bradford will still represent the company as general counsel.

MR. G. J. SMITH who for several years has most acceptably filled the position of master mechanic of the South Covington & Cincinnati Street Railway Co., has accepted a similar office with the St. Louis & Suburban, of St. Louis, and entered upon his new work.

MR. SIDNEY H. SHORT, it is reported, has gone to England to stay. He has accepted the position of consulting engineer with a new concern to be started by Dick, Kerr & Co., at Preston, for the manufacture of electric railway motors, generators and controllers.

MR. C. F. MOORE, who was treasurer of the Interstate Telephone Co., of Cleveland, O., has recently been chosen secretary of the Akron Traction & Electric Co., and has removed to Akron. This company is to be consolidated with the Akron, Bedford & Cleveland, in July.

MR. F. E. WOODWARD, formerly engineer of the Suburban Light & Power Co., Boston, in April last, was appointed chief engineer of the power station of the New Brunswick Traction Co., at Milltown, N. J. Mr. E. G. Grant, formerly with the Block Plant Electric Light Co., is his first assistant.

MR. JULIUS A. LEMCKE, who was a short time ago elected a director and treasurer of the Indianapolis Street Railway Co., has been obliged, on account of the pressure of private business, to resign. He was then made first vice-president, and the offices of secretary and treasurer were consolidated. This change puts Secretary W. F. Mulholland in both positions.

MR. MATTHEW T. CRONIN, who has for several years been chief train dispatcher of the Kings County Elevated R. R., of Brooklyn, N. Y., recently resigned to engage in business for himself at Bayonne, N. J. As an evidence of the regard in which he is held by his late associates, Mr. Cronin was, on the evening of May 13th, presented with a handsome gold watch and chain, the employes of all departments participating. Supt. E. W. Hartough, in a few well chosen words, made the presentation.

COL. THOMAS M. JENKINS has resigned from the superintendency of the South Covington & Cincinnati Street Railway Co., and accepted a position with a St. Louis company. To show the appreciation in which he is held by his late employes, Col. Jenkins was tendered a banquet and presented with a handsome solid silver service set on the evening of May 12th. The happy event took place in Elk's Hall in Covington. The First Regiment band was secured and at the head of 500 of the employes marched to Col. Jenkins' house, where he joined the parade. A visit was then paid to Pres. James C. Ernst and to the treasurer, Geo. M. Abbott, both of them being serenaded. The hall was packed, and everybody enjoyed the feast which had been prepared. President Ernst made a witty speech and George Taft, one of the conductors, in a most graceful and happy manner, presented the silver set. Col. Jenkins made a feeling response.

OBITUARY.

MR. ALBERT PACK, the well known Detroit, Mich., capitalist, died on Monday, May 29th, from the effects of a surgical operation. He was 57 years of age and had been one of Michigan's most active and enterprising business men and politicians, being largely responsible for the election of Pingree for governor in 1896. Together with Henry Everett, of Cleveland, Mr. Pack built street railroads on about 50 miles of Detroit streets not occupied by Johnson's lines and established a three-cent fare. The lines were later consolidated with Johnson's lines.

PENNSYLVANIA CAR WHEEL CO.

The Pennsylvania Car Wheel Co. desires most emphatically to deny the rumor that it has sold out to other parties. The impression was evidently founded on the fact that its rapid and very large increase in business has made it necessary to increase the capital stock from $100,000 to $200,000 and to take in additional properties; but the management has not had, and does not now entertain any idea of disposing of the business or plant. The success of this concern has been highly satisfactory to all connected with it.

NIGHT PHOTOGRAPH BY ARC HEADLIGHT.

We are indebted to Mr. H. P. Wellman, superintendent of the Ashland & Cattletsburg (Ky.) Street Railway Co., for a photograph which graphically illustrates the power of the electric headlight, which is his own invention. A description appeared in the "Review" for April, page 276.

The photograph was taken on a dark night at a point midway on the line. The arc headlight had a 14-in. reflector, ½ in. "Electra" carbons, and current used was a little less than 6½ amperes. The time of exposure was five minutes.

While much detail of the picture has necessarily been lost in reproduction in engraving, the photograph from which the cut is made is sufficiently clear to enable the reading of signs pasted upon the first pole and to count the poles for a distance of fully 1,500 ft

NIGHT PHOTOGRAPH BY LIGHT OF WELLMAN ARC HEADLIGHT.

NEW PLANT OF FALK CO.

The Falk Co., of Milwaukee, is at present a very busy concern. The contracts for work have come in so rapidly of late that the increase in the size of the plant has become an absolute necessity. The company has purchased eight acres of ground close to the present shops and will there erect new buildings. A machine shop, 100 x 200 ft. in size will be built, and a foundry, equipped for casting steel, occupying the same amount of space, will be put up. There will be a power house 60 x 140 ft. and an office building 40 x 60 ft. The entire plant will have electric motors for driving the machinery. It is expected that even this large increase in space may, before long, prove insufficient and all the buildings are to be erected with a view to possible longitudinal expansion. The shipping facilities will also be made as perfect as possible. The Chicago, Milwaukee & St. Paul will run a spur directly to the plant and immense cranes are to be erected to transfer heavy work from foundry and machine shop to any place desired.

Besides the enormous business the Falk Co. is of itself acquiring, it has recently absorbed the Cloos Electrical Engineering Co., of Milwaukee. This company made devices for controlling high voltages, particularly oil switches in which an imported, acidless oil is used. These switches have made it possible to do away with arcing between high voltage terminals and take away a large percentage of the ordinary danger to the operator. The absorbing of this plant will greatly increase the importance and the output of the Falk Co.

Regarding the work under way and the contracts lately made there may be mentioned one for the change of a five mile cable line of the Metropolitan Street Ry., of Kansas City, Mo., to the electrical system. The company has also a contract for the complete construction of a 14-mile road between Oskosh and Neenah, Wis. In the gear departments the orders are extensive and there is much activity in cast welding. A contract has just been closed with the Chicago Union Traction Co., for three complete cast welding equipments and for a license to weld joints under the Falk patents. The same equipments have lately been furnished the Boston Elevated Railway Co., and a full equipment of welding machinery, described in our last issue, has been shipped to Buenos Ayres for the account of Kincaid Waller & Manville, the London tramway engineers.

STREET CAR BUILDERS' COMBINATION FAILS.

The plan to consolidate the leading street car building interests of the country which at one time had every indication of going through has fallen down. Whether another attempt will be made is at present uncertain but the probabilities are strongly unfavorable. The principal hitch in the program seems to have been the fact that while the various interests were willing to go into the deal, practically none of them was willing to do so on the usual combination basis, of a portion cash and the large part stock. The car builders all wanted all cash.

The scheme was to incorporate in New Jersey for $18,000,000 divided into $8,000,000, 7 per cent cumulative stock and $10,000,000 common. Economy of administration was figured to increase net earnings by reducing expenses in the sum of $1,250,000 per year.

The concerns contemplated in the plan were the Laconia Car Co., of Laconia, N. H.; the Watson Car Co., of Springfield, Mass.; the Newburyport Car Co., the Briggs Carriage Co., of Amesbury, and the J. M. Jones Co., of Troy, N. Y. These were regarded as the Eastern group, and options were secured upon all but one. Elsewhere were the American, St. Louis and Laclede Car Cos., of St. Louis; the J. G. Brill Co., of Philadelphia; the Jackson & Sharp Co., of Wilmington, Del. Barney & Smith Car Co., of Dayton, O., the street car department of the Pullman Car Co., the Stephenson Co., of Elizabethport, N. J., and the J. G. Kuhlman Car Co., of Cleveland, O.

Besides these there were the Peckham Motor Truck & Wheel Co., of Kingston, N. Y.; the McGuire Manufacturing Co., of Chicago, and the truck works of J. G. Brill, of Philadelphia. In some cases, where the making of street cars was only a part of the manufacturing business carried on, as with the Pullman and the Jackson & Sharp Cos., the consolidation would have meant only an agreement to make no more electric cars, for the physical work of manufacture would have been generally consolidated into large plants.

The Fond du Lac (Wis.) Street Ry. will be completed and in operation by July 1st.

FIRST FRANCHISE TAX IN MISSOURI.

On June 7th the first assessment of a street railway franchise tax was made by the State Board of Equalization under the new act recently passed. The road selected was the St. Louis & Suburban Railway, of St. Louis.

Before assessing the board listened to arguments from the officers and attorneys of the railway company, who protested against the assessment as unjust and unfair. Evidence was also offered as to the value of the property of the company, the market and par value of the stock and bonds, and statements as to the gross and net earnings of the road.

One member of the board offered the following resolution, which was voted down:

"The board, having under consideration the assessment and valuation of the property of the St. Louis & Suburban Railway Co., after being fully advised of all and singular the matters and things relating to the character, extent and value of the property owned, used or leased by said railway company on June 1, 1898, finds that the total value of all the property of said railway company, measured by the market value of its stocks and bonds on the date aforesaid, is $3,587,000. It is, therefore, ordered by the board that the whole property of said railway company, as aforesaid, be assessed and valued for taxes of 1899 at $1,783,500, of which $543,010 is to represent the assessable value of the tangible property and the remainder, $1,250,490, to represent the assessable franchise value of said railway company, which is by the board distributed and assessed against the several classes of property owned by said company, as follows:

29.16 miles track and trolley wire	$291,600
86 motor and passenger cars	72,240
13 other cars	2,080
2 sweepers	200
Lands, buildings and machinery	176,890
Franchise	1,250,490
Total	$1,793,500

The resolution which did pass by a vote of three to two was offered by Mr. Crow, and reads:

"The State Board of Equalization, having given the St. Louis & Suburban Railway Co. opportunity to be heard personally by the board, and having heard the said St. Louis & Suburban Railway Co., through its officers, agents and counsel, and having carefully considered the facts set out in the return, schedule and supplementary statements of the said company, all evidence of value and all matters bearing upon the question of the value of the property of the company, and considering the cost of construction and equipment of said railway line and the location thereof, and its traffic and the market and par value of the stocks and bonds, and the gross receipts and net earnings, and the franchise owned by said street railway and the value thereof on June 1, 1899, on motion, the State Board of Equalization assesses and values for taxes of 1899 the property of the said company as follows:

29.16 miles of track and trolley wires	$291,600
86 motor and passenger cars	72,240
13 all other cars	2,080
2 sweepers	200
Lands, buildings and machinery	176,890
All other property	1,250,490
Total	$1,793,500

The "all other property" represents the assessment against the franchise, but the wording was chosen as placing the case in more desirable condition to take into court, as the railway company will lose no time in taking an appeal, and the board is anxious for a decision before making any further assessments of street railways.

The company will go to the highest court in the state and expects to be able to reach the United States Supreme Court, if necessary, on a question of constitutionality. What the courts will decide is altogether an unknown quantity.

Attorneys of high standing having no connection with either side seem to be about equally divided in their opinions, some declaring it will hold while others are equally certain the law has not a peg to hang on.

One thing is sure, if the assessment stands the taxes of the Suburban will be raised from $11,000 in 1898 to $36,000 in 1899, and as the road has never been a dividend payer it will mean a practical confiscation of the property. The same result would follow in the case of many other roads in the state. A few of the best paying properties might be able to stagger under their burden, but the weaker ones certainly could not earn enough money to keep out of the hands of the sheriff. What the lawmakers expect to gain by thus throttling improvements and better service is impossible to comprehend.

VIRGINIA ASSOCIATION.

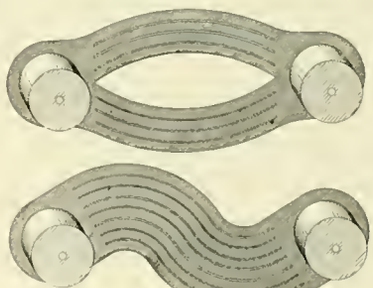
The first annual meeting of the Street Railway and Electrical Association, of Virginia, was held at the Hotel Jefferson, Richmond, on May 16th. The following representatives of the various companies forming the association were present: R. D. Appersen, Staunton Street Car Co.; Howard P. Page, Norfolk & Ocean View Railway Co.; Wm. Rexborough, Norfolk Railway Co.; J. R Curtis, General Electric Co.; C. W. Uthoff, Columbia Incandescent Lamp Co.; Julian Binford, Jr., Tower-Binford Electric & Manufacturing Co.; E. R. Williams, Richmond Traction Co.; R. A. Byrns, Ohio Brass Co., New York; William Todd, Virginia Electrical Railway & Developing Co., Richmond; E. W. Trafford, Richmond Railway & Electric Co.; C. T. Phillips, City Street Car Co., Staunton; R. D. McClure, City Street Car Co., Staunton; J. A. Cooke, Richmond Traction Co.; W. P. Woodson, Lynchburg & Rivermont Street Railway Co.; T. P. Cowardin, Richmond Traction Co.; R. L. Williams, Norfolk Street Railroad Co.

The following papers were read: "Track Bonding," by R. D. Apperson; "How to Increase Revenue of Electric Light Stations," by W. P. Woodson; "Park Amusements," by E. R. Williams; "The Use of the Wattmeter on Electric Cars to Check the Unnecessary Use of Current," by J. R. Curtis.

The association were the guests of the Richmond Traction Co. at a dinner given at the Jefferson Hotel.

MORRIS ONE-PIECE RAIL BOND.

Elmer P. Morris, 15 Cortlandt St., New York City, has placed on the market a new rail bond for which are claimed the advantages of larger contact surface and higher electric conductivity. This bond is made of either flat stripes or round wire and may be placed under the fish plate or around. The bond is also made to attach to the heel of the rail, and, in fact, can be substituted for any other make of bond now in use.



The terminals are made very large to insure a large contact surface between the bond and the rail, and the separation of the connecting portion into comparatively narrow strips or small wires gives the flexibility which is so necessary to a long life. The accompanying illustrations show two of the shapes into which the bond is usually bent.

The terminals are made solid and the ends are drop-forged to the exact sizes required. The bond has terminals from 5/8 in. to 1 in., and is made in sizes having the carrying capacity of from No. 0 to No. 0000, and of any length desired, when placed under the fish plate; it is larger than No. 0000 when placed around the fish plate or on the heel of the rail. Mr. Morris is ready to book orders for future delivery.

THE WHEELING STRIKE.

The employes of the Wheeling (W. Va.) Railway Co., who on April 8th struck for a 25 per cent increase in wages, have the sympathy of the public, and while the cars are all running on schedule time the traffic is very light. The sympathy is not manifested by obstructing the company's tracks since the fine and imprisonment of four men for this offense, but the public largely patronizes buses run by the strikers. There is no present indication of a settlement.

PORTABLE AIR COMPRESSING APPARATUS.

The Christensen Engineering Co., of Milwaukee, has recently placed on the market a very neat and compact air compressing plant, to be used wherever electric current is available, for such purposes as cleaning car cushions, operating pneumatic tools for clipping, caulking, riveting or drilling, and for general purposes. The apparatus herewith illustrated weighs about 1,400 lb. and is strictly portable and self-contained. The air compressor has a capacity of 50 cu. ft. of free air per minute, and is of the same pattern as the company is putting on the market for air brake purposes. It is prepared to furnish this style of portable apparatus in sizes ranging in capacity from 10 cu. ft. to 300 cu. ft. of free air per minute.

CHRISTENSEN PORTABLE COMPRESSOR.

The air compressor is self contained and all the working parts run in a bath of oil, the motor being arranged on the top of the compressor, and connected to the compressor crank shaft by means

WITH COVER REMOVED.

of a gear and pinion of a special pattern first introduced by the Christensen Engineering Co.; the teeth of the gear and pinion are sections of a true helix, which construction, it is claimed, makes their operation practically noiseless, and increases their durability fully 25 per cent over that of the ordinary straight faced spur gear and pinion.

The compressor delivers air into the reservoirs from which a hose connection carries the compressed air to the point where it is to do the work. The action of the compressor is controlled by means of an automatic governor, which operates by the air pressure accumulated in the reservoirs, in such a way that the motor stops whenever the pressure is at a maximum and stops when it is at minimum, with any desired variation between the two extremes.

The compressor is not provided with a water jacket, as experience has shown that in this form of construction, the compressor will run half the time without any undue heat. This makes the apparatus much more convenient than if it was necessary to have cooling water around the cylinders and the back heads, thereby introducing extra complications and need of care taking.

The box which encloses the motor compressor and also the electrical apparatus is water tight and it is so arranged that access is readily had to the various parts of the apparatus by simply opening doors arranged in the box for that purpose.

This apparatus is now being used in riveting the structural iron in course of erection on the new Post Office Building in Chicago.

On June 8th a foundry in Milwaukee, which made a large number of castings for the Christensen Engineering Co., was burned and many of the Christensen patterns were destroyed. The company has duplicates of all patterns, however, and this loss will not put it back in filling orders.

WILCOXON FOUND GUILTY.

In the United States Circuit Court at Springfield, Ill., on June 9th a jury returned a verdict of guilty in the case of C. N. Wilcoxon, for using the mails to defraud, and the court sentenced him to pay a fine of $500 and costs, amounting in all to about $1,200.

The swindle is as unique and interesting as it is unusual and reprehensible. Last June Mr. W. L. Ferguson, who was then manager of the lines at Decatur, Ill., received a proposition written on the letter head of the Richmond & Eaton Traction Co., Richmond, Ind., and signed by John M. Case, president of the company, to come to Richmond and take the management of the new road. The inducements were very liberal and by a strange accident the parties whom Mr. Ferguson wrote had in mind a project bearing a name very similar and which was being backed by responsible men. On the strength of the letters Mr. Ferguson resigned his position in Decatur and received his appointment as general manager of the Indiana road taking effect June 1, 1898. Just at this time C. N. Wilcoxon appeared in Decatur, applied for the position about to be vacated and was employed, which position he has since held.

Plausible letters from "John M. Case, President" accounting for delay in construction kept Mr. Ferguson in Decatur for several weeks. Whenever he tried to set a date to come to Richmond, a telegram from Detroit or some other point would state absence of Mr. Case on business and a request to postpone a few days or a week. In this way Mr. Ferguson was kept away for over a month, until one day he arrived in Richmond only to discover there was neither any Mr. Case, or railroad or position. The whole correspondence of two or three months was placed in the hands of the post office secret service, and in a short time the printer who printed the bogus letter heads was found in Muncie, where Wilcoxon had relatives, and who identified Wilcoxon as the party who had ordered and paid for them. Many other unmistakable proofs were discovered and in January a United States grand jury indicted Wilcoxon for using the mails to defraud. He was arrested and on January 6th was released on $1,500 bail, the bond being signed by Wm. L. Shellabarger, who was then secretary of the Decatur City Electric Ry., of which Wilcoxon was manager. The case came up for trial in February. Wilcoxon sprung a surprise by coming into court with a double, the two men being dressed exactly alike even to smallest detail of cuff buttons and necktie. Outside of Wilcoxon's own attorney few persons present could distinguish one from another. The case, however, did not get to trial, and was continued until June when the result was reached as above stated, after a trial lasting three days.

The United Traction & Electric Co., Providence, R. I., is being sued by David N. Smith of New York City for $500,000. Mr. Smith claims the company owes him this amount for failure to transfer stock.

ECHOES FROM THE TRADE

BOOTH & FLINN, of Pittsburg, Pa., have made contracts with the Consolidated Traction Co. of that city to the amount of from $600,000 to $700,000, for the reconstruction of its suburban rapid transit line.

THE GARTON-DANIELS ELECTRIC CO., of Keokuk, Ia., maker of the well-known Garton lightning arrester, advise us that it is busier now than at any previous times. The company's sales for May were equal to one-third of the total sales for 1898.

THE AMERICAN ELECTRICAL WORKS again takes advantage of Decoration Day to send to its many friends a delicate and extremely well executed steel engraving of General Grant. It belongs to the series which includes Washington and other great Americans.

THE PARTNERSHIP heretofore existing under the firm name of Wilson, Thomson & Co., Brooklyn, N. Y., manufacturers of the Wilson Patent Trolley-Pole Catcher, has been dissolved by mutual consent, Mr. Thomson retiring. The business will be continued under the name of Wilson & Co., and all obligations of the old firm have been assumed by Wilson & Co.

THE ELECTRICAL INSTALLATION CO., of Chicago, street railway contractor, believes in putting its advertisements in a permanent form and has sent to its friends handsome card cases of seal leather; the card of the company is in gilt letters on the inner side of one pocket and the name of the recipient also in gilt is on the other pocket. The editor is pleased to have received one.

THE UNIVERSITY OF TENNESSEE last year erected a new building for the department of mechanical engineering and mechanical arts. The need of such a building has been manifested for some time and the trustees decided to put up one fully adapted to the uses for which it was designed. It is named after Joseph Estabrook, in recognition of his valuable services as president from 1834 to 1850.

THE CLEVELAND FROG & CROSSING CO., Cleveland, O., has found expansion a necessary policy. The company's Eastern business has increased to such an extent that it has been deemed expedient to have permanent representation there. The firm of L. J. Buckery & Co., of 257 Broadway, N. Y., has therefore been appointed the Eastern agents and will henceforth control all the Eastern business.

THE JACKSON & SHARP CO., of Wilmington, Del., has just delivered to the Syracuse, Lakeside & Baldwinsville Railroad Co. a number of new double deck cars. The railroad company will put them in for summer use. They are quite a novelty in the vicinity of Syracuse and will without any doubt prove a great card for the company's summer suburban traffic. The cars will seat about seventy-five passengers.

THE G. P. MAGANN AIR BRAKE CO., of Detroit, has recently issued a pamphlet describing its storage air brake system which managers will read with interest. The advantages claimed for this system are: 1. Absence of complicated machinery on the car. 2. Constant air supply. 3. Positive and instantaneous release of brakes. 4. Noiseless operation. 5. No leakage. 6. Economy in use of air. 7. Economy in first cost of brakes.

THE PHILADELPHIA EXPOSITION management advises us that a special building for transportation exhibits is being constructed; it is 450 ft. long and has four tracks, giving a total length of trackage of about 800 ft. It has already received several applications for space in this structure, and is assured of a creditable exhibit of street railway cars and equipment of American manufacture, which are already exported in considerable numbers.

THE MICA INSULATOR CO., of New York City, is especially equipped for the manufacture of material used by the makers of electric vehicles. It is having great success with its "Micanite" insulation and is so certain of giving satisfaction that it offers to send free, for trial, a set of rings and segments for motors and samples of its "Micanite" and "Empire" insulating cloth and paper. The company has a branch office on Lake St., Chicago.

ADAM COOK'S SONS, 313 West St., New York, advise us that engineers who have used their "Original Albany Grease" report splendid results in lubrication with a saving in repairs impossible where mineral greases were formerly employed. Those in charge of fast running machinery recognize that the matter of expense for repairs is an important one and that a pure lubricant is essential to keep the machinery in order, and the "Albany" grease is continually growing in favor.

THE B. F. STURTEVANT CO., whose well-known "chimneyless" factory is situated at Jamaica Plain near Boston, is making an addition to its already large floor space for electrical work. Another story is being added to two of its shops, one 125 ft. by 50 ft. and the other 100 ft. square, both of which will be used for this purpose. The increase in this department has been enormous. The company is now making electric motors up to 125 h. p. and generators up to 100 kw.

THE NATIONAL SUPPLY CO., of New York, makes the claim that its "Standard Cold Water" paint for both interior and exterior use has features of excellence not to be found in any oil paint made. The three strongest talking points are that it resists fire and water and will not turn yellow with age. The company makes a great variety of colors adapted for use on cars, factories, bridges, warehouses, electric plants, barns, and in fact anywhere, indoors or out, that paint is used.

THE W. H. ELLIOTT ELECTRIC CO., of Cleveland, O., has been so favorably affected by the prosperous conditions of the country that it has found its present shops entirely inadequate to the increasing business. The company has moved into new quarters at 1076 Hamilton St., where it has double the room it had before and double the facilities for turning out its products. The company is a popular one and will need every facility the new and larger works afford, to supply the demands of its trade.

THE JEFFREY MANUFACTURING CO., of Columbus, O., maker of electric and compressed air coal mining machinery, has just issued its mining department catalog No. 16. The book is very complete and shows numerous illustrations of air drills, electric chain machines, self-propelling trucks, bits, electric motors, shearing machines, reels and cables, electric haulage machinery, and in fact every device to make the cutting out of coal possible and cheap. The catalog contains much valuable information and will be sent on application.

LEHIGH UNIVERSITY, Bethlehem, Pa., announces a summer course of study from July 5th to August 16th and applications should be made to "The Secretary of Lehigh University, South Bethlehem, Pa.," before July 1st. This summer school was organized in 1893 by the department of Civil Engineering. In 1898 was made a part of the regular program and in addition to the regular courses, ordinarily given to students of the University only, it has been decided to offer a number of courses in various departments which will be open to all applicants qualified to take them. The courses include electrical engineering.

THE CLAYTON AIR COMPRESSOR WORKS, of New York City, is just now sending out its catalog No. 10 which is one of the most complete books of the kind issued. It embodies the latest and highest types of air compressing machinery and contains illustrations and lists of sizes of standard patterns and descriptions of the Clayton type of compressor. The book will be found valuable for its data and tables relating to compressed air transmission, capacity lost by air compressors in operation of various altitudes, etc.

A. L. WHIPPLE has joined the ranks of the Chicago street railway supply men, and opened a pleasant office in the Chamber of Commerce Building, where he represents the Western interests of the E. T. Burrowes Co., of Portland, Me. He already enjoyed a wide acquaintance among the steam road people, and is rapidly getting to know the Western managers of street railways. He reports an excellent Western trade in the Burrowes car curtain, and that the factory is working up to full capacity. Mr. Whipple will make his home in Chicago.

THE UNIVERSITY OF WISCONSIN has issued a circular outlining courses of graduate study in electrical engineering to begin September 27th. The University of Wisconsin is essentially a college of mechanics and engineering. The laboratories are all well equipped for instruction and investigation and the most advanced students can find all their requirements fulfilled. There are separate laboratory equipments for the divisions of electromagnetism and dynamos, alternating currents and applied electro-chemistry. Catalogs and all information desired will be furnished upon application to the registrar, W. D. Hiestand, or to Prof. D. C. Jackson, Madison, Wis.

THE CHRISTENSEN ENGINEERING CO., of Milwaukee, Wis., will soon increase its facilities. The great popularity of the air brakes made by this company is responsible for this necessity. The orders are pouring in from all parts of the country and the shops are overrun with work. While it is true this air brake company is manufacturing brakes in large quantities for foreign car companies, the bulk of the orders is for this country. It is reported that there is hardly a street railway company of any size east or west which has not ordered brakes from this company, and the continued activity will oblige it to extend its plant in no small degree.

THE AMERICAN ELECTRICAL DIRECTORY AND BUYERS' MANUAL, published by the E. L. Powers Co., of New York, is out. This is a valuable work for all concerns having electric apparatus for sale, as it gives a complete list of all the electric lighting central stations in the United States, Canada and Mexico, and a great deal of information regarding the financial condition of the companies, the names of officials and the capacity of the stations. On the other hand, for the use of consumers there is a complete list of manufacturers and larger dealers in electrical supplies. The current issue is No. 1 of the seventh volume. It is published quarterly.

THE ELECTRICAL INSTALLATION CO., in the Monadnock Building, Chicago, puts forward its thirteen years' experience in the highest class of work as a guarantee for the future. The company is one of entire financial responsibility, thorough organization and equipment and is prepared to contract for the complete construction of electric railways and lighting plants. It names among its customers many of the best and most successful roads in the country, the range extending east and west, north and south. The company has recently taken the contract for completely rehabilitating the electric lighting system of Vicksburg, Miss. Work is to be started at once and completed within 90 days.

THE VAN DORN & DUTTON CO., of Cleveland, O., has decided to give special attention to its motor and armature department. The first move in this direction was the securing of the services of Mr. W. H. Elliott as manager. Mr. Elliott will unquestionably prove a valuable acquisition to the company. He has had more than 15 years' experience in connection with electrical matters and is fully and thoroughly qualified for the position he is filling. The Van Dorn & Dutton Co. is an extensive manufacturer of steel, malleable and cast iron gears and pinions and of rawhide combinations. It is also fully equipped for repairing armatures, generators, dynamos and motors and can promise quick delivery of all work put in its hands.

THE NEW PROCESS RAWHIDE CO., of Syracuse, N. Y., lately received a letter from Charles H. Mayer, treasurer of the York (Pa.) Street Railway Co., regarding a rawhide pinion which has been in use for 14 months. Mr. Mayer said the pinion had been in service on an average of 105 miles a day for all those months and that its wearing qualities had proved equal to any steel pinion he had ever seen. The teeth had been worn to a keen edge without a break and the gear had not been injured in the least. This pinion was one out of a lot and was simply a sample of all the rest. The New Process Rawhide Co. is in constant receipt of just such testimonials and they prove, as nothing else can, the excellence of the pinion the company makes.

THE FOREST CITY ELECTRIC CO., of Cleveland, O., is directly in line with all the large concerns of the country in feeling the boom in trade. It seems as if this company could not get room enough for its work. Not long ago the company moved into new shops, where it had about double the space of the old. It had just begun to feel comfortable in the new quarters when another boom came along, and, though the works are kept going night and day and a double force is employed, the demand still keeps ahead of the possible supply. The company was obliged to have more room, and it is now building an addition to the works which covers 30 x 120 ft. This addition will be finished in a few days, and then the company hopes to be able to catch up on orders and in the future meet every demand with promptness.

THE STEWART HARTSHORN CO., East Newark, N. J., manufacturer of the popular shade roller, publishes a humorous paper called "Hartshorn's Roller," which has reached Vol. XI., No. 4. It is a 16-page paper, well illustrated, and full of admirably selected jokes. One cannot help reading it through and enjoying it, and at the same time one cannot help seeing and being impressed with the excellent qualities of the Hartshorn roller. This shade roller has been on the market for years. Thousands of people have used it and are using it, but it is safe to say that but few out of the many have any conception of the number of excellent features it possesses. The publication will afford much interest to any reader and will give much information regarding a most valuable and necessary invention.

THE G. P. MAGANN AIR BRAKE CO., of Detroit, Mich., recently received a very strong testimonial from John Busby, superintendent of the Detroit & Pontiac Railway Co. Mr. Busby was emphatic in saying the Magann brake had proven superior to any he had ever used. The brake has been in use on this road for more than a year and the experience with it has led Mr. Busby to speak in the most flattering terms. He mentions a number of other air brakes he has tried, but says on one account alone, that no repairs have been required and no motors to keep in order, the Magann is by far the best of them all. The company has been operating 12 cars with this brake. They will make 400 stops without recharging and on two cars which lay over night at one end of the line there is only a loss of three or four pounds of air during the night.

THE CONSOLIDATED CAR FENDER CO., of Providence, R. I., is meeting with remarkable success with its fenders. The orders were never so large as during the past month. It is now supplying fenders to the Metropolitan Street Railway Co., New York; Omaha Street Railway Co., Omaha, Neb.; Ottawa Car Co., Ottawa, Ont.; Des Moines City Railway Co., Des Moines, Ia.; Paterson Railway Co., Paterson, N. J.; Troy City Railway Co., Troy, N. Y., and Union Depot Railroad Co., St. Louis, Mo. It has also shipped a large number of parts of equipments to City Electric Railway Co., Port Huron, Mich.; Hartford Street Railway Co., Hartford, Conn.; Staten Island Midland Railroad Co., Stapleton, N. Y.; Meriden Electric R. R., Meriden, Conn.; Fair Haven & Westville Railroad Co., New Haven, Conn.; Auburn City Railway Co., Auburn, N. Y.; North Hudson County County Railway Co., Hoboken, N. J.; North Jersey Street Railway Co., Jersey City, N. J.; Middletown-Goshen Traction Co., Middletown, N. Y., and Utica Belt Line Street Railway Co., Utica, N. Y.

THE FOSTER ENGINEERING CO., Newark, N. J., is advertising its Foster pressure regulator by distributing decks of playing cards, which ought to prove very useful during the summer season.

THE STREET RAILWAY DEPARTMENT of the Western Electrical Supply Co., of St. Louis, Mo., is still progressing rapidly and pushing to the front its street railway products, which have now a national reputation; this is due to pluck and push, backed by the excellent assortment of standard goods, and the reputation of the manufacturers whom it represents.

THE FILER & STOWELL CO., Milwaukee, reports that it is very busy. Within the past few days it has received a number of orders for engines, which include one simple engine 18 x 42 in. and one cross-compound 16 and 30 x 48 in., both direct connected, for the Woonsocket Street Ry., Attlesboro, R. I., two tandem compounds 18 and 36 x 48 in. for the Queen City Cotton Co., Burlington, Vt.; two cross-compounds, 28 and 56 x 60 in. and 18 and 36 x 48 in., for the Berkshire Cotton Manufacturing Co., Adams, Mass. The company has just shipped to the Chicago & Milwaukee Electric Ry. a center-crank corliss engine of 750 h. p.

GOULD & EBERHARDT, of Newark, N. J., designers and builders of machine tools, have just issued a booklet in which some pertinent questions are asked and some strong statements are made. All the latter the company is fully prepared to back up, and as for the former the contrasting illustrations make the most complete answers. The booklet is called "Like This," and the company asks if you had not better do "Like This," instead of "Like This." This particular booklet shows contrasts to prove that the Eberhardt sand sifter is the best on the market. The firm also deals in shapers, drill presses, cutters, grinders, lathes and hundreds of other machines and devices used in manufacturing plants.

THE H. W. JOHNS MANUFACTURING CO. had its new fuse on exhibition at the electrical exposition at the Madison Square Garden, New York City. This fuse is of the enclosed type and does not arc but indicates. It is known as the "Noarc" fuse and embodies features which cannot fail to secure the approval of all who use it. It is claimed to be sure, safe and accurate. The H. W. Johns Co. is very busy in all its lines but is particularly so in its electrical departments. The company has for some time past been employing a double force in the factory, working both night and day. It has orders ahead now for over 200 miles of overhead material, many of the orders being for export. The demand also for the "Vulcabeston" insulation, made by the concern, is constantly growing and is thoroughly liked by all manufacturers of electrical machinery.

THE EMERGENCY HOSE BRIDGE, made by the Ohio Brass Co., of Mansfield, O., was illustrated and described in the May issue of the "Review." This company has recently begun the exclusive manufacture of this device and is having great success with it, not only as regards sales but in the expressions of satisfaction received from all who have used it. The largest railway companies in the country have adopted this bridge. Among them may be mentioned the Syracuse (N. Y.) Rapid Transit Co., the Chicago City Street Railway Co., the Toledo (O.) Traction Co., the Nashville (Tenn.) Street Railway Co., the Knoxville (Tenn.) Traction Co. and the People's Railway Co., of Dayton, O.

This hose bridge is a thoroughly practical device and is reported to have never yet failed to meet any conditions or emergencies to which it has been applied.

THE WESTERN ELECTRIC CO. keeps the trade thoroughly posted on all the new devices and inventions it has ready for the market. The company has just distributed catalogs on the "Petite" arc lamp, a circular descriptive of the "Matchless" electric lighter, the "S. K. C." lightning arrester, the "S. K. C." single phase motors and type G transformers. The company has made a contract to furnish a Chicago building with one 40-k. w. Western Electric direct current generator and a switchboard for the same, and will install the apparatus and do the wiring for 500 16-c. p. lamps. It is also putting 10 motors in the Great Northern Hotel, Chicago, to operate the ventilating apparatus, laundry and other machinery. The United States Express Co. has a 30-k. w. Western Electric direct generator, to be used for running 400 16-c. p. incandescent lamps. These are but samples of the orders daily received by this company.

"WONDERLAND '99" is the title of a handsomely gotten up book published by the Northern Pacific Ry. It is a work of over a hundred pages, profusely illustrated and printed on the best of paper.

The book is written in an easy, entertaining style and affords graphic descriptions of what is indeed the "Wonderland" tributary to the railroad system which traverses it. The author takes his reader from what he very truthfully calls the "Lake Park Region" of Minnesota through Dakota, Montana and Washington, giving running descriptions and fine photographic views of the country. The route includes the canyons, the Yellowstone region and the Yellowstone National Park, the geysers, Mammoth Hot Springs, over Mount Ranier into Alaska and skirting Puget Sound and the Pacific Ocean leads the way into California, until the eye rests upon the snow capped peaks of Mt. Shasta.

Think of it! Mt. Shasta, Mt. Hood, Mt. Ranier, Mt. Adams—all on a trip to or from California by way of the Northern Pacific Ry.

THE B. F. STURTEVANT CO., of Boston, Mass., early recognized the demand for electrically driven fans, which was sure to follow the general distribution of electricity for power purposes. Its first fan motors were built about 10 years ago, since which time designs have been perfected, the number of types greatly increased, and a large electrical department established. Some of the recent products of this company in the way of special electric fans are presented to its Bulletins H. and M. The former relates to the enclosed fans, the latter to propeller ventilating wheels. The wonderful endurance of a well designed and thoroughly constructed fan blower is very emphatically evidenced by a recent statement of The William Kennedy & Sons, Ltd., Owen Sound, Can., to this effect: "We have two Sturtevant pressure blowers in use, one of which has run over 32 years steady, and often 24 hours per day, and is apparently as good as when installed, although no one has as yet seen the inside of it. The other has been used for foundry purposes, and has been in use for about 30 years or so."

THE WISCONSIN ENGINEER for May contains an interesting sketch of Prof. J. B. Johnson, the new dean of the College of Engineering, University of Wisconsin. This branch of the university has been growing constantly in importance, and a year ago it was deemed advisable to establish a deanship. Prof. Johnson was called to fill the chair, but does not take up his work at the university until next fall. In the meantime he is traveling in Europe making a study of the industrial systems of education in the old country.

The number contains many other interesting articles including one by Prof. Burgess, E. E., on "Electro Chemistry," and one by Prof. D. C. Jackson on "Electrolytic Corrosion of Water and Gas Pipes." Both of these authors are members of the university faculty.

Among other subjects discussed by various writers are the following: "Terrestrial Magnetism," "Photography of Sound Waves," "Photography in Colors," "Progress in the College of Mechanics and Engineering," "Outline of Trip made by Junior Civil Engineer."

GATES & RANDOLPH have taken the offices on the ground floor of the Monadnock Building, Chicago, formerly occupied by Sargent & Lundy; the suite is No. 13-15. They are handling the apparatus of the Triumph Electric Co., Cincinnati, for direct current work; of the Warren Electric Manufacturing Co., Sandusky, O., for alternating work; of the Empire Electrical Instrument Co., New York, for portable switchboard alternating and direct current instruments; of F. A. La Roche & Co., New York, for switchboards, circuit breakers and switches; of the Sterling Arc Lamp Co., New York, enclosed arc lamp for all circuits. It is the purpose of Gates & Randolph to operate a miniature electric lighting plant in their new warerooms, using a "Triumph" motor running a "Warren" alternator through a La Roche switchboard, with "Empire" instruments and transformers, etc., with arc and incandescent lamps and motors running through the same circuit. Gates & Randolph

are old timers in the electrical business and we predict for such a team a large volume of business. They will not only handle electrical apparatus, but they will undertake contracts for street railway and lighting plants. In addition to the companies mentioned the firm represents the Card Electric Co., of Mansfield, O., and the Sterling Arc Lamp Co., of New York.

THE E. P. ALLIS CO., of Milwaukee, finds it impossible to anywhere near keep up with the demand for heavy engines for electric railways. Orders are pouring in from both home and abroad. The company is now engaged on a very large contract for the Metropolitan Street Railway Co., of New York, for 11 of the largest engines of the kind ever built in this country, if not in the world. These engines will each be of 4,500 h. p., having a maximum capacity of 7,000. The cylinders are 46 and 86 x 60 in. and the distance from the foundation to the top of cylinders is about 38 ft. 3 in. There is a hollow shaft with a diameter of 37 in. at center and an opening 16 in. in diameter extending the entire length. The journals are 34 x 60 in. Three of these engines have been delivered and one more is in transit.

The company is also building two engines for the Boston Elevated Railway Co. of the same type as the above. Also two of 2,500 h. p. each for the South Side Elevated Railway Co., Chicago, two of 2,250 h. p. each for the Metropolitan West Side Elevated Railway Co., Chicago, and one of 1,000 h. p. for the Northwestern Elevated Railway Co., Chicago. It is building two engines, 2,500 h. p. and 1,200 h. p. for the Metropolitan Street Railway Co., Kansas City, Mo.; one of 2,000 h. p. for the North Jersey Street Railway Co., Jersey City, N. J., four engines, two 1,600 h. p. and two of 1,000 h. p. for the Milwaukee Electric Railway & Light Co.; one of 1,600 h. p. for the Toledo (O.) Traction Co.; one of 1,300 h. p. for the Consolidated Street Railway Co., Grand Rapids, Mich.; one of 1,300 h. p. for the New Orleans & Carrolton Railway Co., and three 1,000 h. p. engines for service in Richmond, Va. Besides these the company is at work on four 1,000 h. p. engines for Bristol, four of the same capacity for the London Tramways Co. and three 1,600 h. p. for the London Electric Lighting Co., all of England. There is also a great amount of smaller work goin on, both for this and foreign countries, all of which is causing the company to run full capacity and full time.

ROUTE TO THE CONVENTION.

The Boston & Albany R. R. is perfecting arrangements to take the Boston delegates and visitors to the annual street car convention to be held in Chicago next fall, in the most comfortable manner. It will run special cars through to Chicago, connecting at Albany with a special train on the New York Central. The Boston & Albany is a splendidly equipped road and affords its patrons excellent service. Its cleanliness is a marked feature. By sprinkling its road bed thoroughly with oil the dust is kept down, and passengers can travel comfortably in the dryest weather.

CHEAP EXCURSIONS.

For the meeting of the National Education Association, at Los Angeles, Cal., July 11th to 14th, cheap excursion rates have been made and delegates and others interested should bear in mind that the best route to each convention city is via the Chicago, Milwaukee & St. Paul Ry. and its connections. Choice of routes is offered those going to the meetings on the Pacific Coast of going via Omaha or Kansas City and returning by St. Paul and Minneapolis. The Chicago, Milwaukee & St. Paul Ry. has the short line between Chicago and Omaha, and the best line between Chicago, St. Paul and Minneapolis, the route of the Pioneer Limited, the only perfect train in the world.

All coupon ticket agents sell tickets via the Chicago, Milwaukee & St. Paul Ry. For time tables and information as to rates and routes address Geo. H. Heafford, general passenger agent, Chicago, Ill.

FOREIGN FACTS.

The Poole & District Light Ry., of Poole, England, has been authorized.

Extensions to the electric tramways in Bristol, England, are about completed and cars will be running by July 1st.

The overhead system will be in use this month on the Giant's Causeway, Portrush & Bush Valley Railway & Tramway Co., Ireland.

The tramways at Darwen, England, have been purchased by a new company, and they are to be converted from steam to electric traction.

The London United Tramway Co. has received permission from the London County Council to reconstruct the tramways in Hammersmith with the overhead trolley system.

The taxpayers of Lowestoft, England, object to a proposed electric tramway being constructed on the Marine Parade, and the petitioners have asked for a change of route.

Newcastle, England, is anxious for an electric railway, and is only waiting for Parliament to pass the tramway bill. The telephone company has withdrawn its opposition.

The Plymouth, England, tramways committee has recommended the adoption of electric traction on the Hyde Park and Compton routes. The estimated cost is £18,000, but the committee believes it will pay.

An electric road has been built between the towns of Ashton and Denton, England. A trial trip was made on April 3d from Denton to Gee Cross and on May 28th the first electric car was run the full length of the line.

The doctors in Hastings, England, have declared that the introduction of electricity into the city will injure it as a health resort, and this has caused a committee in the House of Lords to throw out a bill for an electric road.

Plans are reported for an immense water power plant in Italy, and the electric energy generated is to be used for traction purposes on the Bergamo-Lecco, the Bergamo-Seregno, the Bergamo-Milan and the Bergamo-Breslio railways.

The British Electric Traction Co., of Pontypridd, Wales, is applying to the Light Railway Commissioners for the privilege to extend its present tramway from Porth, from the terminus at Pontypridd, in the direction of Cilfynydd.

The Eastern Telegraph Co., of Cape Town, has brought a damage suit against the Cape Town Tramway Co. for £50,000. It is claimed that the leakage from the tramway company's electric wires interfere with the telegraph company's cable system.

The New General Traction Co. has been organized in England to build electric roads and lighting plants. The company is in an extremely prosperous condition financially and is now engaged in the construction of three tramways, Douglas Tramway on the Isle of Man, and one each in Coventry and Norwich.

H. Collbran, an American contractor for the Seoul-Chemulpo Ry., is just completing the construction of an overhead-trolley electric street railroad of some six miles in length in Seoul, for a Korean company. The materials for this road are from America and Japan, the car bodies having been neatly constructed by the Japanese.

Mr. F. Armstrong, British consul at Milan, Italy, is urging British manufacturers of electric appliances to keep their eyes on Italy as a field for trade. He speaks of the great exposition of electricity in all its applications now in progress at Como, and says the government is at present contemplating the construction of large water power plants for generating electricity, to be utilized for traction purposes. The railways in Italy are nearly all state property. The Mediterranean, one of the biggest companies, has experimented very successfully with electricity on its line between Milan and Monza. The Edison Co. supplies a current at 3,600 volts, which is transformed to 500 volts at the Milan station. For 60 k. w. the railway company pays £9.20 a year.

NEW PUBLICATIONS.

THE OTHER SIDE is the title of a 16-page weekly to be issued shortly with Allen R. Foote, editor, which will aim to fairly collate the current views and expressions of writers and thinkers on both sides of such questions as treat on the relations of the public to quasi-public institutions. The Other Side Publishing Co., Chicago; $1 per year.

MR. ALLEN RIPLEY FOOTE, author of the "Law of Incorporated Companies Operating Under Municipal Franchises," has in press a new book entitled "Municipal Public Service Industries," which is full of interest to railway managers and students of street railway problems. Mr. Foote proposes a system under which he believes the mooted questions of public and corporate rights can be justly and equitably settled "provided each party is willing to make a settlement that will conform with the requirements of correct economic principles uninfluenced by any other considerations." Cloth bound, 268 pages, price $1. The Other Side Publishing Co., Chicago.

THE MUNICIPALIZATION OF STREET RAILWAYS was the subject considered in the twenty-ninth annual joint debate of the University of Wisconsin, held in December last, and a full report has just been published by the university. The question as put by the president of the evening, Prof. D. B. Frankenburger, was: "Is the present system of private ownership and operation of the street railway line of the city of Chicago preferable to a system of municipal ownership and operation?"

The debaters for the affirmative were Benjamin Poss, Joseph Loeb and Wm. S. Kies. On the negative side were Wm. F. Adams, Warren M. Persons and Emerson Ela.

At the time of debate the question was one of especial interest, as it was then Mr. Yerkes was making his formidable fight for a renewal of long franchises. The question is at all times one of interest to any taxpayer of any city. The young men engaged in the debate were many months in preparing for the fray and thoroughly posted themselves on the subject. There was a genuine effort to bring out the strength and weakness of a system of municipal ownership of street railways and they handled the subject in a masterful manner, thoroughly interesting a large and a very critical audience.

The judges were Prof. Charles H. Haskins, Hon. Burr W. Jones and Prof. Chas. S. Slichter. They gave a unanimous decision for the affirmative.

VOL. IX. JULY 15, 1899. NO. 7.

Even the most progressive and aggressive of the professional friends of labor are not exempt from some of the disagreeable results of unionism, as is witnessed by the fact that the firm of Pingree & Smith of Detroit, in which Governor Pingree is the senior partner, last month found it necessary to declare a lock-out and shut down its factory in order to vindicate its right to manage its own business.

How far a misplaced sympathy can lead men to their own disadvantage was shown in Cleveland during the Big Consolidated strike. A foreman employed by the Cleveland Foundry Co. had ridden to his work in a street car operated by non-union men, and the employes of the foundry demanded his discharge; to enforce the demand 400 quit work on June 20th. June 28th the greater number of these men returned to work; the offending foreman is not yet discharged and the net result to the men is the loss of a week's wages.

The action of the South Park Commissioners, the body having control of the parks and boulevards in the south division of the city of Chicago, in prohibiting the use of automobiles in the parks or on the boulevards, together with the arrest of officers of one of the automobile manufacturing companies on the charge of disturbing the peace when they violated the board's order, and their subsequent discharge when the case came to trial, all savor of an advertisement. If the order against automobiles was secured at the instance of the makers we congratulate them; if it was issued in good faith by the park board we feel that a "campaign of education" would not be amiss.

It is not improbable that the haulage of freight in large quantities may be diverted into other channels if not soon undertaken by the railway companies of some of our large cities. Already in New York City, where this subject has been considerably agitated, an automobile company has been organized for transporting merchandise about the city. A number of the most prominent merchants in the city are among the organizers of this company, which it is expected will do away with a large number of trucks and delivery wagons and their attendent expense, and will be able to handle the goods in larger quantities and much more expeditiously than with horses.

Within the last few years some steam railroad companies, notably the Boston & Albany and the Long Island, have sprinkled their roadbeds with crude petroleum in order to lay the dust and prevent the growth of vegetation. These experiments have been reported as quite successful in every instance where oil has been thus applied; the cost is stated to be about $150 per mile per year. It had occurred to us that sprinkling the roadbeds of electric interurban lines having a private right of way might be equally desirable, but we had no idea that oil could be thus used with advantage on roads subjected to wagon traffic.

It is now stated, however, that the experiment of treating country roads with oil is to be made near Des Moines, Ia., under the direction of the United States Department of Agriculture. The results will be awaited with great interest.

There was probably more rioting and ruffianism connected with the strike on the Big Consolidated system, of Cleveland, last month, than has attended a street railway strike since that at Milwaukee in 1896. The strikers and their "sympathizers" attacked the cars with bricks and stones, injuring in more than one instance women and children who were passengers, and beat into insensibility the non-union men who were trying to exercise one of their "unalienable rights"—that to earn an honest living. Great damage was done to the company's property, the cars being defaced and switch points broken or carried away—everything that was loose suffered. When the police forcibly dispersed mobs a loud protest went up against allowing the city thus to aid the company.

The question at issue was the vital one of whether the company should be permitted to hire and discharge its employes without the advice and consent—otherwise, dictation—of a labor union. The terms of the settlement finally reached show that the company was willing to accede to all reasonable demands.

The Supreme Court of Ohio has affirmed the verdict of a lower court, which awarded $10,000 damages to a woman for a permanently injured leg. The original claim was for $20,000. We do not know how severe or painful or disabling the injuries in question may be, but we cannot forget that it will take the fares from 200,000 passengers to pay it, and then the company has its expense to meet incurred in carrying all these people, which will bring the number up to fully 350,000. As the road is by no means a

large one, nor the city in which it operates a big city, the burden is sure to be a heavy one to bear. In this particular case the amount may have been deserved, though $10,000 looks large to us and is usually a balm the curative effects of which are surprising. It is easy to spend other people's money, and juries are no exception to the rule.

And now comes the vehicle with many names,—on no one of which any agreement has as yet been reached,—the horseless carriage to compete with the time-honored street car. To what extent its rivalry will mean competition and a dividing of the present business of hauling passengers, we will know more later. It would not appear, however, that it is likely to make any serious inroads upon street railway earnings as the bicycle has done. Its use for a long time will be confined to the class who can and now do patronize the horse and carriage or cab. In Chicago automobiles will take the place of a line of carettes, which are the embodiment of all that is terrible in appearance and use, and the fleshless horses which drag them can now seek some quiet spot to die. But when it comes to undertaking to handle large volumes of people with anything like regularity and expedition it will have to be done on rails and not on pavements.

The horseless carriage has, however, come to stay, and soon will displace horses in all our large cities for the general cab service. As they multiply they will become cheaper and already they have almost ceased to be a novelty or attract attention.

While the use of the three-wire system in street railway work has been tried and abandoned in several instances as unsuccessful, this method of electrical distribution presents many attractive features to street railway engineers, and it is an open question whether the system has been given a sufficiently exhaustive trial to definitely determine its value in traction work. It still remains to be seen whether the early failures in the application of this system were due to any inherent and insuperable difficulties or to such defects in the engineering details as will always occur in the introduction of entirely new methods. This system will again claim the attention of street railway men owing to its proposed introduction upon two large railway systems, those of the Consolidated Traction Co., of Pittsburg, Pa., and of the London United Tramways Co., of London, Eng., the latter being described elsewhere in this issue. Theoretically considered, the three-wire system offers a great advantage over the two-wire in the amount of copper required for transmitting a given amount of energy, as in the simplest case it requires but one-fourth the copper to transmit a given current at a given loss. This follows from the fact that by doubling the voltage only half the amount of current for the same energy is required. In practice, however, a neutral wire is used of the same size as the positive and negative wires and this brings the amount of copper up to three-eighths of what is required for the two-wire system in case the grounded circuit contains as much copper as the overhead lines. When the track alone is used to carry the return current, without being paralleled by any ground wire, the amount of copper in the two-wire system is halved, and the saving of copper in this case by the use of the three-wire system would amount to only one-eighth of that used in a complete two-wire circuit, or one-quarter of the overhead copper. It is obvious, therefore, that for a railway having a single overhead circuit with a grounded return the saving in copper, although considerable, is far less than is the case in a lighting system where there are no tracks to replace part of the copper in the circuit. The actual amount of copper saved may vary from one-eighth where no copper return is used, to five-eighths where the grounded copper is equal in amount to the overhead copper, and in practice it would fall somewhere between these limits. The necessity for using considerable grounded copper has become in recent years more and more apparent both on account of reducing the resistance on long lines of railways and preventing the electrolytic action on neighboring pipes by providing a path of greater conductivity, and the more thorough the construction of the return circuit the more nearly would the saving of the three-wire system approach the higher limit of five-eights.

The greatest difficulty in the application of the three-wire system to railway work, and this is the point on which its success or failure probably hangs, is the division of the road into two such sections that the loads on each shall be approximately equal throughout the entire day's run. If this condition is not fulfilled the three-wire system must assuredly prove a failure as the disadvantages of an unbalanced three-wire system are such as to prohibit its use. If a balance is not maintained the machines on the overloaded side will carry too much of the load, while those on the other side will be running comparatively light. The overloaded feeders will also have a drop in potential which tends to unbalance the system still further, and in this condition the maximum capacity of the machines can never be utilized. The question of balance is, therefore, of the utmost importance.

One of the earliest if not the first attempt to apply the three-wire system to street railway work was made in the city of Milwaukee upon a straight line of double track, one track using the positive trolley wire throughout its whole length and the other track using the negative wire, and all of the tracks being used as the neutral conductor. As the same number of cars operated on both tracks the system would probably have been successful if the roadway had been level, but as there was a decided grade all in one direction all of the current was consumed by the out-going cars, while those on the return track operated chiefly by gravity. The system here was abandoned because the whole load practically was carried by the machines on one side of the system.

In the case of the Lowell & Suburban road this system was adopted with considerable success. This road does a heavy business over a double track line to its park, about six miles from its power station. The track losses were very large and there was a good opportunity to obtain a balanced load, so the track feeders which were carried overhead on the two-wire system were changed over to feed one side of a three-wire system, using the rails as neutral conductors. The efficiency of the distributing system was thus found to be greatly improved.

It is to be doubted, however, whether the three-wire system will ever prove to be of much benefit to small roads, where the outlay for copper on the two-wire system does not involve excessive amounts. Unless the traffic is heavy and the road can be conveniently divided into two evenly balanced sections the three-wire system is hardly applicable, but in the case of a large system such as that of the Pittsburg Traction Co. the conditions seem to be very favorable to its use. This company's lines, as soon as the new power

house is completed, will be fed from a single generating station. The lines are divided into forty sections, each insulated from the others, and each section is supplied with a separate feeder running directly to the station switchboard. The feeder switches have a double throw with two sets of contacts, one contact throwing the feeder on the positive side and the other connecting it to the negative side of the system. The balance will thus be maintained between the forty different sections each of which can be thrown on either side of the system. Certain of the down-town sections will necessarily be run upon the positive side on account of their intersections with the overhead lines of other railways, at which points the insulation was only designed to take care of the fluctuations in pressure between two circuits of approximately the same potential and would be entirely inadequate for the protection of lines of 1,000 volts difference of potential, which would exist between the positive and negative lines. These down-town sections will be balanced by running the up-town sections on the negative side, still leaving a number of intermediate sections which may be thrown on either side of the system to regulate the balance.

The conditions in the case of the London United Tramways, described elsewhere, urge the use of the three-wire system still more strongly than on a single trolley road. The prohibition of a track circuit by the authorities compels the use of a double over-head trolley and a complete copper circuit, so in this case the use of the three-wire system permits nearly the maximum saving of copper over the two-wire system, which means a large reduction in the investment for this road.

The result of these departures from the ordinary practice by these two large systems of railways will be watched with the greatest interest by street railway men, and their success would undoubtedly establish a permanent place for the three-wire system in street railway practice.

For nearly 10 years there has been pending in Detroit a sharp controversy between the street railway companies and the city, and one of the contentions has been the rate of fare. The economically absurd experiment of seeking to improve and cheapen the service by building a competing line was tried in 1895. A company, the Detroit Ry., later the Electric Ry., was chartered solely for the purpose of giving 3-cent fares; the old company, the Detroit Citizen's Street Ry., met this rate for a year and then restored the old rate of six tickets for 25 cents. At about the same time the Detroit Citizen's Street Railway Co. purchased the stock of the Detroit Railway Co. and the management of the two roads was consolidated; on such of the lines of the Detroit Ry. as were yet operated tickets were sold at the rate of 3 cents each.

Mr. Pingree, through whose efforts, largely, the Detroit Ry. secured its franchises and was built, has never ceased to exert his influence in favor of a reduced street car fare and about a year ago opened negotiations with President Johnson, of the Citizens company, with a view to municipal ownership. The proposals and terms were secret and the public knows but little concerning the preliminaries.

January, 1899, the now celebrated McLeod bill was introduced in the Michigan Legislature. It aroused the opposition of the business men of Detroit, who asked that it be amended so that the question of purchase should be submitted to popular vote. However, the bill became a law on March 24th. April 1st Messrs. Pingree, Stevenson and Schmidt were chosen Detroit Street Railway Commissioners by the Common Council in accordance with the provisions of the McLeod act. The McLeod act and the history of the controversy up to the appointment of the commission were published in the "Review" for April.

Funds were raised by the Good Government League and quo warranto proceedings instituted against the commissioners shortly after their appointment. July 5th the Supreme Court of Michigan rendered an opinion, in which all the judges concurred, that the McLeod act is unconstitutional and void as being in conflict with that provision of the state constitution which says: "The state shall not be a party to or interested in any work of internal improvement, nor engaged in carrying on any such work, except in the expenditure of grants to the state of lands or other property."

The Commission and the owners of the railways reached an agreement as to the value of the property and franchises, $15,325,000 cash, or $16,800,000 in 4 per cent, 50 year bonds. As the Commission feared an adverse decision of the Supreme Court (which has since been rendered) a plan was devised for avoiding its consequences, and the scheme as submitted to the council was, briefly:

The Street Railway Commission to organize a new company to be called the Detroit Municipal Railway Co., which is to buy the street railway properties from the present owners, receive a 30-year franchise from the city and give 3-cent fares, i. e., five tickets for 15 cents, and also lower priced school and labor tickets.

This company is to join the old companies in mortgaging the property for $17,500,000, to secure an issue of 4 per cent. 50-year gold bonds. To further secure the bond holders in case of default, the city to grant a "security" franchise giving, in that event, the right to operate the lines for the remainder of the 30-year term and for 18 years longer, and to charge a 5-cent fare.

A sinking fund to pay the bonds to be provided.

The Commissioners to hold the stock of the new company in trust and transfer it to the city if the latter can legally take it; or, if not, the city to have the power to tax the company so as to prevent it from making any profit whatever.

A month ago it seemed quite probable that the council would accept this proposal and pass the necessary franchises, after perhaps first submitting the question to a popular vote. Consideration, however, failed to show any legal authority for such a referendum or that it would have any effect; the council was not willing to grant a "security franchise" providing for 5-cent fares in event that operation on a 3-cent basis proved a failure and the present owners would not accept a lower rate; also, the citizens opposed to the whole scheme announced that they would contest the validity of the council's action in the courts. In view of these facts the committee of the city council, on June 27th, unanimously reported as being adverse to any action looking to municipal ownership at present, and the whole matter was laid on the table.

This action followed by the decision of the Supreme Court leaves everything as it was at the beginning of the year

Those who have casually followed the trend of events cannot be blind to a strong personal interest at stake contingent on the successful culmination of the deal for both Governor Pingree and Mr. Johnson. The former cannot, it is thought, expect to receive any further distinguished political office at the hands of either his city or state, nor

certainly of the country at large. As chairman of the commission operating the street railways of Detroit under municipal ownership, he would have had for three years at least, an enormous political power to turn into whatever channel he desired, which would have put him in the position of being able to direct who should hold the offices he could not himself attain. As to the Johnson interests, they had everything to gain:—an extension franchise for 30 years on the property which if not paid for reverted with the franchise secured without any trouble. If the city could have been held to the proposed terms then they would have turned their bonds into cash or held them as good investment securities as long as the interest was kept up.

And now all these carefully laid plans which have attracted so much notice, and which must have cost somebody a pretty penny, have come to naught. A striking inconsistency on the part of Pingree was the attempt to restore 5-cent fares on the 3-cent lines, under the plea of temporary advisability of a uniform rate, with the promise to reduce on all lines on some rosy morning in the dim, undetermined future.

July 11th the city council of Detroit took the municipal ownership ordinance from the table, and after a prolonged struggle passed it by a vote of 19 to 14. The "security" franchise provides for 5-cent fares in the event of the 3-cent experiment failing. It is stated in the press reports that the mayor has announced his intention of vetoing this ordinance. This being the case, Governor Pingree has yet another victory to win before he can operate his road, that is, he must increase his majority in the council to two-thirds.

The street car mail service in Rochester, N. Y., is a great success. It has only recently been adopted, but is proving very satisfactory.

ELECTRIC LINE TO THE PYRAMIDS.

In the "Review" for May, 1897, page 317, we published a letter from a correspondent in Cairo, Egypt, who gave some interesting observations on the electric railway lines of that city, and the plans of the company for building an electric road to the Pyramids. At that time it was expected to have the road in operation before the close of the year, but delays of various kinds ensued and the line has but recently been opened for traffic.

The Societe Anonyme des Tramways du Caire commenced the operation of cars in 1896, having at that time about 18 miles of track, four separate branches diverging from the center of the city and going to Abbassiyeh, the English cavalry barracks; to Bulak, to old Cairo, and to the Citadel, familiar to our readers because of the massacre of the Mamelukes.

ON THE ROAD TO THE PYRAMIDS.

The extension to the Pyramids begins at the west end of Kasr-el-Nil bridge, one mile from the center of Cairo; the Government would not permit the tramway company to lay its track on this bridge, and the plan of building a new bridge was once considered, but later abandoned. From the starting point at the west end of the old bridge the tramway extends up the west bank of the Nile a distance of two miles to Gizeh, and thence in a westerly direction for 7½ miles to the foot of the Gizeh Pyramids and the Sphinx. The power house is on the east bank of the Nile, at the rear of the new Egyptian Museum, near the Kasr-el-Nil bridge.

The line to the Pyramids is single track with turnouts, but is soon to be made a double track road throughout. It is laid with 45-lb. T-rails, placed on cross ties; the track is bonded with "Chicago" bonds, two to each joint. The overhead construction is with bracket arms; two trolley wires are used. Mr. Giullaume Rizzo, engineer of the tramway company, supervised the construction.

The cars are of the enclosed type, seating 28 persons each, adapted to European requirements for first and second class passengers. They were supplied by "La Metallurgique," a Belgian manufacturing house. The trucks and bodies of the car are mostly of iron. The Westinghouse Electric & Manufacturing Co. supplied the motors and brake controllers for the cars. Two steel motors, wound for 500 volts, are mounted upon each car, each motor giving an output of 20 h. p. at 500 volts, turning at 375 r. p. m. These motors are wound for a revolving speed less than is customary in American practice. When testing the speed of the cars, it was found that one hauling two trailers filled with Arabs, a gross weight of 20 tons, obtained a speed of 45 kilometers (30 miles) per hour. The brake controllers are made according to a special Westinghouse device. When the lever is turned to the brake side of the controller, the circuit between the overhead trolley wire and the ground is broken, and the motor becomes a generator, the current acting as a brake by retarding the revolving armature. The motormen are all native Arabs; so are the conductors. Their uniform is of tight fitting yellow duck cloth, with a black belt.

The fare for the journey is five piastres out, and the same back, equal to about 50 cents, American money. The trip from the Bridge to the Pyramids can be made in 14 minutes, but it is usual to take one hour for the round trip. The trams are patronized almost entirely by the native Egyptians. The scarcity of European patrons is very marked, but is probably accounted for by the fact that the typical victorias of Cairo can be hired for almost the same price as the tramway fare.

Our illustrations show a number of scenes along the line; not the least interesting feature is that in two of these scenes there is nothing save the Turkish numerals on the dash board of the car to indicate that the picture may not have been taken on the Egypt Electric line of Cairo, Ill.

FREIGHT ON TROLLEY ROADS.

One of these days a very large proportion of many articles of merchandise such as ice, milk, meat, coal and other household necessities, which are now carted about our streets—and in many cases a long distance—will be handled in suitable cars on street railway tracks. We are so engaged with other

SCENES ON THE ELECTRIC ROAD TO THE PYRAMIDS—WESTINGHOUSE EQUIPMENT.

matters, and the difficulty of securing the necessary city and in some states, state legislation, that for the time being the subject is a dormant one; but in time it will force itself upon the public and there will be a positive demand which railway companies will be glad to supply, and city councils will not dare pass by unnoticed.

Take, for a simple instance the market supplies of Chicago. They center down along South Water St. and here from 4 o'clock in the morning until noon there is one continuous jam of vehicles. These, when loaded, separate in all directions, many of them hauling 10 miles to the north or south. The time consumed in making this distance under the most favorable circumstances is nearly two hours. The same service could be furnished on tracks to general distributing points in not to exceed 35 minutes, and then the wagon haul would not exceed 10 or 15 minutes at most—a direct saving of nearly one hour after allowing for the time

required for the one extra loading. This plan would, of course, necessitate tracks close to the curb in the street where the wholesale produce houses are located, but the removal of hundreds of wagons and horses, would give so much additional street room that, despite the space occupied by tracks, the street would be relieved.

Almost every large city has its great center where the produce is received in wholesale and distributed out to smaller dealers. The utilization of street cars appropriate to the transportation of such articles once tried, would be found so desirable no one would want to go back to the present ancient method. While it is not practicable to retail ice from car tracks, it can, however, be hauled in car loads at night to distributing stations from which the longest haul by wagon need not exceed one mile. The saving in loss by melting, which in extremely hot days frequently amounts to 10 per cent of the load per mile, would be no insignificant matter. Coal, also, while not to be delivered from cars to house, could be carried in original cars and set into distributing yards from which the wagon haul would be short.

Perhaps, however, no single item begins to approach in importance the handling of milk. Under present arrangements the milk leaves the farm in cans on wagons, and is hauled a distance often reaching four or five miles, over all kinds of roads and in all sorts of weather. It is then set out on a platform where it stands until the milk train comes. It finally reaches the city and the milk is unloaded onto platforms from which the wagons take it and go direct to customers, or haul it to their barns, where it remains until night or the next morning, as the case may be. There are immense milk routes in this city distributing several car loads daily where the milk is hauled from five to seven or eight miles to depots, and from there taken to customers. The saving which would be effected if this milk could be taken from the steam cars and loaded on an electric car and swiftly run out to the milk depot and there pushed into the building for unloading to the wagons, would amount to a thousand dollars a day on a very conservative estimate.

The foregoing are intended to be suggestive rather than exhaustive ideas on a subject which before a great while is bound to be a live question. It behooves managers to give the matter careful study and consideration and to post themselves fully as to the local conditions and requirements of their own cities.

It would hardly be expected that in England the subject would have already received attention, as electric cars are only now coming to be generally understood and appreciated; nevertheless, an English journal in commenting on the success of an electric freight line in this country, remarks:

> There is no reason why the tramways in England, now equipped or soon to be equipped with electricity, should not be similarly used, and connected wherever possible with the railways and the docks. It would be an easy matter for manufacturers, warehousemen, and large shopkeepers to connect their places with spur lines; to load their merchandise during the daytime, and have it transported over the electric street railways between midnight and 5 o'clock in the morning, when passenger traffic in most English cities is suspended. The municipalities could also use the street car lines at night for many of their services, such as the removal of street sweepings and snow, and the distribution of road making and road-repairing materials. It ought to be possible, too, for coal merchants to distribute their supplies at night by means of the trolley lines.

The Electrical Review, of London, in commenting on the same subject, says:

> In busy cities it would undoubtedly be an enormous gain to have effected silently and expeditiously during the night, a transfer of goods and merchandise, which at present occurs with excessive dirt, noise, obstruction, and discomfort during the day. But we cannot see that the idea is practicable, if it involves the laying of branch tracks and feeder systems all over our larger towns. The capital expenditure upon these extensions would make the cost of the new method of transit too high. We rather think that a solution will be found for the problem in the design of freight trailer cars which can be run either on the tramcar rails or on the ordinary roads. Such trailer cars would then be loaded as at present and taken by horse or manual traction to the nearest point of the electrical tramway system, where they would be picked up by the first train of freight cars going in the desired direction.
>
> We commend the idea to the attention of firms engaged in the manufacture of electric passenger cars in this country; as we feel convinced that were successful cars of this type designed and built they would be quickly adopted, and would be found of immense service in the distribution of raw materials and manufactured goods in many of our larger cities.

It is not by any means among the impossibilities that our English friends whom we are inclined to look upon as following our lead in nearly all matters street railway electrical, may surprise us by introducing a distribution system while we are yet commencing to study the problem.

BOLD ROBBERY IN PHILADELPHIA.

Early on the morning of June 19th a party of masked men entered the receiving office of the Fairmount Park Transportation Co., at Belmont, in Fairmount Park, Philadelphia, and after securing the receiver and five other employes, blew open the safe and took about $4,000, the receipts for Saturday and Sunday. Accomplices of the robbers cut the telegraph and telephone wires connecting with the company's main office, thus aiding them to escape.

A number of persons were arrested on suspicion, but up to the present writing nothing has been proved against them.

SALE OF CANCELED TICKETS AT BIRMINGHAM, ALA.

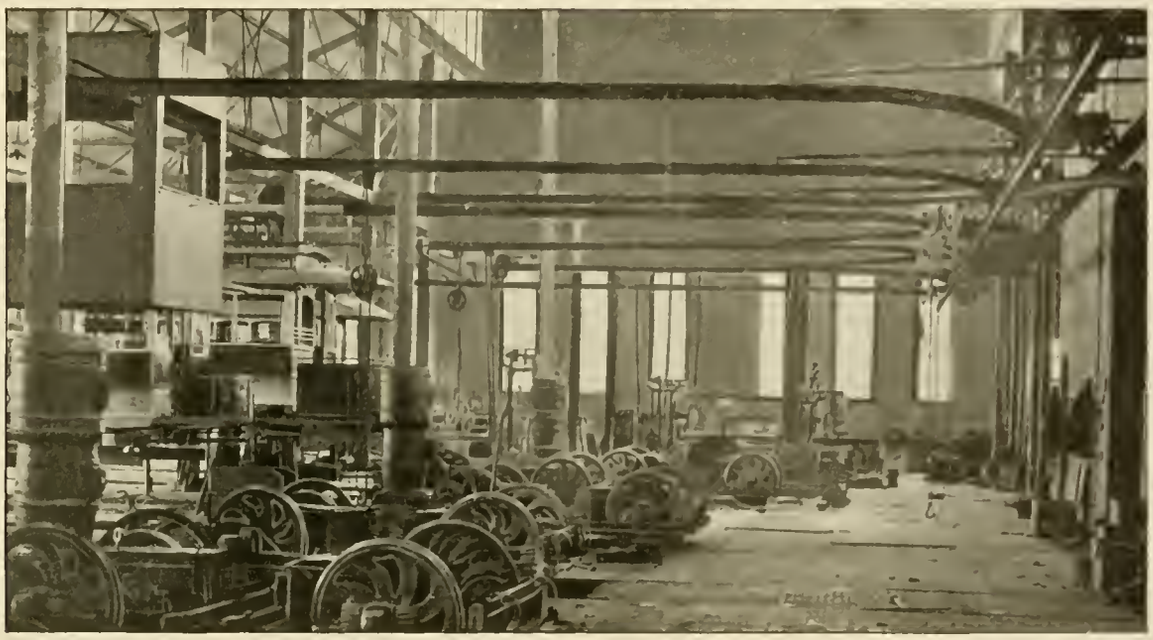
In the "Review" for June, mention was made, under the heading "Another Fraud," of the arrest of a boy who was selling canceled tickets of the Birmingham (Ala.) Railway & Electric Co. Inquiry develops the fact that the loss suffered by the company was greatly exaggerated in the reports, and was in fact only $1.30. Mr. J. B. McClary, general manager of the company, further advises us that our informant was wrong in stating that the method of destroying tickets practiced by the company was to merely tear them in two and throw into trash boxes. He states that the custom is, and always has been, to burn the canceled tickets each morning, in the office stove or under the boilers in the power house, according to the season. In last May the man having charge of this work was ill for a few days and his substitute inadvertently put a few of the canceled tickets into the trash box.

An injunction has been granted restraining the West Park Board from interfering with the West Chicago Street Railroad Co. in laying tracks across Washington and Humboldt boulevards. The court holds that the streets of the city extend across the boulevards and the Park Board cannot prohibit any use of the streets; it can only regulate the manner of crossing.

Power Station and Shops of the Louisville Railway Co.

The electrical repair shop of the Louisville Railway Co. was built in the summer and fall of 1898 after designs of W. T. Cook, chief engineer and master mechanic. It is a model of convenience in its general arrangement and the labor saving devices in handling cars and motors are particularly interesting. The building is of brick, 195 ft. long by 97 ft. wide, one story high, and is located at 18th and Walnut Sts.; it replaced a number of older buildings and is adjacent to the wood working and paint shops of the company. The roof is of slate supported on iron trusses.

The armature room, blacksmith shop and storeroom are separated from the main repair and machine shop by brick partitions as shown on the plan. The armature room is about 30 x 70 ft.; the store room, 25 x 80 ft., and the blacksmith shop, 25 x 50 ft. The equipment of these smaller shops is indicated on the plan. The equipment of the machine



INTERIOR OF SHOP—LOUISVILLE RAILWAY CO.

ENGINE ROOM—LOUISVILLE RAILWAY CO.

shop consists of 4 lathes, 3 drill presses, 1 planer, 1 shaper, 1 bolt machine, 1 boring machine and 1 wheel press.

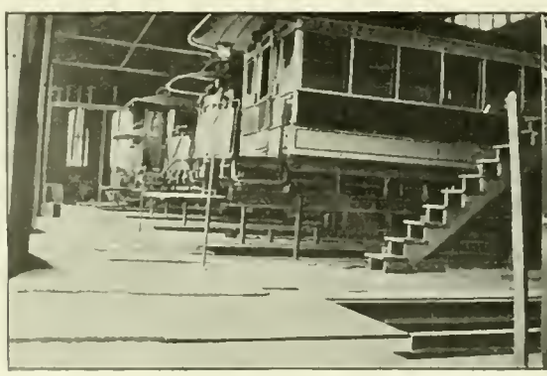
There are eight car pits, each provided with a car hoist of Mr. Cook's design. This hoist is shown in detail in one of the large drawings, and reproductions from photographs of one of the pits and of the cars when raised are given, and the method of operation will be apparent from an inspection of these illustrations. The car body is lifted by two I-beams, each of which is moved vertically by two square threaded screws; the screws are prevented from rotating by being rigidly fastened to the I-beams at their upper end. The nuts for these screws are bushings in the hubs of 30-in. sprocket wheels; they have their bearing on balls resting on a suitable base plate at the bottom of the pit. Pipes sunk in the ground provide pits for the lower ends of the screws.

The four screws are raised in unison by means of a chain passing around the four sprocket wheels and a driving wheel at the front end of the car pit. The driving pulley, marked "A" in the drawing is on a vertical shaft which has a beveled friction pulley at the top. The vertical shaft is driven from a shaft placed below the floor in a transverse pit extending the length of the building. The screws are driven either up or down by throwing in contact one or the other of two smaller beveled pulleys. The smaller beveled pulleys are mounted on a splined sleeve so that they may be moved lengthwise of main driving shaft, but turn with it; they are thrown in and out of contact by means of a lever connected to the hub.

REPAIR SHOP OF LOUISVILLE RAILWAY CO.

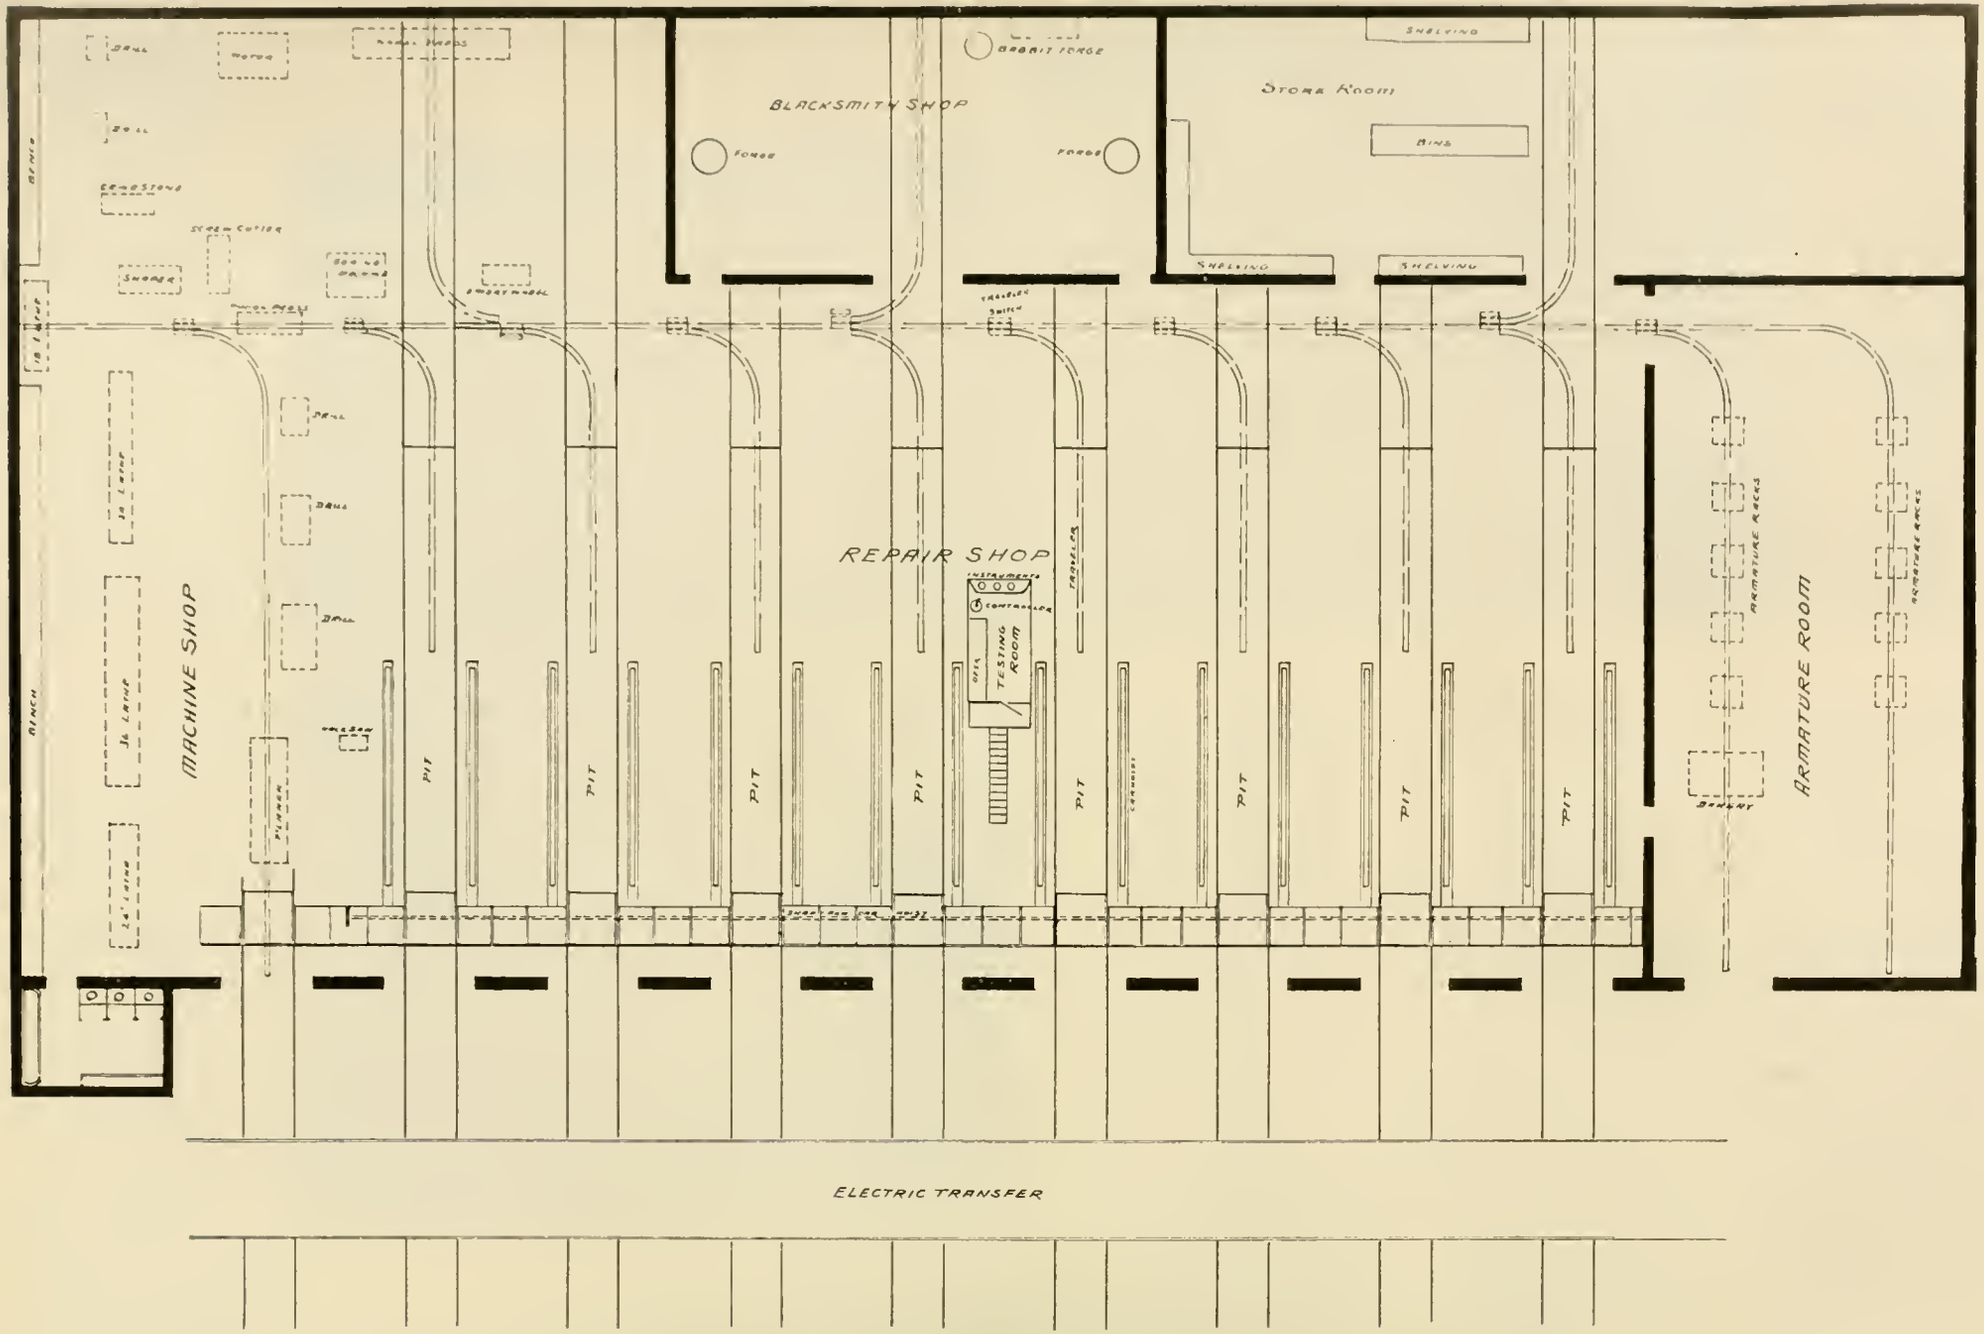
The main driving shaft extends along the eight pits, having a pair of pulleys for each of the hoists and at the end of the building is belted to a friction clutch driven from the line shafting. The pit containing this long shaft is covered with iron plates.

Another feature of particular interest here is the overhead traveler system for handling armatures and other



CAR LIFTING JACK.

VIEW OF PIT.

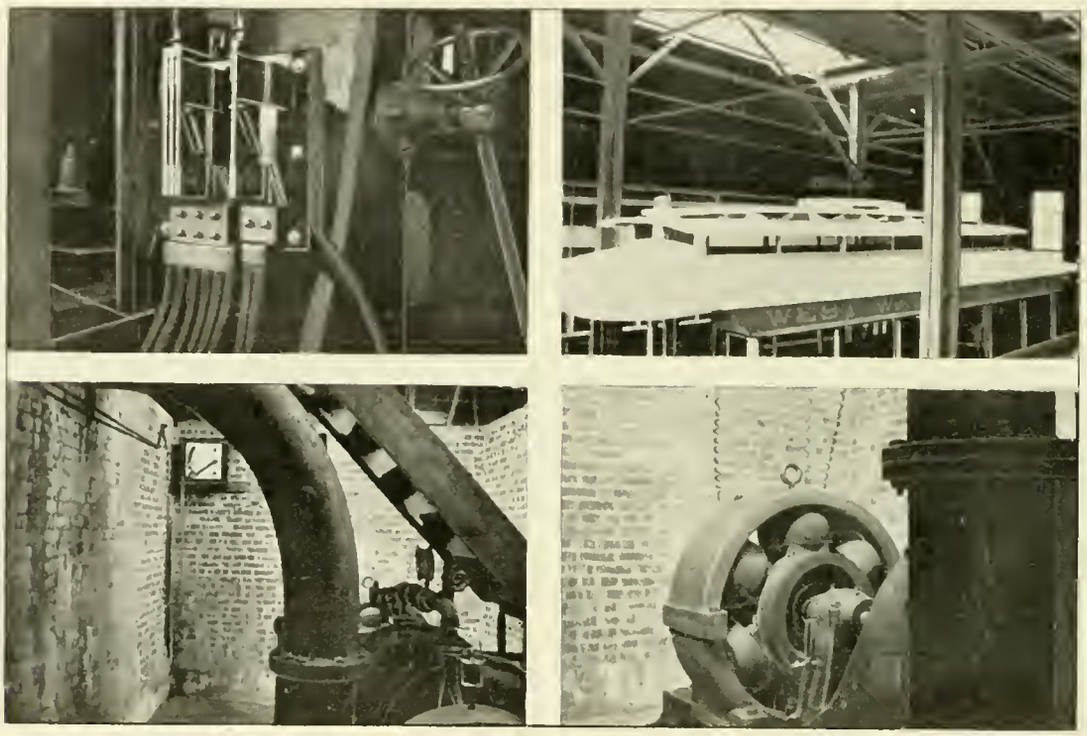


REPAIR SHOP OF LOUISVILLE RAILWAY CO.

heavy pieces. The tracks are I-beams supported as shown in the illustrations by rods from the roof trusses and brackets attached to the walls. The floor plan of the shops shows the location of the main and branch lines.

Instead of the ordinary tongue switches at the junction points of the traveler system there are trolleys moving on transverse ways. Suspended from the switch trolley are two or three sections of traveler rail onto one of which the carrying trolley is run; then the switch trolley is shifted transversely and the carrying trolley run on to the other track. The switch trolley is shifted by a gear worked from the floor by an endless chain. Stops are placed on the switch trolley on each side of the sections of traveler rail so that when the latter are shifted a carrying trolley on the branch line cannot run off its rail; the main line is always open, which is the great advantage of the device; also by no possibility can a carrying trolley run off at a switch. This switch is the invention of Mr. Snead, of the Snead-Van Alstine-Meldrum Co., of Louisville.

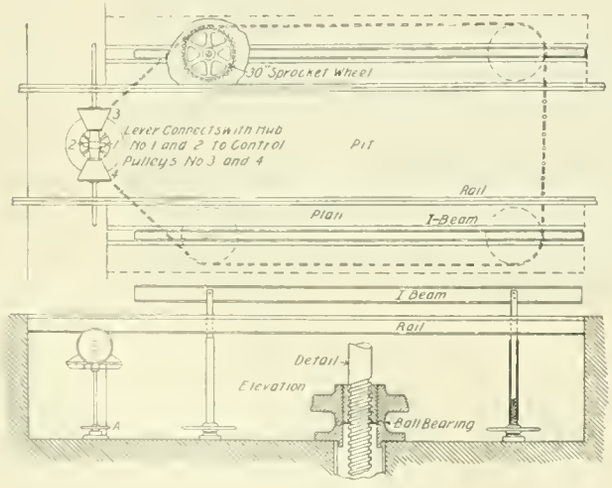
The power house is located at one side of the system, the supply of condensing water having been the controlling factor in choosing a site. The building is of brick; the roof is tin lined with sheet iron and asbestos. The power house is 235 ft. long by 112 ft. 6 in. wide; it is 19 ft. to the eaves and 43 ft. to the peak of the roof.



NEGATIVE LEADS ON LARGE GENERATOR. TRUSSED TROLLEY BOARD ON CARS.
PUMPING PLANT FOR CONDENSING WATER.

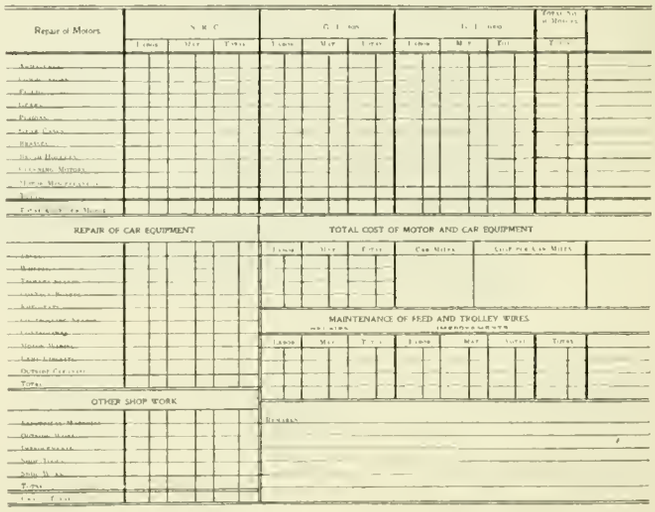
The boiler room is 235 ft. by 52 ft. 6 in. The boilers are 18 in number; 4 Babcock & Wilcox of 250 h. p. each with mechanical stokers made by the same company; 6 Heine of 200 h. p. each and 8 return tubular of 50 h. p. each. There are six Hoppes purifiers for the feed water. Six new Babcock & Wilcox boilers are now being installed.

There are two stacks, one 135 ft. high and 7½ ft. in di-



CAR LIFTING JACK.

REPAIR SHOP REPORT Louisville Railway Company



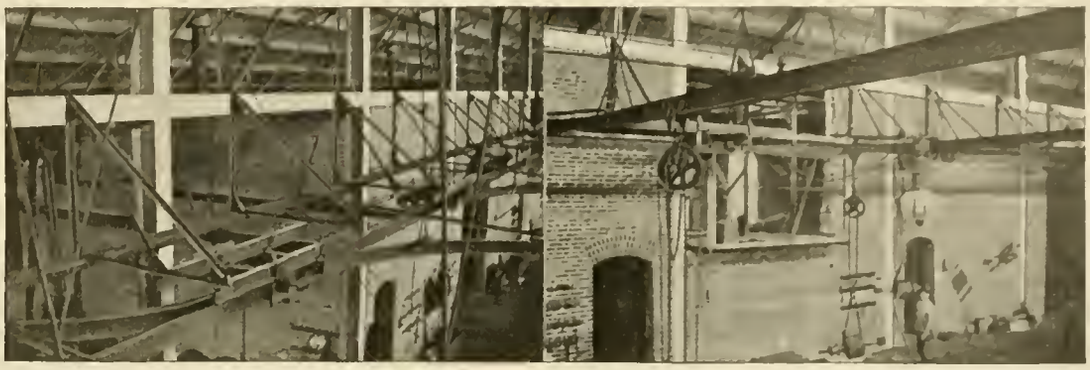
ameter and one 200 ft. high and 12 ft. in diameter; both are built of brick and lined with fire brick for half their height. No economizers are used.

The steam piping was made by the Crane Co. The flanges are all shrunk on and the pipe ends spread so that the gaskets come in contact with the pipe. The pipes from the boilers lead to a 20-in. header supported on rollers. There are no elbows used with pipes above 2½ in. in diameter, the necessary change in direction being effected by long bends. All the piping is covered with asbestos; the Holly drain system is used to return the condensation in the pipes.

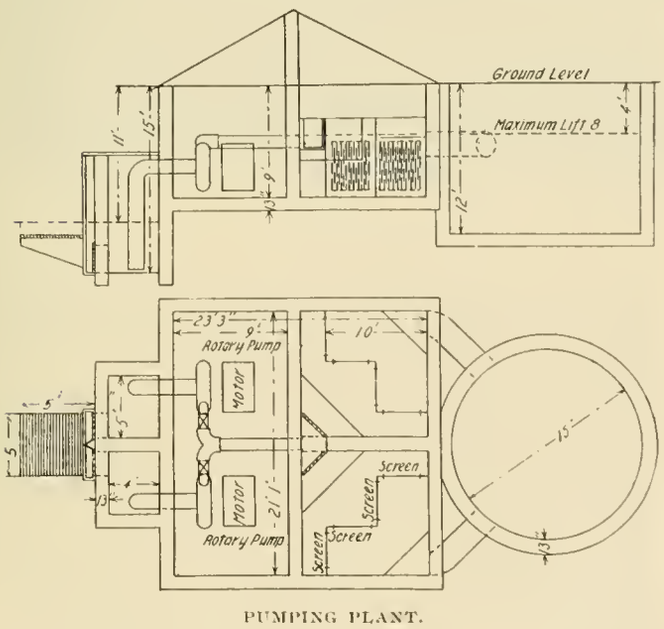
The engine room is 235 ft. long by 60 ft. wide. There are 7 engines, 1 vertical cross-compound, 4 horizontal cross-compound and 2 250-h. p. tanden compound. The large vertical engine was built by the E. P. Allis Co., and has cylinders 40 and 78 in. by 48 in. stroke. It operates at 75 r. p. m. The valve gear is of the Corliss type; an automatic safety device closes a butterfly valve in the main steam pipe if the speed becomes three revolutions above normal.

The fly-wheel is 25 ft. in diameter with a face of 24 in.; it weighs 160,000 lb. The main shaft is 27 in. in diameter with 24 x 48 in. journals. The engine is equipped with the Rochester lubricator and pressure oiling system.

The engine is designed to work most efficiently with a load of 3,000 h. p. It is direct connected to a 22-pole G. E. generator rated at 2,500 kw. The specifications were drawn by Mr. W. T. Cook, chief engineer of the power station, and called for an output of 3,000 amperes at 550 volts continuously, with a 50 per cent. overload, the rise in temperature above that of the room not to exceed 45° C., and the machine to be able to carry an overload of 100 per cent for short intervals without injury or serious sparking; the electrical efficiency specified was 95 per cent.

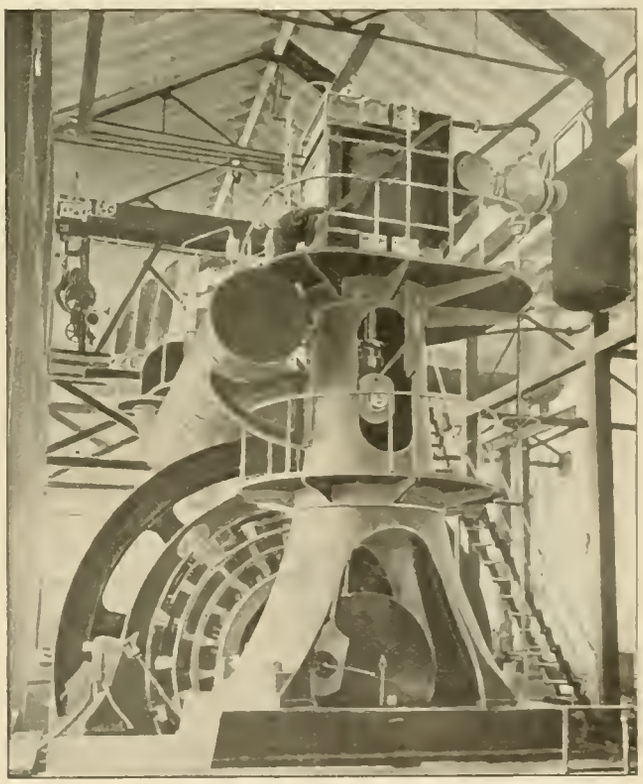


VIEWS OF TRAVELER SYSTEM IN SHOP.



PUMPING PLANT.

The foundations for the large engine are 19 ft. deep and 38 x 25 ft. at the base. First was put down a layer of concrete 2 ft. deep; this was covered with 70-lb. rails, next came 6 in. of concrete and a second layer of rails; next 6 in. of concrete and a third layer of rails; on this was 12 in. of concrete and 13 ft. 6 in. of brickwork; on top of the brickwork were placed stone caps, 18 in. thick, which are flush with the floor.



2,400-K. W. GENERATOR LOUISVILLE RAILWAY CO.

The other generators comprise four G. E. 500-kw. machines direct connected to the cross-compound engines and

four Edison 150-kw. machines belted to the two smaller engines.

The condensing apparatus consists of 4 1,000-h. p. Blake twin vertical condensers, 1 Worthington elevated cone condenser of 4,500 h. p. capacity, and 1 Reynolds vertical crank and fly-wheel jet condenser of 500 h. p. capacity.

The pumping station for handling condensing water is of particular interest. The condensing water is drawn from a small creek which is practically an open sewer and badly polluted by the refuse from woolen mills located above the power house; it is therefore necessary to strain this water before it can be used without danger of clogging the condensers.

This pumping plant is located at the bank of the creek and is all below the ground level except the roof. It is shown in plan and section in one of the line drawings. The water flows through a horizontal grating and is admitted through gates to one or both of two suction wells, which are 4 x 5 ft. and 15 ft. below the ground level. The pump chamber is 9 x 21 ft. inside and contains two Morris rotary pumps driven by direct connected 25-h. p. motors. The speed ranges from 200 to 300 r. p. m., the regulation being effected automatically by means of a float in the cistern or reservoir. The pumps deliver the water to the straining chambers through gate valves. The straining compartments are each 10 x 10 ft.

The reservoir is a circular cistern 15 ft. in diameter by 12 ft. deep. The maximum lift is 8 ft.

For cleaning the straining chambers a valve is placed in the bottom of each chamber and when this is opened the accumulated dirt is flushed out and carried to the creek through a drain which empties down stream from the intake.

The motors for this plant were built by Jas. Clark, jr., according to the specifications of Mr. Cook.

The switchboard has only positive leads, the only ground wire being a voltmeter connection. It is equipped with Weston ammeters and voltmeters and a Thomson-Houston wattmeter. The return wires from the line are carried directly to the machines.

The Louisville Railway Co. is a consolidation of all the street railway companies in Louisville, and was chartered in 1893. It operates 140 miles of track, 130 by electricity and 10 by horses, and has 500 cars and 650 horses. The company has, since the consolidation, been under the management of Mr. T. J. Minary, who, in 1897, was also chosen president and has since filled both offices. Mr. Minary was vice-president of the Central Passenger R. R., one of the consolidated roads, when the American Street Railway Association was organized, and has been active in that association. He has long been one of the representative street railway men of the country, and is one of the few horse car managers who has continued in the business.

T. J. MINARY.

The other officers of the company are: Vice-President, St. John Boyle; secretary and treasurer, S. G. Boyle; superintendent, T. J. Funk; chief engineer of power station, W. T. Cook.

SITUATION IN DETROIT.

(From our Special Correspondent.)

A very serious blow has been dealt to municipal ownership in Detroit. The Supreme Court of Michigan, in an unanimous decision handed down July 6th, states very positively that the McLeod act, under which the Detroit Street Railway Commission was created, is unconstitutional. The decision is very sweeping in its scope and covers every point of the proposed purchase plan by Governor Pingree and his friends.

This decision, which is given in full on another page, has had a very dampening effect upon municipal ownership in Detroit. In the first place the financiers from the East who had figured on taking the large issue of bonds that was necessary in making the deal, state positively that, should the ex-commissioners and the city council endeavor to formulate some plan to get around the action of the Supreme Court, that with this very strong and positive decision just handed down, that it would be impossible to dispose of the bonds in the financial market.

However, Governor Pingree still claims that the plan as outlined in the "Review" last month, that is, the formation of the Detroit Municipal Railway Co. to buy the properties and operate them for the city, will be pushed on just the same as if nothing had happened. The security franchise, running for 48 years, which is necessary for the successful carrying out of this plan, has been sent to the city council and there it received a very cold reception. It is in the hands of the ordinance committee with a good chance of never being heard from again.

So it can be said that Governor Pingree has on his fighting clothes once more. His lieutenants are already building the fences, and Hazen S. Pingree for the fifth time is a candidate for mayor of the city of Detroit. Aldermanic candidates that will favor anything that looks like municipal ownership are being selected in the various wards of the city and that question will be made the sole issue in the next campaign.

The local representatives of Messrs. Wilson and Johnson, in behalf of the street railway owners, have nothing to say in regard to the change in the situation.

(By telegraph, July 12th.)

By a vote of 19 to 14 the city council of Detroit last night granted the Detroit Municipal Railway Co. a 48-year franchise over all streets now occupied by street railway tracks. The company consists of Gov. H. S. Pingree, E. G. Stevenson and J. C. Hutchins, the present vice-president and general manager of the Detroit Citizens' company. By the terms of the ordinance the Detroit Municipal Railway Co. is to buy all of the street railway property in the city and operate the same. The rates of fares are to be six tickets for 25 cents, with universal transfers to all lines; eight tickets for 25 cents two hours in morning and evening. All profits from the operation are to go to the city aside from providing a sinking fund to care for bonds issued to the amount of $17,500,000. The present owners have agreed to sell to the new company, taking this franchise for security, for $16,800,000 in 4 per cent gold bonds and it is generally believed that the franchise passed last night can be passed over the veto of the mayor; this requires only three more votes. Mr. Hutchins entered the street railway commission yesterday on the resignation of Carl Schmidt. From his connection with the Citiens' company it is thought that the present city ownership plan was assured before he entered the new company. Governor Pingree today stated positively that should the present franchise be defeated that he would run for mayor this fall on the Republican ticket, indorsing only candidates for aldermen pledged to this franchise and thereby carry out in name and effect his municipal ownership ideas.

Shops of the Consolidated Traction Co., Pittsburg, Pa.

The Frankstown barns and shops of the Consolidated Traction Co., of Pittsburg, which were somewhat briefly mentioned in the "Review" of February, 1899, are now fully equipped, and the completeness of the entire installation is such as to make it one of the finest shops of its kind in the country. The plant comprises three main buildings each being the full length of the city blocks, the buildings being separated by two intersecting streets. There are also two smaller buildings used for store houses. The first of these buildings is known as the operating barn which, in addition to the main barn, contains a number of offices and rooms for special purposes arranged along the Frankstown Ave. side of the building.

First comes the receiver's office where the conductors make their returns. There are six divisions of the road from which returns are received at this office, and the returns of each division are kept separate by being deposited in separate drops arranged along the side of the office, each bearing its special route number. This saves the receiver the work of sorting out the various returns. Next to this comes the despatcher's office, the division superintendent's office and the motormen's room. The latter deserves a word of commendation, as it is neatly and comfortably furnished and provides a pleasant and attractive room for the conductors and motormen. One side of the room is entirely covered with lockers, each man being provided with a separate locker, in which are kept the uniforms, rubber coats, hats, etc., when not in use. A row of long tables placed along the center of the room are used for lunch tables, and on several of them are to be found checker boards and other games for passing away the time when not on duty. That this room is appreciated is shown by the number of the employes who are to be found there at almost any time.

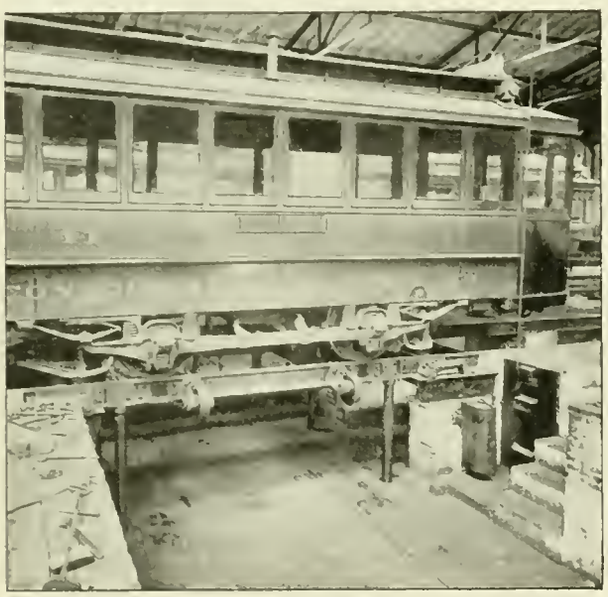
Next to the motormen's rooms is a lavatory, which is fitted up with marble and contains the most modern sanitary appliances. Beyond this is located a heating plant for heating the barns and offices by hot air. The air is distributed through the building in large galvanized iron pipes, containing numerous outlets, which are carried on the roof trusses around three sides of the building. The hot air from the furnace is forced through these outlets into the room by means of a fan driven by a small steam engine. All of the buildings are heated in the same way, and there is a small boiler plant situated in a separate building for supplying steam for the engines which drive the fans. The steam from the boilers is all piped underground to the different heating plants, and the offices are also all supplied with steam radiators for use at such times as the general heating of the barn is not required.

A room for the night repair men completes the subdivisions of this barn. This room contains a locker for each night employe, a small store room containing such small parts as may be required for light repairs at night; this room is also used as the office of the barn foreman. The open part of this barn contains eight parallel tracks which are divided in the center of the building by a transfer table and track. The cars are brought into the building on either of the first four tracks, where they are washed, and are then placed on one of the other four tracks, all of which are pit tracks, by means of the transfer table. Here the car equipments are inspected and if found to be in good order the car is run out into the operating yard ready for service again. The transfer table, which was designed by the general foreman of the shops, Mr. John Rogan, deserves a word of attention. The frame is of the ordinary construction and contains a wooden platform, on one side on which is mounted a No. 3 Westinghouse motor of 30 h. p capacity, which is geared to one axle of the transfer table. The motor is controlled by a street car controller which is mounted on the platform alongside the motor. The current is supplied from underground conductors placed in a conduit between the transfer table rails exactly similar to an underground electric sys-

MACHINE AND REPAIR SHOP—CONSOLIDATED TRACTION CO., PITTSBURG.

tem. There are five of these transfer tables across the different shops all of the same design. There is a single circuit breaker in the operating barn which controls all of the circuits in the barn and in case of any trouble on those circuits the entire barn is cut off from the line.

Outside the operating barn is the operating yard, where the cars in service are temporarily stored. On one side of this yard are a sand house, coal and wood bins, and a lubricant store room. In the sand house wet sand is dried for use on the cars in a dryer, which consists of a stove around which a large hopper is placed. The wet sand is shoveled into this hopper and after being dried falls out through an opening around the bottom of the hopper. Although only a small amount of sand is dried at one time in this way, the operation of drying is kept up every day, and enough dry sand is stored away in the summer, when but little is used on the road, to supply the amount required during the winter. The coal and lubricants stored in this yard are only for a few days' supply for the cars and are always accessible to



BRYAN CAR DISMANTLER.

the employes. These stores are recruited at short intervals from the main store house.

The machine and repair shop is situated at the further end of the operating yard, and it is in the equipment of this part of the plant that the greatest interest centers. Directly in front of the entrance is a Murphy wheel grinder, by means of which the car wheels are trued up without being removed from the car. The car is run over the pit where the wheel grinder is located and is supported independent of the wheels. The journal box covers are opened and each axle is centered between a pair of adjustable lathe head centers and the track underneath the wheels removed, so that the axles and wheels revolve on the centers by operating the car motors. Four emery wheels are used, one being placed against each wheel, and these are revolved in a direction opposite to that of the wheels by means of a system of shafts and belting. The emery wheel shafts are driven at a speed of 1,600 r. p. m. by a No. 3 Westinghouse motor. The operation of grinding up a set of car wheels in this machine is complete in about a half hour from the time the car is run over the pit.

Further along on the same pit track with the Murphy wheel grinder are situated two Bryan car dismantlers, the operation of which is perhaps the most interesting of any work in the repair shop. These machines consist essentially of a section of track a little longer than the wheel-base of a car which has a vertical movement upon four screws. These screws are turned all at the same speed by means of lines of shafting placed beneath the pit floor, which form three sides of a rectangle, and are connected together and to the screws by means of bevel gears. The shafting is driven by a No. 3 Westinghouse motor. At the four ends of the fixed track, just outside of the movable section, are pivoted arms which may be turned up vertically and on the ends of which are shoes which turn in under the frame of the car truck to support the weight of the car when the section of track under the wheels is dropped.

The operation of the dismantler is as follows: The car is run over the pit so that the wheels rest on the movable section of track and the arms on the stationary track are turned up to catch the frame of the truck. The straps and covers of the journal boxes are then removed, allowing the wheels and axles with the car motors upon them to be dropped down from under the car upon the movable track and onto a truck which carries them off sideways from under the car into an extension of the pit. They are lifted out from this part of the pit by the overhead crane which deposits them on the floor of the repair shop. A number of sets of wheels, axles and motors, all mounted and ready for use, are kept on the floor near the dismantler and a pair of these is picked up by the crane, lowered into the side pit, rolled onto the movable rails, lifted into position and fastened under the car. The whole operation of removing both pairs of wheels and car motors and replacing them with new ones ready for service requires but 23 minutes. The crane which handles this work operates over the entire central section of this building where all the heavy repair and machine work is done. It is a 10-ton crane built by Pawling & Harnischfeger, of Milwaukee, and the operations of the shop keep it in pretty constant use.

In this same section of the repair shop are also several other interesting machines, one of which is a 100-ton hydraulic wheel press, in which the car wheels are pressed upon the axles. Here is also situated a 38-in. New Haven Machine Works' lathe, which is used exclusively for turning up axles and steel centers for steel tired wheels. This company is now using wheels with steel tires 1¼ in. thick and with 2¼ in. tread, which are shrunk onto steel centers turned to 30½ in. diameter. The steel tires are faced up on the inside to gage and are then placed on a special heater where they are heated and expanded by natural gas. The heater consists of a cylindrical drum on top of which is a 1-in. gas pipe bent into a circle a little larger than the diameter of the tires. This pipe acts as the gas burner, being bored with a row of small holes all around the inside. The tire is laid down inside of this circular pipe, the gas flames from which impinge upon it, and a circular iron disk is laid over the tire to concentrate the heat upon it. In about 15 minutes the heat expands the tire sufficiently to allow the steel center to be slipped into it and after cooling the two are shrunk rigidly together.

There is another special machine in this part of the shop, designed by the foreman of the shop, on which keyways are cut in the car axles without removing the wheels. The machine is composed of an ordinary drill press on the table of

which is fastened a bed about 3 ft. in length. A carriage with clamps for holding the axle and wheels travels on this bed, its motion being derived from a screw which is driven by a belt from a shaft which engages with the shaft of the drill press. The tool used for cutting keyways is a side and end cutting tool which is set in the chuck of the drill press, and the axle travels along under this tool over the length of the keyway to be cut.

The standard keyway for the axle gears are 7 in. long, 1 in. wide and ½ in. deep, and these keyways are cut in an axle without removing the wheels in 20 minutes.

Along the side of the building parallel to the central section where heavy repairs are made are the blacksmith shop and the general repair shop. The blacksmith shop contains four forges, one of which has a movable hood and stack which can be raised to any height necessary for handling large or high pieces of metal in the fire.

In these shops, as well as throughout the whole of the company's buildings, each man is supplied with a locker for keeping his tools, etc., and each workman is supplied with a set of tools for which he is held responsible. If a man loses a tool he is charged for it, but when tools are worn out in service a new tool is issued from the tool room in exchange for the worn-out tool.

The tool room is a small room partitioned off from one side of the general machine shop and here all the tools used in the shops are made and repaired. This room contains a 16-in. Blaisdell lathe, a No. 2 Brown & Sharpe universal milling machine and a No. 2 Brown & Sharpe universal grinder. Besides containing the tools this room is also used as a sub-storeroom for repair parts. This stock, in quantity about sufficient for one day, is drawn from the general storehouse daily on a requisition from the foreman of the shop, and is then given out to the workmen from the tool room. This method of giving out stores is followed in all the different departments.

The general machine shop is very fully equipped with machinery for making all the metal repair parts used on the cars, and these parts are all made to standard dimensions and are interchangeable. The machines here include a screw cutter which is used for recutting all the old bolts, etc., removed from the cars, three upright Prentice drill presses and one Smith Machine Co. radial drill press, one Gould & Eberhardt shaper, one emery stand, a 24 in. Pond planer, a Bullard boring mill for boring car wheels, a 12 in. Betts slotter for cutting keyways, a 24-in. Johnson lathe used exclusively for armatures, a 12-in. Prentice lathe for boring armature bearings and a 22-in. Blaisdell lathe for general work.

The Prentice lathe used for boring armature bearings is equipped with a special arrangement for this work. The armature bearings are iron boxes with babbitt linings. The babbitt is run into the boxes, the parts of which are clamped together in a jig mounted on the tool carriage of the boring lathe, and the babbitt is bored out with a boring bar.

A special iron mould is also used for pouring the babbitt axle bearings, which has a smooth finished iron core on which the bearing surface of the babbitt is molded. This produces a finished bearing which is taken out of the mold and is ready for use on the car without any machine work or finishing.

INTERIOR OF CARPENTER SHOP—CONSOLIDATED TRACTION CO.

The electrical repair department occupies one end of the general repair shop and contains the usual machinery, tools, and apparatus for winding armatures and fields and for making any kind of electrical repairs. This department does not contain any special apparatus, however, which need be mentioned here.

The entire shop is run by a 50-h. p. Westinghouse motor belted direct to the overhead line shaft, which runs the full length of the shop. Each machine has a separate countershaft belt to the line shaft. The building is heated by a hot air plant identical with the one described above. An electric transfer table, the same as already described, runs across all the tracks in the machine and repair shop. A compressed air plant is also used in this shop for cleaning the motors, armatures, controllers, car cushions and the machines in the shop. The air is piped to outlets all through the building from a cylindrical reservoir at one end of the shop. The

pressure in the reservoir is maintained at from 65 to 100 lb. by means of an automatic regulator worked by compressed air. The air is compressed by a small rotary pump and a direct connected motor of the Westinghouse make, which runs when the pressure in the reservoir falls to 65 lb. and stops when it reaches 100 lb. The regulator is merely a starting switch in which the handle is connected to a plunger which works against a spring by compressed air, stopping and starting the motor within the limits of pressure, as stated.

The machine shop, carpenter shop and paint shop are each of about the same size and are contained in the same building, which is partitioned into three divisons by two brick partition walls. The middle division of this building is the carpenter shop, which contains all the necessary machinery for building complete cars. The wood working machinery is all of the manufacture of J. A. Fay & Co., and includes a mortise machine, a tenon machine, a double head reversible shaper, a 26-in. planer, a sticker machine for cutting any kind of molding, a boring machine, a band saw, cross cut circular saw and a circular rip saw which cuts at any bevel up to 45°, a joiner and a 12-ft. turning lathe used chiefly for turning out drums for controllers.

Besides these wood working tools, this shop also contains an edge grinder for planers and joiners, and a Rodgers saw sharpener adapted to either band, cross or rip saws. The machinery of this department is run by a 50-h. p. Westinghouse motor placed in a basement about 10 ft. below the shop floor. This drives a line shaft in the basement to which the machinery is belted down through the floor. In this shop is done both repairing and also the complete building of cars. A number of the Allegheny Traction cars which were injured by fire last year were entirely rebuilt in this shop, and several baggage and pay cars have also been built by the company. The pay cars are handsomely finished both inside and outside, and are run all over the different divisions of the company's lines, paying off the men wherever they are employed without occasioning any loss of time. There is now building in this shop a flat truck car which is to be used exclusively for hauling wheels, axles, motors and other heavy machinery from the store house and between the different shops.

The paint shop occupies the third division of this building and contains eight parallel tracks which are crossed at the center of the shop by an electric transfer table. Each of the eight tracks is long enough to hold four cars, two on each side of the transfer table, making the total capacity of the shop thirty-two cars. This shop is often filled with cars to be either entirely or partially painted, as the company make it a rule before putting out either the summer or the winter cars to have them all painted so as to look perfectly fresh and new. Located in the center between each of the eight tracks are rows of posts about 12 in. square and 6 ft. high. Each of these posts is provided with two swinging brackets which may be turned toward either track, one bracket being about 2 ft. from the ground and the other near the top of the post. By turning these brackets all one way and laying a plank across them a scaffold is formed from which every part of the car may be reached by the painters. This system is very convenient, as it saves the use of ladders and also the work of moving scaffolds about the shop. These brackets are always ready and are placed in every part of the shop alongside of all the tracks.

INTERIOR OF PAINT SHOP—CONSOLIDATED TRACTION CO.

On one side of the paint shop is a brick fireproof storeroom with iron doors, where the supply of paints, varnishes and oils are kept. Along the partition wall are placed a large number of racks where sash, glass and sash materials are stored.

On first coming into the paint shop a car is dismantled of its polished brass parts. These are first washed in lye, then in muriatic acid, after which they are rinsed in water and packed in sawdust to dry. The old varnish and paint on the car is then removed with a special varnish remover, which takes off all the old varnish and paint without discoloring the wood underneath at all. The car is next painted in flat colors, then varnished, and refitted with the cleaned brass parts, giving it the appearance of an entirely new car.

The chief remaining parts of interest about this plant are the storage departments, both for cars and supplies, both of which are installed on an unusually large scale. The car

storage barn is similar in general to the buildings already mentioned and is practically a continuation of them separated by an intersecting street. This building contains 12 parallel tracks each long enough to hold 10 cars, giving the building a capacity of 120 cars. A transfer table runs across the center of this building. There are two separate buildings besides those mentioned used for the storage of materials in large quantities. One of these is divided into three rooms, the first containing oil, paint and waste, the second scrap brass and copper, and the third, coal and salt. Next to this building is a large lumber shed which is well filled with seasoned wood for repairing and building cars, and the last building of this group is a general storage house for all the supplies for each division of the road. The materials in this house are all assorted in bins and racks and on the front of each is painted in large letters just what materials it contains. There is a track through the center of this building on which all the bins and racks face, and a storeroom delivery car runs through this building to all the divisions of the road distributing the supplies wherever they are needed.

This company also has another large car barn quite a distance from the Frankstown Ave. barns, situated at the corner of St. Clair and Bunker Hill Sts., which is known as the Bunker Hill barn. The receiver's office and motormen's room here are fitted up in about the same manner as the Frankston barns. This barn has 18 parallel tracks running through it, all of which have pits about 25 ft. long just where the tracks enter the building. A transfer table crosses all the tracks a little beyond the end of the pits, and this barn is also heated by a hot air plant. Only light repairs such as can be done without the aid of machinery are made here, the pits being chiefly used for inspection purposes.

MAINTENANCE AND REPAIR OF ROLLING STOCK.

BY J. W. GREER, GENERAL MANAGER YOAKUM TEX. IMPROVEMENT CO.

PART III.

In the old horse car days a hay fork, a spade, a scrubbing brush, and copious supplies of water from a convenient hose, backed by plenty of elbow grease, served the dual purpose of relieving the cars of the mixture of mud and hay and other accumulations of filth, and also of the paint, which seemed to be put on the cars largely with the idea of having it scrubbed off again at the earliest possible moment. Of course the nature of animal traction was such as to require a great deal more scrubbing and the freer use of water both inside and outside the cars than is necessary with mechanical traction, or would be admissable where electricity is used as a motive power, but even in horse car days the writer could never see the necessity of flooding a car day after day or night after night, thereby causing the posts to rot off at the sills, and eventually the sills themselves to decay and destroy the whole car body. More panels have cracked, more joints have worked loose, more sash have rotted off at the tenons, in short more cars have been destroyed by the too free application of water than have ever been worn out by the strains of service. Water is a good thing in its place, but one of the poorest uses to which it can be put is in flooding either the inside or outside of a modern street railway car. The class of material in which a modern car is finished, and the skill of the mechanic who does the work are equal, and in many instances superior, to that employed in the construction and finish of the average piano, and the cost of the car is much greater. No one ever thinks of turning a hose on a piano, either inside or out.

Compressed air for cleaning cars, motors, dynamos, switchboard equipment, and in fact everything connected with electrical equipment, has nearly all the advantages of water without its disadvantages, and has many superior claims as a cleaning agent where water could not be employed at all. The reader need not fear that the writer having mentioned compressed air is going to advocate a change in equipment. No one appreciates better than the writer how sore a subject "change of equipment" is to many managers, as he has seen everything in the line of street railway motors from the Sprague Nos. 5 and 6, F 30, S. R. G., W. P., etc., down to the latest General Electric, Westinghouse and Walker single reduction series-parallel equipments. But the man who believes that compressed air has no field in street railway work is badly mistaken. Whether it will prove a success as a motive power on railroads we shall leave, for the present, to the capitalists now backing the latest experiments in that line; if they succeed we ought not to sulk in our tents, but accept the result.

At present the applied field of compressed air on railways is in braking, cleaning cars and motors, operating hoists for lifting car bodies, motors, wheels, and other heavy parts, and for operating punches, pneumatic drills and other tools. Its field of usefulness is even greater in the power house, and the writer may at some future time discuss its use in lifting water from deep wells, circulating and cooling condensing water for re-use, etc. An air plant for the uses here enumerated is a simple and inexpensive affair, consisting of any antiquated street car motor belted to a compressor of suitable capacity, from which leads of ordinary 1-in. or 2-in. iron pipe are carried to the point of use desired. There is practically no serious loss in transmitting air, and the pipes can be laid overhead, on the surface, or in the ground, as is most convenient. A small automatic compresser, say 6 in. x 6 in., costing about $300, will usually be sufficient for the shops and car sheds of the average street railway. If your water supply is taken from city mains through a meter, the cost of the air plant will be saved many times over, in decreased water tolls alone.

If you are fortunate enough to have your power plant, car sheds, and shops, all located at the same point, one compressor of the duplex or cross compound type will furnish air for all of them. Locate the compressor in the power plant and belt it directly to the counter shaft; you can pick it up or let it go with a clutch equally as well as a dynamo. If your electric machinery is direct connected, then use a motor belted to the compressor. Small compressors are, when self contained, usually provided with small slide valve engines, which are so wasteful that it is more economical to use current generated by highly efficient units than to take steam directly from the boilers for the self contained compressor. Air compressors offer the greatest resistance at the end of the stroke and for this reason they are inclined to have a jerky motion when direct connected to a motor or engine. Flexibility is gained by belting, and ease of action by "duplexing" or cross compounding, which enables the maker to so arrange the two crank pins with reference to each other that the load is coming on one as it goes off the other. The writer uses a cross compound compressor, 12

x 12 in. and 6½ x 12 in., turning at 110 r. p. m., which has a capacity of 174 cu. ft. of free air per minute and delivers at 135 lb. This machine is belted to a counter shaft, which also turns high frequency alternating lighting machines, yet the action of the compressor is so smooth that no perceptible fluctuations of voltage occur. This compressor along with other duties lifts 400,000 gallons of water each day out of a 4½-in. well. The indicated horse-power at full load is 30. We have also a self contained tandem compound compressor (one of the best of its type) of the same dimensions as the first mentioned, which does the same work and can be made to compress up to 200 lb. pressure.

The method of using compressed air to clean cars, motors, and other equipment is through a hose and nozzle just as water is used, a separate hose being used for cleaning motors or other parts liable to be oil soaked. The pressure used varies with the work to be done, from 5 lb. for floor sweeping or dusting a dry car, to 100 lb. or more for removing mud or grease. After the dust or mud has been blown off the paint, the outside of a car can be gone over carefully with a sponge and chamois skin dipped in water and stains removed from the varnish, which cannot be blown off. The air pressure may be constant from the compressor and varied as desired by the use of a valve nozzle. As little oil as possible should be used to lubricate the air cylinders of the compressor so that the air will be free from contamination. If the cars are upholstered it is best to heat the air quite hot when cleaning the cushions, as the heat destroys disease germs and insects, while blowing the dust out equally as well as if cold.

Accumulations of dust and dirt among the cables and lead wires beneath the seats of closed cars, and under the floors of open cars, lay the foundation for deterioration of insulation and consequent short circuits. Blow the dust and dirt out of the cables, off of the sills, from around the posts, between the lining and side walls, in fact, reach every crevice and crack from motors to roof, and after you think you are through it often pays to go over the car again.

The car cleaner if not a painter by trade should at least have worked in a paint shop until thoroughly familiar with the properties of the various materials used in painting a car and the proper method of cleaning paint and varnish without injuring it. A man who knows that if the varnish is abraded the color will "peel," or who notices that the varnish has "crawled," or the paint "turtle-shelled," or that the putty is "working," or that some places need retouching, is cheaper at any price than an ignorant man. While one is able to see at a glance the points that need attention, and thus report to you, so that the stitch in time may be taken, the other simply knows how to squirt water or air through a hose, and has no conception of whether what he is doing is a detriment or a benefit, and oftener than otherwise, does not care.

One of the most important points in the maintenance of rolling stock is to see that the cars are kept thoroughly varnished, for as long as the varnish retains elasticity and thoroughly covers the car neither the paint nor woodwork can deteriorate. As long as varnish retains elasticity it will catch dust and dirt and is susceptible to stains. Considerable skill is required to clean a newly varnished car without injuring the polished surface, and when once the gloss has been removed the varnish soon gets "dead," then it "scales," and as there is nothing left to hold the paint on, it in turn "flakes" or "peels." Put a man to cleaning cars who knows these things and the work of your paint shop will decrease about half, and the cars will always look well, for the intelligent interest of a thinking mechanic is behind the work.

Clean cars make business, and it is largely due to the fact that the cars are neater and better kept since the substitution of electricity for mules that the patronage has so greatly increased. The expectoration ordinances passed by the city councils of several progressive communities have helped greatly in keeping cars clean.

Cars should be swept out and dusted every night, but should be cleaned only in daylight. An extra car should be provided for each cleaner, and the cars run in and thoroughly cleaned in rotation as often as necessary, depending on the weather, nature of the soil and habits of your patrons and employes. Never under any circumstances allow a car to go out on the road filthy; it will pay far better to run one car short on the line until it can be cleaned. It is the little things which make and save dollars in the street railway business, but not littleness.

The writer worked at one time for a street railway company doing a business of $400 per day, one-third of which was net, and yet owing to a difference of opinion between the president and the landlord as to who should pay for $12 worth of plumbing there was absolutely no water available in the office of the company for drinking or bathing. That the president's office was in another part of the city it is needless to say. Put the means of keeping clean in the way of your employes and you will never have to complain of lack of neatness. In one corner of the engine room of our plant a board partition was built enclosing a space 8 x 10 ft.; in this was placed a 6-ft. copper lined bath tub costing $6.50, and a porcelain basin costing $4; the men about the plant ran a ½-in. pipe from the exhaust steam heater, and another from the cold water pipe to the bath room. We hung an 8-in. shower head above the tub and at a total cost of $14.50 had a bath room which so far as convenience and effectiveness is concerned is just as good as can be desired. A sign was put on the door, "No one but employes allowed to bathe in this room." The result was: An engine room kept clean, the machinery kept bright, the fire room swept, and a set of men who leave the plant for their homes looking and feeling like gentlemen. Further, and largely because of such little things, the corporation enjoys the confidence and respect of its employes. Say a word against the company or its methods to one of them and you either retract or fight on the spot.

The owner of the aggregation of interests under the corporate head of the Yoakum Improvement Co. is an English gentleman living in Liverpool; when the Spanish-American war began he purchased an American flag (cost probably $3) and sent it over with his compliments, requesting that it be raised above the standpipe of the water works, the highest point in the city. This was a little thing, but if you could have seen the crowd at that flag raising and hear the cheers for the Englishman you would have realized strikingly what a little tact will do to make a corporation popular with its employes and also with the masses, upon whom its existence depends.

Put a bath room and a reading room at each car shed and fit them up cheaply but efficiently. Do not fill the reading room with agricultural reports and Sunday school books, but buy paper backed novels, take the daily papers, subscribe for all the best electrical and mechanical publications, buy sets of chess, dominoes and checkers, and have the thing

absolutely free; then provide for keeping it clean and orderly by appointing a competent janitor, and furnishing him a barber's chair and a shoe polishing outfit, letting him take all he receives from the men for work in his line as his salary. Limit his charges to one-half or two-thirds the usual rates and prohibit him from annoying the men by soliciting patronage. The result will be, an employes' club, a set of contented men; when you need an "extra" you can put your hand on the crew instantly; gambling houses and saloons lose patronage; habits of neatness inculcated which prevent the employe from defiling the cars or allowing others to do it; less car cleaning is needed; less repairs to rolling stock; more patronage because everything is in good order, and goes with a snap only found where the employe has the interest of the company at heart, because he knows the company is interested in him. In the next paper, will be discussed the handling of car bodies and motors with the pneumatic lifts, cleaning motors with compressed air, and the use of pneumatic tools in the shops.

CHICAGO UNION TRACTION CO.

The organization of the Chicago Union Traction Co. was perfected at meetings of the stockholders held June 29th and 30th. Mr. W. S. McCrea was chosen temporary president of the Union Traction and as such received from Mr. Yerkes the two leases of the North and West Chicago properties giving as the nominal consideration therefor two silver dollars. The necessary formalities, examination of papers, transfer of stock, etc., occupied the greater part of two days and the delivery of the two leases was made at 11:45 p. m. June 30th. The terms of these leases and data concerning the property were given in the "Review" for June, page 374.

The stockholders of the new company elected the following directors: W. L. Elkins and P. A. B. Widener, Philadelphia; R. A. C. Smith and H. B. Hollins, New York City; Jesse Spalding, Charles L. Hutchinson, William Dickinson, Walter H. Wilson and C. K. G. Billings, Chicago.

The directors chose officers as follows: President, Jesse Spalding, Chicago; first vice-president, R. A. C. Smith, New York; second vice-president, Walter H. Wilson, Chicago; general manager, John M. Roach, Chicago; treasurer, J. H. Eckles, Chicago; assistant treasurer, L. S. Owsley, Chicago; secretary, J. C. Moore, Chicago; auditor, F. E. Smith, Chicago. John P. Wilson was appointed general counsel.

Mr. Spalding, the president, was born in Bradford County, Pennsylvania, Apr. 15, 1837, and graduated at the Athens Academy.

His early life was spent upon his father's farm, and later he was engaged in rafting logs down the Susquehanna River and Pine Creek. He was soon buying lumber for his employers, and when 23 years of age he was buying and shipping for himself. In 1860 he came West and realized the possibilities of Chicago as a lumber mart, and he determined to come here at no distant date. He accordingly established mills at Menekaunee, Wis., and at the mouth of the Cedar River, and established a sales yard in Chicago at Lumber and 12th Sts. Mr. Spalding was largely interested in the opening of the new lumber district at 22d St., which then had no street car connections. Partially through his energies the Lake Michigan Ship Canal & Harbor Co. was organized, which opened a canal across the peninsula from Sturgeon Bay to Lake Michigan, shortened the lumber route to Chicago by 150 miles and placed the shipping of lumber upon a safer basis. In 1892 the Government purchased the canal and made it free to the public. It was Mr Spalding who built Camp Douglas at the breaking out of the war. He has been always prominent in the counsels of the Republican party, and in 1883 President Arthur appointed him collector of the port at Chicago and in 1889 President Harrison made him one of the commissioners of the Union Pacific R. R. Under Mayor Colvin Mr. Spalding was for three years a member of the city council, and was instrumental as chairman of the finance committee in completely restoring the financial credit of the city. There are few men who have exercised a wider influence over the mercantile, political and social interests of Chicago than Mr Spalding, he is now a director in the Commercial National, Garden City and Hibernian banks and is president of the Spalding Lumber Co.

John M Roach is too well known among street railway men to require introduction to them, having been the general manager of the Yerkes System in Chicago; J. C. Moore has been secretary and treasurer of the North Chicago Street R. R.; L. S. Owsley has been secretary and treasurer of the West; J. H. Eckles is president of the Commercial National bank and was comptroller of the currency under Mr. Cleveland. F. E. Smith resigned as auditor of the Massachusetts Electrical Cos. to accept his present position; prior to the Massachusetts combination he was auditor of the Lynn & Boston and the Beverley & Danvers roads, of Lynn, Mass.

ELECTRIC CARS ON CHICAGO CITY CABLE LINES.

A little over a year ago the Chicago City Ry. was obliged to erect overhead electric wires on the down-town cable lines in order to accommodate its patrons while the Clark St. line was closed by reason of the railroad track elevation work at 16th and Clark Sts. These wires were removed as soon as the necessity for bringing electric cars over these tracks was over; now electricity is to be again used on the State St. line, this time because of repairs at the 21st St. cable station.

It will be necessary to rebuild the foundation of the cable driving machinery at this station. Recently one of the iron bedplates cracked; in addition to this the brickwork of the foundation has been injured by the oil and tar from the cable that fell upon it, and collected in the pits under the driving drums. This driving plant was erected in 1881, when the cable engines developed only 500 h. p.; they are now giving 3,000 h. p.

There are in this station three pairs of steam engines; the foundations of the pair first installed are in need of repairs, but it has not yet been decided whether to rebuild them, or take out these engines and put in a motor.

The State St. line between Van Buren and 63d Sts. will be operated by electricity, that portion north of 39th St. from the 21st St. station, and south of 39th St. from the 52d St. station of the company.

The company has for some years used a 600-h. p. motor for driving cable machinery in the 52d St. station; and this motor is now being placed in the 21st St. station, where it will run as a generator, being driven from a flywheel on the station jack shaft.

It has not yet been decided what provision will be made for handling the traffic on State St. north of Van Buren. The original intention was to run cars east on Van Buren to Wabash, and thence north on Wabash and around the cable loop; the Union Elevated Railroad Co. objected to having wires attached to its structure, and until a settlement is reached horse cars will probably be used on the State St. line below Van Buren St.

In the course of erecting the overhead work, which was done between June 22d and July 11th, 137 poles were set in one day, which is believed to be a record in pole setting.

ENJOINED FROM SELLING BONDS.

Justice Lambert, of the New York Supreme Court, has enjoined the Lima-Honeoye Falls Railway Co. and its receiver, Chas. B. Hill, from selling $40,000 worth of bonds issued for the sole purpose of rebuilding the road and erecting an electric lighting plant. D. A. Crage and Wm. F. Tench, a firm of Buffalo contractors, rebuilt the long abandoned steam road between these two cities, remodeling it into an electric line. The trolley road lost money and was again partially abandoned while still owing the contractors $10,042.50. The bonds were held in trust by A. F. Williams to be delivered to the contractors when the road was completed and it is alleged that Williams transferred the bonds to other parties for $10,000, which was much less than their value, and that no part of this money was paid to the contracting firm. The contractors ask that the transfer be declared illegal, and that judgment be given them against the railroad.

The tramway on the Blackpool (Eng.) promenade has been changed from the conduit to the overhead trolley system.

Decision in the Detroit Case.

Text of the Decision of the Supreme Court of Michigan Holding the Law Providing for Municipal Ownership of Detroit Street Railways to be Unconstitutional—Interesting Resumé of the Question of State Ownership in Michigan.

Mr. Justice Moore wrote the opinion of the court as follows:

Horace M. Oren, attorney general, vs. Hazen S. Pingree, Elliott G. Stevenson, Carl E. Schmidt.

This is a proceeding brought to test the validity of an act entitled "An act to authorize the City of Detroit to construct, acquire, maintain and operate street railways, and to construct extensions thereof." The provisions of the act material to this discussion are as follows:

"The people of the State of Michigan enact:

Section 1. That the common council of the city of Detroit, be, and is hereby authorized and empowered to appoint by resolution at any time within the next twenty years, three persons, electors and free holders of said city, who shall constitute a board of commissioners, to be known as the Detroit Street Railway Commission. One of said commissioners shall be appointed for the term of two years, one for a term of four years, and one for a term of six years. Their successors shall be persons of like qualifications, and shall be appointed by the common council on the nomination of the mayor of said city at the expiration of said term for the term of six years. Vancancies shall be filled by appointment by the mayor, and persons so appointed shall hold office for the unexpired term. All members of said commission shall hold their offices, respectively, until their successors are appointed and qualified. Any person otherwise eligible may be appointed as aforesaid, notwithstanding he may hold other office, excepting that of alderman.

Sec. 5. The said commission may in their discretion and upon such terms and conditions as they may deem advisable for the interests of said city aquire, by deed, lease or other satisfactory conveyance from the company or companies owning the same to said city, any street railway or railways existing at the time of the passage of this act and lying wholly within or partly within and partly without said city, operated by the same company or companies, together with the property, assets, rights, privileges, etc., owned and used in connection with or pretaining to said railways, including rights to routes belonging to such company or companies upon which a railway shall not be in operation, and may operate and maintain said street railways so acquired, for the carriage of passengers and freight for hire.

Sec. 6. Said commission may provide for the payment of rentals or other obligations and may provide for a sinking fund for the discharge of any liens upon any of the property acquired by them, and may pledge the earnings and receipts of said railways for these purposes, and may use the earning in operating and maintaining the same, and may use any surplus of earnings in acquiring any bond secured by lien upon the property so acquired, or may use such surplus in making needed extensions or betterments to said railways. Said commission shall have no power to incur any obligation on behalf of said city except such as shall be chargeable only upon the railways and property so acquired and the earnings and increments and extensions thereof.

Sec. 7. The said commission shall manage, maintain and operate any street railway so acquired or extended, and may purchase from the revenue therof all lands, tracks, cars, motors, dynamos, machinery, equipments, tools and furniture necessary and useful therefor to be used in connection therewith, and may establish rates of fare for the carriage of passengers and freight, provided the rates of fare shall not exceed those now charged by the Detroit Citizens' Street Railway Co. In operating any railway so acquired, the commission may exercise such other general powers as are possessed or exercised by boards of directors of corporations organized under the laws of this state providing for incorporation of street railway companies.

Sec. 8. After acquiring any railway or railways pursuant to section five hereof, said commission shall have the power to enter into agreements with any street railway company having a line of street railway, for or in relation to the exchange of tickets and transfers, and for the carriage of passenger, use of tracks or operation of cars, provided that such agreements shall not be inconsistent with or in violation of the terms of the conveyance or contract mentioned in section five hereof.

Sec. 11. All causes of action relating to or arising out of the owning, operating or control of any street railway constructed or acquired by said commission shall be prosecuted by or against said commission by the name herein designated and said commission shall carry into effect, pay or discharge any order, degree or judgment, in any suit or proceedings to which it shall be a party, in like manner as if the same were prosecuted or defended by said city: Provided, that no action for negligent injury arising out of operation of said railway shall be maintained unless it be commenced within one year from the time when the injury was received, nor unless notice shall be given in writing within thirty days from the time of such injury to the said commission, its secretary or attorney, of the time, place and circumstances of such injury and of the nature thereof.

Sec. 12. Nothing in this act shall be construed as granting any franchise to any of the existing street railway companies, or as extending the life of any existing franchise, or as implying any franchise rights in the case of reversion of the property to the grantors or their successors; and said commission is hereby expressly prohibited from granting or extending the life of any franchises under any of the powers conferred upon it by this act."

After the passage of the act the common council at an adjourned special meeting appointed the defendants as members of the commission, and they at once entered into negotiations for the purchase of the various street railways in Detroit.

The case is one of vast importance not only because of the magnitude of the interests involved, but also because the law provides an entirely new departure in this country, in relation to the ownership and management of one of the most important interests in the business world. We are not favored with precedents which will aid us, because with all their zeal and ability, counsel have not yet been able to find where an undertaking just like this has been entered upon. We have, however, had the benefit not only of well prepared written briefs, but of such oral arguments as the learned counsel who have given the questions involved special thought and investigation, cared to make. We have endeavored to give the case such attention as its importance deserves.

It is claimed on the part of the attorney-general the act is unconstitutional and void for the following among other reasons:

1. Because said act undertakes to confer upon the city of Detroit authority to engage in a work of internal improvement, contrary to the provisions of section 9 of article 14, of said constitution.

2 Because said act undertakes to confer upon a municipal corporation powers which are neither local, legislative nor administrative, contrary to the provisions of section 38, of article 4, of said constitution.

3. Because said act purports to give to said "Detroit Street Railway Commission" mentioned in said act, unlimited and unrestricted power to contract debts for and loan the credit of said city of Detroit, contrary to the tenor and effect of section 13 of article 15 of said constitution, which provides that the legislature shall provide for the incorporation and organization of cities and villages, and shall restrict their powers of taxation, borrowing money, contracting debts and loaning their credit.

4 Because the powers to contract and purchase sought to be conferred by said act upon said "Detroit Street Railway Commission" cannot be either conferred upon or exercised by said commission, under said constitution.

5. Because said act attempts to clothe said "Detroit Street Railway Commission" with legislative powers as to street railways and the operation and management of the same.

6. Because said act is an unlawful interference with the rights of local self government vested by said constitution in the citizens of said city, in that it undertakes to take out of the control of the Common Council and Board of Estimates of said city the several matters of purely local concern, above mentioned, and vest the

same in the said "Detroit Street Railway Commission," which is a body of members of which hold their offices for long appointive terms, are a law unto themselves and are subordinate and responsible neither to said citizens nor to their representatives in any manner or form."

Is the act contrary to section 9, article 14, of the constitution? The section reads as follows: "The state shall not be a party to or interested in any work of internal improvement nor engaged in carrying on any such work, except in the expenditure of grants, to the state, of land or other property." It is doubtless true, as argued by counsel, that the state legislature is given a general grant of legislative power and that its power to legislate is subject only to such limitations as are imposed thereon, by the express or implied limitations contained in the constitution of the state or the constitution of the United States.

To understand the force and effect of the provisions of our constitution in relation to the attitude of the state toward internal improvements, it may be well to consider the experience of other states, and of our own state prior to the adoption of our present constitution.

The war of 1812 demonstrated the great need of a better system of intercommunication between the various portions of the country; the condition of the highways, both land and water, was such that troops and provisions could be moved but slowly and at great expense. This was also true of the products of the country.

Succeeding the war of 1812, the state of New York entered upon the construction of the Erie canal. Its construction was doubtless of great benefit to the agricultural and commercial interests of the state, and especially to the city of New York. Other states were prompted to follow the lead of New York and projected the digging of canals, the improvement of waterways and the construction of railroads. Nearly all the state constitutions adopted between 1830 and 1850, either gave the legislature permission or made it mandatory to "encourage internal improvements within the state." Many enterprises of this character were entered upon, which were ill-advised; so many of them were undertaken, many of the states incurred obligations they were unable to meet. The rate of interest in these new countries was much higher than capital commanded in Europe. Money from there after 1830 was furnished almost without limit to be invested in the various projects devised by the several states. The state debts increased from thirteen millions in 1830, to one hundred millions in 1838. After the financial crisis of 1837 came, foreign capitalists who sought to draw out this money were unable to do so. An effort to collect these obligations proved abortive. Upon one pretext or another, many of the states repudiated their debts made for internal improvements. The states most disastrously affected were Maryland, Pennsylvania, Indiana, Illinois, Louisiana, Mississippi and our own state. 2 Cyclopedia of Political Science, 571.

For the period between 1835 until the financial panic of 1837 occurred, the state of Michigan had a wonderful growth. The opening of the Erie canal, and the facilities for travel furnished by the great lakes, made it comparatively easy for the residents of New York, New Jersey and New England who were seeking to better their condition to reach our borders. The climate was good and the soil was fertile. The example of New York in constructing works of internal improvement was thought worthy of imitation. The constitution adopted, upon the admission of the state into the Union, provided "internal improvements shall be encouraged by the government of this state; and it shall be the duty of the legislature as soon as may be to make provisions by law for ascertaining the proper objects of improvements in relation to roads, canals and navigable waters, and it shall also be their duty to provide by law for an equal, systematic and economical application of the funds which may be appropriated to those objects." The governor of the new state in a message to the legislature called its attention to its duty to act under the constitutional provision. The legislature was not slow to respond. A canal was projected from Mt. Clemens to the mouth of the Kalamazoo River, and one around the Falls of the St. Mary. A number of state railroads were surveyed and their construction entered upon. To meet the expense the governor was authorized to borrow upon state bonds, issued for the purpose, five million two hundred thousand dollars. These bonds were all negotiated, though owing to the failure of one of the companies and one of the banks, which undertook to negotiate them, the amount for which they were negotiated never found its way into the state treasury. It became evident the amount of the loan would not begin to complete the internal improvements already begun. Then came the financial panic, bankruptcy and financial ruin were upon every hand. The state, at a great sacrifice of its property, made an arrangement with its creditors, which left its credit good, but left it badly in debt

Cooley's History of Mich. 279.

Campbell's History of Mich. 495.

As the result of this experience, the state had the canal at the St. Mary's River which was afterwards taken over by the federal government, and is now one of the most important improvements upon the great lakes; a short section of a canal which has never been of any use except to furnish water power to private parties, and some uncompleted railroads which the people were glad enough to have sold to private corporations. Justice Cooley states the situation in detail: Cooley's History of Mich. 289.

"The works of internal improvement still remained on the hands of the state, and in the day of its poverty and trial they were continually calling upon a depleted treasury for money to keep them in progress. But now that the great bubble of speculation and inflation was burst, it became plain to the comprehension of the dullest that some of the state's projects were wild and chimerical, and they were abandoned altogether. Such was the case with the projected canal from Mt. Clemens to the mouth of the Kalamazoo River, which it is now seen would be worthless, if constructed. The only works, of much promise, were the central and southern of the three railroads, which were now very well under way. But doubts were arising in the minds of the people, whether the state had been wise in undertaking the construction and management even of these; whether it was possible for the state to do either the one or the other with the same prudence and economy as could private owners.

"These doubts soon matured into a settled conviction that the management of railroads was in its nature essentially a private business, and ought to be in the hands of individuals. By common consent it came to be considered that the state in entering upon these works had made a serious mistake; and the legislature in an act for funding the loan bonds, invited proposals from state creditors for the purchase of the state railroads. The times were not then propitious; but in 1846 the Central and Southern Railroads, so far as they were then constructed, were sold by the state, to corporations which had been chartered, for the purpose of purchasing. The aggregate price was two millions and a half, a sum very much below what had been their cost to the state. But the people felt the roads were well off their hands, and as has been said by one familiar with the whole history. 'Here virtually ceased to exist all our works of internal improvement. Nothing but the debris of our airy castles remained; and that only to plague our recollections.' The two great railroads when taken up by corporations went rapidly forward to completion; and they soon became great national highways, whose utility to the state was quite equal to the highest expectations ever formed concerning them.

"Having all their bitter experience with internal improvements fresh in mind, when they formed a new constitution, in 1850, the people resolved to put it out of the power of the legislature again to involve them in extravagant projects. And here we reach another landmark, significant in itself, but especially notable when contrasted with the provision respecting internal improvements which has already been quoted from the constitution of 1835. In 1850 the people deemed it necessary to prohibit what in 1835 they commended; and they now provided that the state shall not subscribe to or be interested in the stock of any company, association or corporation, and also that the state shall not be a party to or interested in any work of internal improvement, nor engaged in carrying on any such work except in the expenditure of grants to the state of land or other property. These were very positive provisions; and by adopting them the people believed they had rendered it impossible that projects of doubtful wisdom and utility should be engaged in at the public cost.

"But diseases in the body politic, like those in the human system, are likely to take on new forms from time to time and they are not to be exorcised by words, or kept off by constitutional inhibitions. The mania for internal improvements at the cost of the public when it returned fifteen years later under the administration of Gov. Crapp took on the form of aid to railroad corporations by the several municipal bodies of the state. Such aid was being given in other states, and railroads as a consequence were being constructed

with a rapidity never paralleled. Michigan was lagging behind the rest of the country; why should not this be so? Every town which should subscribe to the stock of a railroad would immediately receive a full return in the enhanced value of its landed property, and would have the stock besides. This was what was commonly said and commonly believed; and the legislatures, well reflecting the common desire, passed a general law under which townships and cities were to be permitted to vote aid to railroads. The railroads, under another general law, might be laid out anywhere by the projectors at pleasure, so that monopoly in these public conveniences seemed to be effectually provided against. The governor vetoed the railway aid act, but the legislature passed it over his veto. The business of voting aid to railroads was soon active, and the most visionary scheme was found as likely to receive aid as any other, perhaps more so, for more work would be done for it. Nothing is so easy as to build railroads if it can be accomplished by dropping votes into a box. Only fossils and croakers will disturb the public mind by reminders that the sums voted must at some time be paid, and that the roads when built may pay nothing towards them. The state in detail, by its corporations, was fast plunging into indebtedness, which had already reached an aggregate of several millions, when the process was arrested by a decision of the state Supreme Court that the act under which the voting had taken place was unconstitutional.

"The decision was a bitter disappointment to many, and the public clamor for a time was loud and earnest; but a movement to obtain an amendment to the constitution which would permit such municipal aid to railroads was unsuccessful, and the excitement soon died out. The people had taken the "sober second thought," and had become convinced that municipal corporations in their power to contract debts or to expend public moneys should be confined closely to proper municipal purposes. And this conclusion may be taken as a third conspicuous landmark in the history of internal improvements in Michigan."

The cases referred to by Justice Cooley were, People vs. Salem, 20 Mich. 487; Bay City vs. State Treasurer and Thomas vs. Port Huron, 27 Mich. 320.

We think it may fairly be said of the case of People vs. Salem, the opinion was rendered upon the ground that the tax proposed would be levied for a private rather than a public purpose. This, however, cannot be said of the case of Bay City vs. State Treasurer. In the last named case it is held the construction of the railroad was an internal improvement within the meaning of the constitution, and that what the state could not do, it could not authorize the townships and cities to do. The language of the opinion is not susceptible of any other construction. It is very clear from what has been quoted from the history of Michigan, written by Judge Cooley and published in 1885, that he so construed the decisions cited. The language of the opinion is as follows:

"Our state had, once before, a bit of experience of the evils of the government connecting itself with works of internal improvement. In a time of inflation and imagined prosperity, the state had contracted a large debt for the construction of a system of railroads, and the people were oppressed with heavy taxation in consequence. Moreover, for a portion of this debt they had not received what they had bargained for, and they did not recognize their legal or moral obligation to pay it. The good name and fame of the state suffered in consequence. The result of it all was that a settled conviction fastened itself upon the minds of our people, that works of internal improvement should be private enterprises; that it was not within the proper province of government to connect itself with their construction or management, and that an imperative state policy demanded that no more burdens should be imposed upon the people, by state authority, for any such purpose. Under this conviction they incorporated in the constitution of 1850, under the significant title of 'Finance and Taxation,' several provisions expressly prohibiting the state from being a party to or engaged in carrying on any work of internal improvement, or engaged in carrying on any such work, except in the expenditure of grants made to it; and also from subscribing to, or being interested in, the stock of any company, association or corporation, or loaning its credit in aid of any person, association or corporation. Article 14, sections 9, 8 and 7.

"All these provisions were incorporated by the people in the constitution as precautions as against injudicious action by themselves, if in another time of inflation and excitement they should be tempted to incur the like burdensome taxation in order to accomplish public improvements, in case they were not content to wait the result of private enterprise. The people meant to erect such effectual barriers that if the temptation should return, the means of inflicting the like injury upon the credit, reputation and prosperity of the state should not be within the reach of the authorities. They believed these clauses of the constitution accomplished this purpose perfectly; and none of its provisions had more influence in recommending that instrument to the hearty good will of the people."

The doctrine of these cases was again affirmed in Thomas vs. Port Huron, 27 Mich. 320. These cases all hold that what the state cannot do itself, cannot be done through the aid of inferior municipalities.

Counsel urge that the doctrine announced in People vs. Salem; Bay City vs. the State Treasurer and Thomas vs. Port Huron, was never accepted as correct by the profession in this state, and is contrary to the decisions of other courts. If we understand the logic of the argument, it is, that those cases should be overruled. We have had occasion recently to consider a contention of like character and supposed we had so clearly expressed ourselves, that the doctrine of those cases could no longer be questioned. We do not deem it necessary to repeat what was said upon that subject in Dodge vs. Circuit Judge, 76 N. W. Rep. 315.

Counsel suggest it is as competent to authorize the city to own and operate a street railway as to acquire and maintain a public park, water works, a lighting plant or a fire department, or to construct drains or construct sewers. It may be somewhat difficult to draw the line as to what a municipality may properly do and what it may not do, but all the things above mentioned are authorized and defended because it is a proper exercise of the police power. An adequate supply of water is needed for protection against fire. Fourth edition Dillon Municipal Corporations, sections 144, 146.

There can be no matter of higher public concern to any city than the supply of pure and wholesome water for all useful purposes and as population becomes more and more compact and cities grow, the ability of the individual member of the municipal corporation to supply his individual wants in that direction constantly diminishes and in all larger places it becomes a matter of absolute public necessity that the city itself should directly or indirectly provide the supply. Nothing so affects the health of the community as the character of its water supply. Prentise on Police Powers, 303.

Drains and sewers and parks are all needed in the interest of public health; 2 Dillon Munic. Corp. 4th ed., Sec. 598; Kinne vs. Bare, 68 Mich. 625; Prentise on Police Power, 56, 131, 242. Lighted streets tend to the prevention of crime. Police powers have their origin in the law of necessity; Prentise Police Power, 4. The exercise of these powers has little in common with what is sought to be done here.

It is urged that the internal improvements contemplated by the constitution must be of sufficient magnitude as to concern the people of the state. Citing Sparrow vs. Commissioner, 56 Mich. 575, and that street railways are mere local improvements, or a strictly local interest not known at the time the constitution was framed, and are not such improvements as are contemplated by the phrase, internal improvements, citing Street Railway Company vs. Detroit, Federal R., 646; Railway Co. vs. Mills, 85 Mich. 634.

It is not claimed these cases are directly in point, but that some statements contained therein lead to the conclusions just stated. The questions involved in this case were not at issue in the cases cited, and the opinions do not tend, in our judgment, to support the contention of counsel. We shall have occasion later to consider whether the improvements are of sufficient magnitude to be deemed internal improvements.

It is said if the theory of the atorney-general is sound, the city of Detroit cannot construct a macadamized road, or pave a street, or build a sewer. It is a complete reply to this suggestion to call attention to the fact that by sections 23 and 38 of article 4 and section 1 of article 11, the constitution has given to townships the control of highways, and to the cities and villages the control of the streets, for all purposes germane to their use.

It is said that while steam railroads are in a sense public highways, in another and legal sense they are not public highways, but that street railways are in every proper sense, public improvements within the meaning of our constitution. Our attention is called to the case of the Sun Printing & Publishing associa-

tion vs. Mayor, etc., N. E. R., 503, as sustaining this contention. It is true that case holds that it is within the legislative power to authorize the city to construct a street railway under the streets of New York, and when constructed to lease it for not less than thirty-five, nor more than fifty years, at a rental not less than the interest paid by the city for the construction, and one per cent in addition. The writer of the prevailing opinion stated the case was not free from difficulty, and the court considered the case, "hoping to reach a result that will afford necessary relief to the city and at the same time preserve the general policy of our system of government." It appears in that case that pursuant to the provision of the act the commissioners entered upon their duties and located a road to be built under the streets, through the main portions of the city, and then tried to induce private capitalists to undertake its construction. No private capitalists were willing to undertake the construction of the road and it was undertaken by the commissioners for the city.

In the course of the discussion reference was made to certain cases decided by the Ohio court, and this language is used: "We do not understand that the views above expressed are in conflict with the Ohio cases. In that state the constitution does not limit municipal expenditures to 'a city purpose.' We do not, however, wish to be understood as approving of those cases especially in so far as they sustain the right of a city to construct a railroad mainly outside of its own territory and state." In conclusion the opinion is as follows:

"Our government was established by the people for their own protection and welfare. Their policy was to foster and protect individual industry and enterprise. To such policy we owe our advancement as a nation, and to such we may look for our future prosperity. The constitution should be construed with reference to this general policy, and ordinarily railroads should be constructed and operated by private capital. The situation, however, in the city of New York, is most peculiar. A long, narrow island lies between two rivers, so narrow in places that there are practically but two or three streets through which the masses must reach its business center. The population of the city during the last half century has increased from three hundred thousand to over a million and a half of people. The travel upon its existing railroads during the last twenty years has increased from one hundred and fifty million in 1874 to upwards of four hundred and forty-eight million in 1894. It was conceded upon the argument that the crowded and congested condition of the travel upon the streets in the city renders the proposed structure necessary. These considerations have induced us to give to the provisions of the act a most liberal construction. The commissioners located the road, and tried to induce private capital to construct and operate it. In this they have failed and the situation is such that the city must itself construct the road or go without it. Here we have a demand for a great public highway, which private enterprise and capital will not construct. It is necessary for the welfare of the people, and is required by them. It is public in character and is authorized by the legislature. Our conclusion is, that under the circumstances and situation here presented, the proposed road may properly be held to be 'for a city purpose,' and that the acts are not in contravention of the provisions of the constitution."

The doctrine stated in the Ohio case cited Walker vs. Cincinnati, 21 Ohio S. 14, is contrary to the holdings of this court, as has already been shown, and cannot be reconciled with the later cases of Taylor vs. Commissioners, 23 Ohio St. 22; Wyscaver vs. Atkinson, 37 Ohio St. 80 and Counterman vs. Dublin, 38 Ohio St. 515. It is evident the conclusion reached in the prevailing opinion is based upon the ground that because of the crowded condition of the city and its peculiar shape, the improvement was a necessary one and that as private capital and enterprise would not enter upon its construction, it was lawful to authorize the city to do so. None of the conditions existing in New York justifying the city, if it was justified in entering upon the construction of the road, exist in Detroit. The city is already well supplied with means of transit, and if abuses exist in the management, the authorities have ample power to correct them. The dissenting opinion in this case is more in harmony with the law in this state, than is the prevailing opinion.

We are not entirely without light in relation to what constitutes an internal improvement within the meaning of the constitution. We have already seen that steam railroads come within the category. In the case of Ryerson vs. Utley, 16 Mich. 270, it was held that an attempt to improve the navigation of the Muskegon River by removing therefrom sand flats, came within the constitutional inhibition. In Hubbard vs. Springwells, 25 id. 152, it is said that a macadamized road is a work of internal improvement. "The shortness of the road does not change its character. The restriction is not against great works, but against all works of that kind, and the case comes within the language and intent of the prohibition." The court held that work of that character must be done by the local authorities because under the constitution they had been entrusted as we have already stated, with the care of the highways. In Anderson vs. Hill, 54 Mich. 477, it is held that a township cannot be authorized to vote money to aid in deepening or straightening the Dowagiac River, because it is an internal improvement. The court said "that the straightening or otherwise deepening the channel of Dowagiac River in Van Buren County expresses a work of internal improvement, needs no argument." * * * * If the legislature has the authority to pass a law permitting the majority of the legal voters of a particular township to impose a tax to aid the state in the work of an internal improvement, it has the authority to impose such by direct enactment without the intermediate step of a vote of the people and against their wish, and the rule is well settled if it has not the power to impose such tax directly, it cannot authorize the imposition of the tax indirectly through a vote of the municipality or people."

In Sparrow vs. Com. of Land Office, 50 Mich., 367, it was held that straightening and opening the channel of Cedar River was an internal improvement, though the decision was put upon another ground. Justice Campbell used this language: "There can be no doubt of its being a work of internal improvement. That phase is as broad as language can make it. It can make no difference for what direct or indirect purpose of public utility an improvement is made so long as it comes within such definition, and it can make no legal difference over how much of the state it passes. All works of convenience, whether for travel, drainage or irrigation, are similar in their nature when small and large, and works for all of these purposes have been made of all dimensions, and for large and small districts. It is impossible to draw any line of magnitude. Any such work that is deemed important enough for the state to construct is within the rule, and if not built in the permitted way is within the prohibition." Justice Champlin agreed with this statement, while Justice Cooley said he did not intend to question the correctness of the decision in Ryerson vs. Utley and Hubbard vs. Springwells. In Wilcox vs. Paddock, 65 Mich., 23, it is held that the straightening and deepening of Maple River is an internal improvement within the meaning of the constitution. The constitution of Minnesota has a provision that "the state shall never contract any debts for works of internal improvement or be a party in carrying on such works." A bill was passed providing for a board of railway and warehouse commissioners, who were authorized to erect a state warehouse or elevator at Duluth, for public storage of grain. This was held to come within the constitutional inhibition and the learned judge enters upon an extended discussion of what constitutes internal improvements and the authorities relating thereto. It is too long to insert here. This language is used in the opinion: "The time was when the policy was to confine the functions of government to the limits strictly necessary to secure the enjoyment of life, liberty and property. The old Jeffersonian maxim was that the country is governed the best which is governed the least."

At present the tendency is all the other way and towards socialism and paternalism in government. This tendency is perhaps to some extent natural as well as inevitable as population becomes more complex in its relations. The wisdom of such a policy is not for the courts. The people are supreme and if they wish to adopt such a change in the theory of the government, it is their right to do so. But in order to do it, they must amend the constitution of the state. The present constitution is not framed on any such lines.

When the reasons arose for placing in the constitution the provisions in relation to internal improvements, judged from our standpoint, the railroads were imperfect, their passenger cars were not much heavier than the large stage coaches and would carry from eighteen to twenty-four passengers. In many instances the rails were flat bars of iron, less than an inch thick, laid upon rails of wood and kept in place by spikes. The roadbeds were not well graded nor heavily ballasted; the locomotives weighed from two to six or seven tons. Cars were passed over the steeper grades by counter weights of box cars, weighted with stone, which balanced them like

window weights balance window sash. As there were no long railways, there was no freighting, except light articles, for any considerable distance. The rolling stock was cheap and scanty; great weight and great speed would have destroyed the tracks. The entire cost of building what is known as the Michigan Central road to Marshall was about $2,000,000, and it is probable the value of all internal improvements entered upon by the state was less than $5,000,000.

Campbell's History of Michigan, 484.

The pleadings show that the various street railway companies own and operate in Detroit, one hundred and forty-one miles of street railways which the defendants propose to take over; if the tracks inside the car barns and abandoned tracks be added, the single track milage is about 179 miles. There is a bonded debt upon these roads of upwards of $10,000,000, and their property is regarded as worth between $5,000,000 and $17,000,000. It is currently reported the commission propose to pay upwards of $16,000,000 for this property, besides assuming its indebtedness. By virtue of agreements made between these companies, there are run on their lines in Detroit, cars owned by other companies, which start from Pontiac, Oakland Co.; Mt. Clemens, in Macomb Co.; Ann Arbor, in Washtenaw Co., and the city of Wyandotte, in Wayne Co. The tracks of these roads are laid in a very substantial manner. The cars of the outside roads will accommodate fifty to seventy-five passengers each, are of great size and run at frequent intervals. It is a matter of common knowledge that over some of these lines, cars marked "special" are now run at frequent intervals carrying freight. An electric road is now projected from Ann Arbor to Lansing, and from other of the lines now reaching Detroit to various points in the interior of the state. This method of transit or some improvement thereon is yet in its infancy. It does not require one with the ken of a prophet to see that in the near future the villages and cities of the state will be connected with a network of methods of rapid transit.

By the terms of the bill, section 5, "The said commission may in their discretion, and upon such terms and conditions as they may deem advisable for the interest of said city, acquire by deed, lease or other satisfactory conveyance from the company or companies holding the same to said city any street railway or railways existing at the time of the passage of this act, and lying wholly within or partly without said city, operated by the same company or companies, together with the property, assets, routes, privileges, etc., owned and used in connection with or pertaining to said railway, including rights to routes belonging to such company or companies upon which a railway shall be in operation, and may operate and maintain the said street railways so acquired for the carriage of passengers and freight for hire."

Another section provides that after acquiring any railway pursuant to section 5, the "commission shall have the power to enter into agreements with any street railway company having a line of street railway for or in relation to the exchange of tickets and transfers and for the carriage of passengers, use of tracks or operation of cars," provided such agreement shall not be contrary to the provisions of section 5.

It is stated in the briefs of one of the counsel for defendants that during the past year the railways of Detroit carried forty-five millions of passengers. The state roads of 1850, crude as they were, provided improved methods of moving passengers and freight over what had before been in vogue. The electric roads of 1899 are still greater improvements for the same purpose. The rails used by the electric railway are much heavier, and more substantial. The track is much more substantial than those used prior to 1850. The cars will accommodate three or four times as many people. The transit is much more rapid.

The entire cost of all the improvements entered upon by the state would not amount to one-half the amount which the record discloses the commissioners expect to pay for the property they intend to take.

To say the system of railroads as it existed in 1850 constituted internal improvements within the meaning of the constitution, and that the system of roads existing in Detroit, which are to be taken over by the commission, and the lines leading thereto with which said commission is allowed to make agreements for deeds, leases and in relation to the exchange of tickets and transfers, is not a system of internal improvements within the meaning of the constitution, is to deny to words in common use their ordinary and accepted meaning. If the legislature may authorize the city of Detroit to enter into the proposed arrangement, it may authorize any other municipality to do so, and by concert of action, between the various municipalities, they may cover the state with means of rapid transit, owned and operated by the municipalities. This would enable the state to do so by means of agencies called into being by itself, what it cannot itself do, and what the constitution forbids it doing.

It is said that the constitution was adopted a long while ago, and this is a gigantic age in which enterprises are being formed on a scale so vast as to be almost beyond comprehension, and the constitution ought to be given a construction in keeping with the spirit of the age. This argument is more properly addressed to the people than to the courts. Constitutions do not change as public opinion changes. Their provisions do not mean one thing one day and another another day. The written constitution is the most solemn declaration of the people in relation to the powers of state. It was drawn by their representatives selected especially for that purpose; it had their approval at the polls. Every officer of every kind in the state is required to take an oath to support it, before he can enter upon the duties of his office. It is not a pleasant duty to declare that a law passed by the legislature and approved by the governor is not valid. When such a law is enacted courts cannot for a moment hesitate in performing that duty, disagreeable as it is. The provisions of the constitution involved in this controversy have been in existence for nearly half a century. As we have already shown, they were construed along the lines of this decision nearly thirty years ago. The people of the state have not indicated in the way provided by the organic law any dissatisfaction with these provisions. The courts cannot substitute their judgment of what the constitution ought to be for what the people have made it. Its provisions must remain and control until the people see fit to change them in the way provided by the constitution itself.

McPherson vs. Secretary of State, 92 Mich. 377.

It is not necessary to discuss the very serious question whether a commission could be authorized to buy from five to eighteen million dollars' worth of property and subject the city of Detroit to the liability growing out of the operation of upwards of one hundred miles of electric street railways without giving the citizens and taxpayers an opportunity to say whether they wanted to purchase and operate such a business or not; nor is it necessary to discuss the other questions raised by counsel, for if we are right in our conclusion that the law is unconstitutional this disposes of the case.

We were asked by one of the counsel in his oral argument whatever our decision in this case might be to decide the question whether the city under any circumstances may build or buy lines of street railway in its streets all lying within the city limits and lease them upon such terms as the city authorities shall deem to be for the best interests of the citizens. It is not necesary to pass upon the question just stated in order to dispose of this case. The law under consideration involves much more than the simple question of municipal ownerhip of the tracks within the corporate limits, and in the decision of the case before us we do not deem it wise to express any opinion upon any question other than the one before us. It will be soon enough to pass upon the other question when it is necessarily before the court, and when the court can have the benefit of the conditions and surroundings then existing.

We think the law unconstitutional, that there is no such office as the "Detroit Street Railway Commission," and that defendants have no title thereto, and that judgment of ouster be entered.

The other justices concurred.

DETROIT & LAKE ORION RAILWAY CO.

The management of the Detroit & Lake Orion Railway Co. has cause for congratulation in the rapid progress it is making with its enterprise. The power house is a brick building designed and erected under the supervision of J. G. White & Co., of New York and Baltimore. The equipment comprises two 250-h. p. Cahall boilers, two 300-h. p. Ball & Wood engines, two 200-kw. Crocker-Wheeler direct-connected railway generators, one 60-kw. Crocker-Wheeler booster and one 90-kw. lighting generator.

The Metropolitan Street Ry., of New York, has decided to issue $5,000,000 more stock; its present stockholders will be permitted to take one-eighth of their holdings in the new stock at par.

WHICH HAS BEST RIGHT TO GONG?

Down in Savannah, Ga., the street cars have for a long time been equipped with a special type of rotary gong, the pealing tones of which penetrate a long distance. Recently the fire department became enamored of these bells and straightway equipped all is apparatus. Then nobody could tell whether it was a steamer coming down the street and to be scared, or just the electric car and pay no attention. The city council finally ordered the street railway people to pull off their gongs and go find themselves others which are different. It was at this critical juncture that the vice-president of the company, J. H. Fall, expressed himself as follows on the relative responsibilities of fire department and street cars:

"I cannot help but think that the council acted hastily in this matter. I have no doubt that the intentions were of the best, but if some representative of the street railway company had been given an opportunity to discuss the question the council might have been brought to see the matter in a different light. The only question is how the number of accidents resulting from collisions with street cars can be decreased. If two vehicles are approaching each other rapidly, even on a narrow street, an accident can be avoided by the driver of each vehicle sticking rigidly to the right hand side of the street. A street car motorman cannot avoid an accident in this manner. The car is pinned down, as it were, to two lines of rail. Either the vehicle or person occupying the track in front of it must clear the right of way or there is trouble, unless the motorman is fortunate enough to stop the car in time to prevent the accident.

"Again, an engine or a patrol wagon coming along the street, can avail itself of the entire street. If a man or child or a wagon suddenly comes upon its route from a cross street the driver can swerve his team to one side or the other and thus avoid an accident. The street car has no such advantage. It must either keep straight ahead or come to a full stop, and the latter is not always possible. Again, admitting rotary bells to be of advantage in preventing accidents, I think the argument is altogether in favor of their use by the street cars as against the fire apparatus. We have a number of street cars constantly on the street for the greater part of twenty-four hours. The fire department, with a less number of vehicles than we have cars, makes a run once a day, or once a week, and sometimes only once a month. The rotary gongs are, of course, an advantage to the fire engines, and they should not be without them, but the proportion of our need to theirs is as 100 to 1. In all probability, estimating the number of hours which each car is upon the streets, and placing against it the estimated number of hours which each vehicle of the fire department is upon the street, the proportion is probably nearer 500 to 1. That is, supposing all the street cars to be equipped with rotary gongs as well as the vehicles of the fire department the street car bells would be heard 500 times on the streets to every time a fire engine bell was heard.

"What we want to do is to reduce the possibility of accidents to a minimum. The bells are not attached to the cars for ornament. If the council says so we will attach a church bell to each car."

RAILWAY CONSTRUCTION IN MEXICO.

The manner of obtaining concessions from the Mexican Government for building railways and the way in which the roads are built and operated are explained in an interview with Mr. John P. Ramsey, general manager of the Rio Grande, Sierra Madre and Pacific Railroad, published in Modern Mexico.

Charters are obtained through the Department of Public Works and Communications, usually by individuals who reserve the right to transfer them to a company to be afterwards organized. The Government of Mexico maintains a monopoly of all railroads operated in the Republic, but the right to operate them for a specified time is often conferred upon corporations. When governmental assistance is given in the way of subsidies the franchise is usually given for 99 years after which the road reverts to the Government.

The Government then maintains representation on the board of directors and an inspector at all times on the work, not only when the road is under construction but after it is in operation. General offices may be located at any convenient place, but if not in the City of Mexico a representative must be stationed at that city. All plans must be approved by the Government. Subsidies vary in amount according to the difficulties met with in construction and range from $7,000 to $25,000 or even higher per kilometer. They are paid in Government bonds, in lands, or in both. The cost of construction of a standard gage road will vary from $10,000 to $50,000 per mile in mountainous districts.

Across the barren desert lands the work is performed most economically with teams and scrapers. The men live in camps along the line and food and water is drawn by teams from the nearest point of supply. Where sand is encountered the expense of supplies is very high. Water costs 50 cents in gold per barrel in camp. After the track is laid trains are used in covering the sand with clay and a heavy form of disintegrated lime called "calichi" which is found in large quantities. The labor employed is largely of the native "peon" class and a certain proportion of white and black Americans, the lowest wages being $1 per day in Mexican money.

There are no duties charged on materials of construction imported from the United States or elsewhere. After completion one man for every two miles will keep the track in good condition where traffic is light.

The fuel used is bituminous coal and cord wood. Coal costs from $4.25 to $6.00 per ton and wood is as low as $2.75 per cord. The wood used is principally "grease wood" roots dug from the sand hills by the Mexicans and transported to market on the backs of burros.

The rolling stock must include first, second and third class cars in accordance with Government regulations. No changes in the rates of fare may be made without authority and publication for 15 days if decreased, or 30 days if increased.

NOTES FROM NIAGARA FALLS.

The Niagara Gorge Railroad Co. commenced running under its new management on Saturday, July 1st.

It is expected that the International Traction Co. will open its electric car service across the new suspension bridge at Lewiston on the lower Niagara river some time during July.

Sunday, June 25th, was the heaviest day the Youngstown & Lewiston electric road ever had. Under the management of Mr. Frank G. Lott this road is capturing much new business.

Mr. L. D. Rumsey, president of the Youngstown & Lewiston electric road, has purchased river front property in the village of Youngstown for $3,500. It is the intention of the company to build a wharf on the property for the purpose of affording dock facilities for excursion steamers, the idea being to book excursions for Rumsey Park, on the line of the road on Lake Ontario. It is understood several thousand dollars will be expended in beautifying the park before next season.

The International Traction Co. hopes to have connection made between its Falls St. tracks and the upper steel arch bridge at Niagara Falls before August 1st. Plans have been submitted to the commissioners of the New York State reservation covering the proposed track on the Riverway from Falls to Niagara St., and as soon as the commissioners approve the plans, at a meeting soon to be held, the work of track laying will commence.

New York state factory inspectors are investigating the working hours of the employes of the Rochester Railway Co. The law in question provides that the men shall not be required to work for 10 consecutive hours. According to the schedule of the company, the men work 11 hours a day, in beats of five and six hours, with intermission of from one to five hours, and such an arrangements, the company holds, does not run counter to the provisions of the act.

A CORRECTION.

In describing the attractions of Sans Souci Park, the new Chicago pleasure resort, in our June issue, page 423, it was stated that Mr. W. R. Inshaw had built the large switch-back merry-go-rounds which are now operated in New Bedford, Mass., and Schenley Park, Pittsburg. Messrs. Norman & Evans, of Lockport, N. Y., advise us the statement as printed was incorrect, they having themselves built the two merry-go-rounds mentioned. We regret having inadvertently credited them to the wrong party.

IN THE POWER HOUSE.

This department is devoted to the construction and operation of electric railway power houses. Correspondence from practical men is specially invited. Both the users and makers of power house appliances are expected to give their views and experiences on subjects within the range of the department.

IMPORTANCE OF THE POWER HOUSE.

Mr. Granville C. Cunningham, who is well known to American street railway men as chief engineer of the Montreal Street Railway Co from 1892 to 1897, when he left Canada to become manager of the Birmingham (England) tramway system, recently read a paper before the Institution of Civil Engineers on "Mechanical Traction by Electricity," in which he gives his preferences in power house equipment and summarizes the results obtained in the plants under his management.

It is pointed out that the financial superiority of electric traction all lies in the saving in power, and for this reason the power house is the point on an electric system to which the skill and intelligence of the engineer should be mainly devoted.

Horse traction—by which is meant the cost of horse-keep, wages of grooms, shoeing, veterinary expenses, but excluding drivers' wages—is 3½d. per car-mile in Glasgow and 5d. in Liverpool. Glasgow is level and the annual car mileage is 7,000,000; Liverpool is hilly and the annual car mileage 4,000,000. As opposed to these figures the cost for fuel, wages, oil, and maintenance of the plant is placed at a little less than ½d. per car-mile for a level city and a little more than ½d. for a hilly city. Mr. Cunningham continues:

"But in order to insure this low cost of working, every care must be taken in the power house. In choosing its site, it should be placed so close to a plentiful supply of water, where all that is requisite for condensing purposes may be had at a nominal charge, or merely for the cost of pumping. A river, canal, pond, or the sea, would afford what is needed. It should be conveniently situated for the supply of coal from railway line, canal, or wharf, so as to save the charges of handling fuel. One shilling per ton saved in cartage would amount to a very considerable sum in a year in a large traction station. But, needless to say, the most important matter is the type of engines, boilers, and heat-savers to be used. The writer favors low-speed (70 revolutions) compound condensing engines, such as are built by numerous firms; boilers of the Lancashire or Galloway type, with Green's economizers. A plant of this character was constructed and worked under the writer's charge on the Montreal Electric Street Ry., with the result that the cost of producing current was a little under our farthing per kilowatt-hour, and the cost per car-mile less than a half-penny in the open months of the year, when coal could be obtained for 9s. per ton. The consumption of coal was 3.38 per kw. h., or 2.60 lb. per e. h. p. h., and this was maintained during months of working. The average for a whole year was only 2.75 lb. per e. h. p. h. It is not pretended that this is a phenomenally low rate of consumption. On board many of the large ocean-going steamers as low as 1.50 lb. of coal per h. p. has been reached with triple-expansion engines; but the writer believes that few electrical power houses have been able to show better results than those mentioned. Nor is the result to be attributed to a very large output; precisely similar results can be obtained by using similar appliances on a smaller scale. In the Montreal house there were six 800-h. p. engines, and the daily output of current averaged 43,000 units. But the author has recently obtained similar results with a small cable plant on the Birmingham cable system. In 1897 this plant consisted of a pair of single-cylinder engines running at 53 revolutions of 287 maximum horse-power, with Galloway boilers, and no special heat-saving appliances. It was necessary to increase the engine power to meet increased traffic. The author put in a pair of superposed compound condensing engines of 400 h. p., running at the same speed as before, and obtained condensing water from a well in conjunction with a tank and cooling tower. The result was that the consumption of fuel was reduced from about 325 tons per month, or 8.9 lb. per car-mile, to 6.5 lb. per car-mile; and the introduction of Green's economizers has further reduced the consumption to 4.7 lb. per car-mile, or to about 3 lb. per h. p. h. On the Birmingham small cable system, the saving does not amount in money to a large sum, but on a great electric system running, say, 7,000,000 car-miles in the year, 4 lb. of coal saved per car-mile, at 9s. per ton, amounts to 5,625l. per annum; and it is this consideration that gives emphasis to the plea for an economical power-house plant.

"To return to the previous line of argument. Note what a large saving is effected when a cost of ½d. per car-mile for power is substituted for 5d.; on a car-mileage of 7,000,000 it means no less a sum than £131,250 per annum! and indicates the source whence the increase of net earnings may be obtained to pay for the heavy cost of electrical installation. The whole cost of working a large electric system, including working charges of all kinds, should be under 5d. per car-mile; but this can only be obtained with a carefully constructed power house, where the works-cost of the current is cut down to a minimum.

"The limits to which this note had to be confined prevent the introduction of any more elaborate figures or statistics than those given; but enough has been said to indicate that, in the writer's judgment, it is to the power house that the chief attention should be directed in order to insure the financial success of an electric system. Other parts of the system claim attention, but it is on this that success or failure mainly turns. More money can be lost on the one item of power than would pay all the other working charges; and whether the high potential system with transformers, or the multiple unit system be adopted, the successful working ultimately depends upon having engines and boilers that will do their work with a low consumption of fuel."

STEAM VS. ELECTRIC AUXILIARIES.

At the recent meeting of the National Electric Light Association in New York Mr. W. S. Barstow presented a very interesting paper entitled: "A Local Transmission System—Development and Operation." The paper described the system of the Brooklyn Edison Co. and contained valuable data on the relative advantages of electric and steam station auxiliaries. On this subject Mr. Barstow said:

"When the Union station was first discussed, the Brooklyn company made every endeavor to weed out all details that tended to poor economy, and thus start the system with a modern, up-to-date generating plant. Among the various items was discussed the question of station auxiliaries. As a result of these investigations the Union station was designed and equipped with all auxiliaries electrically operated, the steam from the boilers being used only in the main engines.

"There is often brought forward the question as to whether the loss in feed-water temperature, etc., will not more than balance the high efficiency of the electric auxiliary. Owing to the fact that it is impossible to find two plants of equal size operating under similar conditions, an exact actual general comparison between steam and electric auxiliaries is difficult to obtain. The ideal conditions of a steam auxiliary in regard to efficiency would be: First, no loss of radiation from supply piping or the device itself; second, sufficient waste exhaust to be entirely condensed in a supplementary heater at all station loads; and, third, the replacing of such condensed exhaust back in the boiler. Under these ideal conditions all heat units of the exhaust of the auxiliary could be recovered, and such a system would be perfection. In the ordinary central station we find that the radiation of supply piping and the pumps themselves involve a loss of 25 per cent, and that the pumps require more steam than can be condensed in the feed-water heater under different conditions of load, thereby allowing surplus steam or heat units to escape to the atmosphere, and also that it is impractical in the majority of cases to return to the boiler the steam condensed by the feed-water heater,

owing to the presence of oil, and that the methods of separating the oil from such water are naturally slow and in themselves involve a loss of heat or expenditure of energy. Thus the entire problem becomes one of actual practice rather than theory. With electric auxiliaries driven from the main engine, or auxiliaries connected with the main engine, the economy of the auxiliary is very nearly the economy of the main engine itself. In other words, the electric auxiliary can develop a horse-power on the shaft of the pump with about 18 pounds of steam, including losses. This is about one-fifth of the energy required by a steam auxiliary best suited to the conditions; but, on the other hand, the electric auxiliary returns no energy back to the plant, and a certain allowance must be made for the loss in feed-water temperature. In considering the two systems in any individual plant, comparisons should be made both with systems using economizers and exhaust heaters, one using supplementary heater with steam auxiliaries and the other electric auxiliaries without supplementary heater. In many cases the highest efficiency can, no doubt, be secured by using a few steam auxiliaries that would furnish just sufficient steam to be condensed in the supplementary heater, varying the use of the steam auxiliaries with the load.

"The actual energy required by the electric auxiliaries at the Union station, with a load of 2,732 i. h. p. on the main engine, is as follows:

	Electric horse-power.		Per cent.
Air pumps on surface condensers	11.6	or	.42
Circulating pumps on surface condensers	14.4	"	.53
Boiler feed-pumps	23.6	"	.87
Total of main auxiliaries	49.6		1.82

"Reducing this to indicated horse-power at main engine, 66.8 i. h. p., or 2.45 per cent of the total steam used in the station.

"In addition to reducing to a minimum the energy required by the station auxiliaries under ordinary conditions, the building was so constructed as to alter somewhat the conditions and reduce to a considerable extent the amount of work itself which the auxiliaries were to accomplish. This applied particularly to the method of circulating the water for the surface condensers. Two large tunnels, each 12 ft. high and 8 ft. wide, were constructed, side by side, beneath the entire foundations of the building, with their openings below the mean tide level and extending out into the bay. These tunnels, constructed of heavy masonry and extending directly beneath the large surface condensers, are always filled with water, which rises and falls in both tunnels equally, according to the tide of the bay. The circulating water is taken from one tunnel by a direct-connected electric centrifugal pump, passed through the surface condenser and discharged into the other tunnel, the discharge pipe extending below the lowest water level. This construction forms a water loop in which both legs are of equal length, and in which loop are located centrifugal pump and surface condenser. Thus, when the water is once started, the columns balance one another, so that very little power is required by the centrifugal pumps. In order to prevent an air pocket from forming and breaking at intervals the discharge column, an air-pipe connection is carried from the top of the discharge opening in the condenser to the air pump, a very slight turn of the valve sufficing to keep all of the air out of the system. Whereas, under ordinary conditions, about 26 h. p. would be required, under these new conditions but 7 h. p. is necessary to circulate water sufficient for furnishing 26 in. of vacuum to 1,500 h. p.

"Among the auxiliaries might be classed the generator field-exciters. The question of economically exciting the fields of large alterators has been one which has often been overlooked to a large extent as a matter of small importance. Exciters directly connected to the shaft of the engine operating the alternator, or belted to the same shaft, have introduced more or less trouble, as any variation in the speed of the main engine produces a cycle in variation of field regulation which is at once disastrous to the good operation of the system. After carefully studying the subject, the following plan was adopted in the Brooklyn installation:

"A high-tension, synchronous motor, directly connected to a low-tension, direct-current generator, is directly connected to the bus-bars of the station, to which are connected the main alternators. The low-tension, direct-current generator, connected in multiple with a small regulating storage battery, excites the fields. Should the voltage on the main system vary to a greater or less extent, no variation occurs in the voltage of the field excitement, since the synchornous motor which depends for its speed on the speed of the main generator, and not on the voltage, supplies power to the direct-current exciter. Should the speed of the engine vary to any extent the battery acts as a regulator. The battery also is of such a capacity that the entire exciting set can be shut down for one hour without any variation in the exciting voltage, the battery automatically discharging. If, in place of a synchronous motor set, a rotary transformer were used, the result would be somewhat unsatisfactory, since a variation in voltage, as well as speed on the main generator, would affect the field current. Of course, belted or direct-connected exciters can be used with the battery with equally good economical results, but independently operated exciters furnish a more flexible system."

Mr. Barstow's paper contained other matter of interest to lighting station engineers, but the discussion turned principally on the question of auxiliaries. In reference to another of the company's stations where steam auxiliaries were used the author stated that the boiler capacity increased over that necessary with electrical auxiliaries and about balanced the extra capacity of engine and generator for the latter equipment. Steam auxiliaries used 11 or 12 per cent of the total steam and electrically operated auxiliaries about 3 per cent.

Mr. Creden stated that in the Harrison St. station of the Chicago Edison Co. the steam auxiliaries took about 14 per cent of the total steam and that 10 per cent of the heat was returned in the feed water, leaving 4 per cent as the net steam required to operate the auxiliaries.

Mr. Walker pointed out that for electrical auxiliaries to be economical economizers must be used to heat the feed.

In conclusion, Mr. Barstow stated that the relative economy of the two systems depended on local conditions, and largely on the char-

acter of the load. In some plants electrical auxiliaries would be costly and in nearly all cases a combination of steam and electrical auxiliaries is preferable.

Another interesting comparison made by Mr. Barstow was the influence of the load factor. By shifting 2,000 h. p. from other stations the load at the Union station was so manipulated that on one day the load factor was 80 per cent and on another 25 per cent, the total kilowatt-hours generated being the same. A careful record of the costs on the two days, 24 hours each, showed the cost per kw. h. to be 70 per cent less with the 80 per cent load factor than with the 25 per cent load factor.

MECHANICAL DRAFT.

Mr. Walter B. Snow, of the engineering staff of the B. F. Sturtevant Co., Boston, in the course of a lecture before the Engineering Society of Columbia University, discusses the quantitative efficiency of a boiler as affected by the system of draft as follows:

"No greater waste occurs in modern steam boiler practice than that which is inherent in the employment of a chimney for the production of draft, namely, the loss of heat in the escaping gases. As the chimney depends for its action upon the maintenance of a temperature difference between the internal gases and the external air, it is manifest that, with a chimney, this waste can never be eliminated. It may be palliated, it is true, by the building of higher chimneys, so that the same intensity of draft may be obtained with a lower stack temperature. But such means of providing for the utilization of the otherwise waste heat is expensive. For instance, if, with an external temperature of 60° and an internal temperature of 500°, sufficient intensity of draft is produced by a chimney 100 ft. high, it will require a height of 175 ft. to produce the same draft when the temperature of the gases is reduced to 250°. In addition, the means provided for extracting this heat will increase the resistance, and provision for overcoming the same will have to be made by greater chimney height.

"In the case of a fan, however, the power expended as measured in heat units necessary to produce the same results, may, under ordinary conditions, be only about one seventy-fifth of that necessary with a chimney. In other words, the fan renders available for utilization practically all of the heat wasted by the chimney, while it possesses the further advantage of readily creating the additional draft required when heat-abstracting devices are introduced.

"Messrs. Donkin and Kennedy, in 17 independent boiler tests, found the heat lost up the stack when no economizer was used, to range between 9.4 per cent and 31.8 per cent of the total heat of combustion. As it is not practicable to cool the gases to atmospheric temperature, it is evidently impossible to utilize all the heat, but the ordinary economizer should, with mechanical draft, show a saving of between 10 and 20 per cent.

"The average results obtained by Roney from tests of nine plants thus equipped were as here presented:

Temperature of gases entering economizer	526.3°
Temperature of gases leaving economizer	269.6°
Decrease in temperature of gases	256.7°
Temperature of water entering economizer	150.4°
Temperature of water leaving economizer	297.1°
Increase in temperature of water	146.7°
Fuel saving, in per cent	14.64

Although not developed to the same extent as the economizer, the air heater, by which the heat is transferred from the gases to the air supplied to the furnaces, has been introduced to a considerable extent with satisfactory results. In experiments with the Marland apparatus, Hoadley showed that the waste of the flue gases could be reduced to only 5 per cent of the total heat value of the fuel, with an accompanying expenditure of only 1 per cent of the steam generated for driving the blower.

"The latest practice points to the introduction of flue air heaters for the abstraction of further heat from the gases after their passage through the ordinary type of economizer.

"The importance of mechanical draft in the adoption of means for utilizing the waste heat, is well exemplified in the introduction of retarders and of ribbed tubes. Both of these increase the resistance and almost invariably require fan draft to enable them to create the saving of 5 to 10 per cent which may be thus secured.

"The facility with which the intensity of the draft and the volume of air supplied can be regulated when a fan is employed for draft production, has always been recognized as one of the most valuable characteristics of this method. Such regulation makes possible the most perfect distribution of the air and its reduction to the minimum amount will produce satisfactory combustion.

"Variable draft is necessary to maintain a constant steam pressure. The operation of the fan is automatically regulated, so that the slightest variation in the steam pressure causes considerable change in the speed, and consequently in the draft."

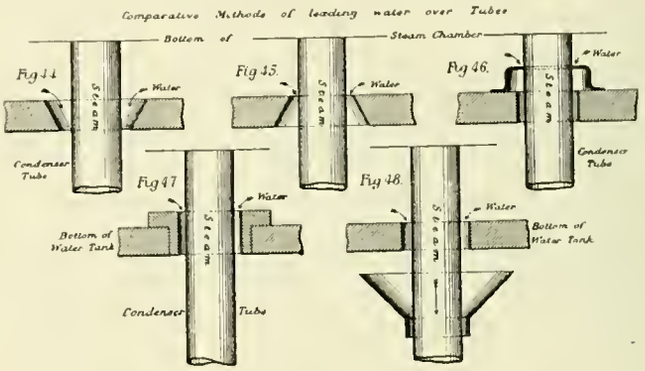
EVAPORATIVE CONDENSERS.

Abstract of a paper read before the Institution of Mechanical Engineers, England, by Harry G. V. Oldham.

Continued from page 383.

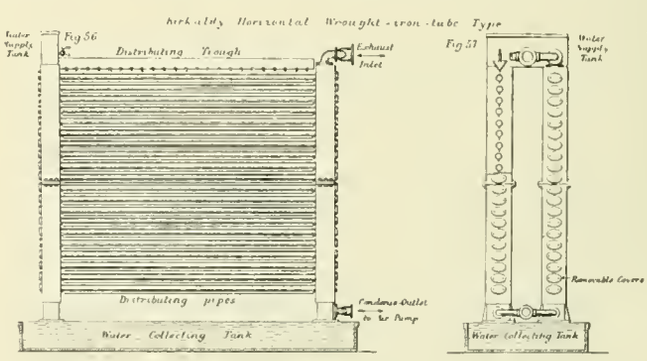
Some difficulty has been experienced with vertical types in getting the water to start down the tubes evenly. Figs. 44 to 48 show various arrangements adopted. Fig. 45 works better than Fig. 44; Fig. 46 is the Wright construction and is designed to provide a place for sediment in the condensing water so that it would not clog the openings about the tubes.

An evaporative condenser of the horizontal type built 26 years ago in London, is still working, giving a satisfactory vacuum. It



consists of 8 sections each with 32 wrought iron tubes of the type shown in Fig. 11; the tubes are 1 in. internal diameter and about 13 ft. long.

A similar condenser is shown in Figs. 56 and 57, and is principally in use abroad. It consists, as usual, of two end boxes into which galvanized wrought iron tubes are expanded. The ends of these boxes have small gland-shaped covers opposite the end of each tube, to facilitate the expanding and examination of the joint. The water distribution is carried out by means of a triangular V-shaped



trough with holes drilled through the bottom. This condenser is suitable for condensing 2,000 lb. of steam per hour. Its height is 10 ft., its total length 12 ft., and its width 5 ft. Such condensers weigh about 3.7 lb. per lb. of steam condensed.

A cast iron condenser of the vertical type, Figs. 58 and 59, consists of two rows of vertical pipes S leading out of two horizontal pipes connected at the top by bends. A is the exhaust main, and B the air-pump suction pipe for drawing off the condensed steam. The vertical pipes are 4 in. diameter. A cast iron trough D is fixed above the vertical pipes, and immediately above each pipe the

trough is perforated by a hole which allows the water to fall directly on the center of the bend, the water passing down the whole length of the pipe to the collecting tank F. The delivery pipe from the circulating pump is shown at E. The whole apparatus is supported above the cast iron tank F. The vertical pipes are about 5-16 in. and the larger pipes ½ to ⅝ in. thick. In connection with the above condenser some valuable experiments were made by Mr.

Michael Longridge in his report to the Engine, Boiler & Employers' Liability Insurance Co. in 1892.

Table I, with a diagram, Fig. 60, are taken from this report, showing the temperature of the circulating water and circulating pump discharge with the number of pounds of circulating water per hour. The conditions were unfavorable, owing to damp weather and the position of the overflow tanks. The pipes were coated with a thin scale outside, but were clean within. It will be seen in line seven of the table that 800 lb. of steam are condensed per hour, and also that the make-up water on line ten was 600 lb. per hour. This works out to ¾ lb. of water being evaporated per pound of steam condensed.

In a paper read by Mr. Row before the Manchester Association of Engineers in 1897, some interesting experiments were described

Vertical cast-iron-tube Type.

Fig 58

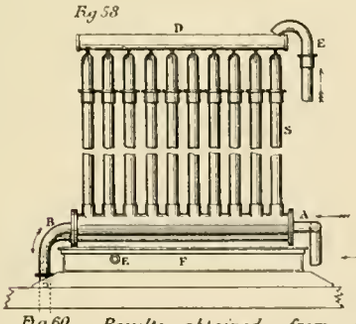

Fig 59

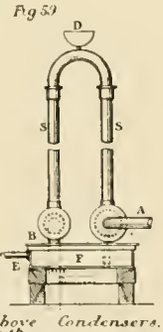

Fig 60. *Results obtained from above Condensers, on a wet day Sept. 12th*

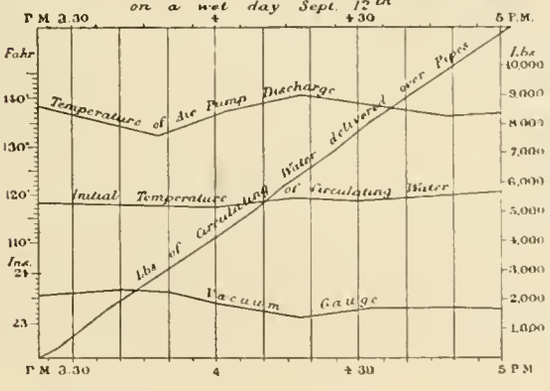

showing the value of air currents directed upon vertical tubes with water passing over them. Figs. 61 and 62 represent the experimental apparatus used. The plain tube test was conducted with a tube shown in Fig. 61 before being indented. The steam was admitted into the tube at the valve A, the condensation water dropping into the receiver B, the vacuum being induced by the ejector C, while the condensation water was drawn at stated periods from the cock D. The cooling water was raised by pumping and allowed to trickle in a thin film from the pan F; the water not evaporated fell into the receivers G and G1 and was repumped. The test shown in Fig. 61 was conducted in a precisely similar way with the addition of the casing H, through which an air current was induced by an ejector in branch J. The plain tube in No. 1 test was 16 ft. long, 1½ in. internal diameter, and 16 standard wire-gage thick. This was afterwards indented, as in Fig. 7, for tests 2 and 3, when it measured 14 ft. 5¾ in. long. The total condensing surface exposed to the atmosphere was 8 sq. ft., including the surface in the pan G and receiver B. Table II shows the results of these tests.

On the basis of Mr. Row's tests with air current, deducting 25 per cent of the results obtained under experiment, and taking the condensing efficiency of indented copper as equalling 6 lb. an hour per square foot of surface, it is possible for an evaporative condenser for 200 h. p., allowing 20 lb. of steam per i. h. p., to be enclosed in a casing 3 ft. 6 in. square, standing 12 ft. high. With reference to the foregoing single-tube experiments, the air current was induced to pass the surface of the tube in a way that is not obtained in present practice. The fan, if placed at right angles to the tubes at the bottom, would force the air against the opposite casing, almost entirely destroying the nature of the air current, after which it would have to find its way at any angle past the tubes. It

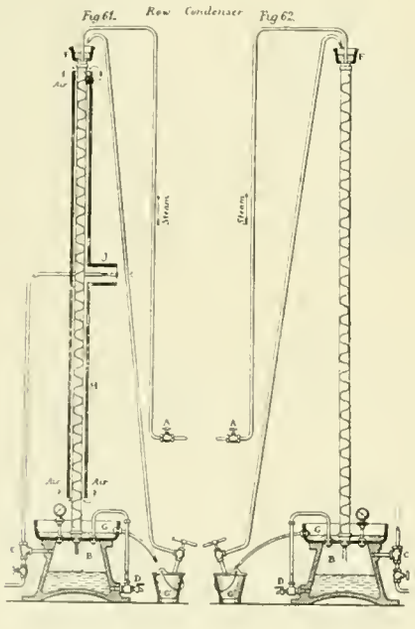
is very doubtful whether a condenser of the size given would be capable of dealing with 200 h. p.

It has been shown by experiment that by the use of a current of air passing over the surface of a tube upon which water is running, the efficiency can be increased from 40 to 50 per cent. Taking full advantage of this 50 per cent reduction in surface, an evaporative condenser of the vertical brass-tube type should not require more surface than an ordinary surface condenser—that is, about 2 sq. ft. per i. h. p.—though satisfactory results have not yet been obtained on these lines. Various arrangements of fans are shown in Fig. 65, which represents a tube with a small fan at the lower end, the tube being exposed to the atmosphere. This tube might be enclosed, as in Figs. 66 or 67, without great loss of efficiency. Fig. 68 shows a fan working in the center of a circular condenser with concentric rings of tubes. The fan may be arranged at the top of the condenser as in Fig. 69, but such an arrangement would have little if any advantage over the former method shown in Fig. 68. A fan fixed directly under rectangular boxes, as shown in Fig. 70, is not so good as the fan placed as in Fig. 68. An even more inferior method is that in Fig. 71, in which the fan is arranged, as shown, below rectangular boxes. The fan in Fig. 72 at B is also very inefficient, while the design at A is not to be commended at all. The type of condenser in most cases governs the arrangement of the fan. The efficiency of the fan itself is not here considered so much as its steam-condensing value. The examples given in Figs. 65, 66 and 67 are merely theoretical. These various arrangements are working in one or the other of nearly all vertical type condensers, and the efficiency of the apparatus is to a certain

extent increased thereby in all cases. It is not advisable to use a fan at all in horizontal condensers, and this type should really be designed with sufficient surface to do without their use. In the horizontal wrought-iron tube condenser each square foot of surface should condense from 2 to 4 lb. of steam per hour—that is, about 8 sq. ft. per i. h. p. The value of a fan as increasing the hourly condensation under existing circumstances when working with vertical-type condensers cannot be taken at more than 20 per cent. and very often this amount is reduced to 10 or 5 per cent, or even lower. Where condensers are not designed to take the maximum load, fans are sometimes used to carry the engines over the maximum load. The style of fan that appears to find most favor for this class of work is one with blades such as could be laid on the surface of the cone, the backs being radially straight. The faces delivering the air are concave with convex backs. The blades are set at an angle in the usual manner. Water should not be allowed to fall on the fan blades. The power required to drive the fan varies from 1 to 2 per cent, or sometimes more of total engine power.

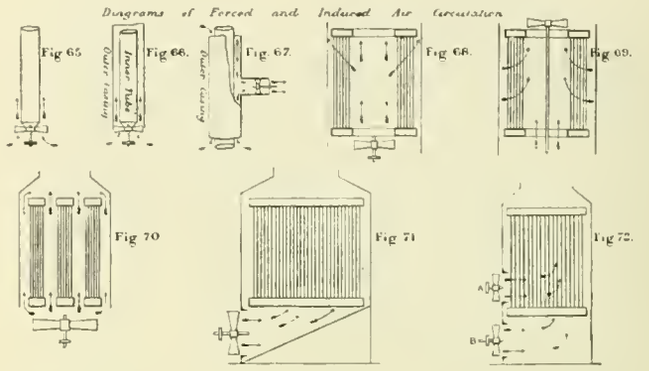
DESIGN.

It is very important that ample means should be allowed for cleaning, especially upon the outside surface of the tubes. One square foot of tube surface would evaporate half a gallon of water per hour, so that if the water is only moderately hard the amount of deposit in a year would be considerable. The circulating water itself should be kept clean. One method of removing very hard scale from the tubes is to stop the water in circulation and to pass steam into the condenser, when the difference of expansion between the tube and the scale causes the latter to crack; it can then, as a rule, be easily removed by hand. The exhaust pipe may enter either at the top or bottom of the condenser. This pipe is generally made of mild steel plate 3-16 to ¼ in. thick, with substantial faced flanges riveted to each end; and pipes 18 to 24 in. diameter are often erected in complete lengths 40 to 50 ft. long. They should, if possible, have a fall towards the condenser, but if circumstances do not permit of this, they can be



so arranged as to drain back into a chamber at the lowest point in the run from which a pipe is led to the air pump. The outlet pipe from the bottom of the condenser is led with a fall direct to the air pump. Where the condenser is about 29 or 30 ft. above the hot well, this run of pipe may be dispensed with. The condenser water then drains through a pipe directly into the hot well. The air pump then deals with the air from the top of the condenser only, from which a much smaller pipe is led to the air pump. Between the condenser and the air pump a cooler is fixed, into which a spray of water is admitted as in an ordinary jet condenser, thus reducing the final temperature of the air.

All joints should be machined, and made even more carefully than steam joints. The joint may be made with rubber insertion, asbestos, or asbestos soaked in boiled oil. When the whole of the pipe work and condenser is erected it should be tested under water pressure, the pressure from a water main being usually sufficient for this. On the occasion of starting a certain condenser it was found that the vacuum could not be maintained. Examination was made of all the points, and a few noticeable leaks were stopped, but still it was very far from being tight, and continued to give trouble. At last it was decided to test the whole apparatus under water pressure, when the leaks were detected and made good, with the result that the required vacuum was obtained. Another case in which air leakage caused trouble was when the feed pumps were abnormally large for the boilers they were feeding, and



pumped a considerable amount of air along with the water. It is desirable to place the condenser as near the engine as possible to save cost of pipes, bends, etc., and also to reduce the risk of leakage. Condensers are working satisfactorily at a distance from the engine of 100 to 120 ft., and in some cases even more. The horizontal type should be exposed as much as possible, the best place being upon the roof. Care should also be taken, especially in the plain tube or wrought iron horizontal type, to shield the tubes from the direct action of the wind, which the author has observed to sweep a portion of the nest of tubes quite devoid of circulating water. Vertical condensers with fans and without casing are invariably placed in the open. The practice of connecting several large engines up to one condenser should be discouraged, but where the engines are small they may be connected into one exhaust main with controlling valves to shut off each as required. Where the engine room is being extended or newly built, the roof should be flat and made water-tight, and in one or two places sloped to a gully, covered by a wire grating. Connections are made from these gullies to the circulating pump. The condenser is built upon girders, and the circulating water after passing over the tubes should be allowed a fall of 3 or 4 ft. before it reaches the roof. This is a very effective means of lowering the temperature of the cooling water, or, a wrought or cast iron tank of ample area and about 2 ft. deep may be placed under the condenser. Duplicate plants are not required with a condenser, the steam being exhausted into the atmosphere while any slight repair is made good.

The average cost of evaporative installations is about 20s. per h. p., exclusive of the cost of air and circulating pumps and connections. When compared with jet condensers the cost is no doubt greater, but including reservoir construction and cooling apparatus the evaporative condenser is more economical. Some judgment must be used when selecting a condenser for any particular purpose. When ample room and good foundations are at hand and the condenser has to be worked under rough conditions, the cast iron type is more suitable and cheaper than other types. The horizontal condenser, fitted with wrought iron or copper tubes, is far more efficient weight for weight, and occupies much less room than the cast iron condenser. The scale can be more easily removed from the plain tube than from cast iron tubes. Greater success has been obtained with a distribution of water over the tubes in the horizontal type than with the vertical type, and when space permits the former is recommended.

The vertical brass tube with fan is adopted when space is very limited. Condensers of this kind do not at present give those results which were expected, too much value having been placed upon the fans; but even if ample cooling surface is allowed, the

author considers that no difficulty whatever should be experienced with them.

Various kinds of pumps are used, but that which seems to find most favor for this class of work is the ordinary centrifugal pump

It is very important that an efficient air pump should be used The size as designed or an ordinary surface condenser would be generally suitable for an evaporative condenser of the same capacity.

SIX-MINUTE HEADWAY ON SINGLE TRACK.

Newark, N. J., June 30, 1899

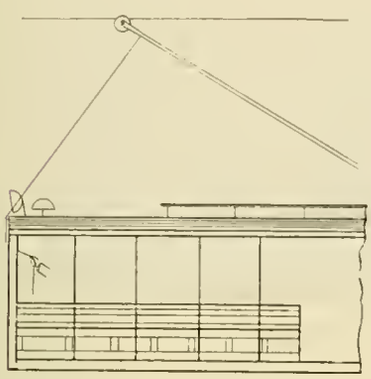
Editor "Review": If your correspondent "Single Track" (May issue, page 295) will place his passing sidings equidistant, ¾ mile apart, and run his cars or trains at a uniform speed of 15 miles per hour, he can give the six-minute service required. Let him also adopt a reliable system of block signals and it will prevent much anxiety.

R. R. B.

CONDUCTORS' ORDER.

Oakland, Cal., June 27, 1899

Editor "Review": The following copy of an order recently issued on our road may be of use to managers who have had trouble from similar causes. In writing orders to the men the endeavor is made to have them perfectly plain.



"To conductors: I have endeavored in the following sketch to give you an idea of how I want a trolley rope held at crossings, switches and curves. Do not stand away from the window (storm fronts are used) and put your arm through the rope and your hand in your pocket; you would not hold it in that manner if you expected the trolley to jump, and I want you to hold the rope as though you expected it to jump every time. Stand up close to the glass, take in all the slack rope and then keep a tight hold on the rope until the danger point be passed. Do not attempt to collect fares with one hand and hold the rope with the other; the fares can wait until you have passed the point of danger. I shall expect to see every man obey this order to the letter, and thereby avoid further breakage or delay on the line."

Yours Truly,

G. Robertson,
Div. Supt. Oakland Transit Co.

FREIGHT ON TROLLEY ROADS.

Last month we published an editoral note on the freight traffic of urban and suburban electric railways which has caused Mr. J. C. Bonner, of the Bonner Rail Wagon Co., of Toledo, to write us the following interesting letter on that subject:

"We note with interest your editorial in current issue of the 'Review,' relative to the carrying of freight on trolley lines, and quotation from decision of Judge Marean of New York. In the freight business perhaps no one has endeavored to give the subject of this haulage, more consideration during the last three years than ourselves, and we feel assured, you have taken the only true position relative to its developement on the trolley roads.

"Very many managers, as you know, are earnestly considering the question. All that remains now, is a few more injunction proceedings, and favorable court decisions such as secured in the Supreme Court of New York, and this field of operation will be generally enjoyed. Probably the most active undertakings in this line have been at neighboring cities, Detroit, Cleveland and Pittsburg and we are inclined to think to some degree the result of our personal efforts to induce freight haulage. All the roads are doing well, and so far as we have learned, with no objection from any source. Of course, our interest in the matter has been to encourage the use of rail wagons and we think our system is dearest in the affections of the road managers and their patrons. They have been experimenting, and there were as many plans for the operation of freight service as there are different road managements.

"You will be very much interested in our more recent experiences. Briefly, we have always contented the haulage of packages alone either in cars carrying passengers or in separate express cars does not develop the best results. Still this service is most gratifying to freight patrons, nor does it meet with any objection from country dealers. On the other hand the latter are very liberal and it is to such business the roads owe their largest portion of package freight.

"The present situation in Pittsburg is that four express cars are hauling the suburban package freight. At Cleveland, four roads with a central station for receiving and distributing freight, are thoroughly and systematically conducted. Their freight auditor visited us recently and stated they must look for greater facilities in order to care for the heavy shipments and also the farm produce. A change was under consideration when the late strike was declared. At Detroit, the roads first operated suburban package delivery using passenger cars, and charge alike for passengers and packages. Now, two of the roads have rented passenger cars from the Detroit Citizens Railway Co., making two or three round trips a day. The seats have been taken out of the cars for the purpose of placing freight. All the roads, however, maintain independent or individual freight departments.

"The Detroit managers have promised, as soon as the question of municipial ownership is decided, to take up and favorably consider our proposition, that is, a central freight station for the interchange of freight under one management, and a pro rating of the earnings of the package haulage express freight, which is to be transported in remodeled passenger cars; these cars to act as motor propellers for rail wagons as trailers to them, for carrying the heavy and bulky freight, this last class of freight being by far the largest part of business offered to trolley roads.

"I will quote from a few of many recent letters endorsing our efforts in the development of freight haulage. Hon. Martin Dodge, Director of Road Inquiry of the U. S. Department of Agriculture, writes us in part as follows: 'In my last report to the U. S. Government, I made special mention of your rail wagons and recommended them. This will be published as a Farmer's Bulletin and generally circulated throughout the country.'

"We have about 25 letters that come from the most representative jobbing houses of Detroit. The B. Stroh Brewing Co. says: 'Your freight service between here and Pontiac is excellent, as a customer can place his orders in the morning and having the goods reach him the same day. It also saves cartage at both ends as your wagons call for the goods at the shipper's place of business and deliver them to the purchaser's door. We wish the same service could be established between Detroit and other suburban towns like Mt. Clemens, Wayne, Plymouth, etc. Phelps, Brace & Co., wholesale grocers write: 'We wish to say that the Bonner rail wagon system for delivering freight, is admirable for the jobber, the manufacturer and the retailer. It gives quick delivery of freight, much quicker than our customers have been having. We would patronize the system extensively if it were extended, and we hope it will be.' Dwyer & Vhay, wholesale dealers in foreign fruits, write: 'We have given you the bulk of our business to Pontiac, as the trade orders goods shipped that way. It is especially serviceable in shipping perishable goods as their is less handling than in any other way.' J. C. Hamblen, wholesale oyster house, says: 'Your system of collecting, transporting and delivering freight is far superior to anything of the kind, that has come under my notice. Our consignees express themselves as well pleased with the service.' Other letters are of a similar tenor.

"Just now, we are building an invoice of rail wagons to be shipped to England, within 30 days, where we have sold the wagons and where they will be installed in the service of the Isle of Man Electric Co., operating some 75 miles of road at Douglas, Ramsay and other towns. The wagons will be utilized in the haulage of farm produce, granite, ores from the mines, farm fertilizers, etc."

The street railway employes of Macon, Ga., have effected an organization with a large membership of motormen and conductors. Their charter was adopted at a meeting on June 10th which was held at midnight so that the men could all attend after finishing their last night run.

LONG DISTANCE TRANSMISSIONS FOR ELECTRIC RAILWAYS.

There seems to be no doubt that in the near future long distance transmissions by means of polyphase currents will form an important feature of electric railway practice. A number of instances of this practice have already been mentioned in the "Review," and a new road has just been projected in the Kootenay country of British Columbia which will be operated by means of a power plant which contains a number of most interesting and unique features. It should also be added that this is but one of a considerable number of polyphase transmissions in the Pacific Northwest, where there has lately been remarkable activity in the projection and construction of long distance transmissions operated by water power. While for the purpose of supplying power for general purposes and especially to mining machinery the induction motor has now become a worthy rival of direct current machinery, street railways will undoubtedly continue to be operated from substations containing rotary transformers for the production of 500-volt, direct currents.

The West Kootenay Power & Light Co. whose plant is described in detail in the Journal of Electricity of May, 1899, contains an unusual number of useful and instructive features. This plant is essentially a power plant, only a small percentage of its output being applied to lighting purposes, and so various are the uses to which this power has been applied and with such eminently satisfactory results that a considerable extension of the service is to be made, which will include an electric railway which is to be installed at once

The engineering features of this plant are most interesting. The power house is situated on the Kootenay River which forms a connecting link between Kootenay Lake and the Columbia River, and the Bonnington falls from which the power is supplied are situated near the lower end of this river. At low water these falls, both upper and lower, are capable of delivering 267,000 horse-power but the lower falls, a part of which the West Kootenay company has utilized have an available head of 40 ft. at low water and are capable of delivering 100,000 horse-power.

The company constructed a canal cut out of hard rock, 650 ft. in length and 26 ft. wide, the lower end of which widens out into a forebay 54 ft. wide. The forebay is shut in by a dam of solid concrete 32 ft. high and 26 ft. wide at the bottom, tapering to 6 ft. wide on top. Across the head-race 150 ft. from the concrete dam is a wooden dam sloping at an angle of 42°, constructed of sills and timbers securely fastened between two high bluffs. This dam is 44 ft. high and has 5 sluiceways across the bottom, the object of which is to control the supply of water to the forebay at all times.

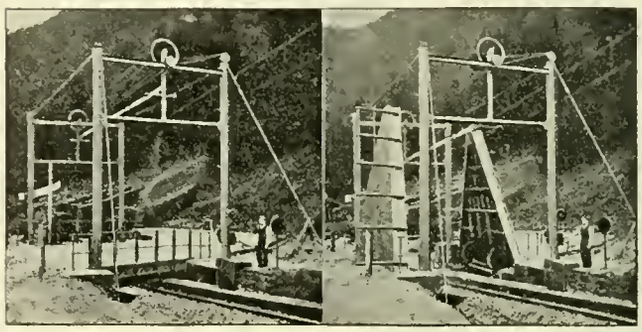
The back of the dam really forms one side of the power house and of the tail-race which runs at right angles to it, being a pit 20 ft. wide by 30 ft. deep and extending nearly the length of the power house, which is 66 ft. The dam is provided with two feeders of 9 ft. each and one of 10 ft., the upper ends of which are closed with wooden gates. Two outside frames extend upward of 30 ft. and the racks for raising and lowering the gates are bolted to the wall of each pit. The gates are each provided with a small iron floodgate, and the main gates are raised and lowered by means of headgate irons bolted to the top of the dam. The winches controlling these is operated by one man. Three steel penstocks run through the dam into the hydraulic room of the station, each penstock carrying a standpipe nearly as high as the top of the dam. To the lower end of each penstock is bolted a housing which contains a pair of 39-in. horizontal cylinder gate turbines, the housing being supported on I-beams laid on the retaining walls of the tail-race. The draft tubes 22 ft. long and 10 ft. in diameter are bolted to the bottom of the housings. The generators are coupled direct to the turbine shafts, and three exciters are driven by three independent 12-in. horizontal gate turbines contained in cast iron flumes connected to the housings of the large wheels from which they derive their water supply.

The dynamo room contains two 750-kw. generators and one of 1,500 kw., all of the standard General Electric revolving field type. These run at a speed of 180 r. p. m., have 40 poles and deliver 3-phase currents at 1,100 volts.

The transformer room is a separate compartment at one end of the dynamo room and contains the necessary capacity of air-blast transformers; they are 12 in number, each of a capacity of 250 kw. These deliver a potential of 20,100 volts to the line. The pole line is a double line extending to Rossland, a distance of 31 miles, the profile of which varies in height by over 2,200 ft., and a step-down transformer station is situated at the latter town. A branch is taken off the main line at a point three miles from Rossland which runs to Trail, B. C., a distance of four miles. At this town is situated the great smelter of the Canadian Pacific Railroad and a transformer station at this point provides 3-phase currents at 550 volts for the operation of various parts of the smelter. At this point an electric tramway is to be immediately built, the operation of the plant in all kinds of weather having been so successful as to encourage the company to extend its operation to railway work.

LIFT BRIDGE FOR A GRADE CROSSING.

A recent number of the Schweizerische Bauzeitung has an illustrated description of a peculiar grade crossing which was installed on an electric railway between Stansstad and Engelberg, in the Canton of Unterwalden, Switzerland. This road, which is about 14 miles long, is operated on the overhead trolley system and a rack is employed on the steep grades. This rack is in the center of the track and projects about 3 in. above the tops of the track rails. At a point near Engelberg the electric line requires a



A SWISS GRADE CROSSING.

rack, where it is crossed by a post road, and to prevent the rack from becoming clogged with dirt from the post road and also to give more headroom that the ordinary height of the trolley wire allowed an elaborate crossing was built.

There are two lift bridges, triangular in shape, and a movable section of the overhead conductor. The bridges are shown open and closed in the illustration; as the bridges are opened the trolley wire is lowered, and vice versa. The bridges are operated by gears and the wire by a windlass.

IN THE ORIENT.

Press dispatches contain the following item concerning electric railroading in the Far East: "Since the introduction of trolley cars into Korea several children have been run over and killed in Seoul. The people to the number of several hundred burned one car and smashed another. The Japanese and European engineers narrowly escaped death. The ignorant people attributed the drouth which has continued for some time to the construction of the electric railways."

Further reports published here under date of July 3d say: "Late oriental advices say that 20 ringleaders of the rioters who destroyed and burned the electric tramway cars at Seoul last month were executed in public at Korea's capital four weeks ago. They met their fate bravely. Their heads were cut off and exhibited in public as a warning to all evil doers. It was believed that this summary action would also have important influence upon the leaders of the Korean rebellion, which was assuming large proportions."

The Employes Mutual Benefit Association of the Syracuse Rapid Transit Railway Co. formally opened its club house last month with an entertainment lasting through the afternoon and evening. The rooms were handsomely decorated and a musical and literary program was given.

RECENT STREET RAILWAY DECISIONS.

EDITED BY J. L. ROSENBERGER, ATTORNEY AT LAW, CHICAGO.

PASSENGERS DO NOT CEASE TO BE SUCH AT ONCE ON ALIGHTING.

South Covington & Cincinnati Street Railway Co. v. Beatty (Ky.), 50 S. W. Rep. 230. Mar. 22, 1899.

There was no error, the court of appeals of Kentucky holds, in refusing to give an instruction that "a passenger upon a street car ceases at once to be such, upon alighting from such car." It does not think that such an instruction embraces the law. The injury, for which it here affirms a judgment for damages in the plaintiff's favor, was caused by his being struck by a car on a parallel track, going in the opposite direction to that of the one from which he had just alighted, and crossed behind in an effort to go to the other side of the street.

AN INVITATION TO ALIGHT.

Citizens' Street Railroad Co. v. Hoop (Ind.), 53 N. E. Rep. 244. Mar. 14, 1899.

The allegations of the complainant in this case, that, as the car approached the crossing, the conductor, who was standing near the plaintiff (Hoop) on the platform, invited and notified the latter "to alight from said car by stepping one side, and with his hands, passing plaintiff by him, to allow him to step down and off said car," were not contradicted by any answers to special interrogatories, of which there were a number. And, the appellate court of Indiana, in affirming a judgment for the plaintiff, goes on to say, after stating this fact, the rule is approved by many authorities that "a passenger is justified, as a general rule, in obeying the direction of the employes of the carrier; and, if he receive injuries obeying them, the carrier is liable, even if it appears that, if he had not obeyed, he would have escaped injury."

RIGHT TO SELECT SWITCHMEN.

Grand Avenue Railway Co. v. Lindell Railway Co. (Mo.), 50 S. W. Rep. 302. Mar. 21, 1899.

Where a city charter such as that of the city of St. Louis empowers any street railway company to use the tracks of any other company upon payment of just compensation for the use thereof under such rules and regulations as may be prescribed by ordinance, and an ordinance is passed requiring the company desiring to use another company's tracks to construct and keep its connections with such tracks, the supreme court of Missouri holds that the duty of keeping the connections justifies the requiring of switchmen to be employed to handle the switches; and that, when the whole cost of paying the switchmen is thrown upon such company, along with the responsibility of keeping the connections, the right to select the agents, for whose conduct it is responsible, and whose wages it must pay, is properly conferred upon it, instead upon the company owning the tracks.

PERSONS CROSSING STREETS MUST EMPLOY PROPER PRECAUTIONS FOR THEIR OWN SAFETY.

Dieck v. New Orleans City & Lake Railroad Co. (La.), 25 So. Rep. 71. Nov. 21, 1898. Webster v. Same Company, 25 So. Rep. 77. Jan. 23, 1899. Rehearings denied Feb. 6, 1899.

In the first of these cases, the supreme court of Louisiana says that the authorities are numerous and uniform to the effect that a person whose business or pleasure occasions him to use the streets of a city which are traversed by electric cars, and particularly at crossings, is guilty of negligence if he fails to employ proper precautions for his safety. He is bound to look and listen for the approach of cars, and to exercise ordinary care and caution to avoid possible danger of a collision; and, should he see an approaching car in close proximity, it would be his plain duty to halt until same could pass by, rather than run the risk of an accident by attempting to cross the track in front of it. Failing to take such necessary precautions for his safety, the injured party is guilty of that negligence which deprives him of the right to reimbursement for injury received. In the second case, the supreme court declares that one who heedlessly attempts to cross ahead of a car properly managed if injured, has no one to blame but himself. It is true that one on foot has a right to cross the street where he pleases, provided he exercises the right with due caution. It is his duty to use due care

INCREASE OF DANGER MUST BE MET WITH AN INCREASE OF CARE.

Price v. Charles Warner Co. (Del.), 42 Atl. Rep. 699. Jan. 6, 1899.

It was contended in this case that the doctrine of the superior right of a street railway company has no application to street crossings. But the superior court of Delaware answers that it would certainly be contrary to public policy, and in violation of the rights of a street railway company, to allow its tracks to be blocked at street crossings by the negligence of drivers of vehicles. The public, using due care, have the right, in vehicles or on foot, it goes on to say, to cross street railway tracks, as well within the blocks as at street crossings. There is, however, this difference: The company has knowledge that at street crossings a larger number of persons and vehicles are usually found crossing the track than at other places, and this imposes upon the company the need of greater care at street crossings than where the danger is less. The company and the traveler are required to use such reasonable care as the circumstances of the case demand, an increase of care on the part of both being required when there is an increase of danger. The right of each must be exercised with due regard to the right of the other, and the right of each must be exercised in a reasonable and careful manner, so as not unreasonably to abridge or interfere with the right of the other.

HAD RIGHT TO SUPPOSE BOY WOULD REMAIN WHERE HE WAS.

O'Rourke v. New Orleans City & Lake Railroad Co. (La.), 25 So. Rep. 323. Mar. 7, 1899. Rehearing denied Mar. 20, 1899.

Here it appears that a boy 11 years of age, standing at night on the off side of the down-town track of the defendant's street railway, waiting for a car on the up-town track (which was furthest from him) to pass, and, that car having passed, without looking up the track nearest him, to see whether or not it was safe to cross, stepped on the track, 12 or 15 feet in front of an aproaching down-town car, tripped and fell, having his foot crushed. This, the supreme court of Louisiana holds, was a case of want of care on the boy's part, barring recovery of damages; it being shown that, notwithstanding effort on the part of the motoneer to arrest the car, it could not be done in that distance.

The motoneer had a right, the court particularly holds, to suppose that the boy was waiting for his car to pass, and to expect that he would remain where he was out of danger until it had passed.

The projection above the rail only half an inch of an unbeveled plank, placed between the rails of a street railway track, the court further holds, constitutes no such faulty construction or dangerous obstruction as would justify holding the street railway company responsible in damages because of a person tripping over the same and falling, all that is required of municipal corporations being that they keep the streets in a reasonably safe condition for a person exercising ordinary care and prudence, which rule can hardly be extended further as to street railways.

ACCIDENTS SAID TO SOMETIMES PRODUCE RESULTS STRANGER THAN FICTION.

Basting v. Brooklyn Heights Railroad Co. (N. Y.), 57 N. Y. Supp. 119. Mar. 24, 1899.

In this case, where the second appellate division of the supreme court of New York affirms a judgment for $6,500, with costs, in favor of the plaintiff, a young woman about 20 years of age, the

court remarks at the outset that the trial was peculiar in the fact that the plaintiff was the only witness to the accident, but that a careful reading of her testimony satisfied it that there was no possible alternative to the submission of the issues to the jury, and that it is difficult to predicate error of a submission of questions to the jury when a failure to submit would have involved reversal.

Among other things, the plaintiff testified that the car had stopped, and that she was in the act of alighting from the rear platform, with her right hand upon the rail of the dashboard, and one foot in the air, ready to step off, when the car started, by reason of which she was thrown forward, instead of backward. Counsel for the company insisted that such a story bore its own refutation. But the court answers that it is not prepared to agree to that, as the study of accidents shows strange and inscrutable results, sometimes stranger than fiction. And so, while it is unable to tell the method, it holds that was just the question properly submitted to the jury, and that it cannot interfere with the verdict.

Furthermore, the court holds that it is not strange that, in the excitement of her fall, she did not clearly notice, and afterwards remember the number, of the car. And this is the more important in this connection, because it appears that the plaintiff's inability to remember the number prevented the defendant from making a witness of the motorman or conductor, it having no report of such accident, although its rules required reports of accidents.

SIGNAL MUST BE COMMUNICATED BY CONDUCTOR TO IMPOSE LIABILITY.

Armstrong v. Metropolitan Street Railway Co. (N. Y.), 55 N. Y. Supp. 498. Jan. 24, 1899.

It is not doubted that if the jury could find from the evidence that the conductor communicated to the gripman the passenger's signal to stop, and that the gripman, in response to that signal, slackened the speed of the car for the purpose of allowing the passenger to alight, it would be proper for the latter to prepare to get off the car, and it would be negligence for the gripman to suddenly, without warning, increase the speed of the car before he had reasonable time to alight, says the second appellate division of the supreme court of New York. But, the evidence in this case not going beyond proving that the plaintiff signaled the conductor, the court a second time reverses a judgment against the company, on the ground that no negligence on its part was shown.

True, the plaintiff testified that, after he gave the signal to the conductor, the car slowed up; but, the court insists, there is no necessary connection between the two facts. When the location of the accident is considered, having in mind the duty imposed upon the company to operate its cars with a reasonable degree of care, so as not to injure pedestrians or vehicles lawfully in the highway, the court continues, a mere change in the speed of the car is not to be presumed to be in response to a signal from the conductor; nor does it evidence on the part of the gripman an intention or purpose to give the passenger an opportunity to alight.

The slackening of the speed of a car may be due to the exercise of reasonable care in the operation of the car with respect to pedestrians or vehicles; and in the absence of knowledge that the conductor had signaled the gripman to stop, and that he was in the act of doing so in response to the signal, the court holds that the plaintiff would have no ground for assuming that a change in the speed of the car was intended for his benefit or convenience.

STREETS MUST BE MAINTAINED IN REASONABLY SAFE CONDITION.

Citizens' Street Railroad Co. v. Ballard (Ind.), 52 N. E. Rep. 729. Jan. 24, 1899.

The apellate court of Indiana, in affirming a judgment against the street railroad company, holds that the trial judge properly instructed the jury that the decedent had the right to presume, and to act on the presumption, unless he had knowledge to the contrary, that the street was in a reasonably safe condition for travel by him if he used due care; and the fact that he knew or had reason to believe the street unsafe would not perclude him from using the street, but in such case he must use care proportioned to the danger of which he knew or had reason to apprehend; and if he did not know or had reason to apprehend danger, or knew it, and used care proportioned to the known or reasonably apprehended danger, and notwithstanding such care was injured, then, so far as contributory negligence was concerned, there might be a recovery.

Even if the street railway was built under a contract with the county commissioners, when the highway became a part of the city, the court holds, it was the duty of the company to maintain its track so as to preserve the public highway in a reasonably safe condition for public use and travel; and that it was its duty to do this whether there was any ordinance requiring it to be done or not. In other words, it says that it was the duty of the company to keep its tracks in such condition as not to render the highway unsafe for the public, regardless of any privilege granted or attempted to be granted by the board of commissioners; and that this duty continued as long as the remained a public highway, no matter within what jurisdiction it might be.

The cases cited by counsel denying the right of a municipality to impose additional burdens to those provided for in the contract with the municipality the court says are not in point. Requiring a street railway company to keep its tracks in such condition as not to interfere with the public use of the street, it insists, is quite a different thing from requiring the company to make a certain kind of improvement prescribed by the municipality, and not provided for in the original contract between the ocmpany and the city.

ACCEPTED ORDINANCE A VALID CONTRACT CONTROLLING LIBILITY FOR STREET IMPROVEMENTS.

West Chicago Street Railroad Co. v. City of Chicago (Ill.), 53 N. E. Rep. 112. Feb. 17, 1899.

On July 30, 1883, there were three street railway companies operating street railways in the different divisions of the city of Chicago; and an ordinance was then passed providing for the payment of an annual car license by said companies. Section 2 of said ordinance provided as follows: "Each one of said railway companies shall hereafter, as respects the filling, grading, paving and otherwise improving or repairing the streets or parts of streets upon which it has constructed its railways, or any of them, fill, grade, pave and keep in good repair, during all of the time the privilege of using said streets or parts of said streets shall extend, eight feet in width where a single track is used or sixteen feet in width where a double track is used, the said eight or sixteen feet to include the railway track or tracks, in accordance with such ordinance as the city council may pass respecting such filling, grading, paving or repairing; and the same shall be done by the railway companies with like material, in like manner and at the same time as required as to the rest of said street not embraced in the eight or sixteen feet in width, except that it may use stone as authorized, or such other material as may hereafter be authorized by the city council, * * * for the space between the rails of each track." In consideration of the acceptance of said ordinance by the companies, the right to maintian and operate their railways was extended 20 years.

This, the supreme court of Illinois holds, made a valid contract between the plaintiff company and the city establishing the share or proportion of the former's contribution for the purpose of grading and paving a street, so as to preclude the imposition upon it of additional burdens therefor.

The language of the ordinance, the court holds, can only be construed as fixing and specifying the duties of the railway company in regard or with respect to all such improvements; and it means that, when the company constructs its railway through a street or a part of it, it shall fill, grade, pave, and keep in repair the width specified.

TOWN COULD NOT EXEMPT FROM TAXATION.

South Covington & Cincinnati Street Railway Co. v. Town of Bellevue (Ky.), 49 S. W. Rep. 23. Jan. 13, 1899.

This was an action brought to enjoin the collection of certain taxes. Involved, especially, was a town ordinance, which provided, among other things, that, "in consideration of said reduction of fares between the town of Bellevue and the city of Cincinnati, and the city of Cincinnati and Bellevue, and in consideration of equipping said line with electric power, and so insuring rapid transit over said line, the South Covington and Cincinnati Street Railway Company is hereby released from any and all obligations to keep

any part of the streets occupied by its track in the town of Bellevue in repair, and is released from the payment of car license except as hereinafter provided, and from the payment of taxes of any and every kind, except an ad valorem tax upon its real estate and personal property."

In affirming a judgment in favor of the town, the court of appeals of Kentucky holds that a provision in the charter of the town that the board of trustees should not grant any special privilege to any person, corporation, or company, nor exempt any such person or persons from the payment of an annual tax, prohibited the town from making the contract claimed by the street railway company; and, besides, that the new constitution, which was at the time in full force, would also seem to prevent the making of any such contract; and that, for these two reasons, the contract, even if it attempted to exempt the value of the company's franchise from taxation, would be null and void.

Moreover, the court expresses the opinion that a fair construction of the contract only exempts the company from the payment of a license tax or fee proper; that is a specific tax for the privilege, without regard to its value. And it says that section 4077 of the Kentucky Statutes does not levy a tax for such purpose, but merely fixes a basis for determining the value of certain franchises; and that it was wholly immaterial, so far as this action was concerned, whether the town authorities of Bellevue were bound to adopt the state valuation as the value of the franchise for city taxation or not, though, as matter of law, the valuation by the state board of the property was, in law, conclusive as to its value for city assessment.

PASSENGERS NOT REQUIRED TO EXERCISE SAME CARE AS CONDUCTORS.

Cobb v. Lindell Street Railway Co. (Mo.), 50 S. W. Rep. 310. Mar. 7, 1899.

On the trial of this case the defendant asked that the jury be instructed that, if the accident resulted in a mutual mistake of the plaintiff and the conductor in relation to the signals that passed between them, and if the mistake was such as reasonably prudent persons in like circumstances might make, the plaintiff could not recover damages. But the judge modified the instruction to read that if it was such a mistake "as a reasonably prudent passenger and a careful and skillful conductor, exercising a very high degree of care, would make under like circumstances, then the plaintiff could not recover." By doing this, it will be observed, he laid down one degree of care incumbent on the passenger and a higher degree of care on the carrier's servant. And now the supreme court of Missouri holds that he made no mistake when he drew the demarkation between the degree of care that devolved on the passenger and that which devolved on the conductor.

The degree of care that a railroad company is bound to exercise for the safety of its passengers, the court holds, is not limited to the construction and equipment of the road, but includes service also.

Moreover, the court says that the position taken by the defendant all through this case seemed to assume that the plaintiff was bound to know as much about the movements of the train as the conductor himself; but, it declares, the law did not charge her with such knowledge.

It also holds that it was negligence to start the car with a violent motion while she was in the act of alighting, even if she was slow in her movements. But, it adds, that if it could be inferred, from the petition, that the accident resulted from an attempt of the plaintiff to alight while the car was moving, that would be the end of her case. And then it says that the petition distinctly stated that the car had so nearly stopped that its motion was scarcely perceptible, and that its sudden and violent starting while she was in the act of alighting was the cause of her fall, and holds that the petition was sufficient to support a verdict for the plaintiff.

GLANCING UP AND DOWN STREET FROM SIDEWALK NOT ENOUGH.

Hickman v. Nassau Electric Railroad Co. (N. Y.), 56 N. Y. Supp. 751. Jan. 3, 1899.

To hold that a woman 56 years of age, in good health and in the possession of her faculties, with an unobstructed view of a street railway track for a distance of several blocks, has met the obligation resting upon her of exercising reasonable care, when she has glanced up and down the street from the sidewalk, and then, with no further exercise of her faculties, walks slowly and deliberately upon the track, with an approaching car fully in view, with its bell ringing, the second appellate division of the supreme court of New York pronounces absurd.

This, the court goes on to say, was not an accident at a crowded street crossing, where the rights of the parties were equal, and where the company was charged with the duty of having its cars in full control, so that while the company was then, as at all times, charged with the duty of exercising a reasonable degree of care in operating its cars, the plaintiff, the court holds, had no right to assume that the car would be in such control that the motorman would be able to protect her against her own negligence.

Nor does the court think that the motorman was bound to assume that this plaintiff, in broad daylight, would continue to advance until she should be in a position of danger. She was walking slowly; she could stop anywhere within two or three feet of the car, and allow it to pass in safety; and, the court insists, unless there was something in her conduct to indicate an intention of crossing regardless of the approach of the car, the motorman was not bound to assume that she would recklessly or heedlessly walk into the danger.

It is not enough, continues the court, that the plaintiff should merely look in both directions; she must look for the purpose of seeing if there is danger; and if her rate of progress in passing over the danger point is so slow that a car, in traveling at a reasonable rate of speed, may be reasonably expected to have come within view, and in such a position as to cause danger, she is not excused from the duty of using her eyes because she may at some previous time have discharged this duty.

Moreover, the fact, if it was a fact, that the plaintiff was somewhat hard of hearing, the court holds, only increased her obligation to make such use of her eyes as was intended, to avoid danger.

Plaintiffs, it adds, have some duties to perform.

PROVISION AS TO FARES IN ACCEPTED ORDINANCE HELD OBLIGATORY.

People v. Suburban Railroad Co. (Ill.), 53 N. E. Rep. 349. Feb. 17, 1899. Rehearing denied April 7, 1899.

A village ordinance granting to a street railway company authority to enter upon its streets and construct and operate its road there, provided that the fare charged shall not be above a certain amount, the acceptance of the ordinance, and the enjoyment of the benefits of its provisions by the company, the supreme court of Illinois holds, must be regarded as establishing, so far as the company is concerned, and as estopping it to deny, that the exaction of a greater sum for the transportation of passengers than said maximum is an unreasonable exaction, and unjust discrimination against those of the public who may desire to travel over said road.

The fact that the ordinance requires that the company shall formally accept it as conditioned, the court holds, has no effect to render the grant a mere private contract, and that there is nothing in the nature of the duty in question rendering it impracticable to enforce the performance of it by writ of mandamus.

Furthermore, if any consideration could be deemed necessary, the court holds that the privilege of entering upon the streets of the village, and erecting poles, stringing wires thereon, and constructing and operating the road by electricity upon and along such streets would constitute ample consideration to render the obligations imposed by the ordinance binding.

That one of the points covered by such restriction of fares is beyond the company's own line, the court apparently does not think makes any difference, if the company has made running arrangements with other companies, and is engaged in transporting its passengers, by means of its own cars and the cars of connecting lines, to said point, especially where the purpose is merely to prevent a discrimination in rates charged in said village and those charged at a specified other place on said company's road, for transportation to said point off its road.

Referring to article 11 of section 12, of the constitution of the state, the supreme court says that it vests in the general assembly

ample authority to enact laws to prevent extortion and unjust discrimination in the rates charged for the transportation of passengers by street railways, and that, notwithstanding the fact that the general assembly has not enacted legislation to carry this provision of the constitution into operation, yet the provision cannot be otherwise regarded than as a declaration of the sovereign power that a corporation operating a street railway owes it as a duty to the public to demand only reasonable prices for transportation of passengers, and to serve the public without unjust discrimination.

JUST COMPENSATION FOR USE OF TRACKS.

Grand Avenue Railway Co. v. Citizens' Railway Co. (Mo.), 50 S. W. Rep. 305. Mar. 21, 1899.

This was a proceeding by the plaintiff company, a street railway corporation of the city of St. Louis, to determine the compensation it must pay the defendant company, under a city ordinance, for the use of the latter company's tracks between certain points. Both companies objected to the award. The plaintiff company, on the ground that the amount was excessive. The defendant company, because too small, in that among other things,, no damages were allowed it for its loss of business by reason of the competition in a field it had occupied as a pioneer, and for the reason that the plaintiff company was not required to pay its proportion of the license or franchise tax imposed upon the defendant company by the city for the privilege of constructing and operating its road.

Now, if the defendant company had an exclusive right to occupy this street with its tracks, the supreme court of Missouri says, its right to compensation for loss of profits from competition would not be a question admitting of discussion; but the contrary, it holds, was absolutely true. When it received its franchise to construct its road and carry passengers for hire, the court maintains, it was not an exclusive right, and under the laws in force, could not be.

The court says that streets are dedicated for public use, and the trust is confided to the municipality to preserve them for that purpose only, so that it necessarily follows that it would have been competent to have granted a rival corporation the right to lay its tracks also on that street, and no action would have accrued to the defendant company for the diversion of its business by reason of this competition. For this reason, and because, in addition, the defendant company accepted its franchise under a contract to permit any other road to use its tracks, the court holds that the idea of compensation for loss of profits from competition must be banished.

It also holds that, inasmuch as the rights to use a part of the defendant company's tracks did not make the plaintiff company a joint owner of its franchise, it need not pay any portion of its franchise tax.

Furthermore, the damages recoverable being limited, by the charter of the city to "just compensation," the court holds that the law excluded not only the diminution of profits by reason of compensation, but as well also the delays, inconveniences, and jolts arising from permitting one road to cross another, as the right of crossing in a public highway is an absolute one, and cannot be made the basis for an allowance of damages.

Then, the court declares, it is the value of the trackage occupied, and not its cost, which must form the basis of the computation of the compensation to be allowed.

Here, after such value was ascertained, the plaintiff company was required to pay interest at 6 per cent on one-half thereof. It was also required to pay one-half of the annual taxes, half of the annual cost of repairs and maintenance of the tracks on the defendant company's own estimate, one-half of the cost of sanding, watering, cleaning, and salting the tracks, and one-half of the cost of renewing said tracks and granite and wood paving whenever said renewals should be required, the plaintiff company being required to give a bond for $15,000 conditional that it would pay its said part of the cost of said renewals. Besides this, and the plaintiff company, having at its own expense, constructed the switches and connections with the tracks of the defendant company where their roads intersected, it was required to maintain the same, and keep switchmen at each, and employed at all hours when trains were running, and pay the same. The plaintiff company was also forbidden to hinder or delay the defendant company in the use of its tracks, and whenever the cars of both companies approached the intersection the defendant company was given the right of way.

These items, the supreme court holds, covered all the grounds upon which compensation could be lawfully allowed.

LEAVING SEAT INSIDE TO STAND UPON PLATFORM.

Terre Haute Electric Railway Co. v. Lauer (Ind.), 52 N. E. Rep. 703. Jan. 26, 1899.

The law applicable to this case was fairly stated, the appellate court of Indiana holds, in this instruction of judge to jury: "If you find from the evidence in the cause that the plaintiff was a passenger on one of defendant's cars, and was occupying a seat inside, in a safe place; and you further find that said car was crowded with passengers, and all the seats were taken, and that the plaintiff arose and vacated his seat to accommodate some lady passengers who had entered the car, and that, on account of the crowded condition of said car, instead of standing therein he voluntarily left it and passed out to the platform, and remained standing on the outside, where the accident occurred—then as to whether or not in so conducting himself he was guilty of negligence is a question of fact, which I submit to you. If his conduct in this respect, in doing what he did under the circumstances, was the conduct of an ordinarily prudent and cautious man, then he was not guilty of negligence. If, on the other hand, in going out upon the platform, under the circumstances, he did that which a prudent and cautious person would and ought not to do, then he would be guilty of negligence."

The appellate court says that it is not negligence per se (in itself) for a passenger to ride upon a platform of a street car, going there directly from the street, or from the inside of the car. The court will not presume that it is dangerous to ride upon the rear platform of a street car.

Furthermore, whether one ride on the platform of his own motion, or upon the request of the conductor, the court holds, would not be material. The rule, it says, would be the same in either instance.

Here the contention on behalf of the company was, not that it was negligence in itself for a passenger to ride on the rear platform of a street car, but that it was negligence for the one who had sued it to leave a place of safety, which he was occupying, for a place obviously more or less dangerous, upon a general request of the conductor, such as a request that some of the gentlemen should vacate their seats in favor of ladies, who had boarded the car, and stand upon the platform.

To this, the court replies that it thinks it clear that it is the duty of the passenger to follow the reasonable instructions, and rely on the judgment, of those in charge of the car, in regard to moving from one part of the car to another, unless it is apparent to the passenger that the movement would be attended with danger. The fact that this particular passenger had responded to a general request, which appealed to him as directly as to any one else in the car, the court holds, should not deprive him of any right he would have had, growing out of a compliance with a request addressed to him individually.

To the further objection that the request was unreasonable, the court answers that the request to gentlemen to vacate seats occupied by them in a crowded public conveyance, in favor of ladies, who would otherwise stand, is not, in this country, so regarded.

The conductor represents the company in the management of the car, so far as concerns the location of passengers. A request from one clothed with authority is practically equivalent to a direction.

INJURY OF INTENDED BOY PASSENGER RIDING IN PLACE OF DANGER.

Udell v. Citizens' Street Railroad Co. (Ind.), 52 N. E. Rep. 799. Feb. 15, 1899.

A boy, finding an open street car which he wished to take crowded, went, on the suggestion of a bystander, to the left-hand side, got upon the forward part of the car, a trailer, placing his feet on the boxing of the axle, and holding onto a portion of a seat with his hands. He neither paid any fare, nor offered to do so,

nor was he asked for his fare by any employe of the company. He had a nickel in his pocket, with which he could have paid such fare, and he intended to do so, if asked for it. He rode in the place described, in a stooping position, on the outside of the car, for about three-fourths of a mile, and until he arrived where he intended to get off and the car began to slow up. Here he was unable to retain his hold and fell off, and was run over by the wheels of the trailer. It further appears that on the left-hand side of the car there was no step or other means of entrance, and wooden strips extended from end to end, to prevent the ingress or egress of passengers. Besides, no passengers had been invited to enter the car on that side that day; the boy had not made his presence known to any of the employes of the company, and none of them saw him when the train was in the act of starting, or while he was hanging on the outside of the trailer after the train was under way, although they might have seen him, if they had made an examination of that side of the car.

Upon a careful review of these facts, giving to the conduct of the boy the most favorable construction, the supreme court of Indiana holds that they do not sustain the proposition that he was a passenger upon the company's car, to whom it owed the duty of safe carriage and immunity from injury. It says: He was not in a place intended for passengers. He was not received as a passenger. His presence on the car was not made known to the company's agents and servants. He did not conduct himself as a passenger.

The company's servants, the court continues, were not required to search for trespassers before starting the cars, and it was not bound to discover the boy, and remove him from the perilous situation in which he had voluntarily placed himself.

The distressing consequences of the boy's act in standing on the outside of the car, or the iron boxing of the axle, it insists, could not be said to be the result of any act or omission of the company or its employes.

The circumstance that the boy had a nickel in his pocket, with which to pay his fare when called upon, it further holds, did not make him a passenger. If he did not intend to pay his fare unless called upon, and left the car, or attempted to leave it, without paying his fare, it says that fact of itself would be entitled to weight in determining the question of his right on the car.

Moreover, as the special verdict failed to show that the boy was a passenger, the court declares that the rules concerning the overloading of street cars and the duty of street car companies to passengers did not apply.

Nor does the court consider that the fact that the boy was but a child aged eight years and seven months made him any less a trespasser, if the other facts found compelled the conclusion that he was wrongfully upon the car.

If, after an ineffectual attempt to get on the car at a proper and usual place, he abandoned that intention and became a trespasses, the court holds, he lost the right to that measure of care and protection which a carrier of passengers is required to extend to one who seeks to be carried as a passengr.

A judgment for the defendant is affirmed.

CONSENT OF ABUTTERS NOT NECESSARY TO ACQUIRE USE OF OTHER ROADS.

Ingersoll v. Nassau Electric Railroad Co. (N. Y.), 52 N. E. Rep. 545. Jan. 10, 1899.

Since 1839 there has been a statute in the state of New York providing that "it shall be lawful hereafter for any railroad corporation to contract with any other railroad corporation, for the use of their respective roads, and thereafter to use the same in such manner as may be prescribed in such contract." This provision is now incorporated into section 78 of the railroad law. But it has been left until this case for the judicial consideration by the highest court of the state of the question of whether it is in conflict with the constitutional proviso that "no law shall authorize the construction or operation of a street railroad except upon the condition that the consent of the owners of one-half in value" of abutting property be first obtained, and with state statutes requiring the consent of such abutters to the construction or operation of such railroads, extensions or branches thereof. The conclusion reached sustains the statute.

After reviewing the legislation of the state upon the subject of consents, the court of appeals says that it is evident that the legislature, from the beginning to the end of this general legislation, has never intended to require consents of local authorities or property owners to the operation by one railroad company of its cars over the tracks of another railroad company by virtue of a traffic contract with such other railroad company, but that it intended to require such consents only to the construction, maintenance, or operation of new railroad tracks constituting either main lines, branches, or extensions.

By the general railroad law, the court says, in order to acquire the right to construct, extend, or operate a railroad upon a public street there must be obtained First, consent of the municipal authorities; second, consent of a majority in interest of the abutting owners, or, if that cannot be had, the consent of the appellate division of the supreme court of the state. When these consents have been obtained, and the railroad corporation obtaining them has in all other respects complied with the commands of the general railroad law, it acquires what is known as a franchise, and one of the important features of that franchise consists in the right to contract with another corporation for the use of its tracks, which right becomes a part of the franchise—a right that neither the municipality nor the abutting owner can take away or impair.

Upon the subject of the granting of similar franchises, the court says that the state constitution has been the subject of amendment, and later of revision, but no single sentence can be pointed out that indicates a purpose of changing the established public policy so far as it authorizes railroad corporations to contract with other railroad corporations for the use of their roads.

It is well settled, further says the court in this case, that a perfected railroad franchise, constituted either by direct legislative grant or by consent of local authorities and property owners in pursuance of the constitution and general laws, especially when followed by actual construction and operation, is a property right that cannot be afterwards taken away or diminished, either by subsequent constitutional amendment or by legislative or municipal action, except in the exercise of the police power or the right of eminent domain.

Salability is an essential element of property, and the destruction or diminution thereof is a taking of property that cannot be done except through the exercise of the eminent domain or of the police power. The salability of the property right in qustion is affected, and its value diminished, if not destroyed, if the assignee thereof cannot make use of it without the consent of the abutting owners.

It therefore follows, declares the court, that if the legislation which it was argued required consents of abutting owners attempts to prevent a railroad corporation from possessing the right to contract for the use of its road with another corporation, from conferring on that other the absolute right to make such use, it is wholly without authority and void. But it adds that it seems to it, as above stated, that the legislature has made no such attempt.

MAKING MILEAGE TAX CONDITION OF GRANTING LICENSES.

Chicago General Railway Co. v. City of Chicago (Ill.), 52 N. E. Rep. 880. Oct. 24, 1898. Rehearing denied Dec. 14, 1898.

This was a controversy over the power of the city to impose a mileage tax in the ordinance granting the company named authority to construct and maintain a street railway on certain streets. It was not denied by the company that the city had the power to impose a money condition as a license fee, or to protect it against liabilities and expenses occasioned by reason of the construction of the railroad in its streets, or for expenses and the like of the city. But the company contended that the ordinance showed an unlawful attempt on the part of the municipality to sell its license, and that it was clearly within the power of the council, by its ordinance, purposes of municipal government; also that, because the ordinance contained other terms and conditions for the protection of the city against loss or disbursements, such as a license fee of $50 per annum for each car operated, there was no room for the presumption that the condition for the payment of the tax per mile was with a view to such purposes.

In these contentions, the supreme court of Illinois, however, declares itself unable to agree with counsel for the company. It holds that it was clearly within the power of the council, by its ordinance, to make this additional condition if it so desired, and that the

courts cannot indulge the presumption that the act was done for an illegal purpose, it being apparent that it could be done legally.

Moreover, if it were true, as contended by counsel, that the purpose of the mileage tax was to compensate the city for granting the privilege to the company to lay down its tracks and operate its street railway, the supreme court declares that it is still, in its opinion, a valid condition, and comes fully within the scope of the power granted to the city by section 3 of the horse and dummy act.

Neither does the supreme court consider that the ordinance in question was unconstitutional on the ground that the company was, by the condition, denied the equal protection of the laws or was deprived of its property without due process of law; nor does it concur in the argument that a general law may be made applicable to all street railways in the city, but no special ordinance can be enacted, and that, because other ordinances had been adopted by the city granting privileges to other railway companies to occupy the streets without exacting this condition, this one was unconstitutional. The statute having given the municipality power to grant or withhold its consent as "it shall deem for the best interest of the public," the power being discretionary, the court thinks that it is manifestly not to be exercised by a general ordinance applicable alike to all cases, but each case must be acted upon with reference to its peculiar conditions and circumstances. If, in the exercise of its sound discretion, the city council shall determine that the best interests of the public do not require the imposition of any conditions whatever, the court goes on to say, it may grant its license without qualification; but if, on the other hand, the public interest requires that the occupancy of particular streets, under peculiar conditions, demands that certain exactions shall be made of the company for the privilege conferred, then the city council has a right to so provide, and no constitutional right or privilege is interfered with.

The supreme court is also of the opinion that, even though it might be held that the condition upon which the permit or license was granted to the railway company was ultra vires, the city not having the power to impose it, nevertheless, the ordinance having been accepted by the company with the condition attached, agreeing thereby to perform it, it became a valid contract between it and the city, the validity of which the company is now estopped to deny.

RUNAWAY HORSES ARE NOT AMONG THINGS TO BE EXPECTED BY MOTORMEN.

Phillips v. People's Passenger Railway Co. (Pa.), 42 Atl. Rep. 686. Mar. 13, 1899.

The injuries to recover damages for which this action was brought were sustained in a collision between a street car and a runaway horse behind which the plaintiff had kept his seat as it ran down a cross street onto the street railway track. The negligence charged against the street railway company appears to have been in the failure of its motorman to stop the car, when called to by the plaintiff to do it. But the supreme court of Pennsylvania reverses a judgment obtained by the plaintiff, declaring that it is unable to see in the testimony any evidence of negligence on the part of the motorman. Indeed, there was no evidence that he heard the plaintiff call to him, or that he was otherwise made aware of the approach of the runaway horse.

It was the motorman's duty, undoubtedly, says the court, to look for approaching cars and other vehicles which might collide with his car; but anything moving with the speed of a runaway horse was not to be apprehended, and he might very well have assured himself that none of the ordinary dangers of street crossings threatened him, without having either heard or seen the approach of the plaintiff.

He had not brought his car to a full stop at the crossing, nor was there, continues the court, any reason why he should, so far as the testimony showed. A motorman certainly cannot be required to stop at every crossing, and look for such extraordinary perils as the one in this case; nor can he be required to stop at all, unless the circumstances are such that it would be imprudent for him to do otherwise.

Moreover, even assuming that the motorman knew the situation perfectly, the court holds that it cannot be said that he was bound, upon being confronted by so sudden and immediate danger, to do what, after mature deliberation, would have seemed to a prudent man to be the wisest thing under the circumstances. Where the sole basis of liability is the omission to perform a certain duty suddenly and unexpectedly arising, there must be not only a consciousness of the facts which raise the duty on the part of the person who is charged with its performance, but also a reasonable opportunity to perform it.

Finally, notwithstanding the disastrous outcome, the court wants to know how the jury could say that the motorman, with the duty uppermost in his mind of saving his passengers, if possible, from an imminent collision, did not judge—and that with reason—that his best chance of doing so lay in attempting to clear the runaway's course ahead of it? And how could they say that such a course would not have seemed to the majority of prudent men, if placed as he was, to have been the best. If he knew anything of horses, it says, he knew that no human foresight can predict the course of a runaway, even for a short space, and that the horse was as likely to attempt to go around the car at the rear as at the front, and that, if maddened, it might dash into his car no matter in what part of the street it was.

A NEW TRANSFER PUNCH.

The accompanying illustration shows a novel form of transfer punch, which is the invention of Mr. Clyde Landers, of Tacoma, Wash., and has for its object the economy of time and money in issuing transfers on street railways. The picture gives a good idea of the size of the instrument, which may be carried in the pocket. The one shown holds 250 transfers in the magazine and by slightly enlarging the case at one end the capacity may be doubled.

The magazine is filled, the date adjusted, and the instrument locked at the office of the company. To issue a transfer the conductor sets a pointer, which is on the end of the small cylinder opposite the time dial, to indicate the route for which the transfer is intended, and then turns the time dial through one revolution, when a transfer ticket bearing the date, time, place of issue and destination is pushed out as shown. The instrument shown will issue for ten routes; the intervals of time are five minutes.

LANDERS TRANSFER PUNCH.

The advantages claimed for this device are that the time cannot be "backed up" and thus mistakes in issuing "late" transfers are entirely avoided; the transfer tickets are more quickly issued than when printed forms have to be punched in several places; the ticket is more easily read; and, as the date is set at the office, the conductor cannot accidentally make an error in or willfully change the date.

The firemen and policemen of Oshkosh, Wis., may ride free on the street cars, notwithstanding the anti-pass law, the company having concluded that the provision in its franchise for carrying firemen and policemen will protect it.

ELECTRIC RAILWAY IN JAMAICA.

The United State consul at Kingston, Jamaica, describes the electric railway in that city as follows:

For some years there has been a mule railway in Kingston, but an electric road covering the lines of the old cars and other thoroughfares as well has just been completed. This new line has about 25 miles of track in and around Kingston, divided into three districts, viz., the lines north of the city, those east of the city, and those in the city. It is a private enterprise, started by Canadian capital, and is called the West India Electric Co. The government license is for a period of 30 years, renewable for further periods at the pleasure of the governor. The company pays 4 per cent of its gross earnings to the government, and assumes the maintenance of the roads and streets occupied by it to the extent of 18 in. on each side of the tracks.

The rates of fare are four cents for each passenger from any point within a district to another point in the same district by most direct route; that is, the fare is practically four cents for each section of the line, and from the end of the line to the east, through the city to the end of the line north, would be three fares, or 12 cents. In addition, the company reserves three front benches on each car, on which a first-class fare—six cents—is charged. The tickets are sold as follows: Seven four-cent tickets for 24 cents, five six-cent tickets for 24 cents, and 10 children's tickets, for under 12 years, for 24 cents.

Passengers are allowed to stand. There are no restrictions as to number of passengers carried, and the same complaints of overcrowding are heard. Cars run every 15 minutes in the city. In addition to regular motors, this company runs market cars before 9 a. m. and after 5 p. m. for country people who carry produce. These cars are trailers, and the fare on them is three cents.

SITUATION IN WICHITA, KAN.

A correspondent in Wichita answering an inquiry in reference to the street railway situation there, states that the press reports are greatly exaggerated and do the city, the judge and the company injustice, to say the least.

In 1890 the city council granted the Wichita Electric Ry. a 20-year franchise for the construction and operation of an electric street railway; this franchise was sold in 1893, together with the entire plant, to the Wichita Electric Railway & Light Co., which now owns the property and is operating under this old franchise. This is the franchise that the city is now bringing action to annul, because, it is alleged, that the company has permitted the line to run down and get out of repairs, and in other ways forfeited the rights granted under the franchise.

When the city brought injunction proceedings in the District Court to compel the line to stop running, the judge granted the petition, but at the same time required the city to give sufficient bond to indemnify the company; but after considering the matter further the city decided that it could gain nothing by the continuation of these proceedings and failed to file the required bond, consequently the cars are still running, and in all probability will continue to do so for some time to come.

The present owners of this line have had financial reverses and being unable to put more money into the line so as to make it a profitable institution, are obliged to dispose of it.

In 1897 the Wichita Railway, Light & Power Co., was organized for the purpose of buying up the old line, rebuilding it and installing an electric light station in connection with the railway; after 18 months of hard work financing the company and fighting the existing Light company, the new company has not yet been able to get the thing started, but is still at it and may make the deal go in spite of all opposition. The present outlook is more favorable than ever.

The franchise which was given to the new company had a time limit in it for the completion of the work, besides a cash forfeit, which the city proceeded to take when that time was up and the line not finished.

Our correspondent has been assured that the city will stop the pending litigation and grant new franchises to a new company which will buy up the present line and invest money to make necessary improvements. The property of the old company may be had for little more than its scrap value.

The present condition of the street railway line can be attributed to the boom of some 10 years ago when everybody went wild and laid a foundation here for a city of the size of Chicago; the car lines then went all over the town and into the corn fields in the country; every new addition had its car line. When the boom burst it carried down with it the majority of the people, and the car company found itself with miles of lines that paid nothing; these lines were from time to time pulled up, until we have now about 17 miles left. This mileage, if in proper shape, would prove profitable. Wichita is fact growing now, and in a very substantial manner; its wholesale and jobbing interests are enlarging every day, and there is certainly a future for it.

The newspaper notoriety which has been given the litigation is unfortunate, because, as stated, the report does all parties injustice and makes it more difficult to finance a new company.

EXCURSION PERMITS.

The Birmingham (Ala.) Railway & Electric Co. has for some time made a practice of giving half-rates to excursion parties in charge of teachers, and has found the traffic profitable. Until recently it has been necessary to make arrangements in advance to secure the reduction in fare, but Gen. Mgr. J. B. McClary has devised a means for those desiring to secure the reduced rates to do so without any inconvenience whatever. Teachers' excursion rate permits have been sent to all the teachers in the county and when one of these is presented with a party of 20 the conductor collects for the round trip and gives the holder of the permit a certificate of payment good for the return trip.

BIRMINGHAM RAILWAY & ELECTRIC COMPANY.

TEACHERS' EXCURSION RATE PERMIT.

To Conductors East Lake, Ensley and Bessemer Divisions:

The bearer, _____

Is entitled to half fare rate for the round trip, for twenty or more, when in a body both ways. The holder of this permit will show it to Conductor, who will collect one fare on outgoing trip and give bearer return check for the number of passengers paid for. This return check will be accepted by conductor on incoming train as full fare. Check to be made out in duplicate, original to be turned in by outgoing Conductor.

This permit good until _____

No. _____ _____ **Gen. Mgr.**

Not Good for Any Number Under 20.

BIRMINGHAM RAILWAY & ELECTRIC CO.

_____ DIVISION.

This Certifies that _____

holder of Excursion Permit No. _____ *has paid me for* _____ *passengers to* _____ *Conductor on incoming trip will accept this for* _____ *passengers without further payment. Good only for this date* _____ *Conductor.*

Signature of holder of Excursion Permit O. K. _____

Date _____

INSTRUCTIONS TO CONDUCTOR. You will fill this out in duplicate and get holder of permit to sign both original and duplicate. You will turn in original with cash to balance and give permit holder the duplicate, which will be good for return passage. J. B. McCLARY, G. M.

NOT GOOD FOR ANY NUMBER UNDER 20.

The permit is on a card $4^1/_2 \times 2^5/_8$ in. and the certificate is a blank $5^1/_2 \times 3^3/_8$ in. Both are shown herewith somewhat reduced in size.

The conductors and motormen of the Middletown (O.) Traction lines were granted a raise of wages from 15 cents to 17 cents per hour last month.

The projected electric railway between Grand Rapids, Muskegon and Grand Haven, Mich., is being delayed for want of steel and copper. The promoter, however, says it will be completed this year, notwithstanding.

ELECTRIC TRACTION ON TRAMWAYS.

Extracts from a paper read before the Cleveland Institution of Engineers, Stockton-on-Tees, by J. Clifton Robinson, May 29, 1890.

Mr. J. Clifton Robinson, managing director and engineer of the Imperial Tramways Co., and several other tramway enterprises, delivered an admirable paper before the Cleveland Institution of Engineers, in which he recited in careful detail the history of the progress of the electric railway, and described the installation and construction of several of the most conspicuous tramways of Great Britain. We regret that space forbids its publication in full, and we content ourselves with extracts, which are valuable as showing the prevailing views of the best English engineers on the several forms of electric propulsion.

THE ACCUMULATOR SYSTEM.

There cannot be a question that the ideal method of electric traction would be to have the power "self-contained" in the car —in other words, the "accumulator system." It would rid us of many difficulties, if only those which it itself possesses could be got rid of. In the first place, the ordinary rails (if the line had been properly built) would suffice, no "bonding" or other special preparation being required. But against this there arises the fact that from the "dead weight" required to be carried by the car—from three to four and one-half tons on each car, in addition to the electric motors—a very strong road-bed is required, and few of our existing horse tramways have been laid with either rails or road-bed sufficiently strong to carry such traffic.

There would be no poles or wires above ground and no danger of electrolysis from leakage of current underground, so that two very material objections that at first told against the progress of the overhead system would be removed. The electric power used would not be exposed to such risks as floods and snowstorms impose on everyone of the underground systems yet proposed, and whether for overhead or underground, all objections under the Board of Trade restrictions, or the obligation placed upon us because of the near vicinity of our lines to Kew Observatory, would at once disappear. It may be asked why, with all such advantages, I am not a whole-hearted advocate for the promotion of accumulator traction, and the answer is not difficult to give—practical success with the system has not been as yet secured. The present disadvantages are many. If the road-bed has to be reconstructed owing to the existing construction being insufficient to carry the great weight of the cars, the accumulator system presents no saving in that direction. It is true the copper bonding of the rail joints for the return current is not required, but what is saved here is in my opinion balanced by the extra strength of the track which the enormous weight of the accumulator car would require. Again, the cars themselves are rendered much more costly in proportion to the paying load they carry, and this goes far to meet the cost of the poles and wires of the overhead system, if indeed it might not exceed it.

Owing to the opposition in Hanover and some other continental cities to the use of overhead wires in the central and more showy parts of the town, the system has been adopted of using a combination of overhead and accumulator traction and of the accomplishment of very fair results under this method there can be no doubt. But it will at once be seen that this is a most costly expedient, combining practically the costs and disadvantages of both systems, for the weight of the accumulators has to be dragged by the car during the whole of its course, however many miles it may run outside the boundary with the power drawn from the trolley wire. The only economy in the use of the joint method is this, that current not only sufficient to move the car is obtained through the trolley wire, but also current to re-charge the accumulators. The system works fairly well, but like all compromises, it is not one that can be de plano recommended for adoption. A portion of the Birmingham tramways has for some years been worked by accumulators, but the results there have not been such as to encourage the extension of their use, the latest figures showing that the expenses per mile considerably exceed the receipts.

About two years ago I carefully inspected and reported upon a most interesting line in Paris, newly inaugurated and running from the Madeliene to three terminal points at Levallois, Courebevoie, and the Pont de Neuilly. It is a reproduction, on a sufficient scale to give practical results, of a system introduced at Hagen in Westphalia, Dresden, etc., and may be considered as showing the use of accumulators under their most favorable conditions. The accumulator in use is constructed on a later principle, capable of bearing the shocks and jars of every-day tramway life, each car carrying 200 "units" of 40 lb. each, making a total dead weight of 8,000 lb. for each car. The chief novelty in this interesting line appears to be in the provision for re-charging the accumulators on the car. The method of distribution of current is arranged on simple lines. The cars carry enough power to run into the city from the several termini and back again, and the re-charging of the accumulators is done at the outer point. By this means any delay or crowding in the city center is avoided, and the cars there move in and out, as automatic machines. From the power house three feeder cables are led; the first, about 700 yd. in length, reaches a distribution post at the main terminus at Pont de Neuilly; the second, a mile and a quarter in length, carries current to the terminus at Courbevoie; and the third, two miles in length, crosses the river and proceeds to Levallois, the remaining terminus. (St. Ry. Rev., Aug. 1897, p. 505.) At each of the termini the feeder is led into a distribution post placed at the roadside, and outwardly resembling a pillar letter box. When a car reaches the terminus, the conductor places a length of elastic cable, connecting one end with the necessary apparatus in the distributing post, and the other with the terminals of the cells in the car. No electric skill is required from the conductor, the attachment of the elastic cable being automatically signalled to the power station and the charge being regulated there. The defect of this system is that the act of charging occupies seven or eight minutes, and more often 10 or 12 minutes, so that unless the distribution posts are increased in number the headway of the cars running is thus restricted. The three lines join up at various points, and the Madeleine furnishes a common terminus. Thus the cars there start off every three or four minutes, but the individuals local services are restricted in the manner stated.

UNDERGROUND SYSTEMS. I.—CONDUIT.

In another part of this paper I have hinted at the restrictions laid upon electric traction in this country by the Board of Trade rules, and when we leave the overhead system to consider the various inventions for providing haulage through electric currents borne and distributed underground, it is found that this restriction is not lightened, and that so far as the United Kingdom is concerned, stringent limitations are placed upon such a use of electric power.

Underground electric traction takes one of two forms. (1.) A continuous conductor, from which current is taken off by direct and sustained contact, similar to the contact of the trolley wheel in the overhead system, and (2) by intermittent contact with points provided on the surface of the road. In either case, certain requirements for the public safety are demanded, and these, while perhaps stronger in the case of surface-contact systems, are needful in any form of underground working. These requirements are:

1.—The Board of Trade regulation as to the drop in potential. This, of course, only applies where the rail is used for the return current, but even where a separate metallic return is provided, leakage requires to be provided against.

2.—The open slots and rails (in the conduit) and the metal studs (in the case of surface contact) and any other visible fittings must offer no impediment to ordinary street traffic.

3.—There must be no possibility, mechanically or electrically, of accident to persons, horses or other animals, or property arising from the electric currents leaking to earth.

4.—Interruption from flood, frost, or other climatic causes must be reduced to a minimum.

I do not wish to dwell on cost, but it must be evident that constructionally any underground system must considerably exceed in cost the overhead trolley. In operation, maintenance, loss from interruption and other features, the underground systems are more costly and are thus eventually less economical from a commercial point of view. The question of cost may perhaps be set aside in certain circumstances, such as the impossibility of obtaining assent to the use of any other system, but the question of "possibility" must in this country be subject to the operation of the first condition set forth, for if the Board of Trade rules as to potential and insulation cannot be satisfied the question of the use of underground currents in any form must be put aside. I am not satisfied that any invention yet set forth can fulfil those conditions, although the at-

tention of electrical engineers is being steadfastly directed to the solution of the problem. And until probably our own experience at Hammersmith is fully solved, the discussion of underground conduits or surface contacts has in Britain only an academic value.

The earliest conduit system in Europe was that at Blackpool in Lancashire, which was opened in 1883, and has been working since then till now. It is a line of under two miles in length and is worked by means of a conductor borne in a space between the rails. Contact is made by a "collector" from the car taking off current, and the return current is taken by the rails, which are bonded. The line has not been extended or imitated. Indeed, I believe an application to the Board of Trade is even now being made by the corporation for an order to convert this conduit to the overhead trolley.

The leading example of the use of the conduit system in Europe is at Buda-Pest, where since 1888 about 14 miles of tramway track have been operated on a system devised by Siemens & Halske. The remainder of the Buda-Pest tramways "outside the zone," are, it may be mentioned, worked by overhead wires, and the conversion of all horse tramways to electric traction has been completed, the conduit thus operating little more than a fifth of the tramway systems of the joint cities.

The conduit in Buda-Pest has several well-marked features. The rail on both sides is double, the slot on the right hand or inner rail receiving the flange of the wheel, which is here in the middle of the wheel surface in place of being at the edge, as in ordinary railway and tramway practice. On the outer side this slot serves a double purpose, receiving the wheel flange and also admitting the electric conductors which take off the current from the fixed conductors in the underground channel. The channel is constructed practically in the same way as that used for cable traction, with shaped metal yokes at distances of 4 ft., and a concreted hollow, heart-shaped, held in place by the yokes. In the chamber thus formed are two electric conductors, formed simply of T iron, and insulated with porcelain insulators. The positive conductor conveys the current to the car motor and the return current is carried with the negative. In this way it is claimed that electrolysis of gas and water pipes cannot arise, but it is obvious that this only remains true so long as there is a perfectly insulated earth return. A good deal of pains is taken to prevent ordinary rainfall from affecting the line, by means of sumps and manholes every 50 yd. and at street crossings, and ordinary obstructions in the slots are removed by wooden shovels or clearers of special form. The defects in this as a workable system in this country are several. The width of the slot is, in some instances, 1½ in., and the wear and tear of the traffic is constantly tending to increase this space. In these days of bicycles—not to speak of ordinary light traffic—such openings could not be permitted here, and the widening of the opening of course increases the possibility of the electrically charged conductors being reached, either intentionally or accidentally.

II.—SURFACE CONTACT SYSTEMS.

Although the course of electric experiment has during the past ten or twelve years brought forth many proposals for a system of "closed conduit" or surface contact, my remarks beyond a few general facts will be confined to three illustrations—two of them in actual operation, and the third now in process of development and perfecting, which appears to promise a fairly good solution of the problems presented. It must be kept in mind that the demands made upon a surface contact system are greater than in the case of a conduit. In addition to the difficulties inherent in both, the surface contact presents, as its name implies, an actual living electric current flush with the roadway, and therefore some more or less elaborate means must be provided by which these points where the current is brought to the surface must be "dead" except when the car that is to take off current from them is momentarily passing over the charged stud. Methods more or less ingenious have been devised to secure this but it must be evident that such apparatus tends to be costly in whatever form, and presents a serious risk at all times that the "cut-off" may fail and that the metal surface stud may remain as a great danger to every one crossing or using the roadway and particularly the foot passengers. In outward actual appearance a surface contact line presents no difference from an ordinary horse tramway beyond the presence of the metal "studs" with more or less frequency.

The records of the Patent Office indicate that Professors Ayrton and Perry were the first to devise and patent a surface contact system. They did not, however, proceed to practically test such a system, and the idea did not come into prominence until some years later. Diatto invented a system having some merits. The switches floated in mercury actuated from a solenoid carried on the car. A short piece of experimental line was constructed and the results obtained were satisfactory. The Claret Vuilleumier system in Paris was the next to be put into practical operation. (St. Ry. Rev., July, 1897, p. 451.) In this system the contacts are electrically charged from rotating switches placed at intervals in the streets. These switches have a number of contacts corresponding to the number of street contacts they are to operate. As the car moves ahead the switches rotate by a ratchet action synchronously with the cars, and maintain electrical contact with the studs underneath the car. The results obtained in operation are of an encouraging nature, although there have been times when the rotating switch would get out of synchronism with the car, and herein lies the weak point of this system. The Johnson-Lundell system was first tried in the streets of New York, and the results were, in a general way, satisfactory. The switches are placed under the street, and are worked by a solenoid connected in series with the car, the solenoid working one contact switch being in series with the solenoid in the preceding switch, so as to ensure the closing of one switch before the breaking of the other. The street contacts are placed at intervals of 8 ft.

The Claret-Vuilleumier system has this objectionable feature that no two cars can approach each other within the distance covered by the distributing chambers, that is to say a distance of about 100 yards. This is a serious drawback in the event of any breakdown or interruption of the line, as this space of 300 ft. remains dead and and inoperative; and it has the further disadvantage that no car can approach another within the block, so that in case of pressure of traffic when it is desirable to run cars at very short intervals, a limit is imposed which is not desirable. This system presents a further difficulty militating against its general adoption in this country, namely, that from the number and intricacy of its parts it would probably be found impracticable, or at least very costly to work it without the rail return current. Despite its ingenious mechanism and its two and a half years of successful working, I am not able to speak favorably on the system for this country, and its chief value must lie in its testimony to the practical success of a "surface contact" working.

In the Monaco surface-contact electric tramway there are two rows of studs, each placed about 10 in. inside the rail, and the car is in consequence furnished with two skates for a double row of contacts. The studs are round and stand above the road level about half an inch, and an arrangement of levers and springs provides that the skates shall always press sufficiently on the studs to make good and efficient contact. A small battery is carried on the car to start the current, and from it a slight current is given to the left hand bar (looking forward as the car goes) which is really used for the return current. The first contact makes connection direct to the supply current, which is then transmitted to the motor by the right hand contact bar, then returning through the left hand skate to the power house. At the instant of contact with the "positive" stud, current is set up through the feeder cable actuating a switching apparatus in the distribution vaults, and so the power is carried to the motor. When the shoe leaves a stud it becomes electrically "dead," and the current is being drawn from the next stud in advance, and so throughout the journey. The distributing vaults in this case are at a distance of about 218 ft., each chamber controlling 45 studs. These vaults, or rather pits, are about 6 ft. 6 in. in depth and measure $8\frac{1}{2} \times 3\frac{1}{2}$ ft., a manhole gives access to the pit for inspection, and the working of each car as it passes over the section can actually be watched in the subterranean vault as the connection is made and broken for each stud in succession. The rails are used for the return current. One feature of the working is that the cars can run back and forward on the single line with equal facility, and can closely follow one another when required.

More recently Professor Silvanus Thompson and Mr. Miles Walker have devised a very ingenious improvement in surface contact systems, combining the more salient advantages of the Johnson-Lundell, Diatto and other systems.

The disadvantages generally of surface contacts are:

1.—Complications.

2.—The disadvantage as compared with the slot conduit that double insulated earth returns lead to complications.

3.—The contact "studs" are objectionable, in that they present an irregular street surface.

4.—In the case of a network of tracks, there would be difficulty in preventing short circuiting during the passage of the car unless the contact "studs" are raised to such a height as would make them objectionable.

When a "mixed system" is used, the "overhead" and "accumulator" systems work easily together, because in that case the car, being in contact with the overhead wire, passes on without delay, the trolley just simply remaining idle. With a combination of overhead and underground conductors, the "surface contact" claims advantage over the open "conduit," as there is no delay as in the case of conduit, in fitting the plough or conductor into the slot or removing it on return. The car only requires to be fitted with the "shoe" or skate underneath, and passes on indifferently from the overhead to the surface contact portion of the route.

CONCLUSION.

I have very carefully examined into every new proposal for tramway traction, and have visited many places to test by actual inspection every new invention. But at the present moment my judgment is that the electric trolley "holds the field." It is simple in construction, easy in maintenance, cheaper than any rival in capital cost, and more economical in working cost from day to day than any other method yet known.

NEW SUPPLY HOUSE.

The firm of Gates & Randolph has been formed for the purpose of selling electric appliances and contracting for the complete outfitting of electric railways and electric lighting plants. The firm is composed of J. Holt Gates and Robert J. Randolph, both men having been long and intimately connected with electrical matters. Offices and warerooms have been opened in the Monadnock Building, on the ground floor. Connections have been made with several large and important electric appliance manufacturers and in its wareroom the firm proposes having some displays which cannot fail to prove interesting and attractive.

Mr. J. Holt Gates has also had an extensive experience in this

J. HOLT GATES.

field. In 1885 he became associated with Westinghouse, Church, Kerr & Co. in the Chicago agency it had just taken of the Westinghouse Electric & Manufacturing Co.

This house had only recently been organized in Pittsburg and Mr. Gates spent an entire year in the shops of the company there, studying the details of the business. The knowledge thus obtained he has since put to good use. Leaving Pittsburg, Mr. Gates went to Texas for the company, staying there for three years. He then came to Chicago, and after seven years service with the Westinghouse company, took the position of manager of the sales department for the Siemens & Halske Co. He remained with this concern for some years, but eventually went into business for himself, as the agent for various electrical manufacturing houses. He has been thus engaged for the past five years. Mr. Gates in-

R. J. RANDOLPH.

stalled the Auditorium Hotel electric plant, one of the model plants in Chicago.

Mr. Robert J. Randolph is one of the pioneers in the electrical field so far as Chicago is concerned. He began his work in it about 30 years ago and was associated with Charles J. Vandepoele in the company he organized in the early 70's. Mr. Randolph sold the first five arc light machine made by this company to a Rockford, Ill., manufacturing concern and it is still in working order. Soon after this the company turned out a 40-light machine and it created no end of speculation among electrical people.

The Vandepoele Co. became merged into the Thomson-Houston Electric Co. and Mr. Randolph went with the Excelsior Electric Co. and has been manager of its Chicago office ever since until about a year ago, excepting an interval during which the Excelsior closed its Chicago branch. It was the final closing of this branch about a year ago which led Mr. Randolph to look for other connections. He accepted the management of the Sterling Arc Lamp Co., of New York, where he has remained until the present copartnership with Mr. Gates was formed on the first of last May.

The experience of both Mr. Gates and Mr. Randolph in connection with electric work and appliances is all the guarantee needed that the new firm will meet with success.

HALF FARE BILL DEFEATED.

A bill was recently introduced in the Connecticut Legislature providing that during school hours, New Haven and Hartford school children should ride in the street cars at half fare. The bill also contained a similar clause for workingmen. The bill was referred to the Committee on Railroads, which reported unfavorably upon it, holding it to be unconstitutional, being class legislation. A substitute bill was then introduced making the same provision for school children, which applied to the whole state. In this shape the bill passed the House and came up in the Senate on a motion to concur with the House and reject the report of the Railroad Committee. Several senators opposed the bill on the grounds that it would be the entering wedge for a great many other bills of a similar nature, that workingmen of all descriptions would demand the same right, and that many of the roads in the state could not afford to issue the half fare tickets required.

A viva voce vote showed about twelve senators opposed to and four or five in favor of the bill, which was rejected.

The Montreal (Can.) Street Railway Co. is engaged in making some extensive improvements. It is building new shops and car house, new office buidings and laying new track.

NOTES FROM DENVER.

From Our Own Correspondent.

The consolidation of the street railway systems of Denver, Col., as noted in the "Review" for March last has been followed by a great deal of work in rebuilding track and rolling stock and further extensive improvements are contemplated. The Denver City Tramway Co. now owns and operates all the street railways of Denver except the Denver, Lakewood & Golden R. R., and it is interested in that one.

The company has decided to abandon the use of trailers and all single truck cars as rapidly as they can be replaced by the new type of rolling stock. Since the consolidation the company has taken on 128 new men. New cars are being turned out at the rate of 12 per month, six at the company's shops and six by the Woeber Bros. Car Co. Forty-nine cars have been finished and 16 more are in the shops. All of these are combination cars and were made by splicing closed motor cars and open trailers, thus disposing of 130 cars of the old equipment.

All of the smaller cars which were of suitable size were thus used. There were 79 open trail cars, 57 of which were old 28-ft. cable grip cars, and 69 motor cars which could not be spliced for combination cars because of wide difference in the hight, width and shape of roof. These will be spliced to make long open and long closed motor cars.

The company now has 158 miles of track and is preparing to build about 20 miles more if franchises are secured. The old cable lines, aggregating 32 miles, and what is known as the Argo horse line, 5½ miles, will be changed for electric traction. The old West End Street R. R., 10 miles, is to be changed from standard gage to 3 ft. 6 in. to conform to the other lines. Some of the West End cars have already been changed for the narrow gage, and all are to be painted red which is the company's standard color.

A new "Y" has been placed at the terminus of the Aurora line and the track improved by laying some new rails; the center poles have been removed and side poles substituted.

The line to Fairmount Cemetery has been extended a quarter of a mile into the cemetery and a loop, waiting room and two sidings built to provide better terminal facilities for the funeral train service. The present arrangements bring the funeral trains directly to the rear of the chapel at the cemetery.

A number of 32-ft. combination cars equipped with G. E. 800 motors have been put on these lines and make the round trip of 12 miles in one hour. They are run on a 15-minute headway. The traffic is very heavy, particularly on Sundays.

At Colfax Ave. and York St. where a number of lines center, the company in conjunction with the Gallup Floral Co. has erected a handsome station. The flower company has its office and displays its cut flowers and plants in the waiting room, while a large lawn set out with flowers makes the surroundings very attractive. At night the waiting room is illuminated by about 1,000 incandescent lamps.

The company has 75 pairs of Brill No. 27-D ("perfect") trucks which are being placed under the new cars. A number of maximum traction trucks, which have given good service for several years, are on hand but as the company has decided to use only trucks with wheels all of the same size it will rebuild these, using two pairs of large wheels to make a swing bolster truck.

The company has 125 new double equipments of G. E. 58 motors which have been substituted for the old equipment. Among the new equipment are 200 Syracuse electric headlights.

The car service has been improved on a number of lines, the headway being reduced wherever the traffic justified it. The company is now operating 136 regular cars and 22 extras are put on night and morning for the park line. It is the intention to build a central power station and a down-town car barn.

Iron poles are being placed in the business section of the city and the wooden poles removed. Within the last two months a great deal of new trolley wire, hangers, etc., has been put up. Some of the cable tracks are being removed as they are not needed since the consolidation.

The first trolley party of the season was given on May 27th; the party filled four large 16-bench cars.

One of the stockholders in one of the old companies is contesting the legality of the consolidation in the courts; the decision will doubtless turn on whether the law prohibiting the consolidation of railways is held to apply to street railways. It is generally understood here that the persistent attacks on the company made by one of the daily papers are largely because the manager of that paper failed in an effort to become the company's attorney.

The Boulder Railway & Utility Co. has been organized and has a franchise to build and operate street railways in Boulder and the adjacent county. It will get 18 cars from the Tramway Co.

It is reported that the H. J. Mayham Investment Co. is behind a new company organized to build between Denver & Boulder by way of Westminster University, Louisville, Marshall and other towns; this line is to be 32 miles long and cars will enter Denver over the Tramway's tracks.

The Denver, Lakewood & Golden R. R. has put in service a number of combination baggage and express cars.

The company had decided to adopt safety gates manipulated only by the motorman.

Smoking is permitted only on the two rear seats, and if a passenger begins smoking when in any other seat the conductor hands him a printed slip (shown reduced) which never fails to take effect.

Smoking is permitted only on the two rear seats of open or combination cars.

The Denver City Tramway Co.

The company has had more or less trouble of late because of poles breaking, and when the broken pole was reported the car crew could not readily tell the exact location so that the wreck crew would lose time in getting to the place. Now each pole has its number painted on it. Each line is numbered consecutively, beginning with 1, the two poles which are opposite one another being given the same number. Where several lines use the same track for a portion of their routes and then branch off, the poles on the branch lines follow the numbers on the main line. A broken pole may now be exactly located, as "Pole 47, right side, 11th Ave. line on Ogden St.," and no time is wasted in finding it.

The Denver City Tramway Co., in 1897, completed down town terminal loops which were illustrated in the "Review" for February, 1898, page 91. These loops are now used by the cars on 23 lines and the company is engaged in laying the connecting tracks necessary to bring the other 12 lines operated by it to this terminal. A new transfer station has been built at the loops for the convenience of passengers.

The Loretto Heights Railroad Co., which operates a line of horse cars, 3½ miles, from the terminus of the Tramway's South Broadway line west and south to Ft. Logan, has been engaged in litigation with several of the steam railroads trying to secure a grade crossing. There are five steam tracks used by eight railroads, and a compromise has been reached under which the street car line will tunnel under the track, the expense of $6,000 to be borne half by the Loretto Heights and half by the steam roads.

R.

WAGES INCREASED AT MONTREAL.

Last month the following order was issued by Mr. J. L. Wanklyn, general manager of the Montreal Street Railway Co.:

"(1) On and after July 16th, all permanent employes in the operating department and workshops will be insured in an accident insurance company of good standing, and the premium will be paid by the Montreal Street Railway Co. This insurance will amount to $1,000 in the event of death from accident either on or off duty, one-half of this amount for total disablement, and $5 per week indemnity for time lost through injuries or diseases specified in the policy, full details of which will be given when the final arrangements are made with the insurance company.

"(2) Motormen and conductors who have been regularly in the company's service for two years and over will have their wages increased to 15 cents per hour.

"(3) In addition to the above advantages, motormen and conductors who have been regularly in the company's service for five years and over will receive free uniforms."

HEAVY ELECTRIC SHOP LOCOMOTIVE.

The value of electric locomotives for industrial purposes is becoming more and more generally recognized and almost every week sees them adopted by some industrial establishment. The J. G. Brill Co. has just turned out a very interesting example of this type of machine for the Sandusky Portland Cement Co. Fig. 1 shows the machine ready for operation; it is mounted upon double trucks and is to have four motors. By means of very heavy constructive features and special ballast the weight is to be brought up to 14,000 lb., which will give a draw bar pull on a dry rail of considerably more than 3 000 lb. as ordinarily calculated. Probably under favorable circumstances the electric motors will bring this up to 4,000 lb. The machine is 19 ft. long over the end sills by

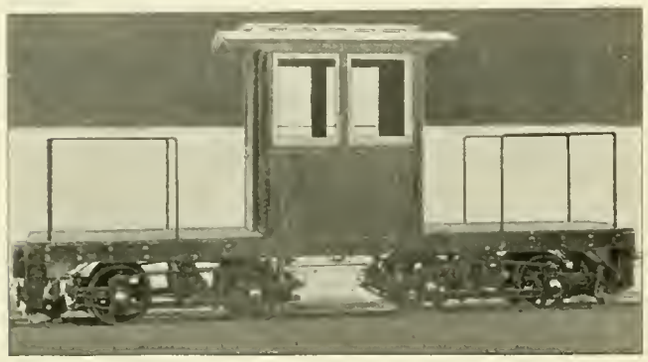


FIG. 1—BRILL ELECTRIC SHOP LOCOMOTIVE.

4 ft. 3 in. wide, and is intended to run on a shop track of 2 ft. gage; the height over the trolley board is 9 ft.

Fig. 2 shows the special form of Brill truck designed for this class of work. The truck frame is a steel casting and the ends are of T-iron. A center-bearing bolster rests an nests of helical springs; there are also journal springs. This combination makes not only a very compact but a very easy riding truck for work of this character. An ingenious arrangement of the parts makes the bolster have what is practically a swing motion. It is allowed to rock on the helical springs and in order to bring it always to a central position four small helical springs are provided which bear against the central columns of the frame. With a truck which runs at such moderate speeds this amount of swing or side motion

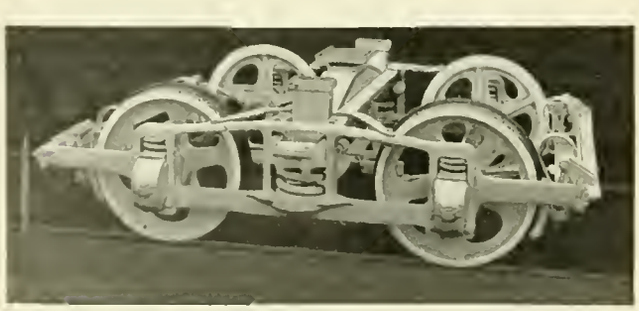

FIG. 2—TRUCK FOR ELECTRIC LOCOMOTIVE.

is ample for the purpose and reduces the danger of climbing the rails to a minimum. With a 4-ft wheelbase such a locomotive as this can run around any curve that is likely to be required in shop practice.

The motorman is protected by a small cab placed in the center of the platform. This cab is 5 ft. long and is provided with a sliding door. Pipe railings are provided on both sides, with openings next the cab. The machine seems to be one specially well adapted for use of establishments where heavy pulling is required and where the sharpest curves are of necessity encountered. The use of a double track of the kind described is of great advantage, making derailment very difficult. At the same time in spite of the heavy total weight it is very easy on the track. With all the weight on that has been contemplated the load per wheel will be considerably less than 2,000 lb.

STRIKE AT AKRON, O.

June 20th the employes of the Akron (O.) & Cuyahoga Falls Rapid Transit Co. went on a strike. Some time previously the men had asked for an increase in wages and the matter was referred to arbitration; the decision provided for an increase of 2 cents per hour for trainmen and 2½ cents for other employes. A broad article for the arbitration of all questions that might arise in the future was tacked onto the findings and the refusal of the company to accept this caused the strike.

The following day the article was modified to read as follows: "When any meritorious grievance or dispute arises and we cannot agree upon a settlement among ourselves, we will agree to submit the same to a board of arbitrators, one to be selected by each of the parties hereto, and the two thus selected to choose the third, provided that no demand shall be made to arbitrate any question involving the violation of any rule of the company now in force or any reasonable rule that may hereafter be adopted, or the conduct, carelessness or competency of any employe." There was no objection to this form and the men returned to work.

GRASSES AS SAND AND SOIL BINDERS.

The protection of earth embankments has long been an important question with the steam railroads and the increasing number of interurban electric roads is making the subject of interest to our readers. The U. S. Department of Agriculture has received many inquiries concerning grasses as sand and soil binders, and we take from a recent publication the following extract describing the grasses suitable for protecting embankments:

For holding embankments where a firm turf is required, couch or witch grass does excellently well in the Northern and Middle States. This well-known grass is widely distributed throughout the north temperate regions of the Old and New World. It presents a number of forms, some of which have been regarded as distinct species. All are good hay grasses, but are objectionable in fallow land because of their widely spreading and very persistent joined rootstocks. In the Northwest—Nebraska, Montana, etc.—there is a variety called "blue stem," which is very highly prized and much used for hay. In rich soil the stems grow to the height of 3 or 4 ft., and the heads have a striking resemblance to those of wheat. Hence the common names "wheat grass" or "creeping wheat," which have been applied to it by some. Couch grass makes a very tough sod, and is particularly valuable for binding railroad embankments, banks of canals, ditches, or other slopes which it is desired to hold in place. A well-marked variety of the species grows in sands along the sea coast, and is useful there as a sand binder.

Hungarian brome grass is a good turf former, and may be employed in much the same way as couch grass. The creeping rhizomes of the brome grass are not so strong as those of the couch grass, and as a soil binder it is less to be depended upon.

In the Southern States, where the couch grass does not succeed well, Johnson grass or the finer Bermuda may be substituted for it. Johnson grass produces a great mass of extensively creeping, strong rhizomes, and when once the ground is filled with them, it is almost impossible to eradicate them. Bermuda grows more upon the surface, and upon a light or sandy soil succeeds better than Johnson grass. In binding together and holding levees of sand and loose soil against floods, in preventing lands from washing, or in filling gullies, Bermuda is of the greatest value, and at the same time is one of the very best pasture grasses for the South. If there is considerable moisture in the land, and the soil is somewhat clayey, knot grass may be substituted for Bermuda. In the Southern States knot grass is especially well adapted to cover silt or bare slopes on the banks of ponds or rivers, or for covering the soil of "sink holes." Moderate submersion does not injure it.

BRAKE SHOES.

At the Atlanta convention of the American Street Railway Association, in 1894, a committee consisting of D. F. Henry, president of the Federal Street & Pleasant Valley Passenger Railway Co., of Pittsburg, Pa., and Powell Evans, foundry sales agent for Wm. Wharton, jr., & Co., Incorp., of Philadelphia, presented a special report on the subject of brake shoes. (Report A. S. R. A., 1894, pp. 152-180; St. Ry. Rev., 1894, p. 621.) At this meeting a committee consisting of Henry C. Moore, of Philadelphia; Ernest H. Davis, of Williamsport, Pa., and Powell Evans, of Philadelphia, was appointed, with instructions to investigate the subject of the adoption of a standard style of brake shoes, conduct experiments, and report the data collected, and the committee's conclusions at the next meeting. So far as can be learned this committee never made a report.

The A. S. R. A. committee of 1894 estimated the total annual expenditure of the street railways of the United States for brake shoes and labor in changing shoes when worn out to be in excess of $670,000 per annum. The subject is of fully as much importance now as it was five years ago, and it is our intention to collect here the available data concerning the coefficient of friction, the wear of the wheels due to brake shoes, and the durability in service, which are three of the important points to be considered in choosing brake shoes.

For the following summary of brake shoe patents, early tests and digest of the literature of brake shoes, we are indebted to Mr. John C. Whitridge, associate editor of the Railroad Gazette, who courteously placed at our disposal an unpublished manuscript on "Brake Shoes for Cars."

PATENTS.

An examination of brake shoe patent records for the last 30 years is interesting, but not very instructive, as the large majority of the brake shoes patented are useless and have never come into general use, if they have been used at all. A list of about 40 patents, issued since 1865, includes all the best known ones or those under which large numbers of brake shoes have been made. Among these 40 are the Congdon, Ross, Meehan, Lappin, Sargent, Schoen, Whitcomb, Corning, Allen & Morrison and Kinzer patents.

Beside these several hundred patents have been issued which are of no value, many of those of early date covering crude devices for attaching the brakeshoe to the head or holder; the adoption by the M. C. B. Association of standard dimensions for brakeshoes and a standard brakehead of the type originally patented by Mr. James Christie has been of great benefit in making this important detail uniform on almost all roads.

Almost every common material has been suggested or tried for brake shoes, such as wood, stone, glass, metal with rubber inserts, wood inserts, cork inserts, and one patent provides for the use of rope packed into cavities in a cast iron body; more lately what is known as the "composition" brake shoe has appeared, consisting of a mixture of iron turnings and borings, saw dust, asbestos, resin, plumbago and linseed oil pressed into a cast iron casing. Another composition material is made from iron turnings, asphaltum and mineral cement. All the common metals have been tried in many different forms and combinations; thus there are plain brake shoes of cast iron and cast steel, forged iron and forged steel, malleable iron and chilled iron, while it would seem that these materials have been combined in almost all conceivable ways.

Among the patents which are interesting because they show what a meager notion their inventors had of the requirements of a suitable brake shoe, are the following:

J. H. Champlin, Jan. 24, 1865, No. 45,975. Case for insertion of stone block which bears on wheel. Set screws permit of an adjustment of the block for wear.

O. J. Hardgrove, Feb. 27, 1866, No. 52,848. Hinged brake shoe, which grips the sides of the wheel, as well as bearing on the tread and flange.

H. L. Perrine, May 7, 1878, No. 203,495. Brake shoes made from rolled channels and the sections.

J. H. Mitchell, Sept. 30, 1879, No. 220,165. Brake shoe with cast iron body having cavities filled with rope or other textile material.

C. F. Wohlfarth, Aug. 16, 1892, No. 480,982. An oil chamber in the cast iron body connected by wicking to recesses in the face filled with sections of belting or other similar material. The surfaces in contact to be oiled to prevent squeaking. Linseed oil has been found to answer best "in practice."

J. O'Brien, Nov. 6, 1894, No. 528,553. A brake shoe having a nest of rollers on the face of the shoe which are brought in contact with the wheel during an application. Object to avoid "danger of sliding wheels" and "to provide a brake shoe which is strong and durable and at the same time simple and inexpensive in construction."

TESTS PRIOR TO 1895.

The data on friction between dry metal surfaces given in the earlier editions of the Engineers' Pocket Books are from the experiments of Morin and Rennie; in later editions the subject is treated in a different manner, but the relations which pressure, speed and contact bear to one another are not correctly stated.

Kent's Pocket Book, 1895, contains a table of coefficients of friction of rest as the result of experiments made by Rennie in 1829 which would indicate that as the pressure per square inch increases the coefficients of rest increase up to the point where abrasion takes place. The range of pressures used was 187 to 784 lb. per square inch, and the metals tried were wrought iron on wrought iron, wrought iron on cast steel, steel on cast iron, and brass on cast iron. It is questionable whether these results have any value.

Morin's "Laws of Friction" are also stated and explained to be in error. They are as follows:

1. The friction between two bodies is directly proportional to the pressure; i. e., the coefficient is constant for all pressures.

2. The coefficient and amount of friction, pressure being the same, is independent of the areas in contact.

3. The coefficient of friction is independent of velocity, although static friction (friction of rest) is greater than the friction of motion.

Morin's experiments were made in 1831 and these erroneous "laws" are to be found in many text books on the subject published within the next 50 years. They also appear in even modern works, for instance, the Century Dictionary contains the following misleading statement, evidently copied from some old work:

"Friction is partly due to the adhesion of bodies, but the greater part of it is the result of their roughness. The friction proper is independent of the velocity and of the area in contact, it depends solely upon the nature of the two surfaces and upon the pressure upon them to which it is directly proportioned."

No really reliable data are given by Kent on the friction of dry metal surfaces.

It was demonstrated by M. Poiree, in 1851, that constancy of friction held good for velocities not exceeding 10 or 11 miles per hour, but for greater velocities the resistance of friction appeared to diminish in the same proportion as the velocity increased. Other experiments for the purpose of deducing laws of friction have been made by Coulomb, Rennie and Jenkins, but in all cases they were made with bodies at comparatively low velocities.

In 1878 Capt. Douglas Galton made some experiments with trains on the London, Brighton & South Coast Ry. for the purpose of determining the coefficient of friction between surfaces in contact, moving at high velocities, in connection with the action of brakes in use at that time. These experiments gave excellent results, but were of narrow scope, covering only the action of cast iron and wrought brake blocks when used in connection with steel-tired wheels. These tests were reported to the Institution of Mechanical Engineers of London by Capt. Galton and these reports were reprinted in book form by the Westinghouse Air Brake Co., in 1894, with a preface prepared by Mr. R. A. Parke, its eastern representative. Mr. Parke also calculated a formula covering the relation between the mean coefficients of friction and the speed which would conform closely with the observed data of the tests.

A committee of the M. C. B. Association in 1891 reported the principal results of a series of shop tests conducted at the Aurora shops of the Chicago, Burlington & Quincy R. R. for the purpose of determining the friction of different metals, principally hard, medium and soft cast iron, malleable iron and wrought iron in connection with chilled iron wheels. The apparatus used was a Thurston oil testing machine adapted to the purpose by introducing a chilled wheel 11½ in. in diameter and by using miniature brake shoes 4 in. long by 1 in. wide. The load on the shoe was maintained constant and weighed by means of levers and weights,

while the tangential pull was measured by means of weights and lever scales. Each test was of 10 minutes duration and the shoes were weighed before and after each test, to determine the wear. During the following year similar tests were made with a steel-tired wheel, but these latter experiments were never made public. The most striking feature of these tests is that with soft and medium cast iron the highest friction is given at the beginning, while with hard cast iron and malleable iron the maximum is not reached before from three to four minutes run, after which the friction is about constant, and about equal to that of soft and medium cast iron; wrought iron does not show this action to so marked a degree.

In 1891 and 1892 the Pennsylvania R. R. made some useful experiments for the purpose of obtaining a comparison of the retarding power where one and two brake shoes were used per wheel, the same total pressure per wheel being used in each case. The effect on the retarding power of long and short brake shoes and brake shoes of different materials was also investigated; likewise the relative wear of these different kinds of shoes in continued service and the relative effects of the various brake shoes on the wheels. These tests were made by allowing cars to run down a grade of 80 ft. to the mile and applying the brakes after the desired speed had been attained. The observations were recorded in a dynamometer car. The results of these tests were presented to the M. C. B. Association in 1893 and were abstracted in the A. S. R. A. report of 1894, and are unsatisfactory in so far as the stops were made from low speeds, a limited variety of shoes and only chilled wheels were used, and because the measurements were obtained in units not properly comparable with similar work done at other times.

At the annual meeting of the M. C. B. Association in 1893 a general committee of twelve was oppointed to outline and conduct a series of service tests to determine the relative wear of a wide variety of brake shoes, each member representing a separate road. Five of these roads eventually declined to take part, leaving seven roads to carry on the work, namely, the Fitchburg, Chicago, Burlington & Quincy, Chicago, Burlington & Northern, Chesapeake & Ohio, Lake Shore & Michigan Southern, New York Lake Erie & Western and Norfolk & Western. Each of these roads conducted tests with the shoes selected, a list of which will be given in connection with the laboratory tests. Each car under test had one truck equipped with soft cast iron brake shoes made by the Pennsylvania R. R., entirely of new metal, no scrap being used, while the other truck was fitted with a set of the special brake shoes which were included in the test. The cast iron wheels under test were principally 33 in. in diameter and the steel-tired wheels were quite evenly divided between 33-in., 36-in. and 42-in. wheels. The wear of the shoes in each case was reckoned relatively to the wear of soft cast iron reference shoes.

The wear of the wheels was determined by the Lake Shore & Michigan Southern only, by making plaster casts of the tread and flange before and after the tests. These records plotted together showed the amount of wear. The diagrams taken are reproduced in the proceedings of the M. C. B. Association for 1895.

LITERATURE.

The following references to articles in the Railway Master Mechanic and the Railroad Gazette may prove of convenience to those who wish to investigate the subject more fully.

1889. Ry. M. M., Nov., p. 678—R. R. G., Oct. 18, p. 193—Paper by Mr. W. D. Sargent, "The Best Metal for Brake Shoes," before Western Railway Club.

FRICTION OF BRAKE SHOES.

As practically all the available data on the subject of the friction of brake shoes are from the results of the M. C. B. laboratory tests a proper introduction will be a summary of the work done by that association.

In 1879 the relative efficiency of different brake shoes was discussed, and some rough experiments made on a pair of car wheels mounted in a lathe were described. In 1880 a report was presented giving the results of shop tests to determine the relative wear of cast iron, wrought iron and Congdon brake shoes. In 1881 was begun a discussion as to the advisability of adopting a standard form of shoe; in 1886 the Christie form of shoe and head became the standard of the association.

In 1889 the question of the best metal for brake shoes came up for discussion and a committee to make shop tests was appointed. In 1891 the results of tests on small shoes (previously referred to) made at Aurora were presented.

In 1893 a committee on laboratory tests and a committee on road tests were appointed; both committees reported progress in 1894. In 1895 the committee on road tests made a final report, which appears in the M. C. B. proceedings for 1895, pp. 111-131. The committee on laboratory tests filed a report in 1895 (M. C. B. Proceedings, pp. 131-160) and in 1896 presented in full the results of between 1,200 and 1,500 tests (M. C. B. Proceedings, 1896, pp. 198-278.)

Since 1896 the only brake shoe tests on the M. C. B. apparatus, results of which have been made public, were tests of the "Diamond S" shoe made for the Sargent Co. at Wilmerding in 1897 and tests of the Corning shoe made at Purdue University in 1899.

The M. C. B. brake shoe testing machine was removed to Purdue University, LaFayette, Ind., in 1898. An illustrated description of this machine was published in the "Review" for November, 1898, page 830, and nothing further concerning it need be said here.

The brake shoes tested were of the M. C. B. standard dimensions, 3⅜ in. wide by 13¾ in. long, to fit the standard brake head. The face of each shoe was turned or ground to fit the test wheels, which were without taper and approximately 33 in. in diameter.

All tests corresponded to emergency applications of the brakes, that is the full pressure was applied and kept on until the wheel was stopped.

The great majority of the tests were made from initial speeds of 65, 40 and 30 miles per hour, and with braking pressures of 10,733 lb., 6,750 lb., 4,000 lb. and 2,798 lb. on the shoe.

The table showing the mean coefficients of friction was prepared from the data published in the M. C. B. Proceedings, from the report of tests made for the Sargent Co., of Chicago, by Mr. Whitridge and from the report of tests made for the Corning Brake Shoe Co. by Professor Goss, of Purdue University, and gives all the results obtained with 13-in. brake shoes on 33-in. wheels at the three speeds and four pressures. But few tests were made on the E, F, G (malleable iron) and N shoes, because the makers did not care to continue the tests. The I, J and K shoes were so easily broken and required so much time to fit them to the wheel that complete records were not obtained. The P shoe was submitted at too late a date for extensive tests to be made.

The tests were run in series of three or more under similar conditions as to speed and pressure, and on some shoes many different series were made under similar conditions. In the table the mean coefficients of friction only are given. For each shoe and each set of conditions there are three figures: The first one is the average of all the averages of the different series made under similar conditions. The second line is the highest mean coefficient from any individual test. The third line is the lowest mean coefficient from any individual test. They are all given in per cent, that is the tangential pull due to the friction of the shoe on the wheel is the given per cent of the braking pressure on the shoe.

Where the braking pressures for tests were different from those given in the headings of the table, foot notes call attention to the fact.

The reports of the tests also show the coefficient of friction near the beginning of the application and also 15 ft. from the end of the stop. The coefficient near the beginning was usually a few per cent greater than the mean. The coefficient 15 ft. from the end of the stop was in general considerably higher than the mean;

MEAN COEFFICIENT OF FRICTION OF 13-IN. BRAKE SHOES ON CHILLED AND STEEL TIRED WHEELS.

FIRST LINE — AVERAGE FROM AVERAGES OF ALL TESTS AT SAME SPEED AND BRAKING PRESSURE — PER CENT.
SECOND LINE — HIGHEST INDIVIDUAL TEST — PER CENT.
THIRD LINE — LOWEST INDIVIDUAL TEST — PER CENT.

DATA FOR SHOES A, B, C, D, E, F, G, H, I, J, K, L, M, N AND P FROM M. C. B. TESTS. * BRAKING PRESSURE — 10,000 LBS.
DATA FOR SHOES 2 AND 6 FROM SARGENT TESTS. + BRAKING PRESSURE — 6,831 LBS. † " " 9,000 "
DATA FOR CORNING SHOE FROM PURDUE TESTS. ▲ " " 4,143 " ‡ " " 5,000 "

steel shoes on both chilled and steel tired wheels frequently gave coefficients 15 ft. from the end of the stop which were twice as great as the mean. The P shoe had a coefficient 15 ft. from the end of the stop that was but little greater than the mean.

The diagram, Fig. 1, shows the range of the mean coefficients graphically, for braking pressures between 6,750 lb. and 2,798 lb. The heavy solid lines are steel tired wheel tests and the dotted lines chilled wheel tests. In general the higher pressure gives the lower mean coefficient, the lower pressure the higher mean coefficient, and intermediate pressures would give intermediate values for the coefficient. The fact that these lines have considerable length shows the variation of the coefficient with the pressure.

The relative position of the groups of lines shows the variation of the coefficient with the speed.

For the convenience of those who prefer to compare the frictional qualities of shoes by considering the lengths of the stop rather than the coefficients of friction the diagram, Fig. 2, has been prepared. This diagram is based upon the coefficients of friction

13-IN. BRAKE SHOES ON STEEL TIRED AND CHILLED WHEELS.

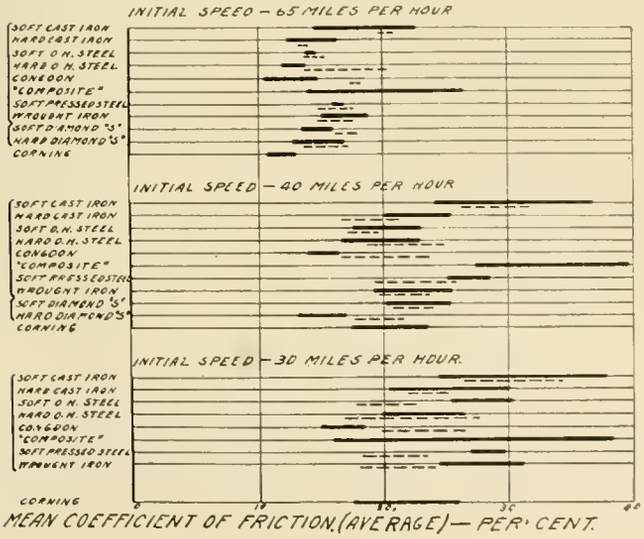

FIG. 1.

RELATIVE LENGTHS OF STOPS.

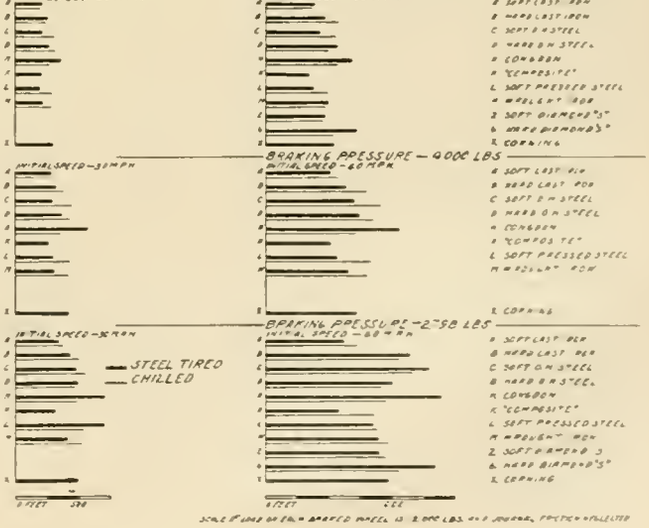

FIG. 2.

given in the table; journal friction and retarding forces other than the friction of the brake shoes are neglected. It should be remarked that the lengths of stops obtained on the testing machine cannot be properly compared, because the initial speeds varied slightly, though nominally the same, and the friction of the bearings of the machine varied greatly, thus causing variations in the lengths of the stops even when all other factors were equal.

The scale of feet on Fig. 2 is computed on the assumption that each shoe has to absorb the energy of a mass of 12,000 lb.

In Fig. 2 the heavy lines are for the tests on the steel tired wheel and the light lines for the tests on the chilled wheel.

Only the stops for 30 and 40 miles per hour are plotted, as street cars seldom run at much higher speeds.

The various shoes tested are to some extent described in the table; the following list also gives the makers:

A.—Soft cast iron; made by Pennsylvania Railroad Co., Altoona, Pa.

B. Hard cast iron; made by Ramapo Iron Works, Ramapo, N. Y. The ordinary cast iron so extensively used for brake shoes corresponds to this rather than to the A shoe.

C.—Soft open hearth steel; made by Solid Steel Co., Alliance, O.

D.—Hard open hearth steel; made by Solid Steel Co.

E.—Malleable iron; made by the Dayton Malleable Iron Co., Dayton, O.

F.—Special steel tire malleable iron; made by same company.

G.—Special chilled wheel malleable iron; made by same company.

H.—Congdon shoe, cast iron body with wrought iron inserts; made by the Sargent Co., Chicago.

I.—Meehan shoe, cast iron body with crucible steel inserts; made by the Sargent Co.

J.—Lappin shoe, chilled iron; made by the Lappin Brake Shoe Co., New York.

K.—Safety ("Composite") shoe, body of hard cast iron with wooden plugs set in the face; made by the Composite Brake Shoe Co., Boston.

L.—Soft pressed steel; made by the Schoen Manufacturing Co., Pittsburg, Pa.

M.—Wrought iron (pressed); made by the Schoen Manufacturing Co.

N.—Sargent special shoe, cast iron body with chilled iron inserts; made by the Sargent Co., Chicago.

P.—Kinzer shoe, cast iron shell filled with a composition made of iron turnings, saw dust, asbestos, plumbago and linseed oil; made by the Kinzer & Jones Co., Pittsburgh, Pa.

2.—Soft "Diamond S," soft cast iron poured about a bundle of expanded steel sheets; made by the Sargent Co.

6.—Hard "Diamond S;" made by the Sargent Co.

X.—Corning shoe, chilled body with soft gray iron insert; made by Corning Brake Shoe Co., Corning, N. Y.

Tests made with brake shoes 17 in. long showed practically the same coefficient of friction as did the 13-in. shoes. This was due to the ends of the long shoes lifting from the wheel when heated during a stop so that the area in contact was practically that of a 13-in. shoe.

A few tests of flanged brake shoes showed a higher coefficient than plain shoes at 65 miles per hour and a lower coefficient at 40 miles per hour; the tests were too few to warrant conclusions.

EFFECT ON THE WHEEL.

The effect of the different shoes on the surface of the chilled wheel as observed in the laboratory tests is as follows:

A. Small particles adhere to surface of wheel making it rough; this roughness increases with the number of applications.

B. Same tendency but to a less degree.

C. Tends to smooth surface of wheel. Metal of shoe flows somewhat when heated and particles accumulate at the end of shoe last in contact with wheel.

D. Tends to smooth surface of wheel and metal of shoe flows as with C but to a less degree. Particles pile up on surface near end last in contact with wheel, the effect being to decrease the extent of the surface in contact.

H and I. Metal of insets flows and is forced into cast iron body between insets. These shoes roughen the surface of the wheel slightly.

K. Roughens surface of wheel about the same as B.

L and M. Effect on wheel similar to C.

P. No tendency to roughen the wheel and imparts a high polish.

On the steel tired wheel the effect of the various shoes was as follows:

A, B and K. At low pressures tend to smooth surface of wheel. At high pressures particles adhere to wheel and tend to make it rough as with chilled wheel but to a less degree.

D. Scores wheel badly.

C, L and M. Score wheel but not so badly as D.

H and I. Steel and wrought iron insets roughen wheel.

P. Fills irregularities of wheel surface and imparts to it a high polish.

From the remarks of Mr. A. M. Waitt, then general master car builder of the Lake Shore & Michigan Southern, in discussing the report of the M. C. B. Committee on Road Tests of Brake Shoes, we take the following data concerning wheel wear. (M. C. B. Proceedings, 1895, p. 164, et seq.) The method pursued by Mr. Waitt was to take plaster casts of the wheel trials before and after the shoes were in service. The wear, taking the soft cast iron shoe as a basis, was:

Shoe.	Chilled wheel.	Steel tired wheel.
A	Standard.	Standard.
B	Not tested.	About equal.
C	Much less.	About 4 times as much.
D	Slightly more.	About 50 per cent more.
E	About equal.	About equal.
F	About equal.	About equal.
G	About equal.	About equal.
H	About equal.	About double.
I	About equal.	About double.
J	About equal.	About 50 per cent more.
K	About equal.	About equal.
L	Less.	About 50 per cent more.
M	Much more.	About 3 times as much.
N	About equal.	About equal.

DURABILITY OF BRAKE SHOES.

The M. C. B. Committee on Road Tests (M. C. B. Proceedings, 1895, pp. 128-129) tabulated the comparative wear of different shoes for the same service as follows:

Shoe.	Chilled wheel.	Steel tired wheel.
A	1.00	1.00
B	.86	1.06
C	.17	.42
D	.10	.31
E	.53	.51
F	.83	.67
G	.83	.81
H	.31	.30
I	.31	.21
J	.55	.27
K	.70	.77
L	.11	.29
M	.11	.29
N	22	.33

These comparisons were made by equipping one truck of each test car with the soft cast iron (A) shoes and the other truck with the shoes to be compared with it, and the number of pounds of metal ground of the two sets of shoes compared.

While it is usual to say that under such conditions each set of shoes is subjected to the same service it is not true. The energy absorbed by a brake shoe is, other things being equal, a direct function of the coefficient of friction, so that if a shoe have only one-half the coefficient of friction of the standard shoe it does but half as much work in running the same mileage and hence should wear out two of the standard shoes to give the same service as the latter.

But as comparative service tests are usually made in the manner described, and as the coefficient of friction of the shoe to be tested is not always known, perhaps the accepted method is the best one.

NEW SCHEME OF FARE COLLECTING.

Mr. Romie Loomis, whose letter head bears the words "versatile painter" Chattanooga, Tenn., writes he has fully solved the problem of collecting fares, in a manner entirely new and novel, and desires to have a committee appointed to witness a demonstration of his method.

MOTOR POWER ON TRAMWAYS.

From a paper read at the Engineering Conference of the Institution of Civil Engineers, England, by Thomas Parker, M. Inst. C. E.

Horse traction is the oldest method by which tramways have been operated, and there are ample data available. Its slowness, the occupation of a great length of the road, and the bad sanitary conditions caused by the refuse from the animals, the element of risk in the temper of the animals, variable cost of food, the great destruction of the horses by the very heavy work. These facts and conditions by long usage have become unnoticeable, and do not appear to come within the scope of public vision, when judging of the efforts made by engineers to replace the horse by mechanical means. But the always present cash quantity has condemned horse-traction on tramways.

Steam is quicker than horses, less costly for results, but has greater disadvantages, viz., much greater weight, and occupying greater length of road, the emission of carbonic acid, sulphurous acid, steam and smoke, practically into the dwellings along the route, and among the people, the unsightliness and noise, make its use in public streets a painful burden to the community, and as experience shows, not to be borne when better means can be found. The objections leave little hope for the future of direct steam-driven tramways.

Compressed air is a more congenial agent, and has better prospects of success than steam, if the two had to settle their differences alone.

It is free from many objections compared with steam. There is little interference with the atmosphere; the small amount of direct firing makes it possible to use only one carriage for motor and passenger; water need not be carried; the total dead load to passenger is in its favor; it needs frequent stations for supplies, as the distance it is possible to run with one store of pressure is limited. Its friends are very active at present, and it is hoped we may hear their case and obtain some practical account of its working. It appears to have higher economy than can be obtained by steam direct. The author has no working data he can give.

Endless cable, as a method for driving tramways, has high merits in many respects. It occupies a minimum length of road; its speed is fair; it is free from nuisances of steam or horses, and it is handy. Its drawbacks are: Heavy initial outlay; its occupation of the street; the slot difficulty, of carrying sewer and other requirements in or across the street in which it is laid; the continued noise of the running rope under the streets, causing, in some instances, considerable depreciation in value of property; the stoppage of the whole system upon the breaking of the cable; and the heavy costs attendant upon the system. Taking the statistics of installation, there are very few cable roads being put down now, and we may accept the verdict of the public that the cable has ceased to compete successfully with other methods.

There are some tramways being driven by gas engines working on the car, but no reliable practical data are available. The verdict of passengers is that they are required to inhale a considerable admixture of coal-gas with the atmosphere in the neighborhood of the cars.

At the present time, electricity is, by general accord, selected as the best method for driving tramways. In electricity we have a very flexible system which admits of great variation of powers being used at varying points on the same system. There is no nuisance, as with steam or horses. The minimum length of road occupied; speed can be low for inter-town work and high for suburban traffic; cars are easily handled; energy is used efficiently; maintenance is not excessive; streets are not more occupied than simply by the pair of rails, so that taking up streets for laying sewers and pipes, or other needs, is not complicated. The disadvantage is the conductors being carried overhead. Conductors have been used in other forms, but it appears fairly that the overhead wires, by their small cost, the simplicity and security of insulation, and the readiness with which repairs can be carried out, are accepted, at least for the present.

Accumulators have been introduced on to cars to carry them through the crowded streets, being charged while in the suburbs, running from the line and discharged by inter-town running. Accumulators have been installed, on their Bournbrook section, by the Birmingham Central Tramways' Co.; but, although still running, have not met expectations. The loss of capacity of the cell under the conditions of use was a great difficulty.

The energy required to drive the accumulator cars was approximately 4.6 horse-power hours per car-mile, while the quantity of energy necessary to drive a car of equal capacity with overhead conductors, 2.15 electrical horse-power hour per car-mile, the speed being much faster and the gradients heavier.

Operative Costs of Running One Car-Mile by the Different Systems Enumerated.

	Horse Traction.	Steam Traction.	Cable	Electric Overhead.	Liverpool Overhead Railway.

* Could not obtain reliable figures for generating costs.

Electricity as a means of driving light or heavy railways is under best conditions if employed for long runs, and under its most inefficient conditions when called upon to make frequent startings. There is by the steam locomotive practically the same energy with one journey per day as fifty journeys per day. For electricity it is necessary first to put down the motive plant, dynamos, and conductors, throughout the system, and to provide the motors for hauling the trains. For lines where few trains are required, electricity does not compare with steam, as the capital outlay for running a few trains is the same as for running a number.

If we take a case, say, for two towns 50 miles apart, such as London and Brighton, which would support a continuous connection, and by the length of the run put electricity under good conditions, electricity could give 15-minutes' interval trains, and run at 75 miles an hour, doing the distance in 40 minutes by trains of 100 tons, at 2½d. per train-mile, covering costs of power. Such a case shows how completely electricity takes the field under fair conditions, and the advantages are not only in point of power, cost, and speed, but the track need not be so costly, as the weight can be evenly distributed throughout the train, the weight of the train being brought in for adhesion and traction. A 100-ton train would be equal capacity for passengers to a steam train of 140 tons. The cost of maintenance of permanent way and risks would be much reduced.

If we turn to a case where electricity is under its worst conditions in comparison with steam, we are able to refer to well-matured data. The Liverpool Overhead Ry. is such a case. It has been running for nearly seven years, and is in direct comparison with a number of similar lines worked by steam.

A most important difference between electric motors and the steam cylinder when starting into motion is, that in the electric motor no effort is obtained unless current is passing through the motor, and the torque is proportional to the quantity, while steam gives its efforts and is liberated to exhaust only in proportion to motion.

Steam was early in the field, but the requirements needed to make moderate success possible are only of modern achievement. The conditions of the vehicle and road make still further variation of the boiler, engine, and condenser necessary before the steam motor car can be a standardized article of manufacture. With regard to gear, steering, brakes and wheels, there are openings for improvements and new applications.

There are some good approximations to success of the steam type.

Much has been done to render tolerable the close association of passengers with mechanical movements and rapid explosions form-

ing the combination we call an oil car. Still much is needed with regard to safety from explosion and fire, reduction of vibration, and efficient transmission. The prospect is that it may be practical, with reasonable first outlay, depreciation, and cost of fuel, to run an oil car successfully for a much less cost than horses. The movement has brought about great improvements in the oil engine, but only light oils have been successfully used. Electricity is chiefly used as a means of igniting. Speeds of 1,000 revolutions are obtained, or 500 explosions per minute.

In applying electricity to motor cars, we first met the question of weight of accumulators. This has, by improved motors, gear and accumulators, within very recent date been reduced to 1 horse-power-hour delivered on to the car at about 56 lb. inclusive, so that 5 cwt. of cells is sufficient to operate a car, as against 16 cwt. two years ago. Motors, gearing, and methods of steering have been much improved. The following data is one of the best examples I have had the opportunity of testing:

Weight of car, complete, without batteries	9 cwt.
Weight of batteries	5 "
Total	14 "
Total weight, with four passengers	20 "
Discharge, on level, 12 amperes at 80 volts	9 miles per hour
Approximate horse-power	1½
Safe distance	40 miles
One motor, double reduction gear	1,200 revolutions

WISCONSIN LAW TO PREVENT THE MISUSE OF TRANSFERS.

The Wisconsin Legislature at its last session passed an act to prevent the unlawful and fraudulent use of transfer tickets issued by street railroad companies, which was approved Apr. 8, 1899. This law is as follows:

Section 1. No transfer ticket, or written or printed instrument, giving or porporting to give the right of transfer to any person or persons from a public conveyance operated upon one line or route of a street railroad to a public conveyance upon another line or route of a street railroad, or from one car to another car upon the same line of street railroad, shall be issued, sold or given, except to a passenger lawfully entitled thereto.

Sec. 2. No person shall issue, sell or give away such a transfer ticket or instrument as aforesaid to a person or persons not lawfully entitled thereto, and any person or persons not lawfully entitled therto who shall receive and use, or offer for passage, any such transfer ticket or instrument, or who shall sell or give away such transfer ticket or instrument to another with intent to have such transfer ticket or instrument used, or offered for passage after the time limit for its use shall have expired, shall be guilty of misdemeanor, and upon conviction thereof shall be punished by fine of not less than five dollars nor more than ten dollars for each offense.

Sec. 3. Emergency clause.

WORCESTER & WEBSTER STREET RAILWAY CO.

The Westinghouse Electric & Manufacturing Co. is providing an electric equipment for the new road now under construction by the Worcester & Webster Street Railway Co. The road connects Worcester, Mass., with Auburn, Oxford and Webster, a distance of 17 miles, passing over one of the most picturesque routes in New England. The line terminates at Lake Chaubunagungamuag, the prettiest inland water in Massachusetts, much frequented by excursion and pleasure parties. The power house is centrally placed, and will contain two 250-kw. Westinghouse "engine type" generators, direct connected to steam engines, to work at 120 r. p. m. Great care is being taken in constructing the track; the rails are specially heavy and the roadbed is ballasted with gravel. The cars are to be of extra size, having a seating capacity for 36 persons, and capable of carrying 90 passengers. Each car will be provided with double trucks, and two 50-h. p. Westinghouse high speed motors. The 100 h. p. applied to each car will give an average speed of 35 miles an hour. Westinghouse air-brakes will be attached to the cars, together with compressed air whistles, telephones, and all the latest appliances.

PRESERVATION OF TIMBER.

Abstract of a paper read before the Western Society of Engineers by Samuel M. Rowe, July 5, 1899.

Perhaps the largest single drain on our timber supply is that for cross-ties for standard gage railroads. There are now in the United States about 185,000 miles of railroad, which, when second, third and fourth tracks and sidings are added, will aggregate 245,000 miles. Each mile requires one tie every two feet, or 2,640 per mile, making a total of 650,000,000 cross-ties. The average life of ties does not exceed eight years; oak a year or two more, but the softer woods much less. Then, assuming that the mean life be put at nine years (much too high) it would require for annual renewals, 72,000,000 ties, nearly 200,000,000 cu. ft. or 2,400,000 M-ft. B. M. of timber. Each annual demand for cross-ties alone must strip half a million acres of our best forests, and the rate of renewal is about 140 cross-ties every minute, night and day, throughout the year.

Until quite recently white oak has been specified by many railroads, the softer woods being rejected, but in other cases, where oak was not obtainable, arbor vitae has been accepted on account of its lasting qualities and lightness, but, because of a failure to resist crushing, tie plates are necessary. In the middle and far West, where oak cannot be used, recourse is had to the pines and the softer woods, the life of which is perhaps not more than half that of oak; in this case the cost of renewals very quickly becomes a matter of importance, reaching 25 per cent per year in some known cases. Another feature deserves attention. The demand for nothing but the soundest and best oak results, to some extent, in the destruction of the softer and less valuable timbers in the scramble for the latter timber; making a still further draft on the timber stock, which is a total loss. The improvidence here practiced will be better appreciated when it is shown that much of this wasted timber can be made to serve equally as well as the best oak and last twice as long. The saving in the first cost is by no means a trifling sum.

The three best known processes for preserving timber, any one of which is effective in this direction, are the Burnett, the zinc-tannin, and the creosote or dead oil process; the basis of the two former is chloride of zinc. There is probably no question but that the creosote process is the most effective, but its great and increasing cost generally tends to inquiry in the direction of a cheaper method or agent. The chloride of zinc process has so far met this and passed through a sufficient test to show its efficiency and reasonable cost.

In all these processes the timber is first prepared for the absorption of the chemicals. So far steam has been used for this purpose at such a temperature as will not injure the fiber of the wood, but still be hot enough to permeate the pores of the timber and start the natural saps; freeing the cells preparatory to the extraction of the sap by vacuum after steam is withdrawn. It is presumable that in steaming the saps are altered and cooked so as not to so readily ferment should any fail to be expelled during the operation of steaming and the treatment in the vacuum. The steaming and vacuum are common to all processes; the result to be secured being the opening of the pores of the wood and the expansion of the vapors, thereby giving the best possible exposure to the solution to be absorbed. It is claimed that this can be done thoroughly by drying, by heating the retort by steam coils without exposing the timber directly to the steam, but to this there are two objections. A sufficiently intense heat to dry in any reasonable time would injure the fiber of the timber and cause serious checking; and when it is said that to dry timber sufficiently, three or four days are required, it will be seen to be out of the question where it can be done by direct steam in four to six hours.

The second step common to the three processes is to let the solution containing the chemicals into the retort without admitting air, so as to give every facility for rapid absorption. Then by a force pump additional pressure is put on the solution, generally up to 100 lb. per sq. in., under which the charge is held for some hours, the time varying according to the character of the timber.

With the creosote or the Burnett processes, withdrawing the solution completes the process. With the zinc-tannin process the charge is subjected to a further similar contact with a solution of glue, which, being withdrawn, is followed by a solution of tannin extract; both of which are subjected to pressure as with the chloride

application. Generally the glue is mixed with the chloride solution, thus saving one operation. Which is the best, is still a question not altogether settled, but the preponderence of reason seems to be on the side of the separate application of the glue, it being reasoned that the chloride will be more viscous with glue added, and hence will not be absorbed so freely. Another weighty reason is that as the glue and tannin absorption, being largely superficial where most needed, there is no need for the glue to penetrate deeper than the tannin with which it is to combine; and, indeed, should it go further than the tannin, the gelatine not being neutralized by combining with the tannin, may be deleterious, and become an agent of destruction instead of a preservative. The Wellhouse, or zinc-tannin process, from which good results have been secured, has been to apply the glue with the chloride so that this question may not be deemed vital.

Relative to the effect on the zinc-tannin treated wood, that may be attributed to the steaming or to the absorption of the chloride and glue, or to both, a somewhat peculiar effect may be noted. This was noticed where a block of treated wood was subjected to a test as to its absorbing power along with a block of untreated timber, both being immersed in cold water. Both pieces were of heart timber, and there was little or no observable difference in density. The untreated timber absorbed water much the more rapidly at first, but afterwards losing, in its rate of absorption, the treated block reached and passed it. This would seem to indicate considerable disturbance to the pores of the wood by the treatment, and also some loosening or parting of its fibers. In this connection it is well to say, with regard to the efficiency of the described operation, that what was secured by natural absorption of clean water in 30 days, is secured in this treatment by four hours' steaming and a like time with 100 lb. pressure on the solution.

The glue and tannin are added to the Wellhouse process with a view to plug up the outer pores of the stick, protecting the chloride, which is very soluble, from wasting out by repeated wetting and drying, as happens in the case of railroad cross-ties in seasons of rains.

The Burnett process uses the chloride in much the same quantities, and where laid in a dry country, show excellent results. The Southern Pacific R. R. has used the Burnett process for a number of years, and as a result has brought its cross-tie renewals down to a little over 4 per cent, which indicates a life of 20 years, and this largely with soft timbers.

As before mentioned, soft timbers, short lived without treatment, can thus be made useful and lasting, no doubt taking the absorption more freely than hardwoods, yet, it is in no wise conceded that soft woods alone should be treated. It is believed that experience will show that the hardwoods and the heart timber of the pine, usually retained for other purposes than for cross-ties, will take sufficient; and that, all in all, they are valuable about in proportion to their density and maturity of wood and not in proportion to the amount of chloride or other antiseptic absorbed. The variation in different timbers should not be deemed of so much importance, since the varition in any lot of timber of the same kind is very marked; no two parts of each stick are the same, neither is any one piece just the same as another. Hence the conclusion that some general rule or average is alone practicable. In calculating the amount of antiseptic necessary, the average character of the timber must be considered. Usually from 1½ per cent solution for very dry and open grained pine, to 3 per cent for obdurate or green timber is deemed sufficient. One quarter to ½ lb. of pure chloride is deemed sufficient per cubic foot of timber, and the strength of the solution is governed by the limit of absorbing power of the timber. The writer has a section of a sawed tie that absorbed not over ¼ lb. per cu. ft. (probably less than 1-5 lb.), which, after 13 years' service in the track, is as sound as the day it was cut from the tree, excepting ¾ in. on the bottom and less on the sides. It is believed possible to benefit the best timber that is offered. Nine years is a high average life for a good white oak, probably too high, but it is believed that these same ties can be made to last 15 years. Seasoning a year under shelter will do much toward it, as well as vulcanizing, or steaming and drying; and if a pine tie, that usually goes to pieces in less than 5 years, can be found after 13 years, to be good for three or four years, then surely a white or burr oak can be made to last 20 years.

The writer has observed ties, treated and in track about 12 or 14 years, that, upon removal, were still better than the average tie in an overland railroad with which he was familiar some years since. And there were none of these treated ties in the condition usual at the time of removal, 10 or 12 years earlier; that is so far gone as not to be recognized as ties. Also hemlock ties have been seen that were put in during construction and entirely replaced in 8 years, while treated hemlock ties, after 8 to 12 years, were still in the track and largely serviceable; the removals on the same line were also largely serviceable had they been left in.

One of the principal drawbacks to the adoption of a policy in this direction has been the large first cost of the plant, which is heavy for a road that is living only from "hand to mouth." In such cases there has been little use to discuss the matter, but, now, railroads are, as a rule, thriving, so that for managers there remains little excuse for clinging to past shiftless and wasteful practices. No attempt will be made to go into the economics of the matter, as the correctness of the position is so patent as to obviate any necessity of argument.

The first cost of treating the woods deters many railroads from adopting some process of wood preservation, and it is only by its importance being impressed upon those in authority that this difficulty can be overcome.

The timber which railroads use is bulky and large in quantity, and improved methods are required for handling both the timber and the solutions used in the process. But when the plant is installed a small force only is needed to operate it, and the savings in cost of renewals of cross-ties and bridges are so great that the cost of the works when capitalized becomes insignificant.

S. L. NELSON'S BIRTHDAY.

Mr. S. L. Nelson, general manager of the Springfield (O.) Railway Co., was 40 years old on June 23d and celebrated the occasion by making a personal gift to each of the employes of the company. The amount was proportioned to the length of service and the total was in excess of $600. Supt. L. O. Williams, who has ably assisted Mr. Nelson for the last four years, received $250.

Mr. Nelson was not permitted to have the gift making all his own way, and was the recipient of a handsome leather covered chair from his men and some silver mounted desk furniture from the office force; Mr. W. B. McKinley, president of the company, presented a gold watch.

Mr. Nelson's letter to the men was as follows:

"Dear Sir: A man has but one opportunity to celebrate his 40th birthday. On such an occasion, when other events, in which you have taken an important part, it becomes a pleasure to associate you with the event. I celebrate not only my 40th birthday, but practically my seventh year as manager of the Springfield Railway Co. Some of you as employes have gone through the many ups and downs with me, and to your aid, assistance and efforts many of our accomplishments have been due. To show my personal regard for each one of you and my personal appreciation of your services, I desire to present and hope you will accept a small contribution. Having advocated a gold standard, and to be consistent so far as practicable, the contributions are to be made in that coin of the realm. Wishing you and yours continued good health, prosperity and happiness, I am, your friend,

"S. L. Nelson."

CHANGES IN ATLANTA.

The financial merger of the Atlanta Ry. and the Atlanta Consolidated Ry., of Atlanta, Ga., has resulted in a number of changes in the operating department. H. N. Hurt has been chosen superintendent of the Atlanta; W. H. Glenn, purchasing agent; N. W. L. Brown, electrician and superintendent of construction, and Thomas Elliott, chief engineer. All of these gentlemen held similar positions with the Consolidated. In May last Ernest Woodruff, president of the Atlanta Ry., was chosen president of the consolidated.

A system of transfers will be operated between the Atlanta line and the Consolidated, and the two will be connected at Neal's school and the cars for Decatur will then run through Inman Park. A fifteen-minute schedule to Inman Park will give the residents of that place a seven and one-half minute schedule to the city.

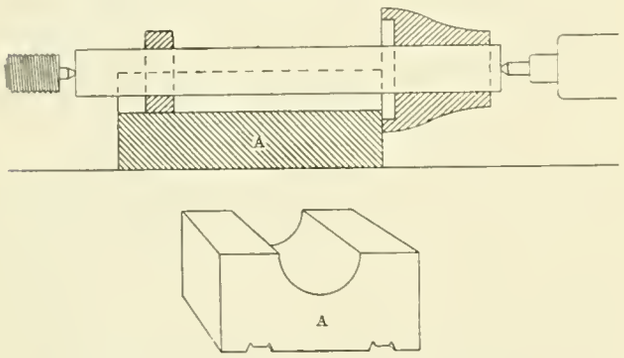
A successful trial trip of an electric car has just been made at Leeds, England, between Boar-lane and Headingley

MECHANICAL DEPARTMENT

CASTING SOLID BABBITT BEARINGS.

Taunton, Mass., May 25, 1899.

Editor "Review": The accompanying sketch will show the method used by me in casting solid babbitt bearings for the armature and axle bearings of G. E. 800 motors. There is always some wear on the outside of a bearing shell and also on the hole in the bottom bearing which receives the pin to prevent the shell from turning, and this wear determines the life of the shell; when the wear becomes enough to allow the shell to rock, the life is greatly shortened. If solid babbitt bearings are used the whole bearing may be thrown into the melting pot when the wear becomes excessive and new bearings made at only the cost of labor; there is no shell to throw away or partially worn bronze bearing to scrap.



FOR CASTING SOLID BABBITT BEARINGS.

The block A is made of cast iron; it is machined to fit the guides on the lathe bed and turned to the exact diameter of the outside of the bearing, with a boring bar carried between the lathe centers. When bearings are to be cast an arbor of the exact diameter of the inside of the bearing is placed in the centers; on this arbor are two collars, which are movable, so that the length of bearing may be varied. If the bearing is a flanged one a collar with a recess turned in it is used at one end as shown in the sketch.

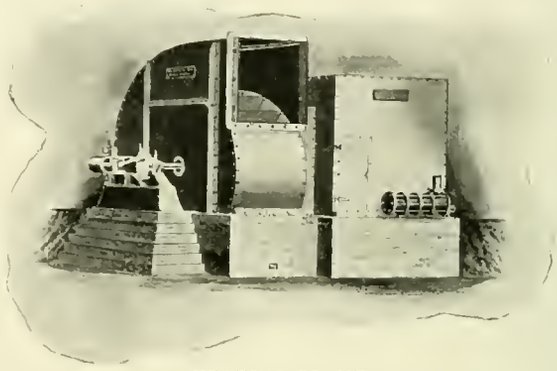
HEATING CAR BARNS BY THE BLOWER SYSTEM.

The blower system, whereby heated air is forced throughout a building by means of a fan, has already found general adoption in many classes of buildings. In some instances such as in the case of car barns, peculiar advantages are claimed for it. The car barn should necessarily serve a double purpose; it should protect the cars from the weather, and should provide a means for the ready removal of snow and ice in winter. To secure the latter result the pit system has been generally adopted, and in the older installations, steam pipes were strung round the sides of the pits. The melting of snow and ice on the trucks and car body above is under this arrangement a relatively slow process.

With the blower system, however, great rapidity is secured, the hot air pipes being laid beneath the floor and between the pits, into which large volumes can be readily delivered. The heated air as it passes up beneath the car greedily absorbs all moisture in its path, while at the same time playing its part in heating the entire structure.

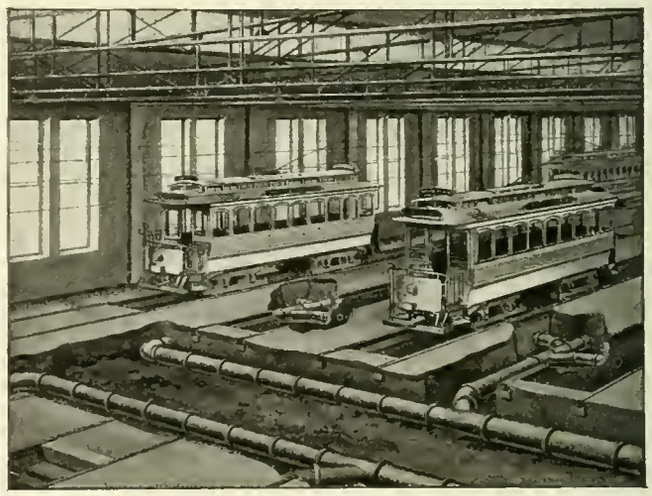
A car house equipped in this manner is shown in the accompanying engraving. The pipes are of tile with tight joints, and the air is supplied by a hot blast apparatus such as that shown in the other engraving. This apparatus consists of a steel pipe heater made up in sections through which steam is passed. The entire heating surface is enclosed within a steel plate jacket, and air is drawn across the pipes by means of the fan. This fan, which is of steel plate with suitable braces, is in the plant illustrated, driven



HEATING PLANT.

by a direct connected engine, so that it may be operated at all times independently of all other machinery.

From the outlet of the fan, connection is made to the various pipes and ducts. Incidentally a pressure above the atmosphere is



CAR BARN HEATED BY BLOWER SYSTEM.

maintained within the building, so that the leakage is outward, and the ingress of cold air at cracks and crevices is obviated. This type of apparatus is designed and built by the B. F. Sturtevant Co., of Boston, Mass., and the car barn illustrated is one of a large number which have been equipped by this company.

A NEW ACETYLENE HEADLIGHT.

A new headlight for the use of acetylene has been tried experimentally on the Lafayette (Ind.) Street Ry. and has given most gratifying results. In the ordinary acetylene headlight for use on locomotives, the gas is made in a separate apparatus and stored in a small gasometer from which it is supplied to the lamp. In the new lamp, which is the joint invention of Supt. E. B. Gunn, of the railway company, and Mr. Laban Sparkes, the gas is gener-

ated in a small reservoir similar to that of an oil lamp, and is made only as fast as it is consumed. The details of this apparatus will be seen by reference to the following diagram.

The reservoir A was taken from an ordinary oil headlight and divided in the center by a sheet iron diaphragm into two compartments, one for the calcium carbide, the other containing a coiled pipe one end of opening into the carbide chamber and the other end leading to the burner. The cylinder B is fastened on top of the coil chamber into which it opens, and contains a cap on top by means of which cylinder B and the coil chamber are filled with water.

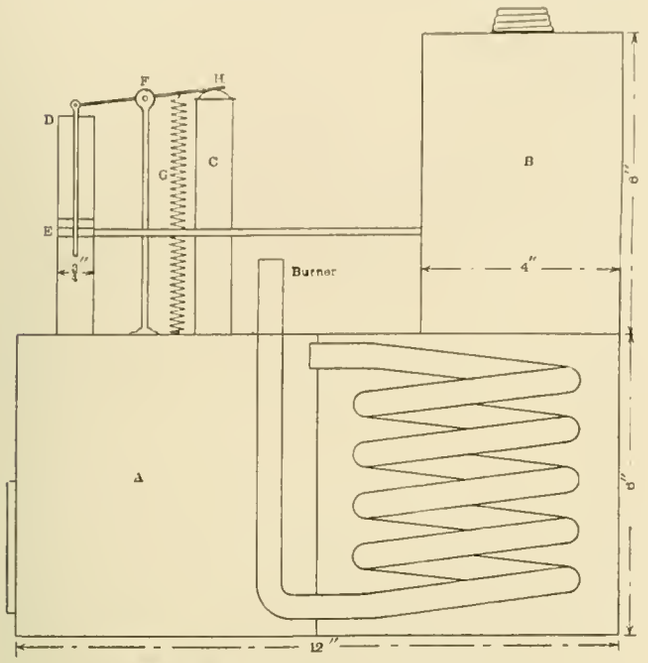


DIAGRAM OF ACETYLENE HEADLIGHT.

From the top of the carbide chamber where the gas is generated rise two ¾-in. pipes, C and D. The top of the pipe C is covered with a rubber diaphragm, which rises and falls according to the pressure of the gas in the carbide chamber. The pipe D, contains a valve E, the globe of which is moved by the vertical rod connected to the lever F, and the water is led into this pipe from the lower part of cylinder B by a small horizontal pipe as shown in the diagram. The operation of the lamp is as follows: A suitable amount of calcium carbide is placed in the reservoir A, and the cylinder B, and the coil chamber are filled with water. The water passes through the horizontal pipe to the pipe D from which it falls into the carbide chamber and generates the gas. The amount of gas made is regulated by the valve E. When there is no pressure of gas in the chamber the diaphragm lies flat on top of the pipe C, and this allows the spring G to pull down the lever F, which opens the valve E, this admitting water to the carbide chamber. As the pressure of gas increases the rubber diaphragm swells up and raises the lever F, closing the valve E and shutting off the supply of water from the carbide. The generation of gas is thus regulated automatically by the position of the diaphragm which varies with the pressure of the gas in the chamber A. The gas is taken out from the top of this chamber through the coiled pipe which keeps it cool by being immersed in water and passes from the other end of the coil to the burner. Considerable trouble was experienced in devising a method of regulating the lamp which would not get out of adjustment from the jolting of the car but the regulation by means of the rubber diaphragm has been found to meet this requirement perfectly.

The lamp used in this test was provided with a [illegible] cu. ft. burner which was found to be rather larger than necessary, as small objects on the track were readily seen at a distance of 600 ft. from the car. The lamp is said to be quite economical.

NEW TYPES OF SUMMER CARS ON THE WEST CHICAGO.

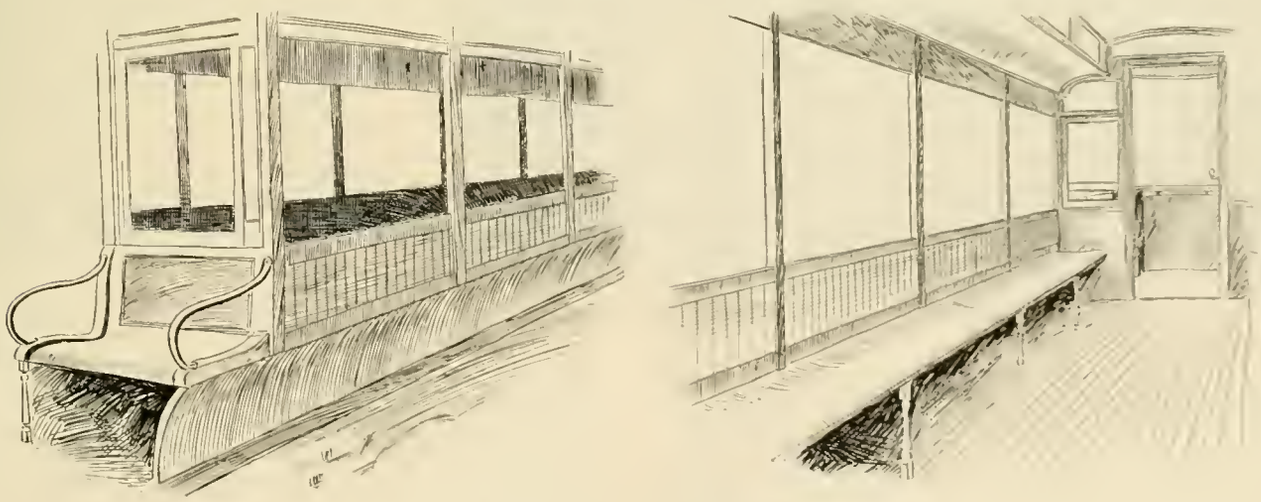
The West Chicago Street Railroad Co. has as an experiment put in service two summer cars which are quite different from the types heretofore used on the city lines in Chicago. The object in view is to find a car which will be convenient and yet offer fewer chances for passengers to get hurt through carelessness.

One of the cars is the regular open, side entrance summer car with the foot boards cut off except at the platforms; these short pieces forming the platform steps are hinged and those on the left side of the car are folded up against the sill and fastened so that passengers cannot stand upon them. This car has short cross seats with center aisle and seats 40 passengers. Along the sides are two rails, the upper one being at the height of the top of the seat. The platforms are large. The car has curtains at the sides.

The other car has been altered from a cross-bench open car by boarding up the sides between the end bulkheads to the height of the ordinary window sills, and removing the cross seats and replacing them by two longitudinal seats facing the interior of the car. The end seats, that is the two short benches at each end which face the dashers, were left in place.

These cars have now been running for about three months. Neither the patrons nor the company like the car with cross seats. While it holds the regular number of passengers the narrow aisle makes it crowded and it is almost impossible for the conductor to work his way through.

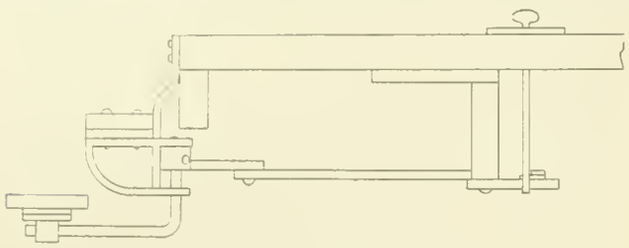
With the other type, however, everybody seems much pleased. The longitudinal seats have a large space in the middle of the car and the capacity is only two less than regular. But the company has not yet decided to adopt it. A test of its merits will be made this summer and if it proves entirely satisfactory, the lines will be equipped with this type of car.



SUMMER CAR ON THE WEST CHICAGO.

EXTENSIBLE CAR STEP.

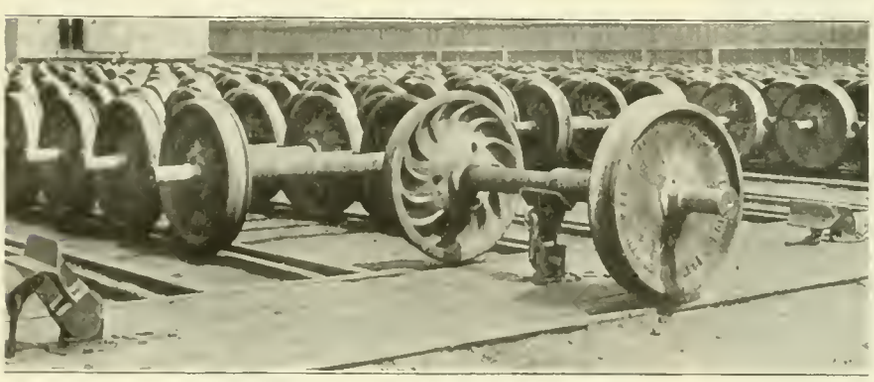
Mr. Albert Blum of Cincinnati has recently patented an extensible step particularly adapted for side entrance street cars. Instead of using only one running board placed midway between the car floor and the rail it is proposed to place this stationary running board higher, so as to make an easy step to the car floor and place a second movable step about midway between the stationary step and the ground. The movable step will be supported on a number of metal arms pivoted in brackets fastened to the car-body and also pivoted to the step, so that as the arms swing in a horizontal plane the step is swung out for use. The step is to be manipulated by a hand or foot lever on the motorman's platform or by a suitable arrangement of solenoids as may be desired. We understand that a car on the Millcreek Valley line is to be equipped with this step.



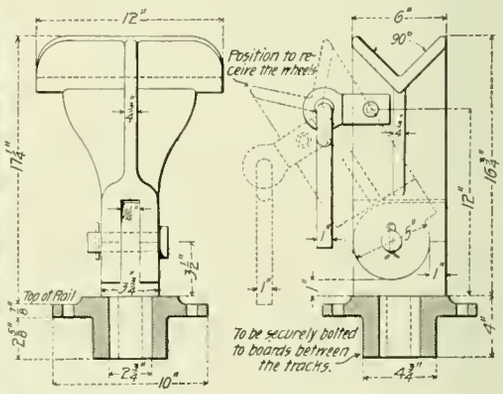
BLUM EXTENSIBLE STEP.

JACK FOR TURNING MOUNTED CAR WHEELS.

The accompanying illustrations for which we are indebted to the Railroad Gazette, show a jack for turning mounted car wheels designed by Mr. D. C. Ross, general foreman of car department of the Michigan Central R. R., and installed at the Detroit shops of the company. The tracks for storing the wheels are at right angles to the shop track, and the jacks are placed at the intersections of the center lines of the tracks. A casting with a 2¾-in. hole in the center is fastened in place for a base plate; the jack consists of two parts, the lower portion fitting into the hole in the base plate and the upper one turning about a horizontal pivot. When in use the jack is inclined as shown dotted in the line drawing, being supported by a swinging link. The momentum of the moving wheels carries the jack to a vertical position and lifts the flanges clear of the rails so that they can be swung around and pushed off onto the spur track. When not in use the jack may be turned over flat on the ground as shown at the right of the half tone.



WHEEL STORAGE TRACKS, MICHIGAN CENTRAL SHOPS.



JACK FOR TURNING MOUNTED CAR WHEELS.

A Northern Pacific passenger train ran into a Grant Street electric car in Seattle, Wash., June 3d, killing 1 passenger and severely injuring 18 others. The accident occurred near the Washington Iron Works. In the scramble to get out of the car the people jumped into the bay and had a narrow escape from drowning. The water is 15 ft. deep.

THERMAL TESTS FOR CAR WHEELS.

During the past six months Professors Goss and Smart of Purdue University, have made some very interesting experiments for Mr. T. A. Griffin, president of the Griffin Wheel Co., of Chicago, on thermal tests of car wheels, and the heating to which a car wheel will be subjected in service.

The wheel specifications of the Pennsylvania Railroad Co. provide for a thermal test, which consists in pouring a ring of cast iron 1½ in. by 4 in. in section about the tread of the wheel; this ring is to be poured from one point on the circumference and is to be removed two minutes after the pouring has ceased. It has been urged that this test is much too severe in view of the maximum heating that occurs in actual service, and also that wheels made to pass this test have a shorter life in service. The wheel makers can make a car wheel to withstand the Pennsylvania thermal test, but if the generally accepted belief that such wheels have a shorter life is true it is evidently to the interest of all parties that specifications be modified, if in fact they are too severe.

The first series of tests were made at Purdue and were to determine the maximum heating of the wheels due to braking. The tests were made on the M. C. B. brake shoe testing machine. In order to determine the temperature reached by the wheel under the action of the brake shoe four series of holes were drilled in the back of the wheel, and were filled with beeswax, sulphur, tin and lead, having melting points of 140°, 240°, 440° and 610°, all Fahrenheit, respectively. When beeswax melted in a hole 2 in. from the circumference it was assumed that the plate of the wheel at that point had reached a temperature of 140° F.

A soft cast iron brake shoe, M. C. B. standard, was applied with a pressure of 2,800 lb. and the wheel driven continuously at the rate of 30 miles per hour for 20½ minutes. After six minutes' running the brake shoe was heated to a cherry red and continued so to the end of the test, throwing off scintilating sparks. At the end of the test, an examination of the wheel showed that sulphur (204°) was melted in hole No. 2, 3 in. from the tread, and wax (140°) was melted in hole No. 5, 8 in. from the tread. The tread of the wheel was blue and in spots small cracks were visible where the chilled iron had disintegrated. The body of the wheel showed no cracks. After 29 minutes the heat had worked into the wheel so that wax melted on the hub. No part of the wheel more than 2 in. from the tread was hot enough to melt tin (440°).

A second wheel was tested by a continuous run of five minutes at 50 miles per hour under a braking pressure of 2,982 lb. After two minutes the brake shoe was dark red, and after three and a hali minutes bright red all through, particles of the shoe following and adhering to the tread of the wheel. At the end of five minutes the conditions were so severe as to threaten the destruction of the shoe and the test was stopped. The wheel at the end of this five minute run showed the tread to be badly burned, with heat cracks in spots. The body of the wheel showed no cracks. Wax (140°) had been melted 4 in. from the tread, and sulphur (240°) at one point 2 in. from the tread. After standing 21 minutes the heat had penetrated into the wheel sufficient to melt wax (140°), 12 in. from the tread of the wheel, and after 30 minutes the same temperature was reached at the hub. Sulphur

(240°) was not melted at a distance greater than 2 in. from the tread. No part of the wheel 2 in. removed from the tread was hot enough to melt tin (440°).

The Pennsylvania thermal test was applied to similar wheels at the works of the Griffin Co. in Chicago. Holes filled with tin and with a mixture of tin and bismuth melting at 350° F., and radial lines drawn on the wheel with stick sulphur were provided to show the temperatures attained. The results showed that in the thermal test the heat does not permeate the wheel equally all around, the rise in temperature being most rapid in that side next to the pouring, and least rapid at a point diametrically opposite. The difference was shown in the record of the thermal test presented. Thus, a point 2 in. from the tread reached a temperature of 240° in 1 min. 24 sec., while a point diametrically opposite was 2 min. 28 sec. reaching the same temperature. On the other hand, the action of a brake shoe must lead to uniform heating, a condition which probably is less severe upon the wheel than the unequal heating of the thermal test.

In the brake shoe test sulphur was melted 3 in. from the tread. During a 20 minute run sulphur did not melt at a more distant point than this. In the thermal test, however, sulphur melted at the same distance from the tread (3 in.) in 1 min. 24 sec. That is, the time required to heat the plate of the wheel 3 in. from the tread is 14.64 times as long with the brake shoe as in the thermal test.

As showing the severity of the braking test one car with its eight wheels braked as in the test would require the full power of a 90,000-lb. locomotive to keep it in motion at the speed of the test.

The maximum temperature of a point 3 in. from the tread was 240° in the braking test and was 350° in the thermal test in from 4 to 5 minutes after pouring.

A third series of tests was made in which the channel provided for the molten iron had different dimensions from those called for in the Pennsylvania specifications. They were as follows: Width at the bottom, 1 in.; width at the top, 1½ in; depth, 3 in. The channel extended down to the beginning of the fillet between the flange and the tread. These dimensions give a weight of metal cast about the wheel which is about 75 per cent that prescribed by the Pennsylvania test.

The molten iron was poured into the mold from two diametrically opposite points. The ring was poured in two parts, the first filling the channel-way for one-half its depth (1½ in.). An interval of one minute was allowed to elapse between the end of the first pouring and the beginning of the second, after which the pouring was resumed and the channel-way completely filled. The time of pouring each section was about eight seconds. The temperature of the iron was such that the ring when cool was free from wrinkles and layers. The ring was not removed from the wheel, but was allowed to cool in place.

The maximum temperature of a point 3 in. from the tread was 440° F.; the time required to reach the temperature of 240° in these tests was to that in the braking test as 3.56 is to 20.5, or as 1 is to 5.75.

From these tests Mr. Griffin draws the conclusion that the thermal test of the Pennsylvania road is very much too severe and the modification of the specifications followed in the third series of tests is thought to be amply safe.

SALE OF SAN JOSE (CAL.) R. R.

The San Jose (Cal.) R. R. was sold under foreclosure proceedings on May 19th to George Tourney, secretary of the German Savings & Loan Society of San Francisco, who stated, however, that he was acting for himself and other individuals, and not for the society. This road comprised nearly 10 miles of track and was the property of Jacob Rich. Mr. Rich spent $475,000 in its construction and operation; he complied with every demand of the public for extensions, though the business did not warrant them, and as a result was forced into insolvency. The judgments against the road amounted to $350,000. It was bought for $225,000 cash.

Of late the road has been doing a good business, and under the new management it may become a paying investment.

The Chicago, Harvard & Geneva Lake Ry. was opened for traffic July 4th.

LONDON UNITED TRAMWAYS.

The first company to introduce the overhead trolley system within the City of London, is the London United Tramways Co., and this concession was obtained only after persistant effort on the part of the company's engineer, Mr J. Clifton Robinson, who had been pressing his proposals on the attention of the council since 1894. Concessions have now been obtained for about 17½ miles of route of which 4½ miles are within the County of London. The company is also endeavoring to obtain franchises for 13½ miles more which with some further extensions in view would bring the total length of the line up to 40 miles. The whole of the system will be equipped with the overhead trolley system except about a mile and a half, which will be constructed with the electric conduit system.

The general features of these lines were described in a paper on "Electrical Traction on Tramways," read by Mr Robinson before the Cleveland Institution of Engineers, at Stockton-on-Tees, and the engineering details in some respects are quite different from anything to be found in this country. The overhead system is a notable departure from general practice having a double trolley line connected up on the 3-wire system. The territory covered by these lines is in the western suburbs of London. A map of the system was published in the "Review" for November, 1898, page 841.

The entire system will be operated from one station near one end of the lines which are now being built in Chiswick. This is a large one-story building of brick and freestone, 154 ft. long and 106 ft. wide, divided into an engine and boiler room. The engine room will contain a 25-ton travelling overhead crane carrying over the length of the room. There will be three vertical cross-compound condensing engines of 750-h. p. each, connected to two 250-kw. generators each, running at 90 r. p. m. A fourth engine running at 94 r. p. m. will be direct connected to a 500-kw 3-phase 5,000-volt generator with a frequency of 25 cycles per second.

The lighting units will consist of two 2-crank tandem compound engines each directly coupled to a 75-kw. 500-volt generator running at 400 r. p. m. Surface condensers of the Admiralty type will be used.

One motor generator set, consisting of one 3-phase synchronous motor of 500-kw. capacity at 5,000 volts and two direct connected 250-kw. 500-volt generators, will be located in the engine room for converting from direct to alternating currents and vice versa, for convenience on light loads and as a spare generating unit.

The boiler room has a steel frame construction of extra strength in order to carry the weight of the coal storage bunkers holding 500 tons of coal, economizers, flue and water tanks which are to be carried on the floor above the boilers. There are eight horizontal water-tube boilers in this room each having a capacity of evaporating 8,250 lb. of water per hour at a steam pressure of 160 lb. These will be fed by mechanical stokers of the "Coking" type to which coal is delivered by weighing hoppers from the coal bunkers above, thus securing a record of the exact amount of fuel consumed by each boiler. The economizers will consist of 360 tubes in 36 sections, provided with motor-driven scraping and cleaning arrangements.

The stack is built of steel plates in rings, lap jointed and rivetted, tapering upward and ending in an ornamental cap. It is entirely self supporting and is lined with fire bricks. Its height is 200 ft. above the foundations; the clear inside diameter is 10 ft.

The coal supply is delivered from the ground level outside the station to the coal bunkers over the boilers by a gravity-bucket type of conveyor capable of handling 40 tons per hour. The same conveyor also removes the ashes, dumping them into a special bin from which they can be readily removed. An additional coal storage of 2,000 tons capacity will be provided north of the boiler room from which it is intended to deliver coal direct from the railroad depot 700 ft. distant by means of a gravity bucket conveyor. Alongside the coal siding entirely below the ground will be placed a receiving hopper with the apparatus for delivering coal to the conveyor, thus enabling it to be automatically handled from the railroad cars to the company's coal storage and to the stoker hoppers.

The current will be distributed over the whole of the system by lead-covered paper-insulated cables drawn into cement-lined, wrought-iron pipes laid under the sidewalks. Thirty cables radiate from the central station at Chiswick, over 1,000,000 ft. of pipe being required.

The system is almost entirely double track, and over the rails of each track will be located two trolley wires, the two inside wires of which will be inter-connected to form the neutral wire. On account of extreme caution to protect the instruments of the Kew Observatory the company has been prohibited from using the rails as a ground return which makes the double overhead system necessary. This would double the amount of copper required for a single trolley, if connected on the 2-wire system, and in order to avoid this the 3-wire system is used, the two inside wires forming the neutral and the two outside wires the positive and negative sides. The neutral wire is grounded at the station and at that point only.

The overhead system is divided into half-mile sections, and according to the Board of Trade requirements each mile and a half of the line will be supplied by an independent feeder running direct to the station, the neutral side also having a separate feeder for each mile and a half.

Sections of the line extending more than six miles from the Chiswick station will be supplied from sub-stations. These will be fed from the central station through duplicate 3-core lead covered cables carrying 5,000-volt currents on the 3-phase system. The sub-stations will be provided with static transformers for converting the 5,000-volt current to approximately 350 volts. Suitable fans for cooling the transformers will be driven by electric motors. The 350-volt current will be led into rotary transformers which deliver direct currents at 550 volts for the line. The electrical connections are such, owing to the rotary converters feeding into a 3-wire system, that these machines will act both as rotary converters and balancers; that is, in case one side of the 3-wire system is overloaded the rotary converter acting on the other side of the system will act as a motor, and thus assist the overloaded machines.

ELECTRIC RAILWAYS IN SWITZERLAND.

The following data concerning the electric railways in Switzerland have been taken from a report made by Mr. A. L. Frankenthal, U. S. Consul at Berne, published by the State Department under date of June 19, 1899.

The existing electric lines are:

1 main trunk railroad	4	km
2 narrow gage railroads	9	"
1 cog road (Gornergrat)	9.08	"
5 cable lines using electric motors	7.63	"
19 street car lines	103.82	"

Also one narrow gage railroad and one street car line on which electricity is used to some extent.

Sept. 1, 1898, there had been concessions granted for the building of 120 lines of all kinds, with an aggregate projected length of 2,032 km.; 47 of these are to be equipped with electricity. The electric tramway projects were 15, with an aggregate length of 82.5 kilometers.

The concessions for all railways of whatever kind are granted by the Federal Government and are cheaply and easily obtained; the maximum time for which a grant is made is 80 years. When the receipts show a profit of over 6 per cent per annum the maximum fare must be reduced. After May 1, 1915, cantonal or Federal authorities may purchase any road in existence on giving three years' notice.

If an agreement to purchase be entered upon and concluded up to May 1, 1930, 25 times the value of the net earnings for the 10 years previous has to be paid; between the years 1930 and 1945, 22½ times the net value; between the years 1945 and the end of the concession, 20 times the net value is to be the sale price. In case the Canton is the buyer, and the Federal authorities demand control of the property, the Canton is compelled to deliver to the Federal authorities the property acquired at the price paid.

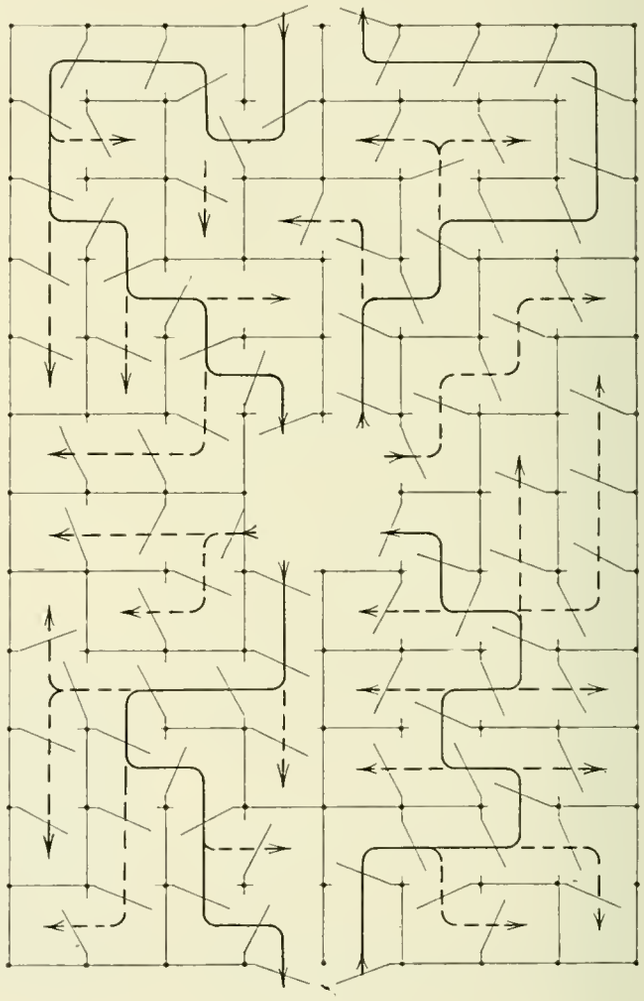
In conclusion the report says:

"The attitude of the Swiss Government is very favorable towards the building of railroads, especially mountain roads, and also electrical conveyances to places which otherwise would be difficult of access by the summer tourist.

"All things considered, the investment of American capital in small mountain roads and electric tramways must be a paying one. Firms interested in this line should send competent men to look over the field of the concessions held. No doubt, profitable arrangements can be made either for the building of roads or for giving financial support to some of them. There is no lack of brains in Switzerland to conceive profitable projects in this line, but there is a lack of means to carry them out. The exceptional conservatism of the people may be another reason why meritorious projects have not been carried out."

AN OPEN MAZE.

The accompanying sketch represents an "open maze" which, doubtless, would prove an attractive feature at almost any park where other than natural attractions are provided. It can easily be built by almost anyone and at small expense. The size of the maze and the arrangement of the true and blind paths may be varied according to the means and ingenuity of the builder. One of the points to be observed in laying out the plan is to have as many cells as possible with more than one door.



OPEN MAZE.

The Albany & Troy Steamboat Co. has a park on an island in the Hudson River near Troy, in which is an open maze with 96 cells each about 4 ft. square. The foundation consists of stringers laid on the ground and covered with planks, making a floor about 32 x 48 ft.

On this floor are set posts of 2 x 4 in. pine about 6 ft. high; they are placed 4 ft. apart each way and fastened to the floor by knees made of strap iron. The tops are fastened and braced by 6 x 1 in. planks running both crosswise and lengthwise of the maze. The partitions, or sides of the cells, are made of rectangular frames covered with wire netting such as is used for fencing chicken yards. The immovable partitions are exactly similar to the doors save that they are nailed in place instead of being swung on hinges. Spring hinges are used so that the doors are all self-closing. The doors are hung to the posts, a cleat being placed on the opposite post so that the door swings only one way.

In the center is a larger cell, 8 x 8 ft., through which both of the paths lead. As shown in the sketch one may start at either

end and go to the center and then return to either end. The doors are so hung that they swing away from the person going through except when he has strayed from the true path into a cul-de-sac and must retrace his steps, then the doors open towards him.

WHY SO MANY ROADS IN SMALL CITIES LOSE THEIR PATRONAGE.

BY J. A. P.

The reasons for so many street railways in small towns and cities losing patronage may be put under five heads:

First. Poor service on other lines when they have "big days" on some one line.

Second. Insufficient attention paid to keeping cars on regular time.

Third. False economy in the purchase of cheap material, etc.

Fourth. Reducing expenses in wrong directions.

Fifth. Failure to keep cars, parks, etc., in proper condition.

When, a few years ago, electricity took the place of horse and mule power in the street railway field no small cities and towns were considered at all progressive until they were equipped with an electric road. Naturally the residents appreciated the novelty and a rushing business was the result. However, the novelty soon wore off and there came a lull in business; what was the result? In place of "keeping everlastingly at it" to bring success managers would reduce the number of cars operated, thus making the service poorer, and this leads to taking up the five causes enumerated.

First. Some street railway officials may be very excellent business men in their particular lines, but when it comes to the operation of a road, they display a notable lack of foresight. One of the most noticeable of these is that whenever they have a big day at a park, ball game or what not, cars are taken off of the regular service on other lines and rushed out to the particular point, thereby giving such poor service on other lines that patrons must either walk to the point where the "Grounds" cars are, or take chances on not reaching the point of interest until late.

Again, when the entertainment is over all cars will be held at the grounds, thus leaving those who desire to ride home from town without cars. At the grounds the cars are loaded and rushed to some point in town, where the passengers are unceremoniously "dumped" and obliged to walk home, while the cars are sent back for another load.

This may be doing a rushing business for one day, but the result on the regular business is bad. Patrons who are regular passengers on some one of the other lines were obliged to walk home, perhaps fully as far as the distance they came from the grounds. These people are the mainstay of the road, year in and year out, yet for the sake of having a big days business managers will put them to all sorts of inconvenience to accommodate a few hundred strangers who may use the cars but once a year. An instance of the effect of such a policy came to the writer's attention a short time since. A road in a small town had attractions at a park, and on all big days the people were hustled from the grounds to the transfer point (?) up town (but all cars were on the "grounds" line); there they were unloaded and obliged to walk the remainder of the way to their homes, while the cars were sent back to get more passengers. One family, whose regular trips every day amounted to twelve, became so bitter, that they declared they would not use the cars again, and have not done so in six months. And numbers of others use the cars only when absolutely necessary since that time.

In a small town distances are not great and if the road displeases the public, the road, not the public, will be the principle sufferer.

Second. A most important feature in street railway operation is to keep the public posted as to when, that is, what minute they can depend on a car. It is too often the case that small roads never place their cars on a regular schedule, but give a car so much time in which to make the round trip. If a line has say 15 minutes between cars, how are the people to know when a car will put in an appearance? People in most instances use cars because they want to reach their destinations quickly; if they do not know when a car is due they walk unless a car "just happens" in sight.

Third. Regular receipts decreasing, officials conclude that expenses must be cut down. This is accordingly done by stopping the operation earlier in the evening. If receipts decrease because a road has secured the ill will of a large number of citizens, it can not be expected that an increase, or even a continuation of present receipts, can be had by still further antagonizing or disappointing the public by a decrease in the number of cars operated or by reducing the number of running hours.

Fourth. Perhaps some may think it ridiculous to assert that buying cheap goods and running a road on a cheap scale, would affect the traffic in any way. Yet experience proves it to be true. A merchant making a show of prosperity always does a better business than his neighbor who is constantly complaining and the same holds good in the railway world. The road whose management is always seeking to keep the plant, cars, etc., in first class condition has the well wishes of the citizens and the more attractive and substantial everything is made, the more pride the citizens take in the line, and the more nickles the road takes in. Can this result be accomplished by using poor material in construction, etc., especially when by using such material you are constantly being interrupted by "break downs"? The purchase of poor goods always results in the road paying out more for repairs than if it confined itself to the best, to say nothing of the annoyance which poor material causes.

Fifth. One of the most important features is to keep cars, parks, etc., in clean and respectable condition. The lack of this is very noticeable in many places. Cars are operated month after month without even being washed, and several years may pass before a paint or varnish brush ever touches them. Dust and grease are allowed to accumulate on both exterior and interior, all of which tends to disgust patrons and they will only ride when absolutely necessary. As for parks, you can not expect to keep your crowds in attendance by charging a high price of admission, and giving a cheap entertainment. Neither can it be expected that respectable people will attend when "all sorts" are allowed to make the park their resort. Too much attention can not be paid to keeping parks respectable.

In this connection it might be well to call attention to unnecessary waste in throwing away "scrap" of any sort. Because a wire or other piece of metal is very small it is perhaps buried in the rubbish pile, or elsewhere than in its proper place. Cents make the dimes; dimes the dollars, and dollars make dividends.

BROKEN JOURNALS CAUSE MISHAP.

A peculiar case of two broken journals on one side of a car was the cause of an accident on the Prospect St. and Lonsdale Ave. line of the Pawtucket Street Railway Co. last month. When within 1,500 ft. of the end of the route both journals on one side of the car broke off causing the car to topple to one side, turn completely around, run up onto the sidewalk and fall over upon its side. There were no passengers on the car, but the motorman and conductor were both severely hurt.

Gen. Mgr. Charles F. Luther of the railroad company made a thorough examination of the car and track at the scene of the accident, and the appearance of the roadway at this point showed that the forward left side journal of the car broke first causing the left wheel to leave the track. The car hanging down at the corner put so much stress on the rear journal on the same side of the car that it broke also with the effect of upsetting the car on its left side. Both journals must have broken within a second of each other, and further examination showed that the brakes had been set on all four wheels at the moment of the accident.

The Camden (N. J.) & Suburban Railroad Co. it is announced must now pay a tax of one dollar for every pole erected along its line. The railway company claims 25 cents to be the proper fee.

The Bay Cities Consolidated Railway Co. contemplates building a new central power house and car shed in Bay City in the event that a franchise can be secured for the streets necessary to give access to the barns.

Two cars came in collision on June 17th on a line of single track of the Milwaukee Electric Railway & Light Co. at a turn in the road near the city limits of Wauwatosa. One of these was an empty east-bound passenger car and the other a west-bound car carrying 12 men to their work at the end of the line. The collision pretty well demolished the cars, but the men escaped without serious injury.

THE CLEVELAND STRIKE.

The strike of the employes of the Cleveland Electric Railway Co. —the Big Consolidated—which began June 10th and ended June 25th was a struggle solely for the recognition of the employes, union, the company having before the strike expressed a desire to adjust all other differences by conference with a committee of its employes and if necessary by reference to a board of disinterested arbitrators. The company took the solid ground that it could not free itself from the entire burden of responsibility for the safe and proper carriage of its passengers, and therefore must be free in the selection and discipline of its employes for whose acts it is responsible.

Cars were operated with great difficulty and it was necessary to cover the platforms with wire netting to protect the non-union men from the missiles thrown at them; eggs and bricks were favorites. About 200 men were brought from Chicago, Toledo, Cincinnati, Pittsburg and other cities to replace the strikers. Every day from the 10th until the 25th, except on Sundays there was a great deal of rioting; firearms were used in some instances but most of the casualties were from stone throwing. The city afforded better police protection during the second week of the strike when it was realized that the disorders would surely grow more serious if not repressed with a firm hand. This of course was deprecated by a certain portion of the public.

Probably no better idea of the issue can be given than by publishing the demands of the strikers, the proposition first made by the company and the agreement which was finally concluded.

The men first placed their demands in writing on June 20th, when the following was submitted:

"First, that the Cleveland Electric Railway Co. upon all matters of differences or grievances existing or arising between said company and its employes will at all times recognize and negotiate the settlement of the same with such committee of its employes as they may from time to time appoint, or any agent or attorney selected by them.

"Second, that in all cases of suspension or discharge of an employe, said railway company shall furnish to such committee of its employes, upon request of the committee, a written statement of the reasons for such suspension or discharge.

"Third, in all cases where it is impossible for the company and the committee to reach a mutual agreement the same shall be submitted to a board of arbitration to consist of three disinterested persons, one to be chosen by the company, one by the committee representing the employes and the two thus selected to choose the third. Their award to be final. That upon the request of such committee the discharge of any employe since April 1, 1899, shall be treated in the manner hereinbefore set forth.

"Fourth, that all the employes now on a strike shall be reinstated to the positions formerly held or occupied by them prior to the 10th day of June, 1899; excepting such employes as have or shall have been found guilty in a court of proper jurisdiction of the charge of malicious destruction of property; otherwise their reinstatement to be made without prejudice.

"Fifth, the parties hereto shall conform to all the terms and conditions herein stated for and during the period of one year from the date of the settlement hereof, and upon which settlement such terms and conditions shall be in writing, and a copy of the same to be filed with the committee of the street railway employes submitting the same, and a copy to be filed with said railway company and the committee of the council to whom the matters herein set forth are submitted."

June 22d the company and a committee of the men reached this agreement:

"The company declares that, in order that its men may have a proper sense of security in their employment, the company will not discharge any man except for cause, which cause will, at his request, be given to him, and he will be given a full and fair opportunity to explain or disprove the same. It declines to submit to arbitration any question of its schedules or the wages it pays.

"The company must reserve the ultimate right to hire and discharge men, contracting with the men individually and not collectively. It is ready and willing to take back into its employment, as it has ever been, such of its former employes as its business demands, aggregating, at the present time, 80 per cent of such employes, and as other vacancies occur will give preference to such former employes, excepting always those who have committed unlawful acts against the company, its property, or employes during the present strike. But the rehiring of all men is upon the express condition that their service with the company's present employes must be loyal, and the latter must not be subjected to annoyance or abuse by them and any violation of this condition shall be deemed cause for discharge.

"The service of employes will be distributed as equally as possible under existing conditions. The company will today be able to give, upon the return of its former employes to its service, 80 per cent of the runs to the former employes; 20 per cent of the runs to its present employes, the remainder of its former and present employes to be placed on the extra list in the same proportion. The method of apportioning these runs between former and present employes to be as follows: The first four runs on the time table of each line to go to the former employes, the fifth to go to the present employes, the next four runs to go to the former employes, the tenth to the present employes, and so on through the time table with the day runs, late runs, and extra list. Temporarily, this adjustment may work some inequality to some men, but the same will be adjusted as equitably and promptly as possible upon these lines."

This was repudiated by the strikers in mass meeting who then drafted an agreement which was said to be "just the same" as the one suggested by the company.

This, the company's lawyers found, was so different from its proposition that it declined to accept it.

June 25th a committee appointed by the city council secured the acceptance by the men of a proposition substantially the same as that first offered by the company. There were five points covered, as follows:

1. Restoration of former time schedules as announced by the company before the strike.
2. Questions of wages of men working short hours, the distribution of extra runs, etc., to be submitted to arbitration if the company and its men fail to agree.
3. Men to be given a full and fair opportunity to disprove charges against them.
4. Questions of schedules and wages not to be submitted to arbitration. The company to take back 80 per cent of the strikers; new men not to be subjected to annoyance.
5. Work to be divided among old and new men as in the offer of the company.

After the strike was thus settled disturbances on the street continued, new men being annoyed and abused by the late strikers and their sympathizers.

The position taken by the public press in general is shown by the following extracts:

"There is no law of Ohio that compels an employer to deny work to a man who does not belong to a labor union, or a Masonic lodge, or the Knights of Pythias, or the Methodist church or the Republican party. The employer is at full liberty to employ any man who is willing to work on the terms offered, union or no union. That is the law, and the civil authorities are bound to protect the employer in the exercise of his legal rights."—Sandusky (O.) Register.

"At the very outset of the trouble the company granted everything save its right to employ whom it pleased. In other words, it refused to recognize the union and insisted on the privilege of managing its own business without interference from its employes. But the strikers were not satisfied. They wanted to dictate the company's policy and when they found that the company would not yield its position they resorted to violence, thereby injuring their own cause and losing what little sympathy they may have had from outsiders. By their actions they not only disgraced themselves, but they injured the cause of labor, to say nothing of giving the city of Cleveland a bad name."—Springfield (Mass.) Union.

"Street car strikers in Cleveland, Wheeling and other cities will not advance their cause much by assaulting women and children and other defenseless passengers on the cars. That sort of work will alienate all public sympathy for the strikers. That kind of striking is not popular."—St. Paul (Minn.) Dispatch.

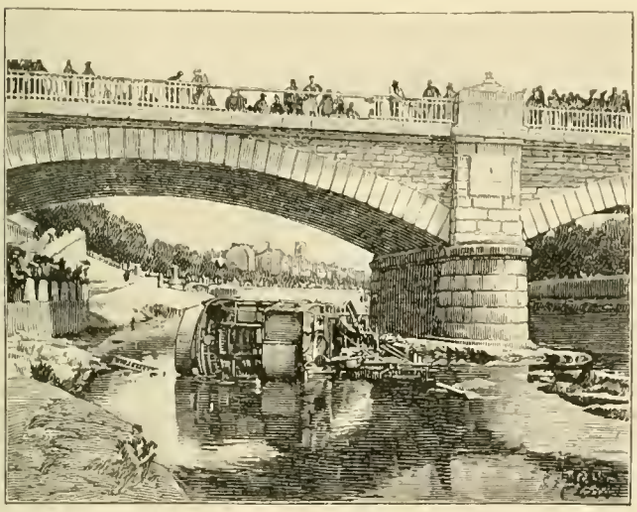
"A significant fact in connection with labor strikes in this country during the last few months is that they have been confined largely to street railroad employes. * * * The explanation is

to be found evidently in the fact that strikes among street railroad employes of late are of a political rather than an industrial character. Labor leaders are taking advantage of the sentiment that has been kindled against street railroad corporations in certain communities to create trouble for their own purposes." New York Commercial Advertiser.

"That this resolution (the resolution adopted June 12th by the company) embodies nothing but priciples of reason and common sense is so plain that even the most blatant of walking delegates should, it would seem, hardly presume to question its terms or its conclusion. * * * The stand taken by the Cleveland railway people is the stand that all free Americans must take unless anarchy is to run riot through the land and law and order is to give place to lawlessness and disorder. There can be no compromise of, and no arbitration on the question that is now uppermost at Cleveland, O." Los Angeles (Cal.) Times.

FALL OF A TRAMCAR INTO THE RIVER DOUBS.

A serious street railway accident occured at Besancon, France, on the evening of May 31st. An electric car running at an excessively high rate of speed became derailed just as it entered upon the bridge of Canot. The car ran onto the sidewalk and after tearing down the iron railing fell a distance of 27 ft. into the river landing on a bed of rocks. In this singular accident there were 3 peo-



TRAMCAR ACCIDENT IN FRANCE.

ple instantly killed and 4 others seriously wounded. The illustration, taken from La Nature, shows the position of the car in the river and also where the railing of the bridge was torn down, which the workmen are temporarily replacing with a wooden rail. In falling the body of the carriage turned on its side and was almost completely demolished, while the wheels and the electric motor fell perpendicularly and stood upon a shelf of rock.

CONTROLLER BURNED OUT.

On the 19th of June a panic was caused on one of the Union Traction cars at Pittsburg, Pa., by the burning out of a controller. A picnic had been held that afternoon at Calhoun Park by one of the churches of the city and the party left for home about 8 o'clock on one of the open cars of this line. The car was crowded with passengers and had reached Reynoldton, where it was proceeding at a 10-mile gait, when a flash occurred at the controller followed by a brilliant display of burning copper. The car was quickly brought to a standstill but not before a number of excited passengers had jumped off, several of whom sustained injuries, though none was fatally hurt. The passengers remaining aboard the car were unhurt.

ELECTRICAL TRACTION AND INDIAN LIGHT RAILWAYS.

Reported by the Philadelphia Museum.

From the viewpoint of the electrical engineer, a very important conclusion has been arrived at by the Indian authorities regarding the motive power of one, at least, of the light railways about to be extensively constructed throughout the Empire. This is the railway that will enter the Kashmir valley.

Hitherto it has been considered likely that the Kashmir road would be more or less of the same pattern as the other Indian hill railways already in existence. The fuel question was one, however, which bristled with difficulty. There was wood enough, but it was not considered desirable to denude the hillsides, and coal would have had to be brought all the way from Bengal. Under these circumstances it is not strange that the eye of the engineer should have fallen wistfully upon the boundless store of water power rushing to waste at his feet. The point was to apply it. The use of electricity as a motive power for locomotives was no new thing; but its application to the working of a line of railway 180 miles in length would hardly have been deemed practicable until quite recently. The progress achieved in the last few years, however, in the matter of transmitting electric power over comparatively long distances with comparatively small loss of efficiency has been so great as to render the suggestion quite feasible. Besides, the electric power possesses advantages peculiar to itself which specially recommended it for the uses of a hill railway. The experience of short lines already established on this system proves that electric traction gives a more uniform turning effort than does the locomotive in steam traction. The difference has been put at something like 40 per cent. This allows the use of a much lighter engine to draw the same load, and admits of working up by gradients which a steam engine could not surmount, except with the assistance of a rack rail. These advantages are so essential in hill work that in some cases it has actually been found expedient to use electric traction rather than steam, even where the electric power has to be obtained by a steam engine in the first instance.

The Kashmir line will extend from Jummu to Srinagar, a distance of 180 miles. Halfway between is Ramband, on the Chenab River, and here it is proposed to establish the central station. At this point the fall of the river is from 20 to 25 ft. to the mile, and the state engineer, Mr. Nethersole, calculates that a canal of 7½ miles giving 150 head would develop 100,000 h. p., which would be more than enough for the purpose.

The road is estimated to cost between $3,500,000 and $5,000,000. Its gage will be either 2 ft. or 2 ft. 6 in. It has not been determined whether the state of Kashmir itself will do the work or grant a concession to outside capitalists. The important matter for the electrical world is that electricity is being at length recognized as a valuable traction power in such a country as India, where light railways are every year becoming more necessary to the requirements of agriculture and commerce generally. Here there will be wonderful scope for business in the various supplies and equipment necessary for light railroad traffic, and which United States manufacturers are so well able to furnish.

The state of Kashmir is the most northerly and most mountainous in the Empire, and has an area of 80,000 miles. Its chief town is Srinagar. It is reached more easily from the western side of the territory, and Bombay is, therefore, its port of entry.

TROLLEY CAR MAIL SERVICE.

The postal authorities have just decided not to abandon the trolley car mail service between St. Paul and Minneapolis which was ordered some time ago to be stopped. The continuance is due to the recent visit of Second Assistant Postmaster General Shallenberger to those cities where he investigated the subject very thoroughly. The street railway company had a contract for the service for which it received $2,000 per year, which amount, however, was thought to be inadequate. The company therefore refused to bid on a renewal of this contract, which expired on July 1st. After conferring with Gen. Shallenberger, the officials submitted a new bid of $2,700, which was accepted. This will result in the continuance of the hourly service between these cities, the same as before.

FOREIGN FACTS.

The Portrush (Eng.) Urban Council is considering a communication received in reference to an overhead electric traction system.

Sir E. Ashmead Bartlett has secured, among other concessions from the Turkish Government, one for an electric railway at Smyrna.

Croyden, Eng., is about to acquire the railway of the Croyden & District Tramways Co., the purchase price for which will be about £50,000.

At a recent meeting of the Tramway Committee of Dundee, Eng., it was decided to build an electric railway in that city to connect the two lines now in operation there.

The tramway system of Aukland, N. Z., has been acquired by an English company, which will considerably extend the system and install electric traction. The estimated cost is $800,000.

The third-rail system will be used this summer on a trial section about 2 1 3 miles long of the Vienna tramways. Two trains will be used, each consisting of two trail cars with a motor car on each end.

The Madras Government has recently given an order authorizing the construction of a system of electric tramways in the district of Madura. This will be the first supply of electricity from a central generating station in India.

The Corporation of Chester, Eng., is considering the advisability of acquiring the railways of that city. The city electrical engineer has prepared a report on the practicability of running the system by electricity in which he recommends the adoption of the open conduit system.

The City & South London Electric Ry. extension which was advertised to be opened in July will not be completed for at least three months. A tunnel has been constructed under the Thames, making the extension practically a new line. A new power house is being built for this part of the line.

The new electric railways of Blackpool, Eng., were inspected last month by Major Cardew, on behalf of the Board of Trade, and a provisional sanction was given to run the cars pending the decision of the Board. The electrical equipment of the cars is being pushed rapidly and is nearly completed.

The annual meeting of the stockholders of the Ottawa (Ont.) Electric Co. was held on June 26th. A dividend of 6 per cent was voted and a sufficient sum set aside to increase the surplus to an even $75,000. President T. Ahearn and the old board of directors were re-elected for the following year.

During the Motor-Car Fete held in Paris last month the excitements of that occasion were augmented by the performance of a motor car named the "Never Content" which is said to have been traveling about at the unusual speed of 65 miles per hour. This car, moreover, is described as "noiseless."

The Glasgow Corporation Tramways is inviting bids for the supply and erection of a complete 3-phase traction plant, the electrical machinery of which includes 3-phase generators, direct current generators, rotary converters, boosters and static transformers. Bids have also been invited for the supply of 80 trolley car bodies.

An action has been brought by Mr. Blackwell, of London, against Messrs. Greenwood & Batley, Albion Works, Leeds, to recover £608, the price of trolley standards and other goods supplied for the electric railway of the Leeds Corporation. One of the trolley standards broke, injuring three passengers, and the corporation was held liable for the damages. It in turn claimed and received the amount, including costs, from Greenwood & Batley, who now counterclaim the sum from the plaintiff on the ground that the standard was of adequate strength and that the fracture was due to abnormal pressure or to a collision previous to the accident. Decision was reserved.

The electric railway on the Isle of Man, between Douglas and Ramsey, was opened for traffic last month over the full distance. Part of this line was opened last year, but the full distance of 17 miles and a double track has just been completed. The line is on the overhead system, and the road opens up a beautiful country practically unknown to tourists heretofore.

The first step towards providing Brighton, Eng., with a much needed electric railway system was taken by the County Council in adopting the report of the Tramways Committee, recommending that aplication be made for powers to construct and operate an overhead system of trolley roads. The route covers nine miles of roadway and the current for the road will be taken from the existing electrical supply station.

Cornelius L. Hester, a London electrical engineer and contractor, who is visiting in Pittsburg, Pa., states that a syndicate has been formed for the purpose of building a network of trolley roads in London as soon as the County Council shall give it permission. In that city the operation of a street railway by a private corporation is almost impossible, and Mr. Hester considers it a matter of course that the lines would pass into municipal ownership after completion.

The Potteries district of North Staffordshire, Eng., will soon have an extensive system of electric railways. Concessions from 18 different local authorities enabled the British Electric Traction Co. to amalgamate various roads under the name of the Potteries Electric Traction Co., which was organized in 1898. The lines when completed will comprise 35 miles of track constructed on a uniform gage of 4 ft. A part of this system is now in operation and the balance is under construction.

The death of Mr. Guyer-Zeller will have the effect of considerably shortening the Jungfrau railway, as it is intended by his heirs to complete this road only as far as the Eier section without proceeding any further up the mountain. The enormous expense and the engineering difficulties of building this line have been so great as to discourage any further extension of the line, especially in view of its uncertain earning capacity. The Eier section reaches nearly 10,000 ft. above the sea level.

Considerable anxiety is felt by the authorities of the Greenwich and the Kew observatories in regard to protecting the magnetic registers from disturbance by a number of new electric railways which are now projected. The value of the magnetic records which have now been carried on continuously for nearly 60 years, will depend, according to the report of the Astronomer Royal, entirely on the conditions under which electric traction is used. Steps have been taken to have a special clause inserted for the protection of these observatories.

The district near Nice, France, is to have an electric railway system, the power for which will be obtained from the water power abounding in that neighborhood. A company was formed which utilized the waters of the Var, by piercing a tunnel and erecting a reservoir from which a considerable fall was obtained. This will provide power for the tramways in the district of Cannes and Nice. These lines will also be extended to Beaulieu and Monaco. The lines at Cannes started running in January but were stopped for several weeks on account of their interference with the telephones. This was remedied and the service was continued in February. A line has also been built from the Monaco station to the town of Monaco, and another from Monte Carlo to the Casino Gardens.

THE WHEELING STRIKE.

The situation in Wheeling, W. Va., has not improved to any great extent, the local papers reporting that on June 20th there were five cases of assault upon individuals growing out of the street railway strike.

This strike began on April 8th and had the active sympathy of the citizens of the city; this sympathy has waned considerably, however, and on June 16th at a meeting of the members of the chamber of commerce and other citizens some remarkable resolutions were passed. In substance they were:

"Whereas the strike has greatly interfered with business and given the city a bad name, and it ought to be settled: First, we urge the parties concerned to come to an agreement before June 20th. Second, if they do not do so we hereby give notice that after that date we shall patronize the street cars."

Surprising as it may seem this is reported to have drawn angry protests from the strikers.

The boycott placed on the Bellaire, Bridgeport & Martin's Ferry Street Ry., of Bridgeport, O., April 25th was raised on June 25th. This line is owned by the Wheeling Railway Co., and the boycott was designed to assist the strikers on the Wheeling line. Experience showed it to be without any affect on the situation in Wheeling, and work a great hardship on the employes of the Bridgeport lines who were satisfied with the wage scale and wanted to work.

A settlement was reached on June 29th on the following terms: 11 hours per day; 18 cents per hour; new men to be retained in service. It will be remembered that before the strike which began on April 8th, the company offered 18 cents per hour, but the men demanded 20 cents. After 83 days idleness the men thus accept what was offered at the beginning.

PECULIAR ACCIDENT ON THE CHICAGO ELEVATED LOOP.

On the evening of July 3d there was a very peculiar accident on the Chicago Union Elevated R. R. In some manner a short circuit was established between the contact shoe of one of the Lake St. motor cars and the arm supporting it, thus making direct connection between the third rail and the track return. A fine electrical display followed for a few instants until the circuit breakers in the power houses opened. There were repetitions of the fireworks at short intervals until the 1,500,000-c. m. stranded copper feeder cables supplying current to loop were burned out at three different points. The traffic was delayed for over an hour because of the mishap. We have been advised that the serious consequences resulted because of the attempts to keep circuit breakers closed after they had first opened.

LIGHT RAILWAYS IN ARGENTINA.

Mr. D. Mayer, U. S. Consul at Buenos Ayres, having received numerous letters of inquiry concerning the light railways in Argentina, prepared a statement on the subject which was published in the Consular Report advance sheets June 14, 1899. The letter is as follows:

On December 31, 1897, the Legislature of the Province of Buenos Ayres passed a law authorizing the construction of light railways of 1 meter (3.28 ft.) gage throughout the Province. The Government was to fix the tariffs, regulate the construction and working of the lines, and the right to expropriate any railway so constructed at cost price was retained; so that it was difficult to determine what benefit there could be for the concessionnaires.

Moreover, there were two articles in this law capable of any interpretation that the authorities might like to give them, when the railways were once built; for instance, paragraph 3 of article 5 says:

"The lines may be laid upon the public roads, or on one side of same, so long as they are constructed under the required conditions, and the company is bound to keep them in order."

This might easily be construed to refer to the whole road; nor do I see in the law any article giving the right to expropriation of land, so that the company would be bound to use the roads or be at the mercy of the landowner, equally disastrous alternatives.

Article 6 says: "Every company shall be bound to construct the works necessary to guarantee the efficient working and security of the railway."

As article 5 gives the Government the right "to regulate the construction and working of the lines," it is at least presumable that it will dictate to the company any work that it may consider necessary for "efficient working and security."

It will not surprise railway men at least to learn that concessionnaires have made little effort to obtain permission to construct light railways under the above law. Six months later (July, 1898), the supplementary regulations appeared; these applied chiefly to the form in which the petitions for concessions shall be made, the periods allowed for presentation of plans, execution of works, etc., and, in agreement with the law itself, left all powers in the hands of the Government, to whom the companies would be bound hand and foot.

For instance, articles 25 to 29 prescribe that fences, barriers, signals, and continuous brakes shall not be exacted except when the Government shall think fit, and a company would hardly be willing to accept such indefinite conditions. The regulations for working are as numerous and as vague as those for construction, and I frankly can not see what profit a railway company can gain, by the time it complies with all the conditions expressed and implied in this law.

But, apart from these considerations, the question presents itself, With what capital are these light railways in the Province of Buenos Ayres to be built? And, secondly, Are they to be constructed with a view to competing with existing broad-gage lines, or as feeders to them?

To the first question, I answer without hesitation, With foreign capital; and for railway purposes it is hardly likely to be other than British capital. If this be admitted as correct, it disposes at once of the second question, for it is improbable such capital would be forthcoming for the purpose of competing with the Great Southern, Central Argentine, Buenos Ayres & Rosario, Western, and Pacific railways.

Another difficulty lies in the condition (article 5, paragraph 1) that the roads shall be meter gage, as this would involve transshipment of produce; further, each light railway branch would need repairing shops, running sheds, etc., for the same reason that the difference in gage would not allow the light-railway engines or wagons to run into the broad-gage railway shops for repairs. As feeders, therefore, it would appear that the light railways can hardly be a success, unless the law be modified and equal gage allowed.

A STREET CAR WRECKED.

A car on the Sherman Heights division of the Chattanooga (Tenn.) Rapid Transit railway was wrecked on the night of June 7th at a point known as Henderson's switch, the car behind the dummy being derailed and ditched, injuring several passengers. At the time of the accident it was thought to be caused by the car wheels splitting the switch, but on investigation it was found that the switch had been tampered with. The switch was in such a position as to warrant the belief that it had been thrown while the dummy train was passing over it, being left open for the engine and closed to the car. A few days previous to the accident an intoxicated passenger named Whittenberg had been put off a car on this line and it is now stated that the Rapid Transit officials have secured evidence to show that Whittenberg, in order to be revenged upon the company, deliberately wrecked the train by manipulating the switch. A warrant has been issued for Whittenberg's arrest, and he has been in hiding ever since.

RAN INTO A CHERRY TREE.

A Hoboken, N. J., trolley car bound for Rutherford, on June 18th, left the track while descending a steep grade. The car was running at a lively speed when it left the track, and crossing the road it dashed through a fence and brought up against a cherry tree with a suddenness that unseated all the passengers, none of whom, however, was hurt. Had the cherry tree stopped its progress, the car would have plunged over an embankment directly in front of where it was stopped.

THE METROPOLITAN MUNICIPAL RAILWAYS OF PARIS.

The Metropolitan underground railway system of Paris, some parts of which have been in course of construction for several months is to comprise nine different routes, six of which have been determined and which will comprise the system which is being pushed to completion as rapidly as possible in view of the Exposition in 1900. The last three routes are to be constructed eventually, but probably not for several years. The total length of these six lines is 62.911 km., which may be subdivided as follows: Underground lines, 40.339 km.; open cuts, 11.725 km., and viaducts, 10.847 km. The routes of this system may be divided into circular and transverse lines. The circular line is an intramural one following the course of the boulevards around the outer edge of the city. The transverse lines run straight through the city and these lines are connected to the circular line by a number of branch lines. The part of this system actually under construction is one complete line

MAP OF THE PARIS METROPOLITAN MUNICIPAL RAILWAY.

and parts of two other lines. The first is the principal transverse line running east and west connecting the Bois de Boulogne and the Bois de Vincennes. It runs through the avenues of the Grand-Armee and the Champs-Elysees, the Rue de Rivoli and the Boulevard Diderot and along the Course de Vincennes up to the gate of the same name. Of the other two parts in course of construction the most important is the one running from the Place de l'Etoile to the Trocadero intersecting the preceding line in such a manner that it will be possible for passengers from the Bastile and the Rue de Rivoli to take a train directly to the Trocadero. The other part being built starts from the Porte Dauphine following the avenues Bugeaud and Victor Hugo to the Place de l'Etoile. The latter portion is the comencement of the circular line mentioned above. The construction of this road is the subject of two interesting articles in La Nature by M. A. Cunba, from which this abstract has been prepared.

The Place de l'Etoile will form a grand central station from which a large number of the lines will radiate in different directions. This station will form the end of the Etoile-Trocadero line at which point the track is in the form of a loop. This will facilitate the movement of trains at the terminus by avoiding any switching. The Porte Maillot-Champe-Elysees line crosses the Place de l'Etoile where it touches the loop of the former line tangentially and at this point of contact, which is opposite Wagram Ave., a double station will be built common to both lines. The Porte Dauphine-Wagram Ave. line crosses the two preceding lines but on a lower plane, the face of these rails being at this point 14 m. below the surface of the ground so that there is no actual junction. The station of the latter line, however, will be placed vertically beneath that of the two former lines so as to permit passengers to change from one line to the other without remounting to the street surface.

The substructure of the Metropolitan is constructed by the city, while the superstructure and management of the road are conducted by a special company known as the Metropolitan Co. The principal line has been divided into 11 parts, which with the two parts of the branches makes 13 parts actually under construction. The building of all of these parts except one has been let to contractors, and the remaining part is being built by the city. There was a great deal of difficulty in carrying on such a considerable work as building an underground railway in the short space of eighteen months in the midst of Paris, and it required all the energy and ingenuity of the engineers to accomplish this remarkable problem of construction without obstructing traffic in the streets.

The method of operation is very simple in principle. The contractors have sunk vertical pits where the earth from the tunnel is raised, and these pits are placed at short distances along the route so as to present as many working fronts as possible, and also to reduce the time necessary for boring between them. In a great many places they have been able to make use of a shield operated by a hydraulic press, which in spite of its high price of $24,000 effects an economy in the whole work by reducing the amount of wood work required for sustaining the roof of the tunnel. The shield in some cases includes the whole section of the tunnel which in this case requires but a single operation for the construction of each successive ring. At other times the shield only includes part of the bore and in this case a second operation is required to remove the earth comprised between the diameter of the shield and the future diameter of the tunnel.

In either case the function of the shield is not to pierce the soil, but to temporarily sustain the roof of the tunnel. The laborers are placed between the head of the shield and the front of the bore where they dig and cut out a space into which the shield advances. When the necessary space has been cut out the hydraulic jack is called into use. This is held in place against the wooden braces in

the finished part of the tunnel and forces the shield to advance into the new cut. In this manner the ground is always sustained by the metal cylinder of the shield. There are always a dozen metal rings behind the shield and when the latter is moved forward the last ring is dismounted and set up next to the shield. The masonry is laid as soon as the shield is moved forward and the ring supporting it is not moved for five or six days in order to give the cement time to set.

Unfortunately it is not always possible to make use of the shield, as, for example, in cutting around curves; and at several points also the contractors have not been able to get the shield delivered in time, and as the loss of even a day was not to be considered they prosecuted the work in the old fashioned way. In this case an advance passage is opened and this is thoroughly boarded and braced with wood and no more of the tunnel is opened until this part is completely finished.

The contractor for the ninth part of this line has devised a bold and novel method of construction which has given excellent results and permits the work to be carried on very rapidly.

He commences by establishing an advance passage of 2 m. in height along the line of the road. Then he constructs a second passage above the former one separated from it by 40 cm. of ground, and the roof is completely constructed in this passage using the upper ground to support the arch. Every ten meters he makes openings in the ground separating the two passages so as to carry away all the excavated material in the lower passage. This lower passage also performs another important service after the masonry has been set and dried. It is then necessary to remove the earth between the two passages and this is done by throwing it down in the lower passage and in falling the whole tunnel is cleared from side to side between the abutment piers. The later are built of concrete 2 meters thick and 3 meters long with a column of earth between parts under construction. The work progresses very rapidly, the passages advancing about 4 meters a day; although it should be added that the work is carried on for 22 out of 24 hours each day.

There is no serious difficulty in making the excavations as the sub-soil of Paris is composed of chalky clays, crystalized carbonates and loam. Occasionally a wall of ancient construction is encountered and there is also considerable filled in ground.

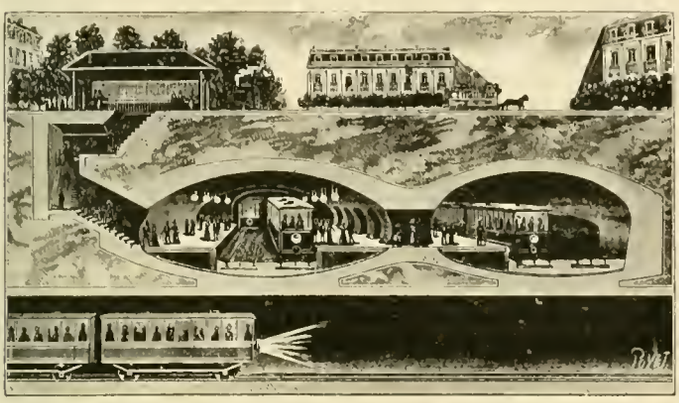
The Metropolitan has upset the system of sewerage in the streets in which it runs, notably in the Rue de Rivoli where the sewer had to be dug out and was replaced by two smaller ones situated one on each side of the tunnel.

There are two types of stations. Where they are sufficiently beneath the surface of the ground they have been built of masonry as in the case of the Place de la Nation. This work requires great prudence. In some cases there has been danger of meeting with bodies of water which would break in upon the station yard. It has then been necessary to build up as close to the side of the rail as possible. In this case the stations have been built with iron beams which sustain the embankments. To do this the foundations of the embankment are first constructed in underground passages opened for this purpose. When these are finished the soil from the street is removed and beams are put in place 14 meters apart which rest on the stone pillars. The embankment is at once built up and the interior soil is removed by means of the vertical pits.

The station at the Bastile is an uncovered one and its construction constituted a very interesting engineering problem on account of the presence of the Saint Martin canal.

One trouble which has been met with from the start is the removal of the excavated earth. From some points tramway lines have been used to distribute it to the suburbs. In other cases lateral passages have been tunnelled for conveying it to the Seine, and when these facilities failed horses and wagons were employed.

The ventilation has not been procured in any special manner and in the completed tunnels no ventilating apparatus will be used. The air will not be vitiated by gas from locomotives as in the ordinary railroad tunnel. The stations and all the underground lines will be brilliantly illuminated by means of electricity



DOUBLE STATION AT THE PLACE DE L'ETOILE.

STATION AT THE PLACE DU PALAIS-ROYAL.

NASHVILLE (TENN.) RY.

The Nashville Railway Co., a new corporation, has been organized at Nashville, Tenn., and has acquired the property of the Nashville Street Railway Co. (46.9 miles), the Nashville & Suburban Railway Co. (7.5 miles) and the Citizens' Rapid Transit Co. (10 miles), and consolidated the three roads under one management. The parties controlling the new company also own and control the Cumberland Electric Light & Power Co.

The officers of the Nashville Ry. are: Frank S. Hambleton, of Baltimore, president; E. C. Lewis, Nashville, vice-president; E. G Connette, general manager; N. P. Yeatman, secretary and auditor; A. H. Robinson, treasurer; Richard Emory, superintendent and engineer.

A NEW CAR HOUSE FOR MILWAUKEE.

The Milwaukee Electric Railway & Light Co. is negotiating for the purchase of the St. Gall's church property which comprises a tract of land 320 ft. by 200 ft. in the heart of the city. Mr. John I. Beggs, manager of the company, states that if this property can be secured there will be built there the finest street car station in the country, at a cost of about $500,000. The building is to hold 100 or more of the company's cars. The building will be four or five stories high and will contain the general offices of the company, an assembly room for employes with a complete gymnasium, baths and library, and an elevator for lifting cars to the upper floors, where light repairs will be done.

The purchase of the property is not yet concluded, and the work on the building will not commence for some time.

CAR TRUST AGAIN.

While it is impossible to get anyone to actually father the statement, there is a lively rumor that the car builders' trust is once more forming, this time under more favorable conditions. Several of the larger builders have again expressed willingness to go into a combination if the Brill Co. is placed at the head of affairs. The truck builders are not included in the deal.

PERSONAL.

MR. MAX BERG, of the Ohio Brass Co., has been spending two weeks vacation with friends and relatives in Chicago.

MR. MITCHELL JEANNES has been appointed general manager of the Fox River Electric Ry., Green Bay, Wis.

MR. J. L. YOUNG, JR., has been appointed auditor of the Richmond (Va.) Traction Co., succeeding Mr. J. A. Cook, who resigned last month.

MR. C. C. LEWIS, formerly with the Pennsylvania Steel Co., has become connected with the International Traction Co., of Buffalo, as engineer of ways.

MR. JOHN R. GRAHAM, president of the Quincy & Boston Street Ry., will be manager of the Quincy division of the lines of the Massachusetts Electric Cos.

MR. C. W. MOFFETT has taken the management of the Boston office of the Heine Safety Boiler Co., succeeding Mr. Russell Walker, who recently resigned.

MR. THOMAS WILSON, lately engineer in charge of extensions recently built at Harrisburg, Pa., has been appointed assistant engineer for the Buffalo Traction Co.

L. B. FRENCH, of Detroit, Mich., advises us that he has in course of construction a line from Toledo to Adrian, a distance of 30 miles, and is in the market for material.

MR. W. A. HELLER, who recently resigned as superintendent of the Lewiston & Youngstown road, has been appointed superintendent of the Niagara Gorge Railroad Co.

MR. J. A. MAXWELL has been appointed master mechanic of the Troy City Railway Co.; he recently resigned as superintendent of motive power of the Cortland (N. Y.) & Homer Traction Co.

MR. ELWIN C. FOSTER, general manager of the Lynn & Boston Railroad Co., will be in charge of the North Shore properties (from Boston to the Merrimac Valley) of the Massachusetts Electric Cos.

MR. S. H. BENNETT, who recently resigned as secretary and treasurer of the Atlanta (Ga.) Railway Co. after three years service, was presented with a diamond ring by the employes of the company just before leaving.

MR. FRED H. FITCH, general manager of the Sioux City Traction Co., was on June 17th chosen a director and vice-president of the Electrical Installation Co., of Chicago, in which he is financially interested.

MR. F. L. HART, of Baltimore, who has been the engineer in charge of the re-equipment of the Anacostia road of Washington has been appointed general superintendent of the Washington railways recently consolidated.

MR. J. L. WEEKS, who has for several years been western manager and special representative of the American Steam Gauge Co. has been chosen treasurer and general manager of the company to succeed Mr. R. G. Harmon, resigned.

MR. O. T. CROSBY, who was one of the leading factors in effecting the Washington consolidation, has temporarily severed official connection with these properties and is now in Europe with his family seeking a much needed rest.

HON. ALEXANDER B. BRUCE, of Lawrence, Mass., has been elected president of the Lowell, Lawrence & Haverhill Street Railway Co., to succeed Col. G. H. Campbell, who has held the position for several years, but has been forced to retire on account of ill health.

MR. CHARLES F. THOMPSON, secretary, treasurer and director of the Lane & Bodley Co., of Cincinnati, on July 1st resigned these positions, thus severing connections with the company with which he has been identified for 35 years.

MR. F. G. LOTT succeeds Mr. W. A. Heller as superintendent of the Lewiston & Youngstown Frontier Railroad Co., Lewiston, N. Y. Mr. Lott was formerly with the Buffalo & Niagara Falls Electric Light & Power Co. in a similar capacity.

MR. SAMUEL G. BOYLE has been elected secretary and treasurer of the Louisville Railway Co. to succeed Mr. James Pettus, who retires on account of ill health. Mr. Boyle is a stockholder and is thoroughly versed in the affairs of the company.

MR. A. F. EDWARDS, formerly general superintendent of the Yonkers Railroad Co., has been chosen general manager of the Virginia Traction Co., and also of the lighting company, of Petersburg, Va.; these two properties will soon be consolidated.

MR. HENRY C. MOORE, president of the Trenton Street Railway Co., has been elected vice-president of the United Power & Transportation Co. controlling about 15 street railways in Philadelphia and near-by territory; he will continue as president of the Trenton company.

SUPT. H. E. REED, of the Gloucester (Mass.) Street Ry., has resigned as such to accept a position in western Pennsylvania, and has been succeeded by Mr. H. C. Pedric, who has been for several weeks assisting the superintendent in order to familiarize himself with his new duties.

MR. H. S. COOPER has resigned as superintendent of the Schenectady (N. Y.) Railway Co. For the last 15 years Mr. Cooper has been engaged in electric railway and lighting work, and since 1893 has been with the Schenectady road which he brought from a receivership to a good paying basis.

MR. AMOS F. BREED, president of the Massachusetts Electric Cos., was accidentally wounded by a stray bullet on July 4th, and quite seriously injured. He is doing as well as could be expected and will recover if no unexpected complications occur. His friends while deeply regretting the accident, are thankful that it was no worse.

PRESIDENT ROSSITER of the Brooklyn Heights Railroad Co. announced under date of June 17th that the railroad and property of the Prospect Park & Coney Island Railroad Co. had been leased, possession being given at midnight of the 17th. Mr. Ira A. McCormack was appointed general superintendent in charge of operation and Mr. J. C. Brackenridge chief engineer in charge of maintenance of way, buildings and construction.

MR. GEO. H. SCRANTON, superintendent of transportation of the Columbus (O.) Street Railway Co., tendered his resignation as such last month, and Mr. George Wishner, foreman of the Oak St. line, has been appointed to fill the place temporarily. Mr. Scranton will leave on September 20th for Havana, where he will superintend the construction of an extensive street railway system in that city which is to be built by a company of Eastern capitalists.

MR. S. F. PEARSON, chief engineer of the Metropolitan Street Ry., of New York, is now in Sas Paulo, Brazil, in which city he and associates have franchises for street railways and lighting systems. Mr. Pearson expects to return next month. Mr. R. C. Brown accompanies Mr. Pearson and will have charge of the construction of the lines; Mr. Brown is well known in this country from his connection with the Widener-Elkins-Whitney syndicate as engineer.

MR. JOHN T. BRAMHALL, of the passenger department of the Monon, recently published an interesting article in the Western Electrician in which he reviews the power generating plants of previous international expositions in relation to that of the Paris exposition of 1900. Nearly three years ago Mr. Bramhall made the suggestion to the directors of the Paris exposition to establish a central power plant at the coal mines of DuNord and Pas-de-

Calais, which are within 100 miles of Paris, and by establishing a long distance electrical transmission plant for the power requirements of the exposition, not only to effect considerable economy and saving of space for exhibitors, but to keep pace with the advance in engineering which has marked every successive international exposition. The Corliss engine of the Centennial exhibition in Philadelphia, 1876, was in reality the first world's fair power plant; the electrical power plant of the Chicago exposition in 1893 marked another great advance in the engineering art, and it remains to be seen what progress in engineering skill shall mark the Paris exposition of 1900. We understand that Mr. Bramhall proposes to follow up his suggestion by making the proposed plant applicable to the street railway system of Paris.

OBITUARY.

MR. CHARLES B. THURSTON, of Jersey City, N. J., died at his home in that city June 14th. Mr. Thurston was born in New York, April 2, 1832, and all his life has been identified with transportation interests. The Jersey City & Bergen Railroad Co., of which Mr. Thurston was president, joined the American Street Railway Association in 1882 at its third meeting and the following year Mr. Thurston was chairman of a committee that reported upon the diseases of car horses, then a vital question with street railway men. Mr. Thurston continued as president of the Jersey City & Bergen until it merged in the Consolidated Traction Co. in 1893. He was also a special agent of the Pennsylvania R.R., president of the Port Richmond & Bergen Point Ferry Co., the Millstone & New Brunswick Railroad Co., the Fayetteville Water, Light & Power Co., of North Carolina, and was a director in a number of other corporations.

MR. W. J. BURNS, treasurer and general manager of the West End Traction Co., of Pittsburg, died in Paris while on a pleasure trip. Mr. Burns was most highly esteemed by all the employes of his company and they are preparing to send an appropriate floral tribute when the remains arrive in this country. Mr. Burns was born in Allegheny about 60 years ago, and has been active in business since a young man. Twenty-five years ago he entered the transportation field becoming interested in omnibus lines, then horse cars and later electric railways.

MR. EDWIN JACOBY, president and treasurer of the Toledo, Bowling Green & Fremont Electric Railway Co., Toledo, O., died at his home in that city on July 5th after an illness of two weeks. Mr. Jacoby was 65 years of age, and was born in Monroe county, Pennsylvania. He came to Toledo during the troubled years of the war, and immediately enlisted and went to the front. After the war, he located in Cleveland with the Fairchilds Scale Co., and there he was married to Miss Isabella Ames, of that city. He returned to Toledo in 1869, and entered the lumber business in the firm of A. Andrews & Co., of which he was the company. In 1871 he established a lumber business for himself and under his own name, and this he maintained up to the time of his death. He was also one of the incorporators of the Holcomb National Bank, and was its vice-president. He belonged to no societies, but counted all who knew him as brothers and friends. He leaves to mourn him his loving wife and two sons, Walter E. and Harvey F.

Shortly before Mr. Jacoby's death, Mr. W. B. Brockway had been placed in temporary charge of the road pending President Jacoby's illness.

ELECTIONS.

THE NORTHERN OHIO TRACTION CO., which is a consolidation of the Akron Traction & Illuminating Co. and the Akron, Bedford & Cleveland Railroad Co., has chosen officers as follows: President, H. A. Everett; vice-president, Will Christy; treasurer, J. R. Nutt; secretary, C. S. Moore; general manager, L. S. Beilstein.

THE MADISON (WIS.) LIGHT & RAILWAY CO., which recently succeeded to the Madison Street Railway Co., last month elected officers as follows: President, John S. Ward, of Chicago; secretary, treasurer and general manager, Charles R. Johnson, jr., of Madison; vice-president, J. A. H. Watson, of Chicago; directors, John S. Ward, J. A. H. Watson, C. R. Johnson, jr., and Benjamin F. Wells.

THE METROPOLITAN STREET RAILWAY CO., of Kansas City, Mo., chose directors on June 15th, re electing all of the surviving members of the old board and C. W. Armour, of Chicago, to succeed the late S. B. Armour. The director chose officers as follows: President, Walter H. Holmes; vice-president, L. E. James; general manager, Conway F. Holmes; treasurer, W. E. Kirkpatrick, of Chicago. It is announced that W. A. Satterlee will probably be appointed assistant general manager.

THE WASHINGTON (D. C.) TRACTION & ELECTRIC CO. has now completed the purchase of the Metropolitan Railroad Co. of that city and the stock of the old company, amounting to 18,000 shares, has been placed in the name of the new holding company with the exception of six shares, one each of which is made out to the gentlemen forming the board of directors. These are Mr. Kountze, the New York banker, C. A. Lieb, O. T. Crosby, F. C. Stevens, Nathaniel Wilson and Arthur P. Gorman. These men will probably also be chosen directors of all the other companies in the consolidation as well as of the holding company.

UNION TRACTION CO. OF INDIANA.

We are indebted to Mr. Charles L. Henry, of Anderson, Ind., for the details of a recent consolidation of electric railways in the gas belt of Indiana.

The Union Traction Co., of Anderson, first bought all the property of the Marion City Railway Co. The Muncie, Anderson & Indianapolis Street Railroad Co. was organized and bought all the property of the Citizens' Street Railway Co., of Muncie. Next the Union Traction and the M., A. & I. were consolidated under the name of the Union Traction Co., of Indiana.

This company now owns the Anderson property, the Marion property, the Gas City property, the Muncie property, the Elwood property and the intervening interurban lines from Anderson to Marion and the line from Alexandria to Elwood now in operation. It is also ready to commence the construction of a line from Anderson to Muncie and one from Anderson to Indianapolis, for both of which it now has complete rights of way. This will constitute the property of the company when completed, with the probable addition of five miles of railway from Daleville (midway between Anderson and Muncie) south to Middletown, and another five-mile addition running east from Frankton to and intersecting with our present line from Anderson to Alexandria. This will give a total of 160 miles of road which will all be operated from one central station to be erected in Anderson. The three-phase system will be used with rotary transformers at Muncie, Daleville, Marion, Alexandria, Elwood and Oaklandon, the latter place being a small village about 12 miles out from Indianapolis. The system will connect with the Indianapolis Street Ry. lines at the State Fair Grounds north of Indianapolis and cars will run into the city over the lines of that company.

The central offices of the company will be at Anderson. The capital stock of the company is $4,000,000.

The directors are Philip Matter, of Marion, president; Charles L. Henry, of Anderson, secretary and general manager; George F. McCulloch, of Muncie, treasurer; William C. Sampson, of Muncie; James A. Van Osdol, of Anderson; Randal Morgan, of Philadelphia, and Frederick Strauss, of New York.

The company has issued $5,000,000 of 5 per cent bonds dated July 1, 1899, due in 20 years.

RIGHT OF WAY OF MILL CREEK VALLEY ROAD.

The Mill Creek Street Railway Co., of Cincinnati, has recently been engaged in litigation with the village of Carthage concerning its right of way. The Court of Common Pleas some time since held that the street railway company had no rights in the village streets, the Circuit Court on July 1st reversed this decision and enjoined the residents in Mill Creek Valley from removing the tracks. The company began operating cars at midnight, July 1st, and will rebuild the tracks which had been torn up, and extend to Glendale

HALF FARES.

The City & Suburban Ry., Washington, D. C., has voluntarily increased the wages of its conductors and motormen from $1.60 to $2 per day.

The first electric car to be run in Portsmouth, N. H., made its trial trip on June 26th. The new road is about ready to be opened to the public.

Lightning struck an electric car on the East Avenue line in Kalamazoo, Mich., May 31st. Ten passengers were badly shocked but none were injured seriously.

Memorial Day tested to the utmost the capacity of the Syracuse (N. Y.) street car companies. It is estimated that between 60,000 and 80,000 people were carried.

The Oakland (Cal.) Transit Co. has gone back to the system of giving transfers for any day and all day, so that passengers can ride all over town for one fare.

The motorman of a car which unfortunately killed a man at Winfield, L. I., was arrested by the local police and locked up all night in the same cell with the remains of deceased.

The Musicians' Protective Association of Denver, is protesting wildly against the proposal of the Denver City Tramway Co. to hire a Chicago band to furnish music in the parks.

A Chicago justice decided in favor of the plaintiff a suit for 5 cents damages for breach of contract, brought against the Lake Street Elevated because a seat was not provided.

An annual picnic was held on June 30th by the street railway employees of Pittsburg, Pa., at Kennywood Park. A program was given which included all kind of sports and amusements.

July 1st the wages of the employes of the Rochester (N. Y.) Railway Co. were restored to the scale in vogue prior to March, 1896, when the hard times made a cut of 10 per cent necessary.

June 14th the Eighth street line of the Cincinnati Street Railway Co., was blocked for some hours by the falling of overhead wires; considerable damage was done to poles, light wires, lamps, etc.

The Collins Park & Belt Railroad Co., Atlanta, Ga., has asked for franchises for extensions which Pres. J. C. Simmons states will involve the outlay of $2,000,000, all of which has been secured.

The employes of the Chillicothe (O.) Electric Co., are to be regaled with free soda water during the hot weather. The company is having a fountain erected expressly for the use of the hot and dusty employes.

The rumor of a consolidation of the Metropolitan, the Third Avenue and the Manhattan Elevated roads of New York and the Brooklyn Rapid Transit is discredited in New York because there has been no reflection of any such deal in the stock market.

On Sunday, June 4th, the Knoxville (Tenn.) Traction Co. carried 24,600 passengers. This is the biggest day any street railway company in Knoxville has ever had and the public is giving Gen. Mgr. C. C. Howell credit for the great popularity of the system.

The breaking of an overhead trolley wire on the Jamaica Ave. line of the Brooklyn City Railway Co. caused a panic among the passengers, who commenced jumping from the car. In the rush to escape from the car five passengers were hurt by falling from the steps.

In return for furnishing it with free current for charging the accumulators for its police and fire departments, the city of Oshkosh has granted a franchise to the Citizens' Traction Co., of that place, to supply patrons with light, heat and power for a period of 35 years.

The Supreme Court of Ohio has affirmed a verdict rendered in favor of Lida M. Hunter against the Cleveland & Elyria Railroad Co. for $10,000 damages for the permanent injury of one leg, suffered in a collision of one of that company's electric cars with the plaintiff's buggy.

The quarterly report of the Brooklyn Union Elevated Railroad Co. for the three months ending Mar. 31, 1899, shows: Gross earnings, $511,764; operating expenses, $299,571; net earnings, 212,192; other income, $21,485; fixed charges, 104,912; net income, $107,495; corresponding quarter last year, $61,305.

The street railway lines of the Milwaukee Electric Railway & Light Co. have opened up a large territory for trolley excursions of which Milwaukee is the center. A universal system of transfers is in vogue within the city limits and the lines have been lately spread out to the surrounding suburbs north, south and west of the city.

The Washington (Ind.) Street Railway Co. opened its new park last month and a free entertainment was given by the Lyons Comedy Co. which attracted large crowds. A theater has been erected in the park with a large seating capacity, and free entertainments will be given during the summer on Tuesday, Thursday and Saturday evenings.

Three electric railway power plants are now in course of construction in New York City whose aggregate capacity will reach the enormous total of 200,000 h. p. The Metropolitan plant will have a capacity of 70,000 h. p., the Third Avenue will have 66,000 h. p. and that of the Manhattan Elevated, though not yet announced, will bring the figures up to about the total mentioned.

The city of Los Angeles, Cal., has less than 100 policemen and the Los Angeles Railway Co. has accordingly issued instructions to carry free only policemen who have badges with a number less than 100 and collect full fare from those having badges with a higher number. There are a number of persons wearing police badges who are not connected with that department.

It has been officially announced by Mr. George Gould, president of the Manhattan Elevated of New York City, that the corporation is well advanced in its plans for changing its motive power from steam to electricity. The system to be employed has not been decided upon further than the fact that it is to be a third rail system. A contract for 9,000 tons of rails for this purpose has already been closed.

The State Excise Board of Ohio, consisting of the attorney general, the state auditor and the state treasurer, have received returns from some of the street railways of the state, which show a large increase in receipts over the previous year. The Columbus Street Railway Co. showed gross earnings amounting to $706,000, an increase of $70,000 over the previous year, and the Cincinnati Street Ry. gross receipts of $2,300,000, nearly $300,000 more than last year.

A war is being waged in Camden, N. J., between the city council and the Camden & Suburban Ry. The trouble arose out of the company's attempt to lay a double track on Haddon Ave. in spite of the council's prohibition to do so unless the company paved Haddon Ave. from curb to curb. President Scull, of the railway company, contends that the company has the right to lay the tracks as the privilege was given three years ago to the West Jersey Traction Co., which has since consolidated with the present company. General Manager Harrington was arrested with a number of laborers on the work, and the question will be settled in the courts.

LATEST FROM DETROIT.

The street railways of Detroit issued orders to trainmen, July 13th, that on and after 6 a. m., July 14th, 3-cent fares were to be accepted.

Governor Pingree on July 13th issued the following proclamation:

"To the People of the City of Detroit: The fight for 3-cent fares which has been going on for ten years is substantially won. If the plans proposed by the Municipal railway are agreed to by the common council of this city, within ten days every citizen of Detroit can ride upon any street-car line by the payment of 3 cents, and at the same time receive a transfer good upon any other line. A person paying 3 cents upon a car of the Detroit railway can receive a transfer for any line of the Citizens' company or the Fort Wayne & Belle Isle railway, and the same will be true of any one purchasing a ticket upon any car of the Citizens' railway or of the Fort Wayne & Belle Isle railway.

"Unless the plan proposed in the working ordinance of the Municipal railway, which provides for a straight 3-cent fare, is carried out, there will be no hope for the people of Detroit to secure the 3-cent rate at any time within the next ten or fifteen years, and perhaps at no time in the future. The opposition to this plan does not come from the tens of thousands of workingmen and workingwomen, who cannot afford to ride in carriages, and many of them who cannot afford to purchase bicycles, but it comes from those who are well able to pay any price that may be demanded by the street-railway trust of the United States, which is closing its grasp upon all of the large cities of the country and hopes to secure Detroit as one of its milking grounds.

"The opposition further comes from a so-called committee of citizens who have raised a large sum of money to retain lawyers to rummage through musty records and ancient charters to see if some excuse can be given for preventing the people from having that which by right and honesty and good government they are entitled to.

"The opposition further comes from scheming and selfish politicians, who hope by delay and childish excuses to deceive the people and postpone the payment of 3-cent fares until a few more elections, to the end that the issue may be kept alive and they may fatten upon it, instead of having it settled and buried, in order that new issues and new plans for the advancement and progress of the city may be undertaken.

"You have stood with me in all these fights, and if you continue to stand with me, and not be deceived by the tongue of slander and the hypocritical claims of pretended reformers, who have slept while you have been fighting, and who expect to fight while you are sleeping, we will win a victory that will make our beloved city famous throughout the world.

"My object in issuing this circular is to call your attention to the conspiracy which has been formed against you and to warn you that the ancient enemy that has followed your tracks and mine in years past has received new life and new blood, has purchased new daggers and armed itself with new bludgeons, in order that the act of assassination may be performed with keener thrust and with stronger blow.

"HAZEN S. PINGREE."

Those who enjoy remarking coincidences in dates will not fail to observe that the Bastille fell on July 14th.

The New Haven Car Register Co. has just closed a contract with the Third Avenue road, of New York, for several hundred registers; it also recently equipped the St. Joseph, Mo., road with registers.

The Simonds Manufacturing Co., Pittsburg, has patented and built a new device for making wire fence. Several of these machines are now in operation in connection with the regular business, turning out three-quarters of a mile of wire fence per day. This fence is especially adapted for the use of street railway companies for fencing right-of-ways and suburban roads. This company is the well-known gear and pinion maker of Pittsburg and has made extended improvements the past year. It has added a new patent department and increased the capacity one-third. It is now building a Bryan car dismounting machine which will take cars from the trucks and replace the motor in 22 minutes. A new gear cutting machine and a wheel truing machine have also been added. The company reports a shop full of orders.

MISSOURI STREET RAILWAY LAW.

A revision of the street railway laws of Missouri was passed by the legislature recently adjourned, the act being approved by the governor on June 19, 1899. This law, which takes effect at once may be briefly summarized as follows: Sec. 1 permits existing railroads which have acquired routes to lay their track notwithstanding the line may be within three streets of an existing road and Sec. 2 repeals the St. Louis street railroad act of 1860 in so far as it is inconsistent with this. Sec. 3 is the same as Sec. 1 but applies to cable roads. Sec 4 is similar to Sec. 2.

Sec. 5 authorizes the carrying of mails but not so as to impede or delay passengers and Sec. 6 requires trolley wires to be 22 ft. high and to be protected with guard wires. Sec. 7 requires a full stop of cars 20 ft. from a railroad crossing. Sec. 8 refers to bridges connecting Missouri with another state and Sec. 9 provides for the conditional sale of railroad property and retention of a lien by the seller until payment is complete. Sec. 10 requires such sales, etc., to be recorded by the Secretary of State, and Sec. 11 provides such contracts already existing may be recorded. Sec. 12 repeals previous laws as applying to these contracts.

Sec. 13 provides that five or more persons may form a street railway company, and Sec. 14 relates to the manner of securing right of way, the rates of fare, and acquiring or disposing of railway property. Sec. 15 makes Sec. 14 applicable to existing companies. Sec. 16 allows increase of capital stock or bonds by majority vote of stockholders and Sec. 17 allows issue of preferred stock by majority vote of stockholders.

In accordance with this law five street railways controlled by the Brown Bros. syndicate of New York have filed notices of increase of capital stock preparatory to their consolidation. These roads are the Lindell, the Union Depot, the Grand Avenue, the Central Traction and the St. Louis Traction.

The Lindell's capitalization is to be increased from $2,400,000 in stocks and $3,000,000 in bonds to $10,000,000 in stocks and $10,000,000 in bonds. This includes the Missouri system.

The Union Depot capitalization is now $4,000,000 in stock and $3,627,000 in bonds. It is to be increased to $10,000,000 in stock and $10,000,000 in bonds.

The capitalization of the Grand Avenue Railway Co. is now $500,000. It is to be increased to $10,000,000 in stock and $10,000,000 in bonds.

The capitalization of the Central Traction Co. is now $3,000,000. It is to be increased to $10,000,000 in stocks and $10,000,000 in bonds.

The capitalization of the St. Louis Traction Co. operating the Fourth St. cable line is $2,000. It is to be increased to $2,000,000 in stock and $2,000,000 in bonds.

STRIKE RIOTS IN LONDON, ONT.

The strike of the street railway employes in London, Ont., culminated in rioting on July 8th. The men having charge of the cars were stoned and forced to take their cars to the barn or abandon them. Several cars were derailed and almost completely wrecked. Finally the mayor read the riot act and called on the regular troops to disperse the mobs.

The company has long been anxious to come to a settlement with its former employes, but the men refuse to make public their grievances.

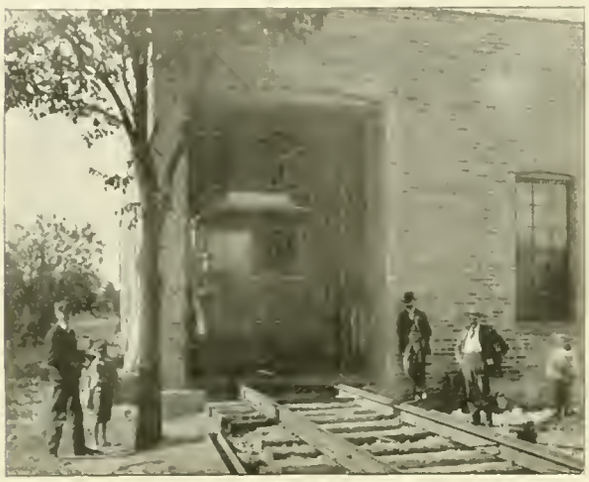
Hayes & Arthur, street railway supply agents of Cleveland, O., have moved to larger quarters in the Cuyahoga Building; they are extending their field, and are now carrying one of the most complete line of street railway supplies in the country. They report a very prosperous season.

The horse cars on the 28th and 29th St. crosstown line of the Metropolitan Street Railway Co., of New York, have been permanently retired and the compressed air cars which have been in experimental service for some time will be regularly introduced. These cars have been awaiting the completion of the compressed air plant at the West 23d St. car barn, which is said to be the largest in the country and which has been built at a cost of $500,000. Fourteen of these cars will be in regular service and six will be held in reserve for occasional trips over connecting routes.

HARVEY CHARGING STATION OF CHICAGO ELECTRIC TRACTION CO.

In the "Review" for May, page 333, was a brief description of the improvements the Chicago Traction Co. was then making. It was expected that the charging station at Harvey (158th St.) would be in operation by June 1st, but because of delays from various causes it was not completed until later and has been in regular operation since July 5th.

The accompanying illustrations show the exterior of the building,



EXTERIOR OF STATION.

the engine, and the basement with its elevator and trucks. The building is of brick, 26 x 70 ft., and divided longitudinally by a board partition having a space 10 ft. 6 in. wide for the car track. The other portion of the building is divided by a cross partition, one room containing the engine and generator, and the other the station battery. The engine is a 50-h. p. Nash gas engine and is belted to a 40-kw. Eddy generator. The generator, the station battery, the charging mains, and the electric elevator for shifting the car batteries are all connected in multiple and thrown in and out ac-

VIEW IN BASEMENT.

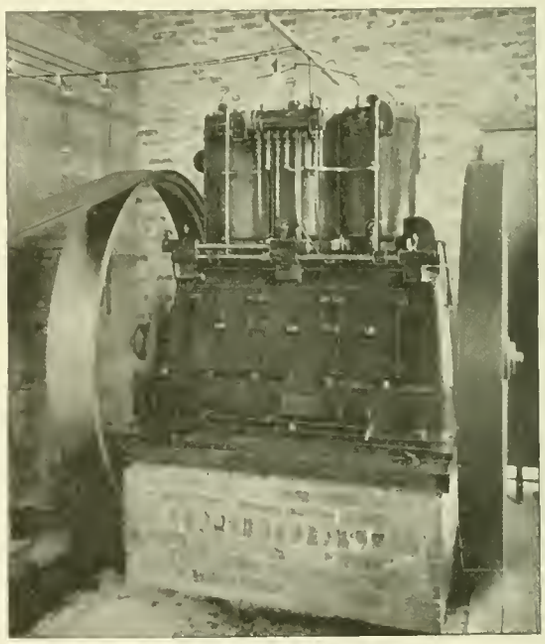
cording to the state of the several batteries as reflected in the station instruments.

The instruments comprise three Weston ammeters and one Weston voltmeter and, together with the necessary switches, are mounted on the partition between the engine room and battery room. The engine is run from 5 a. m. till 12:30 a. m. each day, and is reported as giving the best of satisfaction. There are 95 cells in the station battery; only 81 are used at one time, however.

In the basement, immediately under the car track overhead, is laid a track of light T-rails, 19-in. gage, on which two 4-wheeled cars run. Terminals for charging the car batteries are at either end of this track and in the center is a Sprague electric sidewalk elevator driven by a 30-h. p. motor. When a car reaches this terminus of the road it is stopped over the elevator, which, with one of the small cars upon it, is run up; having received the battery, the elevator is lowered and the small car pushed over to the charging terminals by hand. The track and trucks for handling the batteries in the basement are of the Hunt industrial railway type.

The Nash gas engine, which is made by the National Meter Co., of 84 and 86 Chambers St., New York, has proved that it can meet all the requirements of electric lighting service and numerous direct connected units have been installed for such work. For charging storage batteries or for electric power plants, the company builds a special three-cylinder engine. A 45-h. p. engine similar to the one illustrated but direct connected has been in use since September, 1898 by th Penobscot Central Railway Co., Bangor, Me. As experience in these plants shows that the gas engines are satisfactory, the company expects to install its engines in a number of similar ones at an early date.

The economy of the Nash engine is shown by efficiency tests made at the Stevens Institute of Technology in 1897. A 20-h. p. unit was used for generating electricity for a lighting circuit and the



50-H. P. NASH GAS ENGINE.

candle power of the electric lights was stated to be from 14 per cent to 121 per cent (depending on the age of the lamp) greater than the candle power of the gas used, had it been burned in an ordinary flat flame gas burner instead of the engine.

The engine in the Harvey station uses gasoline, the gasoline tank being in a small wooden building in the rear of the station. The engine here was installed by Mr. W. H. Patton, of the National Meter Co., and he has been in charge of the plant temporarily.

FATAL ACCIDENT AT PITTSBURG.

As the result of a street car collision on July 2d at Pittsburg, 2 people were killed, 5 were seriously injured and 10 more or less hurt. The accident happened on a steep grade near High Bridge, while the two cars in collision, which were heavily loaded with passengers, were returning from Kennywood Park.

There have been persistent rumors that a strike was imminent on the Brooklyn lines, but the opinion prevails that they are circulated with the object of affecting the Brooklyn traction stocks on the stock exchange.

DERAILED ON A CURVE.

A car of the United Railways & Electric Co., of Baltimore, Md., was derailed at the Baltimore & Ohio Bridge near Fort McHenry, on June 29th, causing slight injuries to 14 passengers. In front of the railroad bridge on Fort Ave. is a hill at the top of which the tracks spread slightly before entering the bridge. As the loaded car went up the hill it rocked considerably and as it struck the curve it jumped the track, crossing a space of about 20 ft. and striking a heavy iron girder of the bridge. The girder was bent and twisted and the front platform of the car and all the glass completely demolished. Traffic on the line was delayed an hour while the debris was being removed.

RAILWAY RIOT AT WAUKESHA.

On the morning of July 1st the town of Waukesha, Wis., awoke to an exciting battle between the citizens of the town and a construction crew of the Milwaukee Electric Ry. who were attempting to lay a double line of tracks on Broadway at 5:30 a. m. At this hour the vigorous ringing of the fire bells aroused the town and soon a large crowd congregated where the men were laying the double track which the city had enjoined them from putting down. At about 4:30 in the morning an injunction had been served upon the aldermen and city officials restraining them from interfering with the work of the railway company, but no injunction was served upon the chief of the fire department or upon any of the volunteer members, and when the alarm was rung they turned in and scattered the workmen with streams of cold water. One of the workmen was chased several blocks by a crowd with sticks and stones and three of his assailants were arrested. The general opinion is that the railway company will be eventually successful, but there is considerable disposition to fight shown among the crowd.

WASHOUTS ON STREET RAILWAY LINE.

A bad washout occurred on the line of the East Liverpool (O.) Street Railway Co. at Ralston's crossing, where a trestle formerly stood. On the evening of June 28th the motorman of an approaching car was told by a little boy that the ground was slipping out from under the culvert, and just as he stopped his car at this point about 40 ft. of earth slipped out from under the car and fell into the river. By morning a chasm was formed under the tracks fully 50 ft. wide and 40 ft. deep. The passengers were transferred to the opposite side of the chasm to other cars by walking across the tracks, which were suspended in midair.

Several other slips occurred along the line between East Liverpool and Wellsville. Gravel to the depth of 4 ft. was washed down upon the tracks for a distance of 70 ft. in one place, and before this could be cleared away another large quantity of gravel and dirt came down the hill again, burying the track.

The flood which caused these washouts also left the trestle at Wellsville in a very bad condition, as the trees and logs crushing against the structure threw it about 6 in. out of plumb near its center.

PERTH TRAMWAYS, WESTERN AUSTRALIA.

Messrs. J. G. White & Co., who as previously announced in the "Review" have the contract for designing and supervising the construction of the complete steam and electrical plant of the Perth Tramways, Ltd., Perth, Western Australia, have sent us data concerning the equipment to be installed there.

In the power house will be two 250-h. p. Babcock & Wilcox boilers with wrought headers; two 325-h. p. tandem compound engines built by the Robb Engineering Co., of Amherst, N. S.; two outside-packed single cylinders, double plunger, feed pumps, each capable of feeding the two boilers; two 225-kw. General Electric railway generators direct connected to the engines.

All fittings in high pressure steam piping are made of gun iron; all joints of piping are Van Stone joints. Each boiler is equipped with a No. 12½ Hayden & Derby double tube lifting injector. All valves in steam piping are Chapman's make. All piping will be covered with H. W. Johns fire-felt covering.

The steel roof trusses and purlins for car barn, were furnished by E. B. Gunnaer, of Jersey City, and the corrugated roof covering was furnished by the McCullough Iron Co., of Wilmington, Del.

The cars were made by the J. G. Brill Co., and were described and illustrated in the "Review" for May, page 356.

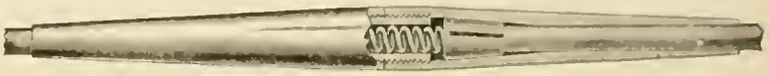
Two miles of the track are laid with 9 in. girder rails, made by the Pennsylvania Steel Co.; the T-rails for the rest of the track were imported from Belgium. The special work is of the hard center construction made by Wm. Wharton, Jr., & Co.

TROLLEY WIRE SPLICER.

Electric railways are not built in a day; however, the element of time is a great consideration and labor saving and quickly applied devices are given first recognition. An article to have high commercial utility in this rapid transit era must be as nearly automatic in action as possible, simple in design, complete in details and offered at an attractive price.

This combination is claimed for the Wood trolley wire splicer, illustrated herewith.

It is made of seamless drawn tubing, divided into two pieces of equal length with a proper tapering towards each outside end to prevent all jarring, and consequent sparking, of the passing trolley wheel. The tubing is amply threaded on joint ends for use with the brass center piece which holds the two splicer pieces firmly together. These splicer pieces are drawn with hole for the trolley



WOOD'S TROLLEY WIRE SPLICER.

wire, but towards the joint ends a tapering chamber is supplied to hold the steel cap, or thimble, which also is regularly narrowed down to automatically clamp itself when drawn outwards by the trolley wire, this reduction in diameter being permitted by slotting the steel cap for seven-eights of its length. The interior of the cap is well corrugated, and firmly engages the trolley wire ends the instant of insertion, and through the taper of cap and chamber, make it impossible to withdraw wires without first removing the steel cap. The electrical conductivity of the splicer is perfect, while the tensile strength is much in excess of the trolley wire.

Wood's trolley wire splicers are made for Nos. 0 and 00 trolley wires. They also are made with center for suspension from ½ and ⅝-in. hanger studs. This splicer is part of the large line of electric railway material made by the Central Union Brass Co., St. Louis. The Central Electric Co., Chicago, is selling agent and maintains an excellent stock.

THE FIRST ANNIVERSARY.

It is just a year since the Chicago, Milwaukee & St. Paul road inaugurated its celebrated Pioneer Limited passenger train service between Chicago, Milwaukee, St. Paul and Minneapolis. This service marked a new era in the railway world in the line of passenger accommodations. At a cost of a quarter of a million dollars that progressive company furnished the traveling public, in its Pioneer Limited train, comforts and facilities the best ever produced. This train has been described many times in newspapers and magazines, but should be seen and examined to be appreciated. In beauty of finish, richness and elegance of furnishing nothing equal to it has ever been attempted by any other road. The car builders were nearly a year in completing the Pioneer Limited trains (there are two—one leaving Chicago for the West and the other leaving the Twin Cities for the East every evening in the year) and they stand today a monument to the builder's art. No regular passenger train service in America is as well known as the Pioneer Limited. From the standpoint of passenger traffic the past twelve months have been the most successful in the history of the St. Paul road, made so very largely by the Pioneer Limited. The patronage of this service is a striking illustration of the fact that the public appreciates a good thing.

The Terre Haute (Ind.) Electric Co., which bought the street railway in that city, has increased wages from 14 cents to 15 cents per hour.

ECHOES FROM THE TRADE

THE JOSEPH DIXON CRUCIBLE CO. again enlightens the public on the history of graphite and lead pencils in "Graphite" for July, Vol. 1, No. 8.

THE WAGENHALS MANUFACTURING CO., Cincinnati, O., has just filled an order from the Cape Town (S. A.) Tramways for two of its slow feed controller handles.

J. G. WHITE & CO. have been appointed consulting engineers for the Elizabeth Street Railway Co. and the Elizabeth City Horse Railroad Co. The work to be done includes about eight miles of track and overhead work together with cars, trucks and equipments.

THE CREAGHEAD ENGINEERING CO., Cincinnati, is building the overhead work for the Dayton (O.), Springfield & Urbana Electric Ry., about 25 miles, and for the Dayton (O.) & Xenia Traction Co., about 20 miles; it also has several other important contracts in hand.

THE GARTON-DANIELS ELECTRIC CO., of Keokuk, Ia., has, since Jan. 1, 1899 shipped its lighting arresters into every state in the Union and also made over 50 shipments abroad. The company advises us that the sales of these devices for the first half of 1899 equal the sales of any preceding year.

THE ST. LOUIS CAR CO. has received an order from the Chicago City Ry. for 60 vestibuled closed cars exactly similar to those recently built for that road by the Stephenson Co. The cars are to be mounted on Moore trucks, which the St. Louis Car Co. will build, the Chicago City furnishing the castings.

THE CENTRAL ELECTRIC CO., Chicago, carries a large line of the favorably-known "Bound Brook" graphite bushings which are reported as being most highly recommended by all railway men who have used them. A bushing is a bearing, and just as friction in the bearings is reduced the earnings are increased.

THE H. W. JOHNS MANUFACTURING CO. has placed its western business in charge of the Manville Covering Co., 173 Randolph St., Chicago, and H. A. Reeves, who has so long represented the Johns company, has sole charge of the railway department. Mr. Reeves is prepared to fill orders promptly from the Chicago stock.

THE BROWNELL CAR CO., St. Louis, has nearly completed an order of 20 cars for the Metropolitan of Kansas City, and has just received a second order from the same company for 50 more. The many friends of Mr. Brownell will be greatly pleased to learn that he is steadily bringing the company's affairs into good condition.

THE CONSOLIDATED TRACTION CO., of Pittsburg, Pa., has recently received 40 new summer cars, 20 of which are used on the Manchester Division and the remainder on the Second Ave. Division. These cars were built at the Laclede works at St. Louis, are 36 ft. in length, and are equipped with storm protectors of the latest design.

THE BULLOCK ELECTRIC MANUFACTURING CO., of Cincinnati, has sent out a handsome card calendar for July with the great days of last July marked in a conspicuous manner and in the border a list of the regiments participating in the battles of San Juan Hill, El Caney and Santiago, and the warships most prominent in the naval fight of July 3d.

THE ELECTRIC STORAGE BATTERY CO., of Philadelphia, on June 14th secured an interlocutory order of injunction against the Quincy & Boston Street Ry. requiring it to refrain from using the Hatch storage battery installed at its South Braintree power house from and after August 1st. It is claimed the Hatch battery infringes Brush patents held by the plaintiff company.

THE PITTSBURG OIL CO., 133-5 W. Harrison St., Chicago, is the maker of "Imperial" boiler compounds and greases and "Premium Franklin" lubricating oils. The motor greases are highly recommended for either summer or winter use and its lubricating oils are well and favorably known. The "Imperial" boiler compound is prepared either as a liquid or as a powder, to suit customers.

MESSRS. SALCEDO & CO., of Gomez Palacio, Mexico, advise us that they are going to build an electric railway between Lerdo, in the state of Durango, and Torreon, in the state of Coahuila, a distance of about 10 miles, and request that the makers of electrical railway equipment will send them catalogs. They would also like to enter into correspondence with engineers who can advise them as to all details.

A. L. IDE & SONS, of Springfield, Ill., makers of the well-known "Ideal" engine, have recently issued a handsomely illustrated catalog of their automatic cut-off engines and special appliances. Among the latter are throttle valves, steam separators, reducing motions, power transmitters and belt tighteners. In addition the catalog contains descriptions of some of the principal details, methods of lubrication, etc.

THE CHARLES MUNSON BELTING CO., of Chicago, which was recently organized, announces that it is now in a position to supply all its patrons with the best belting in the market. For 33 years the Munson belting has had a very high reputation among American makers and the company assures the trade that the same careful workmanship and high grade of leather will always be found in its goods.

THE BETHLEHEM STEEL CO. on June 26th formally took over all the property, etc., of the Bethlehem Iron Co. under a lease. The officers of the Bethlehem Steel Co. are: Robert P. Linderman, president; Edward M. McIlvain, vice-president; Abraham S. Schropp, secretary; C. O. Brunner, treasurer; R. W. Davenport, general superintendent; Owen F. Leibert, chief engineer; Charles P. Coleman, purchasing agent.

WILSON & CO. will be the name of the new concern succeeding to the business of Wilson, Thomson & Co., the members of the latter firm having dissolved partnership by mutual consent, Mr. Thomson retiring. All obligations of the old firm have been assumed by Wilson & Co. This company makes the Wilson patent trolley pole catcher, and is sole agent for the United States and Canada for the Frank Ridlow Co., of Boston.

THE STAR LUBRICATING OIL CO., of Cleveland, O., is the maker of high grade lubricants for all purposes, including oils, gear, curve and motor greases and belt dressings. Besides lubricants, the company handles the "Excelsior" boiler compounds and has had great success in this line. The compounds are prepared after making an analysis of the boiler water used; this analysis is made without extra charge. The company will send samples free on application.

THE FALK CO., of Milwaukee, as announced in our June issue, last month suffered the loss of its blacksmith and special work shops by fire. The company was at that time building extensive additions to its plant and will be in position to care for all orders promptly. The new buildings now in course of erection on an eight-acre lot near the old plant comprise a machine shop 100 x 200 ft., a foundry 100 x 200 ft., a power house 40 x 60 ft. and an office building 40 x 60 ft.

THE WESTERN ELECTRIC CO., Chicago, has recently issued two new circulars; Bulletin No. 104 describes the "S. K. C." alternating current lightning arrester, and Bulletin No. 7002 is descriptive of arc lamps and their manufacture. Among late orders and contracts taken by the company are for the equipment of the building of Fortune Bros., 225 Des Plaines St., Chicago; for wiring 5,000 lights in the Williamson Bldg., Chicago; two 100-light W. E. arc machines and 220 W. E. open arc lamps for the city of Winnipeg, Manitoba.

THE JOYCE-CRIDLAND CO., the well-known maker of jacks of Dayton, O., reports a very good trade among the street railways. This company makes a specialty of jacks suitable for railway work both in car houses and on the track. It claims that its No. 176 jack for track work has many advantages over others on the market. This jack has a rise of ¼ in. for each stroke of the lever; the capacity is 5 tons. A special feature is that the lifting toe is at right angles to the lever so that when placed under a rail the lever lies lengthwise of the track instead of crosswise of it.

THE MILLER-KNOBLOCK CO., of South Bend, Ind., has recently completed a sprinkling car for the St. Charles Railroad Co., of New Orleans, in which city there is an ordinance requiring the street car companies to sprinkle the streets through which their cars run. This sprinkler is of the latest improved type built by the Miller-Knoblock Co. and it will carry 2,500 gallons of water. It will also sprinkle from either end of the car, or, if desired, from both ends at once. The railway company announces that the new sprinkler will be put into operation immediately upon its arrival in the city.

THE NORTHERN PACIFIC RY. has recently completed a new branch line from Spokane to Lewiston, the chief city of northern Idaho, situated at the junction of the Snake and Clearwater Rivers. From this point the Northern Pacific is rapidly building two other branches directly into the heart of the agricultural and mining districts. This section is known as the Buffalo Hump country, which has been recently found to be very rich in mineral and agricultural products, and the Northern Pacific has just published an interesting folder describing the Hump mining regions to which their new extensions are the only railway connections.

ELMER P. MORRIS, 15 Cortlandt St., New York, advises us that Henry L. Prather, New England Bldg., Cleveland, and the Miller Electrical Maintenance Co., Pittsburg, have been appointed agents for his material. The first of the new one-piece Morris bonds were turned out the first week in July. Business is reported as very good in wire, iron poles, brackets, car wheels, etc., shipments having been made to Genoa, Italy; England, Africa, Cuba, South America and Trinidad during June. On July 10th all the business assets and liabilities of Mr. Morris were transferred to the Morris Electric Co., of which Mr. Morris is treasurer.

THE WESTERN ELECTRICAL SUPPLY CO., of St. Louis, states that its street railway department has been doing a most gratifying business. It is especially pleased with the excellent sales of the Kalamazoo trolley wheel, for which it is general agent. It has sold this wheel to nearly all the roads throughout the South and West and has yet to find where it has not given most satisfactory service and done all that was claimed. This wheel has in every instance been most heartily endorsed by the superintendents and master mechanics of roads that have used it, and the company thinks it has in this wheel the best thing of the kind on the market.

THE MICA INSULATOR CO., of New York, Chicago and London, reports a very heavy increase in the volume of business during the last two months. The company's insulating materials, "Micanite" plates, segments, rings, etc., "Empire" insulating cloths and papers, and M. I. C. compound, are being used very extensively by the leading builders of electrical machinery throughout the United States and Europe, and "Micanite" segments are now in use by nearly all the large builders of generators and motors. Parties having had no experience in the use of "Micanite" will do

well to correspond direct with the company at New York, Chicago or London.

THE DORNER TRUCK & MANUFACTURING CO. advises us that it has closed a contract with the Logansport Commercial & Manufacturing Association by which the latter will erect for it a large foundry and machine and truck shop at Logansport, Ind. The Dorner company will also receive a cash bonus to locate in Logansport. Chicago capital has been interested and the company will soon be in position to carry on the foundry and truck business on a large scale. The company's office and warehouse will be continued at the corner of Mason and Belden Sts., Cleveland, and it will also have offices in Chicago and New York. There are numerous orders on hand and as the merits of the company's trucks are being recognized by managers, new orders are being taken.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING CO. has received an order from the Sioux City (Ia.) Traction Co. for a new generator of 550 h. p., "engine type," 550 volts; it will be direct connected to a steam engine running at 90 r. p. m. This generator will work in multiple with the other machines already installed and will serve to greatly increase the efficiency of the system. Since the recent consolidation of the street railways the service has been much improved; the Sioux City Traction Co. has found it advisable to add a number of new cars and has bought several Westinghouse quadruple equipments of 125 h. p. each. These motors will be attached to each one of the axles so that the cars will have 100 h. p. which will enable them to maintain their speed on the steeper grades.

WESTINGHOUSE, CHURCH, KERR & CO., Chicago, are making an important addition to the electrical power house of the Detroit & Pontiac Railway Co. This contract was received after inspection of the railroad recently equipped for the Detroit, Ypsilanti & Ann Arbor Railway Co. by Westinghouse, Church, Kerr & Co. and so successfully operated. They are erecting 500-h. p water tube boilers, furnished with Roney mechanical stokers. In place of the horizontal engines which have been in use for sometime, the plant, when remodeled, will include two Westinghouse steam engines of 400 h. p. each. A number of new cars will be added, each of them driven by Westinghouse electric motors. The operation of the Detroit, Ypsilanti & Ann Arbor has been so highly satisfactory in every respect, that the directors of the Detroit & Pontiac desire to have, as near as possible, a fac simile.

THE CHISHOLM & MOORE MANUFACTURING CO., of Cleveland, O., has recently acquired the business of the Rail Joint & Manufacturing Co., which name will be abandoned and the joint will be known as the American Standard Rail Joint in the future. This company is one of the largest manufacturers of chain hoists and cranes in the United States, and has an extensive factory in Cleveland. In addition to its already very large works, it is now building a malleable iron works, 100 x 318 ft., a building for the annealing and shipping department 60 x 190 ft. and a machine shop 60 x 180 ft. The company has increased its capital stock from $100,000 to $300,000. The business of the American Rail Joint Co. has increased steadily, and had become so large that it necessitated it owning works. Col. W. E. Ludlow, the well-known manager of the American Rail Joint Co., will continue to act as manager for this department for the company.

THE FAMOUS FILTER CO., of 314 N. Main St., St. Louis, has during the past month made 28 sales of its well-known "Famous" waste oil refiner and purifier. Among the purchasers were: Tiffin (O.), Fostoria & Eastern Electric Ry.; St. Louis & Belleville Electric Ry.; St. Louis, Belleville & Suburban Ry.; Ripley (Tenn.) Electric Light Co.; Lebanon (Ill.) Electric Light Co.; the Merchant Mills, Mobile, Ala.; Newbern (Tenn.) Electric Light Co.; Berlinger & Son, New York City. Berlinger & Son got 1 No. 5, 3 No. 6 and 12 No. 7 filters. The "Famous" was described and illustrated in the "Review" for March, page 187; those interested in the subject may obtain detailed information concerning the experience of those who have used the apparatus by addressing the company and asking for a copy of "Advanced Modern Engineering Practice." The company will also send free to street railway power plants a limited number of clean oil testing outfits.

THE CREAGHEAD ENGINEERING CO., of Cincinnati, O., has just issued its Catalog No. 15, which comprises 90 pages, profusely illustrated, descriptive of railway line material. The design of this company's material is the result of experience in the building of railways and the devices made by it have been thoroughly tested and approved by many of the best railway engineers and superintendents. As far as is consistent with good practice the devices are made light in weight; they are carefully designed to place the material where needed and to present a neat and pleasing appearance. Convenience in attachment and repair is a point the company has always kept in mind and this has often secured the preference over goods in which cheapness of manufacture seemed to be the principal object sought. New designs are placed on the market from time to time, and the company is always pleased to receive suggestions along this line. Copies of this catalog may be had on application to the company.

THE UNION BOILER TUBE CLEANER CO., of 262 Penn Ave., Pittsburg, was organized in 1895 for the purpose of engaging in an entirely new business, that of removing the scale from the interior of the tubes of water tube boilers, and it is said to be at the present time the only concern making a special business of such work. The company has its specially designed machinery, which was briefly described in the "Review" for June, page 382; and is able to make contracts for cleaning all types of water tube boilers under heavy penalty for non-fulfillment. The company also sells and leases its apparatus, which is protected by patents both here and abroad. The users of boilers have fully appreciated the value of the company's devices and the resulting demand has compelled frequent enlargements of the manufacturing plant, since it started in May, 1895; quite recently the working force has been more than doubled in an attempt to keep up with orders. The flexible shaft used for boilers having curved tubes was designed by this company, other flexible shafts having proved unable to withstand the wear and tear.

THE B. F. STURTEVANT CO. presents an example of how the development of a large business leads to the manufacture of certain types of machines. Beginning back in the early 60's to make fan blowers, the necessity of building attached engines became more and more apparent as the demand for large, independently driven fans increased. During the 70's the "steam fan" thus became an important product, and from the building of vertical engines it was but a step to the design of the horizontal type for driving large fans. The work was continuous and exacting, demanding the utmost care in design and construction. With the advent of electricity as a motive power, the Sturtevant Co. immediately began the design and manufacture of its own motors for direct attachment to its fans, so that the electric fan now stands as a rival of the steam fan. Having thus become manufacturers both of high speed engines and of electric motors, it was but another step, and a natural one, to the union of these two elements, the latter in the form of a dynamo, and the production of a high grade generating set. With an exceptionally complete line of small and medium sized engines in various types, and an equally extensive equipment of dynamo patterns, it is thus possible to make up almost any desired combination. Thus has this company become not only manufacturers of fans, but also of engines, motors and dynamos and their combined resultants, electric generating sets. The company has just issued a pamphlet entitled "2,500 Witnesses," which is a handsome bit of typographical work. It is a list of buildings and steamships where the Sturtevant system of apparatus is installed for ventilating and heating.

NEW PUBLICATIONS.

DERRAH'S STREET RAILWAY GUIDE for Eastern Massachusetts and Rhode Island has reached its fourth edition which has just been issued and contains a number of features not to be found in the previous editions. The book contains a fine map of all the street railway lines in eastern Massachusetts, southern New Hampshire and eastern Rhode Island, all of which country is covered by a network of more than 1,500 miles of electric railway, all of which is in direct connection with the city of Boston. The Guide contains handsomely illustrated descriptions of a number of trolley rides on various lines, also special features such as night cars in Boston, route and rates of fare, distances, running time, time-tables, and in fact full information for reaching every point on the electric line radiating from Boston. Mr. Robert H. Derrah, by whom the work is compiled, has made a study of these lines for many years and is in the street railway excursion business at 113 Devonshire St., Boston. The Guide bears the official endorsement of the Massachusetts Street Railway Association.

THE UNIVERSITY OF MINNESOTA has issued a new Bulletin giving a general statement of the university courses, the requirements for admission, the courses of instruction, etc. The college of engineering is treated in a supplement published with the Bulletin. The University considers it desirable that engineering students taking the technical courses should have a more liberal education than can be obtained in a four years' course. This has led to the establishment of a five years' course in science and technology in which the usual course is supplemented by more English and general culture studies.

AMERICAN STREET RAILWAY INVESTMENTS for 1899, better known perhaps as the "Red Book," has lately been issued from the press. This manual of the street railway properties of the United States and Canada is the oldest, largest and most complete of the financial publications treating exclusively of street railways and by reason of accuracy of its data has become a recognized authority among investors.

The present edition contains 300 pages of solid brevier matter, each page 13½ x 10½ in. It includes reports of about 1,400 companies, giving in each case the history of organization, exact financial description of securities issued, four and five years comparisons of receipts, expenditures, assets, liabilities, etc., description of the plant and equipment, names of officers and references to detailed descriptions of the properties which have from time to time appeared in the Street Railway Journal to which the Red Book is a supplement. The comparison of assets and liabilities is a new feature; another new feature is that of giving the names of brokers handling the securities of the principal companies. The present edition contains 34 maps of important properties.

Published by the Street Railway Publishing Co., 120 Liberty St., New York. Price, $5.00.

DUNCAN'S MANUAL OF TRAMWAYS, OMNIBUSES AND ELECTRIC RAILWAYS, published by T. J. Whitney & Sons, Ltd., of London, has now reached its twenty-second edition which has just been published for the year 1899. This work contains the financial reports and statistics of the tramway and omnibus companies of the United Kingdom and all of the colonial and foreign companies that are registered in English, also giving the dates of their incorporation, and, where fixed and ascertainable, the dates at which their leases or concessions terminate. The present edition contains 428 pages which are divided into the following complete sections, viz.: Metropolitan, Provincial, Scotch, Irish, municipal and foreign lines, each section being arranged in alphabetical order. This edition also contains the fullest information possible to be obtained of the tramway lines owned by municipal authorities.

The work gives the names of the directors and officers of each company, the company's main offices, its capital account and reserve fund and, where sufficient data are given, an analysis of its revenue account. The accounts are all brought down to the year ending Dec. 31, 1898, showing the exact financial status of each of the companies. A comparison is also given of the accounts for the half-year ending June 30, 1898, with those of the half year ending Dec. 31, 1898.

The work contains a complete index in which the tramway lines are alphabetically arranged under each of the different sections given above.

The book is bound in cloth. Price 3s. 6d.

THE ENGINEERS' YEAR BOOK for 1899 has come to hand. This is the publication issued by the Society of Engineers of the University of Wisconsin, and the present issue is Vol. VII. The contents comprise: "Methods of Transmitting Intelligence," by Prof. Geo. D. Shepardson; "The Strength of Gear Teeth," by J. T. Flather; "A Rotary Converter," by Geo. F. Adams; "Theory of Flexture of a Circular Plate or Ring, Loaded Symmetrically About Its Center," by H. T. Eddy; "Western Practice for Determination of the True Meridian," by C. E. Van Barneweld; "Inspection of Erection of Steel Bridges," by G. A. Cassidy; "Some Gold in Peru," by Geo. A. Pratt; "Laboratory Work in the Electrical Engineering Course at the University of Wisconsin," by Frank W. Springer; "The 'Boston & Montana' System of Surveying," by P. B. McIntosh; "Engineering and Finance," by Morgan Brooks; "Water Works for Small Cities and Towns," by C. F. Loweth. Price, 50 cents per number; post paid, 60 cents.

NEW TERRE HAUTE CO.

The property of the Terre Haute Electric Railway Co. was last month sold to Lee Higginson & Co. and Stone & Webster, of Boston, and a new company has been organized to operate the business. The new company is known as the Terre Haute Electric Co., the directors are W. R. McKeen, Demas Deming, J. G. McNutt, John E. Lamb and John T. Beasley, all of Terre Haute. Guy E. Tripp is general manager and M. F. Burke, superintendent.

OMNIBUS AND TRAM SERVICE IN PARIS.

In answer to a Chicago correspondent Consul-General Gowdy at Paris has secured data concerning the omnibus and tram service in that city which were published in the U. S. Consular Reports. There are three tramway lines serving Paris and the suburbs and omnibuses are generally used in the city; the Compagnie Generale des Omnibus owns one of these lines and practically controls the other two. This company's concession expires in 1910.

The passengers carried in 1896 were as follows:

33 lines of omnibuses (26 to 30 places).....	50,030,034
14 lines of omnibuses (40 places)	79,349,631
3 lines of steam tramways	12,862,990
23 lines of horse tramways.....	87,092,926
4 lines compressed air and electricity.....	10,705,340
Total	240,040,291

In 1897 the company had 16,017 horses and the maximum number of vehicles working in one day was 1,130.

The fare on the top of an omnibus is 15 centimes (nearly 3 cents); inside and on platform, 30 centimes (nearly 6 cents). The payment of the last-mentioned fare entitles the passenger to a "correspondence" or transfer ticket to another connecting or intersecting line. No passengers are taken on when the places are filled, either at a station or en route. At the starting points, numbered tickets are handed to the passengers, and when there are more than enough to fill one conveyance the precedence is given to those holding the first numbers. The next omnibus or car starting begins with the number last uncalled on the previous vehicle. The same system prevails at the fixed stations en route for vacant places. No standing in the aisle is allowed. The distance traversed by the various lines varies from two to four miles.

The bonds of the company bear 4 per cent interest and are quoted at about 101; the stock is quoted at about 348.

ELECTRIC FANS IN SLEEPING CARS.

Monon Route sleepers for Indianapolis and Cincinnati leaving Chicago at 2:45 a. m. have been equipped with electric fans. These sleepers are set in Dearborn station for occupancy at 9:30 p. m., and the electric fans will make them cool and pleasant during the summer months. Get tickets at No. 232 Clark St.

NEWS NOTES.

ATLANTA, GA.—The Collins Park & Belt Railroad Co. has in view extensive improvements which will necessitate the enlargement of its power house. J. C. Simmonds, president.

BAY CITY, MICH.—The Bay City, Tuscola & Huron Railway Co., which was organized to build an electric railway from Bay City to Tuscola and Huron Counties, has disposed of its franchises and contracts for rights of way to Benjamin Boutell, of this city, as trustee.

BETHLEHEM, PA.—The Bethlehem & Bath Street Railway Co., has been incorporated with $36,000 capital stock to construct a line between Bethlehem and Bath. Joseph J. McKee, president.

BRIDGETON, N. J.—The Bridgeton & Millville Traction Co.'s line, including the lines to Millville, Cedarville and Tumbling Dam Park, are said to have been sold to a Philadelphia syndicate. The present stockholders will retire.

BROCKTON, MASS.—The Brockton, Canton & Dedham Street Railway Co. has been organized with a capital stock of $200,000 to build an electric line between the cities named in the title. John J. Whipple, Fred C. Hinds and Chas. T. Field, all of Boston, are interested.

BUTLER, PA.—A charter has been granted to the Butler Passenger Railway Co. to construct a street railway in the borough of Butler, to be about eight miles in length; capital stock $50,000. The directors are A. L. Reiber, president; K. V. Ritts, John Berg, James B. McJunkin and Charles Duffy, all of Butler.

CATLETTSBURGH, KY.—Surveys are being made for an electric line between Catlettsburgh and Central City. It is understood that the road will also be extended to Kenova and Ceredo, W. Va.

CINCINNATI, O.—The stockholders of the Cincinnati, Lawrenceburg & Aurora Street Railway Co. have announced an agreement to increase the capital stock from $35,000 to $750,000.

CLEVELAND, O.—The Cleveland & Eastern Railway Co., with a capital stock of $1,000,000, has been incorporated to build an electric line from Cleveland to Burton, with a branch extension from Fullerton to Chadron. The incorporators are H. Clark Ford, Harrison B. McGraw, John Wilson Hart, Frederick A. Henry and S. P. Baldwin.

CLINTON, MASS.—The Clinton & Hudson Street Railway Co. has been organized here, with Alexander S. Paton, Leominster, Mass.; W. R. Dame, Clinton; Wm. H. Tybee, Worcester, Mass., and others as directors.

COLUMBIA, S. C.—A deal to purchase the Columbia Street Ry. and Electric Power Co. has been closed by several Baltimore capitalists, some of whom own the Charleston electric railroad. The price is $257,000.

COLUMBUS, O.—It is reported that the Columbus Central Street Railway Co. is to be consolidated with the Columbus Street Ry. in a very short time. The union of the two lines will doubtless result in a number of improvements being made. E. K. Stewart, general manager.

DETROIT, MICH.—The Wolverine Construction Co. has awarded the contract for constructing 22 miles of track to B. F. Sullivan & Co. The track is to be constructed between Sand Hill and Farmington, and Farmington Junction and Orchard Lake, connecting the Sylvan Lake road with the Grand River electric.

EUREKA SPRINGS, ARK.—The Citizens Street Railway Co., which heretofore derived its power from the Citizens' Electric Co., has been absorbed by the latter. Owing to a friction between the two companies for many months cars have stood idle in the sheds. Operations have now been resumed.

EASTERN OFFICE, 100 WILLIAMS STREET, NEW YORK.

This paper is a member of the Chicago Trade Press Association.

Entered at the Post Office at Chicago as Second Class Matter.

VOL. IX. AUGUST 15, 1899. NO. 8.

The Brooklyn and New York street railway strikes were both flat failures, for which there were two principal reasons—the men had no real grievances and the police suppressed disorder with great firmness.

A Detroit man has become possessed of a wonderful new idea. It is that street car fares are a commodity and should be governed by the market price. The only trouble with this theory is that it is never heard of except when advocating three or four-cent fares. No one outside of a street railway office has ever been known to even think of such a thing at times when the company is spending six cents to carry a five-cent passenger.

Wisconsin has an anti-pass law which makes it an offense for any state, city or county official to ride free on any common carrier. Under this law many street railways have refused to carry policemen free, and during the strike last week in Eau Claire, the mayor refused to permit his police force to officer the cars and protect the new men, as the officers would be riding free. Under this interpretation any fugitive from justice will find the street cars of Eau Claire the safest place of escape, if only he can have charge of the controller handle.

We think that it is in order to congratulate our British cousins upon the fact that the electric railway industry has so grown as to feel the need of an association which shall be representative of it, such an organization having been formed in June last under the title of the Tramway & Light Railways Association. The members are to be operating companies or corporations (local authorities) and individuals; the official organ of the Association is our esteemed contemporary, the Railway World, whose editor, Mr. A. M. Willcox, is honorary secretary.

The new association has our best wishes for success, which in view of the encouragement recently given to electric railways in the British Isles seems certain.

Two months from the date of this issue the advance guards of the Street Railway Convention of 1899 will be pouring into Chicago. Every indication points to a phenominally large attendance, and delegates who have not already made their hotel reservations should do so while there is yet time to secure choice locations. The hotel facilities of the city are ample, but are always in demand during October, hence intending visitors will secure better accommodations if they will only speak a little in advance. The local committee is hard at work and the results will be apparent during convention week.

Practically no space is left in the exhibit hall, and a reallotment has been necessary, reducing the size of the larger applications, in order to take care of everybody. While the floor space is the largest ever provided at any convention, it will all be occupied, and the display alone will well be worth a trip across the continent. Chicago has a royal welcome waiting, and wants at least one representative from every street railway in the country and as many more as can come.

The action of the Hartford Traction Co. in voluntarily reducing its rates by extending the limits of the 5-cent fare on several lines is in accord with the position taken many times by this paper. We have always maintained that street railway managements are liberally inclined and are following broad gaged, progressive policies. But the management alone is in position to know when it is possible to do this. Some time since a committee visited the Legislature and petitioned for an act reducing rates on certain lines of this same road. The request was rejected after careful examination, on the grounds that the existing rates were fair and reasonable. Since that time the business of the company, by good administration, has increased to a point where the management felt justified in reducing its rates by extending the ride, and not only did so on the route previously requested, but on several others for which no concession was asked or expected.

To the casual rider who happens to travel at an hour when the cars are always crowded morning and night, a certain line may appear to be a small Klondike, but as likely as not there are 14 hours in the day when it is running at a loss. Taking all things into consideration the American street car ride gives more for the money than anything we know.

The saving in the cost of operation which can be effected by substituting electric traction or self contained "composite" motor cars for the ordinary steam locomotives for handling passenger traffic on branch lines of steam railroads, is causing the managers of such roads in all parts of the world to give the subject much attention. The ordinary

two car train requires five men to operate it, engineer, fireman, baggageman, conductor and brakeman; a two car train operated by electricity or a "composite" motor car would require but two, or perhaps three men, thus effecting a saving of from 40 to 60 per cent in the item of trainmen's wages.

The length of the steam railroad spur lines and the light passenger traffic over them will doubtless in many cases prohibit the expenditure for copper necessary for operation on the overhead trolley system. For such lines the steam railroads, and in some instances what would be called street railways, have turned to the autocar. We have described several steam, air and gasoline motor cars in the past few years, and at present the demand for them appears to be steadily, though slowly, growing; the greatest demand is by steam railroads, however.

It is extremely difficult to keep in touch with the street railway controversy in Detroit because the current literature on the subject is so very voluminous. On another page is a brief summary of what has happened since our last issue; we venture no predictions for the future.

The Chamber of Commerce, prominent citizens, Governor Pingree, Mayor Maybury, officers of the company and others, have been indulging in much talk and nearly everybody's motives have been impeached. Mr. Pingree attempts to reach the public through proclamations printed on handbills and at least 13 of these have been issued by him, beginning with No. 1, which we reprinted last month.

The 3-cent fare will not be given a trial just now, which is possibly a misfortune. The belief that it is possible to operate a street railway system on 3-cent fares is firmly fixed in the minds of a great many persons, and perhaps the best way to determine whether it is correct is to make a trial. Detroit, for the present, at least, has refused to play dog and let the trial be made. As we do not believe it possible to make a success of street railroading on a 3-cent basis, we congratulate Detroit and condole with the street railway interests which would reap the benefit of a costly object lesson.

Atlanta has a chance to buy the lines of the Consolidated, by paying par for $2,000,000 of stock and assuming the bonded indebtedness of $2,250,000. The property paid four per cent net in 1898. To avail itself of this offer the city is to grant at once, certain franchises now asked for by the company and the latter is to enjoy a practical monopoly in the line of future grants as against another company which threatens to parallel the best lines of the Consolidated. The city in return is to share in any profits over three, four and five per cent for 1900, 1901 and 1902, respectively, and after, with the privilege of purchase at any time it is ready.

The interesting feature of the situation is the timidity which all of a sudden seems to have seized the very people who thought they were thoroughly inoculated with the municipal ownership idea. Now it actually confronts them and they realize that interest must be paid, not only on the present liability, but the cost of future extensions and betterments as well, and that a failure to do business at a profit does not mean a receiver but increased taxation to supply the deficiency, it radically changes the rosy hues of "millions in it," to the risk which continually confronts every business man and corporation. The proposition begins to assume faint outlines of a white elephant to people who all the time considered it an easy matter to run a street railway and pay big dividends.

When the Street Railway Accountants' Association of America was organized in March, 1897, it was recognized that probably the greatest work which the Association could undertake would be the standardization of street railway accounts. Mr. C. N. Duffy presented a paper on the subject designed to elicit a full discussion as to the objects of such a system and the best means of reaching them. The immediate result was the appointment of a committee consisting of C. N. Duffy, secretary and treasurer of the Citizens Street Railway Co., St. Louis; W. F. Ham, secretary of the Nassau Electric Railroad Co., Brooklyn, and John F. Calderwood, auditor of the Twin City Rapid Transit Co., Minneapolis, with instruction to prepare a report.

The committee presented an elaborate report at Niagara Falls in October, 1897, which was approved by the Association. At that time H. L. Wilson, auditor of the West End Street Railway Co., Boston, and H. J. Davies, assistant secretary and treasurer of the Cleveland Electric Railway Co., Cleveland, were added to the committee and the committee made a permanent one. This committee made a second and more extended report at Boston in September, 1898, which was adopted.

When the first report was discussed a question was raised, we believe, as to the wisdom of this Association adopting and recommending a system of accounts without first getting the approval of the Boards of Railroad Commissioners of the various states, since the Commissioners have in many states, the final decision as to what system should be used by the companies reporting to them. The permanent committee endeavored during the following year to have meet with it the Railroad Commissioners of the states which exercise any control over the accounts of street railways, but arrangements could not be made before the Boston convention, and the report as adopted was that of the street railway accountants only. How well the work was done is shown by the report of Mr. Seymour to the National Association of the State Railroad Commissioners and the report of Mr. Duffy to President Calderwood, which are printed on another page. Conference with representatives of the two other associations mentioned in the reports showed that only a few changes were suggested, all of minor importance, and all such as were readily agreed to by Mr. Duffy and Mr. Ham.

It is indeed, a high compliment to the committee which prepared the "Standard System" and to the Association to have Mr. Seymour's committee recommend it in this language:

> It was found that the form prepared by the street railway accountants was so much more advanced in its preparation, so complete and full in its details, and so well adapted for its purpose, owing to the familiarity of those who prepared it with street railway accounting, that we deemed it wise to abandon the work which we had commenced, and advise the endorsement and adoption of the form prepared by them.

We extend congratulations on this praise from such a source, and with a feeling of pride remember that the "Review" was to some small extent instrumental in forming the Street Railway Accountants' Association.

We have had occasion during the past few months to mention a large number of street railway companies in connection with increases in the rates of wages paid, and this

we take it is an indication of the correctness of a statement we have frequently made, that the men at the heads of our street railways have the welfare of their employes at heart. There are at least two reasons why a manager ought to pay his men just as high wages as the company can afford; the company gets better service when the men know their work is appreciated, and, as an individual, the manager is happier, as the condition of the men with whom he works is bettered.

On another page we note that the Columbus (O.) Street Railway Co. has decided to hereafter pay to its employes a dividend upon the wages earned since the preceding dividend day, at the same rate that holders of the company's stock receive. The wording of the resolution indicates that this is regarded by the company as an increase in wages to be determined in amount by the ability of the company to pay, rather than a sharing of profits with employes, and we find it difficult to reconcile the scheme adopted here, with some of the generally accepted economic theories respecting the relations of capital and labor.

In a lecture before the State Convention of Illinois Municipalities, held at Peoria, Ill., in March last, Mr. Allen R. Foote defined interest as the wage of capital, and wage as the interest of labor, and further said: "Wage is a guaranteed payment for the use of capital, and of labor, without risk of loss or right to share in the profit." This latter definition of wage is probably an acceptable one, but in the short statement, "wage is the interest of labor," accuracy has been sacrificed to brevity. To take that statement literally, would be to assume that the value of the service rendered by labor is a certain sum, say twenty (interest at five per cent) times, the annual wages earned by the laborer; it would be nearer the truth to say that wage is composed of interest on labor and a sinking fund payment (or insurance premium). Mr. Foote's theory of profit sharing is that after cost has been properly computed (cost includes interest on the capital invested) any profit should be divided between the capital and labor which have jointly produced it by paying dividends to the capitalist on his money invested, and to the laborer on his wages earned at the same rate per cent. This theory of dividing profits appears to carry with it an admission that wage is not the "interest of labor," because were that so the amount of the capitalist's interest and the laborer's wages should constitute the basis of the division of profits.

According to the more generally accepted theory, wage is paid to purchase labor, as any other commodity is bought, and the wage would therefore be a measure of the value of the service rendered. Waiving all question as to why labor should share in the profit if it is a commodity, and admitting that profits ought to be shared between capital and labor, would not the equitable basis of division be to pay the labor a dividend (at the same rate that the capital receives in excess of interest) on one-half the amount of wages earned? The capital has been invested during the whole of the dividend period, while the labor has been invested from day to day and the average time of the "investment" is but one-half the dividend period.

The suggestions are made in order to call attention to the fact that the increase in wages granted by the Columbus Street Railway is really such, and is much more than the men would receive were distribution made on an equitable profit-sharing basis. In the plan adopted at Columbus no payment of interest on the capital stock is made before the profits are divided; four per cent per annum is surely a very low rate of interest on capital invested in a street railway, so that in fact the Columbus employes receive all the "profit" that is distributed, stockholders getting only a reasonable interest.

THE SITUATION IN DETROIT.

There have been a number of very sudden shifts in the Detroit street railway situation during the past month. On July 14th, all of the street railways in Detroit started to run on a straight 3-cent fare basis, selling five tickets for 15 cents and giving universal transfers.

On July 18th, the city council met and reconsidered its passage of the security franchise, upon which depended the sale of the entire Detroit street railway properties to a company representing the city, and from this action the present owners declared all negotiations at an end. Three days later the Citizens Street Ry. and the Fort Wayne & Belle Isle Ry. stopped the sale of 3-cent tickets and instead of resuming the rate that has been in force for 20 years, six tickets for 25 cents, the rate of 5 cents and no tickets, was established on all lines controlled by these two companies. The Detroit Ry., a 3-cent line, has not increased its service to meet the demand and a resolution is now before the council asking that company to put a two-minute service on all of its lines. The city council states that it will refuse all favors to the street railway people pending a return to the old rates of fares.

Mayor Maybury, who is opposed to "municipal ownership," has had prepared an ordinance which he proposes to try and enforce by law and thereby compel the 5-cent lines in Detroit to reduce their rates of fare, as well as grant transfers. This ordinance, as approved by the council, August 8th, reads:

"It is hereby ordained by the people of the city of Detroit: That the said Citizens' Street Railway Co., its successors and assigns, shall keep on sale on its cars in service at all times tickets to be sold in strips or packages of eight tickets for 25 cents, each of which tickets shall be accepted by said railway company, its successors or assigns, for a single ride for any distance in either direction, over the lines or route operated by the said railway company, its successors or assigns, on a car on which it is presented; and any passenger presenting such ticket or upon payment of one single fare charged by said company, shall be entitled to a transfer ticket good for a continuous ride over any other line or route operated by said company, provided such ticket is presented on the next regular car of the company within 15 minutes after such passenger leaves the car on which he receives such transfer ticket. This ordinance shall not be construed to affect any lines or routes of street railways now owned by the Detroit Railway Company.

"This ordinance shall take immediate effect."

Immediately after the street railway companies refuse to comply with the provisions of this ordinance, as Vice-President Hutchins is certain they will, a new fight in the courts will start in Detroit. Under present franchises the companies affected have the right to charge 5 cents for every ride.

This is the street railway situation in Detroit as we go to press. But it should not be supposed that Governor Pingree and his associates have abandoned the municipal ownership proposition. The governor proudly states that the people can blame only themselves for the present 5-cent

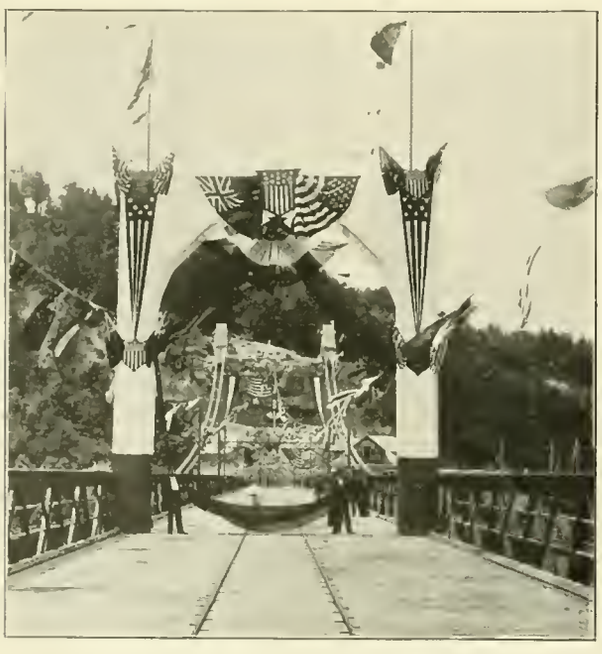
cash fares and, further, that he will keep up the fight until after the election this fall, and if then the voters come to the front, electing a city council favorable to his ideas, that municipal ownership will yet become an assured fact.

In addition to its other street railway troubles Detroit has been threatened with a strike. Vice-President Hutchins and General Manager du Pont made a number of concessions in the matter of rearranging schedules so that the 10 hours work of the men would be within 11 hours, instead of 12, as formerly; also the rate for "tripper" men making less than four hours per day was increased.

The employes' union started out to demand a general increase in wages from 20 and 21 cents an hour, to 23 and 24 cents, and at a general meeting on the night of August 1st, it was agreed to offer to compromise at 21 cents for the first nine months men were in the employ of the company, and 22 cents an hour thereafter. This proposition was submitted to the company's officials and refused, Mr. Hutchins stating that it was impossible at this time to grant a general increase in wages, and he also stated that the question of granting an increase in wages would not be submitted to arbitration, but that all other questions in dispute would be submitted to such a board.

OPENING OF NEW NIAGARA BRIDGE.

On Friday, July 21st, the International Traction Co. formally opened its new suspension bridge across the Niagara gorge a short distance above the villages of Lewiston, N. Y., and Queenston, Ont. This bridge was built by the Lewiston Connecting Bridge Co. and the Queenston Heights Bridge Co., but is now the property of the International Traction Co. The bridge has been fully described



OPENING OF THE NEW NIAGARA BRIDGE.

in these columns. It will be recalled that it has a cable span of 1,040 ft. and that the suspended span is 800 ft. in length. The floor of the structure is 25 ft. wide, and through the center there has been laid a single track for electric cars, the bridge being designed as one of the connecting links in a belt line trolley service about the beautiful gorge.

The bridge was gaily decorated from end to end and presented a very beautiful sight. Hon. W. Caryl Ely, president of the International Traction Co., had sent out handsome invitations to prominent people in the United States and Canada, expressing a desire to have them present at

THE FIRST CAR.

the opening; enclosed in the same envelope was a card entitling the holder to free transportation over all the company's lines on July 21st and July 22d.

The guests assembled at the two ends of the bridge, and shortly after 1 o'clock walked to the center, where the 74th regiment band, of Buffalo, was stationed. After a general handshaking, the officers of the International Traction Co. receiving congratulations from all, the party proceeded to Queenston Heights, where luncheon was served in tents erected in the shadow of Brock's Monument. Numerous speches were made, Mr. Ely presiding as toastmaster.

KILLED BY A RAILWAY CURRENT.

On July 24th, William Crites, 18 years old, was killed by the railway current while assisting a lineman at work for the Union Traction Co., in Marion, Ind.

The lineman was on the pole lengthening out the span wires with a view to setting the poles back farther in the street so as to permit of paving the street farther out. The lineman states that he instructed Crites, who had only been working for the company a short time, to watch the coil of wire which he left on the ground, carrying the end up with him, and not let anybody touch it; but it seems that the wire came in contact with the old span wire, which was charged with electric current on account of leakage at the bell, and transmitted current to the ground, and that Crites for some reason had hold of or touched the wire, thus receiving the full force of the current, and was instantly killed. It is said that the young man had been afflicted with heart disease.

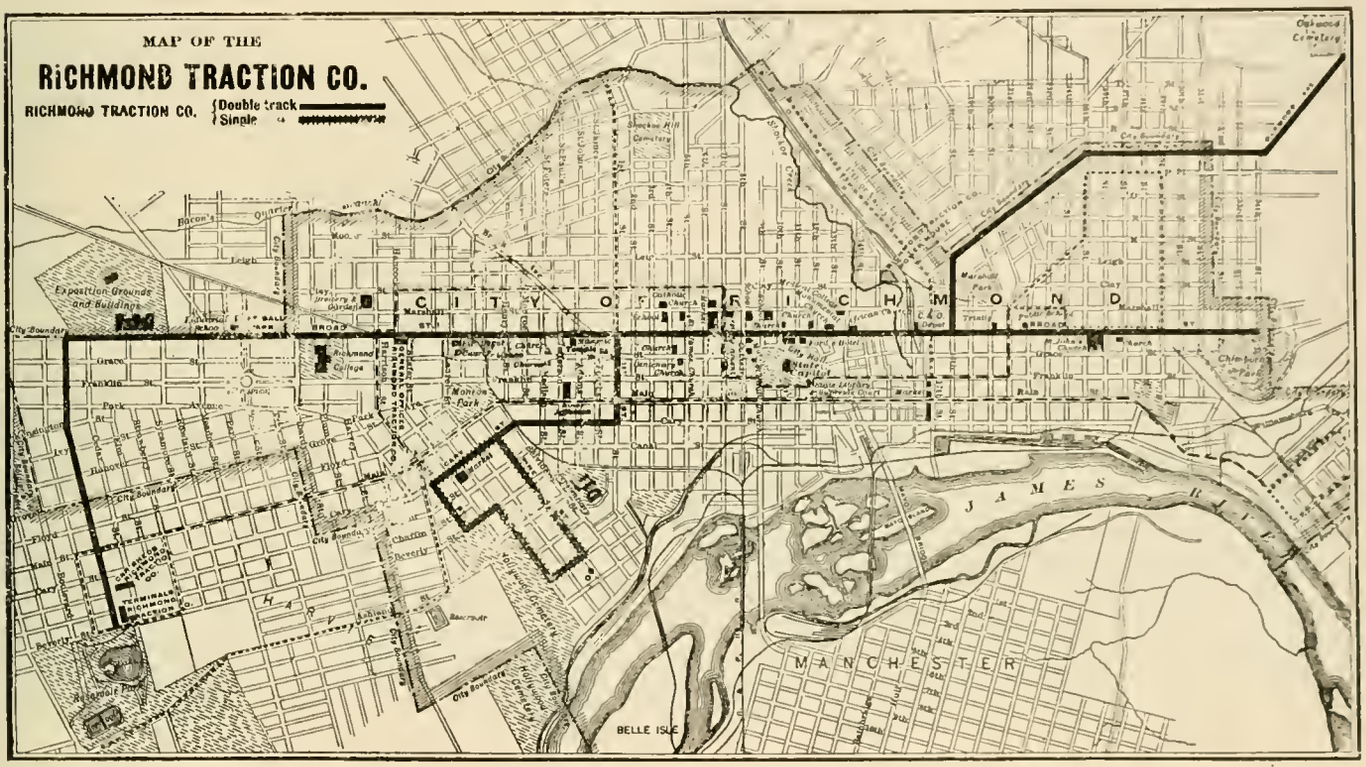
The Chicago Consolidated Traction Co. has been fined $50 for violation of the smoke ordinance.

The Richmond Traction Co., Richmond, Va.

The city of Richmond, Va., which has the distinction of being the pioneer city in the use of the single trolley system has had its street railway facilities increased by a new road, which embodies the latest improvements in this method of traction. The Richmond Traction Co. now owns a system of street car lines comprising 16.04 miles of track, which are shown upon the accompanying map in heavy black lines. The main line of the road passes through Broad St., which is the principal thoroughfare of the city, for a distance of four miles without a curve. Beginning at Chimborazo Park, a beautiful and elevated plateau having a magnificent view of the James River for many miles, this line extends westward to the Exposition Grounds, situated near the western boundary of the city. Along this route or immediately contiguous to it are situated nearly all of the public buildings, markets, churches and places of amusement, among which may be mentioned the State House and grounds containing many historic statues, the City Hall, Masonic Temple, Armories, Base Ball Park, Richmond College, State Library, Soldiers' Home and Lee Monument and two railroad depots, those of the Chesapeake & Ohio and the Richmond, Fredericksburg & Potomac.

From the Exposition Grounds the line turns south following Robinson St. to the Reservoir Park, the most frequented summer resort in the city. From 18th and Broad Sts. a double track branch line extends northeastwardly to Oakwood Cemetery, the burial place of thousands of soldiers, which has been heretofore entirely without street car facilities, and another branch beginning at First and Broad Sts. extends southwestwardly via Cary St. to the picturesque Hollywood Cemetery, which contains many historic tombs, including those of several of the former Presidents of the United States. This section of the road passes through a thickly settled district from which a large amount of traffic is drawn.

The lines are double track throughout the whole system with the exception of the Cary St. loop, which is a single track, and the construction of the road is of the highest order. The tracks in the city are laid with 95-lb. grooved steel girder rails, type 218, of the Loraine Steel Co., while in the suburbs there is one mile of double track on Robinson St. and ½ mile on Oakwood Ave. laid with 60-lb. T-rails. The roadbed consists of white oak ties in a concrete bed, the concrete being 6 in. thick below the ties, extending 6 in. beyond the ends of the ties, and also filling the spaces between the ties, leaving them completely embedded in concrete. This construction has not been found entirely satisfactory to the company, but was forced upon it by the city authorities. Two important objections to this construction have developed which seem impossible to be remedied, while the city enforces this style of construction. One of these is the unyielding nature of the roadbed, which, on account of having no cushion, causes the bolts and bonds at the rail joints to be hammered loose by the action of the cars. The other objection to this construction is the premature destruction of the ties, due to the lack of drainage. The concrete practically forms a series of troughs in which the ties set and from which there is no way to drain off the water which settles around and rots them. Again it is very difficult and extremely expensive to renew the ties, as the only way to remove and put in new ones is by chopping out all the concrete around them. Outside the city limits stone ballast has been used, which entirely obviates both of these troubles.



The overhead construction is neat and substantial. On one portion of Broad St. center poles of steel are used, the poles weighing about 1,000 lb., and carrying cross-arms,

upon which the feeders are run. The remainder of the lines are equipped with steel side poles weighing 700 lb. and span wires. The feeders are all carried overhead and a No. 0 trolley wire is used. The overhead fittings and all the electrical apparatus of this system are of the General Electric type.

The company has a total of 74 cars, 31 of which are open summer cars and the remainder closed cars and trailers. There is also one snow sweeper. The cars are of several different makes including the American Car Co., Jackson & Sharpe Co., and Stevenson & Co. They are supplied with double equipments of G. E. 1,000 motors and Peckham double extension trucks. Each car is provided with two registers, one a cash register of the New Haven Cash Register Co., and the other a transfer register, built by the Sterling Supply & Manufacturing Co. Fenders of the Consolidated Car Fender Co. are placed on both ends of the cars

of this building 32 ft. are partitioned off, which space is used for the machine and repair shop. This building faces on Robinson St. and at the right hand side just beyond the entrance is a large inspection pit, 30 ft. in length and its width covering three parallel tracks. A certain number of cars are brought over this pit and inspected each day and a record of these inspections is kept by a special method which will be explained below. The rest of this barn is for car storage.

The repair shop in the rear of the bar covers a space of 32 ft. x 84 ft., at one end of which is the repair pit shown in the illustration. The machines included in this shop are a drill press, a lathe of 20 in. swing and 8 ft. bed, a Gould & Eberhardt shaper, a Norton emery grinder, an armature rack, water rheostat, and a pivoted crane, whose travel covers this pit, lathe, armature rack and drill press. On one side of this shop is a large board upon which all the shop

RESERVOIR PARK TERMINAL.
REPAIR PIT.

POWER HOUSE.

CAR HOUSE AND SHOPS.
INTERIOR OF POWER HOUSE.

to avoid the trouble and delay of changing them at the terminal points.

The use of these fenders has been attended with great success and the company has avoided several fatal accidents by picking up a number of children at different times who ran directly in front of the cars and who would have undoubtedly have been killed but for this protection. On one occasion three men were walking on the track in a very dark night and were not perceived by the motorman of an approaching car until the car was almost upon them. The car struck them while running at a good speed, and all three were picked up by the fender and carried some distance before the car could be stopped. When the car was brought to a standstill the men on the fender were found to be unhurt in any way.

The car barn is situated one block from the reservoir Park terminus and is a large building constructed of steel columns filled in with brick, steel arches and a corrugated iron roof. It is 84 ft. in width and 224 ft. long and contains 8 parallel tracks, 10 ft. between centers and 192 ft. long. In the rear

tools are hung. Upon this board is shadowed in black paint every tool which belongs upon it, so that in replacing the tools each one always occupies its own place. This board also enables the foreman to see at a glance if all the tools have been replaced at night, and if not, just what ones are missing. The machines are all run by a 15-h. p. Crocker-Wheeler motor standing on an elevated platform at one end of the machine shop.

The repair pit shown in the illustration is arranged so that the portion of the tracks under the wheel base of the car can be entirely removed, and the weight of the car is carried upon four screws running vertically through lugs on the four ends of the stationary track. A truck runs upon a track at the bottom of this pit and this truck contains a carrier which can be screwed up vertically under the car to receive the motors, wheels, etc., when they are disconnected from the car truck. They are then lowered and rolled out into the side extension of the pit, where they are picked up by the crane and transferred to the shop floor or to the machines.

A very convenient method of baking newly wound armatures and fields by electricity is in use in this shop, which was devised by Mr. O. G. Cosby, the master mechanic of the company. It consists of a water rheostat in series with the 500-volt railway current, and in the case of an armature two sections on opposite sides are left disconnected from the commutator and these are connected to the rheostat circuit which allows at first a small and afterwards a gradually increasing current to flow through the armature until the insulation is thoroughly dried out. An ammeter is placed in the circuit by means of which the amount of current supplied at any time is shown. This process, while probably not an economical one where a large number of armatures are being rewound, is extremely convenient and much cleaner than an oven, and where the rewinding of an armature is only an occasional occurrence as in this shop this method of drying is very advantageous.

The company maintains a very methodical and systematic inspection of all its cars, one-sixth of which are inspected each day so that the whole number of cars are inspected each week. A monthly record is posted in the repair shop upon a card containing the number of each car upon one side, and a space for each day of the month opposite each car number. When a car is inspected its condition is entered upon the card for the day of the month on which the inspection occurs, so that the master mechanic and motorman can see at a glance the condition of every car. Those cars marked "bad" are taken into the shop and repaired and this is entered on the card so that these cars are marked "good" on the date of their repair.

In the rear of the machine shop and separated from it by about 15 ft. is a paint shop built of corrugated iron capable of holding two cars. This is entered by means of the track, which runs over the repair pit, and the two parallel tracks in the paint shop are connected by means of a transfer table. Another small corrugated iron building in the rear of the machine shop and to one side of the paint shop is used for a store room for the shop supplies and car materials. It is divided into three rooms in which the stores are systematically arranged. Between the store room and the machine shop is a water tank and pump for supplying buildings with water, as city water is not available at this point. An isolated wooden building near the car barn is used for the line wagon, and also for the storage of the track and overhead material; the superintendent's office is situated in a building on Robinson St., directly opposite the car barn.

The present power house of this road is situated at the corner of 15th and Clay Sts., on the bank of a small stream called Shockoe Creek, but this plant will probably only be used for a short time, as the same interests which own the railway have organized a company for the general supply of electric power whose plant is now in course of construction. As soon as this plant is completed the railway power plant, which is now considerably overloaded, will be abandoned and the road will take its power from the new company's plant.

The power house now in use is a handsome and substantial building of brick and granite, which is partly shown in the accompanying illustration. It is divided into an engine room and a boiler room by a fireproof partition extending through the center of the building between the two roof arches. The roof is constructed of iron trusses covered with slate; the building has a frontage of 212 ft. and is 268 ft. deep. The engine room is equipped with two Hamilton-Corliss tandem compound condensing engines, made by the Hooven, Owens & Rentschler Co.; the cylinder dimensions are 16 in. and 30 in. by 42 in. stroke, rated at 450 h. p., and running at a speed of 102 r. p. m. Each engine is direct connected to a 300-kw. 6-pole G. E. generator. The engines are equipped with Cochran separators, and an auxiliary Chapman gate valve is placed in the steam pipe to each engine for use in case of emergency. The oil cups throughout the plant are fed from a tank placed near the ceiling on the partition wall, from which the oil is piped to all the machinery. After passing through the bearings it is carried to two filters in the basement by means of a system of pipes, and after filtering it is pumped back to the supply tank.

The switchboard is of the standard G. E. type, containing 2 machine panels, 1 station panel and 9 feeder panels. A lightning arrester is placed on the back of each panel in addition to its usual equipment, and instead of a negative panel the return circuits are brought in upon a bus across the back of the two machine panels. Alongside of the switchboard is a daily bulletin to be filled out by each of the three watches during the day. The items entered are the amount of coal

AUDITORIUM, RICHMOND TRACTION CO.

fired, water fed, water per lb. of coal, steam per kw. hour and coal per kw. hour, giving a complete record of the day's run. Each engine has a J. B. Davis & Sons feed water heater and a Dean condenser using water from Shockoe Creek.

The boiler room, which is about 10 ft. below the level of the engine room floor, contains two water tube boilers rated at 300 h. p. each, which have to be forced considerably to equal the engine capacity. The boilers use city water, which is particularly bad and has to be carried into a tank outside the boiler room and purified with boiler compound before using in the boilers. The boilers are fed by two Worthington feed pumps, measuring 7½ x 4½ in. by 10 in. and there is also an auxiliary heater in the boiler room, besides those mentioned above, into which the feed pumps and condenser pumps exhaust.

In front of the boilers is a track upon which a coal car runs from which the boilers are fired. There are scales at the boiler room door where the coal is delivered and each car load of coal is weighed here before being taken to the boilers, where it is fired by hand. Soft coal is used. The boilers are connected to a steel self-supporting stack 125 ft. in height. The room is lighted with two incandescent arc lights and there are three in the engine room, all being run in series on the railway circuit. Gas is also supplied for use during the time the engines are shut down.

Appreciating the value of amusement resorts as feeders to the traffic of its road, the company controls the large auditorium illustrated herewith located upon the line of its road. The building has a seating capacity for 12,000 people and is rented for convention purposes, etc. It is also used for vaudeville performances and other amusements.

The officers of the company are: E. R. Williams, president; W. M. Habliston, vice-president; R. L. Williams, treasurer; Jos. L. Young, jr., auditor, who succeeds J. A. Cook, just resigned, and S. P. Cowardin, superintendent. The road started in operation upon part of its line on June 20, 1896. The construction was in the hands of Mr. A. Langstaff Johnston, consulting engineer, and Mr. S. P. Cowardin, first assistant engineer. Mr. Cowardin then took charge of the building of the electric roads of Norfolk, Va., which are owned by the same interests and returned to take active charge of the Richmond road on Feb. 1, 1899. His management of the road has met with marked success, its operating expenses amounting to a little less than 49 per cent of its gross receipts.

E. C. HATHAWAY.

The organization of the Lexington (Ky.) Railway Co. by a Baltimore syndicate represented by Mr. R. Lancaster Williams, which was noted in the June issue of the "Review," has been followed by the appointment of Mr. E. C. Hathaway as general manager of the company's properties purchased from the Belt Electric Line Co., which operated the electric railway; the Central Electric Co. running the

E. C. HATHAWAY.

lighting plant; the Hercules Ice Co., and the Passenger & Belt Co.

Mr. Hathaway has had an extended experience in the construction and operation of electric lighting, steam and gas plants, and has been employed in the capacity of consulting engineer in the installation of several street railways. He was born in Southboro, Mass., Dec. 1, 1861, and was educated at Lynn, Mass. His first employment was with the Boston & Hingham Steamboat Co., after which he successively filled prominent positions with the Highland Street Railway Co., of Boston; the Boston & Albany Railroad Co.; the Chesapeake Gas Co., of Baltimore, Md., and the Washington Gas Light Co., of Washington, D. C. He was then associated with Prof. T. S. C. Lowe in the building of the Mt. Wilson Ry., of Pasadena, Cal., after which he was employed in the construction of the Colorado Springs Gas & Electric Light Co. He also rebuilt the plant of the Capital Gas & Electric Light Co., of Frankfort, Ky.

Mr. Hathaway was next employed with the Charlotte Consolidated Construction Co., of Charlotte, N. C., which connection he severed to assume his present position as general manager of the Lexington Railway Co., to which he brings a wide and varied experience of the different interests under his charge, which assures their successful management.

MAINTENANCE AND REPAIR OF ROLLING STOCK.

BY J. W. GREER, GENERAL MANAGER YOAKUM (TEX.) IMPROVEMENT CO.

PART IV.

Eternal vigilance is the price of satisfactory work from all classes of machinery and particularly in the case of electric street railway motors. No machinery is operated under more unfavorable conditions than is the street car motor; it is placed within a few inches of the ground, the dust, slush or mud of the street surrounding it, covering it and often penetrating it; its duties consist largely of quick starts, hard pulls, and sudden stops; it is too often controlled by one who has no more idea of its construction or weakness than a 10 year old child has of anatomy. Bearing these things in mind, is it any wonder that in the early days motors would sometimes play out and cars have to be "towed in." The astonishing feature to those who fully realized the conditions was that the apparatus could be made to work at all.

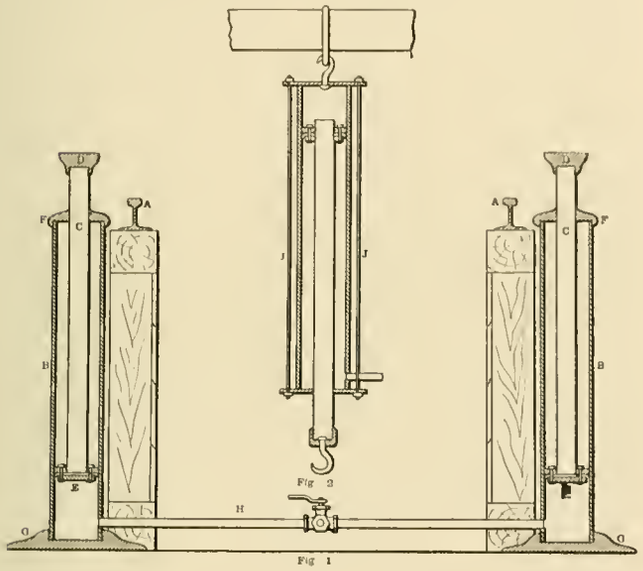
The motors of the present day are vastly superior to their forerunners and give extremely satisfactory service; this is due to the energy of the great electric companies and their willingness to spend money like water in making experiments.

When the writer looks back to the days when he saw Van Depoele with a cheese-box motor on the front platform of a horse car without trucks, geared with a sprocket chain to the front axle, and the car counterbalanced with switch frogs, brake shoes and scrap iron placed under the rear platform to keep the car from tilting up, or to the days and nights (mostly nights) when Sprague tried to make a single 7½-h. p. motor climb a 10 per cent grade with a 12-ft. car, aided and abetted by Crosby, Greene and others, he feels that the names of these men should of right be remembered for all time as the creators of electric railroading.

But speaking as one of the humbler "experts" who helped to work out the first problems of installation and operation, when installation and engineering meant to take a road and, single handed, change everything from the track construction to the office methods, adopt every appliance to fit the local conditions, break in every employe from the steam engineer to the track greaser and from motorman to bookkeeper, and required great assurance and versatility, the writer wishes to record his opinion that the magnificent courage of the capitalists who invested in such unpromising enterprises deserves to rank with the inventors and experimenters. If ever a blessing to man was conceived by accident, born of experiment and nurtured by wealth, it is the electric car motor.

This digression has proceeded far enough, and it is time to return to the immediate subject, maintenance and repair of rolling stock. The motor equipment must be kept clean, and the cleanings, daily, semi-weekly or weekly, according to the conditions, may be rapidly and effectively done by means of compressed air and a hose. But for thorough overhauling, complete examination, and perfect cleaning, the car body should be lifted from the trucks, the trucks rolled out and the motor cases opened, and everything blown out in the most thorough manner, after which a careful wiping with waste or towels (the latter preferred) is in order. With the aid of a pneumatic lift one man can remove the truck from a car or replace it in twenty minutes, and the ease and facility with which the work of cleaning and repairs can be made with the trucks and motors separated from the car as compared with the time required to do the same work with the motors under the car, is not comparable.

A simple and inexpensive lift may be made in your own shop, as illustrated in the accompanying sketches.



AIR HOISTS.

Fig. 1 is an end view of a repair pit fitted with pneumatic hoists for lifting the car bodies off the trucks. In constructing this hoist four air jacks are used, only two of which show in the end view. A, A are the rails of the tracks on which the car stands. The jacks are placed just outside the rails and pit frame, far enough, however, to allow the journal boxes or other projecting parts of a truck to pass when the pistons of the jacks are raised. The construction of each jack is as follows: B is 4-ft., length of extra heavy wrought pipe 8 in. in diameter. This pipe is threaded on both ends with a cap F over the top and a floor plate G at the bottom. C is a piece of pipe 4 ft. 3 in. long and 2½ in. in diameter which forms the piston rod. It is threaded on both ends with a cap D at the top end. The piston E is made of two pieces of iron with a leather cup between them. The top plate of the piston is a 2½ in. flange screwed onto the rod and just filling the pipe B. The bottom plate of E is a solid piece of iron ¼ in. less in diameter than B, and is bolted to its mate as shown; between the two is placed a piece of heavy leather having its edges turned down to form a cup. The air coming into the jack through the pipe H automatically sets out the leather cup against the sides of the cylinder and makes an air tight joint. The hole in the cap F through which the piston rod C passes need to be only a comfortable fit, and not a stuffing box, as no air passes above the piston E.

Each of these jacks will lift 3,000 lb. with an air pressure of 70 lb. or the hoist complete will raise a car body weighing 12,000 lb. The air pipes are arranged in the bottom of the pit and connected in such a way that the air is admitted to all four jacks simultaneously by a single, stop and waste lever valve, in the supply pipe. An extra valve at each jack can be put in the air pipes if desired. The cylinder being 4 ft. long and the intended lift not to exceed 3 ft., 1 ft. is left for bracing purposes between the cap F and the piston E, when the latter has been forced up 3 ft.

When the jacks are not in use the bearings D, D stand level with the top of the rails and completely out of the way. In raising a car body a piece of timber is laid across the sills underneath the car and on D, D. After the jacks are set, they need never be removed, and can therefore be built in the brick or cement floor permanently, or filled round with earth. There is nothing to wear out except the leather cup which packs the piston, and this is replaced when necessary by unscrewing F and pulling the piston out of the cylinder.

Each of these jacks costs less than $25 to build, as follows:

4 ft. extra heavy pipe, 8-in., @ $1.60	$6.40
4½ ft. extra heavy pipe, 2½-in., @ 20 cents	.90
Cap F	2.00
Flange G	3.00
Bearing D	1.50
Flange E	1.50
Plate E	1.00
4 bolts, .20, leather, .50	.70
Labor of assembling	5.00
	$22.00

To form the leather cup for packing the piston of an 8-in. jack, cut a round piece from sole or heavy harness leather, to a diameter of 10 in., place it over the end of an 8-in. pipe and drive a wooden plug (slightly tapered) into the pipe over the leather. The piece of leather should first be soaked in water until pliable; leave the plug in the pipe till the water dries out of the leather, and the latter will retain its cup shape. The wooden plug is, of course, the thickness of the leather smaller than the pipe. Of course the lift can be used for many purposes besides lifting car bodies from the trucks.

In addition to the lift described, a single cylinder or jack, inverted, and hung to a truss or joist overhead should be provided as shown in Fig. 2. As this hoist will lift 3,000 lb., motors can be picked up with it, wheels and axles lifted, one end of a car raised to take out wheels, motors dropped, motor cases opened and closed with it, etc. It is a quick and handy tool, which saves much labor and consequent expense. Instead of screwing the cap F, and floor plate G, onto B, as in Fig. 1, it is better to put a flat plate of wrought iron 10 in. in diameter, over the ends of B, drill a series of holes around and close to the edge of the plates, and connect the two heads together with long rods or bolts J, as shown in Fig. 2.

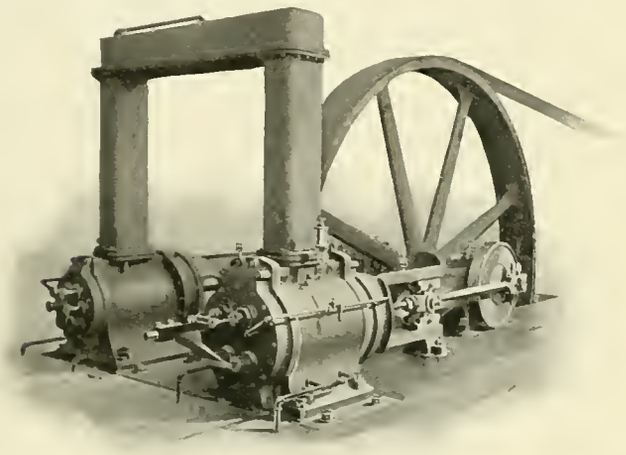
Besides the lifts described, the writer strongly recommends two other pneumatic tools for the maintenance and

repair department of a street railway; these are a reversible boring machine or compressed air drill and a pneumatic hammer.

If one has a pneumatic wood boring machine such, for example, as that made by the Chicago Pneumatic Tool Co., which weighs only 10 lb., almost any of the boring or drilling of a car or repair shop can be done. It will work in any position and in the most out of the way places; holes in places that cannot be reached by a brace and bit can be readily bored or drilled with this apparatus.

After you have used it for boring all the holes or drilling all the iron on a car, you can pass it to the engineer and he will find that a round wire brush on a long rod inserted in the boring machine is the finest flue cleaner he has ever tried. The wire brush is revolved rapidly through the flue and the machine reversed in bringing it back, straightens out the brush for another bout.

The other machine is a pneumatic hammer for the blacksmith shop. This machine, while operated by compressed air, is virtually the same thing as a steam hammer on a



RAND AIR COMPRESSOR.

small scale. The pneumatic hammer used by the writer is made by the Rand Drill Co., 100 Broadway, N. Y.

A simple feed handle regulates the length of stroke, or the force of the blow, and the operation is easily effected by the use of the operating handle, which is so arranged that one man can handle his work and the machine at the same time.

In this connection it may be stated that the air compressor in the writer's shop, and described in a previous article, is of the type illustrated made by the Rand company. This compressor, as stated, has cylinders 12 x 12 in. and 6½ x 12 in., a speed of 110 r. p. m., and compresses 174 cu. ft. of free air per minute, delivering it at 135 lb. pressure.

The writer does not believe in a street railway company embarking in the manufacture of electrical supplies, or in maintaining a complete foundry, machine shop or car building establishment. The trouble with a great number of small street railways is that they have too much machinery and too many men in the shops. The facilities for doing things, and the necessity of keeping the machinery in use, leads to the wildest extravagance, and the small amount saved in making the various supplies "in our shops," is absorbed many times over by the new parts used, where the old could be used longer if the men did not "have to be kept busy at something."

Contrive always to keep just a little more work ahead then can possibly be done by the force you keep. Every man will do his best to catch up, and your road will get value received for the wages paid, which should always be a shade higher than paid by others for the same class of work. Result: contented men, anxious to please, and desirous of holding their jobs.

Five men and two boys (apprentices) are sufficient to do all the work of maintenance and repair of one hundred electric cars, provided they understand their business and are furnished proper tools and machinery. Utility, and not quantity, is what is meant by proper tools and machinery.

The labor should be distributed as follows:

1 machinist and 1 apprentice to repair and clean motors.
1 armature winder to do all electric work.
1 painter and apprentice.
1 carbuilder or woodworker.
1 blacksmith.

The blacksmith must be willing to help both the machinist and the carbuilder, as he will not have enough to do in his own line to keep him fully employed, and both of the others will at times need help such as he can give. Mechanics who are only willing to do one thing are of very little use around the repair shops of a street railway.

In addition to the pneumatic tools already described, the machinery should comprise:

A pneumatic spraying machine for the paint shop with which the painter can rapidly and evenly apply all the first or rough coats of paint.

A hydraulic wheel press of 60 tons capacity fitted with the necessary tools for pressing on and off not only car wheels, but pinions, gears, etc., as well.

A lathe with an 8-ft. bed and a swing of 36 in., geared direct to a motor.

A band saw, a drill press, a grinding machine (emery wheel on one end of the mandril and a grindstone on the other).

An air pipe to the furnace of the blacksmith, and one in the armature room for blowing out fields, armature, etc.

This is all the machinery that is needed in the repair shops of a one hundred car road, and is sufficient to enable the number of men before mentioned to do the work with ease. But there must be at all times for the shop force ten cars out of that number, as follows:

Painter, four cars.
Carbuilder, two cars.
Machinist, two cars.
Car washers, two cars.

The painter should have in his shop always two cars which are being painted from start to finish, and the two cars which are being retouched and varnished. Cars properly varnished and retouched twice a year do not need repainting oftener than once every two years. A painter with less than four cars in the shop is compelled either not to do a day's work or to make a poor job by crowding.

The carbuilder must have continually one car in his shop which is receiving a general overhauling, and another which is receiving the daily repairs incident to the business.

The machinist must have one car in his shop which has the trucks removed and the motors being thoroughly overhauled, while he has another receiving the temporary cleaning and minor repairs.

The car cleaner should have one car cleaned and ready to go out, while he is working on a second car; thus he requires two cars.

Most roads nowadays have a double equipment of cars, but I am sorry to say few of them seem to be able to keep the equipment in shape to do the work intended, hence you continually hear the complaint from passengers, "this road runs box cars all summer and open cars all winter." Men cannot do work unles they have something to work on, so keep the work ahead of them in the systematic way pointed out, and never let a shortage of cars for a special occasion cause you to rob the shops. You might make a few dollars on that day, but you disarrange the shop system, and in the long run it costs you many times the profit made.

SECOND STRIKE AT CLEVELAND.

The strike on the Cleveland Electric Ry. which was begun June 10th and lasted till June 25th was settled, so it was thought, by an agreement reached on the latter date. The substance of this agreement covered five points as given in the "Review" for July, page 490. One of the articles provided that the non-union men employed by the company during that strike were to be retained and not subject to annoyance by the union men who were to be taken back and given 80 per cent of the runs.

The union men acted in bad faith and it was soon discovered that a car with a non-union crew would be stoned and the men assaulted. To prevent this the runs of the cars in charge of non-union men were not posted on the bulletin boards at the barns, so that the "sympathizers" could not be advised of what cars to stone.

The refusal to again post the runs of non-union crews was one of the grievances alleged by the men when a second strike was begun at 4.15 a. m. on July 17th. The immediate cause was the discharge of 10 union men who refused to go out on cars having a non-union man in the crew.

Cars were sent out about 8 o'clock on two lines and were mobbed, the crews being severely beaten. The violence increased and culminated in the blowing up of a car (by placing dynamite on the track) on the evening of the 20th. Later the same night a dynamite bomb was exploded at one of the car barns in an attempt to injure non-union men quartered there. The riots increased in frequency and violence and the state militia was called out to cope with the disorderly elements.

Five hundred troops arrived on the 21st and 500 more were ordered to Cleveland on the 24th. More cars were wrecked by explosives on the 22d and 23d. The first fatality was the shooting of one of the rioters by a non-union motorman.

By the 27th Mayor Farley had reached the conclusion that the time for diplomacy was past and when the city council, which proposed to appoint a committee to investigate the cause of the strike, he made a pertinent speech saying that "now is a good time for everyone to mind his own business." Soldiers were quartered in the school houses against the protest of the school trustees.

The strikers declared a boycott on the street cars, and everybody who rides on them, and on the soldiers, from which much was expected. It was to extend even to persons who sold goods to persons who rode on the cars; naturally this was too sweeping to last.

On the 22d the press committee of the strikers gave out a lengthy statement advocating violence, which was in part as follows:

"Let every man abide by arbitration, if such method of adjudication does not bear the unmistakable evidence of partiality.

"We believe that force can be applied in many instances, and that it is absolutely essential in the present case. Government protects life and property, but does not regard labor in any light whatever. We are lacking a principle in government because we cannot employ the forces of the government to enforce the demands of labor. Government runs the street cars and threatens to shoot the men who dare interfere.

"Therefore the power of the laborers is nullified by the very government which says the laboring man has a right to toil. When any form of despotism arrays itself against the struggling masses, it cannot be successfully coped with by common law. When great aggregations of capital defy law and wipe out competition, thereby diminishing the demand for labor, they must be met by an element strong enough to render their organization futile.

"This is the power the union men wield today. It is a power for great good in the community. It protects the poor from the oppression of the fabulously rich and keeps before the public eye the various stages of progress along the lines of economic development."

Dynamite outrages continued, nearly every day a car was reported having been injured by explosives.

The citizens of Cleveland are growing heartily tired of the violence which has attended this strike, and the press reports of August 9th contain the following paragraph:

"At an enthusiastic meeting of more than 200 business men this afternoon a fund of $10,000 was started for the suppression of lawlessness in connection with the street railway strike. Many speakers denounced the strikers and perpetrators of violence. As a result of the meeting a demand will be made for the establishment of a regular army post in Cleveland. Steps were also taken to increase the police force of the city. The appointment of a committee of five was authorized to take steps to lift the boycott. The meeting resulted from the blowing up of a Wade Park Ave. car with dynamite early this morning."

INDIANAPOLIS RAILWAY CAR PLANT.

The Indianapolis Street Railway Co. is erecting and equipping a plant for the manufacture of all its own street cars. Ground has been broken for the shop building and much of the machinery has been ordered. The building will adjoin the present car barns in West Washington St.; it will have a frontage of 200 ft. and be 200 ft. deep. Mr. Charles Remelius, who was connected with the Detroit car shops, has been appointed master mechanic of the Indianapolis shops now building. The plant, it is announced, will be as well equipped as any in the country, and will employ about 100 men at the start.

It is the company's intention to start building its cars as soon as possible and it is thought that some of the new cars built at home will be in operation by November 1st. For the first three months closed cars only will be built, and then Mr. Remelius will turn his attention to building open cars for service next season. The company expects within a year to build at least 300 new cars in addition to those remodeled. The new cars will each accommodate 50 persons comfortably. When the plant is fully equipped it will have a capacity of a new car a day. The bodies of the closed cars will be 22 ft. in length, with large platforms in the rear, upon which a smoking compartment will be built. The paint shop is designed to hold 20 cars.

The power plant of the company in West Washington St. is being enlarged and a complete new equipment of motive power has been ordered. It consists of a 2,000-h. p. engine, a 1,200-kw. generator, and three new boilers. The contract requires that this plant shall be in operation within six months. The old plant will be used as a reserve. The engine room and boiler room are being enlarged. The company has secured ground for building tracks and switches and will soon be able to land its coal and materials at the plant and shops by rail.

The company has also let a contract for a new car barn in Louisiana St., 100 x 180 ft. It will have a capacity of 50 cars, and will be finished, it is announced, by October 1st. The McLean Place barns will be enlarged, so as to accommodate 200 cars.

A large amount of reconstruction of track is being carried on, and about 25 miles will be rebuilt this year. All the reconstructed track is being laid with welded joints and eventually it is intended to weld all of the tracks of the system.

A new baggage car, built by the Cedar Rapids (Ia.) and Marion Street Railway Co. was put into service on that road on July 22d.

In the second trial of the suit of the City of Toledo against the Water Street Ry. last month, the city was awarded $8,860, which is $42,000 less than the verdict returned at the first trial. Both sides are dissatisfied and have asked for a new trial, the city claiming the damages incommensurate, and the railway company considering them excessive.

TRAFFIC ON CHICAGO ELEVATED ROADS.

All of the elevated roads in Chicago have shown marked gains in their traffic. During the first six months of 1899 the Metropolitan is reported to have carried 2,200,000 passengers more than in the corresponding period of 1898, the gain being about 19 per cent; for July the gain was about 26 per cent. The company does not make public information, but the talk of the stock brokers is to the effect that it has earned a dividend every month since the new company began operating.

The South Side for the first half of the year shows a gain of 17½ per cent in gross receipts, and the belief is current that its stock will soon be put on a 4 per cent basis.

Figures for the Lake Street are not at hand, but the increase is said to be very encouraging.

TERRIBLE DISASTER NEAR BRIDGEPORT, CONN.

The most appalling street railway accident of recent years was that near Bridgeport, Conn., on Sunday, August 6th, in which nearly twice as many lives were lost as in the terrible Cleveland bridge accident Nov. 16, 1895.

The Stratford extension of the Milford (Conn.) Street Ry., forming the last section of an electric line from Bridgeport to Ansonia, was opened for traffic on August 3d, having just been completed. About midway between Bridgeport and Shelton the road crosses Peck's Pond on a long bridge which is approached from the south end by an earth embankment descending on a 3 per cent grade for 250 ft. The rails used are 5½ in. deep and on the bridge are 6 x 10-in. guard timbers bolted to the ties. A section of the trestle near the scene of the accident is shown in one of the engravings.

On Sunday the traffic was heavy, it being the first holiday since the line was opened. A car left Bridgeport at 2 p. m. and when passing Stratford, which is two miles from the trestle, had 42 passengers on board. At this writing it is not known whether there were others taken on later or not. When the approach to the bridge was reached the car commenced to rock violently, and finally jumped the track just after passing the first pier. It ran over the ties for a distance of 85 ft., and then left the structure. The car, which was an open one, turned over, spilling all the passengers, who fell into the marsh, some 50 feet below, the car falling on top of them. This fact accounts for the great number of persons killed. Twenty-nine were killed and 12 seriously injured. Watches found on two of the bodies show the time of the accident to have been 3:23.

One man jumped from the front platform of the car when it left the track escaped without serious injury, having landed in soft mud. The motorman also jumped, striking the ties and thence falling into the marsh; he suffered only bruises.

VIEWS OF THE WRECKED CAR.

A NEW RAILWAY FOR STEUBENVILLE, O.

The city of Steubenville, O., is about to grant a franchise for a street railway for which bids have been advertised by the city clerk. The route, which is called the Steubenville and Mingo Route, commences at Ross and Third Sts. and continues in a southwestwardly direction to the city limits of Steubenville. Bids were called for with reference to the terms and conditions contained in an ordinance passed July 11, 1899. All bidders were obliged to specify the lowest rates of fare for which passengers would be carried over the proposed route, viz.: Single cash fare, number of tickets for one dollar, number of tickets for 50 cents and number of tickets for 25 cents.

Only one bid was received from a company known as the Wheeling Co., which gave bonds of $10,000 with the Baltimore Guarantee Co. as sureties. The Wheeling Co. offers to carry passengers at the following rates: Single cash fare, 5 cents; 22 commutation tickets for $1, 11 for 50 cents. 5 for 25 cents; children under 6 years accompanied by adult person, free.

Soon after the accident a force of men was at work removing the dead and injured, the greater number of whom were pinned under the car.

On the next day the coroner's jury examined the scene of the wreck. The car, which had sunk in the mud beneath the bridge, was removed and carefully examined. The wheel flanges were found to be in perfect condition. The brake and brake rod also were uninjured. The location of the controller handle showed that at the time the car left the bridge the current was turned completely off. Bridge experts who accompanied the jury, said that a car running rapidly over the earth approach would acquire a springy, swaying motion, because of the elastic properties of the earth. If a car traveled down the approach at a high rate of speed, they said, it would, at the time the trestle was reached, be swaying considerably. So long as it remained on the earthen foundation there would be little danger of leaving the irons, but when the bridge was reached the elasticity of the foundation immediately would be removed, the bridge being rigid and the tendency would be for the car to spring up from the rails.

George Hamilton, the motorman of the ill-fated car, was arraigned in the Stratford justice court charged with manslaughter.

BRIDGE OVER PECK'S POND.

He pleaded not guilty and the case was continued for one week. The prisoner's bail was fixed at $2,000, which he furnished.

Engineer W. W. Starr, who superintended the building of the bridge, said that the bridge was perfectly safe in every respect. In his opinion, after a thorough examination, the motorman became bewildered as the car commenced to travel fast down the incline and finding himself in a dangerous situation lost his head and turned the current on instead of reducing it.

Since the accident two other cars have jumped the track at other points on the road, no one being injured in either case.

Under the common law there was no civil action sounding in damages for the wrongful killing of a person; pain and suffering, cost of medical attendance, loss of wages, etc., being the elements of damage, no action would lie where death was instantaneous. This rule has been modified by statute in most of our states, but the Connecticut law is rather peculiar in that the damages recoverable where death was instantaneous are limited to $100. The important question in the suits which will doubtless be brought against the company, will be whether falling through a distance of 50 ft. or more is a cause of physical or mental suffering, as no less than 23 of the passengers were killed on striking the ground.

A CHAPTER OF LESSER ACCIDENTS.

July 29th a car on the Montgomery (Pa.) & Chester electric line left the track in Phoenixville and ran into a building. The car was wrecked and a number of persons hurt, but none seriously.

Two cars belonging to the Wilmington & Chester Traction Co. collided on July 8th near Bellevue and 14 persons were injured. The injured were promptly cared for by the company and those who were not able to be taken home were sent to the Delaware Hospital. The safety signal had been tampered with and the cars met on a grade where it was impossible to stop them.

July 30th there was a collision between a passenger car and an express car on the Winchester Avenue road of New Haven, Conn., near Woodmont. It is stated that the accident was due to the motorman of the express car trying to "steal" a switch; he was seriously hurt, being the only one on either car injured.

A slight collision occurred at the junction of 59th St. and Eighth Ave., N. Y. City on July 21st, caused by the stopping of a 59th St. car too suddenly when signalled by the flagman. Three cars were running very close to each other, and when the first made a sudden stop the second and third cars crashed together. Two passengers who stood up to see why the car stopped were knocked down, but not seriously hurt.

An electric car was wrecked on a curve between Joplin and Galena on the evening of July 16th. The car was slightly behind time and was running around the curve at a speed of about twenty miles an hour and its derailment is thought to have been due to a broken wheel flange. After bumping along the ties for 100 ft. the car left the roadbed and plunged down an embankment on one side.

There were about 40 passengers on the car when it left the rails, but none sustained any more serious injury than a thorough shaking up or slight bruises.

July 23d a collision occurred on the Bradford (Pa.) Electric Street Ry. which resulted in the death of one person, a passenger, the severe injury of one of the motormen and lesser injuries to nine others. One car was proceeding up a rather steep grade, followed at a distance of a block or more by a special car going after a funeral party. The motorman of the first car saw the car that he had expected to meet at the next passing point, approaching, and therefore shifted his trolley and started back to make another switch. The special car which had been following was concealed from view because of a curve and the two collided with the result stated.

A serious collision occurred at South Dighton, Mass., on the Summerset & Swansea road on July 17th. At the Gushee hill turnout the motorman of the regular from Summerset car failed to notify the motorman of the down car that specials were following him. The car from Taunton at once proceeded, but had not gone 500 ft. beyond the turnout when the first special came into view through the fog, and before the motorman could put on the brakes the cars came together with a terrible crash, and the second special, coming along, collided with the other two. The motorman of the Taunton car jumped and fell into the river, but was rescued with slight injuries.

A serious collision occurred on the Fort Rouge line of the Winnipeg Electric Street Railway Co. on a curve in River Park, July 12th. One car was returning to the city from the terminus of the park line and had the right of way over the single track as far as the first siding where the car in the opposite direction should have been passed. The first car it is alleged passed the siding without stopping, contrary to orders. The second car which was loaded with passengers going to the park approached the curve at a good speed when it came in sight of the other car. The conductor of the first car succeeded in stopping and even reversing his car when the impact occurred, but the loaded car which was an old one had its vestibule completely wrecked, severely wounding the motorman and several passengers.

During a terrific thunder storm on the afternoon of July 7th, a head end collision occurred on the Akron, Bedford & Cleveland Ry., in which one passenger was killed, three fatally wounded and nine others injured. The collision occurred between a passenger car and a construction train near Season's switch, about three miles from the power house of the suburban road.

Shortly after 1 o'clock in the afternoon a motorman was dispatched from the power house to Northfield to bring back a stone car which had been used in construction work. He received orders from the train dispatcher not to proceed back to the power house before he received orders to do so. After finding the stone car fully loaded the motorman coupled the car onto his motor and waited for orders to move.

While waiting, the heavy storm came on and he could not reach

the train dispatcher by telephone. Believing that the telephone wires were disarranged by the storm and that he might be expected to move, he concluded to pass the Cleveland-bound car at Season's switch.

The northbound car passed Season's switch as per order and proceeded at full speed to the next switch. Some distance from Season's switch the two cars came together on a curve. The stone car cut its way almost through the passenger motor car. There were fully 20 passengers in the car at the time.

Two trolley cars collided at right angles in Brooklyn on July 8th at the crossing of Myrtle and Nostrand Aves. The Myrtle Ave. car was uninjured and proceeded on its way, but the Nostrand Ave. car was thrown across the track, blocking the line for half an hour. The latter car contained about 100 passengers, mostly women and children, several of whom were slightly injured.

PRESS COMMENTS ON THE CLEVELAND STRIKE.

It is the sort of a strike that some so-called labor leaders love to be mixed up with. It means bitterness and bloodshed, death and dynamite, and after it is all over the cause of labor in the city of Cleveland will be worse off than it was before. It cannot be otherwise.—Binghampton (N. Y.) Herald.

It remains to be seen how long the people will submit to the bullying of a mob which has had the effrontery to justify the use of dynamite, and which is now resorting to a vindictive and cowardly boycott. It is the duty of Cleveland to protect every man in the right to work if he chooses; to protect every man who chooses to ride on the cars, and it is equally the city's duty to protect the right of every merchant and shopkeeper to trade with whomsoever he pleases, and whenever and wherever he likes. No quarrel between employer and employed justifies the taking away of these elementary rights. Life and property must be protected whenever or however assailed.

The discharged employe who strives against the supremacy of the law makes a fatal mistake. As the Courier-Journal has repeatedly observed, the law is the poor man's best friend. The law is all that protects the weak and the poor from the strong and the rich, and whenever the law is assailed the poor man deprives himself of his only and most powerful protector.—Louisville Courier-Journal.

A Cleveland physician gave two boycotters an answer that they will not forget in a hurry. Yesterday afternoon he received a call to quickly attend a little girl, who is one of his patients who is at death's door. He started for the child's home. Her father is a motorman on one of the Big Consolidated cars. The physician had proceeded some distance when he was accosted by two men.

"I would advise you," said one of the men, "not to visit that—— scab's house. We know you have been going there, and thought you would be glad of a little friendly warning."

The physician regarded them contemptuously and answered: "Don't boycott me," he said, "although I have visited this child and shall continue to do so. Boycott God, for the child will not live long. Tell God that He must not allow her to enter heaven. Should he insist on doing so, boycott him by refusing to patronize heaven yourself."—Cleveland Leader.

The application of the boycott has assumed such a phase as to show the utter inhumanity of the men who enjoy it. When a doctor is warned by boycotters not to attend a dying girl because her father is a "scab," the heartlessness manifested is suggestive that the men who use it are not entitled to consideration as human beings. Such heartlessness robs the men resorting to such methods of all sympathy, and strikes and strikers are alike classed as relics of a past barbarous age. The term strike has lost its original significance, and now means little less than organized resistance to society and its laws, an organized denial of the right of one man to work unless under prescribed rules, and of another to hire outside of a self-constituted autocracy called a union. Until organized labor modifies its methods in this respect it will never receive the sympathy of the millions of men who are outside it, and the better class inside. In all these unions the strikes are originated, promulgated and managed by the least reputable elements, while the better class submit to a dictation they know to be unwise and unjust. The Review has thorough sympathy with the organization of labor for its own advancement and protection. But such an organization should be on lines that embrace the rights of others as well.—Elkhart Review.

WORK ON THE CHICAGO NORTHWESTERN ELEVATED.

Work has been resumed on the construction of the Chicago Northwestern Elevated R. R., which was organized in 1893 by Mr. Chas. T. Yerkes, and parts of which were built previous to 1896. The building of the road was let to the Columbia Construction Co., which consisted of the same people as those interested in the Northwestern Elevated. Owing to financial difficulties the work was stopped in 1896 until the present year, when a loan of $4,500,000 was made through Blair & Co., of New York, for the completion of the road. To secure the loan the entire capital stock and the bond issue were deposited with the Illinois Trust & Savings Bank. The contract with the Columbia Construction Co. was rescinded and the work is now carried on by the Northwestern.

The company commenced the work on this road last month at Dayton and Halsted Sts., and will push forward rapidly the completion of the section from Dayton St. to one square south of Cleveland Ave., a distance of nine squares. There are gaps between Hudson and Orleans Sts., and between Division and Hill Sts., for which the steel has not yet been rolled. The material is on the ground for the construction of the section from Orleans St., south of Division St., and the section between Hill St. and Institute Place. The material for the line from Institute Place to Michigan St. is at the mills ready for shipment.

The contract has been let for the building of the terminal station at Wilson Ave. This building is to be constructed of brick and steel, and will be 400 x 65 ft. in size. It will have a capacity for housing 40 motor cars, which will be put in operation when the line is open for traffic. The work on the viaduct at Wells St. will be completed in about three weeks.

In all, there will be 25.45 miles of track, of which 23.92 miles will be used for running trains, and the rest for car storage.

From Institute Place to Wilson Ave., a distance of a little more than 5½ miles, the road will be four-track, and it will be two-track from Institute Place to its connection with the Union Loop at Fifth Ave. and Lake St. Express trains will be run, which will make stops only once in each mile between Wilson Ave. and Institute Place. These trains will run from Wilson Ave. into the heart of the business district in a little more than 25 minutes.

The walls of the power house at Fullerton and Southport Aves. are completed, ready for putting in place a part of the trusses for the roof. The stack has been finished.

The present expectation is to have the road in operation by the last of March, 1900. Delay in the turning out of the structural steel by the mills has made it impossible to complete the road and have it in operation as early as was first expected.

Fifty out of a total of 147 cars have been completed and are ready for the track. The present plans include a connection with the Chicago & North Shore Street Ry., which will be made by means of an inclined plane, landing passengers on the station of the elevated road.

Several cars on the East St. Louis Ry. lines were placed at the disposal of the Ladies' Auxiliary of the Protestant Hospital Association on Saturday, July 22d. The cars were officered by a number of the prominent ladies of the city from 6 a. m. until midnight, and a considerable sum in fares was collected by the lady conductors for the benefit of the hospital.

The Missouri state board of equalization has recently made an important increase in franchise assessments of nearly $15,000,000. Of this increase $10,294,355 was upon the street railway systems of the city of St. Louis. Of the balance, $1,500,000 was upon the Kansas City street railways, and $500,000 upon the property of the Western Union Telegraph Co. in the state. The increase of assessment will increase the tax receipts $222,000.

AN ADVERTISING CIRCULAR.

The accompanying illustration and the matter quoted are from a small circular issued by the Rapid Railway Co., Detroit, Mich., for which Milton Carmichael is excursion agent. The advertisement strikes us as being an excellent one and it will doubtless interest the managers of other interurban lines. The reading matter is in part as follows:

INTERIOR VIEW OF RAPID RAILWAY PARTY CAR.

JUST A LITTLE HINT TO CLUBS AND SOCIETIES.

The time of the year has now arrived when it is pleasant to have social gatherings away from home—away from halls and the conventionalities of the winter.

Did you ever think of trying the trolley car diversity?

When the Rapid Railway party car turns out it is as neat as a parlor, cozy and comfortable, so that the occupants cannot help but have a good time. A number of conveniently arranged tables fix it just right for the serving of refreshments or for a card party.

Arrangements easily made at Mt. Clemens for dancing and other socialties.

PATERSON RAILWAYS SOLD.

Negotiations have been concluded for the sale of the lines of the Paterson Railway Co. to the Shanley syndicate, which controls the North Jersey Traction Co. The Paterson company's lines were practically the only ones in the northern section of the state which were not either owned or controlled by the syndicate, of which Mr. B. M. Shanley is the head.

The syndicate has for a long time been desirous of securing the Paterson lines and for some time past there have been heavy sales of the stock, a large number of shares changing hands. As was the case when the syndicate secured control of the North Hudson County Railway Co., and later the New Jersey Electric Railway Co., there will probably be no change in the directory of the Paterson Railway Co. for some time, as sufficient stock will be retained to entitle the present directors to continue to act as such. The control of the road, however, is now in the hands of the syndicate, and it is reported that the stock was purchased at its par value.

ELECTRICAL CONGRESS IN VIENNA.

The Electrotechnical Congress held in Vienna June 15-17, 1899, proved to be a great success, there being nearly 400 delegates and engineers in attendance. The papers and discussions dealt with electric railroads, lighting stations, and telephone and telegraph systems. Numerous excursions to notable electrical installations and other points of interest were made after the business sessions of the congress were over and on the second evening a banquet was held.

PRIZES FOR DIAGRAMS OF OVERHEAD WIRING.

We feel sure that all street railway men who are called upon to design or erect overhead wires on complicated crossings or curves would be interested in knowing of some of the problems that have been met in different cities and the ways in which they were solved.

In order to get information concerning a number of such overhead installations, the "Street Railway Review" offers two prizes for suitable drawings, the necessary description to accompany them. It is understood that we shall be at liberty to use all of the diagrams submitted.

First. A prize of $15 for the best example of overhead work at crossings or curves actually installed where all the overhead wires belong to one company, and there is no necessity for insulating the different lines from each other.

The points on which the award will be based are: a. Difficulty of the problem, such as number and location of switches, crossovers, etc. b. Excellence of the design, which includes the location of the poles, the arrangement of the span wires, pull-off wires, hangers, cars, etc. c. The neatness of the drawings will be considered in making the award.

Second. A prize of $15 for the best example of overhead wires at crossings or curves actually installed where the lines belong to different companies and it is necessary to insulate the different systems from each other. The basis of the award will be the same as in the first class.

RECONSTRUCTION AT MACON, GA.

The Consolidated Street Railway Co., of Macon, Ga., is reconstructing its entire roadbed, putting in 70-lb. T-rails. This makes the third time that the greater part of this road has been rebuilt. It was originally laid with 30-lb. rails, which were afterwards replaced with rails weighing 45 lb., which at the time were considered sufficiently heavy to last indefinitely, but experience has shown that the life of light rails on electric railways is very short.

Through the business districts of the city, where the traffic is heaviest, brick paving is used and a special brick is used next to the rail similar to the pavement of the South Bend (Ind.) Street Ry.

The accompanying illustration shows a "dinky" car which is used on some of the outlying lines of the Macon Consolidated. Many roads in the country are running large cars through thinly populated districts, where not more than seven or eight passengers

"DINKY" CAR, MACON, GA.

are picked up on a trip. Mr. E. E. Winters, superintendent of this company, has several such runs on his lines for which he has utilized cars 10 ft. in length. They were formerly mule cars which have been remodeled and equipped with a single 35-h. p. motor. Each of these cars is run by one man only, and they make such good speed that they have become very popular. The result of their use has been satisfactory to both the company and to its patrons.

The handling of the soldiers which were in camp at Macon during the winter greatly increased the winter's receipts.

ATLANTA ROADS OFFERED TO THE CITY.

As a Result of a Hot Franchise Fight Joel Hurt Makes a Proposition to Sell to the City.

The state of Georgia, on the petition of certain citizens of Atlanta, some time since began proceedings against the Atlanta Consolidated Street Ry. and the Atlanta Ry. to prevent a consolidation of the roads; it is urged that a consolidation would be in violation of a state law, as tending to prevent competition. As we understand the situation, the Trust Company of Georgia, of which Mr. Joel Hurt, formerly president of the Atlanta Consolidated, is president, purchased the stock and bonds of the Atlanta Railway Co. and the stock of the Atlanta Consolidated with the intention of effecting a consolidation, the operation in future to be conducted by the Atlanta Railway & Power Co. The plan to consolidate was abandoned as illegal, but the two roads being owned by the same parties, the officers of the Consolidated were chosen to similar position in the Atlanta Railway Co., and the operation put practically under one management.

The ostensible cause for instituting the legal proceedings was the declared intention of the Atlanta Ry. to take up its tracks in one of the streets, but the railway people contend that the suit is really brought by the Georgia Electric Light Co., which fears the Atlanta Railway & Power Co. would hurt its business.

Mr. H. M. Atkinson, of the Collins Park & Belt Railroad Co., and president of the Georgia Electric Light Co., made applications for street railway franchises covering the city and paralleling the Railway & Power company's lines.

On July 26th, Mr. Hurt addressed the following communication to the council:

"To the Committee on Electric and Other Railways of the City of Atlanta. Gentlemen: I herewith suggest the following propositions to the city government which, if acceptable, I will recommend and endeavor to have promptly accepted by the Atlanta Railway & Power Co. and the Atlanta Railway Co:

"The recent financing of these companies provides for a bonded stock issue of $2,000,000 and a bonded indebtedness of $5,000,000, of which there is reserved for future extensions and improvements $750,000. The bonds in reserve will build a new power and lighting station of sufficient capacity to light the city's streets and to supply power and lights for domestic and manufacturing purposes. It is estimated that after building a lighting station there will be left in reserve a large amount of bonds, which will be used for future extensions of the lines. A proper sinking fund is to be provided for the bond issue. The bonds will all bear 5 per cent, except $225,000 of the bonds of the old Atlanta Street Railway Co., which will bear 6 per cent.

"I propose that out of the annual earnings, commencing January, 1900, the dividends on the capital stock will be the first year 4 per cent; for the year 1901, 5 per cent, and thereafter 6 per cent. All dividends above 6 per cent will be divided one-fourth to the stockholders and three-fourths to the city for improving the streets and for public schools.

"The companies, acting with the city, to lay out and build all extensions of lines which may be needed, and in the event of any disagreement, the same to be determined by a commission to be established by the state legislature.

"The city to have the right at any time, after twelve months' notice to the companies, to purchase the properties by paying par for the stock, after any dividend period, and assuming the bonded indebtedness.

"In order for the city to receive the benefits of such an arrangement and to avoid a constitutional objection, if any, the companies' franchises to be amended in accordance with this agreement.

"If at any time the city of Atlanta should deem it advisable, the arrangement entered into can be terminated at its option, and the present rights of the company be reinstated.

"By this arrangement the companies will continue to pay their taxes, but the paving laws to be so amended as to relieve the companies from paving, except to restore paving which it may remove.

"In order to secure good service to the public, all complaints and criticisms to be left to an officer to be selected by the city, who shall have authority to adjust the same with the companies, and failing, to make complaint to a commission to be established for the purpose.

"The entire matter to be considered and so arranged as to secure to the companies and stockholders their rights and to secure for the public and to the city a proper discharge of the obligations of the public carrier.

"I am moved to suggest this proposition by a consideration of the fact that the franchises which have been granted and have for years proven unprofitable to the owners of the street railway companies, have now grown to a value on account of the increased population of the city, which merits a consideration of the advisability of the city's securing, if possible, a fair interest in the future growth of the property, and the further consideration that the owners of a large majority of the stock of the companies are Atlanta citizens, who will be satisfied with a reasonable return for their investment, and who, it is believed, would be willing to so adjust these public utilities as to secure to the city great benefits in the future, which might otherwise be enjoyed by foreign investors in the stocks of the companies, and which could not be reclaimed until the expiration of the present franchises, running from forty to fifty years.

"It is believed further that by this method the city of Atlanta can now secure and hold in reserve the right to own the properties which may in the near future be deemed advisable. Respectfully,

"JOEL HURT."

Two days later Mr. Hurt modified this proposition by limiting the dividends on the $2,000,000 of stock to 3 per cent for 1900; 4 per cent in 1901, and 5 per cent annually thereafter; all dividends to be paid out of net earnings. After 1902 all dividends in excess of 5 per cent to be paid one-fourth to the stockholders and three-fourths to the city.

As in Detroit many citizens who have supposed they were in favor of municipal ownership, are not so sure of their own mind when brought face to face with the actual proposition; and when they consider the responsibilities to be assumed and the political power involved are unwilling to recommend the deal.

The Atlanta situation has been growing more difficult for several weeks, until Mr. Hurt evidently concluded to make a grand charge on the enemy. A council committee has been appointed to study into the proposition and report.

CARBONDALE TRACTION SOLD.

The controlling interest in the Carbondale (Pa.) Traction Co. has been sold to stockholders of the Scranton (Pa.) Railway Co. and the new officers were chosen on August 1st. The Carbondale Traction Co. is the successor to Lackawanna Valley Rapid Transit Co. and the old Carbondale company, and operates 20 miles of electric railway. It is expected that the road will eventually be consolidated with the Scranton and Wilkesbarre systems, and one of the first things to be done is the changing of the gage from its present width to standard.

Upon the transfer of stock being made E. E. Hendrick, president, and R. A. Jawdin, secretary and treasurer, resigned and the following officers elected: President, Clarence M. Clark, of Philadelphia; vice-president, Frank Silliman, jr., of Scranton; secretary and treasurer, R. A. Jadwin, of Carbondale, who was re-elected.

Mr. Clark is president of the Scranton Ry. and Mr. Silliman is manager.

Mr. C. E. Flynn has been manager of the Carbondale road for several years, and it is largely due to his efforts that the property has been brought up to a condition where it was a desirable purchase. Mr. Flynn will continue as general manager.

MR. LOWRY'S PRIVATE CAR.

A new car built for the use of Mr. Lowry and other officers of the Twin City Rapid Transit Co., and their friends, was placed in service a few days since. It is equipped with a toilet room, buffet, card room, large wicker arm-chairs replete with cushions, carpeted floor, hand-painted panels and ceiling, and all the luxuries which taste could suggest for a parlor on wheels.

The car will be placed at the disposal of President McKinley when he visits Minneapolis.

THE OLDHAM, ASHTON & HYDE TRAMWAY.

The Oldham, Ashton & Hyde (England) tramway, power for which is furnished from the electrical works of the Ashton Corporation, was completed on May 25th last and favorably opened for traffic on June 12th. This road and the Corporation plant are the subjects of an interesting article in the Electrical Review, London, from which the following details have been gathered. The road runs through residential and manufacturing districts, connecting the three cities named; along the route are many sharp curves and

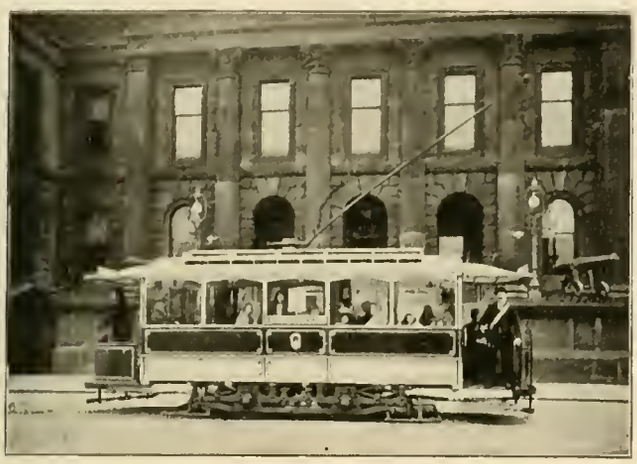


FIG. 1—CAR AND LINE IN ASHTON.

grades, the steepest being about 9 per cent. The line at present consists of eight miles of single track with turnouts, but important extensions are in contemplation. The equipment is of the overhead single trolley type.

Fig. 1 shows the style of cars used on this road of which there are 26 motor cars and 12 trailers with closed bodies mounted upon single trucks of the Peckham cantilever type having a wheel base of 5 ft. 6 in. The cars are 26 ft. long over all with a seating capacity of 26 passengers inside and 2 on each platform. Each car is fitted with two 27-h. p. G. E. motors. The trolleys are of the Boston pivoted type with Dawson swivel heads but these are to be changed in accordance with the recommendations of the Board of

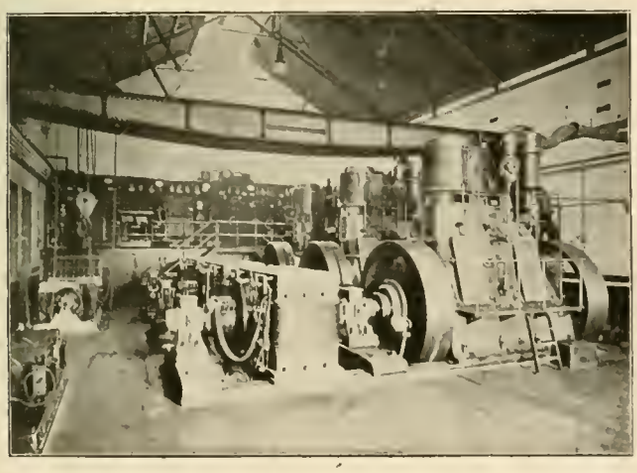

FIG. 2—GENERAL VIEW OF ENGINE ROOM.

Trade to the straight under-running type with detachable heads so that if the trolley jumps off the line and strikes the overhead wires the head will be pulled off without injuring the line work. The K 10 series parallel controllers which are in use at present are to be superseded shortly by the B 13 type, with Westinghouse electrical brakes, one of which is already in use. The trailers as well as the motor cars will be supplied with electric brakes so that the whole control will be in the hands of one motorman.

The road is built to standard gage with 94 lb. girder rails which are machined at the ends for Dick, Kerr & Co.'s patent fishplates. These are 20 in. long and, as will be seen from the illustration, are designed to give a continuous running surface over the joints. The rails are tied to gage every 8 ft. with tie bars and are laid on a 6 in. bed of concrete except where the ground is very soft. At such points the rails are laid on 6 x 12 in. stringers set on a concrete foundation. The rails are bonded with two Chicago bonds at each joint with cross bonds at frequent intervals.

The overhead work is carried principally on iron side poles with span wires, although a few poles with brackets are used in certain narrow streets. Some of the poles carry arc lamps on top. The trolley wire is No. 0 B. & S. of hard drawn copper and is double throughout to avoid overhead switches. Guard wires are also used.

The feeder cables, of which there are 25 miles in all, are lead covered with paper insulation, and are laid directly in the ground without further protection except in the made ground where wooden troughs are used filled with a bituminous compound.

STATION.

The electric station of the Ashton Corporation is a combined lighting, railway and destructor plant and is essentially up to-date, the whole of the pumps and accessories being electrically driven.

The engine room contains three 650 h. p. units each consisting

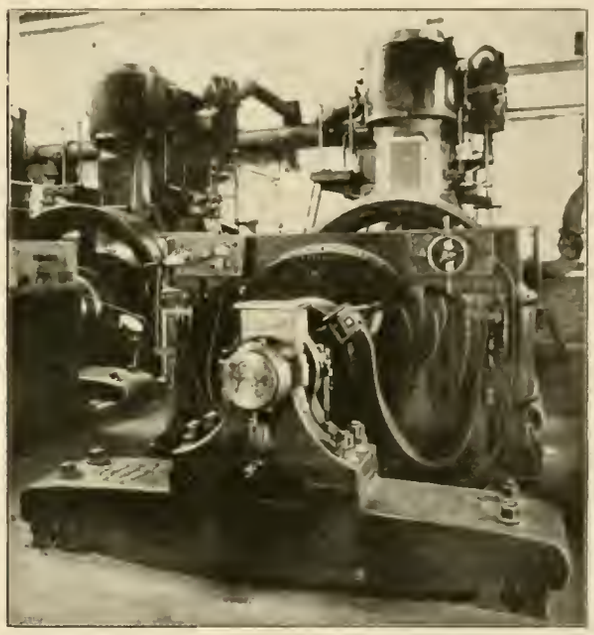

FIG. 3—END VIEW OF GENERATOR.

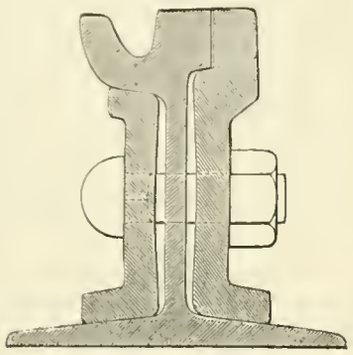
of a Browell—Lindley compound engine direct connected to a 2-pole dynamo made by P. R. Jackson & Co., Ltd. The engines are enclosed with casings and are equipped with Westinghouse and Rite's patent central valve. They are supplied with steam at 140 lb. pressure; the cylinder dimensions are 16½ and 31 x 17 in. The governors are of the Begtrap automatic fly-wheel type which act on both cylinders and are regulated by a sliding weight which can be adjusted to govern at 190 r. p. m. for lighting and 210 r. p. m. for traction. A general view of the engine room is given in Fig. 2 which shows the two fly-wheels on each engine, one between the engine and dynamo 8 ft. in diameter and weighing 3 tons, and the other on the outside of the engine. The latter contains the governor. Forced lubrication is provided for all the moving parts by two sets of oil pumps to each engine, one of which is held in reserve, and the oil is supplied under 25 lbs. pressure. Each engine is supplied with a steam separator, blow-through valves for warming up the cylinders and a water circulation around the slides which is used chiefly for emergencies. "United States" metallic packing is used throughout. The normal capacity of each engine is 500 h. p. non-condensing and 650 h. p. condensing.

A general view of the dynamos is shown in Fig. 2 and a more detailed view in Fig. 3. These are provided with a special winding designed to give 550 amperes at 550 volts for traction purposes, and

680 amperes at 400 volts for lighting. At the left hand side of the pole piece in Fig. 3 will be seen a two-way switch. This is used to cut out the series winding when the dynamos are used for lighting, and on the right hand side is an equalizing switch for running in parallel with the compound winding. The armatures are wound on the Jackson-Sayers patent system, with Lewis and Howitts patent polar extensions. The efficiency of the machines is said to be such that the full load may be switched on or off, with either the shunt



RAIL JOINT.

or compound excitation, without causing sparking, while the brushes need not be shifted under any change of load. The field magnets are of cast steel and the shunt winding is outside the series coils. The armature is 44 in. in diameter and 36 in. long, with a toothed core and wound with copper bars with evolute end connections. The armature core is ventilated and the shaft is hollow, being provided with Lewis's oil throwers which lift the oil from a reservoir and throw it into catchers whence it flows into the bearings. The brushes are staggered, the middle one of "Boudreaux" white metal foil being set a little ahead of the other two which are of copper. The coupling is insulated with ebonite and rubber bushings around the pins and the fields and bearings are magnetically insulated from the bed plate by heavy zinc separators.

There are two smaller machines in the engine room shown at the left of Fig. 2. One of these is a motor generator consisting of a 75-kw. compound generator and shunt motor. The series winding is used when the machine is transferring power from the lighting to

FIG. 4—DESTRUCTOR AND PART OF BOILER HOUSE.

the traction mains but may be switched out when the machine is running on the traction mains to assist the lighting. It is also used for carrying the day lighting load or for charging the storage batteries from either sets of mains. The other small machine is a balancer for regulating the lighting system which is on the 3-wire plan. The two small machines are nearly alike and are in general similar to the large dynamos.

A battery of 240 Plante cells is contained in the engine room back of the switchboard. This has a capacity of 50 amperes for 9 hours or 110 amperes for a short time.

The switchboard partly shown in Fig. 2 contains 9 panels. The first three on the left are dynamo panels, each containing a double pole main switch, voltmeter, ammeter, double pole fuses, shunt switch interlocking with main switch, and shunt rheostat, also a small switch which cuts out with a small reverse current. The latter is used instead of a minimum current cut-out for, as the dynamos are used for traction as well as lighting, if all the cars stopped at once a minimum current cut-out would cut out the line. The fourth panel contains + and — voltmeters, a neutral ammeter and plug bars for four feeders, one for balancing distributor and one for traction. Also on the back of this panel are seven plug bars, four for dynamos, two for motor generator and one for battery discharge. The fifth is the station panel with main switch and circuit breaker, lightning arrester, total ammeter and Thomson wattmeter. The next panel is for the motor-generator and contains two volt meters, two ammeters, current direction indicators and a complicated set of interlocking switches for operating the motor generator. Panel No. 7 is the storage battery panel, No. 8 is the balance panel and the last three are feeder panels fitted with the usual apparatus.

The station supplies public arc lights up to midnight and each lamp post is provided with two incandescent lamps which are used instead of the arcs after midnight. These are changed over by a 2-way switch.

The boiler room, partly shown in Fig. 4, contains three tubular boilers of the Lancashire type, each 28 ft. long by 8 ft. in diameter. The heating surface is 990 sq. ft. and the grate area 44 sq. ft. Green economizers are used consisting of 280 9-ft. tubes, the scrapers being driven by a motor. The feed pump is a 3-throw ram pump delivering 4,000 gallons of water per hour against a pressure of 140 lb. An independent injector feed is also supplied. The feed pump is driven by a motor from the 440-volt mains but arrangements are being made to run it at a lower speed on 220 volts.

A separate Ledward ejector condenser is placed in the exhaust pipe close to each engine and fed with a head of 20 ft. of water from a tank over the pump room. From the hot well the water is pumped through a Ledward cooling tower by a centrifugal pump driven by a 22-h. p. motor. A similar pump afterwards raises the water from the cooling tower to the tank above the pump room.

The destructor, Fig. 4, situated at one side of the boiler house, consists of six cells. The gases from the cells are led through two multitubular boilers, each 11 ft. long by 8 ft. in diameter which contain 106 tubes 3½ in. in diameter. The draft passes around the sides and underneath the boilers. The heating surface of the tubes is 1,065 sq. ft. and of the shell plates 154 sq. ft. A small tramway runs around the destructor for the removal of clinker to a mortar mill where it is mixed with lime and sold for building purposes.

MAY NOT CARRY FREIGHT IN DETROIT.

July 27th, Judge Lillibridge of the Wayne Circuit Court enjoined the Detroit street railway companies from hauling freight through the streets of the city. The suit was instituted over a year ago and the decision is based on the fact that there is no city ordinance providing for carrying freight. The injunction is against "carrying, handling, or transporting upon cars over the lines of its railways, within the limits of the city of Detroit, slag, cobblestones, sand, or other material or heavy freight, except that which is necessary to be used by the company in the construction and repair of its tracks and roadbed."

Nearly all of the interurban electric lines about Detroit will be affected by this ruling, as the freight traffic was increasing and promised to soon become profitable.

Later advices state that hauling freight has not been stopped, notwithstanding the order of the court, as the merchants and business men generally demand that it be continued. If the Supreme Court affirms this decision it is almost certain that the suburban lines will be given freight franchises.

The number of passengers last year on the electric railways in Canada was 100,000,000, an increase of over 19 per cent compared with the previous year, when the number was 83,811,306. This is a most satisfactory showing, but the present year will be still more favorable, as there is a steady expansion of electric railway systems in Canada.

INTEREST ON CASH DEPOSITS.

The Cincinnati Street Railway Co. has effected what we believe is a very happy solution of the bond and deposit question which in many instances has provoked hurtful controversy between companies and their employes. Mr. James A. Collins, secretary and assistant general manager, has sent us copies of the resolutions adopted by the directors; they are as follows:

"Whereas, The Cincinnati Street Railway Co. has endeavored to provide a method for bonding its conductors, motormen and grip men by a reliable surety company and at such time to refund to said employes the amounts of their respective deposits, but has been unable to make arrangements satisfactory to a majority of the employes thus interested; and further, it desires to place the said employes with respect to their deposits upon an equal footing with the stockholders of the company; therefore it is,

"Resolved, That a dividend of 5 per centum per annum be and the same is hereby declared upon the deposits of all conductors, motormen and gripmen for the fiscal year ending June 30, 1899, payable on the 15th day of July, 1899 and that annually thereafter on the first day of July succeeding, an annual dividend at the same rate paid stockholders shall be paid to all conductors, motormen and gripmen upon their respective deposits."

On a request from some of the collectors to be permitted to deposit money in lieu of giving bond, the following was unanimously adopted:

"Resolved, That any employe who is required to furnish a bond for faithful performance of duty, etc., may at his option deposit with the treasurer of the company money to the amount of the required bond, upon which said deposit dividends will be paid annually on July 1st succeeding, at the same rate paid to stockholders; same to prevail until further orders."

AMERICAN TROLLEYS FOR PARIS EXPOSITION.

One of the exhibits for the Paris Exposition of 1900 which has been planned by the management is an electric road upon which will be run model cars made by the different manufacturers of the United States. It is expected that each plant will be represented by at least one car. Awards will be made by the Exposition authorities. The over-head trolley system will be used, and the road will be a mile long, connecting the Seine with Vincennes Park, where the overflow exhibits of the Exposition will be placed.

Vincennes Park is six miles from the main Exposition grounds, and it is proposed to make an American line of transportation between the two, consisting of boats on the river for five miles of the distance and the electric road for the remaining distance. Although outside of the grounds this line will be considered a part of the American exhibit.

It is stated that another novelty of the Exposition will be a gigantic umbrella that has been invented by R. E. Sherman of Chicago. It is a steel structure about 350 feet in height. To each rib of the umbrella a car capable of seating 50 people will be attached, and these cars will be lifted from the earth to a point even with the top of the structure, where they will be suspended in mid-air long enough to give a magnificent bird's eye view of the grounds and the city beyond.

WIRE THIEVES CAPTURED.

The Pennsylvania Traction Co., of Lancaster, Pa., has been much annoyed by the cutting and stealing of the copper ground wire connecting its tracks. At 7 o'clock in the morning, on July 5th three men were caught with a large quantity of the wire in their possession, and it is thought with their capture the trouble will cease. The three colored men arrested drove to a junk shop with two bags filled with copper wire, the weight being close to 300 lb. Mr. Miller, the proprietor, thought the wire looked suspiciously like the kind used by the Traction company, and to verify his suspicion, he telephoned to Alderman Cummings, advising him of the affair, and the alderman told him to keep the men in conversation, first buying the wire, paying for the same with a check, the payment on which, of course, could be stopped. Alderman Cummings telephoned the police station, and two officers went to Miller's establishment and took the three men into custody.

CANADIAN ELECTRICAL ASSOCIATION.

An annual meeting of the Canadian Electrical Association was held at Hamilton, Ont., last month for the election of officers for the ensuing year, at which the following officers were elected: President, A. A. Dion, Ottawa; vice-presidents, E. E. Cary, St. Catharines, P. G. Gossler, Montreal; executive committee, J. J. Wright, Toronto; O. Higman, Ottawa; Geo. Black, Hamilton; John Carroll, Montreal; A. B. Smith, Toronto; J. Street, Ottawa; W. H. Browne, Montreal; A. Sangster, Sherbrooke; H. R. F. Wise, Brantford; B. F. Reesor, Lindsay.

The next meeting will be held at Ottawa.

PENNSYLVANIA STREET RAILWAY ASSOCIATION.

At a meeting of the executive committee of the Pennsylvania Street Railway Association, held recently, it was decided to postpone the eighth annual meeting of the association from the first week in September, to Wednesday and Thursday, October 4th and 5th.

The meeting will be held at the Stevens House, in the city of Lancaster. Papers and addresses of interest to members of the association will be read and delivered at the first day's session, while the second day will be occupied with a series of entertainments of interest and attraction to members and visitors in attendance at the meeting.

Announcement of the program and exercises for the meeting will be made in the next issue of this paper.

S. P. LIGHT,
Secretary.

AN ENGLISH STREET RAILWAY ASSOCIATION.

The Tramways & Light Railways Association has been incorporated in Great Britain under the companies' acts, for the purpose of promoting the welfare of the various tramways and light railways in that kingdom. The members of the association may be individuals, who shall pay annual dues of $5, or corporations or companies, who shall pay annual dues of $25. Individuals have one vote and companies five votes. The governing body comprises the president and vice-president and a council of not more than 18 members; the following gentlemen have been appointed councilors by the signatories of the articles of association:

George Richardson, chairman of North Metropolitan Tramways Co., Belfast Street Tramways Co., Blackpool & Fleetword Tramroad Co., etc.

George F. Fry, of the Tramways Committee of Dover, chairman of the London Street Tramways Co., etc.

Emile Garcke, managing director of the British Electric Traction Co., chairman of the Potteries Electric Traction Co., Swansea Improvements & Tramways Co., etc.

J. Barber Gleen, managing director of Provisional Tramways Co., secretary of the Belfast Street Tramways Co., Isle of Thanet Light Railway Electric Co., etc.

W. M. Murphy, chairman Dublin United Tramways Co., etc.

Stephen Selton, parliamentary engineer British Electric Traction Co., etc.

A. M. Willcox, editor of the Railway World, has been chosen honorary secretary of the association and that journal made its official organ.

THE PHILADELPHIA EXPOSITION.

Good progress is being made on the buildings for the National Export Exposition to be opened at Philadelphia, Sept. 14, 1899.

The contractors in charge of the work on the exposition buildings are rushing it with all possible speed. Already the work is two weeks ahead of time, such has been the haste with which it has been pushed forward. Work on the esplanade is being hurried forward with all possible despatch. From plans and descriptions it can be seen that it will be a beautiful place, rivaling, if not surpassing, the famous Court of Honor at the World's Fair in Chicago in 1893.

LICENSE FEES FOR STREET RAILWAY PARKS.

In compliance with an inquiry from the Derby (Conn.) Street Railway Co. in regard to the license charges made by cities for parks and amusement resorts operated by street railway companies, we have addressed letters to a number of roads, from which the following information has been received:

Holyoke Street Railway Co., Holyoke, Mass.; population 45,000; 10 cents admission to park; 5 cents for use of chairs; $1 per season license fee.

Lewiston, Brunswick & Bath Street Ry., Lewiston, Me.; population of the three cities 52,000; no admission fee to park and no license fee paid to city.

Middletown Street Railway Co., Middletown, Conn.; population of 20,000; 5 and 10 cents for admission to park; no license.

Duluth Street Railway Co., Duluth, Minn.; population 60,000; no admission fee to park; admission to theater 10 cents to 35 cents; license fee paid by lessee.

Ottawa Electric Railway Co., Ottawa, Can.; population 55,000; admission fees to park 10, 20 and 30 cents; no license fee.

Lynchburg & Rivermont Street Ry., Lynchburg, Va.; population 30,000; no admission fee to park; 10 cents for seats on pavilion only; no license fee paid.

Central Railway & Electric Co., New Britain, Conn.; population 25,000; no admission fee; 5 cents for seats; no license fee paid to city.

Terre Haute Electric Co., Terre Haute, Ind.; population 38,000; no admission fee to park; no license fee paid city.

Hot Springs Railroad Co., Hot Springs, Ark.; population 17,000; 10 cents admission to park, reserved seats 20 cents; park outside city; county license fee $27 per year.

Allentown & Lehigh Valley Traction Co., Allentown, Pa.; population (Allentown and Bethlehem) 61,000; no admission fee to park, reserved seats 10 cents; $10 license fee paid to city.

Binghamton Railroad Co., Binghamton, N. Y.; has two parks; admission charged to one, the other free; no license fee paid to city.

Schenectady Railway Co., Schenectady, N. Y.; population 29,000; no admission except when park is rented; no license fee paid city.

Easton Transit Co., Easton, Pa.; population 30,000; no admission fee to park and pays no license fee to city.

Birmingham Railway & Electric Co., Birmingham, Ala.; population 80,000; admission to park free, to pavilion 10 cents; park outside city; state license $25 per year.

Cleveland City Railway Co., Cleveland, O.; population 400,000; generally free admission to park, holidays 5 cents; park outside city; no license fee.

Atchison Railway, Light & Power Co., Atchison, Kan.; population 17,000; 10 and 20 cents for admission to shows in pavilion; no license fees.

Jamestown Street Railway Co., Jamestown, N. Y.; population 28,000; admission to park free; no license paid to city.

Fort Wayne Consolidated Railway Co., Fort Wayne, Ind.; population 50,000; admission to park 10 and 15 cents; no city license fee.

Tri City Railway Co., Davenport, Rock Island and Moline; population of three cities 75,000; no admission fee to park, 10 cents to theater; no license fee paid to city.

Consolidated Street Railway Co., Grand Rapids, Mich.; population 100,000; no admission fee to park, 10 cents for reserved seats; license fee to city $10 per year.

Meadville Traction Co., Meadville, Pa.; population 12,000; no admission fee to park; no license fee.

Ashland & Cattlesburg Street Railway Co., Ashland, Ky.; population both cities 10,000; no admission fee to passengers, 10 cents to others in park; no license fee.

St. Thomas Street Railway Co., St. Thomas, Ont.; population 12,000; no admission fee to passengers to park, 5 cents to others, chairs at theater 5 cents; no license fee.

Norwich Street Railway Co., Norwich, Conn.; population 24,000; 5 cents admission fee to passengers to park, 10 cents to others; no license fee.

Manistee, Filer City & East Lake Railway Co., Manistee, Mich.; population 25,000; park free to passengers, 10 cents admission fee to casino; no license fee.

Bridgeport Traction Co., Bridgeport, Conn.; population 65,000; park is rented to picnic parties, etc., who fix their own admission fee; no license fee.

Lowell & Suburban Street Railway Co., Lowell, Mass.; population of city 90,000; no admission fee to park, theater 5, 10 and 20 cents; no license fee.

Geneva, Waterloo, Seneca Falls & Cayuga Lake Traction Co., Seneca Falls, N. Y.; population of these cities 23,000; park free to passengers, admission fee to others 10 cents; no license fee.

Dartmouth & Westport Ry., running from Fall River to New Bedford, Mass.; population of two cities 170,000; no admission fee charged to park; license fee to city $100.

Manchester Street Railway, Manchester, N. H.; population 60,000; 5 cents admission fee to park; no license fee.

Southwest Missouri Electric Railway Co., Webb City, Mo.; population 5,000; no admission fee to park; no license fee; park out of city.

Loraine & Cleveland Railway Co., Cleveland, O.; population 375,000; no admission fee; park 20 miles from city; no license fee.

Denison Street & Electric Railway Co., Denison, Tex.; population 15,000; admission fee to park 10 to 25 cents; no license fee for free show, nominal license fee for pavilion.

New Orleans City Railroad Co., New Orleans, La.; population 300,000; no admission fee to amusement park, except 15 cents fare for round trip on cars; no license fee, but company keeps hotel, pavilion, platform, pier and revetment levee in good condition as per contract with city.

Leavenworth Electric Railroad Co., Leavenworth, Kan.; population 23,000; no admission fee to park; no license fee.

Other replies have been received from roads which do not own or control the parks upon their lines and as these do not bear upon the subject under discussion we have refrained from quoting them.

DIVIDENDS ON WAGES AT COLUMBUS.

Mr. Robert E. Sheldon, president of the Columbus (O.) Street Railway Co., has favored us with a copy of a resolution recently passed providing for the payment to employes of dividends on wages earned. This resolution reads:

"Whereas, The directors of the Columbus Street Railway Co. desire to show their appreciation of the loyalty and efficiency of its employes, and as an incentive to continued faithfulness, be it

"Resolved, That until further ordered by the board, on dates when dividends are declared payable to the stockholders of the company, there shall also be paid to regular employes of this company, additional compensation, the amount of which shall be ascertained by multiplying the total sum of each employe's wages during the preceding three months by such figure as will produce the rate of dividend as is paid to stockholders. To entitle an officer or employe of the Columbus Street Railway Co. to receive such additional compensation, the following conditions must obtain in each instance:

"First, the employe must have been in the employ of the Columbus Street Railway Co. for six months preceding the three months for which extra compensation may be awarded.

"Second, should an employe quit of his own accord, or be discharged from the service of the company, he shall not be entitled to the extra award for the fraction of the three month period."

The company pays regular quarterly dividends of 1 per cent.

The first payment to employes in accordance with this resolution was made August 1st, and the secretary of the company, Mr. P. V. Burington, writing under date of August 4th, states that the company has already received many evidences from the recipients of their great appreciation.

MORE TROLLEY WIRE STOLEN.

On the night of July 18th thieves cut down and carried away 600 ft. of trolley wire on the Buffalo & Hamburg (N. Y.) road. The work was done before midnight, and one of the late cars was laid out, passengers having to walk three miles and take a steam train to get home.

On Sunday, July 16th, electric cars superseded cable cars on the State St. line of the Chicago City Ry.

FUNERAL SERVICE ON THE CALUMET, CHICAGO.

Ever since the Calumet Electric Street Ry. was opened for traffic it has furnished funeral trains to parties desiring them, and the service has been extensively used.

Mr. H. M. Sloan, general manager, informs us that from Jan. 1, 1899, to July 22, 1899, he has furnished 90 funeral trains, aggregating 90 motor cars and 66 trailers. The number of funerals over the road is often as high as four per day. The charges for cars are $8 for a motor car and $3 each for as many trailers as may be desired. This charge is extremely reasonable, two cars replacing 15 carriages and the hearse.

No special funeral cars are owned by the company. The back is removed from one seat of a motor car and a place thus provided for a coffin. While a specially finished and handsomely upholstered car would be appreciated, a single such car would be insufficient for this traffic and probably would excite ill feeling because all could not use it, and the cost of several such cars would be too great.

ELECTRIC ROAD IN MEXICO.

The city of Mexico will soon have an electric railway, good progress having been made in the equipment of the Guadalupe and San Angel lines for electric traction. Mr. C. F. Beames writing in Modern Mexico gives some details concerning the work and we reproduce the illustrations. There yet remains some work in the heart of the city replacing light weight rails with 85-lb. 60-ft. girders.

The power plant is located in Colonia, Indianilla, south of the city and comprises three buildings, engine room, boiler house and coal storage, with steel frames; the walls are of stone and "tepetate" and were erected after the frame and roof were up and most of the machinery in place.

The equipment includes three batteries of Babcock & Wilcox water-tube high-pressure boilers, supplying steam to two McIntosh & Seymour cross-compound condensing engines, each direct connected to one General Electric 425-kw. 550-volt generator operating at 100 r. p. m. There is also a single cylinder McIntosh & Seymour engine direct connected to a 25-kw. G. E. generator for lighting. There is a 25-ton traveling crane in the engine room.

The J. G. Brill Co. will furnish 35 cars, 18-ft. bodies and 27 ft. over all, with cross seats, and large windows to make them "convertible." The cars will be mounted on Brill trucks, equipped with two 35-h. p. G. E. motors.

The work has been under the general supervision of Mr. A. E. Worswick, vice-president and resident engineer of the railway company. Mr. J. Pereira, representing the Babcock & Wilcox Co. in Mexico, engineers from the engine builders, and of the Mexican General Electric Co., installed the apparatus. Mr. H. P. Bradford is president of the railway company.

1—LAYING 60-FT. GIRDERS—TEMPORARY TRACK AT LEFT. 2—POWER HOUSE. 3—INTERIOR OF POWER HOUSE DURING ERECTION OF MACHINERY.

The Birmingham Railway & Electric Co., of Birmingham, Ala., has published a time table of its street railway lines which is embellished by numerous illustrations of the pleasure resorts to which its cars run. This company has two handsomely fitted trolley cars for the accommodation of trolley parties.

THE PENNSYLVANIA CONSOLIDATION.

One of the largest consolidations of electric lighting and street railway properties of which so many have recently been effected, is that of the United Power & Transportation Co., of Philadelphia. In the "Review," May, 1899, page, 353, was an announcement of the incorporation of this company under the laws of New Jersey, and that it had obtained control through the purchase of stock, of three large railway systems in Pennsylvania.

Other properties have been secured from time to time and now the company controls the following:

Wilkes-Barre & Wyoming Valley Traction Co.
Wilkes-Barre, Dallas & Harvey's Lake Railway Co.
Lebanon Valley Street Railway Co.
Trenton Street Railway Co.
Wilmington & Chester Traction Co.
Wilmington City Railway Co.
Chester Traction Co.
Delaware County & Philadelphia Electric Railway Co.
Holmesburg, Tacony & Frankford Electric Railway Co.
Roxborough, Chestnut Hill & Norristown Railway Co.
United Traction Co., of Reading.
Wilmington City Electric Co.
Citizens' Electric Light & Power Co., of Delaware County.
Edison Electric Illuminating Co., of Lebanon, Pa.

The street railways in this list have an aggregate of over 300 miles.

The officers of the United Power & Transportation Co. are: President, John A. Rigg; vice-president, R. N. Carson; secretary, E. J. Moore.

ANNUAL REPORT OF THE GLASGOW TRAMWAYS.

The results of the year's working ending June 1, 1899, shows that the revenue of the Glasgow Corporation tramways amounted to £439,224 1s. 8d. and the working expenses to £318,105 18s. 1d., leaving a gross balance of £121,118 3s. 7d. The gross balance for the preceding year was £100,538 14s. 11d. The years gross balance has been applied in meeting interest, sinking fund, rent of Govan and Ibrox tramways, payment to common good fund, depreciation written off capital, in all amounting to £67,345 12s. 7d., leaving a net balance of £53,772 11s. 0d., which has been transferred to the general reserve fund.

The chief point of interest in connection with this report is the inauguration of the overhead trolley system during the past year and the resolution to adopt it for the whole system. In anticipation of this change a scheme for numerous and important extensions both inside and outside the city, measuring in all 19 miles of double track, has been approved during the past year.

From the list of lost articles found in the cars of the Glasgow corporation it is to be inferred that the inhabitants of that city are particularly absent-minded, especially in regard to umbrellas. No less than 1,123 of these were found on the cars last year, and 1,153 during the previous year. Bags come next, with a record of 742 for the year, and the bundles of clothing number 718. There were 576 purses found, and the total of all articles numbered 6,716, of which 3,490 were claimed.

IN THE POWER HOUSE.

This department is devoted to the construction and operation of electric railway power houses. Correspondence from practical men is specially invited. Both the users and makers of power house appliances are expected to give their views and experiences on subjects within the range of the department.

Mr. H. J. Termohlen, electrician of the Rockford (Ill.) Railway, Light & Power Co., writes us concerning the armature of a D-62 machine, used as a street railway generator, which has had a long life. He wound the armature in June, 1894, and it was put in service July 19, 1894. It burned out July 1, 1899, having been run from 6 a. m. to 11 p. m. every day during the five years, except during two weeks when the engine driving it was being repaired and a new commutator put on the generator.

Who has a better record?

TESTING RHEOSTATS FOR HEAVY CURRENTS.

Mention has been made in these columns of the manner in which the Calumet Electric Railway Co., Chicago, utilizes the swampy land surrounding its power station for a rheostat when testing with heavy currents. The track rails served as one terminal and one or more pipes driven into the ground as the other. Recently General Manager Sloan wished to calibrate his wattmeters and needed a rheostat for heavy currents which could be more readily adjusted.

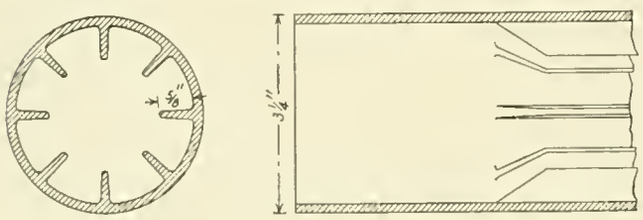
A short distance from the power house are four shallow parallel trenches, each about 10 ft. long, which stand full of water; four sections of old rail were suspended from a wooden frame supported on poles set outside the trenches, and a wire brought from the switchboard and connected to these rails.

The current which this rheostat will carry depends on the surface of the rails submerged, and the number of rails used is accordingly varied to suit the demands. Close regulation is secured by resting one end only of the rail in the trench and raising or lowering the other end. For extra heavy currents two other rails, one 60 ft. long and one 30 ft. long, lying permanently submerged in the wet ground are also connected to the positive terminal.

Currents of over 2,700 amperes have been easily handled with this apparatus.

RELATIVE CONDUCTIVITY OF BOILER TUBES.

Tests made at the University of Illinois in connection with a thesis by Mr. Frank H. Armstrong, of the mechanical engineering class of 1899, show interesting results on the conductivity of boiler tubes. The tubes tested were locomotive boiler tubes about 8 ft. long. The test tube was placed centrally in a 10-in. pipe which was filled with water, an inlet pipe being placed at one end and an outlet at the other. To provide heat a gas burner was placed at one end of the test tube; the burner was supplied with gas and air, each under pressure which was kept constant so that uniform conditions of "firing" could be maintained.



"SERVE" TUBE.

Comparisons between a clean tube 2 in. outside diameter and one covered with 3-32 in. of hard scale, showed 13.8 per cent less heat transmitted because of the presence of the scale.

Comparisons between a plain tube 2¾ in. outside diameter and a "Serve" tube of the same diameter with eight projecting ribs on the fire side, as shown in the sketch, gave 51 per cent more heat transmitted with the "Serve" than with the plain tube. The relative surfaces exposed to the hot gases in these two types of tubes are as 8.9 to 18.0.

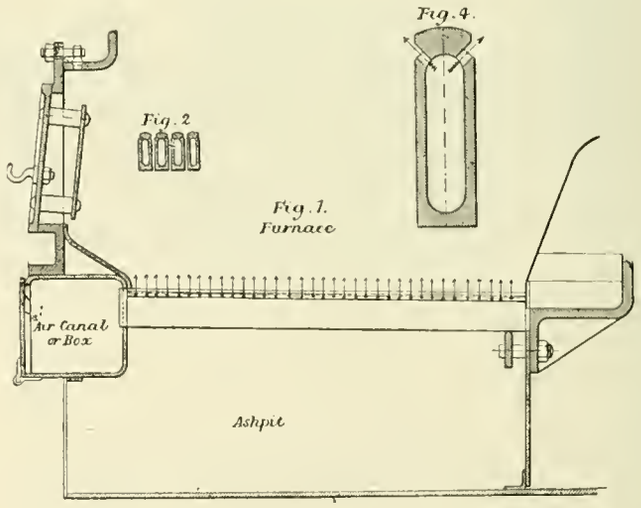
Individual tests under similar conditions varied from 2 to 4 per cent.

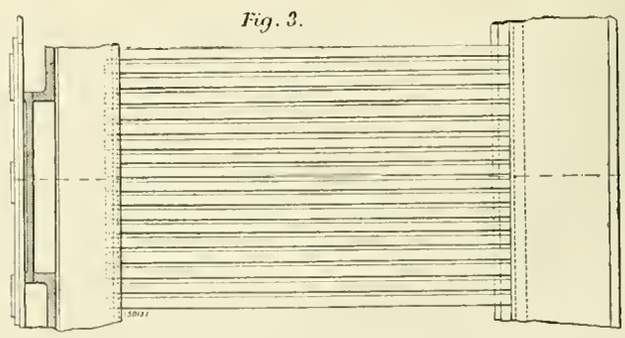
A NEW METHOD OF FORCED DRAFT.

A paper read before the Institution of Naval Architects (England) by Mr. Nelson Foley.

The writer has called the system about to be described new, believing it to be original, and, up to the present, untried, except by himself; but he is naturally open to correction, should such not prove to be the case.

The fundamental principle of the system is that the firebars themselves are utilized as a means of forcing the air into the fire. In order to accomplish this, the bars are made hollow, and are perforated with a row of small holes along each side near the upper surface, the holes being placed at such an angle that the air is forced in jets into the fire through the ordinary spaces between the bars. The front ends of the bars are inserted into a box or canal under the fire door, which is in communication with a fan, as shown in Figs. 1 and 3.





GRATE FOR FORCED DRAFT.

Fig. 2 shows a section of some bars as designed for an experimental trial. It will be observed that the holes are at such an angle as not only to direct the air up among the fuel, but also to induce,

COST OF POWER FOR ELECTRIC RAILWAYS.

Output Measured by Wattmeter in Each Case.

Station.	Month, 1899.	Monthly Output, Kilowatt-Hours.	Cost of Electrical Output per Kilowatt-Hour—Cents.						Gals. Cylinder Oil per 10,000 k. w. h.	Gals. Lubric't-ing Oil per 10,000 k. w. h.	Lbs. Water per Lb. Coal.	Lbs. Fuel per k.w.h.	Price of Fuel per Ton of 2,000 Lbs.	Kind of Fuel
			Fuel.	Labor.	Supplies, Oil, Waste, etc.	Water.	Re-pairs.	Total.						
1.....	Apr.	1,413,517	.270	.165	.041	.034	.042	.552	4.56	1.06	12.13	2.57	...	Bituminous
5. Metropolitan Elevated, Chicago.	"	1,088,885	.377	.227	.026	.027	.031	.688	.9	.53	6.69	4.46	...	"
8.....	"	492,645	.431	.255	.022	.031	.007	746	...	...	...	...	...	"
9.....	"	768,702	.555	.270	.029	.050	.006	.911	...	...	...	...	...	"

by means of the jets, a draught from the ashpits. The top part of the bar is made umbrella fashion, so that the holes may have protection as far as possible from ash, dust, or scoria. Fig. 4 is an enlarged section, showing this feature.

Without being sanguine of a satisfactory result, it was thought that the benefits to be gained in leaving both stokeholds and ashpits open were sufficient to justify some experiments being made on a small stationary water tube boiler. The results have been so far beyond expectation that the subject appears to the writer to be of sufficient interest and importance to warrant his bringing it under the notice of the institution; in fact, it seems to him to bid fair to cause some revolution in forced combustion. The results of these experiments are appended at the end of the paper.

Up to the present only short bars have been experimented with, but a sample bar up to 4 ft. in length has been cast without difficulty; at the same time, where it is possible to have an air box at each end of the grate, the bars need never exceed the moderate length of, say, 3 ft. A method of uniting them in the center has also been devised for such cases as when the front only is available for an air box, and a long grate is desired. It should be noted, however, that it is thought preferable, in order to give facilities for good, stoking, cleaning fires, and keeping the fires in good order, to work always with short grates, and use a high rate of combustion.

It has been observed during the experiments that little refuse falls into the ash pits, that the bars keep perfectly cool, and that the clinker does not adhere to them; in fact, from time to time, the clinker can be removed from the fire without drawing the same.

It has also been noticed that during forced draft the bars do not suffer at all, although it is only fair to say that on one occasion the ends of some bars were burnt because the bridge at the back was not in order, a space being left between it and the bar ends.

It is intended, in adopting this system, that the full advantage should be taken, making the grates moderate in length, and running with forced combustion as a normal condition. In this manner the destruction of fire bars would be reduced to a minimum, and the fires could be regulated to a nicety.

The fire can be regulated also, so that it is a matter of indifference whether the fire-door is open or shut; but, of course, it cannot be overlooked that, at very high rates of combustion, especially with ordinary cylindrical boilers, the fire-door must be kept shut, as with the ordinary ash-pit draft.

RESULTS.

Experiment.	Air Pressure.	Coal, Pounds per Hour per Square Foot of Grate.	Jet Holes.		Bars.		Observations.
			Diameter.	Pitch.	Length.	Surface.	
	in.		in.	in.	ft. in.	sq. ft.	
1	1.38	29	5-32	11-16	2 7½	7	Evaporative trial, careful firing.
2	1.45	32	5-32	11-16	2 7½	7	Evaporative trial, careful firing.
3	1.25	41	5-32	11-16	2 7½	7	For combustion only.
4	1.73	40	5-32	11-16	2 7½	7	Evaporative trial, careful firing.
5	3.15	72	3-16	11-16	1 3½	3.22	For combustion only.
6	3.15	53	3-16	11-16	2 7½	7	Evaporative trial, careful firing.

Presuming a long life for the individual bars, the cost of production need not, it seems to the writer, be considered a serious matter; for the foundry in Naples it comes to about 10 centimes per kilogramme.

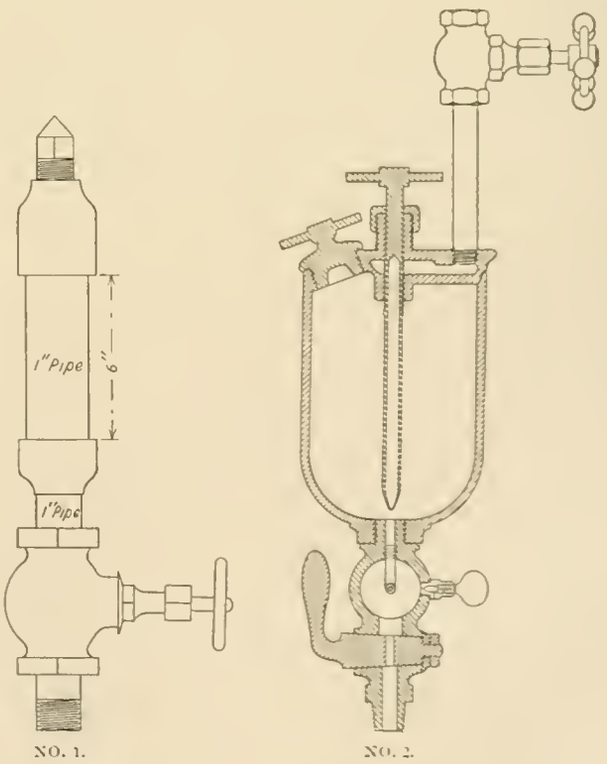
The experimental grate was 2 ft. 7½ in. long and 2 ft. 7½ in. wide, composed of bars of section as shown in Fig. 4; in the case of Experiment 5, however, half the length was bricked over. The air pressure was obtained from a smithy blast, the strength of which was never more than 80 millimeters (3 1-5 in.). Coal, Cardiff of good quality. Height of funnel from bar level, 17 ft. 6 in.

During trial 6 it was thought that for this rate of combustion the passages to the funnel were too contracted. On measuring same they were found to be collectively between 1-6 and 1-7 of the grate area, whereas the funnel area itself was 1-5.

[This arrangement is quite similar to that employed in the Cornelius smokeless furnace described in the "Review" for June, page 381, and the paper is of interest as showing that this type of grate bar is practicable either for forcing the boilers or as a smoke preventing device.—Ed.]

GRAPHITE LUBRICATORS.

The current number of Graphite, published by the Joseph Dixon Crucible Co., contains the following information concerning lubricators for introducing graphite into engine cylinders.



NO. 1. NO. 2.

No. 1 is a home made device constructed of pipe fittings and is screwed into the steam chest; the nipple just above the valve has a brass plug driven into it and a 1-16-in. hole drilled through the

plug. One of these devices, the writer states, placed on the high-pressure steam chest serves to supply flake lubricating graphite to both cylinders of the engine and to the air pump. The lubricator is filled once in three days. The cylinder oil consumption was reduced one-half by using graphite.

The Dixon Co. states that it uses a small hand oil pump of the type often used for supplying oil to small engines, a teaspoonful of graphite being put in before each half-day run.

The Lunkenheimer Co. makes a sight-feed lubricator which it claims will feed graphite automatically and continuously, so that it is unnecessary to provide a sight-feed oil lubricator, though an oil pump is recommended for occasional use, especially when starting the engine. This is No. 2 in the illustration.

CHICAGO CITY COAL HANDLING PLANT.

The Chicago City Ry. has recently installed some coal handling machinery at its power station at 51st St. and Wabash Ave., which has effected a great economy in handling the fuel. At this point there are two stations, one at the old cable plant built in 1886 with two 500-h. p. engines and porcupine boilers of 350 nominal h. p. each, and the other an electric plant installed in 1893 which comprises five pairs of 24 x 48-in. Wheelock engines, improved pattern, each pair driving two 500-kw. Westinghouse generators, and 19 horizontal tubular boilers 72 in. by 20 ft. The boilers in the cable house are fitted with Roney stokers and those in the electric plant with Murphy smokeless furnaces and mechanical stokers. It will doubtless be remembered that for some years the cable engines in this station have been idle, the cable machinery being driven by an electric motor taking current from the electric station.

Prior to February last the coal for this plant was loaded into small cars with a capacity for 1,600 to 1,700 lb. each, which were lifted on an elevator and then wheeled onto a truck running overhead in the two boiler rooms, where the coal was dumped into bins and chutes whence it fed to the stokers by gravity.

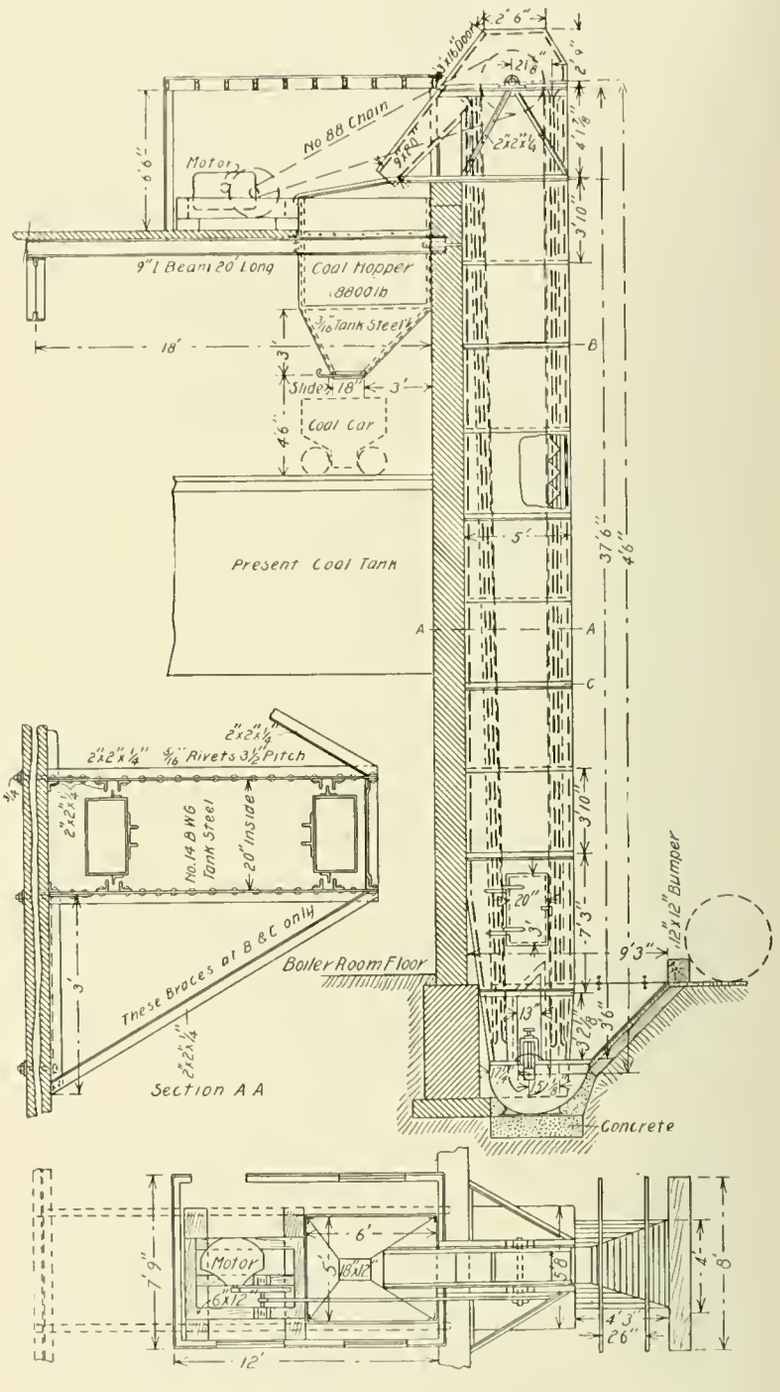
The coal consumption varies from 125 to 200 tons per day and under the old system of handling it two cars and six men were regularly employed, with two extra men about one-third of the time, the cost for labor being about $10 per day. In addition a 25-h. p. engine driving the elevator was run 24 hours per day.

The present coal handling and storage plant was designed by Mr. C. J. Reilly, superintendent of motive power of the company, and the elevator was built by the Link Belt Machinery Co., which used its standard machinery adapted to Mr. Reilly's design, and it has been in operation since Feb. 15, 1899. A 5-h. p. electric motor drives the elevating machinery and one man distributes it to the bins; the total cost for labor is $2 per day. It is seen that the saving of labor alone effected by the installation amounts to $2,920 per year, and the saving due to substituting a 5-h. p. motor for the 25-h. p. steam engine is amply sufficient to cover depreciation on the coal elevator. The total cost of installing the coal handling apparatus was less than $1,200.

The elevator is placed within a rectangular steel shaft on the outside of the south wall of the building; the arrangement of the pits, hoppers, etc., is very well shown by the drawings. The coal bin in the boiler room extends the entire length of the building and has a capacity of 250 tons. It is 180 ft. long, 10 ft. wide and 9 ft. deep, being supported on a row of columns placed 9 ft. apart and 4 ft. in front of the boilers and further braced at the sides by rods suspended from the roof trusses. This bin is covered with planking save between the rails of a 26-in. gage track running over the center of the bin. A hopper shaped car, the body of which is 3 x 5 ft. at the top and 2 x 3 ft. at the bottom and 3 ft. deep, holding about 1,600 lb. of coal, carried on four 19-in. wheels, carries the coal from the upper receiving hopper to the desired point over the bin. As the track is level one man can easily push the car about and thus can distribute from 125 to 200 tons into the bin in 10 hours.

The car is run under a chute from the upper elevator hopper, a slide drawn out, and the car loaded with coal in an instant. When pushed to the unloading point it is dumped by dropping the bottom. This is a much cheaper way of distributing the coal along the bins than to employ a horizontal conveyor; the conveyor would require the attention of one man all the time, whereas now the man alone does the work.

In addition to the 250 tons storage capacity in the electrical boiler house, the bins in the cable boiler house hold 150 tons, and a shed at the south end of the latter 1,000 tons more. All the coal for this station is hauled from two or three miles in wagons, being delivered by the contractors to the shed or to the vertical conveyor. When coal is taken from the storage shed it is loaded into the small



COAL HANDLING MACHINERY—CHICAGO CITY RY.

cars which dump into the receiving hopper of the vertical conveyor. A track is laid from the shed to the hoppers; the rails of this track are shown in the drawing.

The Columbus (O.) Street Railway Co. reports earnings for the week ending July 14th at $15,412, and for the corresponding week in 1898, $12,649. The total increase in July over the same month in 1898 is $9,718.

A movement is under way to eventually secure the conduit system for the street railways of Cleveland, Ohio. A franchise has been sought for a new line out Lake and Hamilton Sts. and over Doane and Woodland Hills Aves. to Newburg, which if granted will be with the provision that the conduit system be used.

THE ARRANGEMENT OF STEAM AND OTHER PIPES, AND THEIR FITTINGS.

A paper read before the Municipal Electrical Association (England) by J. E. Edgcome, Borough Electrical Engineer, Kingston-upon-Thames.

The subject of steam and other piping is one of the greatest importance to engineers of central stations, and indeed to all who have to deal with steam plant. It is a subject upon which volumes might be written and still leave much unsaid. The author does not pretend to advance any especially new or original information, but rather a series of notes based on some little experience, in the hope of eliciting what should prove to be a most interesting discussion, and a discussion from which every member may be able to carry away some useful suggestion, to be put into practice when laying down a new generating station, or when carrying out the inevitable extension of his present works. The arrangement of piping referred to in this paper is proposed for small or for moderate-sized stations, which form the majority, rather than for those very large stations to be found in a few of the big cities, and where, possibly, special arrangements are necessary.

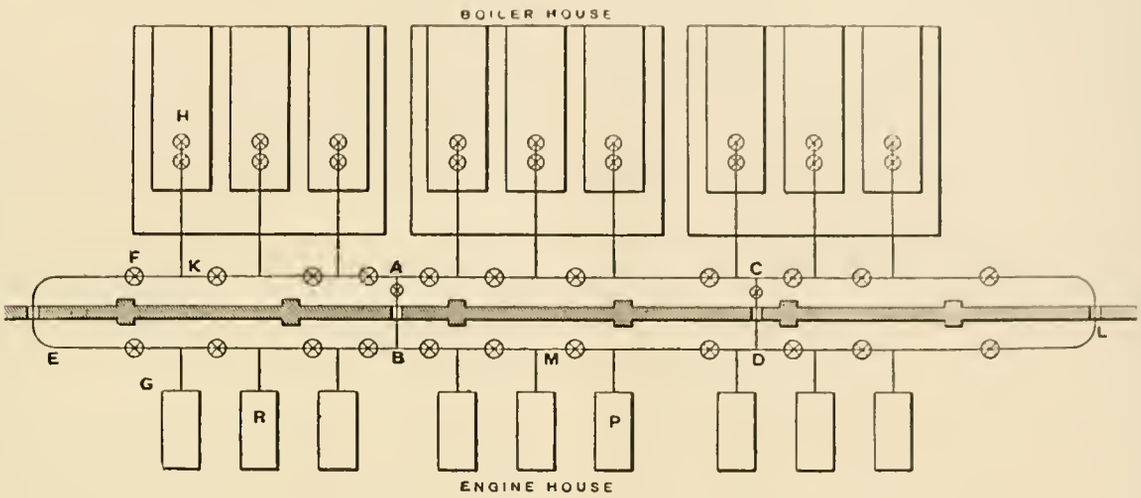


FIG. 1.

STEAM PIPES.

The author is of opinion that in the majority of cases, the best and most favorable arrangement of steam piping is in the form of a steam ring, running from the boiler house through the engine house and returning to the boiler house as shown in Fig 1. It is advisable that the ring should be cross connected at two or more places, as shown at A B and C D, so that in the event of repairs being necessary to any pipe, say at E, the closing of the valves F G does not necessitate, in case boiler H is under steam, that the steam should pass to the engines, say P or R, by the long route K A L M, but by the shorter route K A B M. This arrangement will also allow of considerable lengths of steam pipe being cut out when the engines and boilers upon them are not in use, and will be found to give greater flexibility to the ring system.

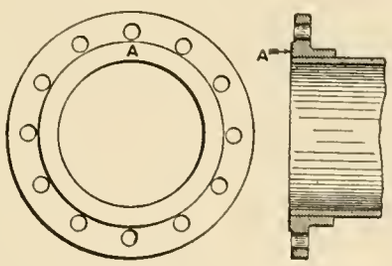

FIG. 2.

In most cases, particularly when the engine house and boiler house are approximately on the same level, it is usually more convenient to carry the steam piping overhead, and where a single line of boilers is installed backing towards the dividing wall, and similarly a single line of engines is laid down with the engines abutting towards the same wall, it is extremely simple to carry out a steam ring system. Where a double row of engines is installed the system becomes a little more complicated, and it is usually advisable to form a second loop of steam piping in parallel with the main ring within the engine house, feeding the engines on either side, the engines in that case facing one another, with the machines outward.

Serviceable and reliable steam pipes may be made up of lap welded mild steel, with heavy wrought iron flanges, the flanges being screwed on hot, and the ends brazed. The flanges must, of course, be faced up to enable good joints to be made. In larger sized steam pipes it will be found that joints can be kept tighter by having the flanges made with a slight boss, which is faced up for the joint, instead of the whole of the flange being faced up for that purpose, as shown at A in Fig. 2; from 1-16 in. to ⅛ in. is sufficient thickness for the thickness of the boss. Steam pipes, where supported on brackets or columns, should be carried on rollers to allow of free contraction and expansion.

JOINTS.

With the higher steam pressures now in use, care and discrimination are required in making and keeping good sound joints. There are innumerable makes of jointing material on the market. Rubber prepared with plumbago makes a good sound joint, which requires taking up when steam is admitted to the pipe, as the material softens with the heat, although it sets into a hard permanent joint when tightened up. An admirable and reliable join is one made with corrugated brass rings, painted with thin red lead.

DRAINAGE.

One of the most prolific causes of trouble with steam piping is that from accumulation of water, and too much care cannot be taken in the thorough draining of the pipes. For this purpose a number of separators should be fitted in the ring on the boiler side to collect the water from the steam where it leaves the boilers, and, in the author's opinion, it is certainly advisable that every engine should be fitted with its own separator, to deal with any water which may be carried over from the main steam pipe.

To deal, however, with the water which will, notwishstanding, collect in the main steam ring in the engine house, it is advisable to connect the ring in several places to steam traps, similar traps being connected to the separators of the engines. The author has found from experience that to permanently connect the engine separators to steam traps, deals more effectually with the water trouble than to constantly blow out the water from the separators as it collects there, especially in view of the difficulty experienced in ascertaining the quantity of water in the separators, except by the use of gage glasses, which are a source of constant trouble owing to the difficulty of getting glasses to withstand the pressure when there is any variation of temperature or when they are subjected to sudden cold draughts.

The connecting pipes from the boilers to the main steam pipe, and from the main steam pipe to the engines, should be preferably of copper, with full swan neck bends to keep the water back as much as possible, and to allow of expansion.

STEAM TRAPS.

These are most necessary adjuncts to the steam pipes; but, although there are some very good steam traps on the market, probably most engineers will agree that an ideal trap has yet to be discovered. All steam traps require a certain amount of attention, and should be fitted with a reliable class of stop valve to enable them to be shut off from the live steam main for inspection and for the renewal of the valves and seatings when necessary. Most of the modern traps will discharge at a considerable height, depending, of course, upon the steam pressure, and it will be found that a quantity of excellent feed water may be collected by this means. When discharging to a height each trap should be fitted with a non-return valve to prevent the column of condensed water in the pipe returning to the trap. It will be found convenient to group the discharge pipes from a number of steam traps into a small tank, having an overflow pipe to the hot well. This will enable the discharge of every trap to be inspected, which is a necessary precaution to ensure that each is in proper working order.

VALVES.

Valves are a very important part of a steam system, and care should be taken to select a class of valve suitable for the work which it has to perform. Full-way valves possess so many advantages over other types that in the most modern plants these are almost wholly used for high pressure steam work, and can be obtained from the smallest to the largest size. The large valves on the main steam ring should each be provided with a small by-pass valve to enable a length of cold steam pipe to be warmed up, and the pressure balanced before the main valve is opened. This will prevent the straining of the joints caused by sudden expansion, and likewise accidents due to water hammer.

When erecting new steam pipes, attention should be given to the thorough cleaning of the pipes, as otherwise fine particles of grit, driven by the steam into the faces of the valves, cut into the seats, causing considerable trouble and expense. The author was informed by one large firm of valve makers that, owing to the trouble they had experienced from this cause, and the expense to which they had been put, due to the necessity of taking down and refacing valves fitted in this manner on new pipes, they intended in future to include in their estimates a certain sum to cover such cost. Where, as is almost universally the case, boilers run in parallel, it is advisable to fit a self-acting valve between the steam ring and the main stop valve on each boiler, the self-acting valve being placed immediately after the stop valve. There are various types of this valve, the usual form being a ball working on an inclined plane. The object in all cases is to provide a valve which shall close automatically when the pressure on the boiler it controls falls below that in the steam ring, as this enables that particular boiler, when thus isolated, to recover itself and to get up a full head of steam upon which the automatic valve reopens and again connects the boiler to the steam main.

BLOW-OFF VALVES.

Where the boiler blow-off valves discharge into one common pipe, as is usually the case, it is very necessary that the blow-off value should be of some type in which the handle shall be practically locked when open. This will prevent the blow-off from a live boiler being forced into a boiler which is standing off for the purpose of being cleaned. Want of attention to this precaution has been the cause of many accidents, frequently involving the death of the men working in the boilers. This locking arrangement is usually carried out by the use of some special form of key, in which the key is held locked in the valve as long as the valve is open, and can only be withdrawn when the valve is shut; and as long as one key only is available it is, of course, impossible for two valves to be open simultaneously. As, however, a key is supplied with every valve, the spare keys, which it is advisable to keep in case of breakage, should be locked up, in charge of one of the engineers, and should not be available in the works. The author remembers seeing on a battery of boilers, which had been carefully fitted with this class of valves, two of the blow-off valves open at one time with, of course, a key to each valve, entirely doing away with the element of safety, and further causing this false feeling of security to become an added danger.

Where the blow-off from the flooding valves of superheaters are led into the same blow-off pipe, and when, as is usual, a type of two-way valve is used which cannot be fitted with a locked key, possibilities of accident are averted by making a stringent rule that the flooding valves must not be opened unless the key of the boiler blow-off valves is hanging within sight.

CHECK VALVES.

The check valves of boiler feed pipes are more convenient, for the purpose of inspection, when fitted with an arrangement which allows the valve and setting to be inspected while the boiler is under steam, and the author would also suggest the convenience of fitting every feed branch with a plug-cock, having a removable handle, to enable each check valve to be shut off for inspection both from its own boiler and from the feed main. A plug cock with removable handle is recommended in place of an ordinary wheel valve, as the latter may be accidentally closed, whereas the handle would be fitted to the former only for the specific purpose of examining the check valve or for completely cutting off the water supply from a boiler when standing off. The feed supply would, of course, in all cases be regulated by means of the check valves themselves.

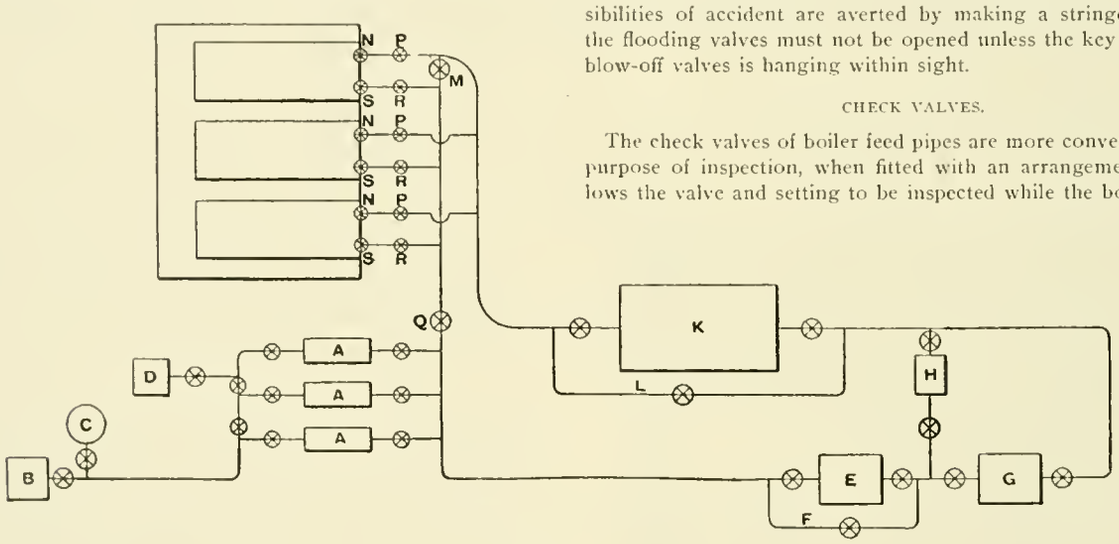

FIG. 3.

Perhaps the author may be permitted to say a few words on the subject of feed water supply. A convenient arrangement is to connect the pump suctions through suitable pipes and valves to the hot well, the cold well, and also to a third supply in case of emergency, and to connect the discharge pipes from the pumps to a double line of piping supplying the feed water either through the filters and one or more economizers, or, if required, direct to the boilers.

In the accompanying diagram, Fig. 3, AAA are the feed pumps, B the hot well, C the cold well, D the tank connected to a third supply, E is a cloth filter with by-pass F; G a sawdust filter fitted in series with E, with a by-pass sawdust filter H, the by-passes being used when the main filters are being cleaned. This arrangement has given excellent results, leaving the boilers clear of all traces of oil, which formerly proved a source of considerable trouble and anxiety. The condition of the sawdust in G and H is a good indication of the condition of filter E, and proves whether or not it is doing its work properly. K is the economizer with the by-pass

L, to enable it to be inspected and cleaned without passing the feed direct to the boilers via Q, which would entail cutting the filters out of circuit. The arrangement of the branches from the hot and cold feed enables the boilers to be fed either with hot or cold water through the stop cocks and check valves pn or rs, and by opening valve m, cold water can be fed through the hot feed check valves, or the reverse should any of the branch pipes or check valves be out of order.

PIPE COVERINGS.

A few words must be said with reference to the various coverings in use for preventing radiation of heat from steam pipes. It is most necessary that all pipes carrying steam should be enclosed in a covering of some non-conducting material. Endless varieties of pipe coverings exist which may be divided into two classes, permanent coverings, and removable coverings.

The former, which are generally wrapped with some description of linen or canvas, have a good finished appearance when colored and varnished, but suffer from disadvantage that the covering is destroyed when it is necessary to remove it from the pipe at any point, and the appearance of the whole length of pipe is spoilt in consequence. Removable coverings are, on the other hand, as their name implies, specially made for the purpose of allowing free inspection of the pipe, but in appearance they are usually clumsy, and do not lend themselves to the neat finish of permanent coverings. It is also questionable whether, as a rule, they are such efficient non-conductors of heat as are permanent coverings.

It would take up too much time to attempt to describe the many varieties of covering on the market. They are all manufactured from some good non-conducting material such as asbestos, magnesia, slag-wool, or felt, and are put on either wet or dry. There are also numbers of coverings which depend principally for their non-conducting properties upon an air space being left around the pipe. Probably every engineer has been induced at some time to try various coverings, and, like the author, has possibly found a few good, many indifferent, and some distinctly bad.

There is no doubt that to obtain an efficient steam supply with a minimum of condensation, every portion of steam-carrying metal must be covered with a thoroughly good non-conductor, and where practicable all valves and flanges should be treated in the same manner. This applies equally to the drain pipes, or, at any rate, to that portion connecting the steam traps. For the sake of keeping down the temperature in the engine house it is generally advisable also to cover the exhaust pipes with some non-conducting material.

Much more might be said on the subject of pipe work, but the author trusts that what he has advanced will fulfil his expectations, namely, to produce a useful and exhaustive discussion on what he ventures to think is a most important portion of central station equipment.

NEW WISCONSIN LINE OPENED.

The Waupaca & Chain o' Lakes Electric Railway Co., a new Wisconsin road, commenced operation of its cars on July 4th. Messrs. W. B. Baker and Irving P. Lord, of Waupaca, have devoted a great deal of time during the past two years to the furtherance of this project, and on the day the cars were started their efforts were well rewarded by the very large patronage given to the road, and interest manifested by the citizens of Waupaca and surrounding country.

The Electrical Installation Co., of Chicago, was awarded the contract for the complete construction and equipment of this road on May 18th last. The work of grading was commenced on May 26th, and the five miles of road completed ready for operation within 32 working days. During the progress of the work a record was made in track laying, 23,000 ft. of track being laid, lined and surfaced within 60 working hours. The contractors had a most complete and efficient organization, working like a piece of well-oiled machinery which made it possible to finish the work within the time required by the railway company. Standard construction was used throughout; cedar ties, 50-lb. T-rail, "Crown" bonds and No. 00 trolley wire.

The Chain o' Lakes is one of Wisconsin's most beautiful resorts, and the patronage already bestowed on the road has demonstrated to the management that they have made no mistake in its construction.

A RAILWAY RESORT FOR CHATTANOOGA, TENN.

Elaborate plans are being prepared to connect the lines of the Chattanooga Electric Railway Co. with Glenwood Park, which is owned by the Glenwood Land Co. This tract surrounds Indian Springs between Avondale and Highland Park and the railway company desires to secure control of this land and gain certain concessions from the Glenwood Land Co.

If the deal is consummated the railway company proposes to make a number of additions to and changes in their present track system. Indian Springs will be made the main entrance to the park and a new line will be built to this point and a number of other lines will be built inside the park property.

The matter concerning the building of a lake covering an area of 25 acres, bath houses, etc., will be drawn up and set forth in a written proposition, to be approved by the directors of the Chattanooga Electric Railway Co., and will then be sent to the officers and directors of the Glenwood Land Co. for their consideration.

The Glenwood Land Co. is said to be quite favorably disposed toward this scheme.

ELECTRICITY ON AUSTRALIAN RAILROADS.

The practicability and economy of substituting electricity for steam motive power on the branch lines of the railways in the colony of Victoria, Australia, are now under discussion and Mr. C. E. Norman, engineer for existing lines (what we call engineer of maintenance of way) is making an inspection of the railroads of America and Europe, giving particular attention to the equipment and operation of electric roads. While it cannot be said that it is probable that the railways of Victoria, which are owned and operated by the Government, will soon be equipped with electricity, yet it is interesting to note that the question is under consideration.

The colony of Victoria has an area of 87,884 sq. miles, with a population of 1,169,000, and has 3,123 miles of railroads, which have been built at a total cost of £38,600,000. In the year ending June, 1898, there were over 43,000,000 passengers carried and 2,408,000 long tons of freight. The ratio of working expenses to earnings was 63.09 per cent, and the percentage of net earnings to capital invested, 2.49.

ELECTRICAL INDUSTRY IN JAPAN.

An interesting clipping from the Japan Times, relating to the electrical industry has been forwarded by Consul General Gowey. Electroplating dates back to about 1887, when a workshop was first started in Mita, Tokyo. The plated articles now turned out are not much different in finish from those coming from abroad. There are about 200 shops now in the city of Tokyo doing electroplating, but most of them are on a very small scale.

The manufacture of telephone apparatus has so far advanced in Japan that, with the exception of springs, for the supply of which foreign aid is still depended upon, all other necessary paraphernalia can be made at home at about one-half the cost of foreign goods. At present, therefore, only a very small portion of telephone apparatus is being imported. Foreign instruments are used in such places as Tokyo and Osaka, where the telephone connections are in brisk demand. The manufacture is carried on both in Government and private shops.

The electromotors made for the Kawasaki Electric Tramway at the Shibaura Engineering Works are the first of the kind made at home, those heretofore used by the Kyoto, Nagoya, and other tramway companies having been obtained from abroad. The Kawasaki Tramway is highly satisfied, we are told, with the Shibaura dynamos; for it has found them, so far as its experience goes, just as good as those of foregn make employed by other establishments. It is said that the Shibaura works have since secured orders to construct a number of the same apparatus for the Hoshu Electric Tramway Co. Of the materials required for their construction, the Shibaura works can obtain at home everything but wheels and springs, which have to be imported.

The loss of traffic due to the Brooklyn strike is estimated at $150,000.

THE ELECTRIC RAILWAY IN COREA.

In the "Review" for July were quoted press dispatches from Seoul, Corea, briefly telling of the riots excited by the electric cars in that city and of the fate which promptly overtook a score of the ringleaders. Two letters from Mr. H. Collbran, recently published in the Railway Age, give interesting accounts of the opening of this road and of the troubles which followed soon after, and we reprint, by permission, the substances of Mr. Collbran's letters. Under date of May 15, 1899, he writes:

"The opening of an electric railway in Seoul, the capital of Corea, on the 1st instant, caused great excitement throughout the country, many Coreans coming from a distance to be present on the occasion.

"It was difficult to ascertain what were the expectations of the people, as they imagined all sorts of things, but it seemed that the majority expected the overhead trolley wire would pull the cars along. One very gratifying feature, however, was the entire absence of all superstition, forming a marked contrast to the fears of the Chinese a few years back when railways were first introduced in that country.

"When the machinery was set in motion at the power house the scene was truly a gay one. All of the cabinet ministers, many officials of the emperor's household department, military and civil officers, city officials of all kinds, etc., were present, and formed a typical oriental picture, in their rich and handsome silken costumes, all eager to participate in the introduction of a 'progressive step' so great as an electric railway.

"Outside the railway yards were thousands upon thousands of Coreans occupying every space where it seemed possible to sit or stand, and there they had been waiting for many hours to see what would happen. Among all the officials none was more prominent or more active than the Hon. Yecha Yun, ex-governor of the city, who, after some four years' residence in Washington, did much toward introducing western improvements into Corea, and who deserves great praise for building such streets in Seoul as have rendered the construction of an electric railway feasible. For nearly 4,000 years the only means of travel enjoyed by Corean gentlemen have been by the use of chairs or litters carried by laborers, and a jump direct from the Sedan chair to an electric railway is certainly an event in eastern life worthy of notice.

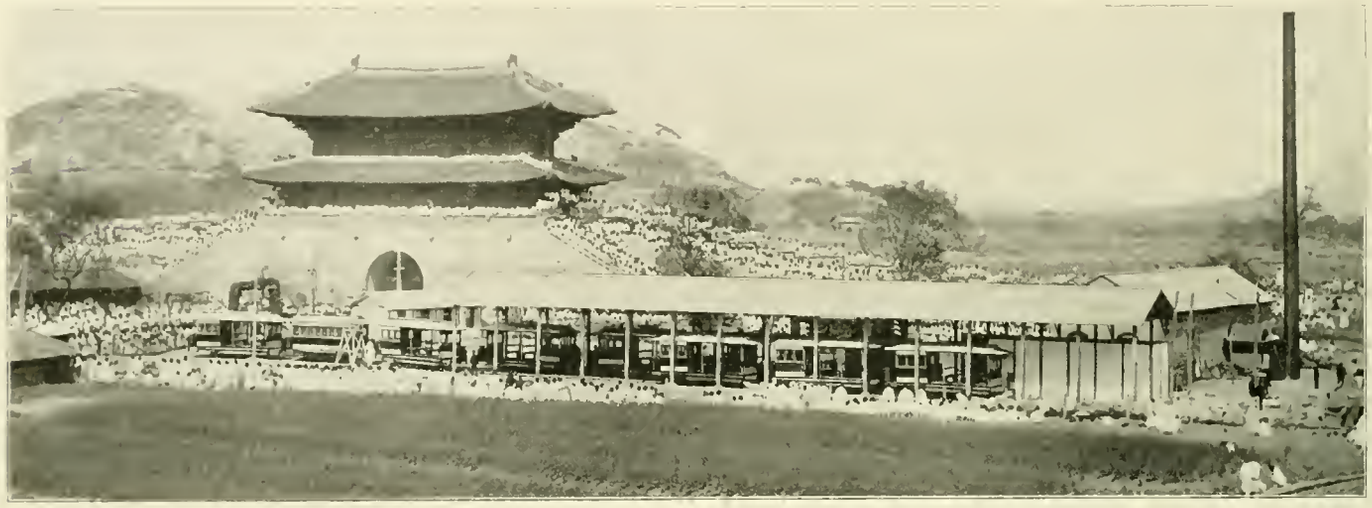

FIG. 1—THE OPENING OF THE ELECTRIC RAILWAY IN SEOUL—POWER HOUSE AT THE EAST GATE.

FIG. 2—GATE OF SEOUL.

FIG. 3—CAR WITH LEADING STOCKHOLDERS.

"When the time came for the first cars to start there was no hesitation on the part of the Corean officials about showing their confidence and all of them quickly found seats. The streets had been lined with soldiers, but notwithstanding these precautions the greatest care was necessary owing to the enormous throngs of people.

An average speed of five miles per hour was maintained, except in one instance, where the track was well guarded, and it was impossible to resist the temptation of discomfiting the police, a number of whom had been instructed to run ahead of the cars: a rate of 12 miles was made for a short distance, quickly leaving the worthy policemen in the rear, to their great consternation and the indignation of their chief, who was riding in the car. No mishap of any kind occurred and after returning to the power house a messenger arrived from the emperor requesting that a special trip be made in order to afford him and his suite, and the crown prince and his suite an opportunity of inspecting the cars. This was promptly complied with. His majesty and the court generally looked on the scene from the palace gates, near the United States legation, and the emperor expressed his pleasure and approval of the new enterprise and its successful introduction. Prince Ye Chai Toon, the head of the household department, a little later on toasted the electric company and said many nice things concerning America and its people.

FIG. 4—A NATIVE CONDUCTOR.

"Some of the rules established for the operation of the railway are curious. For instance, it is not considered necessary in America

to announce that females may ride as well as males; but this forms the subject of the first rule in the schedule issued by the Seoul Electric Co. Can it be possible that so practical a thing as a street car will eventually lead to the destruction of the custom, centuries old, of secluding women, and permit them to travel in open carriages instead of being shut in a closed chair, little else than a closed box?

FIG. 5.

"Again, the company, like others we have heard of in Europe and America, has been confronted with the 'hat' difficulty. This time it is in regard to the men and not women. For ages past men in Corea have worn huge straw hats when in mourning for the loss of a relative. These hats are truly of enormous size—at least as large as a bushel basket—and the Coreans have drifted into the custom of wearing them as sunbonnets. But it now appears that another of their ancient practices is in jeopardy; for the bushel basket must go or treble rates must be charged the wearers.

"The fares vary, according to distance, from 2 to 15 cents. This creates surprise, because the people cannot understand why it costs less to ride so rapidly in a beautiful carriage than in a sedan chair, which can only be carried by coolies.

"In order to accustom the citizens of Seoul to the new method of traveling, and to facilitate the operations of the company afterward, the opening celebrations were practically continued for a full week, until it became possible to run cars quite as crowded as a Chicago State Street car, at a high rate of speed, and the sum

FIG. 6—WHAT WAS LEFT.

total of accidents amounted to breaking the leg of a dog, who was rather indifferent about getting out of the way. This fortunate result was largely contributed to by the aid of the officials of the United States legation, who were indefatigable in securing arrangements that assisted in preventing accidents.

"All the details of arranging the safe opening and accompanying celebrations were under the care of Mr. H. R. Bostwick, of San Francisco—a task involving much anxiety, when the fact is remembered that the Coreans knew nothing of railways or of electricity, and that in Cairo, Egypt, about 60 people were killed during the first week of the street cars in that city. He well earned the comment of a Corean coolie, who, when the cars were being finally turned in, shouted, 'Me Kook Sa Ram Mar-ni Chosse,' which, being interpreted, says, 'The Americans, they are all right.'"

"Extracts from a letter under date of June 6, 1899, are as follows:

"Considerable rain usually falls in Corea during the month of April and is of immense value to the rice and other crops, but this year no rain had fallen since early in January. The country was suffering from a serious drought. Sacrifices were offered to the heavens by the emperor, but all in vain. Early in May the electric railway opened for public service, and although well patronized it was generally stated that the rain did not come because the railway house rested on the rain dragon's back and he was consequently prevented from doing his usual work.

"The common people, believing this, became clamorous for the destruction of the railway, which by that time had been some 10 days in successful operation.

"Just then the first fatal accident occurred. A child ran safely across the track a few yards in front of the car, but was called back by its father, and running right under the wheels, was instantly killed. It needed only the action of the father in holding up the body of the child to the gaze of the mob to excite violence. A rush was immediately made upon the car, the employes were com

FIG. 7.

pelled to fly for their lives and the mob quickly set fire to and destroyed the first car and almost equally destroyed the one following it.

"The excited people then made ready to go and destroy the power house, where the lightning was stored, but by this time the representatives of the company had arrived upon the scene and soon gained control of the situation. They cleared the track and succeeded in running cars through the city again within some two hours after the trouble arose.

"The government authorities have issued instructions to both the military and the police that they are expected to prevent any similar trouble occurring again, but as ill luck would have it, the long-delayed rains commenced to fall about 48 hours after the people had stopped the railway, thereby strengthening the belief that the company had stolen the lightning from the clouds and left little or none for rain and thunder storms, without which the people cannot grow rice and must starve to death."

Fig. 4 is an excellent likeness of the first Corean electric railway conductor. His expression of self-satisfaction is doubtless due to the combined influences of a nice new uniform and a salary of $7.50 per month.

Fig. 5 represents one of the street cars in Seoul in operation under normal conditions. This illustration is also of interest as emphasizing the bushel-basket-hat difficulty referred to in the previous account.

Fig. 6 shows the remains of the first car attacked, the photographs having been taken just after the mob was driven back. Fig. 7 is the second car, with workmen engaged in removing it from the track for the passage of the first car after the trouble was quieted.

TAUNTON SNOW PLOWS.

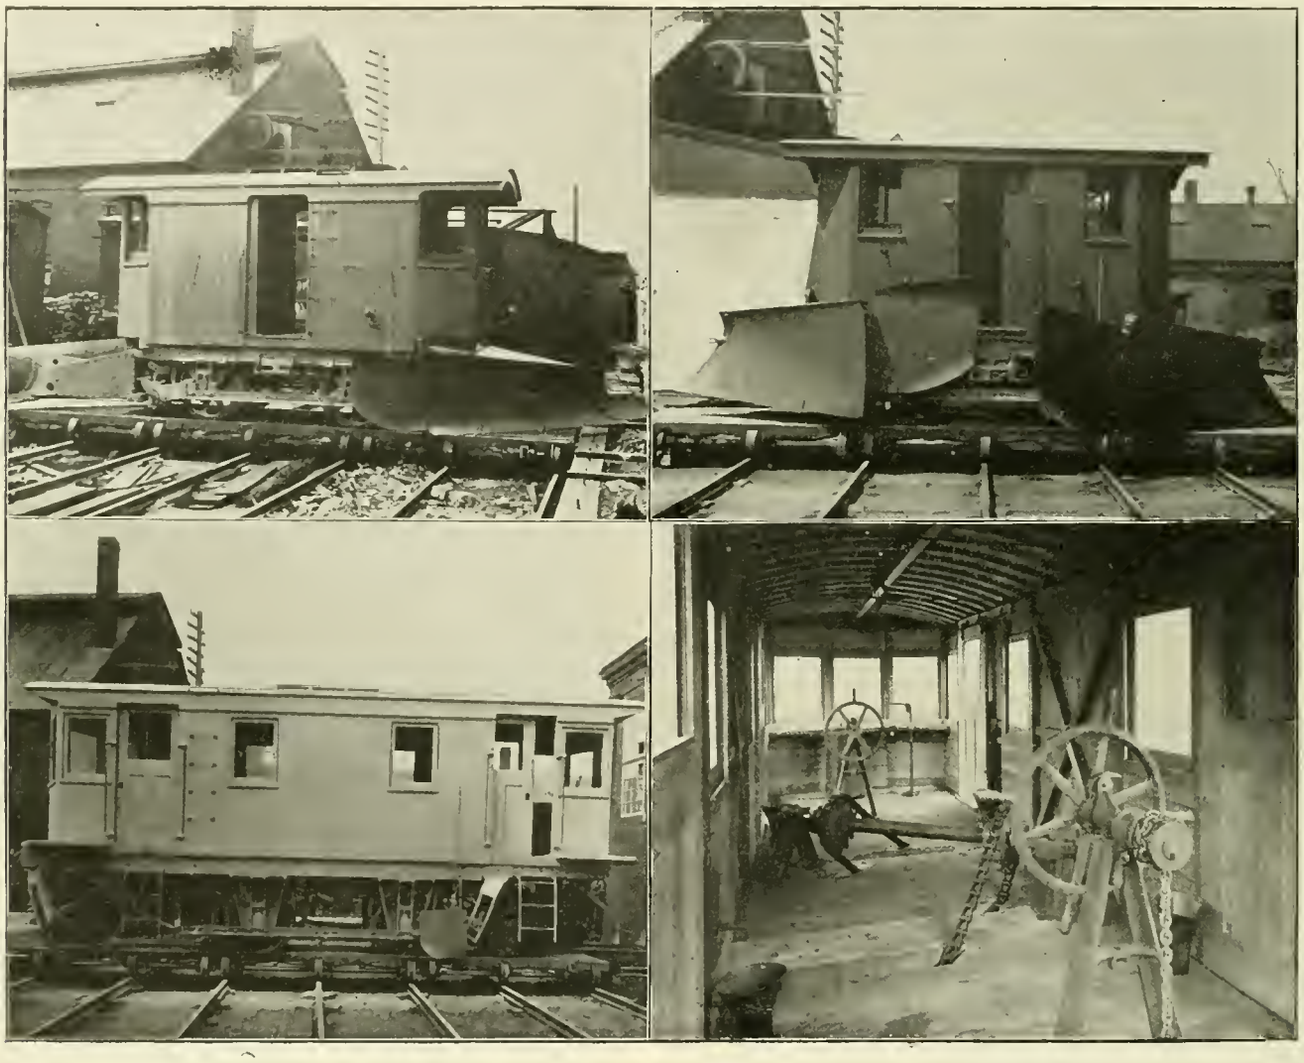
Those managers who will need to purchase snow plows and sweepers for use during the coming winter should now begin to place their orders if they wish to avoid all vexatious delays when the winter season comes. The first snow storm last fall came several weeks before it was expected and for that reason there were a great many roads which were closely blockaded, the plows not being in readiness; it is safe to say that those roads will not be caught in the same predicament again.

Some of the most successful and widely used snow plows and sweepers for electric railway work are those made by the Taunton Locomotive Manufacturing Co., of Taunton, Mass., and the accompanying engravings show the nose and share types of plow and the sweeper of this company.

The double track share plow for double track work in cities weighs 9 tons without motors, and has a share 39 in. high with a spread of 7 ft.; the spread is increased to 9 ft. 3½ in. by wings, and still further increased to 10 ft. 3½ in. by the extension share. The share is carried in front of all the wheels and thus room is obtained to place the motors on the axles. The extension girder, which with its lifting mechanism solves one of the most difficult problems in snow plow construction, is to all intents and purposes entirely of steel, as the castings used fill only a secondary place in the construction. The digger which was originally designed for the Taunton nose plow is now applied to all the company's snow handling apparatus.

The connection can be made for either the overhead or the underground trolley, and for the excellence of the machine as a whole the company refers to the work done during the last two winters in Boston, New York, Brooklyn and Lowell.

The standard nose plow weighs 9 tons without motors and has the following dimensions: Height of nose, 48 in.; spread of nose, 8 ft. 3 in.; spread of nose and wings, 11 ft. 8 in. The main framing of the plows of this type is of hard pine, but the nose framing is of oak and covered with steel plates. Access to the motors is readily had through large trap doors in the floor. Among the desirable points in the design and construction are these: The noses work easily and independently; the wings are pulled in by a kick of the foot and are fastened automatically; the noses and wings are shaped to roll away the snow and not simply to butt it; the operating parts of the plow are all at the ends of the house or cab and the floor is clear; the braking gear is quick and powerful in action.



TAUNTON STANDARD NOSE PLOW.
TAUNTON SWEEPER.

TAUNTON DOUBLE TRACK SHARE PLOW.
INTERIOR OF CAB.

The sweeper illustrated weighs about 25,000 lb. without the motors and has dimensions as below:

Length over sills	27 ft. 4 in.
Length over house	27 ft. 1 in.
Height of rail to top of trolley plank	12 ft. 4 in.
Height of rail to under side of sill	3 ft. 8½ in.
Diameter of brooms	36 in.
Dimensions of sills	11 x 4½ in.
Dimensions of cross sills	8 x 4½ in.
Wheel base	6 ft. 6 in.
Size and weight of wheels	33 in. 425 lb.
Diameter of axles	4 in.
Tread and flange of wheel	2¼ in. and ¾ in.
Greatest width with wings closed	9 ft. 8 in.

The large size of the main and cross sills indicates the substantial construction which is carried throughout the sweeper. The brooms are of a new and improved pattern such that the rattan cannot come out of the broom until it is absolutely

worn out; there is no chance to strew the roadside with broom material by reason of any failure on the part of glue or nails to hold the rattan in place. The brooms are run by an independent motor mounted in the cab; this allows the operator to run the broom at any desired speed with reference to the speed of the machine, that is to say, the machine may be run at a speed not exceeding 1½ miles per hour, while the broom may be run at full speed. This combination is of great advantage in drift work. In this machine the brooms extend clear across both rails in front of the machine so that a path nearly 3 ft. wider than the body of the machine is cleaned absolutely at the front. In addition to the thorough cleaning by the brooms, the sweeper has what it is claimed no other sweeper in the market possesses, namely, a first class digger which will remove ice from the rails in advance of the wheels.

In addition to the broom and diggers there may be put on each side a wing or leveler which breaks down the pile of snow which the broom throws on one side of the track. These wings are operated by counterbalance weights from the interior of the cab, and are quick and positive in action.

The sweeper is propelled by motors on the axles as a car or snow plow is propelled, and the brooms in the front of the machine only are run, the rear brooms in each case being easily raised up, thrown out of gear and held there by a simple and effective lifting device.

The cab is built something like a baggage car, but with vestibule ends and the doors are so placed that all the convenience of an open platform is secured without its exposure. The digger lever is directly over the head of the broom operator and the sand spouts are supplied with large pipes conveniently located. There are four sand boxes in the cab. The sweeper is not mounted on an independent truck, but the running gear is attached directly on to the main frame. This gives a simple and substantial form of construction with great strength. The mechanism is simple and everything is made with reference to easy handling in a storm.

MOB RULE IN LONDON, ONT.

The trouble which had been brewing between the London, (Ont.) St. Ry. Co. and the Street Railway Employes' Union for several weeks culminated on July 8th in a serious riot, during which the troops were called out and the city put under martial law. The strike, which has been in progress for some time, has resulted in the employment of non-union men by the company, and all the morning before the riot rumors were freely circulated that the non-union men were dissatisfied with the treatment they were receiving from the company, and that they were going to run their cars into the barn at 2 o'clock because of a reduction in wages. The rumor was entirely groundless, but as it spread among the union strikers they commenced to congregate near the car barns to witness the strike of their non-union successors. As no strike took place, however, the crowd which was being rapidly augmented, grew ugly, and after two or three cars which had been run into the barn by mistake were again put out on the road, acts of lawlessness were commenced. There seems to be no room for doubt that the mob was an organized affair, as some evidence on this point is already in the hands of the police. The appearance of a violent mob at just this time was also peculiar, as negotiations leading to a settlement had just been commenced between the company and the striking union men. A committee of the city council and of prominent citizens had been waiting for several days for a list of grievances against the company of which the strikers complained, which were to be arbitrated. This list, which was promised several days previous to the riot on Saturday, was not yet completed, but was expected by the following Tuesday, and it is rather inexplicable why Saturday should have been chosen for an onslaught upon the company's men and property, as it was reasonable to suppose that the citizens' committee would reach some decision which would terminate the strike amicably.

When cars 56 and 88, which were put into the barn by mistake, were brought out again to continue their trip, the trouble began. The non-union men were jeered and hissed and some of the mob untied the trolley rope of one car and threw the trolley off the wire. While a constable, who was on the car, climbed upon the roof with the motorman to adjust the trolley, a shower of stones were hurled at the car demolishing the windows and narrowly missing the men on the roof. At this juncture the chief of detectives arrested a man who was throwing stones, but the man was rescued by the mob. A special detective was also set upon by the crowd about this time and after being pelted with stones and eggs was struck on the back of the head by a striker, inflicting a severe scalp wound. The other car which left the barn ran to the end of the route and returned with three lady passengers, but no damage was inflicted upon it.

About 3 o'clock Mayor Wilson, Alderman Parnell and others addressed the mob urging them to disperse and promising to help the sitrikers adjust their difficulties as soon as their grievances were made known, but this had but little effect. After the mayor drove away, the police were unable to clear the street thoroughly, many of the crowd waiting for the appearance of the cars again. After two hours car 88 made its appearance, closely followed by cars 62 and 96. Each was pelted with rocks more freely than the preceding one and most of the glass was broken. No. 86 was next sent up to the barn, and the crowd made a tremendous onslaught upon it. The motorman dropped on his knees in the vestibule to avoid personal injury and the conductor ran into the car and laid down between the seats. The switch point was turned so that the car, instead of running into the barn, continued along to the loop at the end of the line. Here the crew deserted it and it was entirely demolished by the mob. The next car, No. 66, was taken into the barn by the county constable, although every window was smashed. Car No. 58 was similarly treated.

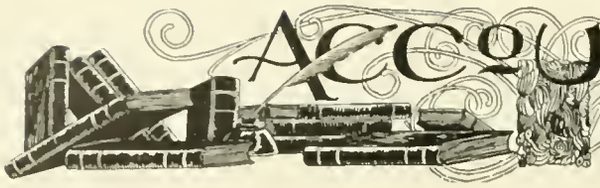
The most vicious attack of the day was made upon car 60, which was about a block behind car 58. The motorman and conductor barely escaped with their lives. A dozen stones crashed through the windows of the vestibule and the motorman sank to the floor with a broken nose, his forehead badly cut, a scalp wound and an injury in the neighborhood of the heart. He was in a semi-conscious condition when with the conductor he was taken from the car and placed in safety by the police. Cars 94, 80, 82 and 84 were similarly treated by the mob, which was now utterly beyond control of the police. An attempt to burn one car by saturating it with coal oil was with difficulty prevented by the police.

The mayor, accompanied by the crown attorney, again drove to the scene of the rioting and after addressing the crowd got their promise not to molest the remaining six cars on the line if they were taken into the barn by the police. The mayor was deceived, however, as when the first two cars coupled together and manned by the police approached the mob they met the same treatment as the previous ones, the two policemen both being hurt with stones, making it evidently unwise to attempt to bring in the other four cars.

Seeing that no more cars were coming the enraged mob started down town to demolish the last four cars stalled there. They were met by the mayor, who read the riot act in the thick of the crowd, but with little effect. Not until the soldiers, who were called out, advanced upon the mob with fixed bayonets would they disperse. The cars were then returned to the barn under military escort at 1:20 o'clock at night. Considerable damage was done to the store windows along the route and the list of the injured is a long one.

The city was put under martial law. In addition to the troops in the city, which numbered only 30 soldiers, 150 more were contributed by neighboring cities. The First Hussars and the regular force at the Toronto barracks were ordered to be in readiness at any time to go to London.

For several days following but few cars were run at night, while those in the daytime were under the military protection. On July 11th the strikers submitted their grievances in writing to the committee appointed by the council to effect a settlement of the difficulty. The committee, after going carefully over the list, came to the conclusion that no real grievance existed, and that it was merely a struggle for the recognition of the union. The company has offered to take back as many of the strikers as it has places for and to submit any real grievances to arbitration. It has, however, refused to be governed by the strikers' union, so under the circumstances no settlement could be made. On July 20th the company had all the positions filled with new men and cars have since been running on schedule time, but under police protection at night. The strikers maintained a bus line for a time, but this service was soon cut down so that it amounted to only a few trips a day. Business has been seriously affected in all branches by the strike, which has now been of several months duration.



CHANGES IN STANDARD ACCOUNTS.

The following report made by Mr. C. N. Duffy, chairman of the permanent committee on standardizing street railway accounts, to President Calderwood of the Street Railway Accountants' Association of America, will explain itself:

[In order that persons not having copies of the report of the 1898 committee in the pamphlet form, to which the references by page and line in the accompanying report refer, may note the changes, we have placed additional references to the "Street Railway Review" of September, 1898, in parenthesis.—Ed.]

REPORT.

St. Louis, July 21, 1899.

An invitation was received from Mr. Wm. O. Seymour, of the Board of Railroad Commissioners of Connecticut, to attend a meeting at the Manhattan Hotel, New York City, on July 11, 1899, to confer with the committee representing the Convention of Railroad Commissioners, and the committee representing the Association of American Railway Accounting Officers, for a general discussion upon the subject of a "Classification of Construction and Operating Expenses of Electric Roads," and I beg to report that Mr. Wm. F. Ham and myself attended this meeting, representing the Street Railway Accountants' Association of America.

The following gentlemen were present at the meeting: Wm. O. Seymour, member of the Board of Railroad Commissioners of Connecticut, and chairman of Committee on Classification of Construction and Operating Expenses for Street Railways; Ashley W. Cole, chairman, Board of Railroad Commissioners of State of New York, and a member of Mr. Seymour's committee; H. M. Kochersperger, comptroller, New York, New Haven & Hartford Railroad Co., and a member of the committee representing the Association of American Railway Accounting Officers; J. D. Greene, auditor of disbursements, Pennsylvania Railroad Co., and a member of the committee representing American Railway Accounting Officers; Wm. F. Ham and C. N. Duffy, representing the Street Railway Accountants' Association of America; H. T. Billings, clerk of the Board of Railroad Commissioners of Connecticut.

After a morning and an afternoon session, in which the report of the committee on "A Standard System of Street Railway Accounting," Covering the Classification of Construction and Equipment Accounts, Classification and Operating Expense Accounts, and Forms of Monthly and Annual Reports, made to the Street Railway Accountants' Association of America, at its second annual convention, held in Boston, Sept. 6, 1898, was discussed, the following modifications and changes were unanimously agreed to by all the gentlemen present:

1. The title of the sub-heading "Car Service," which includes Operating Expense Accounts Nos. 16 to 24, inclusive, and is the second sub-heading under the main heading "Transportation," was changed from "Car Service" to "Operation of Cars." This will necessitate a change in the printed report, as it appears on page 16. (St. Ry. Rev., Sept. 1898, p. 654.)

2. Account No. 8 "Maintenance of Miscellaneous Equipment." The second paragraph explaining what is to be charged to this account, which now reads: "Repairs and renewals of all harness, should be charged to this account," should be changed to read: "Repairs and renewals of all harness should be charged to this account. The cost of replacing horses lost by death or worn out in service, and the depreciation in the value of horses, should be charged to this account." This will necessitate a change in the printed report as it appears on page 25. (Ib., p. 656.)

3. Account No. 30, "Stable Expenses." The first paragraph explaining what is to be charged to this account, which now reads: "Charge to this account the cost of feed, keep and shoeing of horses, replacing horses lost by death or worn out in service, depreciation in value of horses, and all other stable expenses," should be changed to read: "Charge to this account the cost of feed, keep and shoeing of horses, and all other stable expenses." (Ib., p. 658.)

A new additional paragraph should be inserted, which will be the fourth paragraph, to read: "The cost of replacing horses lost by death or worn out in service, and the depreciation in the value of horses, should be charged to Account No. 8." This will necessitate a change in the printed report as it appears on page 35.

4. The number of Operating Expense Accounts is to be 38, Nos. 1 to 38 inclusive, Account No. 39, "Taxes," to be eliminated from Operating Expense Accounts, and classified as a "Deduction from Income." This will necessitate a change in the printed report, as it appears on page 17 (Ib., p. 654), as "39, Taxes," should be stricken out. This will also necessitate a change in the printed report as it appears on page 38 (Ib., p. 659), as it will be necessary to strike out the following: "Account No. 39, Taxes." "Charge to this account taxes on real and personal property used in the operation of the road, track taxes, franchise taxes, taxes upon capital stock, taxes upon gross earnings, car licenses and other vehicle licenses."

Page 15, line 30 (Ib., p. 654, 5th line from bottom of first column), insert the word "and" after 37 and preceding 38; insert a comma after 38. Page 15, line 31, strike out "and 39." "Page 15, line 33, insert the word "and" after "Terminals" and preceding "Insurance"; insert a comma after "Insurance"; strike out "and Taxes."

5. Monthly Report under "Deductions from Income" (Ib., p. 659), the first item is to be "Taxes." This will necessitate a change in the printed report as it appears on page 40, as it will be necessary under the heading "Deductions from Income" to insert as the first item "Taxes."

6. Annual Report under "Deductions from Income" (Ib., p. 659), the first item is to be "Taxes." This will necessitate a change in the printed report as it appears on page 41, as it will be necessary under the heading "Deductions from Income" to insert as the first item "Taxes."

It will also be necessary to change the form of printed report as it appears on page 39. Page 39, line 6, second paragraph, insert the word "and" after 37 and proceding 38; insert a comma after 38; strike out the words "and 39" (Ib., p. 659, third paragraph). Page 39, line 9, second paragraph, insert the word "and" after "terminals" and preceding "insurance"; strike out the words "and Taxes" (Ib., p. 659, third paragraph). Page 39, insert a new paragraph to be the third paragraph and read as follows: "Taxes include taxes on real and personal property used in the operation of the road, track taxes, franchise taxes, taxes upon capital stock, taxes upon gross earnings, car licenses and other vehicle licenses."

It will also be necessary to make the following changes in the printed report in the alphabetical list of items chargeable to Operating Expense Accounts:

Page 49, line 8 (Ib., p. 661), "Depreciation of Horses," "30," should read "8."

Page 53, line 9 (Ib., p. 661), "Horses, depreciation of," "30," should read "8."

Page 53, line 10, "Horses, replacement of," "30," should read "8."

Page 55 (Ib., p. 662), strike out 16th, 17th and 18th lines, "Licenses," etc.

Page 60, line 15 (Ib., p. 663), "Replacing horses," "30," should read 8."

Page 62, line 37 (Ib., p. 663), "Subscriptions other than to attractions," "33," should read "32."

Page 63 (Id., p. 663), strike out 14th, 15th, 16th, 17th, 18th, 19th, 20th, 21st and 22d lines, "Taxes, etc."

After the modifications and changes referred to above were unanimously agreed to by the gentlemen present, Mr. Seymour, chairman of the committee representing the Convention of Railroad Commissioners, announced, that at the annual meeting of his association, to be held in Denver, Aug. 10, 1899, his committee would make a report to the convention, recommending the adoption and use of the Standard System of Street Railway Accounting adopted by the Street Railway Accountants'

Association of America, with the modifications and changes agreed upon, which he would have embodied in his report, and that he was confident that his association would unanimously adopt the report as presented. Mr. Seymour stated that he would have at least 200 copies of the "Standard System of Street Railway Accounting" printed, containing the modifications and changes as agreed upon. Mr. Seymour also stated that he would have blank reports printed to conform with the Standard System of Street Railway Accounting, and that he would have the street railways of Connecticut make their annual reports for the fiscal year beginning in 1900, on these new forms.

Mr. Kochersperger and Mr. Greene, representing the Association of American Railway Accounting Officers, stated that they would report to their association, at its next annual convention to be held in May, 1900, the result of their conference with the committees from the Convention of Railroad Commissioners and the Street Railway Accountants' Association of America, and that as a committee, they would recommend the adoption and use of the Standard System of Street Railway Accounting adopted by the Street Railway Accountants' Association of America, with the modifications and changes as agreed upon embodied into the system.

Mr. Ham and myself, on behalf of the committee representing the Street Railway Accountants' Association of America, agreed to all the modifications and changes that were made, and stated to the gentlemen representing the other two associations, that we would present a report at the next annual convention of our association to be held in Chicago, in October, 1899, that we would embody what was agreed upon, and assured the gentlemen that we were confident that our association would sustain us in what we had done and unanimously recommend the adoption and use of the Standard System of Street Railway Accounting, as modified and changed.

Through the co-operation of the Convention of Railroad Commissioners, and the Association of American Railway Accounting Officers, with the Street Railway Accountants' Association of America, which will certainly be brought about by the action of the committees representing their respective associations, as, unquestionably, the action of those committees will be sustained by the associations, and in view of what the Street Railway Accountants' Association of America has already accomplished in the matter of bringing the Standard System of Street Railway Accounting into general use among street railway companies who are members of that association, Mr. Ham and myself are satisfied that the Standard System of Street Railway Accounting will be used by all of the street railway companies of the United States, and that a uniformity of methods and results, which has been so much desired, and for which we have so earnestly labored, will now be attained.

In explanation of the modifications and changes agreed to, I beg to submit the following:

1. Changing the title of the sub-heading "Car Service" from "Car Service" to "Operation of Cars." Mr. Kochersperger and Mr. Greene stated that the title "Car Service" would conflict with a technical term used in the operation of steam railroads, and with an account that steam railroads carried on their books, which represents a car-mileage account, as I understand it. In addition, it was suggested by these gentlemen that the title of the sub-heading "Operation of Cars" was preferable to "Car Service," and was in uniformity with the title of the first sub-heading under "Transportation," "Operation of Power Plant." Mr. Ham and myself readily agreed to this suggestion, and we both considered not only the objection to the other title well founded, but the name of the new title an improvement over the old.

2. Transferring from Account No. 30, "Stable Expenses," to Account No. 8, "Maintenance of Miscellaneous Equipment," the cost of replacing horses lost by death or worn out in service, and the depreciation in the value of horses. Mr. Kochersperger and Mr. Greene criticised the action of our committee in classifying this item under Account No. 30, "Stable Expenses," a "General Expense" Account, for the reason that they thought that the cost of maintaining horses was a maintenance charge, and should be classified under the same account that carried the cost of maintaining the wagons and horses. They pointed out that the wagons, harness and horses were one, in the sense that the wagons and harness were useless without the horses, and that in their opinion, Account No. 8 should carry the cost of maintaining wagons, harness and horses, in order to have the classification consistent. In this Mr. Ham and myself thought that unquestionably they were correct.

3. Eliminating Account No. 39, "Taxes," from Operating Expense Accounts and classifying it as a "Deduction from Income." In view of the fact that under the Inter-State Commerce Classification of Accounts, the universal standard followed by steam railroads, and the position taken by all of the boards of railroad commissioners throughout the United States that exercise any supervision over the books and accounts of street railways, to consider "Taxes" as a "Deduction from Income," and not as an "Operating Expense Account," and for the sake of bringing about a uniformity of methods and secure the co-operation of the Convention of Railroad Commissioners and the Association of American Railway Accounting Officers, all of the gentlemen representing these two associations being of the same opinion as to the disposition of "Taxes," and in addition being firmly fixed in their opinion that "Taxes" should not be a part of the operating expenses of a road, Mr. Ham and myself agreed to change our classification of Operating Expense Accounts, taking therefrom Account No. 39, "Taxes," and treating "Taxes" as a "Deduction from Income," making it the first item under that heading in monthly reports and annual reports.

A copy of that report will be sent to each of the gentlemen who attended the meeting at the Manhattan Hotel, New York City, July 11, 1899, to the two members of the committee of the Street Railway Accountants' Association, besides yourself, who were not present at the meeting, to the secretary of our association, and also to the two honorary members of our association, Mr. H. H. Windsor, editor of the "Street Railway Review," Chicago, and Mr. E. E. Higgins, of the Street Railway Journal, New York, as both of these gentlemen are deeply interested in the subject, and will, no doubt, give our association the benefit of the columns of their papers to further the work of our committee.

I trust that what was accomplished at the meeting and the action taken by Mr. Ham and myself will be endorsed and approved by the other members of our committee, as well as ratified and confirmed by our association, at the next annual convention to be held in Chicago, in October, 1899.

I shall write Mr Seymour and request him to have printed 300 additional copies of the report that his committee will present to his association at the annual convention in Denver, our association, of course, to pay the cost of printing these 300 extra copies.

C. N. DUFFY, Chairman.

To John F. Calderwood, Esq., President, Street Railway Accountants' Association of America.

The report which Mr. Seymour's committee made to the Convention of Railroad Commissioners at its meeting in Denver, August 10th, contains the most hearty endorsement of the "Standard System of Street Railway Accounting" that could be made, and is a high compliment to the Street Railway Accountants' Association and to its members which prepared the reports. Mr. Seymour's report is as follows:

To the Eleventh Annual Convention of Railroad Commissioners:

At the ninth annual convention of Railroad Commissioners, held in St. Louis in May, 1897, the following resolution was passed:

"Resolved, That a special committee of three be appointed by this convention to prepare a form of classification of the construction expenses and operating expenses of electric roads, to correspond as far as practicable with the forms approved by this convention, and adopted by the Interstate Commerce Commission for steam roads, and that said committee be authorized to invite the co-operation and assistance of the Association of American Railway Accounting Officers; also of the American Street Railway Association, or any other persons possessing expert knowledge appertaining to the subject, and to report the result of these proceedings to the next annual convention of this body."

The persons appointed to carry out the purposes of this resolution were: Wm. O. Seymour, of Connecticut; Ashley W. Cole, of New York, and R. S. Kayler, of Ohio. The committee appointed by the Association of American Railway Accounting Officers to co-operate with the foregoing committee were:

H. M. Kochersperger, comptroller of the New York, New Haven & Hartford Railroad Co.; M. Riebenack, assistant comp-

troller of the Pennsylvania Railroad Co.; H. D. Bulkley, comptroller of the Baltimore & Ohio Railroad Co. The committee as thus constituted met in New York City in April, 1898, and mapped out its work, closely modeled after the forms of the classification of the constitution and operating expenses of steam roads, but the items chargeable under each head of the various accounts were not completed, and we found it impossible to perfect it in time to present to the tenth annual convention, held in Washington in May, 1898. We therefore reported progress, and asked for an extension of time for the completion of the work, which the convention readily granted. At the time of this meeting in New York City it was learned that an organization was in existence known as the Street Railway Accountants' Association of America, which had been engaged for two years in preparing such a classification as we had been instructed to prepare. In accordance with the terms of the resolution appointing us, we sought and obtained the co-operation and assistance of this organization, to which we are indebted for the form herein presented for your consideration and adoption. It was found that the form prepared by the street railway accountants was so much more advanced in its preparation, so complete and full in its details, and so well adapted for its purpose, owing to the familiarity of those who prepared it with street railway accounting, that we deemed it wise to abandon the work which we had commenced, and advised the endorsement and adoption of the form prepared by them. Several slight modifications in the form have been made at the suggestion of the Railway Accounting Officers, and as it is now presented it is unanimously approved and recommended to this convention by your committee and the Railway Accounting Officers associated with us. Emanating from their own accounting officers, the form is more likely to be universally adopted and used by the street railway companies than if prepared and submitted by those entirely outside of their organization, especially if they are assured by our action that it will be accepted and approved by the various state commissions to which they are required to make annual reports. Your committee desire to publicly express their sincere thanks to the committee of the Street Railway Accountants' Association of America, who are the authors of this classification, and whose name, position and address are prefixed to this report, for the cordial and generous manner in which they have contributed the results of their laborious and extended deliberations for our consideration and adoption; also for the valuable assistance rendered by Mr. J. D. Green, auditor of disbursements of the Pennsylvania Railroad Co., who represented Mr. Riebenack upon the committee; to Col. N. H. Heft, superintendent of the electrical construction of the New York, New Haven & Hartford Railroad Co., who kindly gave us the benefit of his expert knowledge of electrical matters; to Col. Charles R. DeFreest, recently clerk of the Railroad Commissioners of the New York, whose assistance and advice was much appreciated; to Henry F. Billings, clerk of the Railroad Commission of Connecticut, and, finally to the committee of the Association of American Railway Accounting Officers, who were associated with us, without whose advice and assistance no good thing can be accomplished in devising correct methods of railway accounting. Respectfully submitted for the committee.

Wm. O. Seymour, Chairman.

WHALOM PARK, FITCHBURG & LEOMINSTER ROAD.

Mr. W. W. Sargent, superintendent of the Fitchburg (Mass.) & Leominster Street Railway Co., sends us a handsomely illustrated pamphlet descriptive of Whalom Lake and Park, the pleasure resort of this company. The park was first opened in 1893 and has become more popular each year, being at the present time a favorite picnic resort for the territory within a large radius; it comprises 60 acres, mostly wooded, on the shores of Whalom Lake. During the summer the Boston Opera Comique Co. has sung to large audiences; the program sent us occupies about a page in a 36-page pamphlet, otherwise filled with advertisements, so that we judge that there are a great many people to be reached through this medium.

The employes of the Washington (Pa.) Electric Street Railway have asked for an increase in their wages from 12½ cents an hour to 15 cents.

ST. LOUIS UNITED RAILWAYS.

The United Railways Co., of St. Louis, Mo., has been organized following the purchase of the St. Louis lines by Brown Bros & Co., of New York. This company will own and control every street railway in the city with the exception of the St. Louis & Suburban line, and it is generally expected that the latter road will eventually become one of the consolidation. The first purchase made by Brown Bros. & Co. in this city was the Lindell system, which also included the Missouri system, the latter having been absorbed by the former some time before. The Central Traction franchise was next purchased. Attention was then turned to the Union Depot system, and it was only a short time before that was taken in. The People's Ry. came next. The last purchase was consummated only a few weeks ago, and took in the National system and the Southern Electric line.

The capitalization of the new company is to be $45,000,000. An issue of stock to this amount is to be authorized. It is said that half will be in common and half in preferred stock. A meeting of the stockholders of the company has been called to be held Wednesday, September 20, for the purpose of voting upon a proposition to issue the company's bonds to the amount of $45,000,000, and there is no question but that this proposition will be carried. While these bond and stock issues are to be authorized, the entire issue will not be placed upon the market. A sufficient amount of the bonds and stocks will be reserved in the treasury of the company to be used for the redemption of all the outstanding bonds of the various companies taken in by the United Railways Company. As these old bonds fall due, they will be redeemed by the new ones and by stock reserved for that purpose. A sufficient amount will also be reserved to meet all outstanding floating indebtedness of the various companies, as well as for the purchase of other lines, franchises, property, etc., that may be desired by the consolidated company. The building of extensions and branches will also be provided for in this manner.

The following officers of the new company have been elected: Edwards Whittaker, president; Murray Carlton, vice-president; Jilson J. Coleman, general manager, and George W. Hunter, Robert McCulloch, George W. Baumhoff and James F. Davidson, division managers.

PICTURES SPEAK LOUDER THAN WORDS.

The almost invariable tendency of female street car passengers to alight from the cars in the wrong direction has been greatly checked on the Staten Island railway lines by a pictoral warning in the shape of a poster with which the cars are decorated.

The accompanying illustration is from one of the signs sent us by the New York & Staten Island Electric Co., West New Brighton, N. Y. The original is 16 x 9 in. and is printed in five colors.

A severe storm which passed over Washington, D. C., on July 16th, occasioned considerable delay upon some of the roads which are supplied with power from the Potomac Electric Power Co. Four poles were blown down at one point on the Georgetown and Tenallytown line, and as these poles carried the feeders, the whole system was crippled. Three cars were also burned out on the Great Falls road.

ENGLISH ELECTRIC LOCOMOTIVES.

Through the courtesy of Messrs. Crompton & Co., of London, we are able to present to our readers some illustrations and details of the electric locomotives which have been built by that company for the City & South London Ry. This road, which was described in the February, 1898, issue of the "Review," was the pioneer underground railway in the city of London. An important extension to this line has been under construction for some time but,

FIG. 1—CITY & SOUTH LONDON LOCOMOTIVE.

although advertised to be completed in July, will not be finished for two or three months yet, owing to the engineering difficulties met with in course of construction. The new line includes a tunnel under the Thames and will be operated from a new power station. Ten new locomotives have been ordered for this road to supplement the 20 others of various makes already in use. The new locomotives are all being built by Crompton & Co., and their general appearance is shown in Fig. 1. They have approximately the following dimensions:

Height	8 ft.	5½	in.
Total length over all	14 ft.	2	in.
Total width over all	6 ft.	10	in.
Length of wheel base	5 ft.	6	in.
Diameter of wheels	2 ft.	7	in.
Gage of track	4 ft.	8½	in.

Each locomotive is fitted with two motors, one of which is shown in Fig. 2. The armatures are built directly upon the axles so that there is no gearing whatever.

FIG. 2—MOTOR.

Each locomotive gives 150 lb. draw-bar pull at 150 amperes, and the maximum speed usually attained is 26 miles per hour. A view of the armatures mounted upon the axles is shown in Fig. 3. The locomotives are built with teak doors and polished plate glass windows. The cabs have wooden floors fitted in sections so as to be easily removable, and the interiors are neatly panelled with polished teak, each cab being provided with two seats and a locker.

The wheels have cast steel centers with tires 3 in. thick and 4¾ in. wide; the motors are suspended from brackets fixed underneath the cab at the four corners by means of bolts and springs. The locomotive is provided with a powerful hand brake, in addition to which there is also a Westinghouse air brake. For the use of the air brake there are two air storage reservoirs of about 18 cu. ft. capacity. These air reservoirs are charged by an air compressor in the cab which is direct driven by an electric motor so that the charging may take place while the train is in motion. Standpipes are situated at the station for charging the compressed air cylinders while the train is at rest.

Each locomotive is wired for two complete lightning circuits, each

FIG. 3—ARMATURES.

consisting of five 16-c. p. lamps in series. Two lamps are used for general lighting of the cab, one lamp is fixed over each commutator and the remaining lamp is used for a portable. The locomotive is also provided with two lamps with red, white and dark slides which are arranged for burning oil.

The controllers used are series-parallel controllers which were specially designed to meet the requirements of this railway by Mr. McMahon, chief engineer of the road. A tachometer reading "miles per hour," is located inside the cab, and is driven from one of the axles. The complete locomotive weighs about 13 tons.

EAST BOSTON TUNNEL ENJOINED.

The supreme court has decided that the Boston Transit Commission is not authorized to proceed with the construction of the East Boston tunnel provided for under the statute of 1897. A previous act authorized the Transit Commission to construct a tunnel connecting Hanover St., Boston, with the surface railways of East Boston and the amendment of 1897 requires the tunnel to be extended so as to connect with the present subway, an additional distance of nearly 2,000 ft. In the opinion of the corporation council the Commission by these acts was granted permission to do one of two things; to construct a tunnel to East Boston either from the surface at or near Hanover St., or from any subway which was already built. This opinion required the Commission to construct the tunnel as soon as the Elevated Railway Co., for whose tracks the tunnel was to be built, should be authorized to begin the construction of its railroad over the route applied for.

Estimates were made on nine different routes for the tunnel and one was chosen by the Commission which would come to the surface somewhere near North Sq. which would be at least 1,500 ft. from the nearest point of the subway and much farther than that from any car entrance to the subway. From the terminus of the tunnel it was proposed to run surface tracks to connect with the subway. This route was chosen because the estimate for it was within the amount of the appropriation, while to connect the tunnel with the existing subway would have considerably exceeded it.

Proceedings were brought by Causten Browne and others against the Commission, and to restrain the City Treasurer from issuing bonds for the cost of the tunnel, the petitioners contending that the connection between the subway and the tunnel must be an actual physical connection, and that a connection by means of several hun-

dred feet of street railway surface track was not such a connection as the statute called for.

In its decision the court says: "It is to be observed that the connection is to be made by the commission, and we can see no sound reason for making a distinction as to that duty at the different ends of the tunnel. As at the easterly end the tunnel must be extended far enough to make a physical connection with the surface tracks, so at the westerly end it must go far enough to make a physical connection with the subway, and as at the easterly end there must be no intervening link between the tunnel side and the surface track side of the point of connection, so at the westerly end there must be no intervening link between the tunnel side and the subway side of the point of connection."

In regard to the cost of construction the opinion states: "But the respondents urge that no such tunnel as is called for under this construction of the statute can or ever could be built with the sum already appropriated, while the tunnel which the commission has voted can be built within the appropriation. This fact does not seem to us of much weight. It is a matter of common knowledge that the actual cost of a public work frequently exceeds the estimate, and appropriations are made from time to time as needed, especially where considerable time is to be taken in its construction."

On these grounds the court has ordered the construction of the tunnel under the present plans to stop.

IMPROVED SERVICE ON THE LAKE STREET ELEVATED, CHICAGO, TO AND FROM OAK PARK.

Mr. Frank Hedley, general superintendent of the Lake Street Elevated Railroad Co., Chicago, advises us that on Monday, July 24th, the company put in effect a schedule giving nearly three times as many trains as heretofore. The improvement can best be appreciated by reference to the table showing the former and the present headway at different hours of the day.

Time.	Old Headway.	New Headway.
12:00 to 1:30 a. m.	45 min.	45 min.
1:30 a. m. to 4:30 a. m.	60 "	60 "
5:54 a. m. to 8:15 a. m.	10 "	6 "
8:15 a. m. to 4:30 p. m.	20 "	7 "
4:30 p. m. to 7:45 p. m.	7 "	6 "
7:45 p. m. to 11:00 p. m.	20 "	7 "
11:00 p. m. to 12:00 m. n.	20 "	10 "

The western terminus of this road is now at Wisconsin Ave. and Randolph St., in Oak Park, 9 miles from the northwest corner of the Union Loop. The total distance on the elevated structure is 7 miles, the last 2½ miles being over surface tracks; the incline connecting the surface and the elevated tracks is about 800 ft. long and lies between West 52d St. and Willow Ave., Austin.

In May last the Lake Street Elevated inaugurated a special express service to the Harlem Race Track, which has been continued since that date, and is greatly appreciated by patrons. The races at Harlem occur during each alternate two weeks, and during the races eight special trains leave from the corner of State and Randolph Sts., at intervals of 7 minutes, the first one leaving at 1:48 p. m., and run to the race track without any stops save at five of the Union Loop stations. The other stopping points on the Loop are at Madison and Wabash, State and Van Buren, Pacific and Van Buren, Madison and Fifth Ave. and Randolph and Fifth Ave.; from this last station to Harlem is 9 miles and the run is made in 25 minutes. Between the Loop and Cuyler Ave. it is necessary to pass regular trains at various points and the schedules are so arranged that the meetings occur where there are cross-overs and sections of third track; the regular trains are shunted to the third track, giving the main line to the race specials. From Cuyler Ave. to the race track the trains run over the lines of the Suburban Railroad Co. The saving in time by the express trains is about 14 minutes.

When the Lake Street road was built it was designed with the idea of laying a third track between the two main tracks, and at various points sections of the third track have been built and are used for switching purposes. The company has under consideration the completion of the third track between Campbell Ave. and W. 52d St., which will enable it to give an express service, the express trains making no stops between these points.

TRAMWAYS IN MILAN.

The following description of the tramways of Milan, Italy, is furnished by U. S. Consul W. Jarvis:

The transit service in Milan is electrical. All the tram lines excepting three start from the Piazza del Duomo (the Cathedral square) and run either to the various railroad stations or through the gates to points beyond the city limits. The lines above excepted are one from the Central Railroad Station that runs past the Northern Railroad Station to the Porta Ticinese Station, another that encircles the city, and a third from Porta Volta to the Musocco Cemetery.

The line that encircles the city is divided into five sections, and the fare on each section is 10 centesimi (2 cents), or 50 centesimi (10 cents) for the round trip. The line that runs from the Central Railroad Station past the Northern Railroad Station to the Porta Ticinese Station is divided into two sections, and the fare on each section is 10 centesimi (2 cents); 20 centesimi (4 cents) for the whole trip. The fare on the line from Porta Volta to the Musocco Cemetery is 15 centesimi (3 cents). The fare on each of the lines starting from the Piazza del Duomo is 10 centesimi (2 cents). But for the benefit of the working and the poorer classes, the fare is 5 centesimi (1 cent) on each line from the Piazza del Duomo and on each section of the other lines before 8 a. m. in the summer and 9 a. m. in the winter.

The total development of track system owned by the commune is 66 miles. But, as some of the trams run over the same track for certain distances at various points, the actual length of track is 42 miles. The contract which the Societa Generale Edison di Electricta has with the municipality of Milan for the management of the city's tramways lasts for twenty years. The commune provided at its own expense the laying down of the tracks, which were transferred to the above society on the payment of 4,500 lire ($868.50) for each kilometer (0.62137 mile, or 3,280 feet 10 inches) of single track.

The commune pays to the above society 25½ centesimi (5.1 cents) for each car per kilometer. From the total yearly receipts are deducted the amounts paid by the society to the commune and by the commune to the society, and the remainder is divided between the society and the commune in the proportion of 40 per cent to the former and 60 per cent to the latter.

The regulations permit of cars carrying more passengers than there are seats, but, to prevent overcrowding, the gates are often closed. Only one gate is opened on each car—which will seat about 18 passengers—and this is always on the opposite side of the car from the parallel track, so there is no danger of stepping off in front of an approaching train. There were 44,559,888 passengers carried in 1898, against 39,736,091 in 1897.

The tram service in Milan is excellent; the cars are run with care and skill, and, when it is possible, at a fair rate of speed. There are very few accidents, although there is a perfect network of tracks in the Piazza del Duomo, and many of the streets through which the trams run are very narrow. The conductors are polite and obliging.

WAGES INCREASED.

Among street railway companies which have found it possible to increase the wages paid to all of their employes are the Union Traction Co., Muncie, Ind., which made an increase ranging from 10 to 15 per cent according to the length of service; the La Crosse (Wis.) City Railway Co., which increased the pay of its conductors and motormen $2 per month and made a rate of 15 cents per hour for overtime, and the Columbus (O.) Street Railway Co., which increased the wages of its laborers 20 per cent; the Lexington (Ky.) Railway Co., which increased the pay of conductors $1 per week, with the promise of another increase; the Glen Oak & Prospect Heights Railway Co., which increased the wages of its conductors 50 cents and of its motormen $1 per week, and the Milwaukee Electric Railway & Light Co., which on July 25th made the rate 20 cents per hour instead of 19 cents.

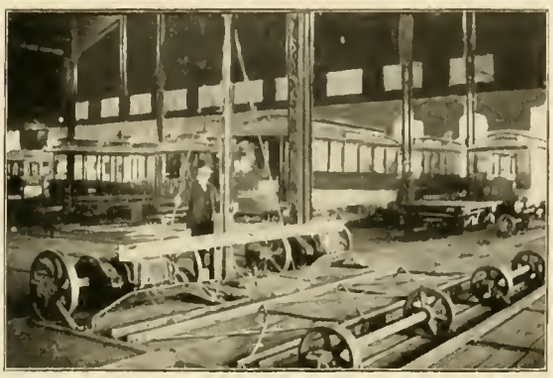
The Columbus (O.) Street Railway Co. also increased the wages of its employes by arranging for a dividend on wages earned.

The Portland (Me.) Street Railway Co. has just put a new system of transfers into operation upon its new lines in the Forest City.

MECHANICAL DEPARTMENT

A NEW TRANSFER TABLE.

The accompanying illustration shows a new transfer table recently installed in one of the car barns of the New Orleans City Railroad Co. There was found to be insufficient track entrances to this barn and to facilitate the movement of cars in this barn the

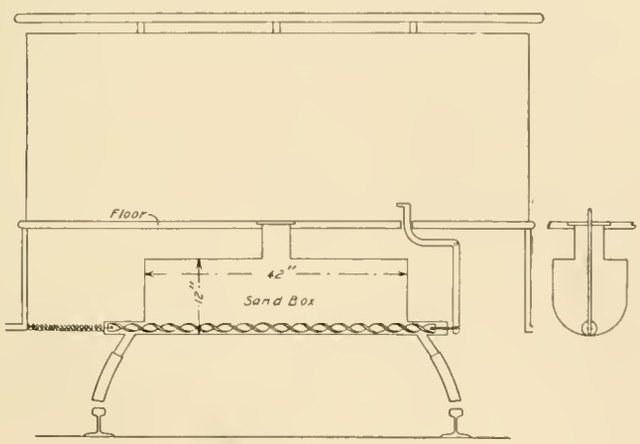


TRANSFER TABLE, NEW ORLEANS CITY R. R.

transfer table shown was constructed. The general arrangement of the table is very well shown in the illustration. It is equipped with two 30-h. p. motors and a K2 controller. An old W. P. rheostat controller is used for the K2 controller. The table was made of an extra length to accommodate the double truck cars used by this company, and since its installation has proved a great success in facilitating the movement of cars about the barn.

PLATFORM SAND BOX.

Mr. Thomas Elliott, chief engineer of the Atlanta (Ga.) Consolidated Street Railway Co. and of the Atlanta Railway Co., has recently designed a platform sand box for sanding both track rails,



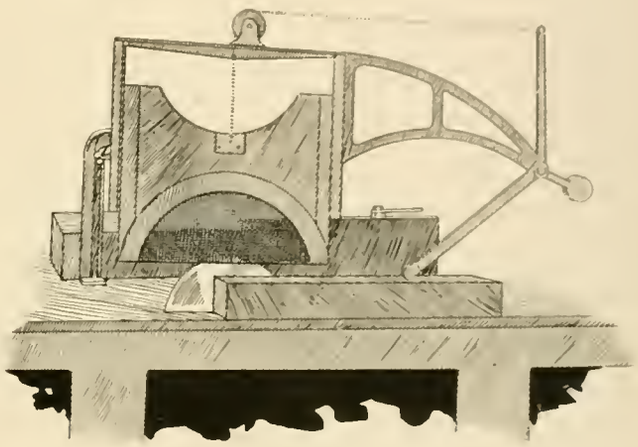
SAND BOX, ATLANTA, GA.

which is shown diagrammatically in the accompanying sketches. The box is 42 in. long and 12 in. deep, with a capacity of 3 cu. ft.; it is placed transversely under the front platform of the car and is filled through a hole cut in the platform and covered by a hinged lid. A pipe extends from each end, terminating over the rail. For manipulating the sand a treadle on the platform is connected to a bar of ¼ x 1½ iron, twisted, extending through the box; on the other end is a spring. When the treadle is pressed down by the motorman the twisted bar is drawn to the right and forces sand out on one rail; when the treadle is released the spring pulls the twisted bar back and forces sand out on the other. In new boxes now under construction a door is placed in the bottom for removing stones or such matter as may inadvertently get in with the sand.

The box is placed so far in front of the wheels that the spouts do not cover the track rails at curves, which is considered an advantage, as it prevents the use of sand at these points which should be kept greased.

SAW GUARD.

In a recent number of Engineering, London, was published a brief description of the circular saw guard shown in the accompanying sketch. It is in use at shops of the London & Northwestern Ry. As seen it consists of a counter balanced cover for the



SAW GUARD.

saw blade which is raised to the proper height to clear the work by the lower arm of the bell-crank lever; this arm has a friction roller at the end which bears on the work.

DOES PAINTING PAY.

BY J. L. J.

There is little doubt but that this question presents itself many times and in many forms, to the management and officials of street railways. The paint shop, if it is a luxury, is a very expensive one indeed, but if it be a standing necessity, it surely is something which demands careful thought. Provided that it is placed under proper system and control, it should then be considered at least one of the best paying investments which any road can make. There are very many reasons why this assertion can be made. Let us study a few of them. The life of a street car is very dependent on the painting, and is very materially lengthened if the body of paint and varnish is kept in good condition, that is, each exposed part so covered by the oily film called paint. Iron parts are not exposed to the elements, and consequently do not rust. If the wood is shielded so that no moisture can enter it, scarcely any expansion or contraction takes place, and there is no opening of the fibers or loosening of joints or tenons, except as they may be wrenched or forced by hard usage. It can easily be seen that with

the expansion which would be caused by rains and contraction from heat, that a car would soon be falling to pieces from what might very justly be called premature decay. It would probably be quite safe to say that one-half of the life of a car is added by its being protected by paint.

Still, in the face of these important facts, the paint shop seems to be regarded in some cases as an extravagance, a sort of necessary evil that must be tolerated. However, strange this may seem, it is true. This feeling comes from a lack of study on the part of the official in charge. There is little doubt but that his mind is taken up by matters of deep and live interest which thrust themselves to the front. But paint and painting should not be put in the background. The reader of this article may urge that it is written by a painter and from a painter's standpoint. The responsive question immediately comes: From what point of view can painting be considered as intelligently as from that of a painter's? Or, who is so well qualified to judge, or knows as much about painting as the man who has spent his lifetime studying that subject?

To illustrate: Some time ago the writer attended a painters' convention, and from all sides criticism was heard on the color of the cars in the city and the lack of harmony in the general effect of striping and ornamenting. More than twice as much money had been used than would have been necessary to give the cars a very pretty and pleasing general effect. But, instead, they had an unkept, blank, repulsive appearance to the eyes of the painters assembled. Some inquisitive party took the trouble to ask who was the designer of the painting on the cars, and learned that some official on the road had conceived the idea and "so ordered it."

To say the least, the man responsible did not consult a painter or even the taste of any lady, or he would have learned that contrast must be had to bring harmony, and vice versa. A disregard of harmony in contrast makes the result tame and flat or glaring and vulgar. No doubt the query is very often made: Does it pay to put on a good finish and also to ornament a street car on the outside? We say, decidedly yes. A company must do so, to a certain limit. Beyond that limit, no. That limit may be found very easily by getting the pulse of the people or watching the dress and taste of the masses and striking an average, thereby getting the happy medium between the flights of fashion on the one hand and the hard, tasteless finish which appears to say "we want the earth," on the other. It must be poor policy to have a car painted in such a manner that it gives an impression of disregard for the sentiments of the people. They who would win from the public must cater, in some measure, to its wishes. It is plainly noticeable that buildings that are built and painted in an inviting and tastful style are more readily taken by tenants than those built with a disregard of taste. There is a class of the traveling public who are almost compelled to ride in any kind of a car that is presented. But there are many who ride for pleasure, and a car so painted that it gives a pleasing effect is a drawing card and leads the thoughts to diversion and rest. There can be no reasonable doubt but that many rides are taken in street cars because they have taken the attention and pleased the eye; which would not have been done if the cars had not been painted in a way that brought a sense of pleasure to the parties who ride in them.

SOME SHOP HINTS.

By courtesy of Mr. H. M. Sloan, general manager, and Mr. W. A. Harding, master mechanic, we are able to describe some rather interesting tools and methods used in the shops of the Calumet Electric Street Railway Co., Chicago.

FIELD COIL FORMER.

Fig. 1 shows an iron former for winding fields which was made to obviate the annoyance resulting from wooden formers breaking and wearing out. It is made to suit the field coils to be wound on it and consists of a former casting and a cover plate. The cover plate has a piece of wood bolted to it and to this is glued a strip of leather where the wire comes in contact with it; this arrangement was the outgrowth of experience, it having been found that either iron or wood would abrade the insulation on the wire. Four slots are cut in the sloping flange of the former and opposite these in the parallel portion are shallow grooves; these permit the insertion of straps or the application of mallet to remove the coil from the former. The shank projecting from the back is held in the jaws of a lathe chuck when winding a coil.

SPECIAL CHUCKS.

For turning bearings special chucks shown in Fig. 2 are used. There are now three sizes used in the shops for W. P. 50 and G. E. 800 armature bearings. The sketches show all the necessary di-

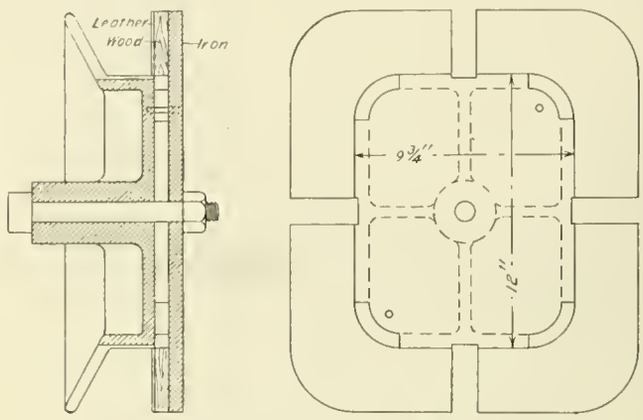


FIG. 1—FIELD COIL FORMER.

mensions. Fig. 2 is used for two styles of bearings, the channel opposite the split side of the chuck being cut to give room for the feather or key, which is on the outside of one type of bearing shell; the other type of shell is round with no projections.

Fig. 3 is a chuck for G. E. 800 armature bearings. For a modified armature bearing which has been designed in the shop for

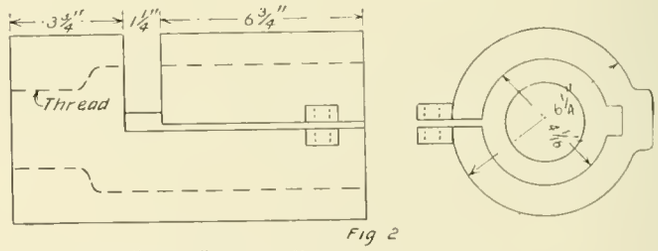

Fig 2

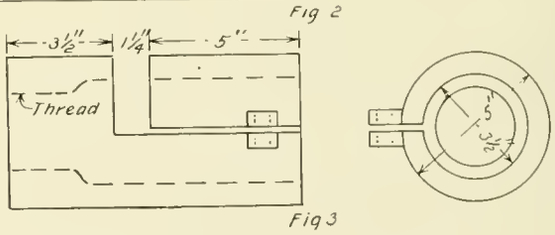

Fig 3

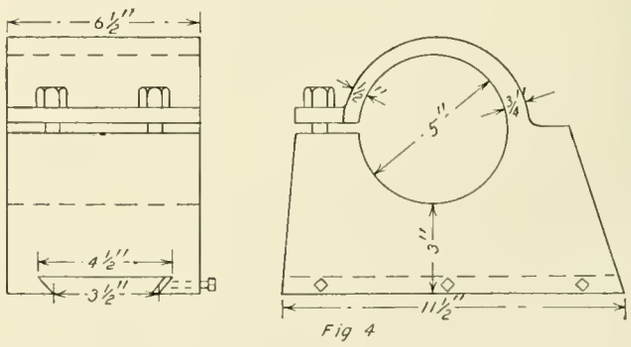

Fig 4

SPECIAL CHUCKS.

W. P. 50 motors there is a third chuck of the same dimensions as Fig. 3, except that the internal diameter is 3¾ in.

These chucks are split along one side and the bearing clamped by a single bolt through the lugs shown. Half the chuck is cut away for a distance of 1¼ in., this being done with a three-fold object; it makes the clamp more flexible, it provides a place for turnings and chips to escape, and it gives the workman a better

opportunity to examine his work and to caliper it at both ends without removing the chuck.

As it has been found that so-called standard bearings are very seldom uniform either in diameter or length, it is not the practice to keep the supply of babbitted bearings turned to these standards, but when a new bearing is used the armature shaft is measured off to give the proper end play. The rough babbitted bearings are of course kept in stock.

Fig. 4 is a special device used for turning the brass axle motor bearings; these are not babbitted. The bearing is solid and clamped in the holder which is placed on the apron of the lathe replacing the tool holder. A boring bar with two tools, one to give the roughing and one the finishing cut, is mounted between the centers and the shell very quickly finished.

PIPE BENDING.

Just before the Fourth of July there was a call for 10 pairs of car side gates which were needed in a great hurry. It was found that extra heavy ½-in. pipe would fit the hooks on the cars, and side gates were made by bending pipes about a former and riveting three cross bars in them. The former is a piece of heavy oak plank shaped at the corners as shown in Fig. 5; the bending tool is a forged fork with an iron pulley mounted near the crotch, the ends of the fork being pivoted to the former. Small iron plates are let into the wood to form bearings for the pivot bolt. The rounded corners of the former protrude in order to allow the bending fork to carry the pipe beyond a right angle, the permanent set always being less than the maximum deflection.

A similar simple former was used in turning out some complicated shapes in bent piping used for making single piece fenders.

CAR SIGNS.

The company starts cars for several divisions from the same terminal and this makes it necessary that each one be provided with a sign indicating the route or destination, of such design that it can be clearly read at a considerable distance. For some years the cars on different routes have been given sign boards of distinctive colors which enable the patrons to tell the destination of an approaching car in the day time. These boards are 12 x 24 in. and were hung on the dasher by a strap-iron hook fastened on one end of the sign board. The boards were painted with the proper route color and on this background the name of the destination was painted in large letters. The signs were reversible, each side bearing the name of one of the two termini of the route. These signs answered admirably during the daytime, but at night the motormen found that on certain portions of the line it was necessary to come to nearly a full stop at every street intersection in order to let persons who might be waiting see whether this was the car they wanted to take. This resulted in a serious loss of

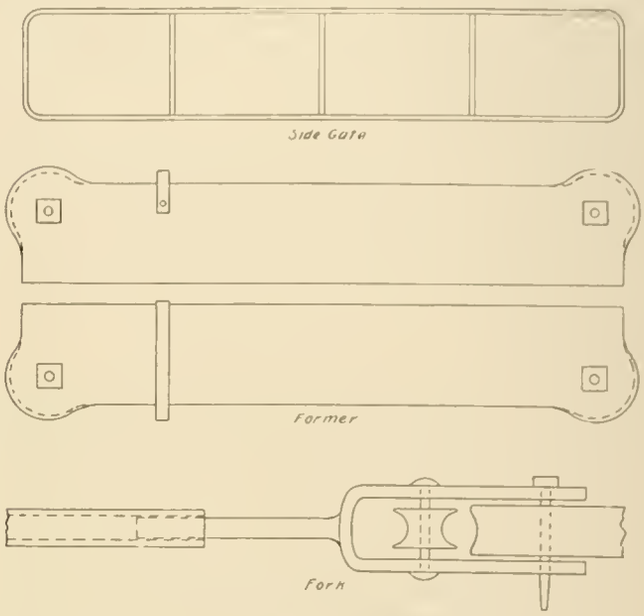

FIG. 5—FORMERS FOR BENDING PIPING.

time and it was decided by the management that a sign which would serve by night as well as by day must be provided.

The first condition laid down by Mr. Sloan was that in daylight the sign must show letters on a background of the route color, and at night show illuminated letters of the route color, the background at night of course being black. A plan in which this condition is successfully met for all routes except those whose color is white or brown, was worked out a few months ago by Mr. Harding.

The route colors are: Red for the Roby division; brown for West Pullman; white for Auburn Park; green for Pullman; yellow for Manhattan Beach, and purple for one of the cross lines.

Experiments showed that the best location for the illuminated signs was at the upper part of the dasher at the motorman's right. Placing the signs on the hoods was considered, but abandoned because of the danger of the trolley rope catching on the box of the sign at the rear end; the location chosen is sufficiently far from the headlight and, as will be explained later, the box is to a considerable extent protected from injury through the carelessness of passengers by the brake staff and the forging bracing the upper end of the staff.

Cars so far equipped with the signs are of two patterns, those with wood dashers and those with iron dashers. For the latter a wooden box 11½ in. high, 24 in. long and 4 in. deep was bolted on the outside of the dasher; this box had a slanting top to shed water. If it is necessary to place any more boxes outside of the iron dash-

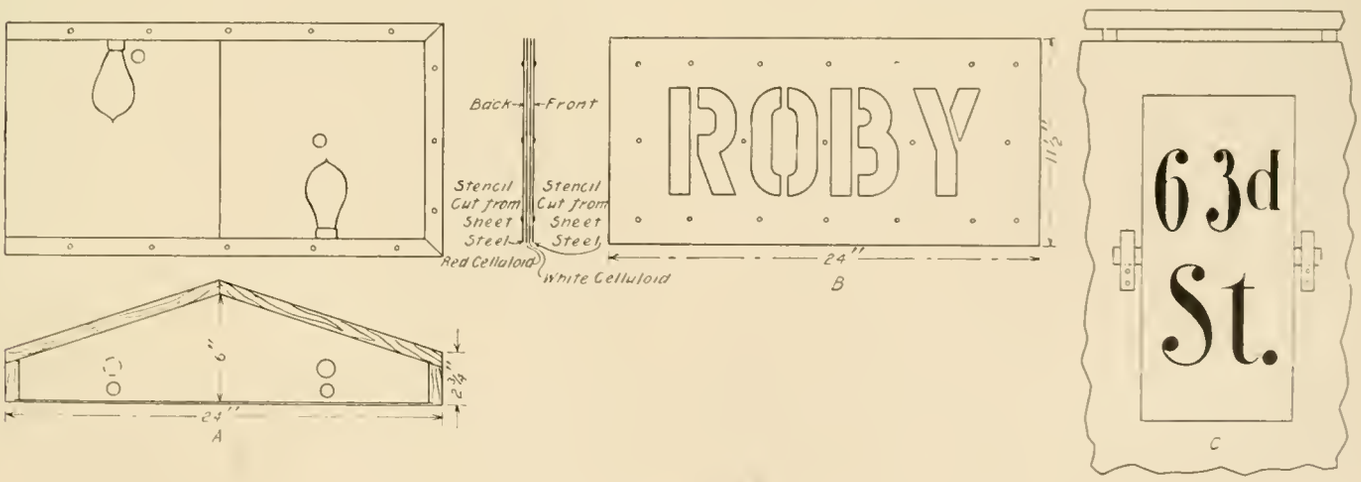

FIG. 6—CAR SIGNS.

ers a malleable iron box without any back will be riveted to the dasher. The standard construction, however, is that used on the wooden dash cars and is as shown in the sketch; the sign board, lamps, etc., are the same for both kinds of cars.

A hole is cut in the dasher near the top and a light wooden box

of the shape and dimensions shown at A in the sketch inserted. This box must be able to stand a little rough usage because passengers will persist in piling or resting packages on it as it projects into the vestibule, but by placing it behind the brake staff and under the braces supporting the latter at the top it is well protected. Strap irons are fastened to the front of the dasher to make the grooves in which the sign slides. Two incandescent lamps are placed in the box as indicated at A. For ventilation there are four holes cut in the box, two in the bottom near the front edge, and two in the back above the lamps.

The sign itself consists of two sheets of thin steel, in which the proper letters have been cut, making a stencil, and two sheets of celluloid, the four being fastened together with small copper rivets. These signs are 11½ in. high and 24 in. long; sheet celluloid is made 20 x 28 in., hence in designing signs, this size should be borne in mind to avoid waste in cutting.

The Roby sign shown at B in the sketch has in front a steel stencil showing the word "Roby," next a sheet of very thin white celluloid, next a sheet of red celluloid, and at the back a steel stencil exactly similar to the front one. Before assembling, the steel sheets are painted on both sides to prevent the inner side rusting when the celluloid is cleaned with a sponge and water.

Some of the divisions have the names of both termini cut in the stencil plates. It is found that the best green is got by using blue celluloid for the color sheet, instead of green.

Exceptions were noted in the complete consistency of the color scheme on the two routes. West Pullman cars by day show white letters on a brown background; only white celluloid is used in the sign and it shows white illuminated letters at night. The Auburn Park line is indicated during the day by black letters on a white background; the sign is a thick sheet of white celluloid on which are painted black letters; at night it shows black letters on a white ground. Special cars are almost always run in the daytime only and the signs used on them have the word "Special" in silver letters on a black ground; this is the sign used on funeral trains.

The signs being removable, cars may be changed from one division to another without causing confusion.

Two of the signs are placed on the car, one at each end, the two lamps in each box and a fifth one which is in the conductor's end, being in series. The cost of equipping a car with these signs is about $10, distributed as follows:

4 steel stencils @ 90 cents	$3.60
4 quarter-sheets celluloid @ 60 cents per sheet	.60
rivets and labor	.20
paintings and labor	.20
2 boxes @ 75 cents	1.50
5 lamp sockets @ 7½ cents	.38
5 lamps @ 18 cents	.90
wire	.40
labor of placing boxes, wiring, etc	1.75
Total	$9.53

Next year Mr. Sloan hopes to have all his motor cars fitted and in the meantime has made a change in the way of hanging the old sign board carried on the dasher so as to prevent them from swinging and scratching the paint. A piece of strap iron is fastened across the middle of the board with the ends projecting about 2 in. to form lugs at the sides. Two pieces of strap iron riveted to the dasher receive these lugs and hold the board in position, as shown at C in the sketch.

SOUTH KNOXVILLE, TENN., LINE OPENED.

On July 3d the first car of the Knoxville Traction Co. crossed the Tennessee River bridge into South Knoxville, carrying some of the prominent citizens as guests, and on July 4th the regular schedule was put into effect. On this day the company's highest previous record of passengers carried was beaten by 7,000. Everyone of the company's cars was put in service and about 35,000 passengers were carried. In consideration of the hard and faithful work done by the employes, Manager Howell gave every man in the employ of the company, motormen, conductors, shopmen, power-house men, etc., $2 extra for the day's work, to show that their efforts were appreciated by the road.

VESTIBULES IN NEW HAMPSHIRE.

The New Hampshire Legislature at its last session passed an act authorizing the Board of Railroad Commissioners to act on the question of vestibules for street cars, its order to be sanctioned by a penalty of $50 per day. On July 20th the board issued its order, which, after reciting the act, proceeded as follows:

With a view to an intelligent discharge of the duties imposed upon it by this act the board has made such investigations as it could by public hearings in Manchester and Concord, to which all street railway managers and others interested were invited, by inquiry among motormen and conductors, and by correspondence with persons in other states, and having weighed all the information and opinions it has been able to obtain, finds:

The electric vestibule is of comparatively recent origin and is still in an experimental state as regards patterns and methods of construction. The objections to it are that it obstructs somewhat the view of motormen and conductors, thereby increasing the liability to accidents, and that its doors interfere with the free and safe ingress and egress of passengers, and these objections outweigh it advantages in cities of more than 55,000 population, where the streets are protected from the wind by high buildings and the volume of traffic is so large as to require frequent stops and almost constant use of the platforms and doors.

That it is not much needed upon lines in cities where the trips are very short, and car men and passengers are exposed to the elements but a few minutes at a time, is obvious.

It is admitted that in outlying and sparsely settled districts vestibules not only protect car men from the inclemency of the weather, but conduce to the comfort of passengers without putting any one in jeopardy, or to serious inconvenience, and no instance can be learned where, when once adopted, they have been discarded.

In New Hampshire all closed cars in use upon the Springfield, Chester & Derry, Exeter, Hampton & Amesbury and Portsmouth roads, and upon the Penacook lines in Concord, and the Hudson Lowell lines in Nashua, which reach into country districts, have been provided with vestibules, and the testimony of managers and car men who have had experience with them is unanimous in their favor.

In Massachusetts they are required by law upon all new cars for use in cities having 55,000 population or more, and similar legislation has been obtained in several other states.

That they will, in the near future, be deemed to be necessary upon all winter cars in cities of less than 75,000 people, and in all towns, we think is certain.

The question which presents itself to us is, whether they shall be had at once in this state, or secured gradually as cars are repaired, replaced or multiplied.

The evident purpose of the Legislature in passing the act quoted was to require them, wherever they are needed, and as all our lines of any considerable length extend into suburban and country districts where this protection is as desirable as upon those on which it is conceded to be necessary, and has already been provided by the voluntary act of the managers, we are unable to find good reason for exempting any of them.

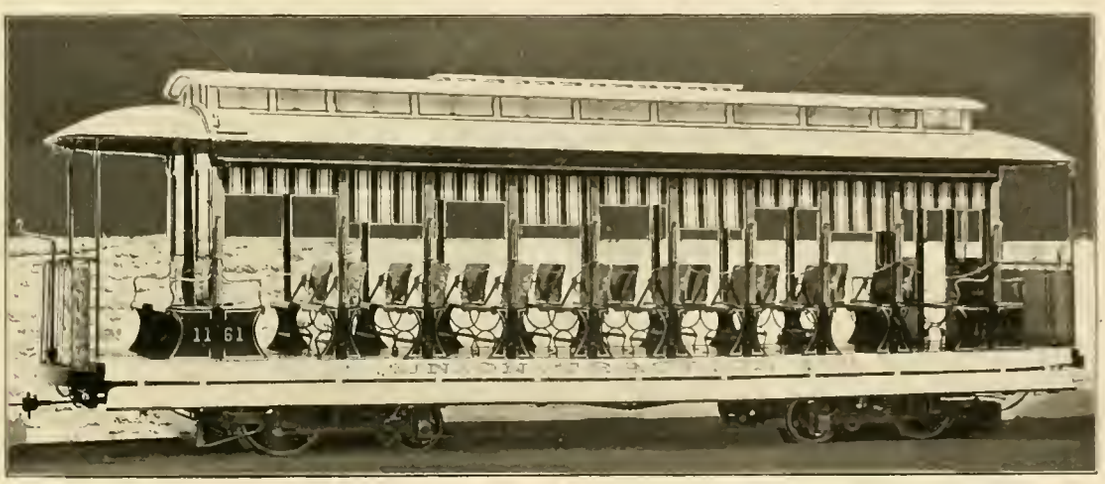
It is, therefore, ordered that all closed electric passenger cars run regularly in this state in the months of December, January, February and March, except those used in cities on lines so short that the schedule time for round trips does not exceed 15 minutes, shall be provided with vestibules of patterns approved by the railroad commission, it being understood that this requirement does not apply to cars run only on special occasions or in emergencies, or to take the place temporarily of those that are being repaired.

The Kansas City Street Railway Co., which, a little more than a year ago, gave $11,000 to the Kansas City convention hall project, has now given $5,000 to the fund, by the offer of which Kansas City hopes to secure the meeting of the next democratic national convention.

An attempt is being made to abolish the grade crossings of the Detroit street railways with the Lake Shore and the Nickel Plate railroads. It is proposed to tunnel beneath the former and bridge over the latter. The city engineer estimates the cost of the work at $179,000.

OPEN CARS WITH CENTER AISLES.

The Union Traction Co., of Philadelphia, has become thoroughly convinced of the value of large cars for the accommodation of its traffic. As has been noted before in these columns, it has been extensively rebuilding its four-wheeled cars, adding to the length and mounting them on maximum traction trucks. Up to the present time no attempt has been made to remodel the open cars, and such a scheme would hardly be considered possible in view of the number of different styles of open cars which the company has in operation. It has, however, ordered a large number of a new type of open cars from the J. G. Brill Co., the first delivery of which was made recently. These are 12-bench open cars with a central aisle. From the passenger's standpoint, they are among the most desirable of all the various types of open cars, as each seat has space for two persons and no more; and when a passenger steps upon the car, no matter at what point, he is sure of obtaining any available seat, no matter where it may be found. Women, children and persons of short stature can enter by the platform steps without difficulty and reach a seat with perfect ease. The platform step has the usual height instead of the 18 in. necessary to reach the step of the open car. During inclement weather, when the curtains are down, neither the conductor nor passengers are exposed, and there is no need of guessing at what seat behind the curtain is empty, and no getting into the car at a point where seats are full and then being obliged to stand with empty seats unavailable except by going out in the rain again. In case of crowding, which in America is accepted as a normal condition at the rush hours, those standing are in the aisle and do not incommode persons who have secured seats. The loss of seating capacity amounts theoretically to one for each cross seat. As a matter of fact, five full-sized people on an ordinary cross seat open car are all of them inconvenienced to a considerable degree, and four really represents the maximum number which can be seated with comfort.



BRILL OPEN CAR WITH CENTER AISLE—UNION TRACTION CO., PHILADELPHIA.

The length over crown pieces is 33 ft. 3 in.; length over all, 34 ft. 3½ in.; width at sills, 7 ft. 1 in.; width at posts, 7 ft. 7 in. The platform is 4 ft. long; to the under side of the sill is 26 in. This gives for the running board a height of 18 in. with a 15-in. riser. Each end of the car is provided with an ordinary platform and a low step 14 in. from the head of the rail, with a 12-in. riser to the floor of the platform. The cars are mounted upon "Eureka" maximum traction trucks with 30-in. drivers and 20-in. pony wheels. Sixteen of the seats are reversible and eight are stationary, giving a total capacity of 58. The reversible back seats are spaced 2 ft. 7 in. between centers. The inside finish is ash, the head lining being three-ply veneer. The Philadelphia system of using brass chains between the posts on the side where passengers are not allowed to enter is followed in this case. These cars are capable when loaded of passing round a curve of as short a radius as 33 ft.; when light they can make even shorter curves. The Philadelphia gage is 5 ft. 2¼ in. The cars are equipped with two Westinghouse No. 38 B nose-suspension motors.

THE BROOKLYN STRIKE.

During the early part of July there was the most persistent talk of a strike of the employes of the Brooklyn Rapid Transit Co., but as more or less strike talk had been heard for so long, many regarded it as merely an effort to influence the market value of the traction stocks. On July 15th a committee waited on President Rossiter to present grievances. After this interview Mr. Rossiter issued the following statement:

"A committee of five Brooklyn Heights Railroad employes, two from the Brooklyn Elevated and eight from the Nassau Railroad called on me this morning. I first received its chairman, Mr. Mackenzie, whose statement I took, and who filed with me a statement on behalf of the other members of the committee. I asked him if he had anything further to state, and upon him replying in the negative he retired, and the remainder of the committee were then called in and stated their individual grievances. There was considerable desultory talk, some specific grievances being pointed out, which I promised to inquire into and, if the facts were as stated, to correct any injustice that might have been unintentionally done.

"The men finally stated they were here for me to sign the agreement, which their chairman had left. I told them I had not looked at it as yet. At their request I took up the different parts of the agreement, as follows:

"'1. That the time tables be arranged upon all lines so as to comply with the ten hour law work day.'

"I informed them that this was being done on every line on the company's system.

"'2. That the prevailing rate of wages shall be $2 for each full day's work, and trips and overtime be paid at 20 cents per hour.'

"Our rate of wages is $2 per day on every line in the system. All overtime over 30 minutes is being paid for, and had been paid for for over a year past at the rate of 20 cents per hour.

"'3. That two-thirds of the cars shall be full day runs.'

"On the existing time tables today 62 per cent of the total runs on the Brooklyn Heights lines are full day cars, receiving $2 per day each, and 55 per cent on the Nassau lines are full day runs, receiving $2 per day.

"That as to the balance of the runs on the entire system our time tables are so arranged that no man receives less than $1.50 per day, while on the Nassau lines when the time tables were turned over and before we commenced active operation it was found that over 50 per cent of the men received less than $1.50 for the day's work, and that 30 per cent received less than $1.25 for the regular day's work.

"'4. That the company shall receive committees of their employes representing the men; that no employ shall be discriminated against for acting on such committee.'

"This has been the practice of the company ever since I assumed charge, and certainly will be continued.

"'5. That no man shall be discharged without just and sufficient cause, and only after he has had an impartial hearing.'

"I stated as to this that no man had ever been discharged from the company and no one would be without good and sufficient reason, and that if any case of injustice was brought to my attention it had always received and would receive immediate attention.

"'6. Extra brakemen on the main line; first—Fifteen to report for work at 4:40 a. m. Balance at 5:30 a. m. All brakemen to be paid from 15 minutes after their reporting time when marked up for runs. When extra brakemen be held for Rockaway or Coney Island runs that they be paid for all time over one hour. That all brakemen, agents, gatemen and platform men be paid 20 cents per hour or any fraction thereof.'

"I merely dismissed this and stated that in view of the present condition I could not consent to any increase of wages, but that the matter of arranging time tables would be looked into, with a view of remedying any reasonable cause for complaint that now exists.

"I am sorry to say that the attitude of the committee impressed me as being the attitude of men looking for a grievance. When individuals on the committee tried to address me at length, as I was glad to have them, the leaders attempted to deter them, and the efforts of the leaders seemed to produce trouble.

"This attitude, however, will make no difference in the feelings or attitude of the company. We have the true interests of our employes at heart, and we will willingly allow no condition to exist which will give rise to a reasonable complaint. We are willing and desirous of hearing genuine complaints, and I think our men generally think so, as indicated by the loyalty of the great majority who have been with us for four years or more.

"I do not believe that the committee which called upon me this morning represents anything more than a small body of malcontents who are influenced not by their conditions or of their fellow fellow employes, but by outsiders who have selfish interests in promoting trouble."

The strike was declared at 4:30 a. m. on Sunday, July 16th, but less than 1,000 went "out," nearly all of them being on the Nassau line. Sunday traffic to Coney Island was light and no cars were running after 8 p. m. By Monday night the strike was claimed to be broken, there being at least 75 per cent of the cars running.

Early Sunday morning the rioting, which usually attends strikes, was begun, but Chief Devery of the Greater New York police force, placed 3,000 men in Brooklyn and effectually protected the company's property. By Monday night fully half of this force was withdrawn. The most serious act of violence was the explosion of two dynamite charges under columns of the elevated road; the damage done in this case was quickly repaired.

Schedules were completely restored by the 22d, and a few days later the men were asking to be reinstated.

During the strike the trainmen who remained loyal were provided with meals at the company's expense, and the rate of pay doubled. Mr. Rossiter believes in keeping men who may be called upon to fight well fed.

A sympathetic strike on the Metropolitan lines in New York was attempted, being called on the morning of July 19th. Less than 200 out of the 3,500 employes quit work, and no trouble caused except on the Second Avenue lines, where some scenes of violence were enacted. By the 21st all Metropolitan cars were running on the regular schedules.

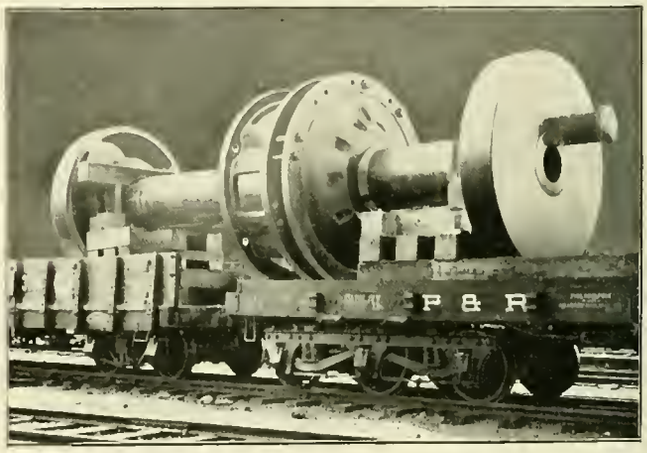
In some quarters it was charged that Mr. Albert L. Johnson, formerly president of the Nassau system, was fomenting the trouble, and it is known that he championed the cause of the strikers and made a donation of $500 to their fund. When the explosion under the elevated became known to Mr. Rossiter he is said to have made a remark to the effect that he could not keep track of all Johnson's men did. This so incensed Mr. Johnson that he caused Mr. Rossiter's arrest on the charge of criminal libel. Mr. Rossiter denied having uttered the words complained of and the case was dropped.

The United States Court has appointed Michael P. Heraty, of Philadelphia, and John C. Weadock, of Bay City, Mich., receivers of the Bay Cities Consolidated Street Railway Co. There was no objection to the petition, which was presented by the Philadelphia Securities Co., trustee for the stockholders, who are the bondholders also. The company has $470,292 in bonds outstanding, on which no interest has been paid for several years.

LARGE SHAFT FOR BOSTON ELEVATED.

What is believed to be the second largest shipment ever made in this country, the Krupp gun sent over the Pennsylvania to the World's Fair being the largest, was made from the works of the Bethlehem Steel Co., South Bethlehem, Pa., on June 9th. The illustration shows the shipment referred to. It is a shaft with crank disks and generator fly-wheel hub assembled on it, all finished complete. This shaft was made for an engine built by the Corliss Steam Engine Co., of Providence, R. I., for the Boston Elevated Ry. The total weight of the shipment was 170,400 lb., and in order to transport it to Boston, the Philadelphia & Reading Railway Co. furnished two cars of 100,000 and 80,000 lb. capacity, respectively, and blocked the shaft so that 60 per cent of the weight was supported on the stronger car and 40 per cent on the other.

The shipment was made over the New Jersey Central, the Delaware & Hudson Canal and the Boston & Albany. This shaft is the first of three for the Boston Elevated Railway Co. It is of fluid compressed nickel steel, hydraulically forged hollow on a mandrel, oil tempered and annealed. It is 37 in. in diameter in the center with



LARGE SHAFT FOR BOSTON ELEVATED.

a 17-in. hole through its axis and is 27 ft. 10 in. long. The metal of which it was made showed tests of 50,000 lb. elastic limit and 18 per cent elongation in test pieces 1 in. diameter and 10 in. long. Shipments approximating this size will frequently have to be made by railroads in the future.

The Bethlehem Steel Co. has in hand orders from the Edward P. Allis Co., Milwaukee, for the Metropolitan Street Railway Co., of New York City, 11 shafts of exactly the same size; also from the Westinghouse Machine Co., Pittsburg, Pa., orders for 16 similar shafts for the Third Avenue R. R., New York City, and two for the Brooklyn Edison Illuminating Co.; also from the Westinghouse Electric & Manufacturing Co. orders for 15 shafts a little smaller in size for the water power plant at Messina Springs, N. Y. The power plants for which these shafts are intended are designed to be equipped with engines of 8,000 h. p. capacity. In all probability even larger units than this will be called for in the future, as the tendency toward centralization of power is in that direction. We have heard that the engines for the power plant made necessary by the change from steam to electricity by the Manhattan Elevated, New York, are to have a maximum capacity of 12,000 h. p. The shafts for these engines will of course be considerably larger than that shown in the illustration.

REAR END LIGHTS FOR TROLLEY CARS.

An ordinance is to be introduced in the Philadelphia Council as soon as that body shall convene in the fall, requiring rear end lights to be carried on trolley cars which run into the city suburbs or along country roads within the county of Philadelphia. The measure will specify that the illuminant shall be oil or other fluid independent of the electric current used in operating the cars and is to be similar in power and construction to the "'bull's eye" lamps in use on steam railroads on the rear of the cars.

RECENT STREET RAILWAY DECISIONS.

EDITED BY J. L. ROSENBERGER, ATTORNEY AT LAW, CHICAGO.

DRIVING TEAM PARTIALLY BEYOND CONTROL UPON EXPOSED TRACK.

Farmer v. Findlay Street Railway Co. (O.), 53 N. E. Rep. 447. Mar. 14, 1899.

Although one driving a team of horses upon a public street has knowledge that a street railway company has negligently removed the pavement from its tracks and conducting wires, the supreme court of Ohio holds that he is not to be charged with negligence if he drives upon the exposed track and wire, not voluntarily, but because his horses are partially beyond his control.

DUTY AS TO LOOKING TO SEE HOW MANY ARE TO GET ON CAR.

Sexton v. Metropolitan Street Railway Company (N. Y.), 57 N. Y. Supp. 577. April 18, 1899.

The second appellate division of the supreme court of New York declares that it is not inclined to admit the proposition that, as a matter of law, where one person is seeking to get upon a car, either stopped or slowed down for the purpose, there is no duty imposed upon the servants of the company in charge of the car to look and see if any one else is following and seeking to take advantage of the car being stopped to board it. That question, it adds, is generally one of fact, depending on the circumstances of the particular case.

MUST BE ALERT TO DISCOVER APPROACH OF CAR FROM THE REAR.

Bossert v. Nassau Electric Railroad Co. (N. Y.), 57 N. Y. Supp. 896. May 2, 1899.

The second appellate division of the supreme court of New York says that it is committed to the doctrine that while it is not negligence, as matter of law, for one driving a wagon at night in the track of a surface railroad to fail to look backward to see an approaching car, yet he may not rely wholly upon the supposition that the railroad's servants will see him in time to give warning, and that he must be on the alert to discover in some manner and by some exercise of his senses the approach of a car from the rear.

SLACKENING OF SPEED NOT TO BE ASSUMED TO BE FOR PERSON ON STREET.

Reidy v. Metropolitan Street Railway Co. (N. Y.), 58 N. Y. Supp. 326. May 24, 1899.

Where, for aught that appeared, the slackening of the speed of a car while passing a crossing might have been due to a cause other than the signal of a person who wanted to get on board, the appellate term of the supreme court of New York holds that, in the absence of proof that such reduction of speed was made in response to such person's efforts to attract attention, he had no ground for assuming that such change in the speed of the car was made for his benefit or convenience, and that he was guilty of contributory negligence in running towards the car and attempting to get aboard it below the crossing.

NO PARAMOUNT RIGHT OF WAY AT CROSSINGS.

Atlantic Coast Electric Railroad Co. v. Rennard (N. J.), 42 Atl. Rep. 1041. Apr. 10, 1899.

The court of errors and appeals of New Jersey holds that the driver of a vehicle upon a road used by the public at large, which crosses the track of an electric railway, must exercise reasonable care to avoid collision, and that the same duty rests upon the motorman of a trolley car in approaching the crossing of such a road, whether the crossing is in the country or in a town; and, in case of accident, the question whether either or both of said parties failed in such duty is one to be determined by the jury, when the proofs on the subject of negligence leave the question in doubt. Neither party at such a crossing, it declares, has a paramount right of way.

NOT RESPONSIBLE FOR NEGLIGENCE OF CONTRACTOR'S EMPLOYE.

Hauser v. Metropolitan Street Railway Co. (N. Y.), 58 N. Y. Supp. 286. May 24, 1899.

This action was brought to recover for injuries done to a horse by falling through the earth between the pavement and a bridge placed over an opening in a public street, opened under a permit from the department of highways for railway improvements for the defendant company, for which a contractor did the work. The plaintiff obtained a judgment. But this is reversed by the appellate term of the supreme court of New York. It holds that for that injury, action did not lie against the street railway company, but only against the workman whose personal act or omission caused the damage, and against the contractor who selected and controlled him.

GOING OUT ONTO PLATFORM BEFORE REACHING DESTINATION.

North Chicago Street Railroad Co. v. Bauer (Ill.), 53 N. E. Rep. 568. April 17, 1899.

Where it did not appear that there was any regulation of the street railway company prohibiting passengers from riding on the platform, but, on the other hand, it did appear that other passengers rode on the platform without objection on the part of those in charge of the car, the supreme court of Illinois holds that it was not negligence, as matter of law, for a passenger to leave his seat in a cable car while a block from his destination and go out onto the rear platform for the purpose of alighting when it reached his stopping place, the question of negligence in such case, it says, being one of fact for the jury to determine from all the circumstances.

LIABLE AS JOINT OPERATORS OF LINE.

Messenger v. St. Paul City Railway Company (Minn.), 79 N. W. Rep. 583. June 14, 1899.

Notwithstanding the contention that they were each operating its part of the line merely as a connecting carrier, but, on the evidence, which was not only that each collected a fare on its portion of the line, but that they owned the cars jointly, employed the same conductors and motormen, each paid half of the wages, had all cars marked with names of both cities, and on the front, "Interurban," the supreme court of Minnesota holds that the St. Paul City Railway Co. and the Minneapolis Street Railway Co. were jointly operating the interurban line, partly owned by each, and connecting the two cities, and that each one is liable for the acts and omissions of the other in operating the same.

BOY AT PLAY TAKES RISK OF RUNNING IN FRONT OF CAR.

Brady v. Consolidated Traction Co. (N. J.), 42 Atl. Rep. 1054. Feb. 27, 1899.

A boy, 9½ years of age, while playing in the street, ran in front of a trolley car which he saw approaching, and was struck by the further corner of the fender. The supreme court of New Jersey holds that there was no element of danger which he did not perceive, or which a boy of his years was not capable of fully appreciating, and that, therefore he took the risk of failing in the attempt which he designedly made.

PILING RAILS IN THE STREET.

Thomas v. Consolidated Traction Co. (N. J.), 42 Atl. Rep. 1061. Mar. 1, 1899.

While a street railway company has the right to place a pile of rails upon the street, temporarily, for its use in reconstructing or repairing its track, yet, the supreme court of New Jersey holds, it is bound to the duty to exercise reasonable care to guard the public

using the street against the danger arising from the rails so placed upon the street, and in the night time to place a guard or signal of warning to persons using the street; and this duty exists whether the pile of rails be placed in the gutter of the street or in some other portion thereof.

DUTY OF DRIVER SEEING PASSENGERS ABOUT TO LEAVE CAR.

Louisville Railway Co. v. Rammacker (Ky.), 51 S. W. Rep. 175. May 23, 1899.

Where a car has stopped, as for example to take on a passenger, signals to stop are unnecessary for a passenger wishing to alight, if the driver, there being no conductor, sees this latter passenger leaving the car, and knows, or, as a prudent man, ought to know, she intends to get off, and, the court of appeals of Kentucky holds, the driver has not only all the notice that the law requires, under any case, for a passenger to give, but he owes to her all the duty that he would if she told him she wanted to get off at that point. But if he does not see her, then she must give notice of her intention to get off.

The court further holds that there was no error in refusing, in this case, where it affirms a judgment of $6,000 for the party suing, to permit the driver to prove that it was usual for persons to leave the car while in motion, without giving notice to the driver. That it is usual or customary for passengers to disregard their own safety, and get off the car while in motion, it declares, will not justify or excuse an act of negligence in starting a car before a passenger has alighted, by reason of which the passenger is injured.

TIME NOT COME FOR RETROGRADE MOVEMENT IN AVOIDING GRADE CROSSING.

Pittsburgh Junction Railroad Co. v. Ft. Pitt Street Passenger Railway Co. (Pa.), 43 Atl. Rep. 352. May 24, 1899.

The time has not yet come, declares the supreme court of Pennsylvania, for any retrograde movement in the work of preventing and avoiding grade crossings either in cities, towns, or country. The act of June 19, 1871, conferring equitable jurisdiction on certain courts as to railroad crossings and providing that, "if in the judgment of such court, it is reasonably practicable to avoid a grade crossing, they shall by their process prevent a crossing at grade," the supreme court goes on to say it is its settled conviction should be liberally construed and rigidly enforced, whenever cases fairly within its letter and spirit are presented. That there are other grade crossings where more trains pass, it does not consider any argument in favor of sanctioning the maintenance of additional death traps. However, in considering the elements of danger necessarily involved in the crossing, the court holds that the fact that the plaintiff company had been using the street for the purpose of shifting its cars was properly eliminated on the trial, as that was clearly a wrong use of the street anyway.

WHEN DUTY TO TRANSFER PASSENGER MAY BE ENFORCED BY MANDAMUS.

Richmond Railway & Electric Co. v. Brown (Va.), 32 S. E. Rep. 775. Mar. 23, 1899.

While mandamus does not lie to enforce mere contractural duties, the supreme court of appeals of Virginia holds that, where the duty to transfer a passenger is made incumbent by law, it may be enforced by mandamus. In such a case, it says it is manifest that a suit at law for damage for a failure to perform the duty is not an adequate remedy, the wrong suffered being a constantly recurring and continual one. Furthermore, it holds that the duty is of the latter character and enforceable by mandamus, where such duty is imposed by order of the county court by virtue of statutory authority contained in the act under which the company is incorporated. It also holds that where a company is required to give transfers under an order which provides that when transferred the passengers shall have all the rights and privileges of any passenger on the line to which they are so transferred, that includes the right to a further transfer from the later line, if regular passengers on that line are given a transfer from it, though this may practically amount to two transfers in the same direction.

WHERE CHILD LEAVES CURB AND GOES IN FRONT OF CAR.

Weitzman v. Nassau Electric Railroad Co. (N. Y.), 57 N. Y. Supp. 1120. May 8, 1899.

A judgment for the plaintiff, an administrator, is reversed in this case, by the second appellate division of the supreme court of New York, because of a refusal to instruct the jury that if they believed that the car of the defendant was running at a moderate and proper rate of speed, and if, at the time the deceased left the curb to cross the tracks, the car was so close to the place deceased was struck that it was impossible for the car, under any circumstances, to be stopped before running over the child, then the verdict must be for the defendant. It is plain, says the court, that, if the jury found such a state of facts to exist, it was incumbent upon them to exonorate the defendant from liability, and that the defendant was entitled to have them so instructed.

NO RIGHT TO CHANGE FROM ONE CAR TO ANOTHER.

Lasker v. Third Avenue Railroad Co. (N. Y.), 57 N. Y. Supp. 395. Mar. 29, 1899.

The plaintiff voluntarily took passage in one of the open cars of the defendant. Subsequently, because of a cold, and of a sudden change in the weather, he left the open car, and boarded a closed car—one immediately in the rear of the open car, and attached thereto. The conductor of the closed car then demanded from the plaintiff his fare, which he refused, for the reason that he had already paid a fare to the conductor in charge of the first, or open, car. Because of this refusal, he was ejected from the last car; and hence this action.

On appeal, the general of the city court of New York affirms a judgment for the defendant company. It says that the demand of the conductor in charge of the closed car for the plaintiff's fare was just and reasonable. The plaintiff had voluntarily chosen to take passage in the open car. If, for reasons satisfactory to himself, and for his own interest, he subsequently wished to take passage in one of the defendant's closed cars, he thus made himself a new passenger, and the defendant had the right to require him to pay the usual fare, and his refusal to pay such fare entitled the company's servant to use necessary physical force to eject him from the car.

LIABILITY FOR FAILURE OF MOTORMAN TO SET BRAKES.

Hoover v. Carbon County Electric Railway Co. (Pa.), 43 Atl. Rep. 74. Apr. 24, 1899.

A failure of a motorman to properly adjust the ratchet to the teeth of the wheel so as to secure the brakes, before he left his car on a turn-out, when he went to help put a derailed truck on the track, the supreme court of Pennsylvania holds, was the negligence of a fellow servant, for which the company could not be held responsible, in an action for damages brought by a conductor on another car for injuries sustained by the first car running down onto the main track, and colliding with his car. Nor does it think that the situation was changed by the fact that a superintendent had said, "Give us a hand to put on the truck." No name was mentioned, and the court says that if the men in charge of the car understood the call as directed to them, they could not have understood it as an order for all of them to leave the car, without properly adjusting the brakes. If the superintendent had directed them first to secure the car, and then to come to his assistance, the court goes on to say, there would have been no negligence in giving such an order; and he might assume that they would act with ordinary prudence in a matter in which their duty was so manifest. An entirely different question, it adds, would, however, have arisen if a passenger had been injured, or if the injury had been to some one not connected with the road as an employe.

NOT REQUIRED TO REFLOOR BRIDGE.

City of Cedar Rapids v. Cedar Rapids & Marion City Railway Co. (Ia.), 79 N. W. Rep. 125. May 16, 1899.

An ordinance imposing upon a street railway company operating thereunder the duty of keeping in repair "such streets and highways as are now paved," and to "pave on all streets and avenues which

may at any time be paved or ordered to be paved" the "portion of the streets included between the rails and one foot outside of the same," the supreme court of Iowa holds, cannot be fairly construed to obligate the company to repave a bridge with oak plank three inches thick laid diagonally on said bridge. In the first place, the court maintains that the bridge is no part of the streets, avenues and highways, within the meaning of such an ordinance, and that the duty to pave or to repair pavement in the street, avenues, and highways does not include such reflooring as stated. It is true, continues the court, that for certain purposes, as for travel, bridges are made part of the streets, avenues, and highways, but in common acceptation, they are recognized as different from that part of the streets, avenues, and highways which are made directly upon the earth's surface. Moreover, it holds that the term "pave," as applied to streets, avenues, and highways, refers to the laying of some hard substance upon the earth, so as to make a convenient surface for travel, and such, it maintains, was undoubtedly the sense in which the language was used in this ordinance.

LIABILITY FOR CONDUCTOR TRYING TO GET ON CROWDED PLATFORM.

Gray v. Metropolitan Street Railway Co. (N. Y.), 57 N. Y. Supp. 587. Apr. 7, 1899.

Any act of a servant of a street railway company which caused the crowd upon the platform of a street car to sway and jostle a passenger, so as to cause him to fall off the car, the first appellate division to the supreme court of New York holds, would be evidence tending to show negligence on the part of the company. Nor does it consider it necessary for the passenger to prove direct contact between such servant and himself, which caused him to fall or be thrown from the car. To sustain a finding of negligence, it holds it sufficient to prove a state of facts from which the inference can be drawn that the act of a conductor in forcing himself upon the front platform while the car was in motion was such as would entirely tend to, and which as a matter of fact did, throw the passenger from the car. The fall of the passenger occurring at the moment the conductor attempted to force his way upon the platform, and there being no other cause for the passenger to fall, the court holds that the jury certainly had a right to infer that the cause of the passenger's falling from the car was this act of the conductor. And in accepting a transfer ticket from a person, while he was upon a crowded platform, the court holds that the conductor assented to his riding in the position in which he was at the time the transfer was taken. In that position, it adds, the passenger was entitled to presume that the company's agent would commit no act which would expose him to unnecessary danger.

DEMAND THAT MUST BE MADE BEFORE BRINGING ACTION TO ANNUL LEASE.

Flynn v. Brooklyn City Railroad Co. and another (N. Y.), 53 N. E. Rep. 520. Apr. 18, 1899.

This was an action brought by the plaintiff, as a stockholder of the Brooklyn City Railroad Company, to set aside a lease made by it to the Brooklyn Heights Railroad Company, to compel the retransfer of all the property that passed under the lease, and for an accounting by the lessee to the lessor.

Now, when a contract founded in fraud is executed by the directors with a third party, upon the express approval of a required number of stockholders, with the intention on the part of all concerned to defraud the non-assenting stockholders, and the scheme will naturally result in serious injury to them or to the corporation, the court of appeals of New York holds that a court of equity will set aside the fraudulent transaction, and compel the delinquent parties to account. Such, as it interprets the complaint, it says, was this case.

The right of action, however, the court goes on to state, belongs to the corporation, and should be brought by it as plaintiff; but, when it will not bring the suit itself, an aggrieved stockholder, after due demand, and a refusal or unreasonable neglect to proceed, may bring it in his own name, upon making the corporation a party defendant. Such an action is not for the benefit of the plaintiff alone, but is representative in character, and for the benefit of himself and all other stockholders similarly situated.

Here, the plaintiff's demand was either of a payment to himself of what he deemed he was entitled to, or of a distribution among of the stockholders of what he deemed they were entitled to. This, the court holds, did not meet the requirements of the situation, because no demand was made that the corporation bring an action to annul the lease. In other words, it says that the plaintiff was not entitled to what he demanded, and that he made no demand of what he was entitled to. And because it deems the demand made insufficient to meet the requirements of the law, for the reason stated, it affirms a judgment sustaining an order dismissing the complaint.

RISKS ASSUMED BY SWITCH TENDER.

Thompson v. Citizens' Street Railroad Co. (Ind.), 53 N. E. Rep. 462. Apr. 20, 1899.

A boy 16 years of age, and of average size and intelligence for a boy of that age, was employed at a street crossing turning switch tongues. One day he threw the switch tongue for a motor car and trailer. Right back of the latter, was a car drawn by horses. These horses were frightened, and prancing about. Believing that he was in danger of being injured by them, after throwing the switch tongue, the boy stepped back further than usual, and was struck by a car on another track.

The proximate cause of the accident and injury to the boy, the supreme court of Indiana thinks, was the threatening appearance of the horses. And the danger of such an occurrence, it holds, was one of the risks of the employment assumed by the boy.

Furthermore, without evidence of the fact, the court says that it can not assume that the body of a trailer car, running at so moderate a rate as 8 or 10 miles per hour would "sway" or rock upon its trucks to such an extent as to strike a person occupying a position near the track, but far enough away from it to escape collision with a car passing at a slower rate of speed.

Upon the question whether a motorman on an electric car and a switch tender working on the same line and for the same company are co-employes, the court states that it entertains no doubt that they sustain that relation to each other.

FRANCHISES AS CONTRACTS.

Dern v. Salt Lake City Railroad Co. (Utah), 56 Pac. Rep. 556. Mar. 14, 1899.

The supreme court of Utah says that a franchise is a contract between the state, or other body granting the franchise, and the party accepting and acting upon it. It is governed by the general rules applicable to contracts, and either party may waive any breach of the conditions of a franshise; and anything which would constitute a waiver of a breach of a contract constitutes a waiver of a breach of the conditions of a franchise.

The waiver of a breach, which, if insisted upon, would forfeit the franchise, or some special right under it, leaves the party in default free to enjoy the privileges granted until the state moves in the matter, and a forfeiture has been judicially declared.

The defendant company having been in operation for a period of about 27 years, and no proceedings having been instituted by either state or city to forfeit any of the rights granted by the franchises to the defendant company, and additional franchises having been repeatedly granted, the court goes on to say that all defaults on the part of the defendant company up to the date of the last franchise (March 18, 1894) have been waived; and the plaintiffs, being strangers to the contract, have no right in the premises.

The act authorizing the city to grant a franchise to the defendant company having imposed no restrictions, except as to the time for which the franchise should be granted, the court holds that no rights could be forfeited, therefore, except for the causes and in the mode prescribed in the franchise.

CARE REQUIRED ON APPROACHING PRIVATE CROSSING.

Duncan v. Union Railway Co. (N. Y.), 57 N. Y. Supp. 326. April 7, 1899.

If the driver of a street car approaching a private crossing has reason to believe that persons are in the habit of coming upon the highway at the time when he is approaching, the first appellate division of the supreme court of New York holds, he is bound to use

towards those persons the same care that he would be bound to use with regard to other persons crossing the street at any regular crossing.

At all times, the court goes on to say, he is bound to run his car in such a manner that he may give warning of the approach of his car to persons having occasion to cross the highway, and that he may be able, like the driver of any other vehicle (having in view the greater difficulty of regulating his car), to avoid running upon people who are attempting to cross the highway, or who have occasion to go across the track in turning their wagons around or turning out to avoid other vehicles.

On the other hand, the plaintiff, the court holds, was not called upon, as matter of law, to watch and listen for the approach of a car using the highway, as he would have been called upon to watch and listen at a country crossing of a railroad company going upon its own tracks, where it had an exclusive right, but it was proper for him to take into consideration the duty of the defendant in running along the highway, and to suppose that that duty would be performed.

Even if the plaintiff had seen the car coming, at a rapid rate of speed, 150 or 200 feet away from the place where he was approaching the highway, as the defendant claimed he might have done, the court holds that he would have had the right to assume that the driver of the car would so reduce its speed when he approached the entrance to the private driveway in which the plaintiff was that persons coming out upon the highway might have an opportunity to avoid him.

RIGHT OF PEOPLE TO CROSS TRACKS BETWEEN CROSSINGS.

Lawson v. Metropolitan Street Railway Co. (N. Y.), 57 N. Y. Supp. 997. May 5, 1899.

The streets, says the first appellate division of the supreme court of New York, are yet intended for every citizen who has occasion to use them. He may come upon foot or in vehicles, up and down the street, as his pleasure or his business requires, and he may cross the street backward and forward in his vehicle, so far as his convenience or business incline him to do so. In doing so, however, he must not needlessly or recklessly or willfully obstruct the street cars in their route, and he must use reasonable care to keep out of their way. But he is not called upon to avoid the use of the street or to delay crossing it because a street car happens to be in sight coming towards him. What he must do, is to endeavor, in crossing the street, so to regulate his act that he shall use the care of a reasonably prudent man to keep out of the way of the cars, and not unduly delay them in their passage.

On the other hand, the driver of a street car is bound, also, to use reasonable care so to regulate the passage of his car as not unnecessarily to collide with persons who have occasion to use the street in front of him. As he can only do that by regulating the speed of the car, it is his duty to use reasonable care to regulate the speed to attain those ends. When one attempts to cross the track of a street car, and has approached the track at such a distance from an approaching car that he has reasonable ground to suppose that he will be able to cross the track, it is the duty of the street car driver to give him a reasonable opportunity to cross, and if, for that purpose, it is necessary for him to check the speed of his car, or even to stop the car entirely for a short space, it is his duty to do it, and the person crossing the track has the right, without being charged with contributory negligence, to assume that that duty will be performed.

Furthermore, the court points out that there is a vast difference between lawfully doing an act, the effect of which may be to momentarily obstruct the passage of a street car, and to put oneself on the track of the car in an endeavor to obstruct it. The latter is a penal offense; the first is not.

PROPER PLACE FOR PASSENGERS IS INSIDE OF CAR.

Thane v. Scranton Traction Co. (Pa.), 43 Atl. Rep. 136. May 1, 1899.

The proper and assigned place for passengers, says the supreme court of Pennsylvania, is inside the car. And it holds that, unless he shows some valid reason to excuse him, a passenger is bound to put himself in the appointed place; and, if he does not, he takes the risk of his location elsewhere.

In discussing the matter of standing on the platform of cars, the supreme court says that it is the long-settled rule that standing on the platform of a moving railroad train is negligence of itself, while, on the other hand, the Pennsylvania cases have practically established that standing on the platform of an ordinary horse car is not negligence of itself, but raises a question for the jury. The electric trolley, it suggests, occupies a position between these two, in respect to this subject.

The principle at the foundation of the rules is, and always has been, the court goes on to say, the same, though in the development of methods of travel the circumstances and conditions have changed. The increased speed upon passenger railway lines, with its resultant danger, now approximates to that of steam railroads, and, indeed, in many cases exceeds the speed of the fastest trains at a time not too remote to be within the memory of every judge on this bench—a time at which the rule as to steam cars was first established. The reasons which were potent in the establishment of that rule then are equally potent in its application now. Therefore, the supreme court holds that where there is room to be seated in the passenger's proper place, and no special and sufficient reason is shown why he should not avail himself of it, it is negligence of itself to remain on the platform of a moving trolley car.

Cases where the car is crowded, and no seat is available, the court adds, rest on a different basis. There the traveler, if he is to get on at all, must stand on the platform, with its rods, etc., to hold by, or inside, with a strap for that purpose. He is presented with a choice of evils, and his action must be judged by the jury—while, on the other hand, the carrier, by receiving him, undertakes and gives him assurance that it will take care of him, and guard him against accident as far as the circumstances permit.

In this particular case, it was undisputed that there were vacant seats in the car, one of which the plaintiff could and should have taken. He chose, instead, to stay on the platform. In so doing, the supreme court holds, he took all the risks incident to that position. The injury he received by being thrown against the dasher, it goes on to say, was the direct consequence of his position, and would not have been received had he been inside. Whether he would have received some other injury, equal or greater, it pronounces conjectural and irrelevant. Besides, it declares that the distinction sought to be made between injury from ordinary risks of the road, and from a collision the result of negligence of the carrier, is not sound. What the passenger took himself, it repeats by way of emphasis, was the risk of his position from any cause.

Judgment reversing judgment for the plaintiff affirmed.

CLAIMS WHICH HAVE PREFERENCE OVER MORTGAGES.

McCornack v. Salem Consolidated Street Railway Co. (Or.), 56 Pac. Rep. 815. Mar. 27, 1899. Rehearing denied April 24, 1899; 56 Pac. Rep. 1022.

It has become a settled principle under the authorities that, where a mortgage is taken upon the property, and even upon the earnings of such a corporation as a street railway company, it is implied, from the nature of the business in which the concern is engaged, and the usual and ordinary management and conduct of such business, that the current earnings of the enterprise shall be first applied to the payment of the current operating expenses, such as for labor and supplies, and for necessary equipments and improvements of the mortgaged property, and that the balance, only, usually termed the " net earnings," shall be applied in payment of the mortgage indebtedness.

This doctrine rests upon the ground that the maintenance of the road and the prosecution of its business are essential to the preservation of the mortgage security. The primary object is to keep the enterprise a going concern, from considerations of both public and private interest. And the management of such a concern, whether in the hands of its promoters or in those of a receiver, is charged with the duty of so marshalling the funds arising from current earnings as to apply them in accordance with the relative equities of the preferred creditors and the mortgagee; and if, through regard for mere convenience, something is taken from the fund and paid to the mortgage creditor, when as of right it belongs to and should have been paid to the preferred creditor, it is not considered inequitable, unless the claim has become stale, to require that the preferred creditor shall be paid from the future current re-

ceipts, or from the proceeds of the sale of the mortgaged property. It is from considerations of this nature that the courts are induced to require, as a condition of the appointment of a receiver, that the mortgagee shall consent to the payment of such equitable demands as are outstanding against the company, which have accrued within a reasonable space of time prior to the receivership, and, even in cases where the condition is not primarily imposed, to require that the receiver shall adjust the current receipt fund in accordance with the equities thus to be ascertained, and under certain conditions, reimburse the preferred creditor from the body of the estate, and to that extent displace the mortgage.

It is often a difficult matter, the supreme court of Oregon goes on to say, to determine what are preferred claims and what are not, depending to a large extent upon the particular circumstances of each case. However, it thinks it clear from the authorities that claims cannot be included which may arise on account of additional equipments provided, and valuable and lasting improvements made. And in no sense can such claims be extended to the inclusion of those of general creditors.

Measured by the understanding thus to be gathered touching the nature of the claims or demands which are entitled to preference over a mortgage, the court holds that two heaters, purifiers and condensers complete, and one water tank, first ingrafted as an experiment, but finally constituted a new and additional improvement, were outside the rule, not being required to keep the enterprise a going concern, though they enhanced the value of the mortgage security and saved fuel, enough, in time, to pay for themselves.

TITLE TO RAILS PASSES WITH ANNEXATION.

Clemons Electrical Manufacturing Co. v. Walton (Mass.), 53 N. E. Rep. 820. May 17, 1899.

After a construction company employed to build four miles of street railway had laid and finished over three miles thereof, except the overhead work, for which the necessary materials were lying upon the ground, the street railway company, apparently wishing to withdraw from its bargain, notified the construction company that it declined to accept the construction, and the construction company accepted the refusal, voting to sell all the material and other property lying on said line of street railway to another company, to be paid for by the indorsed notes of the latter, and agreeing to credit the first company with all sums received on the notes.

This action was brought to recover against the indorser of those notes. He set up that the maker had received no consideration, or if it had received one, that it was illegal. Particularly, was reliance placed upon section 56 of chapter 113 of the Public Statutes of Massachusetts, forbidding a street railway company to sell or lease its road.

Now, if the sale was a sale of personal property only, and of personal property the title to which never had passed to the first-mentioned street railway company, the supreme judicial court of Massachusetts holds that it was no less good if that company refused to accept the title in order that the sale might be made, and because it doubted whether it could make a sale after it became the owner. But suppose that it was understood by all the directors at the time of passing their several votes that what was really intended was a transfer of that company's location to the other street railway company, and that the vote was put in the form which it took to conceal that purpose; if that was the real understanding and bargain between the directors, the court holds that the fact that it was not expressed in their vote would not save the corporate action from illegality. In other words, it says that if in the minds of the movers of the corporations the sale was a means to the abandonment of the road by one company, and its occupation and use by the other, the law would not be blinded to the character of the act because they had wit enough not to betray their scheme in a vote.

The votes of both companies, the court goes on to say, were meant, and were construed by conduct to mean, the tracks which had been laid, as well as the loose material. As to these, it adds that it was all very well for the first company to refuse to accept them; but, it holds, the title had passed as soon as the rails were annexed to the freehold. The construction company had no franchise or easement there. The first street railway company had. And it is not necessary, says the court, to consider whether the rails became real estate, and followed the easement. When laid down, they became part of the first company's road, within the meaning of the statute, whether they were realty or personalty. Only as part of that company's road had they a right to be where they were. The company had no more right to sell its rails for the purpose of removal, with the intent that its road for those four miles should be abandoned, than it had to sell them to be kept where they were, and to be used along with the franchise by the buyer.

For these reasons, and in order that, on a new trial, evidence might be admitted of any conversations or understandings between the directors of the several companies at the time when they were all together, and when the votes were passed, tending to show an illegal scheme, such as it supposed, the court sustained the exceptions of the defendant indorser to rulings for the plaintiff. And if the color of the facts be not changed, it suggests that the defendant will be entitled to a ruling that the first street railway company had acquired a title to the rails which had been laid, and could not lawfully become a party to a transaction by which, in substance, it sold that part of its road.

BICYCLE RIDING BETWEEN TRACKS.

Nein v. La Crosse City Railway Co. (U. S. C. C. A.), 92 Fed. Rep. 85. Feb. 23, 1899.

A man riding a bicycle crossed one of two parallel street railway tracks and continued down the smoothly paved space, four feet wide, between them. He testified that he looked around at the time, but did not see any car. All that he apparently thought of, however, was to reach that space, relying upon his speed to afterwards keep out of the way of any car. But, as a matter of fact, there was a car approaching at not more than 30 to 50 feet away when he crossed into the space between the tracks. He was extremely deaf, and riding at a speed of from 10 to 12 miles an hour, while the car was variously estimated to be going at from 10 to 18 miles an hour, and was permitted a speed of 20 miles an hour by the city ordinance.

It is plain as noonday, says the United States circuit court of appeals, that the conduct of the man was grossly negligent, amounting to recklessness. The space between the tracks is a dangerous place in which to drive a bicycle. It is recklessness to ride there while a car is passing. To ride there relying upon the warning of the gong in order to make timely escape from collision with a coming car is more or less negligent. And a person deprived of hearing is bound to greater diligence, in the exercise of the sense of sight, to ascertain the danger which he knows is probable and likely to come upon him.

After making these statements, the court declares that it is difficult to find language to fittingly characterize the recklessness of this man's conduct. Beyond any question, as matter of law upon undisputed facts, it holds he was guilty of gross negligence.

It is possible, perhaps probable, continues the court, that rapid passage through the air causes exhilaration to a degree that begets indifference to and disregard of danger, or possibly a desire to incur it; but whether such perversion of judgment or aberration of the intellect results from voluntary intoxication caused by the inhalation of ozone, or from the imbibing of spirituous liquors, the law does not excuse the want of ordinary care which one should take to guard one's personal safety.

Nor does the court consider that it was the duty of the motorman to do more than to turn off the current while the bicycler was crossing the track, and not to decrease the speed of the car immediately upon sounding the gong, as that would impose upon these public carriers the duty of the highest diligence, and not the duty of ordinary care, which the law requires. He had the right to presume that the man, upon the sounding of the gong, would timely leave his position of danger. Hence, a judgment on a verdict directed for the defendant is affirmed.

Twenty-five citizens of Lancaster, O., made the round trip to Zanesville, O., at the invitation of the Fairfield Traction Co. last month on a handsome new motor car just put in service. The trip occupied two hours each way. The traction company officials had everything on board for the comfort and pleasure of their guests and the only casualty reported was the loss of President Peters' hat in a gale of wind.

NEW YORK-BROOKLYN RAILWAY TUNNELS.

It seems to be fully settled now that the cities of New York and Brooklyn will be connected by two tunnels under the East River, one of which will be the long talked of terminal for the Long Island R. R. and the other a tunnel connecting the Metropolitan Street Ry. of New York with the Brooklyn Rapid Transit roads. These two tunnels will form the most extensive and costly railway tunnels in the United States, and from present appearances the work upon them will be commenced at an early date.

A tunnel for connecting the Long Island R. R. with New York City was projected years ago, but for various reasons has never been exploited. At the 1899 session of the Legislature three bills were passed in reference to this project. The first bill repealed the provision of the city charter limiting city franchises to 25 years in the case of tunnel railways underneath the streets and authorized the Municipal Council to grant a 50-year franchise, with the privilege of renewal for 25 years more. The second bill provided for the proposed tunnel under the East River, and the third bill provided for the removal of the Long Island R. R. tracks from the surface of Atlantic Ave., Brooklyn, with the additional provision that where a company depresses its tracks it shall not lose its rights to the surface of the streets, but may operate another road by electricity or any other motive power except steam. By the terms of the bill the city will share equally with the railroad company in removing the tracks from the surface of the street. This bill was signed by the Mayor of New York, which leaves the road in a position to begin actual construction at once, and the officials of the Long Island R. R. have announced their intentions to push the work as rapidly as possible. In connection with this there is a plan to have the transatlantic steamers of the American Steamship Co. land at Montauk Point, thus saving 120 miles of steaming, and if this plan is carried out steamship passengers will come into New York over the L. I. R. R. through a tunnel under the East River, and be landed at a depot in the heart of the city at a point near where a number of the large railroad systems terminate.

Where the surface tracks are removed on Atlantic Ave. they will be substituted partly by subway and partly by elevated structure. All the branch lines of the L. I. R. R. connect with the main line at Jamaica, and the Atlantic Ave. line running west from this junction crosses the borough line of Brooklyn near Atkins Ave., where there is a summit in Atlantic Ave., and from this summit the elevated structure will rise so as to clear the next cross street, continuing to Manhattan Crossing, where the road again touches the surface. From Manhattan Crossing to Ralph Ave. the line is underground, where it changes to elevated, continuing as far as Nostrand Ave. From this point on it continues underground to the present terminus at Flatbush Ave., where the station will be depresed to the depth of 18 ft., which will be reached by stairways and elevators. This is the end of the change in the present line in which the city bears part of the expense, and the underground portions will be large enough to accommodate standard cars and locomotives. The tunnel line will leave this station passing under Flatbush Ave., Fulton and Pineapple Sts. to East River, and under Maiden Lane and Cortlandt St., Manhattan, terminating near the line of the west side elevated roads. From this terminus it is expected to continue a Hudson River tunnel at some future date.

The depth of the tunnel under the bed of the river will be 30 ft. and the section under the river will consist of two circular twin tunnels 14 ft. 6 in. in diameter, and the cross section of the land portion will be 22 ft. 8 in. in width with an elliptical roof arch. These sections will not be built for standard, but for special cars, the distance between centers of tracks in the double portion of the tunnel being 10 ft. 9 in. The trains from the Flatbush Ave. station to the Manhattan terminal will be operated by electricity. The estimated cost of the tunnel is $6,000,000.

The other tunnel projected between the boroughs of Manhattan and Brooklyn is the outcome of a proposed combination between the Brooklyn Rapid Transit Co. and the Metropolitan Street Railway Co.

At the corner of Ann St. and Park Row the tunnel will start and proceed under Nassau St. and other streets at a gradually increasing grade until at Fulton Market it will be 100 ft. below the street. There is to be a station there, and passengers will ascend and descend by elevators. It will pass over 50 ft. below the rock bottom of the river, and about 146 ft. below the surface of the water. It rises and reappears at the City Hall in Brooklyn. Under the terms of the resolution the "New York & Brooklyn R. R." is authorized to construct a double track in the tunnel.

The plans of this tunnel have not yet been made public.

GREATER AMERICA EXPOSITION.

It is quite evident that all of that fearless courage and energy which conquered the Great American Desert of our fathers' time and made it blossom like a garden, has not ceased to exist. Omaha has attempted what no other city ever undertook, and is now holding its second exposition the next year after having made the Trans-Mississippi Exposition such a success in 1898. The results of the Spanish war have given the Greater America Exposition a reason for being and it will really prove of great educational value in making the people of this country acquainted with the peoples and countries which have been brought, temporarily or permanently, under our flag.

What are for the present (in the absence of a declared policy on the part of Congress) called the colonial exhibits, are very instructive and highly interesting. The Colonial Building is, of course, occupied with exhibits showing more particularly the natural and manufactured products of these countries. These are supplemented by the Filipino village, the Hawaiian, and the West Indian amusement sections in the "Midway," which prove even more interesting because there are found the people among their natural surroundings.

On August 4th, the Chicago, Milwaukee & St. Paul Ry. extended the courtesies of the road and provided a special car for a delegation from the Chicago Trade Press Association. Two days were spent at the exposition grounds, the management doing everything in its power to make the visit a pleasant one. Most people attend such expositions as this one either for instruction or pleasure and both classes are well provided for at Omaha. The Court of Honor, about which the buildings of the Exposition proper are all grouped, is a surprise to the unwarned visitor; by day it rivals that celebrated section of the same name at the Columbian Exposition, and at night when illuminated, the effect surpasses that attained in 1893. The same may be said of the amusement feature—the "Midway."

The success of this second Omaha fair is assured and is due largely to the untiring efforts of Dr. Geo. L. Miller, president of the Exposition. He has overcome bitter local opposition which for a time threatened to prove a serious handicap and now has the satisfaction of seeing another crown added to his laurels. The Trade Press Association, of which this paper is a member, is particularly indebted to President Miller and Mr. J. W. Cutright, superintendent of the department of publicity, for courtesies shown while in Omaha.

ELECTRIC LINE FOR MARSEILLES, FRANCE.

The Compagnie Generale Francaise de Tramways, of Paris, has a concession to operate an electric street railway in Marseilles and is now engaged in installing an overhead trolley system to replace the horse cars and omnibuses. The concession expires Dec. 31, 1950.

At the present time the fares vary from 2 cents to 8 cents according to the distance, but under the new system a uniform rate of 2 cents will be charged. The company is to pay the city $19,300 per annum for the use of the streets and after the gross receipts exceed 7,000,000 fr. additional payments of 4 per cent on the eighth, 5 per cent on the ninth, and 6 per cent on the tenth and succeeding millions. The state will become the owner of the tracks and appurtenances at the expiration of the concession, and has the right to purchase at any time upon the payment to the company of an annuity to equal the average net receipts for the five best of the seven next preceding years.

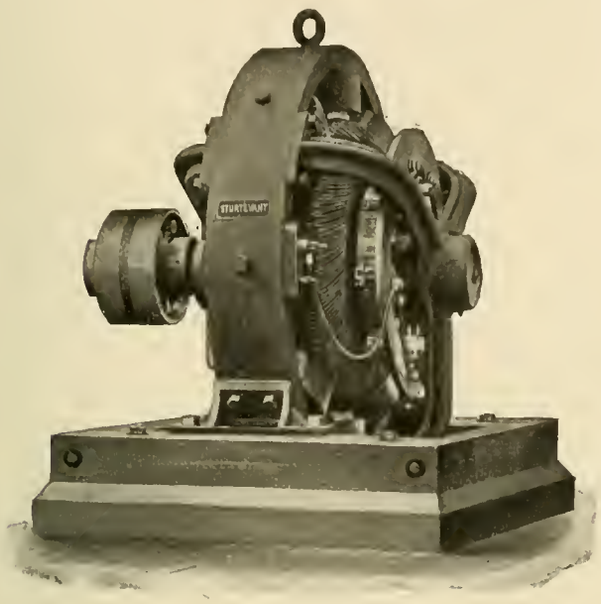
Trolley day was set apart in Vincennes, Ind., for the collection of a sum of money for charity. Free use of the Vincennes Citizens Street Ry. was tendered by the company and ladies served as conductors and collected the fares. There was $566.91 collected. Prizes were given to the amateur conductors who collected the largest amount in fares.

A NEW TYPE OF 8-POLE GENERATOR AND MOTOR.

The accompanying illustration shows a new type of 8-pole machine, which has been brought out by the B. F. Sturtevant Co., of Boston, Mass., and, as indicated by the coupling, is primarily designed for direct connection to a shaft, usually the shaft of a fan.

The field ring, which constitutes the frame of this machine, is made of wrought iron, cast steel or cast iron, according to the size, the sizes ranging from 3 to 138 h. p. in motors, or from a 3 to a 110 kw. in generators.

Wrought iron field cores are used, and a special type of cast iron pole shoe, which by its peculiar shape and size, is one of the principal elements in rendering this machine capable of extreme



STURTEVANT 8-POLE MOTOR AND GENERATOR.

variation of load without sparking of the brushes, or any shifting or adjustment whatever.

The field coils are machine wound, and have large radiating surfaces and good ventilation. The armature cores are built up of laminated, slotted discs, mounted upon a cast iron spider, having a hub projection for the reception of the commutator. These armatures are of the coil wound drum type, and usually have the two circuit winding, although in some cases a multiple winding is used. The special feature of this type of winding lies in the fact that as few as two sets of brushes can be used. The commutator is of large diameter, with pure rolled or drop forged copper segments, supported in a cast iron shell of spider construction, thoroughly insulated with mica and micanite. Reaction brushes of carbon are generally used. Tripod bearing yokes support the shaft, and the bearings are provided with sleeves which in the larger sizes are self-aligning; ring oilers are used.

A GAS AUTOMOBILE FIRE ENGINE.

As a fire engine operates in cities and always upon solid ground in the streets over which it passes, it suggests to the automobile enthusiast the use of an automobile for this purpose, and it is astonishing that the problem has not sooner received practical attention. An automobile of this description known as the Porteu-Cambier engine is described by G. Espitallier, in La Nature, which it is stated has proved very satisfactory in practical use. The motive power is supplied by an oil engine which is placed at the rear end of the carriage symmetrically with respect to the longitudinal axis of the vehicle. It is of from 20 to 22 h. p. in capacity; the ignition is electrical, and the carburretters are of the Longuemare type. The crank shafts are assembled in two couples which act upon two cranks 180° apart, driving a shaft which corresponds to the central axis of the vehicle. This shaft drives by bevel gears an intermediate shaft carrying a set of pulleys. This intermediate shaft is provided with two sets of connections, one of which drives the pumps by means of a train of gear wheels, and the other drives the wheels of the vehicle by means of a belted connection to a counter shaft, the latter being connected by pocket chains to the rear axle. The belted connection between the two transverse shafts is supplied with two sets of fixed and loose pulleys which correspond respectively to two speeds of 15 and 8 km. per hour of the vehicle. Crossed belts are used on these pulleys which are shifted from the fixed to the loose sets by levers, and an extra set of pulleys with a straight belt are also used upon the intermediate axle which permit the vehicle to be run backward. All the belts are enclosed in a sheet iron casing to protect them from the water of the pumps. The disengagement of the running gear and the connection of the pump gear at the intermediate shaft is made instantaneously and automatically, so that the action of the pump commences at the moment the vehicle stops at the scene of the fire.

The suggestion has often been made, and it appears to be entirely feasible, to equip fire engines with electrically driven pumps, for use in cities where overhead trolley lines or power supply circuits are pretty generally distributed. Connections could easily be made between the trolley line and track of a railway without disturbing the street car service. Such an arrangement would furnish a sufficient and unfailing source of power where the necessary agreement could be made between the fire department and the electrical supply company or railway.

In the early days of electric railways an enterprising agent of a prominent electrical company had nearly succeeded in selling a railway plant in a small town when unexpected opposition to the use of the overhead trolley wires was suddenly urged by the newly organized fire department of the town which nearly caused the electric railway scheme to fall through. Seeing that his only chance to sell the road lay in conciliating the fire department, the agent, who was of an inventive turn of mind, wrote an article on the advantages of electrically operated fire engines connected to overhead railway systems which appeared in the daily papers and which appealed so strongly to the fire department as to enlist its sympathy with the trolley scheme. The franchise was granted and the road built, but up to the present time the electric fire engine has not been put in service.

STEAM AND TROLLEY TO UNITE.

The combination of electric railway interests in the state of Connecticut which has recently attracted considerable attention now appears to be much more important than was at first supposed, and evidence lends to the conviction that the combination will include the steam as well as the electric railway interests of the state.

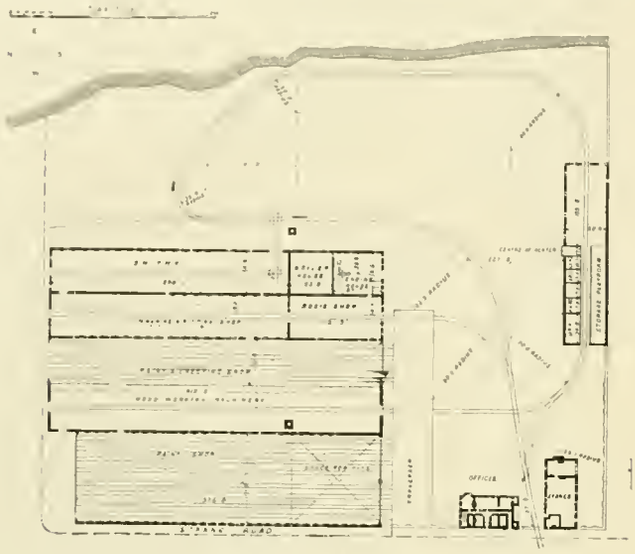
The combine will do business under the name of the Connecticut Light & Power Co., and within a few weeks it has purchased the Waterbury Traction Co. Other railroad and lighting companies are to be absorbed as soon as the necessary arrangements can be made. From the fact that the struggle between the steam and electric railways, which has been a prominent feature in the state legislature for several years, was strikingly absent during the last session it is to be inferred that an understanding has been reached between these interests, and this belief is further strengthened by the fact that the new Colonial Trust Co., of Waterbury, which it is expected will finance the trolley combine contains in its directorate the names of a number of well-known men who are closely identified with the steam and trolley railway interests of the state.

TRANSFER TICKET FRAUDS.

The Waterloo & Cedar Falls (Ia.) Rapid Transit Co. caused the dismissal or arrest of all but two or three of its conductors last month. Three of the men arrested are charged with conspiracy and defrauding the company out of a large sum of money. The plan of operations, it is alleged, was to issue bunches of properly punched transfer checks to each other and to turn them in with their daily reports, pocketing the cash represented by the slips. More than two months ago the leakage in receipts was suspected by the railway people and detectives were employed to ferret the matter out. Various charges, but none of a criminal nature, are made against the other men discharged by the company.

THE ELECTRIC RAILWAY & TRAMWAY CARRIAGE WORKS, PRESTON, ENG.

The Electric Railway & Tramway Carriage Works, Ltd., situated at Preston, England, is the newest and by far the largest street car building concern in Great Britain, and has already demonstrated that its promoters, Messrs. Dick, Kerr & Co., correctly understood the electric railway (or, as our English brethren would say, tramway) situation. As we have heretofore pointed out the short-time



PLAN OF WORKS.

purchase clause in the Tramways Act of 1870 acted to smother enterprise in street locomotion, and this in turn caused stagnation in the manufacture of tramway supplies. The Light Railways Act gave more encouragement to investors in tramway properties and in the last few years there has been a growth in this field that is quite remarkable. The tramway companies found that it was next to impossible to secure early delivery of cars ordered from home shops because all the builders catered principally to the steam railways, and tramcar orders were of secondary consideration.

The new works at Preston owe their being to men who were not only interested in electric traction, but could see farther in advance than others, hence this car building company is first in the field, and with the brightest of prospects.

The works are close to the Albert Edward Docks, and the River Ribble, and have sidings into them from the London & North Western and the Lancashire & Yorkshire Railways. There is every facility for the receiving and dispatching of materials and goods, whether by sea or land. The old buildings on the site have been entirely re-arranged and put into good condition. The buildings, new and old together, are so extensive that of the thirteen acres to which the property extends, from four to five acres are under cover. System and orderly sequence, resulting in efficiency and economy, form the key-notes of the whole plant.

The ground plan gives a good idea of the extent and arrangement of the works. To the right of the entrance are general stores; to the left, the offices of the company; at the south end of the ground, a building for cutting and storing timber and lumber; at the north end of the ground, boiler and engine rooms, bogie fitting, machine, and smiths' shops, carpentry and erecting shops, paint shop, and pit shop where the numerous pits between the tracks admit of the motors being fitted to the electric cars. The experimental track in the grounds is also a prominent feature.

It will be convenient first to refer to the power appliances, and then to deal with the various departments in the order obtained by tracing the progress of materials from the time they enter the works till they emerge as finished cars ready for immediate service.

The power plant comprises two Galloway boilers 28 ft. by 7 ft. 6 in., furnishing steam at 120 lb. to a 14 and 25 by 24-in. horizontal engine direct connected to a Mather & Platt multipolar dynamo of about 250 kw. capacity. This plant is now being duplicated. The machinery in the shops is driven by electric motors and a storage battery of 140 chloride cells, 440 ampere-hours, is used as a regulator and for furnishing light and power when it is desired to run a portion of the shops at night. The larger tools have individual motors and the smaller ones one motor to several machines. In the works there are 25 motors; they are all of 10, 25 or 40 h. p. capacity.

In connection with the power plant, a Green's economizer and a Klein's cooling tower have been provided. The coal store is in front of the boiler house, and the coal is unloaded direct from the railway wagons—which are brought into the works on the railway tracks—into the store. Thence it passes through bunker holes direct to the firing floor. Close beside the latter, and adjoining the coal store, is a storage reservoir for rain water; connections have also been made with the city water mains, so that the public supply can be utilized.

When timber is brought into the works on the railway wagons it is conveyed by the tracks to the building on the right of the plan, which is a plain brick structure 225 ft. long by 50 ft. wide, and one story high, the railway track running right through the building. At the east end is a log band saw mill which can deal with logs up to 48 in. in diameter, and from 30 ft. to 40 ft. long. Storage space for an ample stock of timber is provided, and a large portion of it is occupied with selected and seasoned timber of the highest grade.

The sawn timber is conveyed from the storage shed on the railway track direct into the wood-working machinery and erecting shops, which occupy the two central bays of the main building. All the bays are very long and spacious, the dimensions being shown on the plan. The shops now referred to have light iron truss roofs, are well lighted, and have a concrete floor between each railway track. They are equipped with machines of the latest and best type, which have been obtained from America.

ELECTRIC RAILWAY & TRAMWAY CARRIAGE WORKS, PRESTON, ENG.

Iron and steel materials which have to be forged go around, on coming into the works, to the east side of the buildings and are passed on the railway wagons into the smithy. In the smiths' and bogie shops the construction of the trucks—a most important part of an electric car—is carried on. While the company makes trucks for electric cars, it is also prepared to supply and fit to the car bodies the trucks of the noted American makers. When the trucks which are built on the premises are finished, they are brought out in front of the bogie shop and taken along by a transverser, which runs along the front of all the shops, to the pits at the end of the paint shop where they are fitted to the car bodies. The other ironwork of the cars is worked northward to completion, and is then passed across to the paint shop and fitted in place. In the iron-fitting shop two large galleries run the entire length of the building, where the lighter machines are placed.

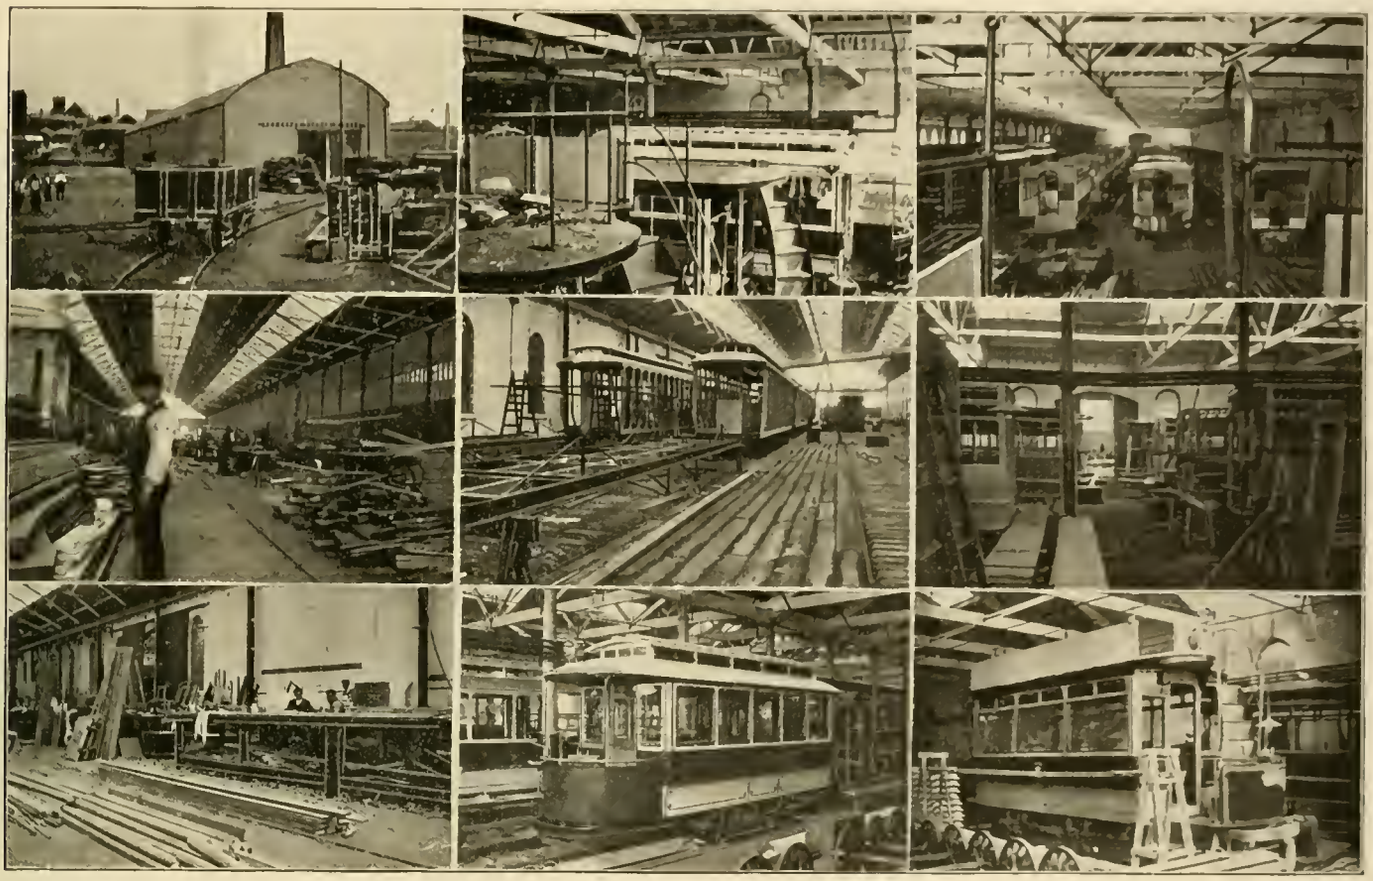
The paint shop requires only little special fitting, but heating arrangements have been provided to keep the temperature uniformly at 65° F. After the finishing touches are put on the car bodies, they are moved along to the pits where the trucks and wheels are attached, and, in the case of electric cars, which will form the majority of the output, the motors are fitted. There is really but one large pit extending the full length of the shop, but between the tracks it is covered over. As there are eight tracks in this shop, and two pit openings in each track, the effect is to give 16 working pits. The depth is ample, so that the men can conveniently work underneath the cars.

When the cars are mounted, and the electric connections and fittings have been adjusted, they are ready for testing. The car is brought out of the paint shop on the testing line, part of which also serves, as already described, for bringing the material into the works. The ground is fairly level, though at the east side, where it rises a little, some cutting was necessary. The track is carefully laid with 56-lb. rails, on creosoted sleepers, and fully ballasted. Its length is a little over half a mile, and is shown on the plan. Including the 15 sets of tracks inside the buildings, the total length of the works is about two miles. The testing line is equipped with overhead trolley wires in the usual fashion, as in the case of an electric tramway. Curves of various degrees of sharpness have been provided on the track, so that the trucks may be tested under a variety of conditions, including those of maximum difficulty.

On the basis of the ordinary size of tramway car with roof seats, the capacity of the works is about 800 cars per annum. Larger cars of the eight-wheeled type both for electric railways and tramways will be turned out when required, and the company will be able, if necessity arises, to build railway carriages. The number of men employed will range from 600 to 800. The manager of the works is Mr. E. A. Stanley, who has had wide experience in America in connection with similar undertakings.

The company now has nearly 500 cars under contract; they are for nearly every tramway of note in the United Kingdom.

The accompanying illustration showing views of the works are from photographs taken by a "Review" representative, when visiting the plant last month. One of the cars built by this company for the Oldham, Ashton & Hyde road is shown on another page.



SCENES IN THE SHOPS.

FIRE AT ST. PAUL.

On July 17th the Ramsey St. station and car house of the Twin City Rapid Transit Co., in St. Paul, was partially burned. The house was divided by a fire wall, one side being but little damaged, while the other half was destroyed. Forty-seven cars were lost, of which 44 were motor cars.

This was the company's principal station in St. Paul and the base of supplies for the St. Paul system. A large amount of supplies for winter equipment, such as stoves, stove boxes, storm windows, etc., were stored here and supplies for the current month had been delivered only a few days before the fire.

The total loss is estimated at nearly $150,000.

At a meeting of the council in Milwaukee last month a resolution was offered for the appointment of a commitee of nine members to confer with the officers of the Milwaukee Electric Railway & Light Co. with reference to the granting of a 4-cent fare.

AMERICAN STANDARD RAIL JOINT.

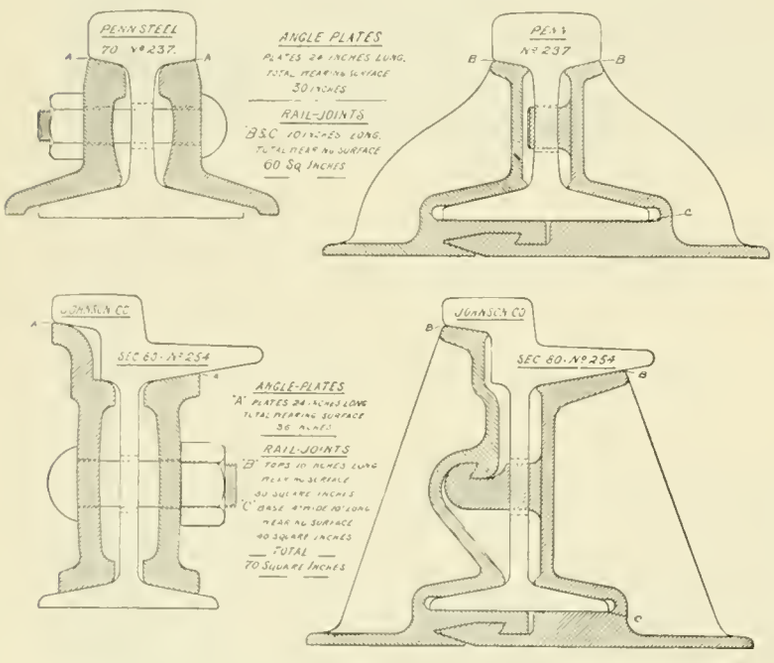
The "American" standard rail joints which are now made by the Chisholm & Moore Manufacturing Co., of Cleveland, O., successor to the American Rail Joint & Manufacturing Co., shows many improvements over those of last season. The locking device at the bottom is now so designed as to be doubled, making it impossible to slip or loosen; also, making a perfectly flat surface to rest upon the ties and when fully driven up making one continuous plate that cannot be forced down, thus tending to pull them out at the top and wearing under the ball of the rail. Another very great improvement is the making of a tight driving fit the full width and length of the joint under the bottom of the rail, thus preventing any settling of the rail. With these improvements it is now believed there can be no friction which would cause wear at any point at which contact to the rail is made.

By making this close contact at the bottom, the carrying or wearing surface has been much more than doubled, and is now stated to be greater than in any other joint or angle-joint in use. To emphasize this point, sections of the "American" joints are shown in juxtaposition to sections of angle-plate joints for the same shapes of T and girder rails.

In the case where angle-plates are used, the width is only about 4 in., whereas, with the joint it is 10 in., which is greater than any tie plate.

Another point on which strong claims are made, is the bracing of the rail at the top; it is claimed that with the use of one of these chairs, or intermediates (which are the same as the joints, excepting in length, being but 5 in.) in the center of the rail, say, about 7 ft. apart, the rail would be held so firmly that there would be no movement of it; and, by keeping the centers of the rail firm, there is much less chance for wear at the joint. These intermediates have the advantage over rods, as they never wear loose or rust off.

After an experience of several years, the manufacturer has decided that it is impossible to make a perfectly fitting joint without making a special pattern for each of the different sections of rail,



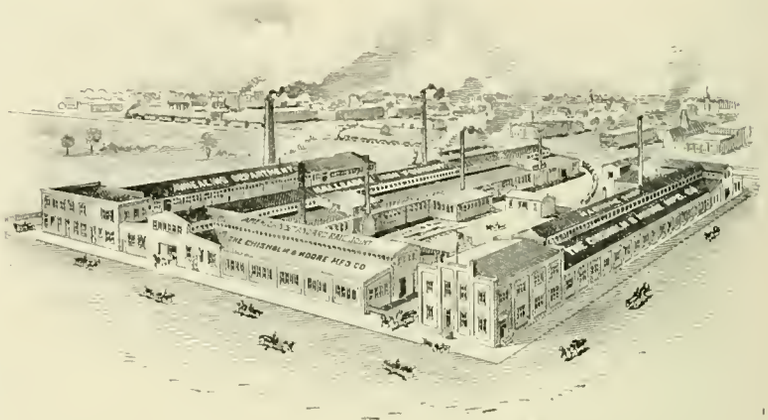
and grinding the joint at certain points, so as to make a perfect fit; and in order to have this work done properly the company determined to build a malleable iron plant of its own, where the work could be done under its own supervision, and machinery could be adopted to do it perfectly.

Our illustration shows the new works just completed, at a cost of over $250,000. In this plant, everything being new, nothing but the latest improved machinery is used, and all work will be guaranteed to be as near perfection as can possibly be made.

In the fitting of joints, special machines that will automatically grind every joint exactly alike, have been designed; this gives a degree of uniformity that is impossible where the work is done by hand. All pattern work, both wood and metal, is done by the most skilled labor that can be obtained in that line.

Probably one of the most important advantages obtained by having its own plant, will be the dispatch with which the company can fill orders; instead of taking from two to four months to fill an order, as in the past, it can now fill all orders in from 30 to 60 days.

Col. W. E. Ludlow, who has been the general manager of the American Rail Joint & Manufacturing Co. since the reorganization



WORKS OF THE CHISHOLM & MOORE MFG. CO.

of that company, will continue the management of this department in the new company, and brings to his work that long experience and careful study which insures success.

MAIL ON CARS IN SPRINGFIELD, MASS..

An attempt is being made by Postmaster Hyde, of Springfield, Mass., to establish a street car mail collection system, but has met with opposition on the part of the street railway, which company's franchise stipulates expressly that it must do a purely passenger business. The question arises whether mail matter would be classed as freight, which the road is not allowed to haul. The company further objects to stopping its cars every time a person wants to mail a letter, and also at the post office to have the mail boxes emptied. It is thought possible that the stopping of the cars might be done away with through the introduction of a device in use in some of the western cities. By means of this arrangement mail can be dropped by a person beside the tracks while the car is in motion. An extra "lip" is built upon the "hip" over the running gear at the sides of the car. From this a slide or chute leads down to a box, and letters dropped in the receiver at the side of the car easily fall down into the box.

AN AMERICAN PLANT IN LONDON.

The generating plant of the Central London Railway, with the exception of the boilers and economizers, is entirely equipped with American machinery and apparatus, even down to the steam and exhaust piping. In a short article communicated to the Electrical Review, of London, the writer comments on some of the details of the machines in a way that should be extremely flattering to the American manufacturers. The Allis-Corliss engines are recommended for their compactness and the provisions which are made for renewing the hard steel surfaces, and the alternators are described as "fine examples of electrical engineering work." After reviewing a number of salient features of the machinery, the writer concludes with a word of praise for the excellent way in which the parts had been packed for shipment.

The Benton & Fairfield Electric Ry., of Fairfield, Me., was formally opened to travel July 22d. Through the courtesy of Superintendent Mansfield, two special cars bearing the officials of the two roads, prominent business men of Fairfield and Waterville, and others, made a trial trip over the road.

GOLD STREET CAR HEATERS.

One of the chief requisites of an electric heater is to be so constructed that the surrounding air has free access to the heated wires, and upon this principle of free circulation of air through the heater the efficiency of the latter largely depends. In the Gold heaters the construction of the resistance coils is according to the method shown in Fig. 1. This consists of an open coil of wire having a high specific resistance and which is entirely non-corrosive. The support of the resistance wire consists of a ¼-in. steel rod which is

FIG. 1.

thoroughly covered with an insulating enamel burned on the rod at a temperature of over 2,000° and which, therefore, is not affected by any heat to which it will ever be subjected. The rod is bent into a zig-zag form and the resistance coil when slipped upon it is held firmly in place, not permitting vibration, and offers the smallest possible amount of friction to the flow of air through the heater.

Fig. 2 shows the interior of the electric car heater in section, which is made to set into the panel under the seat of a car, the front of the heater being flush with the panel. It is lined with asbestos and has an air space provided at the top which prevents the back of the heater from becoming unduly heated.

A car seat under which a Gold standard electric heater is suspended is shown in Fig. 3. As many be seen, the heater is firmly supported by iron brackets in such a position as not to come in

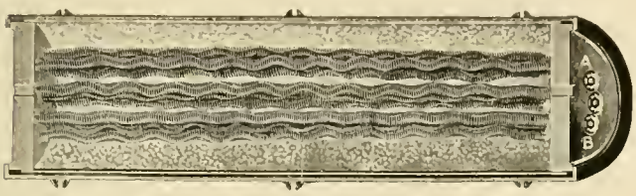


FIG. 2.

contact with the feet or clothing of the passengers. The method of connecting the heater is simple, and means are provided which permit it to be attached or released very quickly.

The resistance coils of these heaters are divided into three circuits, which are controlled from a three-point switch. The connection is made from the trolley into a cutout, then into the switch, from which the heaters on a car are all connected in series. When the current passes through point 1 of the switch the current passes through one-third of the coils of every heater in the car. Point 2 allows the current to pass through two-thirds of every heater, and point 3 passes the current through all the resistance of all the heaters. By means of these changes the temperature in the car may be varied as desired.

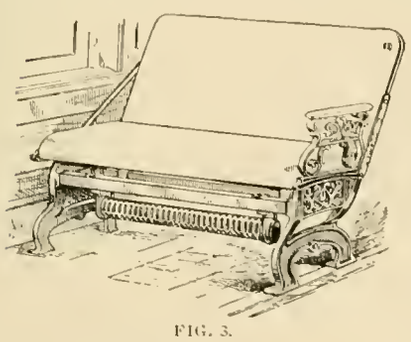

FIG. 3.

Another system of efficient car heating apparatus manufactured by the Gold company is one of hot water circulation, which is in use on a large number of street cars. The generator or stove is suspended below the floor, generally at one corner of the car. It is fed from the top and ashes are removed from the bottom. It is hung on iron brackets which hold it away from the woodwork.

The water coil is inside the stove and the outlet of the coil is connected to a riser pipe which runs up to a sealed jet. The latter is attached to a drum from its back outlet to take care of the expansion of the heated water. The outflow from the sealed jet takes its course through the radiator pipes of the car and returns to the bottom of the coil in the stove. The fire in the stoves only needs attention twice a day, and the pipes are filled with a non freezing liquid which will not rust them.

LIGHT OPEN CAR.

The Quincy Horse Railway & Carrying Co., of Quincy, Ill., has just received a large number of open cars from the J. G. Brill Co. The general type is shown in the accompanying illustration; the cars are 28 ft. 8 in. over the dashers and have 4-ft. platforms and stand 25 in. from the head of the rail to the underside of the sill. They are mounted on No. 21 E. trucks, having a 7 ft. wheel base; the gage is 5 ft. There are two No. 49 Westinghouse motors on each car; the weight without the motors 11,850 lb. The inside

BRILL CAR FOR QUINCY, ILL.

finish is ash and cherry with decorated three-ply veneer headlining; outside they are painted various colors to suit the different routes upon which they operate.

The use of a fancy skirting board below the letter panel is an unusual feature which is a pleasant departure from the severity of the ordinary finish. Round corner seat end panels are used and the trim is of solid bronze throughout. There are electric headlights on all the cars. Taken as a whole these cars show a great taste and neatness.

The Quincy company has departed from the more usual, and we believe the better, plan of providing entrance guards. One of the reasons urged in favor of permitting a passenger to alight on the left side is that he can see danger ahead better than if he gets off on the right hand side and then crosses behind the car.

PARK AT ANDERSON.

With the extension of the Union Traction Co.'s lines in the suburbs of Anderson, Ind., has come a demand for suburban parks and picnic places, several of which have been established. One party has secured a lease for three years on the pretty six-acre grove at Dundee on the line between Elwood and Alexandria. This is the half-way point between the two places. A long side track has been put in and all cars stop here. The grove is adjoining the railway platform. It is the intention to put up band stands, pavilions, summer houses, refreshment stands, swings and other buildings necessary to such grounds and to lay off croquet grounds, ball park and make the place attractive for all kinds of picnics. No intoxicating drinks will be allowed on the grounds. It is to be conducted as a first-class pleasure ground.

STRIKE AT EAU CLAIRE, WIS.

The greater portion of the employes of the Chippewa Valley Electric R. R., Eau Claire, Wis., are on a strike, and for several days there was considerable rioting, which was more violent from the fact that the mayor refused to extend police protection to the cars. The mayor holds that to permit policemen to ride on the cars would violate the anti-pass act passed at the last session of the Legislature.

PERSONAL.

MRS. DR. EMMA L. MERRITT has been re-elected president of the Sutro R. R., San Francisco.

MR. C. T. YERKES has removed his private office from 444 N. Clark St. to the Royal Insurance Building, Chicago.

MR. W. H. PARK has been appointed manager of the park at the terminal of the Youngstown (O.) Park & Falls Street Ry.

MESSRS. P. S. SALTONSTALL AND E. P. SHAW have been chosen directors of the Newport & Fall River (Mass.) Street Railway Co.

REV. C. L. SNOWDEN, Fairfield, Iowa, formerly assistant editor of the "Review," is spending a month in Chicago, and making his headquarters at this office.

MR. GEORGE HOEGER has been appointed superintendent of the Roxborough, Chestnut Hill & Norristown Railway Co., Philadelphia, succeeding Mr. J. C. Lugar.

MR. J. C. LUGAR, lately superintendent of the Roxborough, Chestnut Hill & Norristown Railway Co., Philadelphia, assumed charge of the Wilmington Traction Co. on August 1st.

MR. C. F. HOLMES, general manager of the Metropolitan Street Ry., of Kansas City, is now in London. Mr. Holmes' European trip has improved his health, though the gain has not been rapid.

MR. CHARLES N. COBB, treasurer of the Rockland (Mass.) & Abington Street Ry., since its organization, has turned over his books to his successor, who is treasurer of the Boston & South Shore Ry.

MR. C. W. FOOTE, general manager of the Zanesville (O.) Electric Ry., has tendered his resignation, taking effect September 1st, when he will become manager of the Cincinnati & Miama Valley Traction Co.

MR. GEORGE H. SCRANTON, superintendent of transportation of the Columbus (O.) Street Railway Co., has resigned, and on September 20th will sail for Havana to direct street railway construction work in that city.

MR. C. E. NORMAN, engineer of maintenance of way, of the Victorian state railroads, Australia, is now in this country inspecting steam and electric railroads; he will visit Great Britain and the continent of Europe before returning to Australia.

MR. JOHN P. WILSON, who was tendered the position of general counsel for the Union Traction Co., of Chicago, has decided not to accept the office, as his present engagements are such as to prevent his connection with that company at present.

MR. HARRY DALTON has been appointed superintendent of the Northern Ohio Traction Co. (the consolidation of the A. B. & C. and the Akron road), succeeding Mr. C. D. Smith, who died from injuries received in the recent wreck on that road.

MR. W. H. GLENN, purchasing agent and assistant superintendent of the Atlanta (Ga.) Railway & Power Co., has been appointed superintendent of construction to succeed Mr. N. W. L. Brown, who recently resigned, and will fill the three positions.

MR. E. S. DIMMOCK has been appointed general manager of the Bay Cities Consolidated Railway Co., taking charge August 7th. Mr. Dimmock has had an extended experience in electrical and steam railroad work; he is a brother of W. S. Dimmock, general superintendent of the Omaha & Council Bluffs Railway & Bridge Co.

MR. JOHN C. HENRY, of Denver, Col., the well-known inventor of numerous electrical street railway appliances, has recently perfected a new controller, which is being tested on one of the cars of the Monongahela Traction Co., of Pittsburg, Pa. Mr. Henry is at present in New York, where he is arranging to apply his new controller on an exhibition car and on an electric automobile.

ELECTIONS.

THE NORTH AND THE WEST CHICAGO STREET RAILROAD COS. have chosen officers as follows: President, Daniel W. Hunt; secretary, F. E. Smith; treasurer, L. E. Owsley. The elections are merely to keep up the organization, as the Chicago Union Traction Co. operates the two roads.

THE SPRINGFIELD (O.) RAILWAY CO. at a special meeting of the directors held August 1st, chose officers to succeed Wm. B. McKinley, of Chicago, and Geo. F. Duncan, of Portland, Me., who recently resigned as president and vice-president. Oscar F. Martin, of Springfield, O., was elected president, and Henry J. Crowley, of Philadelphia, vice-president.

THE WINCHESTER AVENUE RAILROAD CO., of New Haven, Conn., on July 31st, chose officers and directors as follows: President, A. B. Turner, Boston; superintendent and treasurer, A. E. Pond, New Haven; directors, A. B. Turner, Boston; A. E. Pond, New Haven; Sidney Harwood, Boston; A. R. Mitchell, Boston; E. E. Floyd, Boston; S. Harrison Wagner, Israel A. Kelsey, James Graham and Henry F. Spencer of West Haven.

THE UNION TRACTION CO., of Anderson, Ind., has made a number of promotions among its employes recently. Mr. B. E. Parker, who has been trainmaster at Alexandria ever since the road started, has been advanced to a similar position at Marion. Mr. Harry Fenton, one of the conductors on the Elwood line, has been given the place of trainmaster at Alexandria. Mr. Hadley Clifford, who was a conductor on the South Meridan St. line, is now trainmaster at Anderson, Ind.

PRESIDENT RIGG, of the United Power & Transportation Co., has made the following appointments for the Wilkesbarre & Wyoming Traction system: General superintendent, Thomas A. Wright; superintendent of transportation, John Clifford; assistant superintendent of transportation, Edward Irwin; electrical engineer and superintendent of motive power, James Fagin; cashier, Pierce Butler; manager claim department, R. W. Day; chief clerk and to be apointed treasurer in thirty days, Theodore Barber.

THE CHICAGO UNION TRACTION CO. has removed the offices of the West Chicago to 444 N. Clark St. We announced last month that John M. Roach had been appointed general manager; since the date of our last issue George A. Yuille, until lately the second vice-president and assistant general manager of the West Chicago, has been appointed assistant manager of the Union Traction. F. L. Fuller, superintendent of the West Chicago, and T. A. Henderson, superintendent of the North Chicago, have the same positions as before the consolidation with the titles of division superintendent.

THE GLOUCESTER (MASS.) STREET RAILWAY CO., the Gloucester & Rockport Street Railway Co. and the Rockport Street Railway Co., control of which was recently acquired by the Massachusetts Electrical Co., have been consolidated, and a meeting has been held for the election of officers and directors. The directors, as elected by the roads, consist of the old members, as follows: P. F. Sullivan, of Lowell, E. C. Foster, of Lynn, Charles Williams, of Wakefield, E. L. Stone, of Lynn, and G. H. Goodspeed, of Boston. The boards organized by the choice of E. C. Foster as president, Charles Williams, treasurer, and E. L. Stone, clerk in each case. Wiliard B. Ferguson, president, and David S. Presson, treasurer and clerk of the company, retired, and the new management will immediately take charge of affairs.

THE TERRE HAUTE ELECTRIC CO. has appointed Mr. Clinton P. Kidder general manager of all its properties, both the street railway system and the lighting plant. Mr. Kidder is a graduate of the Rose Polytechnic Institute and is a trained electrician, besides having had considerable experience in the management of

street railway lines. When the local line was changed from horse to electric power Mr. Kidder superintended the construction of the new plant and was the company's electrician and general manager for several years. Later he was connected with the Cincinnati Incline Plane Street Railway Co., and his last employment was as superintendent of the Overman Wheel Co.'s factory at Chicopee Falls, Mass. Mr. Guy Tripp, treasurer of the Terre Haute Electric Co., who has also been performing the duties of general manager, will return to Boston. Mr. Tripp continues as treasurer with P. P. Thomas as assistant, but will have his headquarters at Boston, making a trip to Terre Haute every six months.

OBITUARY.

MAJ. EDWARD T. ROWELL, president of the Andover & Lowell (Mass.) Street Railway Co., died suddenly on August 4th while going from Boston to Lynn on a Boston & Maine train. Major Rowell was born in Concord, N. H., Aug. 14, 1836; he graduated from Dartmouth College in 1861, and enlisted in the 5th New Hampshires; he served through the Rebellion, being wounded at Gettysburg and at Petersburg, and was mustered out of the service with the rank of major. He was active in politics and engaged in various business enterprises, being manager of the Courier-Citizen-Journal Publishing Co., of Lowell; he served three terms as postmaster of Lowell. Mrs. Rowell and one daughter survive him.

NEW PUBLICATIONS.

THE BOSTON SOCIETY OF CIVIL ENGINEERS has issued its annual pamphlet for June, 1899, containing the constitution and by-laws of the society, with the list of membership.

"THE AUTOMOBILE," a 16-page monthly devoted to the now rapidly expanding field indicated by the paper's name, made its first appearance with the August issue. Our new contemporary is published by the E. L. Powers Co., 150 Nassau St., New York.

"PRACTICAL ELECTRICITY," is the title of a small volume published by the Cleveland Armature Works, which is addressed to a class of readers having some practical knowledge of electricity, such as mechanics who are daily operating electrical machinery without knowing much about its general construction. The subject matter of the book comprises a series of lectures written from daily shop practice on the designing of generators, motors, etc., which have since been thoroughly revised and enlarged by Mr. John C. Lincoln. The work treats of the fundamental principles of electricity, and the explanations and deductions of formulae are very clear and simple. A prominent feature is a list of questions covering the subjects of each chapter for the reader to work out for himself, and his answers may be verified by turning to the back of the book where all questions are answered.

"LE MOIS SCIENTIFIQUE ET INDUSTRIEL," a new French publication, has just made its first appearance with a June issue. The object of this journal, as its sub-title implies, is to present an international review of scientific information, both here and abroad, and the work is in the form of a condensed digest of current technical literature. The editorial staff contains the names of a number of well-known scientific writers, and the subjects which are reviewed in the first number include measures, machinery and apparatus lighting, railroads, tramways, navigation, building construction, industrial chemistry, metallurgy, and other sub-heads which pretty well cover the field of scientific publications. The typographical work is excellent and abstracts are comprehensive, although often rather more brief than the subjects deserve. With the addition to the pages, however, which the publishers promise, the work will form a useful index and resume of current technical literature.

GAS, GASOLINE AND OIL ENGINES, by Gardner D. Hiscox, M. E., was first published in 1897 in order to place before the reader in convenient shape the information concerning explosive motors made in the United States. Prior to the publication of this work there was an entire lack of literature on this subject save such articles as have appeared from time to time in the technical press, European works on gas and oil engines, scarcely even alluding to American engines or practice. The first edition was speedily exhausted and the author prepared a second edition, published in 1898, to which much new matter was added, including some very interesting chapters on the application of this class of motors to road vehicles and launches, a subject of growing interest.

The work contains over 360 pages, standard 6 x 9 size, and is well illustrated. There are 19 chapters which may be grouped under these more general heads: History; theory of gas and gasoline engines; efficiencies; cause of loss in explosive motors; gas engines for electric lighting; the material of power; carburetters and vapor gas; details of constituent parts; lubrication; testing; various types of engines, and motors for different purposes. In conclusion are given a list of the important gas, gasoline and oil engine patents, and a list of the makers of these engines in the United States.

We heartily commend Mr. Hiscox's work to those seeking information on the subject with which it deals; the manner of treatment is excellent, the style good, and the typographical appearance above reproach.

Published by Norman W. Henley & Co., 132 Nassau St., New York. Price, $2.50.

JACKS FOR BARN USE.

The Joyce-Cridland Co., of Dayton, O., has designed the jack, known as No. 220, and which is shown in the accompanying illustration, especially for raising street car bodies in order to change the trucks from summer to winter cars and vice versa, or for removing the trucks for repairs. This work is very tedious and expensive when attempted without an equipment of suitable appliances, and a device such as that shown here is a great convenience; with a pair of these jacks a car can be raised clear of the trucks in less than 10 minutes without the use of any blocking.

The method of operation is to place a beam under the drawbar of the car with a jack at each end of it, the beam resting on the feet of jacks. When the car is raised to a sufficient height trestles are placed at each side to support it and the jacks removed to the other end of the car which is raised in the same manner, it being left supported on the jacks until ready to be lowered, when the operation is reversed. The work can be done in one-third of the time if four jacks are used instead of only two.

The Joyce-Cridland Co. is the maker of all types of lever, compound lever, screw and hydraulic jacks, and among the different varieties are special designs for almost any class of railroad work.

CARRIER FOR HAULING WIRES THROUGH CONDUITS.

Mr. W. L. Mulligan, chief electrician of the United States Electric Co., Springfield, Mass., has invented an ingenious carrier for use in placing wires in small conduits, which will interest electricians who have any conduits under their care. The device comprises a large spiral spring held between side frames and geared to two rubber tired driving wheels, so that as the spring uncoils the carrier is driven forward. At the front end is a third wheel, which is large enough to run over any poor joints that may be in the conduit. The spring is powerful enough to drive the carrier from one manhole to another.

The carrier is used to draw a light string from manhole to manhole; a wire is attached to the string and the cable to the wire.

The first two weeks of July showed a gain of 26 per cent in the traffic of the Metropolitan Elevated, Chicago, over the corresponding period in 1898. Only three ball games were played in this period, so that this traffic increase is not abnormal.

FOREIGN FACTS.

An electric railway is to be constructed between the railroad station and the town of Chiete, Italy.

Application has been made for a franchise to construct an electric railway between Sarria and the Montana de Vallvidrera, Spain.

The electric railways of Hull, Eng., were opened for traffic last month. The present rolling stock consists of 30 motor cars and about 30 trailers.

Magdelburg's first electric railway is now under construction. The work is to be carried out on an ample scale and will cost in the neighborhood of $5,000,000.

The new electric tramways of St. Helens have been officially inspected by the Board of Trade, and a provisional permit to run the cars for public traffic has been given.

The Irish Privy Council have granted an order to the Drake & Gorham Electric Power & Traction Co., authorizing the construction of an electric tramway from Bangor to Donahadee.

The borough engineer of Newport, Eng., has issued an exhaustive report on the proposed adoption of electric railways for that city. The cost of the proposed alteration to electricity would be about £20,811.

City of Carlisle Electric Tramways Co., Ltd., is the name of an English corporation which has been registered to acquire the powers and rights conferred by the Carlisle Tramways Order of 1898. The company will build and operate a railway under the franchise.

The movement to extend the Leeds, Eng., tramways to the city boundary of Rodley is being vigorously pushed, and a petition to this effect to be presented to the Tramway's committee of the city of Leeds is being numerously signed by the taxpayers and residents of Rodley.

The city of Manchester, Eng., is to build a system of electric railways to be operated on the overhead trolley system. At first it was intended to send a committee to New York and Washington to inspect the conduit system here, but after a lengthy discussion the overhead system was adopted.

At a meeting of the stockholders of the British Electric Railway Co. it was stated by the chairman that the installation of the plant for utilizing the water power from the falls of the Gold Stream at Victoria, B. C., had been completed, and the plant had been running satisfactorily since April.

Prof. Kennedy has made his report to the Tramway's committee of Newcastle-on-Tyne, England, to the effect that there is no difficulty whatever in working the overhead trolley and the conduit systems in conjunction with each other. This fact has been demonstrated on several railways in this country.

Among the new electrical enterprises in Brazil is the establishment of an excellent electric railway at Manaos. Mr. Charles R. Flint is the principal owner of this road, which is under the management of Dr. Hebblethwaite. It is 15 miles in length, thoroughly equipped with modern machinery, and has just been put into operation.

The Tramway's committee of Halifax, Eng., has recommended the construction of several new electric railway lines, and the electrical engineer to the corporation points out that with the extended tramway system sub-stations several miles out of Halifax will be required, and these must be supplied with power by means of polyphase distribution.

The Kidderminster & District Electric Lighting & Traction Co., Ltd., has been formed in England with a capital stock of £100,000, for the purpose of acquiring the issued shares of the Kidderminster & Stourport Electric Tramway Co., and of taking over, with the consent of the Board of Trade, the electric lighting order granted to the corporation of Kidderminster.

A novel electrical omnibus built by Messrs. Siemens & Halske, is being introduced upon the Berlin streets. It is equipped with two steering wheels and can be run on the tramway tracks. It has a collector which enables its batteries to be charged from the overhead trolley lines during a journey over the street car lines.

The Corporation of Huddersfield, Eng., has received the sanction of the Board of Trade to borrow £47,782 2s. 4d. for electric traction purposes. Messrs. Greenwood & Batley, of Leeds, have secured the contract for the equipment of the Huddersfield lines, part of which are to be converted to electric overhead trolley at once.

The annual report of the Astronomer-Royal of England states that the continuity of the records of magnetic measurements at the Greenwich Observatory has been secured by building a new magnetic pavilion in which the magnetic instruments have been erected. It is now thought that disturbances due to electric railways, which at one time threatened seriously, have been successfully overcome.

An extension to the Bristol (Eng.) electric tramways is to be made which, with the part previously equipped with electricity, makes about 10 miles of track. This comprises about one-third of the entire system of electric tramways for which the company has acquired a franchise. The entire equipment of the existing lines and the construction of a new power station will cost in the neighborhood of £400,000.

The Cataract Power Co. has purchased most of the stock of the Hamilton (Ont.) Street Railway Co., and it has completed arrangements for the control of the Hamilton & Dundas Ry., and also has control of the Hamilton Radial Ry. Plans have been completed for a line from Hamilton to Guelph and Waterloo, and the Cataract people have been asked to take over the proposed Hamilton, Ancaster & Brantford Electric Ry., but the latter has not been decided on.

A novel electric railway has been built in Berlin to connect the two offices of the Algemeine Electricitats Gesellschaft in the Schiffbauerdamm and in the Louisenstrasse. The line is an elevated one, the track being carried on brackets attached to the walls of the buildings. It is 200 m. long and rises at a grade of 1 in 18 from the first floor of the Schiffbauerdamm. The car is provided with an 8 h. p. motor, and can run at a speed of 8 km. per hour, affording a rapid means of communication between the two offices.

The Railway Commissioners of Sidney, New South Wales, are erecting a power plant of sufficient capacity to operate the whole system of proposed electric railways in that city and at the same time to provide for the electric lighting requirements of the municipality. A committee which has considered the questions of public and private lighting was unable to recommend the use of this station and it was decided by the council not to adopt this power. The station will have a capacity of 20,000 h. p.

A report giving the details of the cost of electric traction has been issued by the tramway department of the Leeds (Eng.) Corporation. The returns cover a period of one year ending March 25th, and the system includes seven miles of track. The car receipts for this period amounted to £48,032, 15s., the car mileage to 934,368 miles; the receipts per mile, 12.33d. and the operating expenses to 4.83d. This does not include interest on capital and sinking fund, or depreciation on electrical plant other than cars. The cost of generating current per Board of Trade unit was .60d. Of the total number of miles ran by electric and trailer cars, motors ran 816,749, and trailers 117,619. The consumption of current per motor car mile was .960 units, and per trailer car mile .480 units. The total units generated for the year was 809,101, less supplied to arc lamps, 32,660.

DEATH OF GEORGE H. WHEELER.

Mr. George H. Wheeler, formerly president of the Chicago City Railway Co., died at the Hotel Champlain, Plattsburg, N. Y., at 8:30 p. m. on August 11th, after a lingering illness.

George Henry Wheeler was born in La Porte, Ind., in 1841. His family removed to Chicago when he was eight years old, and ever since he has made this city his home. His early business career was as a member of the firm of Munger, Wheeler & Co., owners of grain elevators, and he devoted himself to those interests until 1891, when he was called to the presidency of the Chicago City Railway Co. He remained at the head of this road until 1898, making a reputation as one of the most able street railway men of the country. In

GEORGE H. WHEELER.

1898 Mr. Wheeler retired from the presidency of the Chicago City Railway Co. to devote his time to private interests, and was succeeded by the late M. K. Bowen. For many years Mr. Wheeler had been a director of the Continental National Bank and at the time of his death was president of the Washington Park Club, in addition to holding memberships in the Calumet, Chicago and University Clubs and the Sons of the American Revolution. He was a director of the World's Columbian Exposition.

Mr. Wheeler was removed from his home, 1812 Prairie Ave., to Lake Champlain late in July, following a recurrence of malarial fever, of which he had been a sufferer for a year.

Mr. Wheeler leaves two children, Mrs. Lawrence Young, of this city, and Dr. Henry Lord Wheeler, of Yale University. His wife, who was Miss Alice Lord, of Watertown, N. Y., died several years ago.

INCREASED TRAFFIC ON CALUMET, CHICAGO.

General John McNulta, receiver of the National Bank of Illinois and of the Calumet Electric Street Ry., whose stock was the principal asset of the bank, has been directed to advance $368,000 to pay all the indebtedness of the Calumet save the claims due the bank, which aggregate $3,682,300. The court has directed that $73,140 be set aside to repair the Pullman line of the road.

The Calumet is reported to be in an exceedingly prosperous condition, there having been an increase of almost 50 per cent in receipts during the last six months.

Manager Coombs of the Leavenworth Electric R. R., purchased $600 worth of fireworks to be set off near the Soldiers' Home last month.

The rolling stock of the Tacoma (Wash.) Railway & Power Co. is to be entirely re-equipped with new motors, controllers and trucks. A total of 22 practically new cars will then be available. The company let the contract on July 27th for grading a new route for its city park line.

THE WASHINGTON TRACTION & ELECTRIC CO.

The consolidation of the Washington, D. C., street railway properties under the management of the holding company above mentioned, which was described in the June issue of the "Review," has been steadily progressing, and all of the roads are now practically in charge of the new management. The City & Suburban Railway Co., which had agreed to sell out to the new company, was taken over by them on August 1st, and Mr. W. Kesley Schoepf, under whose management the road was entirely rebuilt, retires from the railway business. It will be remembered that the urban portion of this road is equipped with the conduit system, and the suburban portion with the overhead trolley, and it is generally conceded that the City & Suburban is one of the best equipped roads in this country. Its conduit work is specially substantial, and was patterned largely after that of the Metropolitan Street Railway Co., of New York. The suburban line is now completed to a point near Hyatsville, Md.

The change of power on the Columbia Railway Co., another of the consolidated roads which formerly operated by cable, was made on July 23d. When the cable stopped at midnight there remained 1,500 ft. of curved conductor rails to be put in place at the special work on the curves, of which there are 10 upon the road. There was also 450 ft. of grip guard to be removed. This work was all completed and tested out in six hours, and the cars started at the usual time in the morning. This was done under the direction of Mr. Theodore J. King, superintendent of the company, who has been in charge of the rebuilding of the road.

The reconstruction of the Anacostia and Belt lines was commenced on August 1st by Mr. E. Saxton, who has built all the conduit lines in the City of Washington. A large amount of the ironwork has been received and Mr. Saxton expects to have part of the road ready to run by the new motive power in about two months.

The power of the Great Falls is to be utilized for supplying the motive power of the consolidated roads and also the current for the lighting and power plants of the Washington Traction & Electric Co. It is intended to construct a dam below the government dam, and to build sluiceways to convey water to the turbines. It will probably require a year and a half to complete this undertaking, which will involve a considerable expenditure.

At a recent meeting of the directors Mr. George Truesdell was elected president of the Washington Electric & Traction Co. and the other officers were chosen as follows: Charles A. Lieb, vice-president; H. D. Mirick, treasurer; James B. Lackey, secretary, and V. B. Deyber, assistant treasurer.

Mr. Robert Weaver, who remained on the board of directors of the Columbia road at the request of the new owners, resigned as member of the board and the vacancy was filled by the election of Mr. Truesdell. The same set of officers will be placed at the head of all the constituent companies and of the parent company.

A new system of transfers went into effect on the lines of this company on July 16th and has proved very popular. Within the District limit one can ride anwhere on a continuous passage. This means that any person can travel on the Washington Traction Co.'s lines a distance of 10 miles for 5 cents. Even suburban citizens who live outside the city and District limits save about 3 cents on each trip under the new arrangement.

On the opening day of the transfer system the people took advantage of the cheap fares to travel in large numbers. The management of the road is well pleased with the entirely successful manner in which the innovation was received and are assured that it will result in pecuniary profit.

The motormen and conductors on all the company's lines will hereafter all be bonded for $500 each. This plan is an entire change from the old method of requiring the men to deposit cash with their companies, and it is believed by the management that it will be both safer for the company and easier for the men. The companies required their motormen and conductors and other responsible employes to deposit cash when they entered the service, the sum varying from $5 to $25 on the different lines.

Under the new arrangement an assessment of $2.50 will be made, which will be paid by the men to a bonding company. The plan was suggested by General Manager Hart a few days ago, and has been adopted formally.

HALF FARES.

The Northern Ohio Traction Co. will improve its power house at Akron at a cost of $100,000.

Helena, Mont., will soon have a trolley road connecting to East Helena, a distance of five miles, and a 5-cent car fare.

The Chicago Union Traction Co. is completing 50 new summer cars to run in North Clark, Wells, Madison and 12th Sts. and Milwaukee Ave.

The New York, New Haven & Hartford has put the third rail electric system in operation on its Braintree and Cohasset branch, which is 12 miles long.

The work on the Rutland Canadian Ry., between Burlington and Alburgh Springs, Vt., is progressing rapidly, a large force of men being employed upon it.

The North Jersey Street Ry. employes and their friends took possession of Baldwin Park, Jersey City, on July 26th, which was the occasion of their annual outing.

A young man named Mason was arrested and fined $10 and costs for swearing on one of the street cars of Wilmington, N. C. Not being able to pay the fine and costs he was committed to jail.

The Findlay (O.) Street Railway Co. has just erected a new 60-ft. stack over its power house, and a large Turner water tube boiler, recently purchased, has been erected and is about ready for use.

Motorman John Flaherty, of the Citizens' Street Ry. of Muncie, Ind., ran after and caught a runaway team last month, preventing what would have probably been a fatal accident. The horses were frightened by his car.

One, Joseph Miller, has been arrested and identified as one of the men who assisted in holding up the night receiver of the Fairmount Park Transportation Co., Philadelphia, on June 19th. The robbers secured $4,000.

A Missouri couple were married in St. Joseph, Mo., on July 5th on a trolley car. A street car was chosen for the novelty of the situation, and the contracting parties as well as the spectators appeared to enjoy the unusual scene.

Popular conductors on the Syracuse (N. Y.) Rapid Transit line this summer are five Syracuse University men who are spending their vacations in earning a little money which will come in handy next year when college opens.

Proceedings have been instituted by Attorney General Elkin of Pennsylvania, to annul the charter of the Middletown Electric Railway Co. In addition to this the grand jury has indicted the company for maintaining a public nuisance.

The Phoenix (Ariz.) City Ry. has been ordered sold under foreclosure proceedings. The road was built in 1893 and comprises 6½ miles of electric track; interest on bonds has been defaulted for years and the total indebtedness is $356,427.

The Chattanooga (Tenn.) Electric R. R. signed a contract with the Government on July 5th to carry the suburban mails. All the suburban post offices near the city have been abolished and substations of the Chattanooga office established.

The Boston Elevated Railway Co. applied on July 15th for a second track location, thus complying with the law that it should apply for authority to complete at least seven miles of location within a year after the granting of the first location.

Spokane, Wash., has three electric railway companies. There are about 35 miles of electric car lines now in operation. The Spokane Street Railway Co. is petitioning for franchises for two new lines into two opposite suburbs of the city. It agrees to pay two mills per day into the city treasury for each car mile.

A new fraternal order, called the Ancient Order of United Workmen has been formed in Cincinnati, O.; the membership is made up entirely of street railway employes. It is in no sense a labor organization, but is purely a social and beneficiary order.

July 19th was ladies' day at Battle Creek, Mich., and the ladies ran the electric street cars, the steamers on Goguac lake, and the soda fountains of the city. The proceeds of the day were divided between the Woman's League and the Nichols' Hospital.

The motormen and conductors of the Woonsocket Street Ry. had a pleasant outing at Succonesct park on July 24th. A special car was furnished by Superintendent Young, of the railway, who also contributed towards defraying the expenses of the affair.

Some miscreant placed an iron stone roller, some railroad ties and a lot of tile on the tracks of the Monmouth Traction Co., of Bordentown, N. J., on July 22d. The obstructions were fortunately discovered by the motorman of the first car out the next morning.

A prize picnic and moonlight hop was given by the employes of the Cottage Grove Ave. line, Chicago, on July 28th. The affair was held at the World's Fair Park and $800 was distributed in prizes. The picnic was given for the benefit of the employes' club library.

At a recent meeting of the stockholders of the Peninsula Railway Co., Newport News, Va., a controlling interest was transferred to Alexander Brown & Son, of Baltimore, who already owned the stock and bonds of the Newport News & Old Point Comfort Railway & Electric Co.

Some important improvements were commenced in the latter part of July on the First Street R. R., of San Jose, Cal., under the direction of Manager George L. Barker. The new management will put the road in first class condition and the cars are also to be thoroughly repaired and painted.

There is a movement on foot to unite the Citizens Traction Co., of Oshkosh, Wis., and the Fox River Valley Electric Co. of Appleton. If the union is accomplished it is expected that a connecting line will be built from Appleton to Kaukauna and Green Bay, thus traversing the whole Fox River valley.

The Akron, Bedford & Cleveland (O.) line was tied up for some hours on July 21st by the cutting down of about 1,000 feet of trolley wire by striking linemen. The first morning car was stopped at the break and it was late in the afternoon before any linemen could be found to repair the damage.

The Pueblo Electric Street Ry. has purchased 12 city lots in the rear of its present power house from the receivers of the Colorado Coal & Iron Development Co., and work is to be commenced at once on an addition to the power house of 100 x 140 ft. in dimensions. The cost of construction will be $25,000.

For some reason the Citizens' Street Railway Co., of Detroit, determined to discriminate against the Detroit, Lake Shore & Mt. Clemens line, and accordingly the cars of the latter company were last month denied the use of the former's tracks for entrance to the city. The other interurban lines continue to use the Citizens' tracks as heretofore.

A three-year-old baby fell from one of the Portland (Me.) Railroad Co.'s cars last month while crossing a bridge and quickly disappeared into the river. One of the company's conductors, Mr. Herbert Chute, who was riding on the car, dove after the child, which he succeeded in finding, and after being carried down the river by the tide to a steamship wharf, both were taken from the water none the worse but for a wetting.

The United States attorney general rendered a decision last month to the effect that the Havana street railway franchise, known

as the Torre concession, on the evidence submitted is superior to all others, and entitles its owners at their own risk under the permission of the municipal authorities to proceed with the work of construction without the injunction of the military authorities. This opinion has since been confirmed by the Court of Appeals which ends the litigation.

The clerical forces employed by the various roads now under the control of the Washington (D. C.) Traction & Electric Co., are being cut down, and one set of office employes is being introduced for all the lines. The new force is located in the offices of the Metropolitan Street Railroad Co.

The old Sioux City cable power house is being torn down and the material will be rebuilt into a new car barn for the Sioux City Traction Co. with which the old cable road consolidated. The old building was one of the land marks of the city, having been built in 1889, and was a handsome piece of architecture in its day, but with the abandonment of the cable and the introduction of electricity five years ago the old machinery has grown rusty and the building with its well-remembered ball room has long since been abandoned to innocuous desuetude.

With the object of gaining time, the motorman of a Brooklyn, N. Y., car ran back on the track he had just come over, with the result that the car was thrown down a 12 ft. embankment. The car was derailed by striking a switch set for the down cars. The 12 policemen on board shouted for help and blew their whistles. They were heard at the Canarsie depot, whence a wrecking car and the police reserves were sent. The injured policemen were helped to the rescuing car. It was found necessary to dig the motorman out of the sand. The car was a total wreck.

Mr. R. D. Apperson, general manager of the City Street Car Co., of Stanton, Va., sends us a prospectus of a free street fair and trades carnival to be held in that city on Oct. 3, 4, 5 and 6, 1899. The affair is to be held under the auspices of the Stanton Board of Trade, and the City Council has granted to the street fair the absolute franchise of all public highways and buildings. On July 20th, at Highland Park, the leading society ladies of Stanton gave a minstrel show for the benefit of the King's Daughters' Hospital, which was largely attended and highly appreciated.

Mr. Walter Gaston, general manager and treasurer of the Hazard Manufacturing Co., of Wilkes-Barre, Penn., is about to sever his connection with this concern and accept a position with the Taylor Iron & Steel Co., of High Bridge, N. J. Mr. Gaston began his business career with this company when it was known as the Taylor Iron Works 30 years ago. He left it in 1873 and now returns to the same concern after an absence of 27 years. Mr. Gaston expects to be located in New York City. The Taylor company is a large manufacturer of manganese steel, steel castings, car wheels, car axles and ammunition in the line of shells, armor piercing shells, shot, etc.

The investigation of the cause of the accident on the Monongahela Traction Co., of Pittsburg, Pa., which resulted in the death of one man and the injury of several others, resulted in the following probable explanation. There is the privilege given the conductors and motormen of the division to stop for a minute or a minute and a half at Welford's well to get a drink. There were two cars standing on opposite tracks at this point, the one on the eastbound track about half a length farther than the other. As the third car came down the hill the brilliant headlight of the car on the eastbound track must have blinded the motorman and prevented his seeing the car ahead until he was almost to it, and besides, it is a very dark portion of the road where the cars were standing, being heavily shaded with trees close to the tracks.

PHILADELPHIA AND RETURN, $16.45, VIA THE WABASH.

The Wabash will sell tickets, Chicago to Philadelphia and return, September 1 to 4, as above; other tickets, a little higher, giving greater privileges. Write for particulars. Ticket office, 97 Adams St., Chicago.

NEW YORK STATE MEETING.

The seventeenth annual meeting of the Street Railway Association of the State of New York is to be held at Ithaca, N. Y., on September 12th and 13th, and as it promises to eclipse all former meetings in point of interest, instruction and entertainment a large attendance of both street railway and supplymen is desired.

President Rogers and Mr. J. P. E. Clark, of Binghamton, visited Ithaca a day or two ago, and found the local people enthusiastic and very much interested in arranging a program of entertainment. Ithaca possesses unbounded resources as a convention city. There are good hotel accommodations and an excellent meeting place, while Cornell University offers a fine field to those interested in electrical development, and scientific matters generally. The faculty of the institution are very much interested in the forthcoming convention, and will throw the doors wide open. The program of entertainment includes an inspection of the university buildings and the several departments, with a five minutes description of each by the professors in charge of the respective departments, and the following papers will be contributed by members of the faculty:

"Statistics of Street Railroad Construction and Operation," Harris J. Ryan, professor of electrical engineering.

"Experiments on Resistance of Rail Bonds," Prof. H. H. Norris, electrical engineering department.

"Fuel Economy of Railroad Engines," R. C. Carpenter, professor of experimental engineering.

"Polyphase Equipment Used in Cornell University." (Illustrated by practical exhibit of polyphase apparatus.) Prof. H. J. Hotchkiss.

These papers in addition to those prepared by practical street railway men will constitute an interesting and instructive feature of the convention.

The entertainments will comprise a trolley ride to the picturesque environments of Ithaca, including a trip through Cayuga Lake, with luncheon served on the boat; special entertainment and band concert at Renwick Park, and the customary banquet the evening of the first day, which promises to be an elaborate affair, followed by an unusually interesting list of toasts, responded to by brilliant and well-known speakers.

It is believed that this convention will be the most largely attended and the most profitable, from the standpoint of instructiveness, that has ever been held by this Association. The list of other papers to be presented at this meeting is not yet complete but we feel assured that they will in every respect be up to the high standard set by the New York Association.

President Rogers is endeavoring to perfect arrangements for special sleeping car service in and out of Ithaca via the Lehigh Valley and the D. L. & W. railroads. The special service in connection with the regular schedule will provide ample facilities for getting in and out of Ithaca, so that the fact that ordinarily this city is not easily accessible need not deter anyone from attending.

ELECTRICAL ASSOCIATION TROLLEY PARTY.

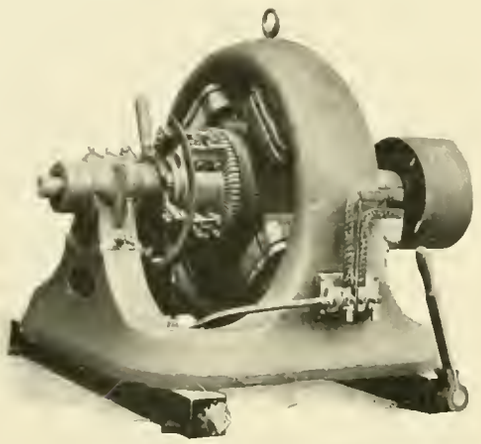
On Thursday, August 10th, the members and friends of the Chicago Electrical Association had a very enjoyable trolley ride at the invitation of the Association. The party, which comfortably filled three cars, assembled at 63d St. and South Park Ave., at 8 o'clock, where they boarded a special train brilliantly decorated with electric lights. After running to the loop at 64th St. and Stony Island Ave., where another delegation was picked up, the train started for West Pullman, where it arrived about 9:30 p. m. A stop of 30 minutes was made at the pavilion at this point, where several ladies of the party volunteered to supply the music for a dance, after which the party boarded the train which next proceeded to Windsor beach. Here another stop was made and the party indulged in another dance. The trip was enlivened by a supply of tin horns and vocal impromptus, and the party reached home about midnight, after enjoying a most agreeable outing.

The Augusta (Ga.) Railway & Electric Co. has decided to erect a bath house for the street car conductors, motormen and other employes of the company. The place will be fitted up with all the necessary equipments for hot and cold baths for summer and winter.

TRIUMPH DIRECT-CURRENT DYNAMOS.

In the accompanying illustration are shown a small belted dynamo and a bar-wound armature made by the Triumph Electric Co., of Cincinnati. This company has been in the field for seven years and claims that there is no more carefully designed or better made apparatus in the market. It prides itself particularly on fine machine work and the reliability and durability of its dynamos and motors.

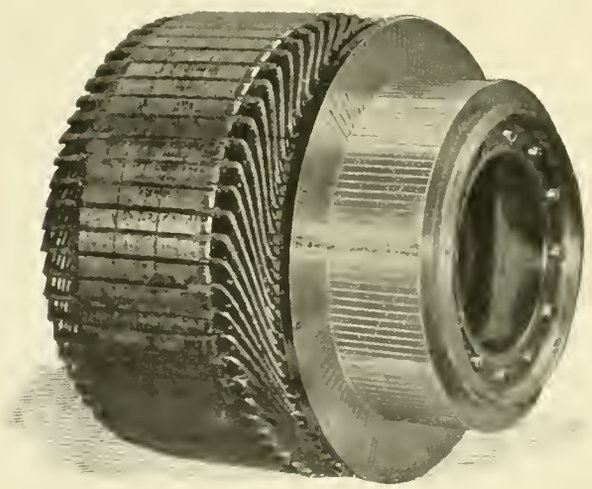
The "Triumph" direct current type of machines has cast-iron multipolar frames, with laminated pole-pieces and cast-steel pole



"TRIUMPH" BELTED DYNAMO.

shoes. Excepting in the smaller sizes, bar windings in armatures are used exclusively without band wires. The armature cores are ventilated horizontally by circular punchings and vertically by distance pieces between the plates. The armature coils are liberally insulated by the best India mica, enclosed in the strongest tape and fiberite board. The commutator bars are drop forged and of such surface that the carbon brushes have never to carry more than 30 amperes per square inch. The bearings are of the best gun-metal and of the ring-oiling and self-aligning type.

Particular attention has been given to the cool running of the machine, even on 50 per cent overloads. The Triumph Co. has



"TRIUMPH" BAR WOUND ARMATURE.

1,600 machines of from 1 kw. to 400 kw. placed in the West. The belted machines for railway work are made extra heavy, both in bearings and windings, and will, it is said, take care of as much as 100 per cent temporary overload without injurious heating or sparking. In sizes above 200-kw. a third bearing is used.

The western office of the company is under the management of Gates & Randolph, at No. 13 Monadnock Block, Chicago.

The new interurban electric railway between Oskosh and Neenah, Wis., is completed and in operation.

FARES REDUCED AT HARTFORD.

The Hartford (Conn.) Street Ry., which operates 70 miles of track, a large portion being suburban or interurban, and charged from 5 to 20 cents fare, according to the distance run, on August 1st made a number of changes in the sections and rates. The sections were rearranged so as to equalize the fares of out-of-town points, on the basis of four miles for five cents, as far as it is practicable, having in view the distance, the density of population and the amount of travel.

The rate from Hartford City to the East Windsor Hill terminus, formerly 20 cents, has been reduced to 15 cents, and the other changes result in large numbers paying one 5-cent fare less than was formerly necessary. Most of the changes made were not requested by the patrons of the line.

LINE TO GENEVA LAKE OPENED.

Geneva Lake, near Chicago, one of the most popular and beautiful bodies of water in the country, is now accessible to thousands who could not conveniently reach it heretofore. The electric interurban from Harvard to the lake, the Chicago, Harvard & Geneva Lake Ry., is now operating and carrying a large number of passengers. The road has a franchise for 50 years, and the right to carry express and all kinds of freight. It penetrates an exceedingly rich territory, which has been trying for 40 years to secure railroad facilities, and aside from the great volume of summer traffic offered, has a fine all the year business. The line is laid with heavy 60-ft. rails, the car equipment includes air brakes, and the road is operated on a dispatching system, with all the modern improvements.

EARNINGS OF CINCINNATI, NEWPORT & COVINGTON.

By courtesy of Mr. James C. Ernst, president of the Cincinnati, Newport & Covington Railway Co., we have received the following statement showing the receipts and operating expenses of that company for the month of June, 1899, and also for the six months ending June 30th, as compared with the corresponding periods in 1898.

The company has just declared a dividend of ½ of 1 per cent, making a total dividend of 1 per cent for the year.

	June.		January—June.	
	1899.	1898.	1899.	1898.
Gross receipts	$63,141.05	$56,955.24	$325,591.95	$303,507.35
Operating expenses	23,064.15	26,435.02	141,603.01	147,571.61
Gross earnings	40,076.90	30,420.22	183,888.94	155,935.74
Tolls, damages, taxes, etc.	11,717.90	9,766.14	75,115.07	60,386.84
Net earnings	28,359.00	20,654.08	108,873.87	95,548.90
Ratio of expenses to earnings:				
With tolls	47.61	56.25	56.72	60.18
Without tolls	36.52	46.49	43.49	48.62

CLAMBAKE OF THE AMERICAN ELECTRICAL WORKS.

In the early part of September the 21st annual clam bake of the American Electrical Works, of Providence, R. I., will mark yet another anniversary of this enterprising concern. The occasion of these outings is one always to be remembered and appreciated by those of the electrical fraternity whose good fortune it is to attend them, and the annual meetings at the Pomham Club have increased in popularity with each succeeding year. Mr. Eugene F. Phillips, president of the company, has become well known as the prince of entertainers, and the occasion of this year's outing is looked forward to with the keenest anticipation.

F. S. KENFIELD. Business Manager.

EASTERN OFFICE, 100 WILLIAM STREET, NEW YORK.

CORRESPONDENCE.

We cordially invite correspondence on all subjects of interest to those engaged in any branch of street railway work, and will gratefully appreciate any marked copies of papers or news items our street railway friends may send us, pertaining either to companies or officers.

DOES THE MANAGER WANT ANYTHING?

If you contemplate the purchase of any supplies or material, we can save you much time and trouble. Drop a line to THE REVIEW, stating what you are in the market for, and you will promptly receive bids and estimates from all the best dealers in that line. We make no charge for publishing such notices in our Bulletin of Advance News, which is sent to all manufacturers.

This paper is a member of the Chicago Trade Press Association.

Entered at the Post Office at Chicago as Second Class Matter.

VOL. IX. SEPTEMBER 15, 1899. NO. 9.

The publishers of the "Street Railway Review" take great pleasure in announcing that Mr. C. B. Fairchild, for many years so well and favorably known in the field of technical journalism, especially in that relating to the street railway industry, has made a business engagement with this publication. He will represent this paper in both its editorial and business departments in the territory east of Buffalo and Pittsburg, and conduct our eastern office at 100 William St., New York City.

We cordially bespeak for Mr. Fairchild in his new relation a continuance of the same favorable response and commendation that have met his former efforts in this field.

We are happy to note that the committees having charge of the arrangements appertaining to the convention have all their plans for the accommodation and entertainment of our visitors well under way. The details will be given in our next issue.

Exhibitors at the convention of the American Street Railway Association, to be held in Chicago, October 17th to 20th, should note with care the recommendations of the general committee concerning the marking of goods shipped to Chicago, and also the arrangements made for preventing overcharges for lumber, labor, etc.

The preparations so far made by the committee are given on another page, and in the same connection will be found a plan of the convention hall and a list of the exhibitors with the amount of space assigned to each.

The papers to be read before the American Street Railway Association are fewer in number than has been usual, there being but five of them. This is not at all a disadvantage, as there will be more time available for a full discussion. The subjects cover five of the principal divisions into which the work of street railway men naturally divides itself—tracks, car equipment, shops, train service, and investments. Each of these reports will be presented by a man of extensive experience and wide acquaintance with the subject of which it treats, and we look forward to a particularly interesting and instructive convention.

The Street Railway Accountants' Association will have but two papers presented in addition to the reports of the committee on "Standard Accounts" and the secretary's report on "Blanks and Forms." There has been so much discussion of the reports on the standard system of accounts at the previous meetings of the association that the executive committee wisely decided to limit the papers on other subjects to two.

It certainly would seem that members of the so-called learned professions would not find it necessary to resort to the weapons of trade unions—strikes and boycotts—to "protect" themselves against competition. Yet in certain Lancashire (England) colliery districts the Colliery Surgeon's Association considered it necessary to issue a notice that on and after a certain date its members would not under any circumstances attend any miners who were members of the Wigan and District Miners' Permanent Relief Society, unless the cases were covered by existing contracts. The cause of this action on the part of the surgeons was the employment by miners of "non-union surgeons" (!) and the threat to "import" still other surgeons.

Our readers will not fail to be interested in the statement, appearing on another page, made by President Everett, of the Cleveland Electric Railway Co., concerning the strike in Cleveland. The whole unfortunate affair has resulted from a determination on the part of the men that their union shall be recognized by the company, and none but union men employed. The company had not taken the advanced ground that the Amalgamated Association of Street Railway Employes has for its objects the fomentation of discord and strikes, and, therefore, the company could not retain as employes members of that association. On the contrary, no objection was offered to the union as such; all that was claimed was the right of the company to employ competent men, regardless of their membership in unions. But now, after the second strike, the company cannot with justice to itself, do otherwise than make non-unionism the test for men seeking employment.

The boycott which at first met with some success is, we believe, gradually falling to pieces of its own weight and it is confidently expected that the citizens of Cleveland will not longer continue to submit to that tyranny which says a doctor shall not attend a man who rode on a Big Consolidated car under penalty of having the boycott extended to him.

Detroit is to have some more street railway litigation. The city council passed an ordinance requiring the Citizens Street Railway Co. to sell eight tickets for 25 cents and give universal transfers, which was approved on August 16th. As announced on another page of this issue the company petitioned the United States District Court and was granted a temporary injunction restraining the city from enforcing the ordinance. This action has caused a number of Mr. Maybury's friends to feel aggrieved; they say that if the company had only waited some one representing the city would have tried to ride for 3 cents under the ordinance and on refusal have gone into the state courts for a writ of mandamus, whereupon a friendly suit would have followed.

This plea for friendliness is highly ludicrous in view of the language that has been used in discussing the Detroit street railway situation for the past six months. As the suit involves the question of the obligation of a contract it would eventually have reached the federal courts, and it is much preferable to save the time that would be necessary to carry the case up to the state Supreme Court.

As to what the result of the pending suit will be there is little doubt. The company feels that it can show 5 cents to be a reasonable rate, even if its ordinance is not held to be a contract.

The testimonial published in another column, which was tendered Mr. Charles T. Yerkes by a committee representing nearly 8,000 of his employes on the occasion of his retirement from the North and West side roads in this city, was a graceful acknowledgment of harmonious relations which had existed between president and men for more than 10 years. On a previous occasion, several years ago, the men desired to tender some tangible expression of their regard, but as soon as it was known a positive request came down from the president's office that the matter be dropped. The boys, however, thought they saw their opportunity upon the occasion of the sale of the roads and the change of management. Mr. Yerkes, however, again sent a special request that no present be sent him, although it was planned to give him a princely gift of remembrance. But the men were bound to show their friendship in some way, and a beautiful testimonial couched in words which are well worth reading more than once was presented, and there is no doubt that the recipient felt even more than he expressed when he told the committee how highly he appreciated the simple token of regard.

The question of presents from employes to officials in charge of operating departments is one on which there is a great difference of opinion, and it is fair to admit that frequently such expressions, made in sincerity and in a spirit of genuine regard, tend to strengthen a feeling of amity between the recipient and the donors. On the other hand, the individual amounts, while small, often come from men with large families to support, and with whom every dollar counts. The one to whom the gift is sent is much better financially able to buy for himself than the men are to give, and it is impossible for some to give, who have the inclination, but who know that in doing so they are taking money which should be used at home. The street railway employes of the country, as a body, are steady, industrious men, with families, men who do not squander their earnings, but put them to the noble purpose of clothing and educating their children. We believe that the wise and generous position is that taken by Mr. Yerkes in a gentle but firm refusal to accept an offering of money value. There are other ways in which the men can show each day their regard for those who direct and govern, and bonds of strong and enduring friendship and esteem can be welded without resorting to an expression in which a money value is involved. That manager who has the welfare of his men at heart in the largest degree, is the one who least of all requires a present to be assured of their feeling for him.

Until quite recently continuous currents have held practically exclusive sway in street railway work, and as far as can be clearly seen at present they will contrive to hold their advantage over the alternating and polyphase distribution in the tramway service of cities and thickly populated sections where short hauls and heavy travel are the rule. Polyphase current distribution, however, is a comparatively new factor in certain classes of railway work, which has undoubtedly come to stay, and it possesses some notable advantages in the case of suburban and interurban railways, and where cheap water powers are available at some distance from the line of the road. A few cases are to be found abroad where polyphase currents are used direct by means of induction motors on the cars, but this method cannot yet be said to have assumed much prominence, although it is one which gives promise of important developments in the future. The general practice at present where polyphase currents are used is to generate them at one central station, the location of which is not important, as far as the cost of conductors is concerned, and at this station if distant from the line, the current is raised to 5,000 or 6,000 volts by means of stationary step-up transformers. From the central station these high potential currents are led to transformer stations located at convenient distributing points along the railway where the current is first reduced in voltage by means of step-down transformers and then changed from alternating to direct in character by means of rotary transformers, giving a continuous current of 550 volts, which feeds into the trolley line.

At first sight the losses incident to the three transformations of the current lead to the impression that such a system cannot be economical, and such would have been the case of a few years ago. In the modern types of stationary transformers, however, and especially in those of considerable size the loss of energy is very slight, amounting to less than 2 per cent at full load, and perhaps 4 per cent under average conditions. The loss in the rotary converter is somewhat greater, amounting to say 6 or 8 per cent, which is required to overcome friction and core losses. The total efficiency of the transformations, therefore, need not fall below 80 per cent in a properly designed plant, but even if a considerably lower efficiency is realized the loss will be less than the drop usually allowed on long direct current lines, while the whole saving in copper due to the use of the high potential circuit remains to be credited to the polyphase system.

Some examples of this method of distribution are now in evidence upon a number of roads in this country, with results which have proved highly satisfactory for the time this system has been under observation. One of the earliest examples of this system was in Lowell, Mass., where the cost of polyphase transmission was shown to be 70 per cent of the cost of a separate direct current power station. An eighteen day test of this system showed an average efficiency of 70 per cent measured from the alternators to

the direct current output of the rotary transformers, the losses including those of two sets of static transformers, the line and the rotaries. The best day's efficiency during this test was 73 per cent. The Chicago & Milwaukee Electric Railway's equipment is on this same general plan of distribution, and although only opened for traffic over its full length for a comparatively short time, is pronounced by its engineer to have shown remarkably good results. This plant will undoubtedly show a higher efficiency than the preceding one, as the generators deliver three phase currents directly to the converter station without the intervention of step-up transformers. The frequency of these generators is considerably lower than the general practice for combined lighting and power plants, being 25 cycles per second, while from 40 to 60 is more common, the higher number being essential where lighting is involved.

A similar system has been introduced in Washington, D. C., where all the city and suburban lines have been consolidated under one operating company. All the lines extending beyond a certain distance from the power house are supplied with three-phase currents and considerable economy over the former separate stations has been realized even with the temporary plant now in use. The Citizens' Traction Co., of Oshkosh, has just completed a plant of this description and two others in course of construction for the Toledo, Fremont & Norwalk and the Dayton & Northern roads in Ohio. Other examples of this distribution could also be mentioned, showing the growing use of this system in railway work, and it may be said that when we come to distances beyond possibly 15 miles the polyphase system must be used for economical transmission.

A farther development of this system promises to be introduced at no distant date which will add still more to the efficiency of such transmissions. This lies in the use of induction motors on the cars, which, as suggested above, has already met with some success in Europe. In this case rotary transformers are entirely dispensed with, and only static transformers are used, which not only increases the efficiency of the transformation but dispenses with the labor of personal attendance at the converting stations. The troubles incident to commutators are also avoided, although the necessity of a double trolley system is introduced. This system was installed in Lugano, Switzerland, in 1896, at Evian-les-Bain, France, and at other places, where it is working successfully.

There are some advantages in the induction type of car motor over direct current types, one of which is the retarding action of the motors when driven beyond a certain speed by the car on down grades. They may be designed to develop a retarding force much greater than their working torque when their speed increases above the normal, and this effect takes place automatically, being inherent in the machine. The working torque may also be increased by connecting the motors in series, the torque being proportional to the number of motors so connected.

No better example of what can be accomplished by everybody pulling the same way, under competent leadership, could be desired than that furnished in the history of the new York State Street Railway Association, particularly in that history, since 1895. At that time—when Mr. G. Tracy Rogers was elected president—the affairs of the association were in a somewhat undeveloped condition: in fact it was little more than a social club. But Mr. Rogers thought he saw in this small collection of street railway men the possibilities of an organization, whose influence would be far reaching and whose power for good to its members, would be practically unlimited. He now has the satisfaction of seeing his hopes fully justified. Under his energetic guidance the membership roll has increased until it includes every prominent system in the state, and its meetings have grown so enormously in value that its influences is felt way beyond the boundaries of its own state. Its methods are carefully watched by officials of similar organizations, and the papers and discussions presented at its conventions are largely read and studied by managers all over the United States.

CONVENTION PROGRAMS.

The papers to be read before the convention of the American Street Railway Association next month are as follows:

"Maintenance of Car Equipment." J. H. Van Derveer, Brooklyn Heights Railroad Co.

"The Modern Street Railway Shop: Its Design, Machinery and Shop Practice." B. L. Kilgour, electrical engineer, Cincinnati Street Railway Co.

"Train Service and Its Practical Application." Ira A. McCormack, general superintendent, Brooklyn Heights Railroad Co.

"Construction and Maintenance of Railway Track." Edward Butts, Metropolitan Street Railway Co., Kansas City.

"Investments in Street Railways: How Can They Be Made Secure and Remunerative." Charles T. Yerkes, president, Chicago Traction Co. and Union Elevated Railroad Co., Chicago.

The papers and reports before the convention of the Street Railway Accountants' Association of America in October are to be as follows:

"Materials and Supplies Accounts." W. M. Barnaby, chief accountant, Brooklyn Heights Railroad Co.

"Car Mileage." H. C. Mackay, comptroller and auditor, Milwaukee Electric Railway & Lighting Co.

"Report of Committee on Standard System of Accounts." C. N. Duffy, chairman.

"Report on Department of Blanks and Forms." W. B. Brockway, secretary of the association.

DETROIT SITUATION.

The ordinance passed by the city council of Detroit, as published in the "Review" for August, page 509, was approved by the mayor on August 16th. On the same day Judge Swan, of the United States District Court, issued an interlocutory order restraining the city, the mayor, council, corporation counsel or any city officials, from attempting to enforce the provisions of this ordinance on the grounds that it was a direct violation of existing contracts (ordinances) entered into between the city and the company. This stops the proposed mandamus for which the mayor had intended to ask the lower courts, to enforce the ordinance and also places the entire matter in the United States courts, where it will probably reach the highest judicial tribunal in the land and settle once and for all the question of whether or not an ordinance is a contract regarding fares, or whether a city can reduce fares below that provided in the ordinance.

The New York Convention.

Seventeenth Annual Meeting of the Street Railway Association of the State of New York at Ithaca, September 12th and 13th A Most Enthusiastic and Well Attended Convention—Papers and Discussions.

The 17th annual convention of the New York State Street Railway Association convened at the New Ithaca Hotel, Ithaca, N. Y., September 12th, at 11:15 a. m., with Persident Rogers in the chair. The meeting was scheduled to open at 10 a. m., but owing to a delay in the arrival of all the morning trains the time was postponed to the later hour. About fifty gentlemen were present when the meeting was called to order, and the roll call showed delegates representing 28 roads in attendance. On motion by Mr. Vreeland, the reading of minutes of previous meeting was dispensed with, and they were approved as printed.

President Rogers then read the following address:

PRESIDENT'S ADDRESS.

Gentlemen of the Association:

It is again my pleasure to extend to you all a most cordial greeting, to this our Seventeenth Annual Meeting. Each succeeding convention has proven more largely attended and interesting than the former, and judging from the papers and topics we have before us for discussion and the environments with which we are surrounded in this beautiful university city, this meeting promises to be no exception. I have often called your attention to the benefits to be derived from a free discussion and interchanging of ideas and experiences at these conventions, and I trust you will not wait to be

G. T. ROGERS.

called upon, but that each one in attendance will appreciate the duty and privilege both by interrogatives and explaining his views on each subject as presented.

In former years it was very difficult to induce members to prepare and present papers, and still more difficult to provoke or obtain a free discussion of the papers and topics presented. One day was sufficient to transact the business of the annual convention, leaving ample time for the pleasure, which our host had in preparation, but the two days we now devote to our meeting are fully occupied. Notwithstanding the general invitation extended, we have often been obliged to depend upon the larger roads for papers and discussion. This should not be. The men connected with the smaller roads, also those in subordinate positions on the larger ones, ought to appreciate the great benefits and opportunities extended to them at these conventions, to present their ideas, and bring themselves more clearly before the street railway world.

It has been my privilege each year to congratulate you on the condition of our association. I attribute our substantial growth and development to the interest that each individual has taken in its affairs. This not only applies to the presidents, but to the various officers and heads of the different departments of the roads, constituting this association. It is the result of united effort on the part of the progressive street railroad men of the Empire State. Our reports of annual meetings are not only sought for by various libraries in this country, but we have many inquiries for them from abroad.

The past year has been one of more than usual advancement in every department of street railway development. Compressed air, as a motive power, is now a practical success, not a theory, and in actual use on the Metropolitan, of New York City. The underground trolley, as used in New York City, has successfully wintered through, and today, I believe, is the acme of street railroad operation in large cities where the traffic will warrant the tremendous outlay. Increase in cost of material continues. Iron and all its manufactured products are in strong demand, and important street railroad and municipal work is delayed on account of the inability to fill orders for material, particularly special work. The use of aluminum in place of copper as an electrical conductor furnishes a possible relief for the embarrassment occasioned by the rapid increase in the cost of copper. Aluminum has already been successfully used to some extent on long distance lines.

Expansion seems to be the order of the day and is not confined to the Government. The street railways of this country have been the means of expanding our cities and reaching out into the adjacent villages and hamlets, and the building of interurban roads has been more marked than ever, and I believe the work will be of untold benefit.

The development of interurban roads is one of the most interesting and promising studies of the day, both sociologically and physically; by it the farm life is relieved of many of the disadvantages which belong to isolation. The new electric railway construction is on a healthy basis. Practical street railway men who are now interested in street railway properties are quietly looking about and planning interurban lines, which, if they build—judging from past experiences, will soon become paying properties.

The interurban railroad proposition is an attractive one, especially to street railway owners and managers who have had experience with city property. The question of franchise is much simpler than in the cities, in spite of the fact that concessions usually have to be secured from a greater number of municipalities. The abutting owner is benefited to a greater extent by having the railway in front of his property than is the case in cities. It gives him direct transportation at his door, and, in fact, the community as a whole is ready to welcome a transportation agency, which is more convenient and cheaper than heretofore existed. In the next place franchises are usually perpetual and the conditions are less apt to be reviewed by a common council with each change of administration. In many cases, mechanical problems, which render the life of the city manager a burden, disappear in the interurban railroads. The track can be built and rails or ties replaced without permanent excavation. There seems to be less chance for radical changes in the development of the interurban roads than in the present city service.

The success which has attended the alternating current has largely contributed to the rapid development of the interurban service, and the cheap accommodation as compared to steam railroads has very materially stimulated the building of these roads. In many instances steam railroads which were losing ventures have been electrified and made to pay handsome returns upon the investment. By experience it has been shown that a trolley line can be constructed, maintained and operated at a less cost than a steam line. The steam railroads recognize this dangerous competitor for short distance travel, and in some instances are doing their utmost to suppress it, but "it is a condition and not a theory that confronts them."

The carrying of freight by electric railroads is one of the most important matters which affect interurban roads, and some of them to a serious extent. In some instances the steam railroads have

questioned the right of the trolley roads to carry freight, but in a recent decision in the Supreme Court of New York, rendered by Judge Merean, it was clearly decided that the trolley roads of this state had a right to transport freight and express matter. I think that the steam railroads stand in their own light in attempting to fight this proposition, as transportation begets freight and creates business, while in a few cases the interurban roads will interfere to a small extent with existing business between two points, at other places it would give more than it takes. There is no good reason why the trolley roads, occupying streets and highways, should not haul freight and express over its tracks as well as any company organized to do a general teaming business, which hauls the same identical merchandise over the same roads in wagons, and which use the streets and pavements of our cities or country roads. The movement of cars drawn by steam locomotives over streets is an entirely different proposition.

The question of carrying the United States mail on electric cars has been discussed both pro and con. I am satisfied that the carrying of the United States mail at the present rate is not a profitable department of the trolley road, but there is no question but that it is a great accommodation to our patrons and a convenience to the public. This compensates, in a large measure, for the meager payment we receive for this service, however, I believe "The laborer is worthy of his hire," and a united effort on our part to secure adequate compensation for the carrying of the United States mail should be made.

The employers and employes of the street railroads of the state of New York are to be congratulated upon the pleasant relations existing between them. This is largely due to the intelligence, ambition and appreciation of the men connected with our roads and the sincere efforts on the part of the employers, to better the condition of employes. As a rule, great care has been taken by the management of our street railroads in the selection of help, and they have been regarded as reasonable, intelligent men, and recognized that each is doing a work as dignified in its way as that of the head of any of the departments, or the president of the company. Merit and ambition have been recognized and promotion has been made from the ranks. An interest and friendship has been taken in the men employed, and the ambition to rise from the lowest place in the ranks has been respected and rewarded. In many instances the men have learned that the management takes more than the usual interest of the employer, not only with the duties connected with the road, but practical sympathies have been shown them in their personal troubles, and no effort has been spared on the part of the management to better their condition. Upon the manager's treatment of employes depends the success of his administration more than upon any other feature.

Too much interest cannot be taken in the mutual benefit aid societies connected with our roads. They are doing a wonderful work in developing a cordial fraternal feeling as well as stimulating an interest in their work. It also gives the management an opportunity to show its genuine friendship and interest for the men as a body, and to assist them in many directions, such as furnishing literature, libraries, club rooms and entertainments; in short, being one of their number. The successful managers of today are men who do not hold themselves aloof from their employes. They are honest in their friendship for the workers in every branch of the service, showing practical interest in their welfare and advancement, listening patiently to all the grievances and discussing them frankly and freely, promptly investigating and correcting any abuses or unfairness which may creep into the service. The manager who conducts his road on these lines teaches his men to be loyal and enthusiastic in the service of the company, creates in them a self respect and manliness, and he need have no fear of strikes. Should one be brought about, the proof of justification would rest with the employes, and the verdict of the public would be in favor of the road.

The operating expenses of the average street railway is 60 per cent of the gross receipts. Labor constitutes from 40 to 60 per cent of the total operating expenses, i. e., from 25 per cent to 35 per cent of the gross earnings goes to pay labor; therefore, when earnings are reduced 5 per cent through hostilities, legislation, or otherwise, the natural result is that the employes will suffer a reduction in wages from 15 to 20 per cent.

The street railroads have pursued a liberal and progressive policy; they not only keep abreast of the times, but have, of their own accord, made good and valuable concessions, and this without moral or legal obligations. The public, as a rule, seem to accept these concessions with a "thank you" at the time, but it is not long before they expect still further concessions and forget the past. Extensions are being made in every large city, gradually increasing the haul but without increasing the fare, and now in large cities 5 cents carries the rider to almost any part of the city, and four or five times as far as it did 10 years ago. Without question, a liberal policy pays everywhere, and the broad gaged, progressive ideas adopted by the street railroads cannot fail to be appreciated by a fair-minded public.

Progressive citizens make successful cities. Villages grow into cities by the efforts of men more than by the force of circumstances. The progressive street railway man of this country has, in many instances, been obliged to fight bitterly in order to carry out the advanced ideas or plans which he may have conceived for rapid transit. Often these plans were far in advance of the times and the public failed to grasp the benefits to be derived from them and has not only made it difficult to carry them into execution, but, in many instances, defeated enterprises which would have added very largely to the public comfort and the advancement of taxable property. The public should take into consideration the fact that a street railroad (differing from almost every other business) must be operated 365 days in the year, and from 18 to 24 hours a day, and the manager must meet the complaints, desires and whims of the public with a pleasant smile and must be like the compass with the four cardinal points. He must understand the people's wants, the employes' wants, the cities' wants and the stockholders' wants, all four having claims which must and should be satisfied. In many cases these interests are conflicting. The people seem to regard the operation of a street railway as a decidedly easy matter. While it may appear so to them—and they, no doubt, intend to be fair—there are difficulties which have been worked out by systematic methods which mislead them in their judgment. No line of business tends more rapidly to build up suburban territory, furnishes cheap, comfortable and healthful homes to people within reach of their business, develops the growth of the city, brings unimproved and dormant real estate into the market and increases the assessed value of city property. The street railroads have done much toward the social and moral advancement of the communities in which they are located.

Much has been said against trusts and consolidation of business interests. We are one of the exceptions. I can state without fear of contradiction, that in every instance of consolidation of street railroads the public has been benefited, and the conveniences of civilized life have been enhanced.

We have been accustomed to hear the familiar expression, "Everything has been cheapened in price, but street car fare remains the same." It is now an undisputed fact that nearly everything has advanced in price, especially material used by street railways, but "street car fare remains the same," and in this connection I will state that twice the accommodation and benefit is being given for a 5-cent fare than at the beginning of the present decade, and hence street car fares have actually been cheapened by more than 50 per cent. What constitutes a ride in a street car today is certainly double the ride of 10 years ago, and the cost of operating is twice as much as under the old method and system. The more than generous distribution of transfers has, I believe, had the effect to quiet the 3 or 4-cent advocate. The average total cost of carrying a passenger is 3.8 for each person, and if one will carefully study the street railway system of New York City he can live aboard the cars for an indefinite period, for a nickel.

The successful managers are those who watch carefully the traffic and regulate their car service by the daily receipts. In many cases it is necessary to withdraw cars from service on the lines where the returns are less than satisfactory, and in others the car speed has been gradually increased to a degree where one or more cars could be withdrawn, and by enlarging the cars, give the same service. Wages by this means have been reduced, reserve equipment obtained, and the maintenance charges also reduced proportionately. The people are being educated to rapid transit, and so far as is consistent with safety, the public demands it. They cannot do otherwise. By the adoption of the highest practical rate of speed the value of property will be approximately increased in proportion thereto, as the outlying land will comparatively be brought just so much nearer the business center. Rapid transit is the most important factor in the building up of residence territory compara-

tively remote from the business center. The general belief that the trolley is "The Juggernaut" of the city, is fast disappearing.

The action of the Supreme Court of our state in granting the Brooklyn Heights R. R. an allowance of $500 against the plaintiff in an unsuccessful damage suit, is greatly to be commended. If this precedent is followed in similar cases it cannot fail to greatly decrease this class of litigation. The greater number of persons injured who commence suit against the street railway, are incited by the unscrupulous and avaricious ambulance lawyers, who know that they have no case, but rely on the sympathy of jurors, or the forcing of the company into a settlement.

The handling of damage cases should be conducted by men naturally qualified for this class of work. They should have the best interests of their road at heart, and yet not be too greatly prejudiced in its favor. They should have good, sound judgment, and be careful of the details to the highest degree and have an even, calm temperament, ever ready for a call, polite and sympathetic. They should be men accustomed to handling all clases of people without combating or irritating, and must never appear over anxious for a settlement.

It has been stated on good authority that the high water mark of bicycles was reached in 1897. In my opinion, the bicycle will be continued as a convenience, but its use as a pastime is on the wane.

The automobile has taken a position of the utmost importance in the transportation of the world. What effect it will have upon street railway travel we are unable to state. It will, no doubt, in a large degree, take the place of the horse, but I question it ever supplementing the street car. As yet it is largely experimental, however, the possibilities of the automobile's practicability in the line of cabs, omnibuses, etc., must be regarded by street railway men with close attention, if not concern.

Much has been said and written regarding the maintenance of parks by street railways; also the question of furnishing free entertainments for the public at these pleasure resorts. There is no question but that this department of our business can be overdone and made unprofitable, and each road should be governed by circumstances and surroundings. For instance, in New York City, the question is, "How can we carry people who desire to ride?" and in smaller cities, "How can we induce the people to ride?" Again, great judgment should be displayed in the location of the park or pleasure ground, as relative to the city and the ability to transport the crowd rapidly. The amount expended in this direction should at least show an equal amount in the returns. There are also other advantages which are evidently overlooked; in the first place, it is a natural tendency for the number of pleasure seekers to increase, and the advantages of a park in the neighborhood of a city are considerable and will appeal to the continually changing number of people. The real value of property of this kind is increased somewhat by its accessibility, but depends largely upon the manner in which the park is conducted. The success or failure, in some instances, is almost entirely dependent upon the proper selection of attractions. The park is looked to for amusement, and unless amusement of some kind is furnished the public, the road depending upon it for increased travel, will, in my opinion, be very much disappointed. The question of charging admission to parks has been thoroughly discussed heretofore at various conventions. In most instances where the sale of liquor has been conducted, I am informed, the parks were failures.

The question of the paving of street as required, under the present railroad law, and the Court of Appeals decision in the Conway case, makes the building of roads or the maintenance of the present ones, especially in villages and small cities, a very serious problem. It is an impossibility for these roads to live and comply with the present state law and do the paving required, and before roads can be successfully financiered or maintained, in these municipalities, they must have some relief from the Legislature. There are many obvious reasons why this legislative relief should be furnished. There is no one element that tends more to build up small cities than rapid transit, and the increase of value of taxable property thereby, alone more than offsets the unfair burden placed upon the railroads to help pay for pavements which they, under mechanical power, do not use.

Municipal ownership has received some very severe blows of late. In nearly every instance where fair propositions have been discussed as to the method or means by which municipalities could become the owners of street railroads, we have seen the municipalities dodge the issue; but if municipal ownership could be obtained by confiscation, no doubt that theory would have plenty of adherents. I believe it has been very thoroughly demonstrated that it would be utterly unwise to place the control of a city's transportation agency in any other than private hands. The interest of a growing city and its street railroads should be mutual, and no pains should be spared on the part of the street railway to meet every fair, legitimate demand made by the city's officials, the public and the press, and all should work together to build up and develop on broad lines, the municipality.

There are two sides to the question of short time franchises. In one instance, the obtaining of capital to finance the property on a short term franchise is not only difficult and dangerous to the investor, but large rates are demanded, and the same degree of permanency cannot be used in construction and equipment, as illustrated by the New York City railway companies, which have expended millions of dollars in the adoption of cable and electricity, and are giving New York the universal transfer system and improved cars and car service, which they could not have done under short term franchises.

The Metropolitan, of New York City, has given the people many evidences of conception and generosity of action and breadth of view, which, when dealing with questions of public interest, always bring about the greatest possible benefit to the community. The proposition made by this company to the city of New York this last year, to furnish them with rapid transit, could not be duplicated by any other transportation agency or individual capital, owing to their inability to provide the transfers that the Metropolitan alone can furnish, a condition due largely to their existing lines. In my opinon, the proposition was a broad and generous one, and upon the refusal of the concessions which they asked for, I am not at all surprised at the prompt withdrawal of the proposition, as it would demand an enormous outlay of capital, upon which the remote future would be called upon for dividends. The result is that the city of New York is still dawdling with the question of rapid transit, and is no nearer the much sought for relief than it was some years ago. It is difficult to predict any relief in relation to the question of rapid transit in Greater New York, except through the efforts of the present companies.

During the past year many miles of road in New York have been changed to the underground trolley, and much new equipment added. Still further important changes are in progress and will be completed as soon as possible. The contemplated tunnel under the East River, when completed, will furnish great relief to the traveling public between these two cities. The purchasing and consolidation of the various roads—including the elevated—in Brooklyn, by the Brooklyn Rapid Transit System, illustrates again the benefits to the public of consolidation. They have already placed the Fifth Avenue, Coney Island branch of the Brooklyn Elevated road under electric operation, and very satisfactory train service is now being obtained.

The purchasing and remodeling of the Brighton Beach Hotel by the Brooklyn Rapid Transit Co. is a new departure, and, I am informed, has been a marked success.

I would call your attention to the purchase and consolidation of the 18 roads in the western part of the state, including Buffalo. I am informed that this consolidation has already proven to be a great benefit to the public at large in that territory.

The history of recent legislation is too fresh in the minds of all of you for me to dwell upon at any length. The general expression on the part of street railway officials in relation to the taxation of franchises is, that a street railway or any other corporation using the streets of a municipality, should pay a tax, based upon its earning power.

The Ford franchise bill, as you are aware, was hastily passed the day the Legislature adjourned. A hearing was granted by Governor Roosevelt, and the corporations of the state presented the reasons why this unjust and illy constructed bill should not become a law. We were treated by him at this hearing with his usual fairness, and our arguments were patiently listened to. We asked, first, that the governor adhere to his message of March 27th, in which he suggested that a committee from both houses be selected to deal with this question and prepare a bill and report to the next Legislature. In case he did not see his way clear to do this, that he reconvene the Legislature and a graduated bill based upon gross earnings be passed. The Legislature was reconvened

and the present bill was enacted, which, in my opinion, is an improvement over the Ford franchise bill for numerous and obvious reasons, among which is the fact that under the Ford franchise bill the franchises were to be assessed as real estate by the local assesors. I am satisfied that the State Tax Commissioners are men of good, sound judgment, and will treat this matter fairly. It is the general opinion, I find, that the street railways are not now paying a franchise tax, and the public as a rule have the idea that we have been exempt from taxation; such is not the case, as we are all well aware. The last published report of the State Board of Railroad Commissioners shows that the combined street surface railroads of this state paid 28 per cent of their net income in taxation and a dividend of but 2.3 per cent on their capital stock.

The following are a few of the arguments which I presented before the governor, and the same will, I think, bear repeating at this time.

One hundred and three street surface railroads submitted annual reports to the state, 49 of which show a surplus amounting to $1,102,855, and 54 show a deficit amounting to $471,848.

Of the $1,102,855 surplus, $805,288 is shown by 12 companies in Greater New York, leaving but $297,567 to be divided among the 37 companies outside of that city.

Of the 103 companies reporting, but 18 declared dividends (5 of these being in Greater New York) the total dividends amounting to $3,069,465, of which the five Greater New York roads paid $2,512,374, leaving a balance of only $557,091 to be divided among the remaining 13 dividend paying roads. Six of the dividend paying roads showed a deficit after so doing. Eight of the 103 street surface railroads mentioned have gone into the hands of receivers during the past four years.

In addition to the above mentioned 8 companies, at least 12 or 15 have gone out of business entirely or saved themselves from going into receivers' hands by making some arrangements with the bondholders.

Briefly, the above report shows that the small and medium sized street surface railroads in New York State, and in fact all the roads with the exception of those in the very largest cities, are struggling along under the most discouraging conditions.

There is $1,683,195,740 invested by the combined transportation companies of this state in roadbed and equipment. A large portion of this enormous amount invested—representing the capital stock and bonded indebtedness of the several companies—has been sunk in a depreciation of the value of both construction and equipment and in expenditure for replacement made necessary thereby, particularly by street surface railroads for the development of mechanical traction, especially electrical, the operation of which for the past decade has been largely experimental, necessitating frequent expensive changes of station and car equipment, and the consignment to the scrap pile of costly machinery, which necessarily had to give way to more improved and modern equipment.

In many instances where horse street railroads were purchased for the purpose of equipping with electricity, the entire equipment, for which high prices were paid, proved absolutely valueless to the purchasers.

In the early days of electrical traction enormous prices were charged for equipments of all kinds; for instance, 10 years ago $3,000 and upwards was the price charged for a car equipment, which today, owing to its crude and undeveloped condition, is worthless, and which can be replaced by a modern, up-to-date outfit for $720.

Without going into details, I would state in a general way, that the same rule applies to track and overhead construction, to car bodies and appurtenances, all of which have to be kept up to date and carefully maintained to meet the requirements of an exacting public.

The interest paid upon that portion of the bonded indebtedness, sunk by depreciation of values, and expended for replacement by the several street surface railroad companies of the state, in order that the city or village wherein their respective roads are located, might be properly subserved, is a material and permanent burden imposed upon each individual road, which should be taken into careful consideration in the adjustment of the important question of taxation.

There was $164,161,692 paid out in operating expenses in 1898, the greater portion of the amount being for labor, proving the benefit of these institutions, and demonstrating the fact, when taking into consideration the immense amount of money invested and the cost of operation, that the net income as shown by the above statement, is small, and proves conclusively that the proposed tax imposed upon the railroad companies of this state would be unjust, unfair and undeserved.

Two years ago the Legislature of this state passed a gross earning tax bill, imposing upon street surface railroads a tax of 1 per cent upon gross earnings (while the tax law affecting steam railroads remained unchanged). This measure imposed a serious additional burden upon provincial street surface roads, particularly the non dividend paying companies.

The street railroad companies of the smaller cities of this state are entitled to consideration and relief, rather than additional burdens. In fact they must receive such consideration and relief, otherwise the number of street railroad companies in receivers' hands will be materially increased.

The State Railroad Commissioner last year made a number of recommendations to the Legislature and had bills introduced in compliance with same, and no fair-minded man can fail to concede that these recommendations and bills were in the line of public safety and convenience, and were both fair and just to the railroads and the public.

It is a matter of congratulation that we have in the Railroad Commission of the State of New York the fair, able, and most painstaking commission, and all interests have been zealously guarded by them. In closing, I congratulate the street railroads of the state upon the degree of prosperity they have attained and upon the intelligence and energy of the management which has made their operation so progressive and successful. Let me add the hope that still greater success in all the elements of railway service, both to managers and investors as well as to employes, will be the reward during the present year.

Next came the reports of the executive committee and the treasurer, which were submitted and accepted. The treasurer's report showed $1,400 in the treasurer's hand, $5,000 having been expended during the year.

The president next announced that there was in attendance the chairman of the New York Board of Railroad Commissioners, Mr. A. W. Cole, and the commissioner's engineer, Mr. C. R. Barnes, and called on Mr. Cole to make a few remarks. Commissioner Cole expressed the regrets of the other members of the Commission at their inability to be present, through the pressure of important official business. He then reviewed briefly some of the work accomplished by the board of which he is chairman, and also by the Convention of Railroad Commissioners of 25 different states, held at Denver a few weeks ago. At this latter meeting a standard system of accounts was accepted, which is, in the main, the same form as adopted by the Street Railway Accountants' Association of America. Mr. Cole was accorded a vote of thanks for his remarks.

The secretary then read letters of regret from officers of the Ohio State Street Railway Association, the American Street Railway Association, the Connecticut Street Railway Association, the Delaware & Hudson Canal Co., the Delaware, Lackawanna & Western Railroad Co., and the New York, Ontario & Western Railroad Co., and from T. C. Platt and B. B. Odell, of New York City.

HOW CAN WE INCREASE THE EFFICIENCY OF EMPLOYES?

BY F. D. ROUNDS, GENERAL SUPERINTENDENT METROPOLITAN STREET RAILWAY CO., NEW YORK.

A few years ago any discussion as to how to increase the efficiency of employes would have been deemed a waste of time by the average street railway manger. His first thought was for his horses, the second for his cars, and very little remained for the men on the cars. The introduction of rapidly moving mechanically driven cars, with the attendant increased liability to accidents, especially when improperly handled, has forced this question more and more to the attention of managers.

There is still plenty of room for improvement, and a careful supervision of these details of hiring and handling men will result in a decrease of accidents, an increase of patronage and a lessened liability of labor troubles among the men employed.

We can increase the efficiency of employes:

1. By paying a rate of wages which will make it an object for men to engage and continue in the street railway service.

2. By making an intelligent selection from among the applicants, taking those who seem from their appearance best fitted for the work, requiring from them a full statement of their employment for some time past and looking up their record.

3. By giving the men a careful education for the duties which they are to perform.

4. By handling employes in such a way that they will feel that they are being treated as men and that they will not lose their loyalty to the company and to their immediate superiors on account of harsh and unjust treatment.

5. By making them feel that intelligent service, loyalty to the company, and a good record gives them a chance for promotion to a better position.

1. The rate of wages to be paid depends of course upon the size and business of the street railway and upon the standard wages of other classes of employment and cost of living in the locality. In some cases it is beneficial to pay a minimum rate of wages for the first year, increasing it the second year and in some cases in the third year. This plan makes the men value their positions the more, from the fact that they have something more to work for, and in consequence they are more careful to hold their places. Liberality in paying employes for extra work and for special service creates a very good feeling on the part of the men toward the company and makes them loyal. In a great many instances this can be done in such a way as to create great satisfaction among the men without imposing on the company any very heavy additional burden in pay rolls. This plan has been carried out by the company with which the writer is connected to a very large extent for the past six years. While of course smaller companies with less earnings could not be expected to do as much, yet it might be interesting to cite briefly some of the ways in which the above idea has been carried out. Men who are detained on the road in blockades caused by fires, accidents, snow, etc., are paid for the time they lose on the road. In snow work the best motormen are detailed on the sweepers and paid double time by the hour from the time they are called until they are relieved from duty, whether they are actually at work on the sweepers or swinging at the car house.

Men called to the office to make reports of accidents or other reports and who unavoidably lose trips by so doing, are paid for their time. In July last, at the time when an attempt was made to tie up the lines by a strike, men who reported for work and who remained on call unable to go out on account of having no conductor or motormen were paid for their time. As a reward for the loyalty of the great body of men who stood by the company and made the strike a failure, the men who worked during the two days the strike was attempted, July 19th and 20th, were allowed double time, and afterwards were given a three days' vacation with pay.

2. In selecting men for service from among the applicants, a great deal is to be gained by carefully choosing those who appear the most intelligent, sober and neat in appearance, requiring them in their applications to give their past places of employment and reasons for leaving same, and investigating these statements. If this investigation is well carried out it will weed out a great many undesirable men who have made false statements.

3. In molding the more or less unskilled labor into competent conductors and motormen, it is well that the man should gain correct first impressions of their work. If a man is instructed as to the handling of his car by a careful and competent teacher, it will save a great deal of trouble later on; also, if he receives a good impression of his relations with and the treatment he is to receive from his new employer, it will tend to make the man careful and attentive to his work from the start. Our company employs a chief instructor of motormen and several assistants, who devote their whole time to the education of motormen. There is also an instructor for conductors, who devotes his time to the education of conductors. The company has a large room fitted up with some 25 controllers and brake handles connected with a spring. The men are given their first instruction in the use of the controller and brakes on these dummies, where they can learn the feeling of the handles, and how to use them without the danger of running down some one with a moving car.

There is also a skeleton car completely fitted up with trucks, brakes, motors, controllers, fenders, lights and with the wiring exposed and connected with power. On this car the men are given instruction in such matters as it is important that motormen should know. After they have spent two weeks in the school and on the road they are put through a very careful examination before being turned in.

In addition to this instruction a talk is invariably given to the men before they are turned in, by the general superintendent or one of his assistants, in the course of which they are told very plainly and forcibly that their connection with the company will depend entirely on their own efforts; that no question of any "pull" or political influence of any kind enters into their service and that their future depends entirely upon what sort of a record they make for themselves. Every endeavor is made to make each man feel that he has entered the employ of a concern which proposes to treat him fairly and to retain his services as long as possible.

4. After a man has been pronounced competent to handle a car and has been turned in for actual service, how long he will remain in this service depends very largely on what sort of treatment he receives from his immediate superiors. The work of a new man on any street railroad is hard and discouraging enough in the long waits about the depot to be assigned to a car, and in the long hours of duty, without the addition of tyranny and unjust treatment on the part of his superiors.

We use what is called the Brown system of discipline in a slightly modified form. A man is seldom suspended from duty without pay, and never until he has had a hearing. In some few cases where men by mistake have been suspended without a hearing and it was found that they were not at fault, they have been advised that the suspension was an error and their pay allowed them for the lost time. When a man is brought up on any charge he is allowed to make as full an explanation as he desires and if necessary, a further investigation is made, so that when a case is finally settled the man feels that he has had every opportunity to exonerate himself. We endeavor to make him feel that an entry of the offense on his record is a black mark which adds so much to the weight of that record, and that when his record becomes too bad, we can do nothing else than to dismiss him from the service and fill his place with some other man.

In many cases where it appears that starters, inspectors or other subordinate officials have treated any man unjustly, the matter has been immediately taken up and the official who was at fault had been given to understand that such action will not be tolerated. More trouble and discontent among the men can be caused by arbitrary action and unfairness on the part of starters and inspectors, particularly the former, than in almost any other way.

5. The feeling should exist among the men that length of service counts for something. The oldest man in the service of the company should invariably have his choice of the schedule runs. When there is a position to be filled as inspector, starter, in the office or in any line higher than that of conductor or motorman, the men on the cars should be eligible for promotion to the position ahead of any person not in the employ of the company, the promotion to be made from among the older men in the service.

With our company the length of services of uniformed men is marked by service stripes worn on the left coat sleeve. One blue stripe for each year up to five years, at the end of five years a gold stripe, discarding the four blue stripes, with an additional gold stripe for each succeeding five years. These service stripes are invariably taken into consideration when making promotions as above.

The significance of these stripes is quite generally understood by the public who use the cars, and in many instances it tends to save a dispute between a passenger and the employe, partly because the employe feels that a number of stripes lends added dignity to his position, which he must be careful to maintain, and partly because the passenger talking to an employe wearing a number of stripes recognizes the fact that they represent several years of service and that the wearer is not a new man.

A long and unusually interesting discussion followed the reading of this paper, a number of delegates taking part.

Mr. W. W. Cole, of Elmira, asked the author if the Brown system of credits and debits was employed in New York City. Mr. Rounds replied that his company employed a modification of the Brown system, but did not have an elaborate system of credit and debit points. The question was asked if the Metropolitan company had had any trouble in defending its rules for the government of its employes, in the courts, in accident cases, etc., to which Mr.

H. A. Robinson, of New York City, replied that it had not to any great extent. Its rules for the ejection of passengers had been called into question a few times, but the only point that had been raised then was the amount of force used. He added that juries usually decided that unnecessary force had been used. Mr. R. E. Danforth, of Buffalo, by request, here stated that in Buffalo a similar system for the treatment of employes was in use as was in force on the Metropolitan lines in New York. No classified records are kept, as in the Brown system, but a man's past general record and the seriousness of the offence are taken into consideration when punishment is necessary.

Mr. Danforth was asked what had been the experience of his company in the matter of giving outings and excursions to its employes. He said that a very elaborate outing had been given all the employes this year, including power station, car house and track men, and conductors and motormen. The company paid all expenses, furnished refreshments, etc., and the management is convinced the men fully appreciated it; it will continue the custom each year in the future. Mr. W. C. Ely, of Buffalo, spoke at length on the relations that should exist between employer and employes. He said the way to increase efficiency of employes is to know the people that work for you and to treat them as one man should treat another in the spirit of kindness and consideration. He referred to the relations between the men of the Metropolitan company, of New York, and Mr. Vreeland, and attributed the failure of the recent effort to induce these men to strike, to the fact that the employes knew Mr. Vreeland and as a body realized that he was their best friend.

Mr. Vreeland said that from observations in many different cities he had become convinced that most of the trouble with employes arose from the handling of the extra forces. He had often asked street railway managers why they had such large extra lists, and found it was necessary because so many of the regular men were out of service on account of suspension for trivial offences. Mr. Vreeland does not believe it necessary or good management to have such a condition of affairs. He said that in his early steam railroad experience, he had handled freight brakemen—a class of men that includes some of the toughest characters found in any line of work—and used simple principles of good will. He is positive men will respond to decent treatment. He reduces the extra forces on his system by reducing the number of suspensions. Whereas the men on his road a few years ago would lose $70,000 a year in salaries through suspensions, they now loose but a very small proportion of that amount. The extra men now earn as much as regular men did at that time. Mr. Vreeland, by request, gave a short account of the organization and efforts of the Benefit Association among his employes. This has been very successful, and is a very valuable adjunct to the operation of the road. The heads of the departments and other officials of the company attend its meetings and are in this way brought into closer contact with the men than would be possible in any other way. An important feature of this association is the extensive circulating library which was established not alone for the employes but also for the benefit of their families. This goes a long way toward strengthening the good feeling toward the company. A public meeting of the Benefit Association is held each year, the company providing the hall, a vaudeville entertainment, etc., at its own expense. This year Carnegie Hall, one of the largest auditoriums in New York, was engaged, and a half hour before the meeting was to begin the hall was packed to the doors, and over a thousand people had been turned away. The Metropolitan company gave all the men in its employ who remained loyal during the recent labor disturbance, three days' vacation with full pay.

Mr. T. S. Williams, of Brooklyn, said his company had endeavored to apply the same principles in dealing with its men as were used on the Metropolitan road and thought the fact that nine-tenth of its old men remained loyal through the last strikes was evidence that the disposition, at least, of the company was appreciated. In his opinion the occupation of motorman and conductor is a higher one than formerly, and more intelligent men should be invited and encouraged to take these positions. One way to accomplish this is to promise long tenure of office if the man is faithful. Mr. T. J. Nicholl, of Rochester, expressed grave doubts as to the value of getting the men together in outings, excursions, etc., thinking that the opportunity thus offered would be utilized to talk over the affairs of the company in an undesirable way, magnify grievances, form unions, etc.; he wanted information on the subject, however. Mr. C. L. Allen, of Syracuse, disagreed from Mr Nicholl and thought men joined labor unions principally for the sick and benefit funds. In his city, therefore, the company had itself formed an organization among its men, with these two latter features. This society has been very successful, paying all of its claims and having several hundred dollars in its treasury It has a club room with all appointments. Mr. Allen considered the discussion that occurred on the street corners as injurious, and not those that occurred in the club room Mr. Nicholl explained that he has no question in his mind as to the value of benefit associations, but does not think it is good to assemble the men together and let them get too intimately acquainted with each other. He wanted the opinions of the delegates from some of the smaller roads. Mr H. S. Cooper, of Schenectady, thought it was better to have the discussions occur where they could be governed Mr Ely said he also represented a small road, the Buffalo & Niagara Falls Electric Railroad Co., and on which the most cordial relations between the men and the management existed, due, he thought, to the fact that the officers of the company became personally known to the men through an organization somewhat similar to the one in New York. He recognizes that the trend of the times is toward organization, and is afraid if he had no organization of his own among his men, some outsider would form one. He raised a laugh by declaring that he believed unions, organizations and trusts are good things—if you are in them. Mr. Vreeland said: "Get your men where you can talk to them." He declared his system is so run that if necessary he could meet and talk with every man on the road at the association's hall, upon just a few hours' notice.

Mr. Edward E. Higgins, of the Street Railway Journal, was accorded the privilege of the floor, and stated that an important consideration in the strengthening of the relations between employer and employe was the treatment of the sick. In his opinion, if the superintendent or general manager would arrange to have serious cases of sickness and trouble brought to his attention, and would then call upon or send a note of condolence or messenger to the troubled household, it would greatly tend to improve the standing of the company with the employes. Mr. Vreeland stated that his Employes' Association acted as a means of communication between himself and his men, and enabled him to hear (through the officers of that association) of particularly sad cases of death, sickness, financial troubles, etc., and he could then set the proper machinery in motion to relieve the conditions, and again and again has his company paid the bills of old and faithful employes where misfortunes had overtaken them.

Mr. Cooper remarked that he gives one week's vacation with full pay each year, to men who have been in his service for twelve months or over and have clean records.

Mr. Cole, of Elmira, asked if anyone present had adopted the Brown system for keeping records of employes. No one had.

ELECTRIC WELDING.

BY R. F. DANFORTH, SUPERINTENDENT INTERNATIONAL TRACTION CO., BUFFALO.

Since the first carriage started on its trip on an iron-clad roadway, the problem of maintaining joints has been an unsettled one. Within a decade we have made steady progress in the improvement of our roadway construction, having gone from a strap to a Richards rail, from the Richards to a 4-in. girder, then to 6-in., and now to a 9-in. girder with its concrete base. Devices innumerable have been exploited to preserve the continuity of the roadway. Wedged joints and bolted joints have been found to be uncertain and miles and miles of rail have been "scrapped" because the ends have become badly battered and the rail surface bent from lack of proper support at the joints.

The question has resolved itself into one of obtaining a practical method of securing a continuous rail by welding the lengths of rail together. Two well known methods have been followed, and it is the writer's desire to present one of these to you.

The Thompson Welding Co. has for years successfully welded together pieces of iron and steel by use of electricity. The Johnson Co. has taken up this process with a view of welding its girder rail into continuous lengths, in the street. Its first method of welding the abutting ends of rail by bringing the joint to a welding

heat by the flow of an enormous current has been found to be a failure, because the homogeneity of the metal was destroyed. In the process of welding now being used in Buffalo, it has been the endeavor to follow as closely as possible the method employed in ordinary welding. After the metal is brought to a welding heat it is worked by being put under a pressure of about 35 tons, which has the same effect upon the material as the repeated blows of the blacksmith's hammer.

Under the former process of electric welding track joints the ends of the rails together, the entire cross section of the rail has to be brought to a welding heat. In the process now in use the ball of the rail seldom reaches more than a dull red. It is believed that the quality of the steel in the rail head is not injured by this low temperature.

In the true sense of the word, the abutting rails are not welded together, but the splice bars are welded to the web of the rail. These bars are of steel of the same quality as the rail, and measure 1 x 3 x 17 in.

The weld is made at three points, the center and ends of the bars. After the center weld is made, the ends of the bars are welded. Each bar has in the center a strip of steel pressed over the face 1¼ in. wide and ⅛ in. thick. The ends of the bar are drop forged, making a pear shaped projection on the side, having an area of about 3½ sq. in. and projecting ⅛ in. above the surface of the bar.

In order to obtain contact for the welder at the point opposite these end projections, a sheet of iron of the same shape as the projection is pressed into the depression on the back, which was made by forging the lug on the opposite side.

The process of making a weld on old rails is in general as follows. The pavement is removed for a space of 20 in. on either side of the rail and about 40 in. along the rail and the material removed to the ties. The splice bars are taken off, and, if the bolt holes in the rail were punched, the holes are reamed out about 1¼ in. or more to remove any check which may have resulted from punching the metal. The joint is then slightly crowned by driving a wedge between the rail and the tie. The three points to be welded are then cleaned by a sand blast. The bars are placed in position, resting on small wood blocks, and the contact points of the welder placed at the center of the bars. By means of a hydraulic device, the jaws are brought together with about 14 tons pressure, the rail web is heated because of the resistence of the metal itself and the current turned on and kept up one minute until the points of contact are brought nearly to a white heat; the pressure is then reduced to about 3½ tons, and at the end of another minute or less, the metal comes to a welding heat. The current is then shut off and the pressure increased to about 15 tons and kept on for one minute, or until the metal "sets." The end contacts are then welded in a manner similar to the method followed in the center contacts, with the exception that the pressure, when the current is shut off, is raised to 35 tons and is kept on for two minutes. Under this pressure the bar is brought in its entire length in close contact with the web of the rail and the upset metal in the boss or projection disappears. After the weld is made the head of the rail is ground to a true surface by an emery grinder and is then complete.

The machines used in this process may be described as follows: The current from the line is passed through a railway booster, which raises the pressure to 500 volts. (This booster is not used where the initial voltage can be maintained at 500 or over). This direct current at 500 volts is then used to drive a rotary transformer generating alternating current at 300 volts. This in turn is reduced to five volts in a static transformer; the secondary circuit consists of a single loop of copper and its ends form the contact points which are brought to bear against the bars.

It is found that at 500 volts the current required is about 250 amperes. The current flowing through the weld at five volts is about 30,000 amperes alternating. With this current flowing through the low pressure secondary circuit, it is found necessary to cool the contacts by circulating water around them.

An ingenious cooling device is used to reduce the temperature of the water so used. A tank is provided upon the top of the welding car, containing coils of pipe through which the water flows. These coils lie close together and the tank is filled with water. The air is forced through the water from a coil lying in the bottom of the tank through perforations in the coil. The evaporation from this cooling tank is found to be 47 gallons in 12 hours.

The welder proper is in the form of a rectangle, the lower portion of which is hinged so that the parts may be moved back and forth in the plane of the rectangle. On the upper portion there is a transformer coil, the primary of which consists of many turns of wire, the secondary being the rectangle above mentioned. This is a solid bar of copper 4½ x 7½ in. in cross section. The hinges in the two sides are spherical contacts. Around the outside of this rectangle is a steel frame of horse shoe form, having at the upper end a modified hydraulic jack. The movement of the piston in the cylinder back and forth moves the lower jaws of the contact points. A varying pressure can be placed on the material grasped between the jaws. The pressure is measured by a pressure gage, placed in a convenient position. The joints in the secondary circuit, the contact points and the transformer itself are cooled by a flow of water.

The sand blast is obtained by blowing sand, by means of compressed air, through a flexible hose. The air is compressed by a motor driven compressor.

The emery grinder previously referred to consists of an ingeniously designed carriage, supporting in its center the emery wheel, and running on two rollers, which are moved back and forth on the surface of the rail to be ground. Its action is similar to a carpenter's jack plane. The depth of cut made by the emery wheel is governed by means of a regulating screw, which raises and lowers the emery wheel. The wheel is driven by a belt from a collar motor mounted on the car.

Welds can be made as described at the rate of a joint every 13 minutes. It is found that the machine will average four joints an hour without any difficulty. In Buffalo the line voltage has averaged 410 and the current required about 375 amperes.

You probably ask why we decided to use the welded joint. The reply is that we find that the welded joint not only solves the problem of maintaining a continuous rail, but also of the best return circuit. The carrying capacity of the bars as welded is greater than that of the rail itself; there is no opportunity for electrolytic action between two dissimilar metals; there are no expanded contacts to work loose and no added investment for copper.

Another question frequently asked is "What do you do about expansion and contraction of your rail?" This is solved in two ways. First, by placing an expansion joint every 2,000 ft.; second, by leaving the bolted joints at the special work.

The reason for doing the latter is found in the method of construction used in Buffalo. When the rail is laid in concrete it is firmly gripped its entire length by this mass of material. The weak points in the rail or in its concrete base are bound to be developed. If there is any tendency for the rail to contract, the movement will be greatest where the pressure upon the rail is least. The rail is liable to break under the great tension at this point. The chances are very small for this movement being near enough an expansion joint to have that joint save the rail. If the rail breaks, a regular expansion joint can be easily placed at the break. In following years the expansion and contraction of the rail will be taken up at that point. In order to thoroughly test this question, track has been laid in Buffalo, both with and without expansion joints. The coming winter will solve the problem.

The effect upon a piece of old track, of welding the joints, is most satisfactory. In one instance we welded 6,000 ft. of 6-in. girder rail, which had been in use since 1891, and whose surface was so badly bent and battered that it was thought to be well nigh useless. The rail had been originally laid on chairs with special two tie joints. We removed the chairs and relaid the track in its proper position, but with low joints. After the pavement was in place (except at the joints) we brought the rail ends up by shims. After the welds were made and the shims removed, the track was found to be in fine condition. After this experience, we welded our track first and resurfaced and relined it afterwards.

The cooling of the weld depresses the joints about ⅛ in. We, therefore, raise the joints to allow for this depression. The old rail in question is considerably worn under the head as well as upon the ball of the rail, and it would therefore be difficult to fit loose splice bars or other mechanical joints so as to obtain a tight fit. The welded bars maintain the joint in its position and make that portion of the rail stronger than any other part.

The cost of welded joints is not materially more than that of the bolted joint with ample bonding. The same result may be obtained with cast-welded joint mechanically, but it is doubtful

whether the cast-welded joint gives as good electric contact as the method described.

At the end of another year the Buffalo Railway Co will be able to present interesting data upon the saving in coal resulting from a perfect return circuit. The work of this year has been largely done with the intent to furnish an ample return circuit to the power stations. As the work progresses, a marked saving is shown in the economy of the station.

The convention adjourned for lunch and the discussion of Mr. Danforth's paper was taken up in the afternoon, the meeting being called to order at 3:15.

Mr. M. G. Starrett, of New York City, asked the author what experience he had had in Buffalo with effect of change in temperature on the electric welds, also did the raising of the temperature of the steel in the ends of the rails in the welding process have any effect on the structure of the steel. Mr. Danforth replied that as far as his experience went, out of 3,100 welds, 17 had broken, and these failures were due to defects in manufacture. In the work they are now doing in Buffalo they do not expect 1 per cent of the joints to break during the coming winter, and they have the makers guarantee to that effect. So far two joints have broken in Buffalo. The heating of the rail in welding has no noticeable effect on the steel. Mr. W. B. Reed, of New York City, asked if the joint is found to be as rigid as the rail itself. Mr. Danforth answered that after repeated testing with falling weights at various heights they had been unable to break a single joint at the joint.

The president called on Mr. Nicholl for his experience with electric welding. He replied that his company had done no work of this kind, but was considering the advisability of electrically welding its joints.

Mr. Alfred Green, of Rochester, was to have read a paper at this point on track bonding, but sent word that he had been unable to prepare this paper. President Rogers, however, called for a discussion on the subject of bonding. Mr. Nicholl, of Rochester, described the methods of bonding in his city. Within the corporation limits the usual supplementary No. 0000 buried wire is employed, but in the suburbs this cannot be used, as the track is T-rail construction without paving and considerable trouble has been experienced from copper wire thieves. Outside the city limits a No. 0000 coper wire bond is used.

Mr. H. S. Newton, of Syracuse, uses in his city a long solid bond soldered to the rail. This is giving fair satisfaction, no trouble having been experienced from the bonds working loose when properly joined to the rail. This company has also had considerable trouble with wire thieves in the suburbs. All the outlying lines in Syracuse are now equipped with the Newton bond under the fish plates, but Mr Newton is of the opinion that welded joints are the real solution to the joint problem except in interurban work, where the rail is exposed.

Mr. Danforth described various methods of bonding employed in Buffalo.

The next paper was

THE PAVING QUESTION.

BY T. J. NICHOLL, VICE-PRESIDENT AND GENERAL MANAGER ROCHESTER RAILWAY CO.

At a meeting of street railway men it would seem to be unnecessary to discuss the question of street paving, from the fact that we have all had unpleasant and unprofitable experience in this line, and further, there is very little left unsaid as to the injustice of compelling electric street railway companies to pave a very large share of the streets of our cities. Be this as it may, however, if we do not keep on reiterating the question in our conventions, the probability is that the old rule "What is everybody's business is nobody's business" will be applicable in our case, the important question would in time be forgotten, and all of us continue to accept the burden with grinning teeth.

It is scarcely the province of this paper, and, in the short time allotted it is hardly possible to consider the different kinds of pavement used,—in fact, it will be better to leave that interesting subject for the engineering departments, but I will say in passing that it is exceedingly important, and a question that, perhaps, many of us do not go into as deeply as we should. It is not at all clear in my mind that city engineers or city councils should have it in their power to determine what kind of pavement should be used between the rails, without being compelled to consult the interests of street railway companies, if they are to bear the expense. The life of our tracks and the interruption and inconvenience that we are to suffer, largely depends upon the kind of pavement that is used between the rails. We all know that a smooth pavement between the rails and a poor pavement outside of the same, will place the traffic really where it does not belong, but I must not dwell upon this interesting part of the subject, although I should like to, very much.

Street improvements, which generally mean new sewers, new pavements, electric conduits, new gas and water pipes, etc., are at present projected and carried through on a much larger scale than ever before in the history of this country, by reason of its prosperous condition. A single season suffices, in a small city like Rochester, to run the expense up into the hundreds of thousands of dollars. Inasmuch as the street car tracks are generally located in the main streets, it is not at all surprising that these streets are the first to receive attention, where, as a rule, there is a double track, which, with 2 ft. outside of the outside rails, covers fully one half of the average street. Now the railway company is called upon to pay fully one half the expense, although it does not in reality use more than the space occupied by the four rails, say 20 to 24 in. in width. This is not all. The rails that have for many years done good service, and might for many more if the street remained unimproved, are not good enough to be relaid in the new pavement; hence they must be removed, as also the ties and sub structure generally. Again this is not all, for does not the street remain impassable for many months? and while it may be argued that some of the traffic will be diverted to other lines, at the same time we all know that but a small portion of it is saved in this way. The great bulk of the traffic is lost forever, and not only is it lost, but during the time the street is torn up the people are educated to walk, use bicycles or other conveyances, so that in the long run the cost to the street railway is probably more than the paving of the entire street.

The electric railway, to my mind, is doing more at the present day to civilize the country and put down crime, than any other institution in the land. It is the great power that scatters or separates people, and makes it possible to extend the areas of our cities, far ahead of the actual necessity of the time giving the people plenty of room to breathe the purest air, and at the same time do business conveniently in the heart of the city; but this is only partially appreciated, without reciprocity.

We find, for instance, that a short time ago a street was opened. The railway company was induced, by much persuasive talk and highly polished prospects, to lay its track therein, and establish a line of travel. Many people build and locate in this vicinity. The value of the land is advanced far beyond its former price, and in a very short time the farm becomes a part of the populated city. A little later the people living in this locality become dissatisfied with an ordinary dirt road, and like all true Americans are progressive in their ideas. They must have a paved street, electric lights, water works, etc., for which I do not blame them, but I do believe that such improvements as they desire in the pay of paving should be made without expense to the street railway company, which is in no wise benefited thereby; in fact, the contrary is the case as I have before intimated, as with a dirt road the tracks could more easily and quickly be repaired, and there is a great inducement for people to use the "poor man's carriage."

Notwithstanding, however, our rights or desires in the premises, an ordinance is passed, the street is improved, and we are asked to pay one-half the bill. "Might makes it right," and we cannot help ourselves, and the dear people (whose bank account we have enlarged by building the road into a locality that did not pay us operating expenses for several years), look on with great satisfaction, and try to feel that they have done a great work, and that the people composing the railway corporation should atone for the sin they have committed in banding themselves together for the welfare of humanity.

I sometimes think that the people who ride in street cars, who believe in oppressing the street railway corporations, and who, in fact, instruct their legislative representatives to see that laws are passed to compel more frequent service, double track, better cars, a seat for every passenger and cheaper rates, etc., never stop

to think that they are going the wrong way to work, and that one dollar will buy only just so much whiskey; in other words, if railway companies were exempt from taxation of all kinds, they could give much better service at a lower rate, in which the whole population would share, instead of the few whose taxes are made lighter by reason of the imposition of a large portion of them on the railway.

In the days of the horse car, the horses of the railway company used the street between its rails, as any other vehicle used other parts of the street, and the pavement between the rails was kept in repair by them. There was some little justice in this, but when horses were supplanted by electricity, and the motor car began its career, the question presented a very different aspect, as the electric car does not in any way use or injure the pavement between the rails; on the contrary, it provides a pair of smooth rails for the use of others, and all the wear and damage to the pavement on that portion of the street becomes properly chargeable to wagons and drays, which constantly use the same. The public however, have been educated in the horse car school, and still cling to the old idea. Perhaps this may be considered good "horse sense," but can hardly be called "up-to-date."

I have said there is a little justice in requiring the railway company to keep the pavement in repair, but why is not every other vehicle required to do the same, which provide no rail; especially, for instance, regular lines of busses and carettes, such as may be seen in New York and Chicago, which constantly travel one route, and, as is the case in Chicago, the route is immediately along the railway tracks, and the gage of the carette being wider than the railway, has resulted in a deep grove being cut about 1 ft. outside of the rails. For this the carette pays nothing, but the railway company, I believe, is compelled to bear the expense. Why should this be? The whole system is wrong and sinful, and the shareholders of the street railways should rise in their might, which is their prerogative as American citizens, and endeavor to get justice. Only justice, nothing more; otherwise we had better go out of the business, or sell our tracks to the people, which I am not quite sure is not the proper thing to do in any case. Then they could make improvements as they pleased and when they pleased, and pay the expense of the same. In such an event, I would, of course, be in favor of leasing the right to use these tracks upon much the same principle as a person or corporation leases the right to run a line of busses or carettes.

I was very much interested in President Boyle's admirable paper published in the Utica Herald of March 23, 1899, (St. Ry. Rev. Apr., 1899, p. 266.), in which he says:

"The fact that a railroad is built, and cannot be picked up and carried out of the city if unjustly treated and taxed, renders it a peculiarly safe object of attack. The people know that even while they are endeavoring to slaughter the corporation, they will miss none of the conveniences and benefits of its service. A railroad cannot afford to retaliate by lowering the excellence of its accommodations. There is everything to gain and nothing to lose. The position taken by a portion of the public is not the loftiest one in the world, but it is exceedingly human." And I quite agree with him, except as to "lowering the excellence of the accommodation." As I have said before, "one dollar will buy just so much whiskey;" if you spend it on taxes and pavements for the benefit of the public and against your own interests, you certainly cannot prevent the "lowering of the excellence of the accommodation," unless the franchise is so valuable that you can well afford it, which I take it is much more the exception than the rule.

Again Mr. Boyle says: "The attitude of the press toward the street railways is perhaps excusable (if sometimes a little aggravating). It is a question of existence with them. As the railroads object to a law which means bankruptcy for them, so a newspaper should not be expected to adopt a policy which means bankruptcy for it, and the newspaper which boldly and openly championed the cause of the railroads would be doomed from the initial letter of its first editorials."

Knowing full well that such is the case, and desiring to reach the public independently, the railway company in Rochester has for some months published a small weekly paper, which is circulated in the cars, in which the public is given an opportunity to see things from the railway's point of view. This has no particular bearing on the pavement question, but I mention it as an idea which is well worth developing in some of our cities, as it tends to educate the public to see that there are two sides to all questions (even when a street railway company is one of the parties). That it has done much in Rochester to open the eyes of passengers as to the trials to which the railway company and its employes are subjected, is already apparent, and the policy of treating everything in a fair and open manner, and ridiculing, rather than "kicking" against some of the common abuses, has had a wholesome effect.

In conclusion, I will quote again from Mr. Boyle's paper—his last remarks, which make a most fitting close to his able argument. Speaking of the state of public feeling towards the railway company, he says: "There is only one law which does justify it, and it is the law under which the highwayman says to the traveler: 'I am a larger man than you are. I am armed and you are not. You are here and can't get away. You have money and I want it. Give it up.'"

If the courts will sustain such gross injustice, there is no doubt but the railways will have to "give it up."

Mr. M. M. Fenner, of Fredonia, opened the discussion by asking for some facts regarding what is know as the Conway paving decision in the Court of Appeals of New York. He wanted to know what the clause in this decision, requiring street railway companies to pave and keep in repair for 2 ft. outside of the tracks, really meant. Considerable difference of opinion existed among the delegates on this point, Mr. Nicholl, of Rochester, believing that it meant a strip 2 ft. wide outside of the outside rail, but Mr. DeForest Van Vleet, of Ithaca, was of the opinion that 2 ft. outside of the rails meant 1 ft. on each side.

Mr. Robinson, of New York, also gave his opinion on the Conway decision.

Mr. T. F. Williams, of Brooklyn, thought that the cost of paving is a franchise tax, and under the new Ford bill companies should not be required to pay it, if double taxing on the franchise value was to be avoided.

Mr. Nicholl, of Rochester, asked for the experience of the delegates on a city's power to compel the street railway companies to repave streets where the paving had settled, owing to poor foundation which had been constructed by irresponsible city contractors after sewers had been laid.

Mr. W. B. Reed, of New York City, stated that it was the practice of the Metropolitan company when notified that the city was going to repair sewer or gas pipes underneath its tracks, to lay side tracks around the excavations. His company had always maintained pavements over sewer and gas pipes even though the work had been poorly done in the first place by the city contractors. This he said was done principally to avoid the expense of litigation on the subject rather than from a feeling of compulsion in the matter.

This ended the regular list of papers for the day, but the Chair called for a discussion on the subject, "Transfers: Their Use and Abuse," and asked Mr. J. H. Steadman, of Rochester, to make a few remarks. Mr. Steadman said he had presented papers on this topic at various conventions and had nothing further to say upon the subject.

Mr. Nicholl, of Rochester, requested information from the Metropolitan company of New York City as to the benefits derived from printing the section of the penal code referring to the abuse of transfers on the back of each ticket. Mr. Robinson, of New York, replied that in his opinion the public read this code to a large extent, and it had a good effect in an educational line. His company had experienced considerable difficulty in making cases against people accused of misusing transfers and had never succeeded in securing a conviction. His company has had the section of the penal code printed on large cards and hung on the rear and front platforms of each car.

Mr. Danforth, of Buffalo, by request of the president, gave the experience of his company with transfers. It has had but two cases of serious abuse of transfers and in these was unable to get sufficient testimony to punish the offenders. Mr. Warren, of New York, in reply to a question, stated that there were 58 different transfer points on the Metropolitan company's system. This company has had considerable trouble in its transfer points. Passengers will board a car a block away from a transfer station, and before the conductor has had an opportunity to collect the fares, will jump from the car and secure a transfer.

The fact was here brought out that there were but three cities in the state that register their transfers, namely Rochester, Buffalo and Syracuse. Mr. Warren considers it a mistake to give a transfer any cash value whatever. Mr. Williams, of Brooklyn, called transfers the nightmare of the street railway manager. His company employs over 40 girls that do nothing but sort and classify used transfers of which 50,000 are returned each day. The company is aware of the fact that it is being defrauded continually both by conductors and the public, through its transfer system, but knows of no way to check the abuse. Mr. Williams thinks that a small additional charge should be made whenever a transfer is given. He also believes that the extensive transfer system on his road tends to greatly increase the number of accidents, owing to the necessity of passengers changing from one car to another at so many different points. Mr. Newton, of Syracuse, wanted to learn from the companies that do not ring up transfers how they keep a check on conductors. Mr. Root and Mr. Warren, of New York, explained the workings of their system quite fully. Mr. Allen, of Syracuse, stated that his road had had considerable trouble with suits brought for improperly punched and dated transfers, which had been refused by conductors.

Mr. Root stated that 425,000 transfers are issued each day by the Metropolitan company of New York. The transfer system, however, has increased traffic enormously and the benefits derived far outbalance the losses from fraud. Mr. Vreeland considered the question purely a local one to be decided by local conditions. He said, in New York one of the rides taken by a transfer passenger was short; either the rider first traveled on one of the long main lines and then transferred to one of the shore cross-town line or vice versa. In Philadelphia, however, both rides were often very long, averaging more than five miles apiece. This is the reason the 3-cent additional fare is charged in the latter city. It is Mr. Vreeland's opinion that the increase in gross receipts per mile of track on the Metropolitan system from $30,000 to over $70,000, is due very largely to the liberal transfer arrangements instituted. After further discussion on this subject, in which Mr. Stedman, Mr. Warren and Mr. Williams joined, President Rogers announced a question meeting, and stated the convention would be pleased to entertain any question on any subject of interest. This opportunity was taken advantage of by several of the delegates. A motion was then made to appoint the nominating committee to name officers for the ensuing year. President Rogers appointed on this committee Mr. DeForest Van Vleet, of Ithaca, Mr. T. S. Williams, of Brooklyn, and Mr. C. Loomis Allen, of Syracuse.

President Rogers then requested Commissioner A. W. Cole to address the convention. Mr. Cole spoke at some length, reviewing the recent work of the New York Commission in testing street railway brakes in New York City and touching upon the relations existing between the railroad commission and the street railway companies of the state. An extended discussion upon brakes followed Mr. Cole's address. The brake invented by Mr. Millen, of New York, was mentioned and described.

The meeting adjourned at 5.20 p. m.

Early in the evening of the 12th the delegates and visitors to the convention were taken in special cars to Renwick Park as the guests of the Ithaca Street Railway Co. Here an elaborate concert by the Ithaca Prize Band was enjoyed.

At 10 p. m. the annual banquet of the association was held at the New Ithaca Hotel.

At 9.30 a. m., on Wednesday, the visitors were taken in special cars over the lines of the Ithaca Street Railway Co. to Cornell Heights. Several stops were made along the way to enjoy the scenery and view the University buildings. At 10.40 a. m. the convention was called to order in Sibley College lecture room with President Rogers in the chair. The first paper was

RAILWAY POWER DISTRIBUTION OVER LARGE AREAS.

BY A. H. ARMSTRONG, OF THE GENERAL ELECTRIC CO.

The formation of the International Traction Co. brought under one management the various roads operating in Buffalo and vicinity. Previous to this consolidation, each of the several roads had its own source of power and the question of the most economical method of operating the entire system was of the greatest importance

The Buffalo Railway has installed in its Niagara Street power house, two rotary converters of the General Electric type in the fall of 1896, power being supplied by the Niagara Falls Power Co. Two additional converters had been added a year later, making a total nominal capacity of 1,600-kw. installed. This converter capacity, together with an engine capacity of 7,500 h. p., supplemented by a storage battery of 1,500 ampere capacity, had operated the lines of the Buffalo Railway Co.

To operate the enlarged system there were three courses open: increasing the capacity of the Niagara St. power house, building a new power house on the other side of the city to work in conjunction with the Niagara St. station, or the adoption of rotary converter sub-stations fed from Niagara Falls. The cars running to Niagara Falls and to Lockport were already partly fed from rotary converter sub-stations and the enlargement of the Niagara St. power house would not contemplate the shutting down of these sub-stations. The operation of all the lines in Buffalo by a single power house was open to the serious objection that either a considerable increase in feeder copper would be necessary or boosters must be used. The amount of feeder copper installed provided for a number of feeding points into the system, and would have to be largely increased if the entire system were fed from a single point, as would be the case with one large power house. Heavier cars, equipped with electric heaters and operating at a much faster schedule are being installed, which would still further increase the amount of feeder copper required to the extent that a single generating station was not looked upon as desirable.

The use of boosters as a permanent means of replacing feeder copper in a system where heavy overloads may be of long duration, is very objectionable, owing to the losses entailed. Overloads of short duration, and especially local overloads due to some special local event can very well be taken care of by boosters, but the cost of the energy lost in boosting daily overloads may be sufficient, as in the present case, to more than offset the interest on additional copper investment required.

The second method of operation, the building of another power house on the east side, was also open to serious objections. The capital investment called for in this case would have been still larger than that required for the additional copper with a single generating station, while the cost of operating two separate stations would have been greater than that of operating a single station of the combined capacity of the two. The required feeder copper also, while less than that for a single station, would be considerably greater than in the third method of operation, by rotary converter sub-stations. The successful operation of a railway system and especially one with suburban branches, calls for as high a schedule speed as can be maintained with safety.

It is, therefore, of paramount importance that the line voltage shall be kept up, as it not only ensures a good schedule being made, but results in less heating of the motors themselves. The rotary converter sub-station system permits sub-stations to be located wherever there is the greatest demand for power, as the comparatively small transmission line required can be carried underground to any locality, while the sub-station itself, requiring no boilers or engines can be located in any neighborhood on account of its cleanliness and noiseless operation. The sub-station also requires a very small amount of floor space for its output as compared with a steam driven generating station, and hence can be located in the business districts where property is high, which, together with the cost of carting coal, would make a generating station in such a locality expensive to operate, especially as it must probably run non-condensing. The largest congestion of cars, and hence the largest demand for power, exists in the business districts, and it is owing to the possibility of locating sub-stations close to the points of greatest demand that makes the converter system especially adapted to the operation of large city railway systems.

As sub-stations can be located where most needed, it is obvious that the amount of direct current feeder copper required for such a system is much less than would be required for the same effective operation with a single direct current generating station, while the high potential transmission line at 10,000 volts would demand but a small amount of copper.

The number of attendants in a sub-station need not exceed two men for a station having a capacity of say—three 400-kw. convert-

ers, so that the labor account would be much less than in the case of a number of small generating stations.

The above advantages apply to the converter system whether the sub stations are driven from a large steam driven generating station, located in the outskirts of the city, and enjoying cheap coal and cheap real estate, or as in the Buffalo sub-stations, they are fed from a water power station.

After careful consideration of the several methods of operation open to them, Mr. W. Caryl Ely, president of the International Traction Co., and Mr. B. Van Horn, general manager, decided upon the adoption of the rotary converter sub-station system as offering the greatest advantages in its economy of operation and first cost of installation.

The method of operating the Buffalo city system, as adopted, involves the installation of five rotary converter sub-stations, besides the operation of the four converters and storage battery in the Niagara St. power house.

The steam plant at Niagara St., however, will be shut down and kept as a reserve, thus permitting the entire lines of the International Traction Co. in Buffalo, Niagara Falls, Tonawanda, and Lockport, to be driven from rotary converters fed by the Niagara Falls power.

There will be a total of six sub-stations, including Niagara St. No. 6, having the following maximum output during the winter months, where heaters will be used:

	Max. Output.	Converter Installed.	Ultimate Capacity.
Sub-station No. 1	760 kw.	800 kw.	1,200 kw.
Sub-station No. 2	870 kw.	800 kw.	1,200 kw.
Sub-station No. 3	1,230 kw.	1,200 kw.	1,600 kw.
Sub-station No. 4	870 kw.	800 kw.	1,200 kw.
Sub-station No. 5	890 kw.	800 kw.	1,200 kw.
Sub-station No. 6	1,600 kw.	1,600 kw.	1,600 kw.
Total	6,220 kw.	6,000 kw.	8,000 kw.

The peak of the load is somewhat in excess of the rated capacity of the converters to be installed, but the storage battery in the Niagara St. station has been increased to 3,000 amperes capacity, and this will be used to take the peak of the load, the ultimate capacity of the station providing for reserve apparatus and increase of traffic.

These six sub-stations will feed into a common feeder network through automatic circuit breakers, the load being taken on the larger stations during light traffic at night. The composition of the various sub-stations will be similar in all respects, with the exception of sub-station No. 6, which is located in the present Niagara St. power house. The other stations differ only in the number of rotary converters of 400-kw. capacity contained in each, the entire apparatus being furnished by the General Electric Co.

Sub-station No. 1 contains two rotary converters of 400-kw. capacity, with an ultimate capacity of three converters, each converter being fed through three step-down transformers of 150-kw. each, reducing the line potential of 10,500 volts to 375 volts, corresponding to 600 volts on the direct current side of the converters. These transformers are of the air blast type and feed directly into the rotary converters, the controlling switches being placed in the primary circuit.

The converters, being of the three phase-type, enable the step-down transformers to be connected in delta, so that the disabling of one transformer of a set does not throw the converter out of service. In addition to the individual switch controlling each rotary converter with its transformers, there is a main emergency switch opening the high potential bus bar circuit of the sub-station in case of necessity, where it is desired to throw out the entire station at once.

Artificial reactance is introduced between transformers and converters to enable the converters to regulate with varying loads, this reactance also being cooled by artificial air draught, for which purpose direct current blower sets are provided in duplicate and feed into a common air chamber, from which individual transformers and reactances draw their supply.

In a large railway system of this character it is desirable to provide a ready means of starting the converters that will be effective and require a minimum time. While any one sub-station is in operation it is, of course, possible to start the converters of a second sub-station from the direct current side and suitable starting resistances are provided for this purpose. This can only be satisfactorily accomplished, however, when traffic is very light, and the line voltage high.

A possible shut down may occur during a time of maximum load when it would not be desirable to start several sub-stations from the alternating current end of the converters, owing to the large lagging current affecting the regulation of the system. To provide an efficient method of starting, there has been installed in two sub-stations a starting set, consisting of an induction motor direct coupled to a direct current generator of sufficient capacity to start one converter.

This method permits the starting of the converters in these stations from the direct current end, which will ensure bringing them into synchronism in a minimum time with the right polarity. The converters in adjacent sub-stations can then be started from the direct current feeder system.

By sub-dividing the city into several sections, each fed from a separate sub-station, the present amount of direct current feeder copper need not be increased to any considerable amount, especially as the track joints are being welded, thus making the ground circuit exceedingly good. With the completion of the different sub-stations, the International Traction Co. will have in operation a model railway system, having sub-stations fed from a single generating station as a source of power, cars using electric brakes operating over tracks with welded joints and high speed suburban lines to the several adjacent towns.

A brief discussion followed this paper, Mr. Newton, of Syracuse, Mr. Ely, of Buffalo, Mr. Nicholl, of Rochester, and Mr. Armstrong taking part.

A paper was to have been read by Prof. R. C. Carpenter, of Cornell University, but this was dispensed with, owing to the unavoidable absence of the author.

SOME ELECTRIC STREET RAILWAY DATA.

BY HARRIS J. RYAN, PROFESSOR OF ELECTRICAL ENGINEERING, CORNELL UNIVERSITY.

During the spring of 1899 copies of a question form for gathering statistical data relating to the construction and operation of electric street railway plants were sent to the managements of some of the plants in our country with the request that they be filled in with the requisite data and returned to the writer. In this request it was stated that average results of the replies would be published. Replies were received from 12 plants that were fairly complete. The data from eight of these plants have been averaged as far as possible. The results form the composite answers to the questions in the form as given below, which was originally sent to the management of each plant.

Whenever percentages appear in an answer they mean that the answer applies to plants aggregating in capacity those percentages of the total average daily kilowatt output for the eight plants.

BUILDINGS.

Size of complete power house, 319 ft. x 574 ft.; 183,500 sq. ft. Engine and dynamo room, 240 ft. x 440 ft.; 105,000 sq. ft. Boiler room, etc., 188 ft. x 440 ft.; 82,900 sq. ft.

Constructive materials:

Foundations: 37.0 per cent masonry; 23.2 per cent concrete; 29.2 per cent concrete and stone masonry; 6 per cent brick in cement; 4.6 per cent not reported.

Walls: 76.8 per cent brick; 12.2 per cent pressed brick front; enameled and pressed brick in engine room; 11.0 per cent steel structure filled with brick.

Roof: 12.2 per cent tile with tar and felt; 11 per cent matched pine on steel structure; 20.5 per cent composition tar roof; 6 per cent wood asphalted; 4.6 per cent wood; 10.5 per cent slate, steel trusses; 16.5 per cent slate over engine room, corrugated iron over boiler room; 18.7 per cent slate on pine sheathing supported on steel trusses and purlins.

Floor: 18.7 per cent vitrified tile laid on concrete arches and supported on steel I-beams; 16.5 per cent concrete; 10.5 per cent wood in engine room, cement in boiler rooms; 23.2 per cent mill construction, hard wood finish; 24.5 per cent wood; 6 per cent wood covered with steel plate.

Car barns: 76.8 per cent, 444,645 sq. ft.; 21 per cent, no report.

Repair shops: 78.9 per cent, 83,722 sq. ft.; 21.1 per cent, no report.

Cost of power house, building only, no reports.

POWER HOUSE EQUIPMENT, MECHANICAL.

Engines:

Total number of engines, 46.

Types of engines: One (125 h. p.) high speed; four (2,100 h. p.) Porter & Allen; sixteen (12,200 h. p.) American Wheelock; one (1,200 h. p.) Green Wheelock compound condensing; twelve (9,250 h. p.) "Corliss" or "Simple Corliss;" three (1,200 h. p.) Simple Corliss condensing; five (3,650 h. p.) Corliss compound condensing; four (2,400 h. p.) Providence Green tandem compound condensing.

Average rated h. p. of each, 700; aggregate rated h. p., 32,125.

Condensing, 8,450 h. p.; non condensing, 23,675 h. p.

Cost of engines erected, including foundations:

Simple non condensing, 15,550, h. p.; cost $14.88 per h. p.

Tandem compound condensing, 2,400, h. p.; cost $20.60 per h. p

Number of spare units, 14; total i. h. p., 9,250.

Boilers:

Total number of boilers 106; steam pressure, 100 to 125 lb.

Rated power:

Fire tube boilers 19—3,800 h. p.	100 lb.
Fire tube boilers 19—3,800	110 lb.
Fire tube boilers 24—7,200 h. p.	115 lb.
Fire tube boilers 6—750 h. p.	120 lb.
Water tube boilers 6—2,250 h. p.	100 lb.
Water tube boilers 7—2,650 h. p.	120 lb.
Water tube boilers 23—5,950 h. p.	125 lb.
Total fire tube boilers 65—14,150 h. p.	100 lb. to 120 lb.
Total water tube boilers 36—10,850 h. p.	100 lb. to 125 lb.
Total Cahill vertical boilers 5—1,250 h. p.	120 lb.

Aggregate capacity of boilers, 26,250, h. p.

Number of spare units, 24; capacity, 6,725 h. p.

Steam fitting and appliances:

System of steam piping: 89.5 per cent single; 10.5 per cent double.

Natural draft: 100 per cent use.

Forced draft: 89.5 per cent do not use; 10.5 per cent use.

Hand firing: 58.1 per cent use.

Mechanical stokers: 41.9 per cent use.

Coal conveyors: 29.7 per cent use.

Ash conveyors: 46.2 per cent use.

Economizers: 15.6 per cent use.

Cost: 11 per cent fire tube boilers with natural draft, mechanical stokers, coal and ash conveyors, installed about 1897, cost $19.75 per rated h. p.

Summary:

Cost of steam plant, including engines, boilers, piping, and all auxiliary apparatus, erected and ready for operation: 17,950 h. p.; total cost, $816,514, or $45.50 per rated h. p.; varying from $29.10 to $56.90, according to date of installation and nature of equipment.

POWER HOUSE EQUIPMENT, ELECTRICAL.

Generators:

Total number of generators 54; aggregate capacity, 25,930 kw.; 17 generators, direct driven, 11,000 kw.; 21 generators, belt driven, 4,530 kw.; 16 generators, rope driven, 10,400 kw.

Average daily load, 9,608 kw.; maximum, 14,437 kw.; minimum, 5,981 kw.

Number of spare units, 17; capacity, 7,090 kw.

Cost of generators, including foundations, etc.:

8—4,600 kw.—direct connected, cost $23 per kw.

16—10,400 kw.—belted, cost $13 per kw.

Switchboard:

Number of generator panels, 59; feeder panels, 131.

Cost of switchboard erected, including necessary apparatus, etc.:

1. Generator panels: No report.
2. Feeder panels: 16.5 per cent, $1.65.
3. Total: 23.2 per cent, $3,600.
4. Per kw.: 23.2 per cent, 3.46.

Recording instruments, 64.4 per cent use.

Wattmeters, 84.9 per cent use.

Summary:

Cost of electrical equipment, including generators, switchboards, wiring, etc., erected ready for operation: 15,050 kw., cost $18.05 per kw.

Grand summary:

Cost of completed station and all contents: Excluding land, 15,050 kw., cost $75.25 per kw.

ROAD AND EQUIPMENT

Track:

Mileage: 58.4 per cent have 213 miles of road and 335 miles of track; 25.1 per cent, 138 miles of track, single or unspecified; 16.5 per cent, not reported.

Rails: 18.7 per cent, 60 ft., 90-lb. girder, a few 60 ft. and others 30-ft. girder and T, ranging in weight from 35 to 107 lb.

Track foundation: 23.2 per cent, dirt mostly, ballasted to some extent with crushed stone; 20.5 per cent, macadam; 4.6 per cent, slag; 10.5 per cent, earth, ashes, broken stone, concrete; 18.7 per cent, 90 lb, 60 ft. girder rails with broken limestone ballast 6 in. deep under cross ties.

Bonds: A variety, generally copper rods riveted, vary in size from No. 4 to two No. 000 B. & S. per rail joint.

Supplementary wires: 23.2 per cent have 35 per cent in excess of feeder copper.

Ties: 6 x 8 in. x 7 ft. average; mostly oak (a few chestnut) spaced 24 in. c. to c. In one instance steel ties 1⅜ x 7 in. x 5 ft. 6 in. spaced 10 ft. apart and laid in concrete were used.

Paving: Depends entirely on local conditions.

	Per Mile of Track	
	Single	Double
Cost of all material used	$ 6,800	$13,600
Cost of all labor required to install	3,680	6,160
Cost of paving, labor and material	6,200	12,400
Total cost of road bed, complete	$16,080	$32,160

This is the average report for 42 per cent. Part earth and part broken stone ballast, 7-in. girder rails, cast weld joints, no bonds.

Overhead construction:

Span wire or bracket construction: 67 per cent, span wire; 16.5 per cent, span wire and bracket; 16.5 per cent, no report.

Size of trolley wire: 83.5per cent. No. 0 B. & S., hard drawn copper, except about 5 per cent of this where No. 00 is used; 16 per cent, no report.

Poles: 39.2 per cent, iron pipe spaced 100 ft. to 110 ft.; 29.2 per cent, steel and wood, spaced 115 ft. to 120 ft.; 4.6 per cent, cedar, spaced 110 ft.; 10.5 per cent, chestnut, spaced 100 ft.

Feeders: 22.5 per cent, have 45 feeders aggregating 1,066,400 ft.; 23.2 per cent, have 125 feeders aggregating 1,900,000 lb., including insulation.

	Per Mile of Track	
	Single	Double
Cost of all material, overhead construction	$2,325	$2,826
Cost of all labor for erection	213	427
Total cost of overhead construction	$2,538	$3,253

The above is for iron poles. For wooden poles material one-third and labor one-half the above.

Equipment:

Number of motor cars: Closed, 1,197; open, 1,008; convertible, 75. Total, 2,280. These figures reported for 83.5 per cent.

Average daily number of cars in use: 83.5 per cent, 698.

Average daily mileage per car: 79.9 per cent, 122.4 miles.

Total car-miles per day, 58.4 per cent, 57,862.

Length of car bodies:

	Closed.	Open.
18.7 per cent	20 ft.	30 ft.
10.5 per cent	16 ft., 18 ft., 28 ft.	27 ft., 30 ft.
4.6 per cent	18 ft.	28 ft.
6.0 per cent	16 ft., 18 ft.	18 ft., 21 ft.
20.5 per cent	28 ft.	22 ft.
23.2 per cent	21 ft.	28 ft.

Cost of car bodies: Closed, 20-ft., $900 to $1,200; open, 30-ft. to 32-ft., $600 to $800.

Cost of trucks: Single, $175 to $250; double and maximum traction, $315 to $425.

Type of motors: G. E. 800, Walker No. 5, Westinghouse Nos. 3, 12A, 49C.

Number of motors per car: Two, except for a few 28-ft cars on which four motors are used.

Rated power of motors: 25 to 50 h. p. each.

Cost of motors and appliances per car, installed: $700 to $1,100, according to size of motors.

Summary.

Total cost of motor car, including car body, truck, motors, and all appliances installed ready for operation:

1. Closed motor car, average, $1,700 to $2,500.
2. Open motor car, average, $1,400 to $2,070.
3. Convertible motor car, average, $2,375.

Roads built between 1892 and 1898, average.

OPERATING EXPENSES.

Kind of fuel and cost delivered:

23.2 per cent, Indiana screening @ $1.07 to $1.25 per ton.

20.5 per cent, soft coal.

6.0 per cent bituminous @ $3.00 per ton and slack @ $2.35 per ton

10.5 per cent, anthracite bird's eye and buckwheat @ $4.46½.

18.7 per cent, bituminous slack @ $.00 to $.70.

Kilowatt-hours per day: 49.7 per cent, 79,480.

COST OF POWER PER KW. H.

Average report for 42 per cent:

Operation:	Fuel	$.0060
	Water	.0001
	Labor	.0027
Repairs:		.00053
	Total, without interest or depreciation	$.00933

COST OF OPERATION PER CAR-MILE.

Average report for 42 per cent; cars of medium size:

Power			$.01015
Maintenance of Equipment:			
Trucks	$.00285		
Motors	.00502		
Car bodies	.00669	Total	.01456
Maintenance of way			.01000
Motormen, conductors, inspection, etc.			.05968
General expenses, salaries, etc.			.00386
Taxes, insurance, legal expenses, damage, miscellaneous, etc.			.01681
Grand total			$.11506

Several delegates expressed their intention of carefully reading this paper at home, but there was no discussion. Next was

EXPERIMENTS ON RAIL BONDS.

BY PROF. HENRY H. NORRIS, CORNELL UNIVERSITY.

The importance of the subject of rail bonding is evidenced by the increasing extent of the papers and discussions about it. Although compared with some of the more showy parts of the railway equipment, its place is very humble, yet the railbond has the ability to do a great deal of harm in a quiet way.

The use of the ground for the return of the power current is out of the question. If the current does not return to the station on the rails, it is probably not coming in through the ground, for that has a resistance much too great for this purpose. The experiments of Mr. J. H. Holt (Electrical World, Vol. XXIV, p. 290) show that the earth may and does often have a very high resistance which is much more than is usually supposed. Between good ground plates 3,000 ft. apart the resistance was found to be from about 70 to over 500 ohms, depending upon the number of terminals in parallel. In street railway work the resistance will depend largely upon the condition of the surface of the soil, but is usually less than the figures just given on account of the large surface exposed to the ground by the rails. The rails are universally used for the return, or are ostensibly so used, for sometimes it is difficult to find the current in the rails when it is supposed to be there. It is as important to have plenty of conducting metal in the rails as to see that there is enough in the main feeders.

A common effect of the poor quality of the return circuit is the destruction of metal pipes in the vicinity, and it is this trouble more than any other that has driven so much attention to the matter of rail bonding. If an easier path is to be found by some other route than that through the rails the current is bound to take that path, or, at least, enough of the current will do so to make the fall of pressure along the shunt path equal to that in the rails. But with the high resistance of the earth it should not be possible for any great quantity of current to leave the rails unless there is trouble with the bonding, for the rails have carrying capacity enough for most cases.

The difficulty in keeping the bonding in good condition is that there are so many electrical contacts to maintain and that they are so inaccessible. When a bond is put in it should be of the best quality in every way so that repairs will be seldom necessary. The requisites of a good bond are both mechanical and electrical. They must not be able to work loose, for a loose bond is of very little use. To this end flexibility is important, for joints will "give" under the weight of cars and the space between the ends of the rails will vary with the temperature. From the electrical standpoint, the conductivity must be good, especially at the joints. The copper resistance of the bond may be first class, but with a joint of small area and insufficient pressure between surfaces, the results will be unsatisfactory. In addition, there must be no chance for oxidation of the surfaces.

The effect of poor bonding is very far reaching. The power lost and the corresponding drop in pressure in the cars amount to something, but the unseen destruction of pipes and cable coverings is more. Even the loss of power is enough to pay for some attention to the matter. The consumption of power should not be calculated from laboratory tests of the bonds or even of road tests when the rails are newly laid, but when the joints have been subjected to the hammering action of the cars and the weather has had a chance to oxidize the contacts if it can.

It would seem unnecessary to state that a frequent inspection of the bonding of a road is desirable, but it is a fact that in a great many roads the matter is not thought of after the rails are once installed. Yet bonds have been found so hot that they could not be touched, dissipating energy at a rapid rate. Of course the trouble with bond inspection is that ordinarily it is difficult on account of the immense number of the connections and from the fact also that it is not considered as important as some other matters. In the test which will follow, bonds have been found with a resistance of upwards of 2 milliohms. With 100 amperes this would mean a drop of .2 volt in this one joint with an expenditure of 20 watts, if such current would flow across it. Of course it would not usually do so but would flow out into the ground in search of a more attractive path. This was a very bad joint, but in the road tested there were several of them. With a possibility of cases like this occurring an inspection of the bonding, if it can be made simply, will prove a good investment of time and money.

The resistance of the rails and bonding of a road should be made both as a whole and bond by bond. By a measurement of the resistance of the whole track return any considerable number of bad bonds may be detected. It is usually the case that bonds will become loose at a section of the road where there is a great deal of racking, and a number usually becomes loose at once. Such sections would naturally be especially watched.

If individual joints can be examined the results are much more satisfactory. The measurements are very simple and if there were but few the matter would be easy to arrange for. The method used in the tests to be described was to measure the current and drop in the joints while the road was in operation. It would have been better to have drawn through them a current by means of a water or other rheostat and then on a pair of millivoltmeters to have measured the current and the drop caused by the resistance of the joint. By connecting one voltmeter between two points on the rail separated by some little distance, the drop will be proportional to the current if the distance between the contacts be kept constant. The contacts may be brushes or sharp joints fixed on the ends of a wooden rod. In order to translate the readings into amperes it will be necessary either to know the resistance of the rail or to calibrate the voltmeter by taking readings when a known current is flowing through the rail. Simple as the method is, it is difficult to apply on account of the great amount of time required for its performance. The tests should be made very rapidly so that the testing apparatus will not interfere with the schedule runs. Where there are thousands of bonds, as is usually the case, it would be almost impossible to make the tests. Mr. Parshall calls our attention to the items making up the joint resistance as the resistance of the copper bond itself; that of the contacts between bond and rail;

and the extra resistance due to the "gathering in" of the current around this contact. After the bonds have once been installed the question of the conductivity of the conductor becomes of comparatively little importance but that of the resistance of the contact is the main item. A measurement of the joint as a whole will tell the whole story.

It is easy to estimate the return resistance which a given road should have, as the resistance of the rails will be about 0.45 ohm per inch mile. Then if the specific gravity of rails be taken at 7.8, the weight per square inch per yard is 10.2 lb. If the weight of rail per yard be known the area is obtained by dividing this by 10.2. A single track road of rails weighing 45 lb. per yard and having a length of five miles should have a resistance of about 0.25 ohm, the two rails being connected in parallel. This is on the assumption that the resistance of the bonds is equal to that of the corresponding length of rail, which is the ideal case. Often the resistance of a joint is less than that of a similar length of rail on account of the assistance afforded by the fish plate, but it is not safe to count on this. If the road cited gave a greater resistance than this the trouble would be in the bonds. The resistance, as actually measured, will usually not be as high as it should be on account of the assistance afforded by neighboring pipes and the moist soil itself, but a test will show in a general way the state of affairs. This test can be readily made by sending a current through the rail and making voltmeter contacts at the ends of the line, a feeder or telephone wire being used for the connecting wire.

The following tests of individual bonds were made by Messrs. P. H. Little and R. L. Reynolds under the direction of the department of electrical engineering of Sibley College. The tests were made on a road of good average construction, the newest part of the track being about two years old, while most of it was much older. The bonds used were of copper wire of two sizes; No. 000 and No. 0, B & S gage. They were riveted into the web of the rail and were about 33 in. long. Such bonds would have resistances of about .175 and .3 milliohms respectively at summer temperature.

Two Weston millivoltmeters were used, one much more delicate than the other. One would answer the purpose if a resistance were used in series with it for large readings. Strictly it would be better to use two voltmeters, one for the current and one for the pressure measurements, for the current varies rapidly and it is difficult to shift the voltmeter connections quickly enough. By means of spring clamps, the voltmeter terminals were connected to points on the rail, the distance between them for current readings being 15 ft. As readings were made on upwards of 500 bonds, it will only be possible here to summarize the results. For location marks the poles were principally used but any other convenient and permanent objects also served this purpose.

The sample from the log shows the general method of procedure.

LOG OF INDIVIDUAL BOND TEST.

Bond.	Location marks.	Drop on rail, Millivolts.	Amperes in rail.	Drop on joint, Millivolts.	Resistance of joint, Milliohms.
387		21.1	121.5	11.4	.09
388		4.	23.5	50.	2.13
389		.5	3	23.5	7.68
390		5.5	32	4.1	.13
391	Pole 60	10.	58.	19.5	.34

It appears from the results that the joints vary in quality from a resistance less than that of the bond itself to more than 10 times that value. On one section of single track of less than one mile in length, the sum of all bond resistances was over 0.5 ohm, there being 302 bonds in this distance. By repairing one-quarter of the bonds this amount could have been reduced about 85 per cent. Even by repairing but 27 bonds the resistance could have been improved to one-third its former value.

The plan of procedure followed in these tests would be out of the question with most large roads and the attempt has been made many times to make the measurements more quickly. The matter is simplified by the fact that if a bond is bad it is likely soon to be much worse and might as well be repaired at once. For this reason it is not usually necessary to know its exact resistance but rather to know that the resistance is high. The resistance of the bonds will never be uniform, but a certain deflection of the voltmeter can be taken to mean a bad bond. If the contacts be pushed rapidly over the track a throw of the voltmeter needle will show a bad bond if it can be carefully watched. There are various difficulties connected with this plan, but none that cannot be overcome. These difficulties are: (1) to operate the device fast enough to work in with a regular schedule; (2) to make a proper note of the bad joints; (3) and to operate with few observers. The apparatus, also, must be simple and within a reasonable cost.

The easiest plan than can be devised is that invented and operated by the electrical engineer of the United Railways & Electric Co., of Baltimore, Md. A small quantity of paint is squirted on the track by compressed air through a valve controlled by the observer. Another scheme is to make a permanent record of the test by the use of a recording voltmeter, which, instead of being run by clockwork, is driven from one of the car axles. The writer has planned an apparatus which he ventures to suggest, in closing, that would do the work, while being simple and cheap. A small platform is suspended from the rear of the car, and resting on a flanged wheel traveling on the rail. This wheel drives the cylindrical drum of a recording voltmeter. The drum is given a spiral motion along its axis by having a screw thread cut into one bearing with the shaft threaded to fit. In case any location marks are desired on the drums the voltmeter needle can be given extra movement by a current sent through it from a cell of primary battery. The contact with the rail is provided by means of brushes pressed on the rails from the ends of the platform.

After the reading of Prof. Norris' lecture, the meeting resolved itself into a business meeting, the first business presented being the report of the nominating committee. This committee submitted the following names as officials for the next year:

G. T. Rogers, of Binghamton, president; Charles Cleminshaw, of Troy, first vice-president; John Boyle, of Utica, second vice-president; A. H. Robinson, of New York, secretary and treasurer; executive committee, G. T. Rogers, H. H. Vreeland, C. L. Rossiter, T. J. Nicholl, and W. Caryl Ely.

On motion the election of officers as submitted by the committee was made unanimous and the secretary was instructed to cast the ballot.

Mr. Rogers announced that three or four new applications had been received from companies desiring membership in the association.

Upon the very cordial invitation of Mr. Ely it was decided to hold the next convention at Buffalo on the second Tuesday and Wednesday in September, 1900.

Mr. Vreeland then made a few remarks on the desire of the association to have the representatives of the smaller roads in the state, and also the younger men prepare and present papers on live subjects at the next convention. He pointed out that this would be of great value to these men themselves, as it would give them an opportunity to bring their views and opinions before the entire street railway industry of the country.

Upon motion a vote of thanks was extended to the Ithaca Street Railway Co., the city of Ithaca and Cornell University for the very cordial reception and splendid entertainment the association had enjoyed.

The meeting adjourned at 11.40 a. m. to enable the members to inspect the different departments and laboratories of Cornell University.

ENTERTAINMENT.

On Tuesday afternoon following the business meeting the delegates and visitors were taken by the trolley cars to Renwick Beach, on the lake, where they were entertained by a concert by the Ithaca Band, one of the most noted in the state.

The annual banquet was held in the large dining room of the New Ithaca Hotel; the members and guests to the number of 80 sat down about 10 o'clock. The tables were tastefully decorated with flowers and ferns, and the Ithaca Band furnished the music. A most enjoyable evening was spent, and when the last course had been served, President Rogers called for order, and in his usual humorous vein explained why the convention was held at Ithaca this year, and complimented the local street railway management on the reception accorded the delegates and their friends, the supply men. He then introduced Mr. DeForest Van Vleet, attorney for the Ithaca Street Railway Co., as toastmaster. Mr.

Van Vleet accepted the position in a very happy manner and introduced Pres. E. G. Wyckoff, of the local street railway, who responded to "Our Guests," saying that he was glad to see among the delegates a number of Cornell graduates. Col. T. G. Williams, secretary and treasurer of the Brooklyn Heights R. R., and a native of Ithaca, followed. He spoke to the sentiment "Our Hosts." Col. A. W. Cole, chairman of the Railroad Commission, next spoke of the reasons for his being present and of the harmonious relations existing between the commissioners and the steam and street railroads of the state. Prof. Cuthbert W. Pound spoke of the great change during the last 50 years in the status of college-bred men in the railway field, and of the special work done at Cornell. Hon. Thomas F. Grady responded to "The Empire State," and sustained his reputation as the silver tongued orator. Pres. Frank J. Sillman, of the Pennsylvania Street Railway Association, expressed his pleasure at being able to be present at this New York State meeting. Prof. E. J. Durand next spoke of "Marine Engineering at Cornell," and was followed by Hon. W. Caryl Ely, who responded to the toast, "The Association." Dr. R. H. Thurston spoke of the fact that the course in electrical engineering was the first of the special courses to be developed at Cornell, having been authorized as early as 1870, and dwelt at some length on the work of Sibley College. Pres. H. H. Vreeland, of the Metropolitan Street Railway, New York, discussed "Rapid Transit" in a brief speech.

Wednesday the delegates went to the University Campus by trolley cars, the "Duplex" cars owned by the company being put at the disposal of the party. After viewing the gorges and other interesting points on the line a business meeting was held in the Sibley College lecture room. After this session the University buildings were inspected, and at 3 o'clock the party started for the steamer landing, where they embarked for a trip up Lake Cayuga. Refreshments were served on board, and this proved a most enjoyable trip.

RENWICK BEACH PARK.

EXHIBITION NOTES.

The Morris Electric Co., of 15 Cortlandt St., New York,, occupied the parlors on the first floor of the Ithaca Hotel with an exhibit which included a full line of everything handled by this concern. Among the important specialties shown in this exhibit may be mentioned samples of Anderson line material, Keystone instruments, General Equipment Co. circuit breakers, Rhoades' bell and register cords, micanite rings, seamless structural steel gongs, pole fittings, National Manufacturing Co. car heaters, spiral bearings, R. Thomas & Sons' porcelain insulators, Hercules rail joints, Morris drop-forged bonds, and series cluster lamp bases.

The American Standard Rail Joints were exhibited by the Cheholm & Moore Manufacturing Co., of Cleveland. O. This concern, which is the successor to the American Rail Joint & Manufacturing Co., has introduced a number of improvements with the present season, which made an interesting exhibit. One of the notable features of this display was the locking device for rail joints which lies underneath the rail and when driven up makes one continuous plate to rest upon the ties. Col. W. E. Ludlow, in charge of the rail joint department, represented the company.

The Weber Railway Joint Manufacturing Co. had an interesting display of the different forms of rail joints which it makes. These included girder joints, T-rail joints, insulated joints, and compromise joints.

The Ramapo Iron Works, of Hillburn, N. Y., licensee of the American Brake Shoe Co., exhibited a line of "Diamond S" brake shoes which are well and favorably known among electric railway men. These shoes are used extensively on foreign as well as American electric railways.

The General Electric Co's. exhibit consisted of a complete line of catalogs covering the diversified products made by that concern, being far too numerous to describe.

The Edison-Brown plastic rail bonds were exhibited by James Hollowood, of New York, superintendent of the shops.

THOSE IN ATTENDANCE.

G. T. Rogers, president Binghamton R. R.
John B. Rogers, treasurer Binghamton R. R.
W. Caryl Ely, president International Traction Co., Buffalo.
J. H. Belser, Buffalo.
H. S. Cooper, Schenectady.
J. A. Wilcox, superintendent Corning & Painted Post Street Ry.
F. G. Maloney, superintendent Maple Ave. Ry., Elmira.
W. W. Cole, general manager, West Side Street Ry., Elmira.
H. H. Vreeland, president Metropolitan Street Ry., New York.
C. E. Warren, secretary Metropolitan Street Ry., New York.
H. A. Robinson, solicitor Metropolitan Street Ry., New York.
F. D. Rounds, general superintendent Metropolitan Street Ry..
M. G. Starrett, chief engineer Metropolitan Street Ry.
W. A. Pearson, assistant chief engineer Metropolitan Street Ry.
E. J. McGuire, civil engineer Metropolitan Street Ry

W. B. Reed, engineer maintenance of way, Metropolitan Street Ry., New York.
Thomas Millen, master mechanic Metropolitan Street Ry
A. C. Tully, purchasing agent Metropolitan Street Ry.
Orin J. Root, Metropolitan Street Ry., New York.
Henry Wells, Metropolitan Street Ry., New York.
A. F. McCabe, Metropolitan Street Ry., New York.
Don R. Almy, Metropolitan Street Ry., New York.
R. L. Post, Ithaca Street Ry.
J. A. Mortimer, treasurer Ithaca Street Ry.
DeForest Van Vleet, Ithaca Street Ry.
Chas. G. Hoyt, Ithaca Street Ry.
W. A. Gordon, Ithaca Street Ry.
Charles Schoepflin, Gardenville & Ebenezer Ry.
Louis J. Riggs, Canandaigua Electric Light & Street R. R. Co., Shortsville.
M. M. Fenner, manager Dunkirk & Fredonia R. R.
T. C. Cherry, assistant superintendent track Syracuse Rapid Transit Co.
A. B. Bond, Syracuse Rapid Transit Co.
Marston R. Cockey, John A. Roebling's Sons Co.
J. N. Du Barry, jr., Consolidated Car Heating Co.
George C. Ewing, Morris Electric Co., New York.
A. W. Harvey, Chas. A. Schieren & Co., New York.
S. H. Dailey, Weber Rail Joint Manufacturing Co.
F. T. Savage, Hildreth Varnish Co.
P. J. Meaney, Trunk Line Association, New York.
H. M. Shaw, Eastern Carbon Works, Rahway, N. J.
W. S. Silver, W. S. Silver & Co., New York.
A. E. Dresser, Ft. Wayne Electrical Works, Syracuse.
C. W. Underwood, Westinghouse Electric & Manufacturing Co., Buffalo.
F. C. Schmitz, Continuous Rail Joint Co., Newark, N. J.
T. H. Kite Powell, Duplex Car Co., New York.
Paul T. Brady, Westinghouse Electric & Manufacturing Co., Syracuse.
G. W. Swan, John A. Roebling's Sons Co.
F. M. Brown, General Electric Co., Syracuse.
F. M. Nellis, Westinghouse Air Brake Co., New York.
C. N. Wood, Boston.

POOL ABOVE ITHACA FALLS.

R. E. Danforth, superintendent Buffalo Ry.
C. Loomis Allen, general manager Syracuse Rapid Transit Co.
H. J. Clark, Syracuse Rapid Transit Co.
J. P. E. Clark, Binghamton R. R.
J. F. Lavien, superintendent Canadaigua Electric Light & Street Railroad Co.
W. Judson Smith, Syracuse, Lakeside & Baldwinsville Ry.
H. S. Newton, manager Syracuse, Lakeside & Baldwinsville Ry.
R. A. Dyer, jr., superintendent Auburn City Ry.
T. J. Nicholl, vice-president Rochester Ry.
H. A. Nicholl, superintendent power Rochester Ry.
A. Green, master mechanic Rochester Ry.
C. J. Kelsey, claim agent Rochester Ry.
H. C. Evans, Lorain Steel Co.
E. W. Throckmorton, Smith, Gray & Co., New York.
Albert C. Gahl, Burnet Co., New York.
A. C. Vosburgh, New Process Raw Hide Co., Syracuse.

A. W. Cole, N. Y. R. R. Commission.
C. R. Barnes, engineer, N. Y. R. R. Commission.
E. C. Stewart, Ithaca.
Dr. R. H. Thurston, Cornell University.
Prof. H. H. Norris, Cornell University.
Prof. C. W. Pound, Cornell University.
Thomas F. Grady, Albany.
Jared T. Newman, Ithaca.
H. J. Ryan, Cornell University.
Frank Silliman, jr., president Pennsylvania Street Railway Association.

Dividends on the preferred stock of the Chicago Union Traction Co. will begin in October at the rate of 5 per cent, being 1¼ per cent quarterly. Net earnings are now said to be at the rate of about 3 per cent on the common stock.

PROGRESS OF THE JAMAICA BAY ROAD.

Work on the new electric road between Brooklyn and Rockaway Beach is being rapidly pushed Considerable valuable property along the water front on Jamaica Bay has been conveyed to the syndicate building the new railway, of which Patrick J. Flynn is the head. As the plans for the syndicate's roadway across Jamaica Bay call for one 70 ft. wide, containing, beside the tracks for the cars, two bicycle paths and a 20-ft. wide macadamized roadway, a splendid route to the seashore, will be opened. It will build up all the marsh lands along the line and enable the sportsmen to reach their favorite fishing and shooting grounds more easily than at present. Already several club houses have been erected on the meadows on the line of the new road. Several hundred piles have been driven for the trestle across the Raunt and across Goose Creek.

NO MUNICIPAL OWNERSHIP FOR CLEVELAND.

The question of municipal ownership of street railway lines received a setback last month in Cleveland, O., where Law Director Hogsett submitted an adverse report on the resolution offered in the city council, providing for the building by the city of street car tracks and leasing them to the highest bidder. He said:

"I know of no law authorizing municipalities in Ohio to either build, maintain, or operate street railroads, either in whole or in part, and am therefore unable to comply with the terms of the within resolution by preparing an ordinance which in my judgment would be valid."

The report of the law director was accepted, which ends the movement for municipal ownership.

CLAMBAKE OF SYRACUSE RAILWAY MEN.

The employes of the Syracuse Rapid Transit Railroad Co. gave a clambake at the Iron Pier at that city on August 24th, which was a credit to all concerned. Over 400 people, including the railway men and their friends, were served at the two appointed hours.

There were two pits in which the food was cooked, both being 12 ft. in diameter; the first was opened at 4 o'clock and the second three hours later. At each serving there were about 200 people.

Music was furnished by Gaylord's City Band, and in the afternoon there was a ball game between the North and South Side employes of the road, with General Manager C. Loomis Allen as umpire.

UNDERGROUND WIRING OF THE TOLEDO TRACTION CO.

The Toledo Traction Co., which also does the commercial lighting, has but recently completed the work of placing underground its lighting mains and feeder wires in the business district of the city. The city council of Toledo on Aug. 31, 1896, passed an ordinance requiring that wires of every description, with the single exception of trolley wires, within the district bounded by Summit, Monroe, Michigan and Cherry Sts., be placed underground by Dec. 31, 1899. This action of the council had been preceded by a great deal of agitation of the subject, and the ordinance was anticipated by the Traction company, as it began its first conduit in September, 1895.

The conduit construction during the first two years, 1895 and 1896, was done by the National Underground Cable Co., of New York, as contractor; since then the Traction company has done the work itself, completing the system Aug. 1, 1899. The telephone, city fire telegraph, lighting and the street railway feeder wires within the district named are now underground and the telegraph companies will soon commence the work of placing their wires in conduits.

The first of the Traction conduits laid were those in Madison St.; in 1896 those in Summit St.; 1st Alley and 2d Alley were put down, and the system has been extended each summer since till it now comprises about 250,000 ft. of cable ducts for the various cables and about six miles of Edison tubes for the lighting system. At the present time about one-half of the conduits are filled with cables.

MONROE ST., TOLEDO, SHOWING TRENCH WITH NINE DUCTS.

The underground district, which is approximately half a mile square, and the location of the conduits and mains, are shown in the maps. Fig. 1 is a plan showing the Edison tubes and giving the number of ducts in each section of the conduit work. The Edison tubes are for the three-wire direct lighting circuits and some of the power circuits. These tubes are in three sizes; the heavy lines in Fig. 1 indicate "400 mains," which are 2½-in. wrought iron pipes, carrying three 400,000-c. m. solid copper wires (about ⅝ in. dia.) placed at the corners of a triangle, 1 in. c. to c.; the light lines are "250 mains," 2-in. pipes with three 250-000-c. m. wires; the dotted line is a "200 main," a 2½-in. lead pipe with three 200,-000-c. m. stranded wires. These tubes are all 20 ft. long, the wires being 20 ft. 4 in. long, giving a projection of 2 in. at each end. The tubes were made by the General Electric Co. The coupling clamp, coupling boxes, elbows, and Y's are all the standard General Electric. Six-way junction boxes are used. The 200 main is a "tie-in" to connect the systems of tubes. For service mains 1½-in. tubes with 120,000-c. m. wires are used.

The direct current three-wire lighting district is to be limited to a radius of a mile from the power house and the mains are in all cases to be connected to the underground system. There are now on this system the equivalent of 40,000 16-c. p. lamps, arc lamps being taken as equivalent to 11 incandescents. Inside of the underground district are about 1,000 h. p. of motors, mostly in sizes from ½ to 10-h. p., which are operated on a 226-volt circuit; this is obtained by tapping the positive and negative wires only, the lighting pressure being 113 volts. Outside of the underground district are other motors, aggregating 1,000 h. p., for which the Toledo Traction Co. supplies power; out to a mile from the power house the current is supplied over a metallic circuit connected to the underground system; beyond the mile limit power motors are placed on the railway circuit.

For passenger elevator service within the underground district a special 500-volt line with two 500,000-c. m stranded cables is laid.

The alternating current lighting system now comprises about 30,000 16-c. p. lamps.

For carrying all the feeders, the special power cables and the alternating current feeders, conduits are laid as indicated in Fig. 1. These ducts are of No. 26 sheet iron pipes, lined with Rosendale cement, ½ in. thick, giving an internal diameter of 3 in. They and the cables were furnished by the National Underground Cable Co. and by the American Electrical Works, of Providence, R. I.

The street railway feeders are shown in Fig. 2. There are 12 500,000-c. m. stranded paper insulated cables, of 31 No. 9 copper wires. Four of these are carried up on an iron pole at Michigan and Madison Sts. and supply the lines in the southwestern part of the city; two are for the northwest lines; five extend down Summit St. to Swan Creek and are connected to iron armored stranded submarine cables to take the current south of the creek from which point the feeders proceed overhead to supply the south lines; one feeder, known as the intersectional feeder, supplies current to sections of the three north and south railway lines which cross the underground district, this feeder being the only one brought above ground within the district.

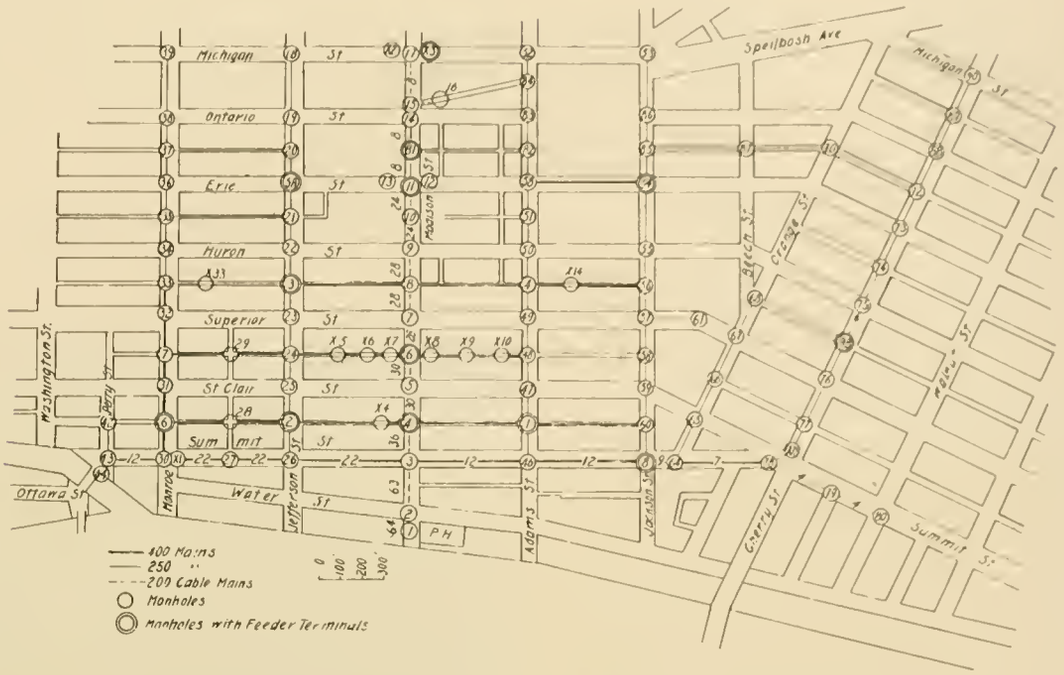

FIG. 1. UNDERGROUND THREE-WIRE EDISON SYSTEM—TOLEDO TRACTION CO.

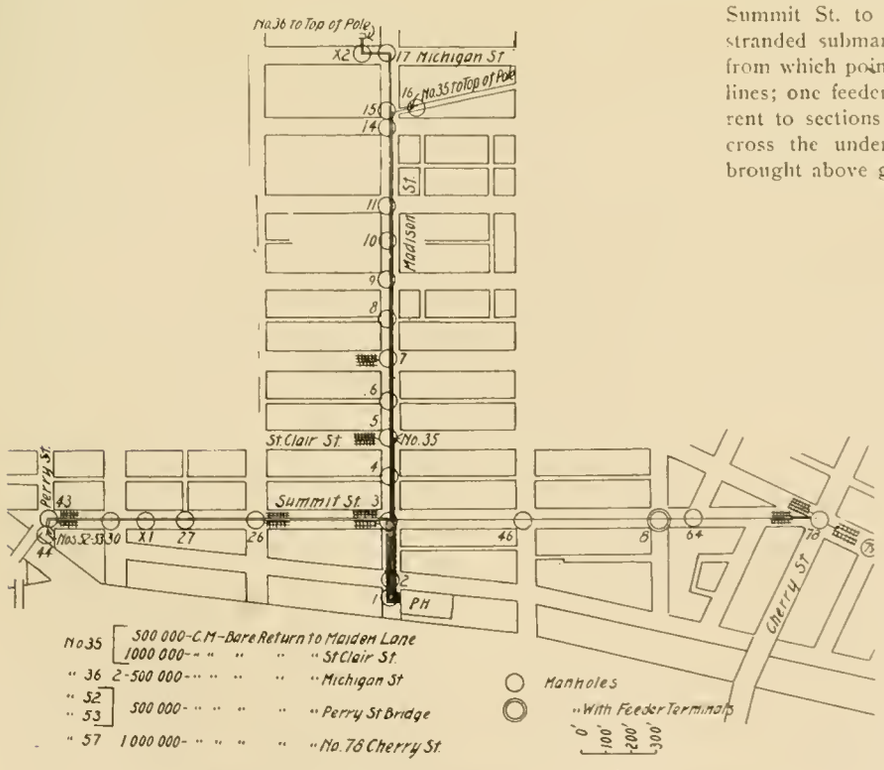

DIAGRAM OF TRACK RETURN WIRES TOLEDO TRACTION CO.

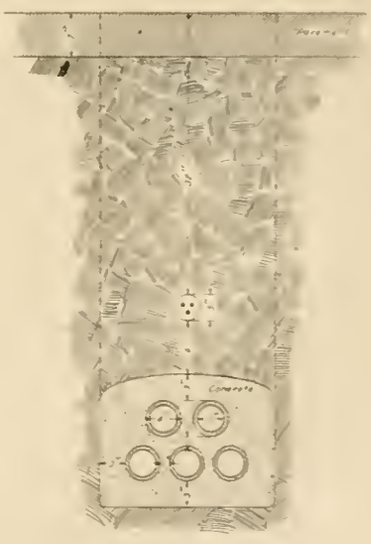

FIG. 4—SECTION OF TRENCH.

The line on Cherry St. (the northern boundary of the district) is fed from overhead feeders carried along Walnut St. All the East Toledo railway and lighting feeders, the feeders supplying current to the northern part of the city and to the Casino are carried overhead on Water St., this being outside the underground dis-

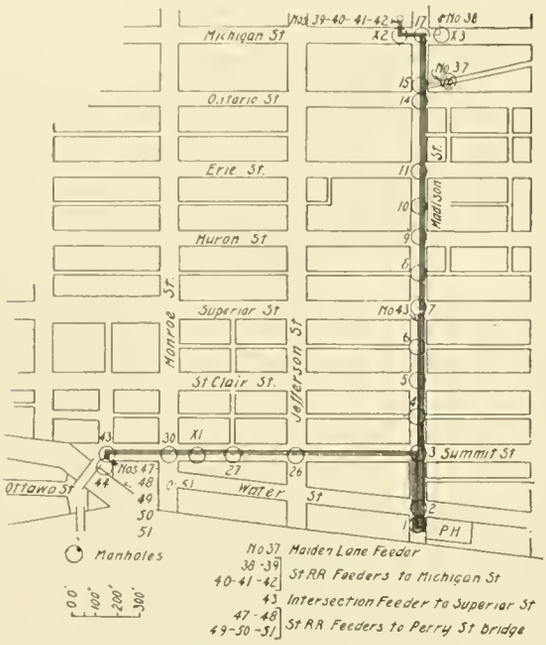

FIG. 2 DIAGRAM OF RAILWAY FEEDER WIRES.

trict. The East Toledo lines are carried under the Maumee River as submarine cables. The Casino, owned by the Traction company but leased, is a pleasure resort on Lake Erie, 4.69 miles from the power house, and has two No. 00 wires that carry alternating current at 2,000 volts for lighting. This current is generated at 1,000 volts and raised in step-up transformers to 2,000.

Rather an interesting feature of the system is the booster used for the railway line to the Casino. This is a 100-kw., 135-volt, belt-driven lighting machine which is run as a booster during the Casino season; the shunt fields are removed and series fields, wound for the purpose, put on instead. At the end of the season the old fields are replaced and the machine used for lighting during the winter.

A series of readings taken one Sunday afternoon when the traffic to the Casino was quite heavy, shows the reasons for using this booster. The voltage varied from 520 to 440, the load being from 200 to 1,100 amperes. The booster raises the voltage 1 volt for each 3 amperes.

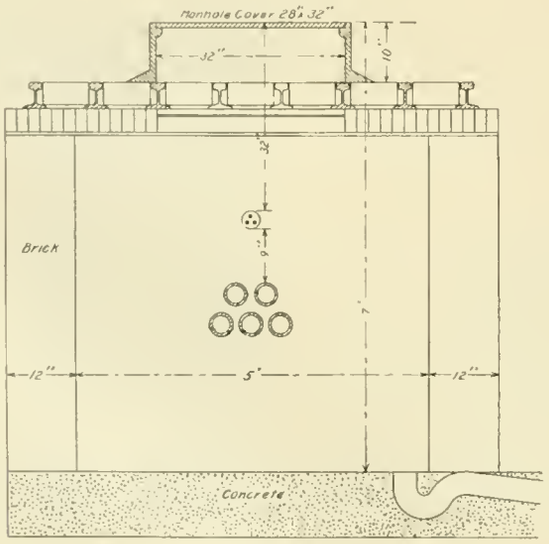

FIG. 3—SECTION OF MANHOLE

There are in all 103 manholes for giving access to the ducts. These vary in size according to the number of junction boxes, etc., it was necessary to install; most of them, however, are 5 x 5 ft. inside and 7 ft. deep, though one is 9 ft. and one 12 ft. deep. One of the manholes is shown in section in Fig. 3; for a 5 x 5 x 7 manhole 2,250 brick are required. For the roof sections of 60-lb. T-rail 7 ft. long are laid across the walls spaced so that bricks may be supported on the flanges, after being cemented a second layer is put on the rails, being laid at right angles to the first set. The manhole cover box is 28 x 32 in. inside. Sewer connections are provided for the manholes where possible; two near the power house are below the river level and are drained by steam syphons.

Fig. 4 is a section of the trench between manholes. The Edison tubes are placed 32 in. from the street surface, about 6 in. below these are the conduits, which are arranged 1 in. apart and filled about with concrete, there being 3 in. of concrete at the top, sides and bottom. The ducts are arranged, according to the total number, in 8 rows of 8, 6 rows of 7, 5 rows of 6, etc.

No. 3 manhole was originally 6 x 8 ft., but was enlarged in Sep-

FIG. 5—REBUILDING MANHOLE NO. 3

tember, 1898, to 10½ x 13 ft.; Fig. 5 is a view taken during this work.

The cables now in place aggregate in length: Street railway feeder cables, 28,000 ft.; street railway returns, 13,825 ft.; 500-volt elevator circuit, 2,386 ft.; 1,200-volt alternating feeders, 7,278 ft.; 6,500-volt arc 32,000; three-wire feeders for Edison tube system, 70,422; total 153,911 ft.

Since the underground feeders have been in use there has been only one interruption, which affected three or four customers for six hours only, which was caused by a burn-out due primarily to a fault in construction. While the expense of the underground work has been very heavy, it has the advantages that there are no poles to maintain and no danger from storms.

New cables will be added as the service demands, and at the present time the company contemplates putting in underground series arc cables for lighting the down-town district.

The underground work is now in charge of Mr. E. J. Bechtel, superintendent of construction. During the construction it was under the supervision of Mr. G. A. Cooke, assistant superintendent of the company, to whom we are indebted for the accompanying illustrations. The superintendent of lighting is Mr. W. S. Smith.

During last month the Atlanta Railway & Power Co. and the Atlanta Railway Co. made contracts amounting to more than $100,000. This expenditure represents the outlay for extensions, equipment and improvements.

The Madison St. car barns of the Allentown (Pa.) & Lehigh Valley Traction Co. was burned on August 30th, together with 10 cars, practically new, and two snow plows. The loss is estimated at $35,000 to $40,000, partially covered by insurance. The origin of the fire is unknown.

HALF FARES.

The new electric road from Toledo to Norwalk will issue 1,000-mile books at a rate of $12.50, or 1¼ cents a mile.

The Long Island Electric Railway Co. reports for the year ended June 30th gross earnings of $86,588, and net earnings of $12,987.

The South Side Elevated of Chicago carried an average of 52,599 passengers a day in August as against 41,770 in the same month of 1898.

The Joliet (Ill.) Street Railway Co. ran its first car to Rockdale on August 18th, taking a party of newspaper men and a few others over the route.

The Alton (Ill.) Railway & Illuminating Co. and the Alton Railway, Gas & Electric Co. have consolidated, and the new company has a capital of half a million.

The Macon (Ga.) & Indian Spring Electric Street Railway Co. has just completed a new power house on which the road has been running since August 29th.

A trust deed for $500,000 to the Royal Trust Co., of Chicago, has been placed on record by the Citizens' Traction Co., of Oshkosh. It is virtually a first mortgage bond.

Mr. John A. Rigg, president of the Reading (Pa.) Traction Co., has announced the company decision to increase the wages of the conductors and motormen 8 1-3 per cent.

The Chicago City Railway Co. has declared its regular quarterly dividend of 3 per cent, payable September 30th to stockholders of record at the close of business September 15th.

The Jackson (Miss.) Electric Railway Co., with five miles of track and operating seven cars, was opened for regular traffic on August 1st.

An exchange says that the Germans call their new electric cabs "automobiletaxameterdroschken." By the time they get through calling them, the cabs are generally out of sight.

The Detroit, (Mich.) Plymouth & Northville Electric Ry. was put in operation to Northville on September 1st, and on that day the town held a celebration in honor of the event.

The Wilkesbarre & Wyoming Traction Co. notified its motormen and conductors of an increase of 10 cents a day in their wages. They will now get $1.80. The increase is unexpected.

The Willimantic (Conn.) Street Ry. charter, which was owned principally by Judge John M. Hall and General Boss, was sold last month to a Boston syndicate represented by J. M. Pettis.

A number of the men employed in the car barns of the Metropolitan Railroad Co., of Washington, D. C., resigned last month on account of an increase in their working hours from 9 to 12.

The management of the South West Missouri Electric Railway Co. has announced that Midway Park, which was formerly a great resort for Joplin and Webb City people, will again be reopened.

The Market Street Railway Co., of San Francisco, recently donated $1,500 to the Red Cross Society of that city for the relief of the soldiers of the First California Infantry just returned from Manila.

The earnings of the United Traction Co., of Pittsburg, Pa., for July, were as follows: Gross earnings, $161,474; operating expenses, $66,646; net, $94,828; interest, rentals, etc., $53,294; surplus, $41,531.

The formal opening of the new street railway in Fond-du-Lac, Wis., took place on the evening of August 12th. Lakeside Park was the scene of the festivities and a brilliant display of fireworks was given.

The Mobile Street Railroad Co. is putting in a large McIntosh & Seymour engine of 500 h. p., together with a direct coupled generator. This has been demanded on account of the large increase in the traffic of the road.

The East Side Electric Ry., of Kansas City, Mo., is now entirely completed with the exception of installing the engine and generator at the power station. The road is expected to be in operation by September 25th.

The Goshen (Ind.) & Eastern Traction Co., which is applying for a franchise intends to build its road on private right of way parallel to the highways. The only franchise asked is to cross the highways at different points.

Some maliciously disposed person has been working injury to the Fond du Lac Street Railway Co. during the past week by burning holes in the seats of the new cars. There are one or two holes burned in nearly all of the cars.

All of the double truck cars of the Union Traction Co., of Philadelphia, are to be equipped with air brakes. The order for the attachment of the brakes to a large number of cars has been given out and they will be applied at once.

The new electric railway from Ypsilanti, Mich., to Saline is expected to be in running order by September 7th, and the management expects to give a big celebration in these cities on the occasion of the opening of the road.

Permission was granted the Dallas (Tex.) Consolidated Electric Street Railway Co. to suspend service of its San Jacinto line for 90 days with the understanding that both the city and the street railway are to begin improving the street.

The new street railway, of Petersburg, Va., which is owned and operated by the Southern Railway & Development Co., was opened for traffic on August 17th. The road when completed will cover 9¼ miles, about half of which is now finished.

Superintendent Ellis, of the Rockford (Ill.) Railway, Light & Power Co. put a new scale of wages in force on September 1st for motormen and conductors. This will increase the wage account of the company about $3,500 for the coming year.

Judge F. W. Downs, of Downsville, N. Y., celebrated the opening of the Downsville branch of the Glenwood street car line by driving the last spike, which was a golden one, in the rails on September 2d. Formal exercises attended the opening.

The first trip over the Syracuse (N. Y.), Lakeside & Baldwinsville R. R. from Long Branch to Baldwinsville was made on August 26th, by Superintendent Newton, Attorney Frederick Pierson and Attorney Wills of the Brooklyn Rapid Transit Co.

A Chicago syndicate which already owns large interests in the South is reported to have secured options on all the electric railway systems and the two inclined railways in Chattanooga, Tenn., and it is expected that a purchase will soon be made.

The work of double tracking the line between Cleveland and Akron was begun this spring and some 8 miles of the 27 owned by the old A., B. & C. company have been completed. The rails used were 70-lb. T, laid on white oak ties 6 in. x 8 in. x 7 ft.

The Cleveland Electric Railway Co., the Big Consolidated, has recently put in operation 50 new open cars built by the Brill company; they are 14-bench cars mounted on Brill double trucks and equipped with two 35-h. p. Westinghouse motors each.

A Brooklyn trolley car caught fire last month in Fulton St., near the Brooklyn Bridge. Flames shot up through the floor and the pasengers formed a bucket brigade, getting the water from a neigh-

boring grocery store. The flames were soon quenched and the disabled trolley was shoved to its destination by a following car. The damage was slight.

During a storm on Saturday, August 26th, at Defiance, O., lightning burned out the armatures of the generators in the power house of the Defiance Light & Railroad Co. which necessitated shutting down the road for several days until repairs could be made.

It is said that William C. Whitney is now one of the largest stockholders of the New York Manhattan Elevated, and that an arrangement has virtually been agreed upon by which Manhattan will be operated as part of the Metropolitan system under lease.

The Northern Ohio Traction Co., which controls the Akron, Bedford & Cleveland R. R. and the Akron Street Ry., has authorized an issue of $3,000,000 bonds, $1,000,000 of which is to retire existing indebtedness and the rest for extensions and improvements.

The United Railways & Electric Co., of Baltimore, has ordered 50 new cars to be delivered this fall. The Brownell Car Co., of St. Louis, will build the bodies of the cars, the Baltimore Car Wheel Co. the trucks, and the Westinghouse Co., of Pittsburg, the motors.

A number of the conductors and guards of the Manhattan Elevated, of New York, are mourning the loss of their beards, the edict having gone forth that all beards must be shaved off, and only men with smooth faces will be employed after November 1st.

Three of the principal street railway systems in Seattle have become the property of a Boston syndicate headed by Stone & Webster, and a fourth road will be transferred to the same people in a few days. The purchase price for the four lines is about $2,500,000.

For nearly a year the Snoqualmie Falls Power Co., of which W. T. Baker, of Chicago, is president, sought entrance into Tacoma. It has recently transpired that the Snoqualmie company has sold the bulk of its power to the street railway combine of Tacoma and Seattle.

Thomas Griffith, of Pittsburg, has filed a bill in equity in the United States Circuit Court against the Duquesne Garden Co. and the Consolidated Traction Co. He charges that he is the inventor of a patent ventilator which the defendant companies are using without any right.

The Union Traction Co., of Anderson, Ind., is negotiating for a large tract of land four miles east of Anderson to convert into an up-to-date park. The ground, thirty acres, has a frontage on White river, and is the most picturesque place between Muncie and Anderson as to river scenery.

An unusual accident at Quincy, Ill., resulted in the death of a conductor. He was on the ground in front of the car for the purpose of reversing the trolley pole, when his arm accidentally struck the controller handle, causing the car to jump forward, knocking him down and running over him.

The Brooklyn Rapid Transit Co. has closed a contract with the Kings County Electric Light & Power Co. for the power necessary to operate the electric elevated railway of the former company. The new power station of the latter company has just been completed and is equipped with machinery of the Tesla system.

President Rossiter, of the Brooklyn Rapid Transit Co., has told a committee of Flushing citizens who petitioned the company for a 5-cent fare to Flushing, that this branch of the road is not yet on a paying basis, and a reduction of the fare would be a bad business policy. He offered to supply monthly commutation tickets at about a 5-cent rate.

The annual report of the Oneida (N. Y.) Street Railway Co., which was filed last month, shows the total receipts were $3,715.10 and the operating expenses $2,974.83. The sum of $220.74 was expended in taxes, leaving a net income of $316.98 and a balance on hand of $386.19. The total number of passengers carried during the year was 79,615.

President Herbert H. Vreeland, of the Metropolitan Street Railway Co., of New York, issued invitations to all the heads of departments of his company, to be his guests on Saturday, August 12th. He arranged a Rhode Island clam bake to take place at the Tonetta Outing Club grounds near Brewster, where Mr. Vreeland has his country home.

The officials of the United Railways Co., of St. Louis, have decided that they will be compelled to change the motive power of the Broadway line from cable to electricity at once, as the track is said to be in such bad repair that it will not last through the winter, although it was intended not to begin the work of reconstructing the line until spring.

The annual report of the Citizens' Street Railway Co., of Fishkill, N. Y., gives the following figures for the year's business ending June 30th: Gross earnings from operation, $34,012; operating expenses, $22,870; net earnings from operation, $11,142; other income, $412; gross income, $11,554; fixed charges, $8,306; net income from all sources, $3,248.

A fast express service is to be established on the electric line between St. Paul and Minneapolis, and it is proposed that the company be authorized to charge 15 cents fare between the two cities on the fast cars. The present service on the interurban line is to be preserved, and the fast cars will pass the slower trains on a series of four switches between the present tracks.

Benjamin S. Lawlor, of New York, who constructed the engines of the battleship Maine and built the first locomotive of the New York Elevated system, has been in Syracuse, N. Y., for a year or more perfecting a new electric compressed air motor, designed to operate street railway cars. He claims his invention will effect a saving of 25 to 30 per cent over electric motors.

An electric pay car has been put into service on the Montreal Street Ry. It is closed at both ends, the entrances being at the side. These are two in number, the idea being to have the men go in one way, get their pay, and make their exit by the other. The inside fittings are not unlike those of the average bank in miniature, there being gratings, a paying window, etc.

It is stated that arrangements have been made whereby the cars of the Chicago & Milwaukee road will connect with the Northwestern Elevated road by means of an inclined plane and run around the Union Elevated loop in Chicago. The Chicago & Milwaukee cars will connect with the Northwestern Elevated over the tracks of the Chicago, Milwaukee & St. Paul R. R.

A firm of Indianapolis brokers has devised a scheme to unite all the electric railways in Indiana in one system, making divisions of the different branches. The firm has gone in a private car over the various electric roads with a party of capitalists they expect to interest in the scheme. The understanding is that the owners of the Indianapolis Street Ry. are also interested in the scheme.

The annual report of the Metropolitan Street Ry., of New York, for the year ending June 30th shows the following figures: Gross earnings, $13,158,630; operating expenses, $6,408,711; operating ratio, 48.70 per cent; surplus, $6,749,919; fixed charges, $4,477,757; net earnings, $2,272,162; other income, $366,893; net total, $2,263,055; dividends paid, $2,471,675; surplus over dividends, $167,380.

The Cleveland City Railway Co., locally known as the Little Consolidated, is now building a new car house at Rocky River, the terminus of its Detroit St. line. The building is of brick, 84 x 340 ft., divided into three bays by brick walls. There are three tracks in each bay. A small repair shop will occupy a portion of the building. This company has recently ordered 12 closed cars from the J. G. Brill Co.; they measure 30 ft. inside and are mounted on double trucks. Brill trucks are used under 10 of these cars and Peckham tracks under two.

THE CLEVELAND STRIKE.

Mr. Henry A. Everett, president of the Cleveland Electric Railway Co., has very kindly furnished the "Review" with the following statement concerning the relations of the employes with the management and the two strikes:

"The writer became the president, and undertook the management of the Cleveland Electric Railway Co. in January of this year. Some time in the December preceding, the motormen and conductors began to agitate the question of organizing a union, and the matter was in progress when the management of the road changed.

"About eight weeks before the strike in June, the scheduled time of certain of the lines of the company was changed so as to increase the speed, and increase the number of trips that each operative would make, by one. However, the hours which they run were not increased. This was done to accommodate travel and to meet the demand which the public was making for more rapid transportation. We believe that but for the formation of this union this change would not have been considered a serious matter with the men, for, while they made one extra trip, they made fewer stops in each run, for it furnished a large number of additional cars and runs to carry the same number of passengers. But this was seized upon and made as obnoxious as possible. The men would run their cars slow up to certain points, and in that way bunch the cars, and then run at a very rapid and unlawful rate of speed at other points, and by thus running rapidly make it appear that it was necessary in order to make their time. We knew this was going on. The city authorities began to arrest the men because of their running at an unlawful rate of speed. In every instance the company paid the fines of the men and protected them, although it knew that the men were not acting loyally.

"One example will serve as an instance: A friend of the company was upon one of the cars when a policeman in citizens' clothes got upon the car. The motorman remarked to the friend, "That's a policeman; I'll give him a run for his life," and he ran the car at its highest possible rate of speed, and, of course, was arrested. The company paid his fine, knowing all of these facts.

"This went on until the company returned to the old schedule, which was done before the strike. No other complaint was being made at that time to the company by the men.

"On the 10th of June of this year the employes, as Division No. 106 of the Amalgamated Association of Street Railway Employes of America, submitted to the company a proposed agreement, which contained no grievances set forth which they desired to have righted. This agreement the company refused to sign, and the men struck. After two weeks an agreement was entered into through the intervention of a committee appointed by the city council of Cleveland, the substance of which was given in the "Review" for July last. You will observe that this made no mention anywhere of union or non-union men; it provided that 80 per cent of the striking employes were to be returned, and that 20 per cent of the force should be new men employed during the strike. The old men agreed to treat the new men loyally, and it was agreed that the company would adjust the men and their runs as speedily as possible.

"No provision was made in the contract as to when men's names should be placed upon the run-boards in the various barns, but in good faith the company, just as soon as it possibly could, assigned to the old men their runs and placed them upon the run-boards, leaving every fifth place vacant to be filled by the new men, expecting to take time enough to select from the new men those most competent and best fitted for the work.

"In less than three days it became apparent to the company and its managers that the old men came back with the full determination to drive the new men out of their positions, and before a week had expired every man connected with the company knew that if the new men's names were placed upon the run-boards they would be driven out, with the expectation on the part of the old men that they would be moved forward and those places filled by the old men. As a consequence the company refused, as it then believed, and still believes, it had a right to do, to place the names of the new men on the run-boards in those runs.

"Also, in cases where for any reason a new motorman or conductor could not take out his run, the old men refused to go out on the run with a new man on the car, insisting that under the contract union men were not required to work with these new men. The company concluded that in these cases there was only one thing to do in order that it might maintain discipline and properly operate its road, and that was to discharge men who thus refused, and it did discharge several for that reason.

"This was the condition of things when, on the 17th day of July, the old men, without presenting, by committee or otherwise, a single complaint or grievance, left the company's employ, and from that day to this have not officially given any notice to the company or made any complaint, but we know that their grievance was that we would not place the names of the new men on the run-boards, and that we insisted upon their working with these men when it was necessary.

"To show you that they did intend to drive the new men out of the employment of the company, it is only necessary to state that when the old men went out of the employ of the company, 12 of the new men were in the hospital, being taken care of by the company, who have received their injuries either directly or indirectly through these men after that settlement was made.

"Since the men went out the last time the company has absolutely refused to either negotiate with them or arbitrate, and has simply filled up its complement of employes and has operated and is operating, its road without the old men, and will so continue from this time on. You have only to read the newspapers of Cleveland to know the violence that has been used to compel the company to yield to these men, and that the violence only ceased when the military compelled it. Then the boycott was adopted, and the newspapers will fully inform you what has been and is being done by respectable citizens and merchants of this city in relation thereto."

The means adopted by the strikers and their sympathizers to gain their ends were described in the "Review" for August. It is difficult to fix a date for the end of the strike; the company now has a full complement of men and the regular schedules have been in operation since August 1st. The boycott declared against the company and intimidation of passengers by placing torpedoes and bombs on the tracks caused a reduction in receipts, but the traffic has been steadily increasing, and within a few weeks will probably be as heavy as before the trouble.

Parties concerned in the assaults on cars are promptly arrested and fined; the fines range from $10 and costs to $25 and costs, the usual charge being "disorderly conduct," which includes the offence of crying "scab" at the non-union men.

CITIZENS TEAR UP TRACKS.

The citizens of Pontiac, Mich., and the Pontiac & Sylvan Lake Railway Co. have been at odds for some time over the question of removing some of the company's track, and the dispute culminated last month by the citizens tearing up about a mile of track before an injunction could be obtained to restrain them.

The trouble between the street railway company and the city is of long standing. Under the franchise granted to the Sylvan Lake Co., and acquired by the Detroit and Northwestern, the company is obliged to pave between the tracks, also a foot on each side, whenever the city sees fit to pave the streets. A franchise has been granted to the Hendrie Co., of Detroit, for a third track and in order to render the three tracks symmetrical it was necessary to change the two tracks in Saginaw St. and the city determined to take advantage of the opportunity to do some paving.

A crowd of citizens and workmen congregated in Saginaw Ave. at midnight and a number of trucks and drays were also in evidence. At a signal three gangs of workmen began to tear up the tracks at as many different points. It was the east track that was attacked, the west track being left free. Only one side of the street was left available for railway traffic.

At a subsequent meeting of the officers of the company and the city authorities, the former agreed to put down grooved track rail as the paving progresses, to pay its proportion of the paving and to repair its track in other parts of the city under the supervision of the street commissioner.

The Milwaukee Electric Railway & Light Co. have agreed to place fenders and guards on all cars operated on their system in Racine, Wis.

IN THE POWER HOUSE.

This department is devoted to the construction and operation of electric railway power houses. Correspondence from practical men is specially invited. Both the users and makers of power house appliances are expected to give their views and experiences on subjects within the range of the department.

POWER HOUSE COSTS, LOUISVILLE RAILWAY CO.

By the courtesy of Mr. W. T. Cook, chief engineer of the power station, we have received the itemized statement of the cost of operating and maintaining the power house of the Louisville Railway Co., Louisville, Ky., from Jan. 1, 1898, to June 30, 1899. This station was described in the "Review" for July, 1899, page 442, but for convenience we enumerate the main equipment here. There are 4 Babcock & Wilcox 250-h. p. boilers with B. & W. stokers, 6 Heine 200-h. p. and 8 return tubular 50-h. p. Six new B. & W. are now being installed. In the engine room are one verticle cross-compound engine direct connected to a 2,400-kw. G. E. generator, four horizontal cross-compound engines, each direct connected to a 500-kw. G. E. generator, and two tandem compound engines each belted to two 150-kw. Edison machines.

The data on fuel, wages, supplies and total maintenance have been reduced to kilowatt-hour basis while the itemized repairs are given in dollars for each month, and appear in the table.

LOUISVILLE RAILWAY CO

REPORT OF POWER STATION FOR 189

IMPROVEMENTS			

It may be interesting to reproduce in this connection a copy of the blank used for making the report of the power house costs. The blank measures 8 x 10½ in., letter size.

POWER FOR INTERURBAN CARS.

Our readers will be interested in the following figures given us by Gen. Mgr. C. A. Denman, of the Toledo & Maumee Valley and the Toledo, Bowling Green & Fremont roads. The Maumee Valley road owns 14 miles of track from Toledo along the Maumee River to Perrysburg, thence across the river to Maumee and down the other bank to Toledo; under an agreement with the Toledo Traction Co. the Maumee Valley cars run through Toledo over the latter's tracks, making a belt line of 23 miles in length.

In January, 1898, the average power per car-mile for 44-ft. cars equipped with two 25-h. p. motors, and seating 48 persons, was 1,859 watt-hours. Mr. Denman states that in summer the watt-hours per car-mile are about the same as in winter, the better track in summer being offset by the heavier loads carried. The average mileage per day of 18 hours on the Toledo & Maumee Valley line is 220 miles for each car.

THE DURABILITY OF WATER TUBE BOILERS.

At a recent meeting of the Institution of Naval Architects (England) Mr. A. F. Yarrow presented a paper upon this subject and gave the results of tests made to determine the comparative merits of mild steel and of an alloy of steel containing from 20 to 25 per cent nickel.

The deterioration of the tubes is probably owing:

1. To the action of acids in the water, due to grease, which, in spite of every precaution, finds its way into the boiler.

2. To the tubes becoming overheated and oxidizing on the outside, through contact with the hot gases when passing from the furnace to the uptake.

3. To the action of the steam, which, if superheated, decomposes, causing deterioration on the inside of the tubes.

The last two conditions occur when the tubes from defective circulation, shortness of water, or from the collection of scale, become overheated.

A "corrosion test" was made by placing specimens in dilute hydrochloric acid; they were weighed after various periods, varying from 21 to 168 hours, the total time of submission being 533 hours.

To summarize these tests, the results showed that the loss of weight in the first series of tests of the nickel steel tube amounted to 5 grams, being 2.63 per cent, and in the mild steel tube to 98 grams, being 52.68 per cent. In the second series of experiments the loss of weight of the nickel steel tube was 7 grams, being 3.72 per cent, and the mild steel tube 100 grams, being 53.19 per cent.

The mild steel lost 16½ times as much as the nickel steel.

A "fire test" was made by placing two tubes side by side in a small furnace. The loss in weight by oxidation was for the two mild steel tubes 78.37 per cent and 76.06 per cent, respectively, and for the nickel steel tubes, 24.47 per cent and 27.60 per cent.

A "superheated steam test" was made by placing two tubes, one of each material, 1 ft. 8⅝ in. long and 1 in. outside diameter by 14 L. S. G., in a furnace, steam at 60 lb. pressure was supplied at one end and allowed to escape slowly at the other so that the steam was highly superheated; the tubes were heated to a bright red. The nickel steel tube at the end of 10 hours had lost 12.7 grams, the weight being originally 612 grams; the mild steel tube at this time had worn out, having lost 85 grams. A second mild steel tube weighing 607 grams was worn out in 8 hours, losing 73 grams; the nickel steel lost 43 grams more during the same time, and finally failed after 21 hours, and a total loss in weight of 78.5 grams.

In a second superheated steam test with tubes 3 ft. 6 in. long, heated to a very dark red, the steel tube was worn out in 84 hours; the first mild steel tube failed after 30 hours and the second after 42 hours.

The conclusions reached are that it is not unreasonable to assume that nickel steel (20 to 25 per cent nickel) boiler tubes will have, as regards acid corrosion, a vastly longer life than those of mild steel, and, as regards deterioration from the action of heated gases or steam, at least twice the durability of mild steel.

Mr. Yarrow states that steels with small percentages of nickel (up to 5 per cent) have a slightly increased durability, but not so much as make the metals of importance for boiler tubes.

ADDITIONS TO THE POWER PLANT OF THE TOLEDO TRACTION CO.

The Toledo Traction Co. is now building an extension to its power house. The engine room was originally 70 x 206 ft., and when the station was illustrated and described in our January, 1897, issue, there was space for the installation of an additional unit at the north end of the room. This space was filled in the fall of 1897 by a vertical cross compound engine with cylinders 19 and 38 by 32 in., removed from the old power plant of the Toledo Electric Co. This engine was built by the Lake Erie Engineering Co., of Buffalo. It is direct belted to two generators, one a 250-kw. Westinghouse alternator, and one a 300-kw. T.-H. alternator; both of these machines were formerly driven from the station jack shaft.

The addition now almost completed is an extension to the engine room, making it 284 ft. long. In the new portion there is to be a vertical cross-compound Allis engine, with cylinders 28 and 60 by 48 in.; this will be direct connected to a 1,000-kw. 500-550-volt Westinghouse railway generator. This makes an addition of 1,000 kw. to the railway capacity of the station, and as only 500 kw. more is needed at the present time, one of the 500-kw. railway machines is to be rewound to give current at 270 volts for the 3-wire lighting circuit.

The company has also installed a battery of two 574-h. p. Heine boilers, completing the boiler equipment. These boilers are fitted with McKenzie furnaces, and two others of the boilers will also be so fitted.

A Warren-Webster feed water heater has been placed in the boiler room; water is delivered to the heater by the pumps formerly used to feed the boilers and as delivered to the boilers, through the economizers by two Blake vertical duplex pumps, each of which has a capacity of from 300 to 500 gallons per minute.

Another improvement in the station is the oil room and oiling system. The oil room is in the basement of the boiler room and contains storage tanks and Turner oil filters. The receiving tanks are rectangular with rails along the top, onto which the oil barrels can be rolled through a window opening onto the wharf, which is adjacent to the building. These tanks are three in number, one of 12 barrels capacity for engine oil, and two of 6 barrels each for the two grades of cylinder oil used. Small pumps transfer the oils from the receiving tanks to pressure tanks of 10 barrels capacity each; hydraulic pressure of 20 lb. is on the distributing system, water being taken from a tank on the roof of the building. Engine oil is piped to the various bearings, but the cylinder oils are drawn from faucets in the engine room and the cylinder lubricators filled by hand. The engine oil only is filtered and again used; it flows by

gravity to a Turner oil filter and thence transferred to the pressure tank.

In order to blow the dust out of the armatures of the various generators in the station, a motor-driven air compressor with a capacity of 17 cu. ft. of free air per minute has been installed. This machine, which was made by the General Electric Co., and the storage tanks are placed in the basement of the engine room. Pipes lead to four points in the engine room, a flexible hose being attached to one of these.

The Toledo Fire Department has placed an 8 x 24-in. whistle at the station of the Traction company for use as an alarm in event of large fires. The whistle is controlled by an electrically operated valve in circuit with the fire alarm circuit.

THE COST OF POWER.

About two years ago the Engineers' Society of Western Pennsylvania appointed Messrs. H. W. Fisher, L. B. Stillwell, W. A. Bole and D. Ashworth a committee to ascertain, if possible, the cost of power, and report the results to the society. In June last the committee made its report, in which are a number of paragraphs that will appeal to everyone who has made similar attempts to collect data on this subject.

The report says: "Your committee met and, after a good deal of discussion, decided to issue to the members of the society and to a large number of manufacturers and users of power, a list of questions to be answered categorically. These questions were carefully selected, and were intended to bring out answers which would be explicit and definite, and were so framed that they could not well be answered except by positive statements of facts. The list of questions was accompanied by a letter setting forth the purpose and aims of the society and issued in such a way as to afford opportunity to impart the requisite information without prejudice to the contributor. Out of several hundred such circulars sent to all the prominent users of power in this section of the country, only about half a dozen met with a response, and all of these except one are incomplete and insufficient. * * * * Undoubtedly the reason why so few people are found to contribute such information as is here sought is because the average user of power does not know."

Concerning the ease with which data on boiler performance may be secured and the value of keeping daily records, it is said: "The chief elements of such an investigation are two only, viz: the water evaporated and the fuel consumed in doing it. These two quantities can usually be obtained accurately by the proper provision of meters for the water and weighing scales for the coal. It is always conducive to economy and good order to have those who are entrusted with the use of any material, realize that an account is expected, and it is also conducive to wastefulness and extravagance to have such people know that no trace is being kept of their doings. The very presence of the meter and the weighing scales is sure to have a good effect. If a daily log is kept, the meter is read and recorded at two or more definite periods each day, and the water thus used is set over against the fuel burned, the most ignorant or careless firemen will be apt to keep a sharper lookout on all the duties entrusted to him, than though he can console himself with the cheerful reflection 'the boss don't know.' The expert investigation (complete boiler test) usually establishes a basis of performance with which the daily performance may be daily compared, and when the performance in daily operation falls below the average, an opportunity is afforded to promptly discover the fact and the reason. If this should lead to an investigation, correction and a restoration of standard good performance, it is no more than should be expected."

Of course the same general information concerning engine performance in a manufacturing plant can not be so readily obtained, but much may be done by a frequent use of the indicator.

In electric lighting and street railway plants the same difficulty is not experienced, as a recording wattmeter will give the output of the generators and with water meter and coal weight records enable the daily performance of the engines to be daily compared with the average performance of the station. The number of companies which are equipping their stations with meters and keeping complete records of the cost of power is constantly increasing, and at the present time nearly every new road has a "Thomson wattmeter" on its switchboard, so that there is every reason why the cost of power for street railways should not be known and placed on record.

By the courtesy of the managers of several of the larger street railway companies we have received since June, 1897, monthly reports of power station costs, which have appeared in this department, and in this issue is an itemized statement furnished by the Louisville Railway Co., showing costs for the 18 months ending June 30, 1899.

Such data are of interest to engineers, but more information concerning the plant would enhance their value. We therefore reprint, with slight modifications, the questions of the power committee which we have quoted and urge those of our readers who are in charge of power plants to assist us in securing data on performance by sending us descriptions of their plants and the cost of operating them.

1. Name of company—.
2. Where located—.
3. Is current furnished for lighting also?

If more than one plant, put in particulars of each plant on separate sheet if possible.

BOILERS.

4. How many boilers employed?
5. Type? (give in detail.) Size? Whether set in battery or singly?
6. Kind of fuel used? Calorific value per lb.
7. Kind of grates? Stokers? Furnaces? Fuel economizer?
8. Mechanical stokers or hand firing?
9. Height of chimney?
11. Name and type of heater employed?
12. Boiler pressure regularly used?
13. Do you exhaust steam for any other purposes? If so, state in full what use, and if possible what amount is so used?—.
14. Have you made boiler tests to determine the evaporation of feed water, and the consumption of fuel? If so, with what result?—.
15. What is the average evaporation of feed water per pound of fuel in actual running?
16. What is the temperature of feed water?
17. Is steam taken from your boilers for any other purposes than for engines reported?—; if so, state in full.
18. Do you measure the amount of feed water used by boilers? How?—.
19. How many hours per day are boilers in use?
20. Can you state the amount of fuel used per day and night in banking fires.

ENGINES.

21. How many steam engines do you employ?
22. Give in detail the cylinder diameter, stroke, revolutions per minute, and rated horse power of each engine, stating whether automatic, cut off, or otherwise?
23. Do you use a condenser? What vacuum do you regularly obtain?
24. Is your power regular or fluctuating? Give details and nature of work it is used for.
25. Have you made indicator tests to determine the horse power of engines?
26. What is the average daily, and maximum daily, horse power of engines?
27. What is the average consumption of fuel, per indicated horse power developed by engines, when at full load?—; also average per day per horse power hour?—.
28. What is the back pressure on engines, when exhaust steam is employed for heating or other purposes?—.
29. How many hours per day are engines employed?
30. How is the power applied?

INVESTMENT.

31. What is the capital invested in boiler plant, and its accessories, including feed water heaters, pipes, foundations, and chimneys, etc.?
32. What is the capital invested in engine plant, and its accessories, including foundations, pipes, etc.?

*Miscellaneous, .002. **Cost of Oil per Barrel.

33. What is the capital invested in real estate and buildings occupied by engine and boiler plants?

DEPRECIATION.

34. What is your estimate for the annual depreciation of value?

35. What is the annual cost of repairs?

OPERATING EXPENSES.

36. What is your annual fuel bill?

37. How many hours per annum is your plant in active operation?

38. What is the cost of fuel per ton on your premises?

39. Have you had experience with other fuels?

40. What is the cost of water for your steam plant?

41. What is the annual expenditure for wages to employes to the plant?

42. What is the annual expenditure for supplies of all sorts for boiler, hydraulic, air and electric plants?

43. What percentage of the general expenses of your business do you consider proper to apportion to power plant? And what does this amount to, expressed in dollars, per annum?

Mr. S. J. Prentiss, engineer of the La Crosse (Wis.) City Railway Co., sends us the following data concerning the operation of his power station:

The plant began operating August 4, 1893, and with the exception of one Sunday has run every day since that time; the cause of the single shut down was a bad splice in the main belt, which did not dry and compelled the plant to lie idle for one day. The engine room equipment consists of one 18 x 42-in. condensing corliss engine and two 90-kw. General Electric generators. Shingle saw dust is used for fuel, about seven wagon loads per 24 hours being required.

The company has 15 miles of track and operates 16 motor cars and from 15 to 18 trailers; in winter snow plows have frequently to be run all night. The cars run from 5:15 a. m. to 11:15 p. m., except on special occasions, when they are kept out till 1 o'clock or later. For the last five years the average time of operating the station has been 560 hours per month.

Mr. Prentiss does not explicitly say that there have been no armature repairs necessary during this time, but from his letter we infer that such is the case and that this is a record for long lived armatures, which beats that submitted by Mr. H. J. Termohlen, of Rockford, Ill., last month.

The American Pneumatic Railway Ditcher & Grader Co. has been incorporated in Illinois. The capital stock is given at $250,000. The company will handle a new machine for ditching and grading, making embankments and cuts, etc., for railways. The directors in the new company are W. B. Doddridge, C. S. Pullman, Rolla Wells, C. T. Westlake and E. F. Goltra. The offices will be located at Granite City, Ill.

THREE ATTEMPTS TO WRECK TROLLEY.

The third attempt to wreck a car was made on the Youngstown Park & Falls Street Ry. on the night of August 9th, by placing a tie upon the track. This makes the third attempt upon the cars of this company, and the man who was seen placing the obstruction on the track was pursued and narrowly escaped being shot. As the car was descending a steep hill the motorman noticed a man lying beside the track in front of the car. He immediately applied the brake and stopped the car, which was going at a slow rate of speed. Meanwhile the man who had been crouching beside the track took to his heels and leaped over a fence. Electrician Birchfield, who was on board the car, pursued the man and fired five shots at him with his revolver, but the fellow escaped, aided by the darkness and thick bushes. In his flight he lost his hat, which was picked up by Birchfield and turned over to the police. The hat has two holes through the top of it, which were possibly made by one of Birchfield's bullets.

The company is making every effort to capture the villian who has three time tried to wreck cars on its lines. The road throughout its entire length is watched during the night by special watchmen. The cars are run carefully and slowly down all grades. Each car has an inspector aboard who walks ahead of the car at every curve and carefully examines the tracks.

NEW YORK CITY TROLLEY EXTENSIONS.

It now seems probable that the long standing contest between the Metropolitan Street Railway Co. and the Third Avenue Railroad Co. in the Washington Heights district of New York City, will be amicably settled. A joint application for extensions has been made by the two companies up the old Boulevard to the junction with the Kingsbridge road, near 169th St. This application has been passed by the Municipal Assembly and signed by the mayor.

The joint application for extensions applies only as far north as 169th St. The Metropolitan wishes to continue thence up Eleventh Ave. to 175th St. The Third Avenue makes further application to continue up the Kingsbridge road to and across the Government ship canal, across Spuyten Duyvil Creek and along 230th St. and Riverdale Ave. to the city limit, there connecting with the Yonkers branch of the Union Railway Co. The Union Railway Co. already has tracks down the new Broadway that will connect with the proposed line at 169th St. This will give the Third Avenue two West Side lines into Yonkers and connections east from Yonkers by way of McLean Ave. and Yonkers Ave. with Mount Vernon and the towns on the Sound.

These extensions would enable passengers to ride by trolley from the postoffice as far as Hastings-on-the-Hudson, the longest single ride, it is said, that Greater New York offers. Whether the fare will be 5 or 10 cents is a question which the company has not yet taken up. It is understood that there will be no opposition to granting the extensions which both roads demand.

TO SETTLE THE MILWAUKEE CONTROVERSY.

The reduction of street car fares has been a favorite project with the city councils of Milwaukee for several years. An ordinance requiring the company to reduce its rate of fare to 4 cents was, after long litigation, held to be invalid by the United States Courts; this decision was rendered May 31, 1898. Following this decision efforts were made to reach an amicable agreement, the company preferring to waive some of its rights for the purpose of securing peace. Mayor Rose and the company succeeded in reaching such an agreement (St. Ry. Rev., Dec. 1898.), but because of opposition on the part of the press and the public the company decided to withdraw its proposals. The subject has been further discussed since that time, and on July 31, 1899, the council passed a resolution looking to an agreement for lower rates of fares.

August 15th the following letter was submitted to the council:

"To the Honorable, the Common Council of the City of Milwaukee—Gentlemen: We are in receipt of copy of the resolution passed by your honorable body on the 31st of July, 1899, relating to the reduction of the street railway fares, which seems to call for an expression of the attitude of our company. We are willing to take up the whole question of our relations with the city; any re-adjustment, however, to be permanent must be based upon considerations, of mutual benefits and mutual concessions, but no attempt at re-adjustment is advisable, unless it is such as appeals to the business sense of the public and insures an enduring settlement.

"The principal franchises of this company do not expire until July 1, 1924, and several not until a latter date, with the right thereunder to charge a 5-cent fare without transfers, and we should not be expected to reduce the earnings of the property unless the city is willing to make reasonable concession which will contribute to the security of our investment. If this principle is frankly recognized, we have little doubt that a conclusion can be reached which will be of lasting and increasing benefit to the people of the city and acceptable to this company.

"The concessions which we are disposed to consider favorably are as follows:

"First—A gradual and increasing reduction in the rates of fare, until a 4-cent rate is secured by the sale of commutation tickets.

"Second—The permanent establishment of the transfer system.

"Third—The extension of the railway lines to the city limits at points necessary for the convenience of the people in the several localities interested.

"Fourth—We are willing, in case the city desires, and has the power to purchase the railways and physical property of the company within the city, to grant an option to purchase on terms to be agreed upon, or, determined by arbitration.

"For these concessions the city should grant to the company:

First—Franchises upon certain streets which will enable the service to the public to be improved, and the railway system perfected.

"Second—An extension of the railway franchises for 10 years.

"The foregoing is intended as an outline of the points which we deem essential. Should your honorable body conclude to take up the negotiation on these lines we shall be glad to meet your committee and endeavor to arrive at an agreement as to the terms of an ordinance."

This was signed in behalf of the company by Vice-Pres. H. C. Payne, Gen. Mgr. John I. Beggs, and Frank G. Bigelow and Charles F. Pfister, local directors.

LONDON UNITED TRAMWAYS.

In our issue for July, 1899, page 487, we published a description from a paper by Mr. J. Clifton Robinson, managing director and chief engineer of the company, of the general features of the London United Tramways. As there stated, the lines to be constructed within the county of London comprise 4.32 miles; of this 2.87 miles will be on overhead trolley system and 1.45 miles on the underground conduit system.

The accompanying illustrations are reproduced from drawings recently prepared by the company's engineers, Mr. Robinson and Mr. H. F. Parshall, consulting engineer. Fig. 1 shows sections of the conduit and Fig. 2 a plan view of the conduit tracks; from these it appears that the construction closely resembles that of the conduit roads in Washington and New York. Fig. 3 is a drawing of the conduit plow. The type of car to be used is shown in Fig. 4. Fig. 5 shows the types of iron poles used; the center pole is designed for a light pole also.

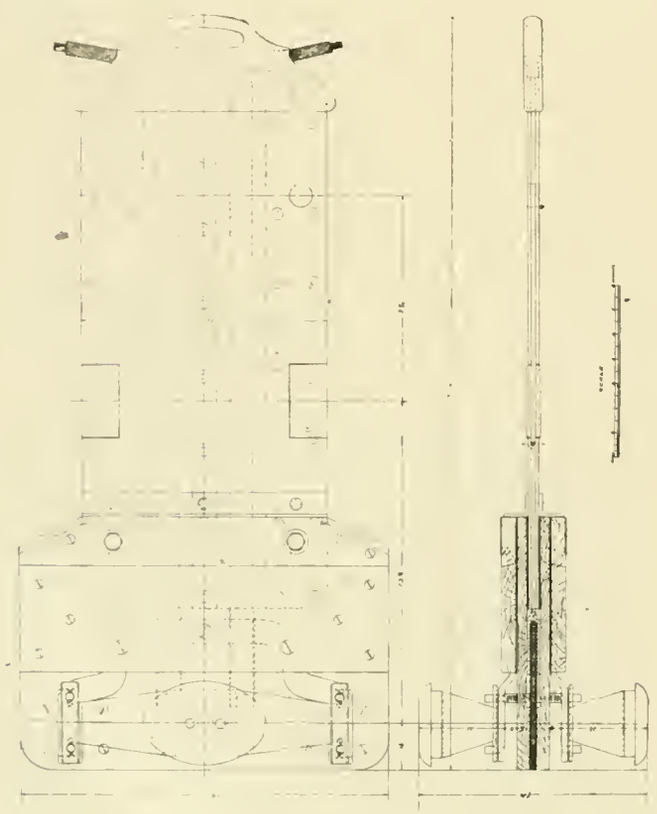

FIG. 3 ELEVATION AND SECTION OF PLOW.

FIG. 5—TYPES OF POLES.

TESTIMONIAL TO MR. YERKES.

A testimonial from the employes of the West Chicago Street Railroad Co. was presented to Mr. Charles T. Yerkes on August 10th, expressing the regrets of the employes on his severing his connection as president of the company and their appreciation of his treatment. A delegation of 10 conductors and motormen were ushered into Mr. Yerkes' office at three o'clock in the afternoon, where the presentation and acceptance of the testimonial took place.

The gift of the men was in the form of a memorial address, engrossed in black ink. Around the body of the address is pen and ink scroll work, a trolley car and a trailer being in the design. The address is framed in oak and reads as follows:

"Memorial address to Charles T. Yerkes, from the employes of the West Chicago Street Railroad Co., Chicago, Ill., July 15, 1899. Mr. Charles T. Yerkes—Dear Sir: With the feelings of the profoundest regret, we have read your letter announcing the severance of your connection with the West Chicago Street Railroad Co., and at a meeting held July 15, 1899, it was unanimously resolved that we take this early opportunity of expressing our regret, and also assuring you of our hearty appreciation, both individually and collectively.

"1. Of your wise and efficient management, even under the fire of unmerited public censure.

"2. Of the faithfulness with which you have kept the pledges given at the beginning of your administration, maintaining them, as you have, through fluctuating money markets and desperately hard times.

"3. Of your successful work along the line of street railway extension, which, in its far-reaching influence, is, perhaps, one of the greatest benefits ever realized by the city of Chicago and its suburbs, and which will increase with the coming years.

"4. Of your strict justice and your many acts of generosity of which the world has not known, and, above all, your personal interest in the men themselves. We thank you for your words of commendation. We are proud of the fact that each man's work, however humble and insignificant it may seem, is considered by you a necessary and important part of the mighty whole.

"In conclusion, we wish to assure you that we will give to the new management the same loyal service which we have given to you during your administration of the affairs of the company.

"Bespeaking for you all the great and good gifts that a beneficent providence can bestow, continued prosperity, and a long life crowned with health and happiness, we remain,

"The employes of the West Chicago Street Railroad Co."

The chairman of the delegation, Mr. Brennan, in presenting the testimonial, made a brief speech in which he expressed the gratification of the men at the agreeable and harmonious relations that had always existed between them and the management, and their appreciation of Mr. Yerkes' work in Chicago.

Mr. Yerkes made an informal response in the course of which he said:

"This meeting touches me very much. Those resolutions touch me much. They show me what the feeling of the men really has been. While I was aware of that feeling, this brings it up afresh.

"What you have stated about my opinion of making presents and showing a regard for employers is all a fact. When Mr. Roach told me of the determination of the men to contribute so that I should have the handsomest watch in Chicago—and as each man was to contribute 50 cents, with the thousands of men, that no doubt would have bought the most expensive jeweled watch—I said: 'Tell the men to stop that. It has always been against my principles.' I said I was opposed to any employer accepting anything of value from employes. Many conditions exist which would preclude the possibility of me accepting anything of that kind. One superintendent at one time securing a post that was somewhat better, the men, in goodness of their hearts, decided to buy him a watch. I knew nothing of it. After I learned of it, I called him to me and gave my opinion this way:

"'Men are asked to subscribe who can't afford it. Those will subscribe because they don't want their associates to feel that they do not regard their employer, or that they are poor. Stop it! If the watch is bought, have them sell it.' From that time on, I don't know of any one receiving any gift of money value from the employes.

"The men are not paid more than they can expend for their needs. Every 50 cents is precious to the men. For that reason, nothing could induce me to accept a token valued in money. I think ever so much more of that (pointing to the testimonial) than I could of all watches and diamonds."

In conclusion he said:

"Gentlemen, you have put me through another ordeal this afternoon. I haven't much more to say, except that I hope the public with whom you come in contact will appreciate you as I do. For these resolutions I thank you more than words can tell. I have pictures in frames, some of considerable money value, but there is none I value as must as I do the black and white in that frame."

NEW CHICAGO CITY RAILWAY OFFICIALS.

September 1st, the following appointments for the Chicago City Railway Co. were announced: Capt. Robert McCulloch, to be general manager; George O. Nagle, superintendent of the road since January, 1898, to be assistant general manager and superintendent; C. N. Duffy, to be auditor.

Capt. McCulloch, whose presidency of the American Street Railway Association made him well known to nearly all the street railway men in the country, comes to assume the management of the Chicago City Ry. under his former chief, Mr. Hamilton, with whom he was associated in St. Louis when manager of National Ry. lines there.

Mr. Nagle's promotion is a very gratifying testimonial as to the able way he has filled the position of superintendent for the last two years.

Mr. Duffy has been the auditor of the St. Louis railways under the management of Captain McCulloch, but is most widely known by reason of the work he has done in connection with the Street Railway Accountants' Association. Mr. Duffy is chairman of the permanent committee on "A Standard System of Street Railway Accounts," and as such did a great deal to bring the standard system to its present degree of perfection and secure its adoption by the Convention of Street Railroad Commissioners. The street railway fraternity of Chicago extends a most hearty welcome to the new comers from our sister city.

STEAM RAILROAD MILEAGE IN THE UNITED STATES.

From the 11th Report of the Inter State Commerce Commission, it appears that on June 30, 1898, the total single-track railway mileage in the United States was 186,396.32 miles, there being an increase in this mileage during the year of 1,967.85 miles. The States of Arkansas, California, Louisiana, Missouri, New York, and Wisconsin show an increase in excess of 100 miles. The aggregate length of railway mileage, including all tracks, on the date given was 247,532.52 miles, the increase being shown as 4,088.11 miles. This aggregate mileage was distributed as follows: Single track, 186,396.32 miles; second track, 11,293.25 miles; third track, 1,009.65 miles; fourth track, 793.57 miles; yard track and sidings, 48,039.73 miles. The length of the single track operated mileage covered by railway reports filed with the commission was 184,648.26 miles, which indicates that the mileage of the country is covered by reports in a substantially complete manner.

SAUGATUCK'S TROLLEY OPENING.

Nearly 7,000 people were present from all parts of the state to attend the opening of the Saugatuck (Mich.), Douglass & Lake Shore Electric Ry., August 19th. The cars commenced arriving early, and continued every half hour during the day to bring the crowds, until the town was filled.

Holland business men came in a body, accompanied by the West Michigan Band. G. J. Dykema, of Holland, and Judge J. McGarry, of Grand Rapids, delivered orations on the public square.

In the evening a display of fireworks and water carnival were given on Kalamazoo Lake. The day closed with a naval battle and the sinking of the Spanish fleet of gunboats.

All the cars of the Exeter (N. H.), Hampton & Amesbury Street Ry. will soon be equipped with air brakes.

THE DEVELOPMENT OF ELECTRIC TRACTION IN THE UNITED KINGDOM.

(Special Correspondence.)

The great and growing development in electric tramway enterprise in this country has only just affected London. While Glasgow, Liverpool, Manchester, Sheffield and Hull have been deeply engaged upon carrying out municipal tramway schemes, the premier city of the world has been content to go jogging along with its old 'buses and its smart, if somewhat extortionate, hansoms. Sometime ago, however, the County Council of London and inter alia many local authorities were somewhat rudely awakened by the enterprising, if not audacious, schemes of Mr. J. Clifton Robinson, the managing director of the London United Tramways Co., who proposed to entirely transform the system of West London tramways. This line of tramways comes no nearer than two or three miles to the center of London, but it penetrates into some of the best and most thickly populated portions of suburban London, and it was apparent to anyone with half an eye that it was most admirably suited to electric working, or, probably, electric working was admirably adapted to its needs.

For this system, powers to use electricity have been obtained, not without a tremendous fight, but opposition has only whetted the appetite of the tramway company, for it is now seeking to add to its already extensive franchises by creating a new system of light railways and tramways which will be connected together and provide a magnificent means of transit to many people who have been hitherto practically unprovided for. No time has been lost in carrying Parliamentary powers into effect, and by the time this reaches you the roof will have been placed on the power house, and, judging by what I have already seen, I should say this country will not be able to show anything better in the way of generating plant or machinery. [A description of the novel features of this road was published in the "Review" for July last, page 487. Some drawings of the proposed conduit work and of the cars and poles are shown on another page of this issue.]

One of the most startling incidents in the history of electric tramway development in London is the publication of Prof. A. B. W. Kennedy's report to the London County Council on the subject of mechanical traction. I need hardly say that Professor Kennedy is one of the most eminent consulting engineers in this country on electric lighting, and it was felt that, when the County Council asked him to prepare a report on the subject of applying electricity to the Council's lines the matter would be most carefully gone into. The general feeling expressed on the report is one of disappointment. It has been an uphill struggle in this country to convince municipal and other authorities that the overhead wire system was the best under most circumstances, but the strong advocacy of Professor Kennedy for an underground conduit will tend to unsettle many people who are considering the adoption of electric working. The professor states that he cannot help doubting whether any system of overhead wires can be really regarded as likely to prove a permanent and final solution of the traction problem in a great city like London. He further points out that at crossings and street junctions the trolley system is inevitably accompanied by such a metallic network overhead as to put it altogether out of the question in busy London streets. Probably overhead wires at street crossings would not enhance the appearance of the streets, but it can hardly be doubted that it is just at these points where the conduit is likely to prove troublesome. Apart from the question of expense, the construction of a conduit system in London will be attended with enormous difficulties. Within a few inches of the surface of most London streets there is an extraordinary mass of pipework, and to lay down a conduit would mean in many cases the bodily removal of these pipes.

To give an idea of the trouble that may be met with from this cause alone it may be mentioned that a certain route was selected on which to lay down an experimental conduit track, but on the engineer examining the route it was found that there are three 30-in. water mains at no very great depth below ground, and for that reason the experiment will be tried along another route. In the opinion of many, however, the foregoing difficulties fairly represent the character of the London roads.

It ought to be mentioned that most of the municipalities in this country who have adopted electric tramways, were in the first instance predisposed in favor of conduits, but an investigation into their probable cost and the inconvenience to ordinary traffic during the construction period, has induced them, without exception, to adopt the overhead system.

Electric tramways are developing very rapidly in the provinces. The Glasgow Corporation has commenced on its large scheme, and last week the Tramways Committee decided to recommend the acceptance of the tender of the E. P. Allis Co., of Milwaukee, which offers engines for £114,554. This is far and away the largest contract for engines ever given in this country, and if the corporation adopts the committee's recommendation, the American firm is to be congratulated.

One of the most interesting systems of tramways yet inaugurated in this country is the one owned by the Corporation of Plymouth, and it is chiefly interesting from the fact that the generating plant has been erected for supplying electricity for lighting as well as for tramway purposes. The problem was a little complicated from the fact that the lighting is carried out by means of alternating currents, but the difficulties have been surmounted in a highly ingenious manner. Combined plants, consisting of an engine driving a continuous current dynamo and an alternator arranged in line or one shaft have been adopted, the whole of the plant being upon a combination or coupled bed plate. The alternator is placed between the engine and the continuous current machine, clutching devices being employed so that the engine may drive either machine, or, if need be, the engine may be disconnected and either machine may be used to drive the other. The following are some of the functions that can be carried out by such a combined plant. The engine may drive both machines, one for lighting and the other for traction, or the alternator may be uncoupled and the plant used only for tramway work; then, again, the continuous current machine may be uncoupled and the plant used only for lighting. When the engine is uncoupled the machines may be run as motor generator for lighting or tramway purposes; for the former purpose the continuous current machine would act as motor, obtaining current from accumulators, or the alternator could be run as a motor, obtaining current from the lighting bus bars, the set being thus rendered of use for tramways.

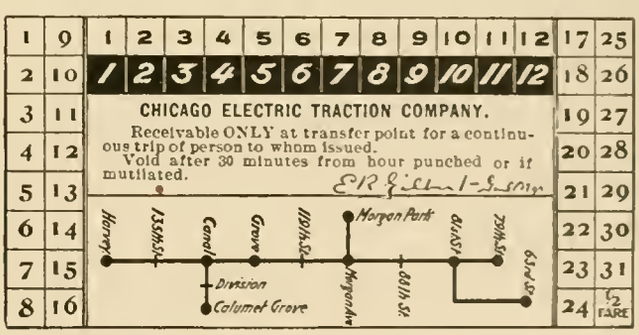
There has been considerable discussion in this country on the subject of combined plants, and the foregoing plant is an interesting contribution to the discussion.

H. S.

London, Aug. 19, 1899.

A NOVEL TRANSFER.

The accompanying illustration shows a transfer ticket designed by Mr. E. R. Gilbert, general manager of the Chicago Electric Traction Co., which, it is believed, is quite original as regards the manner in which the destination is indicated. The ticket is 4 in.



long by 2 in. wide. The day of the month and the hour of the day are indicated by punching out the proper figures in the top and margins in the usual manner. For indicating the destination a diagrammatic sketch of the company's lines is placed in the lower portion of the ticket and it is only necessary for the conductor to punch the proper point on this map.

The Consolidated Street Railway Co., of Bay City, Mich., has been ordered by the city to place safety devices in front of all its cars.

THE BOMBAY TRAMWAYS.

Indian Engineering has the following on the street railway system of Bombay:

There are two institutions of which the people of Bombay are justly proud: The first is the Port Trust, which has done so much to extend the area of the city by judicious reclamation, and to enhance the importance of the port by the construction of docks, jetties, and piers; and the second is the Tramway company, absolutely the best of its sort in the East. The ramifications of that service are already so numerous that the termini are almost as many as the municipal wards; the tariff is so lenient that the cars are patronized by all but the very poorest; the furniture is so decent, and there is so high a tone of respectability pervading the whole economy, that the most fastidious are glad enough to avail themselves of the easy transit. All this, however, would be futile were it purchased at the expense of regularity and celerity of traffic. But one of the greatest boasts of the Bombay Tramway Co. has ever been, that, despite of all the disabilities and limitations of horse traction, the regularity of their service has been their chief recommendation; and now it is proposed to improve this particular department, and increase the company's hold on public popularity by the introduction of electric traction on the overhead system. Mr. F. C. Rimington, the local representative of the board of directors, has applied for the sanction of the Municipal Corporation to this reform, setting forth the advantages which are tersely stated thus: (1) Increased regularity, speed, and comfort of car service; (2) much reduced congestion of traffic in the streets, the space occupied by horses being saved; (3) increased cleanliness of the streets; (4) greater safety, owing to the cars being under more perfect control, and being fitted with more efficient fenders or wheel guards than is possible with horse cars; (5) greater flexibility as a motive power, and consequently increased capacity to meet the demands of a fluctuating traffic. He places the expense of the improvement at Rs. 15,000,000, and asks a modest enough guarantee of possession for 14 years. Knowing what we do of the Municipal Corporation of Bombay, we have no hesitation in saying that the proposal will be accepted with alacrity and thankfulness; and knowing what we do of the methods of the Bombay Tramway Co. we dare to predict that the genesis of electrical traction will be complete in Bombay before in Calcutta it has passed the first stages of incubation. This is, in the nature of things. Municipal institutions in the metropolis of India partake in every way so much of the nature of the megatherium that the observant philosopher is in no way astonished at an extended period of gestation, however much he may chafe under prolonged expectancy.

If the Calcutta Commissioners would but study the question of the Bombay tramways with intelligence and a conscientious desire to profit by its lessons, they would realize that the proposed departure is of the utmost importance to them at the present juncture, when electrical traction has been accepted as the last resource to improve the most inefficient tramway service that has disgraced one of the chief cities of the world.

The history of the Bombay Tramway Co. is pregnant with instruction. The company was formed in America, because Mr. Kittredge, to whom Bombay certainly owes a statue and the Government a knighthood, could not obtain the money locally to float it. This was Bombay's misfortune, and the citizens have never ceased to regret the temporary myopy which prevented them from seeing, in the little Yankee's scheme, a very important factor in the development of the city. Having brought the money from New York, Mr. Kittredge also brought with it American thoroughness, American enterprise, American practicalness, and American adaptability to the surrounding environment. Once the municipal concession of the track was secured, he took good care to allay any public irritation at the monopoly by reducing to a minimum the inconvenience of the lines. These were scientifically laid, and it has long been a significant comment that the streets which the tramways pass are the best kept in Bombay. There are no cobbles to jar the nerves and imperil the salvation of the owners and drivers of public conveyances; and, when repairs have to be done, they are done quietly and quickly, chiefly at night when the busy world is sleeping. Horse traction being the only one feasible at that time, Mr. Kittredge obtained the best and most powerful draught animals procurable in Australia. They were cared for with much humanity; they were housed in the most scientifically constructed stables we have seen anywhere outside of London; their number was large to ensure a fair distribution of labor; and they were fed and tended with a liberality and solicitude which would have done credit to any private owner and lover of horses. The consequence was that few private individuals in Bombay could show a more efficient and atractive equipage than that seen in an ordinary street car. Then, in the construction of the cars, particular attention was paid to ventilation, lightness and elegance of design. The result is a clean, open, and roomy vehicle, which, by the very nature of its structure, renders overcrowding impossible. The details of management are as nearly perfect as human ingenuity can make them. The company demand in their traffic employes a high standard of intelligence and respectability; their ticket system is simple, and, even at the beginning, could not by any chance have produced the nightmare which Mark Twain has immortalized in his jingle—"Punch, Brothers, punch with care." With the introduction of the uniform one-anna rate—a concomitant of electrical traction—the simplicity of the system will be perfected, and the difficulties of management considerably reduced.

All this strengthens our belief in the ability of the Bombay Tramway Co. to make electric cars a huge success, and we would strongly advise both the Calcutta Corporation and the Calcutta Tramways Co. to depute officers to Bombay with the special object of studying the Bombay methods. Herein lies, in our opinion, the only salvation of the Calcutta Tramways.

FIGHT FOR RICHMOND, VA., FRANCHISES.

As was previously stated in the "Review," a syndicate composed of a number of Richmond gentlemen, headed by Messrs. James N. Boyd and Virginius Newton, has made a proposition to purchase a controlling interest in the Richmond Railway & Electric Co., and to put the property in a high state of improvement.

The purchase, however, is conditional, as the council must give the new company the franchises held by the old one without waiting for them to expire.

The question to be considered is a somewhat complicated one, it appears. It is claimed that the committee has no right to take up the matter until the Richmond Railway & Electric Co. agrees unconditionally to relinquish its franchises.

There is, however, another factor in the fight, and, to all appearances, the most important which has so far developed. The fact has come to light that a second syndicate, composed of merchants, bankers and business men generally, has been formed to contest for the franchises. The Richmond Traction Co., which owns competing lines, is also making a strong bid for the franchises, and the contest promises to be a warm one.

RAPID CABLE LAYING.

A method of remarkably rapid cable laying was used under special conditions on the new Victoria Jubilee bridge over the St. Lawrence River, near Montreal. The bridge with its approaches is about 8,750 ft. in length, and is crossed by the transmission line from the water power plant which is building at Richelieu, 16 miles from Montreal.

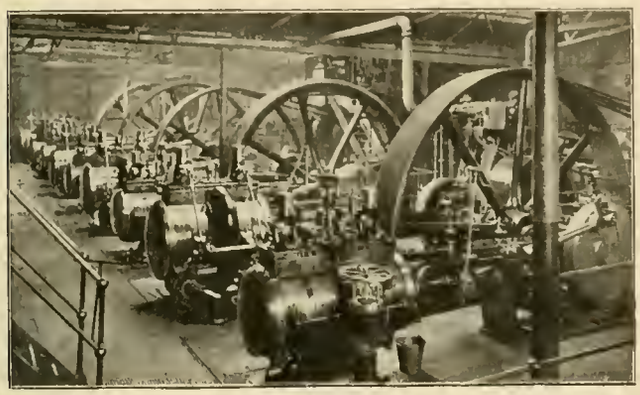
The cables for this section of the line are laid in a wooden box placed on the sleepers 4 ft. outside of the track, and they were laid by means of a locomotive and flat cars. Four flat cars were loaded with reels, each reel containing 1,000 ft. of cable, and jacked up into position ready to pay out. The cable paid out over a cast iron sheave 22 in. in diameter, which was shrouded with leather to avoid abrasion of the lead covers. The ends of the cables were lashed to the cable box and the locomotive was started and kept running at the speed of 4 miles per hour. The cable paid out over the cast iron sheave and extended to the end of the car over two wooden rollers from which it dropped into the wooden cable box on the floor of the bridge. Two reels of cable were laid in this way in five minutes by actual count and 26,000 feet were placed in position, ready for joining, in eight hours.

It is reported that the Terre Haute Electric Co. wishes to buy the Brazil (Ind.) lines.

ENGLISH TYPES OF TRACTION ENGINES.

That fact that American built engines have taken the lead in the English markets for traction purposes is probably due to the greater development of electric traction in this country, but the fact that for lighting purposes, also, American engines are very much in evidence in England, cannot be attributed to the same cause, and is largely due to the fact that orders can be filled much more expeditiously by the American engine builders than be English firms. In a series of articles on electric light and traction engines running in the Electrical Review, of London, our contemporary states: "It is greatly to be hoped that with the growth of electric traction, English engine builders will no longer suffer themselves to be ousted from their own market by American engines. If foreign made engines are to come to England, we should prefer American to any other, but we see no necessity for the continuance of the practice."

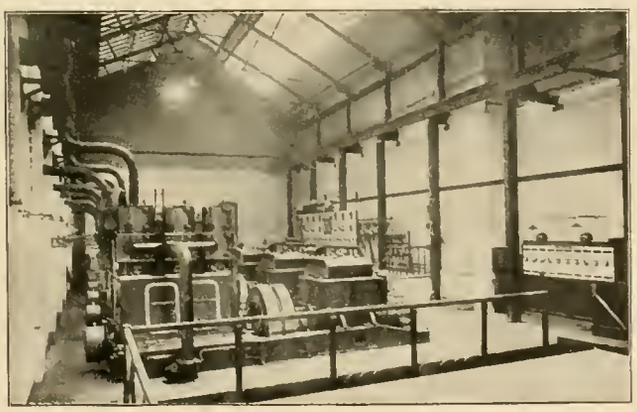
In the same series of articles a number of illustrations are given showing some of the types of engines which are being produced by English manufacturers for the class of work, some of which we



LIGHT AND TRACTION ENGINES—NEWCASTLE-ON-TYNE.

have reproduced as being of interest for the comparison of English with American built machines.

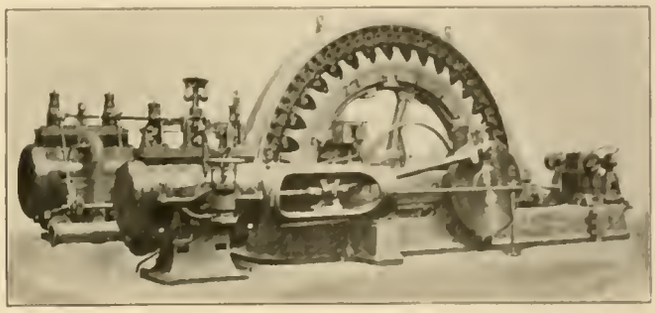
Among the types of engines mentioned are those of G. E. Belliss & Co., Ltd., which are installed in the power plant of the Waterloo & City Electric Ry. These are direct coupled to Siemens Bros.' 200-kw. generators, the units being quite different in general appearance from any in use in this country. The engines are of a vertical 3-crank pattern with a complete tandem compound engine working on each crank. They are designed for a capacity of 300 i. h. p., running at 380 r. p. m., with a steam pressure of 150 lb. at the engine valve. The working parts of the engine are inclosed by a casing to keep out dirt and to permit the use of Belliss' patent system of forced lubrication for the bearings. The speed of these engines, it will be noticed, is much higher than is usual for this class of work in this country. There are six units in this station, which has a provision for still further extension, the units



WATERLOO & CITY ENGINES.

being smaller than are generally used here for stations of this size.

Another and quite a different class of engines are those manufactured by Robey & Co., Ltd., which are installed in the plant of



LIGHT AND TRACTION ENGINE ST. HELENS.

the corporation of St. Helens and in the station of the Newcastle on-Tyne Electric Supply Co. The engines of the St. Helens station is of the cross compound condensing type direct connected to an alternator of 115 kw. capacity, and runs at a speed of 100 r. p. m. The engine and alternator are mounted on a massive iron bed plate and are furnished with continuous lubrication to all the moving parts. The Newcastle-on-Tyne engines are of the same general type, but drive the alternators by rope connections.

WESTINGHOUSE RAILWAY GENERATORS.

The direct-connected railway generators of the Westinghouse company, in which the armatures are built so as to be keyed to the shaft of any engine of suitable power and speed, are provided with a special winding for balancing the magnetic circuits between the different poles which is described in a circular recently issued by that company on direct-connected railway generators.
