It is of great importance that all the brushes of the same polarity be maintained at exactly the same potential. In the older types considerable difficulty was frequently experienced in the operation of large multipolar direct current machines owing to the fact that it was impossible to always secure the same magnetic strength in all the poles, and consequently the potential generated in a set of the armature conductors under one pole was sometimes greater or less than that generated in a corresponding set of conductors similarly located under any other pole of the same polarity. The result of this was a certain difference of potential between the brushes of similar polarity so that currents, sometimes of considerable magnitude, flowed from one brush to another or from one section of the armature winding to another, causing heating of the conductors and sparking. This trouble is remedied in the new machines by connecting together a number of points in the armature winding which are normally of the same potential, by leads through which current may pass from one section to the others of equal polarity to which it is connected in parallel. These currents change in direction and may lead or lag with reference to their respective e. m. f's. so that they magnetize or demagnetize the field magnets, thus automatically effecting the required balance between them. In case an armature becomes decentralized from the wear of the bearings or otherwise, the potential generated in the coils of the armature where the air gap is smallest is much higher than that generated in the coils of corresponding potential on the opposite side of the commutator where the air gap is largest and a current corresponding to this difference of potential tends to flow from one section of the armature to another through the brushes and connecting leads causing sparking and wasteful heating. With this method of balancing, however, the armature could be considerably out of center without causing trouble, as the balancing currents do not flow through the brushes but through the special connections mentioned above.

A further advantage of this method is that it prevents any heavy magnetic pull on one side of the armature if it should get out of center when the bearings become worn. The pull upon one side of a large armature in this case may amount to several tons unless the induction under all the poles is equalized.

THE SPRAGUE MULTIPLE-UNIT SYSTEM.

In the "Review" for December, 1897, we published a description, with sketches, of the electrical car equipment for operating the South Side Elevated R. R., Chicago, on the Sprague multiple-unit system. At the meeting of the American Institute of Electrical Engineers, in May last, Mr. Frank J. Sprague read a lengthy paper on the subject of "Multiple-unit System of Electric Street Railways," from which we extract a portion relating to the equipment of the South Side Elevated, and interesting details as to its operation. While the portion descriptive of the car equipment is in part a repetition of what was previously published in the "Review," we give it here because it is more complete as to some matters and is Mr. Sprague's own statement, he having been unwilling to furnish data for publication in 1897. After an extended review of the development of electric railways, Mr. Sprague said:

It has been already pointed out that the multiple-unit system is an aggregation of transportation units of variable size, each equipped with the power required to operate that unit at a given schedule and under determined conditions, with means for controlling the aggregation from two or more points. This does not necessarily mean that every car is equipped; that depends upon the schedule and the requirements of acceleration, for the method is equally applicable whatever the number of cars that are equipped with motors or the number of motorless or "train-line" cars which are mixed in with them. For example, a train can be made up of pairs, each of which forms a transportation unit consisting of one motor and one motorless car, so that the train can be made up of two, four or six cars, that is, one, two or three couples, thus averaging one motor per car in use. Three and five-car trains can be made up, the third and fifth being a motor car or a train-line car. In any case, two-motor equipments can be put on one-half of the cars and the balance equipped with a "train-line" so as to get one schedule, and when it is desired to increase the schedule motors and a controller can be added to the partially equipped cars.

Of course, the finality of the system on roads with frequent stops, to get the maximum schedule speed, is a motor on each axle, but in a large number of cases and with pivot-truck cars, commercial demands are such that two motors per car are sufficient, and on some service two motors on alternate cars only.

The equipment of the South Side road has been made on a mixed plan, 120 cars first being each individually equipped with two motors, then 30 cars with a "train-line," but without motors, and finally 30 additional cars completely equipped.

The position and arrangement of the South Side yards and the running of trains into a Y at one end and around a loop at the other produces every possible aggregation of cars. Hence, for the equipment, in order to avoid head and tail switching, and to permit of this variable aggregation, there was one vital condition, which was that no matter how trains were made up, like hand movement at the end of any car must at all times mean like track movement relative to the operator, and the system of connections from one car to another must automatically provide for such a result.

THE CAB.

This variation of car aggregation, and the further condition that no seat-room should be taken up by the motorman, made it necessary to provide each car with a movable cab on the platform such that it could be left open for the free use of the ordinary entrance gate when in the body of the train, and yet be readily closed and afford protection to the motorman when at the leading end, at the same time allowing free passage from one car to another. On each car, therefore, at the right-hand diagonal corners the ironwork has been removed and a three-part cab constructed, the outer end being a fixture with a drop window, and carrying in the angle formed by the platform the initial controlling mechanism, being the master controller for the electrical system and the engineer's valves for the air brakes. On each side is a door, each hinged in opposite direction, and folding back one over the other against the header of the car, leaving, when in this condition, the platform clear and the ordinary gate in operation.

When used by the motorman, one or both doors are closed, the iron gate swung in place, and a small protecting cab is the result.

MOTORS AND CONTROLLERS.

Under one end of the car, in place of the ordinary truck, is a motor truck carrying two 50 h. p. (hour rating) standard railway motors of capacity and gearing such as to safely allow the motors to work up to the skidding point of the wheels with 60 per cent of the weight of the car equipment and load upon them. The motors are of the General Electric manufacture and of the usual Sprague suspension.

In the hood of each car is a controller for the motors enclosed behind a trap-door which can be lowered for ready inspection. The controller is of the multiple-series type, is driven by a small pilot motor, and provision is made for at will or simultaneously producing a step-by-step or interrupted by periodic forward movement of the controller, and a continuous or interrupted return movement of it to the off position through various automatics connected with the pilot motor and the initial control circuits.

In addition to the current-varying controller, there is a main reverser, likewise operated by the same agencies as the pilot motor, for determining the direction of the current delivered to the motors, and for instantly opening the circuit of the motors in case of emergency.

Inside of each cab is a small master controller or operator's switch mounted on a standard and fastened to the woodwork of the cab. Through this master controller the pilot apparatus of the current-varying controller and the reverses are governed. It is provided with a movable handle operating a spring-retracted spindle which, through various degrees of movement, makes contact with the reverser circuit and with three determinate positions—coast, series and multiple. Momentary contacts on these various points give any desired intermediate position of the main controller, which has a stepped movement. In order to maintain the controller at any point, or to keep the governing circuits or train-lines energized, the handle of the master controller must be held in position. If the handle is released, whether from accident or design, the spindle instantly returns to coast position, and the controller automatically returns to the off position and cuts off the current, or if the master controller is allowed to go to the center position, the reverser is instantly opened and the controller then comes to open-circuit also automatically.

The arrangements of circuits is such that by the use of a relay and throttle and the proper interconnection between the controlling circuits, the operator is at liberty to do about as he pleases with the master controller, and can rely upon the main controller operating satisfactorily.

For example: He can go to the series or to the multiple position, or from the last reverse movement instantly, and the controller, instead of responding instantly, responds progressively, the pilot being limited in its movements by increment of the main current to or above any definite amount.

The throttle is set just short of the skidding point of the wheels on a normal track, allowing 15 per cent adhesion, and absolutely limits the current input to that which is required by the determined rate of acceleration. Any rate less than this can also be effected by proper handling of the motor controller, so that any movements, no matter how refined, are perfectly possible.

This throttle is in the circuit of one motor only, so that it is equally effective whether in the series or multiple position.

Although there is a master controller on each platform, their construction is such that interference with them is difficult, and has never been known to occur.

THE "TRAIN-LINE."

So far, the system described is that of a secondary electric control of a single controller, but by paralleling the relay and other circuits it is evident that the two or more equipments on a single car can be operated, and also that if these equipments are put on different cars they can likewise be operated, provided means exist for properly connecting the prime controlling circuits and insuring practical synchronism of the different controls and equal work on the different motors. Where the equipments, however, are on different cars, it then becomes necessary to have a "train-line" and couplers, so that a governing circuit which can be energized at various points is made up of a "train-line" individual to either car and couplers of some kind between them.

This "train-line" is necessarily an independent line, not being a part of the main motor circuits on any car. It can be energized, of course, from any electrical source, but for convenience the main source of supply is the one used.

This "train-line" consists of five wires perfectly insulated, made into a common cable permanently located in the car and terminating at each platform in one or more couplers, in this particular case in a pair of couplers, one under each corner of the platform, these couplers being shrouded so as to prevent dirt or rain entering them.

When trains are made up the train-lines are connected by a reversible jumper having corresponding wires, and the system is so disposed and connected that no matter from which corner the connections are made, or how the cars are reversed or altered in sequence, the circuits are automatically established such that like track movement is always assured with like hand movement of the master controllers.

The section of train-line in each car is not a part of the normal controlling circuit individual to the control equipment, but is connected with it with switches, which enables a severance of the two systems, that is, the local-car system and the train-line, so that no matter how many trains may be made up, it is always possible to disconnect the controlling mechanism of any train for any purpose whatever.

The practical result of the system is that every aggregation of cars, whether one or more, has identically the same characteristics in the matter of load, capacity, motor-equipment, rate of acceleration, etc., as are possible with a single car, and every combination is made without the slightest thought being given to pairing of electrical circuits.

AIR BRAKES.

Each car is equipped with an automatic air-brake system, supplied by Christensen air compressors, with a reserve tank, and an equalizing pipe running from car to car, the compressors being started and stopped automatically through an air-governed switch by fall and rise of air pressure.

On each platform, alongside of the master controller, is a small engineer's valve, so that from any selected cab the air brakes can be operated with equal facility.

A balance wire runs through the train, and is included in the same coupling as connects up the electrical train-line, so that when an air governor on any car closes circuit, all compressors start and continue in operation until the last governor throws out. This is to effect equal work on the various compressors and to maintain absolute certainty of air supply at all times.

AUTOMATIC PROTECTION.

If a train should start, three systems of automatics come into play. The reversers go to open circuits, the controllers to the off position and the air brakes also automatically operate.

If the main circuit fails, all reversers open instantly and the controllers must come to the off position, which they will do automatically as soon as current is restored, before current can again be put in the main motors.

So, too, if there is an instant reversal of the master controller. The reversers first open circuit, the controllers return to the off or any determined position, then start again, and are instantly arrested on the first contact. Provision is made so that it is impossible to run backward at more than one-half speed from any platform when operating from that platform.

PERFORMANCE.

For several weeks, on account of lack of equipment, the motors on the equipped cars in the morning and evening hours were subjected to a regular increase of load of about one-third, and at times every motor car has been in operation. The economy of quick acceleration for high schedules has been thoroughly demonstrated. When coasting freely, on test, with car making 15-mile schedule, and under the conditions of grade and station intervals on the South Side road, the energy used at the car was about 73 watt-hours per ton-mile.

A very large number of records has been taken by Mr. Lundy (of Sargent & Lundy, the consulting engineers for the South Side Elevated Railroad Co.), these running into the hundreds, under all possible conditions of acceleration and all sorts of motor and trail car combinations, for determining the best methods of operation, the highest degree of economy under various loads, and for ascertaining track, car and gear resistances, resulting in a very satisfactory equation with speed and weight at factors. These are conclusive of the benefits of this method of operation, independent of the influence on passenger traffic of high-schedule speeds and short time intervals.

The system was put to the hardest test on October 19th, Jubilee Day, and although operating with only 148 cars on nearly 20 miles of total trackage, 240 cars per hour were sent into and out of the loop at Congress St., hour after hour, without a hitch. This was done by reversing trains at cross-overs at three or four different points, thus intensifying the car movement where traffic demands were greatest.

On this particular day, when the car mileage was increased about 80 per cent and with very heavy loads, the central station had six 400 h. p. (standard rating) boilers only in use, with but two men in the fire room, and there was no straining of engines, dynamos or batteries.

As an example of extraordinary duty, the operation during the recent holidays may be cited. During a good portion of the time the central station is reported by the consulting engineers as operating as follows:

Fifty per cent overload for six hours, full load for 17 hours and 74 per cent load factor for 24 hours.

Out of 120 motor equipments designed for individual operation, 119 were in daily operation morning and night, with 28 or 29 trailers, thus overloading the station one-third, and often these trains coming out of the loop from two to five minutes late have made up time before reaching the end of the run, but naturally, of course, at a loss of officiency.

The average duty of this equipment is higher than that of any other elevated railroad in the world. Cars have frequently made as high as 290 miles a day for days in succession, and the average maximum of cars in operation for long periods ran to nearly 100 per cent.

TROUBLES.

So much for the actual results accomplished on the South Side road. The question naturally arises, Have there not been difficulties, and if so, of what character?

Of course there have been, and I should have been surprised, and almost sorry, if it had been otherwise, because it is only through the difficulties incident to the earlier operation of a system of this character that the essentials are fully determined and apparatus developed to a state of perfection.

It is curious, however, that there have been more troubles with what is classed as "standard apparatus" than with that individual to the multiple-unit control. These latter troubles were, first, with the rheostats, which were of new construction, and later, poor brush terminals, cracked gear cases, and with the earlier type of air governors.

With the specific multiple-unit apparatus the principal troubles were with poorly and hastily wound relay coils, too light and unsubstantial construction of auxiliary contacts and improper jumper construction, causing an occasional opening of the controlling circuits.

Taken all in all, however, the preseident and superintendent of the road state that there were less troubles than when starting with their compound locomotives, and on the whole the success of the road has been unparalleled in electric-railway history where so radical a departure has been taken.

CONCLUSION.

Coming to New York conditions, I may say that, based upon the Chicago performance, and allowing for difference of coal cost, the Manhattan road, now operating at 12½ miles actual schedule during time of maximum load, and making about 43,000,000 miles annually, can be operated at over a 16-mile schedule at not exceeding 9 cents, instead of 11.9, and on the existing mileage this would mean a saving, excluding interest on investment, of about $1,250,000 per annum, or allowing interest on investments of about $750,000, to say nothing of any other gains. A 17-mile schedule can actually be made with two motor equipments.

In closing, perhaps I may venture an opinion as to the general features which should characterize a suburban passenger railway

equipment. I think it may be safely stated that the first is the use of the continuous current in the motor equipment, in spite of the claims which have been made and the results accomplished with alternating-current motors, at least so far as we can judge by any present developments.

The problem, then, is whence shall be derived this continuous current, and that depends upon distances. For moderate distances continuous-current generators supplying current directly to the line with or without the addition of storage batteries are preferable. When the extent of the line becomes at all serious, then it must be considered as made up of a number of shorter sections joined together, each of which derives its principal source of supply from a local station, which station can be driven directly by water or steam power, or by an alternating current from a distant station, using a motor-dynamo combined in a single type of machine, the rotary converter, or joined in the form of a directly coupled set, the dynamo end being for continuous current and the driver a synchronous or induction type of motor.

Generally the sub-station should be supplemented by a storage battery, to take care of fluctuations in the load, to make even the duty on the sub-station and, as far as possible, at the central station, and to take care of some portion of the peak-load caused by abnormal variations in the aggregate service at different times of the day.

Of course, with the storage battery comes the necessity of a means of some kind of automatic regulation; there are various methods, but I will not enter into them here.

Looking forward, however, to a perfectly assured future of a heavy service over considerable distances, I may state that the general equipment of such a road should generally involve the following essentials:

High-potential alternating-current transmission from one or two well-placed central stations, with or without static transformers.

Motor-dynamo sets or rotary converters at a number of conveniently placed sub-stations, to convert high-pressure currents into continuous currents of about 600 volts pressure.

Storage batteries of quick charge and discharge capacity at the same sub-stations as the motor converters, to equalize their duty and to prevent sharp variations in the generating plant as well as the sub-station.

A system of feeders and main conductors.

A power rail or trolley wire supplying continuous current, but ordinarily without any switching of currents.

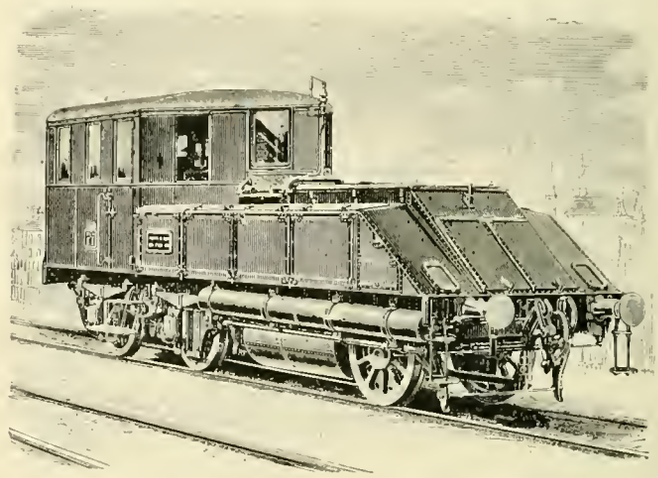
Individual transportation units with a multiple-unit control, so that combinations of cars without regard to sequence or end relation can be made up at any portion of the line independently and controlled from any selected point.

A STORAGE BATTERY LOCOMOTIVE.

The Campagnie de Lyon has in operation a storage battery locomotive built under the direction of M. Baudry, chief engineer, and M. Auvert, engineer of the central service of this company, which has been described by the latter in an article published in the Revue Generale des Chemins de Fer. This locomotive, which is illustrated herewith, was completed in 1897, and since that time has been in trial service upon the line from Paris to Melun. The machine has three axles, of which two only are drivers, and possesses about one-half of the power of the ordinary express locomotives on this road, but it is only necessary to double the number of driving axles to bring it up to the full power. It is connected to a tender carrying the accumulators, the hauling of which absorbs a notable part of the power generated on account of its very great weight.

The three sets of wheels of the locomotive all have the same diameter of 1.1 m. The front wheels are simply pilot wheels and are 6 m. in front of the middle pair. The boxes of the forward axle permit a lateral play of 15 mm. The two rear axles are separated by a distance of 2.2 m. and are driven by electric motors independent of each other. The housing of the locomotive is built in five distinct compartments. The one in the rear, which is situated directly above the motors, is the cab for the motorman and his assistant, and the forward compartment, of which the highest part is only 1.3 m., so as not to obstruct the view of the motorman, contains an air compressor run by a small electric motor of 5 h. p. This apparatus furnishes the compressed air necessary for the operation of the Westinghouse air brakes, the whistle and the starting apparatus. Of the three other compartments, two are situated, one on the right and the other on the left hand side of the engine, and are 1 m. in height. Each of these contain nine cells of accumulators, which, connected in series, are used to excite the fields of the motors and furnish the current necessary for the compressed air and the lighting. They can also run the locomotive at a very slow speed, say from 3 to 6 km. per hour. The fifth compartment, of a height of 1.3 m., contains a large water rheostat which opens and closes the circuits of the motor fields and also regulates their intensity.

The current for the locomotive is furnished by two batteries of accumulators of 96 cells each, which are carried upon the tender mentioned above and which are connected to the motors by four cables. The normal maximum current for which each armature is designed for continuous running is 700 amperes, and the effective power corresponding to this current is 300 h. p. This gives a speed of 103 km. per hour with the wheels revolving at 500 r. p. m. Under the conditions the difference of potential at the brushes is 360 volts. The available capacity of the 18 accumulator cells carried by the locomotive is 1,500 ampere-hours. The electrodes of one cell represent a weight of 140 kg. The total weight of the locomotive is 44,500 kg., of which 12,500 kg. are supported by the forward axle and 16,000 kg. on each of the two other axles.



STORAGE BATTERY LOCOMOTIVE.

The tender is carried on four axles with wheels .99 m. in diameter; the wheel base is 7.7 m. The total weight is 45,800 kg. It contains 192 cells and has a capacity of 1,000 ampere-hours, having an average rate of discharge of 500 amperes. The electrodes of one cell weigh 90 kg.

Upon each driving axle is mounted an electric motor with the armature placed directly upon the axle. The armatures have a commutator at each end. The fields are composed of two large horse-shoe magnets of soft steel placed one in front and the other behind the axle, the pole pieces embracing almost the whole exterior surface of the armature.

The armature is of the Brown type with the winding enclosed in a laminated sheet iron core, the armature conductors being surrounded by micanite and passed through holes close to the surface of the core. Two carbon brushes are used on each commutator.

On its trial trips between Paris and Melun, with a train weighing 147 tons, including the weight of the tender but not that of the locomotive, it has attained a speed of 45 km. per hour. The trials up to this time have been made chiefly to test the working of the locomotive, but a series of methodical trials are soon to be made to test the full capacity of the machine.

The Detroit, Ypsilanti & Ann Arbor Electric Ry. have put six new cars in operation upon its lines. The cars are 50 feet in length, five feet longer than those in use on the line now. Each car will seat 56 passengers, and contains a compartment for the use of smokers, separated from the body of the car by a glass partition. The seats are upholstered.

RECENT STREET RAILWAY DECISIONS.

EDITED BY J. L. ROSENBERGER, ATTORNEY AT LAW, CHICAGO.

FRIGHTENING HORSE BY SPLASHING THROUGH WATER.

Ayars v. Camden & Suburban Railway Co. (N. J.), 43 Atl. Rep. 678. June 12, 1899.

According to the verdict of the jury for the plaintiff, and the decision of the supreme court of New Jersey that it was a question for the jury to determine, the running of an electric car at the ordinary rate of speed through a pool of water upon the public highway is negligence where the unusual noise produced and splashing frightens a horse being driven upon such highway, causing a runaway.

CONDUCTOR AND MOTORMAN FELLOW SERVANTS.

Savage v. Nassau Electric Railroad Co. (N. Y.), 59 N. Y. Supp. 225. July 1, 1899.

The motorman and conductor on an electric street car, the second appellate division of the supreme court of New York holds, are fellow servants, so that the negligence of the conductor, as for example in taking out a car on the wrong track on a densely foggy morning, will be imputed to the motorman, preventing him from recovering from the company for injuries sustained thereby, as in a collision consequent thereon.

SHOULD HAVE HAD KNOWLEDGE OF DEFECTIVE CONDITION OF BRAKE SHOES.

Butler v. New York & Queens County Railroad Co. (N. Y.), 58 N. Y. Supp. 1061. July 1, 1899.

An accident having occurred by reason of the sudden falling of the brake shoes from a car, the second appellate division of the supreme court of New York holds that this was a defect of which the plaintiff, an employe, who was injured by the accident, could not be reasonably supposed to have had notice, although he took out the car, under directions to select the best one, but it holds that it was a defect from which the jury were authorized to find that the defendant in the exercise of reasonable care, should have had knowledge.

ASSUMES FENDER PLATFORM CARRIED BOY.

Green v. Metropolitan Street Railway Co. (N. Y.), 58 N. Y. Supp. 1039. June 30, 1899.

Regardless of whether he has not himself been negligent, the first appellate division of the supreme court of New York holds that reasonable care must be used to avoid injuring a boy after he is placed in a position of danger. As having a bearing on this, especially as to whether a car was promptly enough stopped after it struck a boy, it suggests that, the car in question having no fender in front, but being furnished with a fender under the platform, placed just before the front wheels, the inference could be fairly drawn that against or upon this fender the boy rested for a period of time while being carried a distance which was variously estimated by the witnesses.

SHOULD HAVE BEEN INFORMED OF PERIL.

West Chicago Street Railroad Co. v. Johnson (Ill.), 54 N. E. Rep. 334. June 21, 1899.

On this appeal, the supreme court of Illinois affirms a judgment for $3,000 damages for injuries sustained by a boy of about 16 years of age who was struck on the leg by the sudden flying back of an iron brake lever on a grip car. The evidence was deemed sufficient to justify the jury in finding that the cable train was so crowded as to warrant the boy in pushing past other passengers into the gripman's aisle, where, it appeared, it was not unusual for passengers to stand when riding on similar cars operated by this company, under like circumstances. The evidence was conflicting as to whether the gripman told the boy to move back, or motioned or pushed him back. But with regard to this, the supreme court says that the boy had been accepted as a passenger, and as such was, of necessity, entitled to space in the car, and that the mere suggestion or request on the part of the motorman that he leave the position taken by him, without informing him of his peril, taking into consideration the crowded condition of the car, presented a question of fact as to whether he was guilty of contributory negligence in not obeying, to be determined by the jury, and not to be determined by the court in an instruction.

CROSSING STREETS COMPARED WITH OTHER TRANSACTIONS.

Baltimore Consolidated Railway Co. v. Rifcowitz (Md.), 43 Atl. Rep. 762. June 20, 1899.

In crossing streets, the way the court of appeals of Maryland states the rule, due and ordinary care must be exercised, as in all other transactions of life.

AUTHORIZES CHANGE IN ROUTE.

People, on relation of Long Island Railroad Co. v. Board of Railroad Commissioners (N. Y.), 59 N. Y. Supp. 144. July 6, 1899.

A change in route, not affecting substantially its character, and made in order to obviate objections of the local authorities, the third appellate division of the supreme court of New York holds, might well be deemed a defect such as might be allowed to be corrected under section 59 of the railroad law of that state, which gives the board of railroad commissioners power, before granting a certificate for the construction of a road, to permit errors, omissions, or defects to be supplied and corrected; and it holds that such a change might be disregarded or approved, if made after the filing of the articles of association, and before the application to the board.

MOTORMAN MUST DO ALL IN HIS POWER UNDER THE EMERGENCIES SURROUNDING HIM.

Citizens' Street Railway Co. v. Dan (Tenn.), 52 S. W. Rep. 177. April Term, 1899.

In this case, wherein the supreme court of Tennessee affirms a judgment for $2,500 for the killing of a child four years of age, it holds that, in the connection in which it was used, a charge to the jury was not too strong, nor did it exact too high a degree of diligence, which was substantially that it is the duty of the motorman to keep a vigilant lookout for children in, upon, or using the street, and, upon the first appearance of danger or probable collision with any one of them, to stop his car in the shortest time and space possible. To stop his car in the shortest time and space possible, the supreme court goes on to say, would be but the exercise of ordinary or reasonable diligence under the emergencies mentioned by the trial judge, and this means simply that the motorman must do all in his power under the emergencies surrounding to save human life.

COURT CANNOT LAY DOWN DEFINITE RULES FOR MANAGEMENT OF ELECTRIC CARS.

Lawler v. Hartford Street Railway Co. (Conn.), 43 Atl. Rep. 545. June 8, 1899.

The supreme court of errors of Connecticut declares that it cannot lay down definite rules for the management of electric cars. At the same time, it holds that, in the absence of any law or municipal ordinance regulating the speed of street cars, they must be run at such speed and must be kept in such control as not to interfere unreasonably with the rights of others upon the highway, and reasonable care must be exercised to avoid inflicting injury upon others. More particularly, it thinks it cannot say that, as a matter of law, the defendant was not negligent in running or coasting its car down grade at a speed of what was probably 12 miles an hour.

or in not having more complete control of the car than not to be able to stop it until it had run 130 feet after a collision, or in omitting to sand the track. So that, the finding here being against the defendant, it affirms a judgment thereon for the plaintiff.

CURTAIN RODS DO NOT REQUIRE VERY HIGHEST CARE.

Leyh v. Newburgh Electric Railway Co. (N. Y.), 58 N. Y. Supp. 479. June 6, 1899.

This was an action brought to recover damages for injuries sustained by a passenger by being struck by the end of an iron curtain rod which had just been broken by a strong wind. The plaintiff got a judgment. But this the second appellate division of the supreme court of New York now reverses. It declares that it cannot hold that a common carrier of passengers is bound to use the very highest degree of care in respect to the curtain rods of its cars. The defendant, it holds, was bound to use reasonable care, adequate to the use of the appliance and to the probable results of its use. It was not bound to foresee and prevent such an unusual and not to be expected accident as that developed by the evidence here. It also says that it does not consider that this was a case where the doctrine that "the thing speaks for itself" applies, and that it was therefore incumbent on the plaintiff to establish some negligence on the part of the defendant. That the car was built and the curtains put in by a firm which was proved to be of high standing, and one of the leading car builders of the country, and that similar curtains were in general use on a great many other roads, it points to as showing that care was used and precaution exercised, though not conclusive evidence that the carrier used requisite care.

PARALLELING STEAM RAILROAD IN CONNECTICUT.

Central Railway & Electric Co. v. New York, New Haven & Hartford Railroad Co. (Conn.), 43 Atl. Rep. 490. June 1, 1899.

The supreme court of errors of Connecticut says that the statute gives a steam railroad a legal right to protection against a parallel street railroad until a court has judicially found such road to be of public convenience and necessity. For this reason, it holds that the defendant steam railroad company was a necessary party to the plaintiff's application for a judicial finding that it was of public convenience and necessity, and that as such party the defendant company was entitled to raise all questions involved in the adjudication. The trial judge, it goes on to state, had no power to make the finding asked, if in fact no parallel road was authorized, that is to say, was already duly chartered. The legal right to construct such a road, the court holds, is a condition precedent to the judge's action. It must be found. But the court holds that where the construction of an electric railway was authorized "to a convenient point" in a certain town, "where connections can be made" with a certain named other electric railway, the right to build it would not be affected by the abandonment of the second mentioned railway, especially where the charter merely authorizes, but does not require, the completion of a connection with such other railway.

QUESTION OF NEGLIGENCE IN COLLISION WITH HOOK AND LADDER TRUCK.

Warren v. Mendenhall, receiver of the Duluth Street Railway Co. (Minn.), 79 N. W. Rep. 661. June 26, 1899.

In an action by a member of a city fire department against a street railway company for damages for an injury to him resulting from a collision, at a street crossing, between a street car and a hook and ladder truck driven by him, the question of the defendant's negligence and of his contributory negligence, the supreme court of Minnesota holds, were both for the determination of the jury. As between the plaintiff and the defendant, it was immaterial, the court considers, whether he owned the truck himself, or was driving it as the servant of the city. If he was driving a vehicle which was so unwieldy and unmanageable that it was dangerous to drive it on the public streets, and this was the cause of the collision, it holds that he could not blame the defendant. On the other hand, the court holds that the duties of a member of the fire department of a city, when driving fire apparatus on a call to a fire, might require him to take risks which it would be negligence for a private person to take in pursuit of his private business. Of course, it adds, such a fireman must use ordinary care, that is, care commensurate with the occasion. Aside from any ordinance on the subject, Mr. Justice Canty, who delivered the opinion of the court, says that, in his opinion, the right of way for the fire department would be implied. Order directing a verdict for the defendant and denying a new trial reversed, and new trial granted.

PASSENGER BOUND TO KNOW THAT CAR USUALLY STARTS OR STOPS WITH SOME JERK.

Currie v. Mendenhall, receiver of Duluth Street Railway Co. (Minn.), 79 N. W. Rep. 677. June 29, 1899.

It is the duty of those in charge of a car to give passengers an opportunity to alight in safety, and a high degree of care, the supreme court of Minnesota holds, is required in affording passengers the opportunity to do this. On the other hand, it says that, ordinarily, and usually, a street car jerks to some extent in stopping and starting. And it holds that it is the duty of a passenger to know this, and act accordingly, for the purpose of protecting himself from such a jerk at such a time; and, if he fails to take any reasonable precaution for that purpose, he is guilty of contributory negligence as a question of law, while if he does take such precaution, and is thrown off by an extraodinary jerk, his contributory negligence is a question for the jury. At the same time, it holds that a passenger had a right to assume that the movement of a car, for which the conductor has given the signal to stop, will be the ordinary one, viz. that when a passenger is invited or authorized to alight, and the car is slowing up for him or her to do so, it will not start with a sudden jerk. It further holds that it is not negligence in itself for a woman, after the conductor has, at her request, rung the bell for the car to stop for her to get off, to go and stand for a moment upon the step of the rear platform, with her right hand holding to the rail of a slowly-moving street car, when she believes, and has good reason to believe, that the car is about to stop for her to get off, but that the question of negligence on her part is for the determination of the jury.

RUNNING DOWN STREET SPRINKLER.

Abrahams v. Los Angeles Traction Co. (Cal.), 57 Pac. Rep. 216. May 15, 1899.

The plaintiff was injured while driving a sprinkling wagon by having the latter run down by a street car on the street which he was sprinkling. In affirming a judgment in his favor for $3,000, the supreme court of California says that, in approaching at high speed so unwieldly a vehicle as a modern sprinkling cart, a motorman of an electric car cannot reasonably assume that the track will be cleared as quickly as by a bicycle. In cities, where heavily freighted wagons and vehicles of every description frequently take the track of the street cars, it continues, a common observation teaches, what must be presumed to be well known to motormen, that a warning 700 feet away to the driver of a sprinkling cart, by sounding the car gong, may not be heard by the driver of the wagon; and the motorman would not be justified in quickening his speed to the highest point, and advancing without further warning, on the assumption that the signal would be heard and obeyed in time to clear the track.

BOYS RIDING WITH AND WITHOUT INVITATION OF MOTORMAN.

Little Rock Traction & Electric Co. v. Nelson (Ark.), 52 S. W. Rep. 7. June 3, 1899.

A boy 10 years of age, riding upon a street car without paying fare, by invitation of a motorman in charge of the same, who has authority to receive and let off passengers, the supreme court of Arkansas holds, is not a trespasser. The invitation of the motorman is an act within the general scope of his employment, for which he is responsible to his master. If the boy accepts it innocently, he is no trespasser, and it is the duty of the company to extend to him the diligence due to passengers of his age and discretion.

In entering, riding upon, and leaving street cars, the court further holds, a boy 10 years of age or over is bound to exercise prudence equal to his care, knowledge, and experience. To that extent he

is under a legal duty to avoid danger, and is held responsible in law for acts or omissions contributing to his own injury.

But the employes of a street railway company, the court maintains, are under no obligation to keep a lookout to prevent boys, endeavoring to ride without permission and paying fare, from entering its cars while in motion. Such a boy who does or attempts to do so is a trespasser, and the company owes him no duty save not to injure him wantonly.

Evidence that boys have ridden on the defendant's cars at different times without permission, and at other times by invitation, and without paying fare, the court holds incompetent, as not tending to prove that the plaintiff was or was not entitled to ride on the car he attempted to board at the time he was injured.

MUST MAKE REPAIRS DIRECTED BY ROAD COMMISSIONER.

Maloney v. Natick & Cochituate Street Railway Co. (Mass.), 54 N. E. Rep. 349. June 30, 1899.

By the Public Statutes of Massachusetts, chapter 113, section 32, it is provided that every street railway company shall keep in repair, to the satisfaction of the superintendent of streets, street commissioner, road commissioners, or surveyors of highway, the paving, upper planking, or other surface material of the portions of streets, roads and bridges occupied by its tracks.

This, the supreme judicial court of Massachusetts does not think means that the approval of the road commissioner is a condition precedent to the running of the road, but merely that, if he directs repairs, they must be made.

Furthermore, it being impossible for a road commissioner or superintendent of streets personally to attend to the repair of all the streets, roads, and bridges, so that, in a large town, he must, of necessity, have assistants, the court holds that the fact that an assistant has charge of a certain locality sees the work, and is satisfied, is evidence tending to show that the work is done to the satisfaction of his principal, and to negative the theory that the actual state of things is due to any want of compliance with the directions of the commissioner.

Under another provision of the statutes, the court holds that where an injury is caused by a neglect of the company to repair what it is obliged by statute to keep in repair, notice of the accident must be given it within thirty days, though such notice is not required where an accident is caused by a defective construction.

CANNOT ASSUME BROKEN-DOWN WAGONS WILL GET OUT OF WAY.

Sweeney v. Kansas City Cable Railway Co. (Mo.), 51 S. W. Rep. 682. May 23, 1899.

In no case, does the supreme court of Missouri, division No. 2, consider that a gripman has the right to assume that such obstructions as a broken-down wagon will move out of the way. It further maintains that if the gripman in question could have seen the broken-down wagon on the track in time to stop, had he looked, the presumption was that he did not look, or, if he did look, that he did not heed what he saw, so that in either case he was negligent.

Nor does the court consider that a passenger, who was fatally injured by the car he was on being run into such a wagon, was guilty of contributory negligence in being upon the running board, he having stepped onto the running board when he had reached the place where he wanted to alight and the gripman, through inattention to duty, having failed to stop the car there, was carrying him on to the next street.

There is no question, the court insists, but that the degree of care required of street railway companies towards their passengers is the utmost care and diligence of very cautious persons.

NO INJUNCTION AFTER COMPENSATION FOR RIGHT TO USE TRACKS.

People's Railway Co. v. Grand Avenue Railway Co. (Mo.), 50 S. W. Rep. 829. Mar. 31, 1899.

It is a well-settled principle of law, says the supreme court of Missouri, that where a new duty or cause of action is created by statute, and a particular proceeding, not theretofore existing, to enforce the duty or to vindicate the right conferred, is prescribed, the statutory remedy is adequate, and no other must be pursued. Applying this, the court holds that the proceeding provided by the St. Louis ordinances for the purpose of securing to the plaintiff full and fair compensation for all the injury it might suffer by reason of the delays and inconveniences resulting from the exercise by the defendant of its right under the city charter to connect its track with, and pass its cars over, the plaintiff's tracks, was a valid and adequate one, so that the compensation once having been determined thereunder and accepted by the plaintiff it would not afterwards be entitled to any relief by injunction from any such delays and inconveniences.

ENTITLED TO USE TRACKS FOR OWN CARS ONLY.

South Side Passenger Railway Co. v. Second Avenue Passenger Railway Co. (Pa.), 43 Atl. Rep. 346. May 22, 1899.

By agreement, a street railway company acquired the right to use certain tracks. The use by it was without limit as to amount. But it was a use for itself and its own cars, only. Under these circumstances, the supreme court of Pennsylvania holds that the company had a power of growth, but had no general power of expansion into other fields, or of increase by the absorption of other roads. In other words, the court holds that when the company itself was absorbed by another company, the latter became a practical "assign," which, under the agreement, was entitled to the continuance of all the rights and privileges given to the assignor by the agreement, but nothing more, so that while it was entitled to use the tracks for the cars from the line of the first company, however many, it could not use them in the operation of its leased or consolidated lines, other than for such cars of such first company.

DUTY WHERE CAR SLOWS UP AFTER FAILURE TO STOP AT CROSSING.

Birmingham Railway & Electric Co. v. James (Ala.), 25 So. Rep. 847.

The supreme court of Alabama approves of an instruction to the effect that if an electric car passed a street crossing without stopping for a passenger to alight in response to his signal, and then slowed up to such an extent as would imply, on the part of those persons who had charge of the car, that was an invitation for him to alight at that point, and he endeavored to do so, then it was just as much their duty not to jerk the car suddenly, or give it a forward impetus so suddenly as to imperil his life or his safety, as if it had been at the crossing itself, and that they were under just as much duty to protect him against injury as if the stop had been made right at the street crossing. And the court does not consider that it is negligence, as a matter of law, for a passenger to take, with ordinary care, a position on the steps of a car preparatory to alighting, nor for him to attempt to alight from a car moving so slowly that it would not appear dangerous to do so to a man of ordinary prudence.

DUTY TO CORRECT ABUSES OF JURY SYSTEM.

Messenger v. St. Paul City Railway Co. (Minn.), 79 N. W. Rep. 583. June 14, 1899.

The supreme court of Minnesota admits that it cannot say that there was not some evidence in this case to support the verdict for the plaintiff. But her uncorroborated evidence on the essential and vital point in the case, namely, as to the manner in which she was injured, it insists, was so inherently improbable and unreasonable that the trial court must be held to have abused its discretion in refusing to set aside the verdict, and grant a new trial. And the supreme court itself grants a new trial.

The court says that this rule can be applied by it only in extreme cases. But when such a case is presented it maintains that the court should not hesitate to act. The court which refuses to do anything to correct the abuses of the jury system, it adds, is one of the worst enemies of that institution. Such a court, it believes, is doing what it can to pave the way for the abolition of the jury system, the establishment of "government by injunction," and the establishment of a one-man system, in which the judge who acts as a jury will be altogether too liable to be selected, controlled, or in-

fluenced by great corporations and by men of great wealth or political influence.

LIABILITY FOR INJURY TO TRANSFER PASSENGER BY TROLLEY POLE BREAKING.

Keator v. Scranton Traction Co. (Pa.), 43 Atl. Rep. 86. Apr. 24, 1899.

To change from one line of street railway to another operated by the same company passengers had a block to walk. A transfer ticket issued from one to the other read: "Good upon next south side car within thirty minutes from nine o'clock." The holder walked to the starting point of the south side car. While she was standing on the pavement, the car pulled up. As that was a terminus of that line, the motorman attempted to change the trolley pole to the other end of the car. In doing so, it broke, a piece striking the woman, inflicting a severe injury. When struck, she had moved to a point midway between the curb and car.

The turning point in the case, was on the question of whether the woman was a passenger at the time of the injury, to whom the company owed care accordingly. The supreme court of Pennsylvania, however, stated that there is no definition of the duty of the company to her which fitted the facts of the case. And it called special attention to the fact that the injury to her was from a defect in an indispensable attachment of the very vehicle in which the company had undertaken to carry her.

So far as the transfer ticket was concerned, the court says that it must be conceded that it, on its face, was an undertaking to carry her from the point where the car started to her destination on the south side line, and says that she was not a passenger while on the sidewalk going from one point to the other.

Yet surely, in such situation, under such circumstances, as above stated, the court holds, the carrier's duty to her was what it owed to a passenger—as much so as if her injury had been caused by a rotten step on the car. When she came within reach of the vehicle provided for her transportation, it maintains, the carrier's duty was that she not be injured by the vehicle, if the highest degree of care could prevent it. Such care the company was bound to show affirmatively. It did not attempt to show it. Therefore, the court concludes, it was answerable in damages for her injury.

STARTING OF CARS BY INTERMEDDLERS.

Leavenworth Electric Railroad Co. (Kan.), 57 Pac. Rep. 519. June 10, 1899.

The evidence in this case showed that the plaintiff and her child were passengers on a certain street car, and that she told the conductor to let her off at a particular street. As the car approached that street, it was quite full of passengers. The conductor desired to occupy his time in collecting fares, and, in order to enable himself to do so, asked a conductor of another car, who was off duty, and riding on this car, to let the woman and her child off. This the latter conductor promised to do. He gave the signal to stop at the desired street, but himself left the car at that point in advance of the plaintiff and the child, without giving the starting signal. The child descended in safety, and the plaintiff herself went as far as the steps, when some unauthorized and unknown person gave the starting signal to the motorman. The car started. The woman grew dizzy, and fell to the street.

In affirming a judgment for the plaintiff, the supreme court of Kansas holds that a street railway company is bound to the highest possible caution and prudence in letting off its passengers at its stopping place, and its employes must not merely wait a reasonable time to enable the passengers to alight, without looking to see whether such has been done, but they must see and know that the passengers are safely off before starting the car in motion again.

When a street railway car is negligently started in motion before a passenger endeavoring to leave it has safely alighted from it, and while it is so in motion the passenger is seized with an attack of dizziness, which prevents her from holding on, and in consequence falls off, and is injured, the company is liable.

A street railway company is not responsible for injuries resulting from the act of an intermeddler in the running of its cars, which its employes could not foresee and guard against; but when such act of intermeddling consists in giving the signal to start the car in motion, and the conductor in charge, without seeing and knowing that a passenger has safely alighted before the car started, does not stop it as soon as he can, but allows it to continue in motion in obedience to the unauthorized signal, he will be held to have ratified and adopted the act of the intermeddler, and the company will be liable for the consequent injury as caused by an act of its employe's negligence.

If, by custom among street railway employes, known and assented to by the company, those who are on duty are in the habit of calling for and receiving assistance from those who are not at the time on duty, and an employe off duty, thus called upon, undertakes to render the assistance asked, he will be regarded as in the employ of the company for such service; and, if he negligently abandons the work before completing it, whereby injuries to a passenger occur, the company will be liable.

If, however, such custom does not exist, or, existing, is not known and asserted to by the company, but an employe on duty deputes the one off duty to assist him, and he undertakes to do so, but negligently fails to fully perform it, whereby injury to a passenger occurs, the company is likewise liable, because of the negligent abandonment of duty by the employe directly chargeable with its performance.

PRESUMPTION IS THAT TRACK IS CLEAR.

Kramer v. New Orleans City & Lake Railroad Co. (La.), 26 So. Rep. 411. January 9; Rehearing denied, June 27, 1899.

This was a case of a drunken man lying near an electric street railway track, throwing his feet, or that portion of his legs below the knees, across the track, and in that condition receiving injuries requiring the amputation of his legs near the ankle joint. A verdict was returned in his favor for $12,500. But the supreme court of Louisiana reverses the judgment based on such verdict, ordering that the plaintiff's suit be dismissed, with costs. It does not consider that it can hold that a motorman, entering a curve on a street is required to closely scan the rails beyond the curve to discover the protruding feet of a man in the grass, 70 feet beyond the curve. The presumption is, it holds, that the track is clear; not that this at all releases the vigilance to be exerted by the motorman, but, in estimating that vigilance in such a case as this it authorizes the making of some allowance for a failure of the motorman to discover such objects on the tracks under such conditions. Moreover, it thinks that there is certain to be a difference in the quickness and accuracy of the perception of a motorman in such case, where he has no cause to suspect—still less to know—such objects being on the track, and of a man who puts his handkerchief at the place of the accident and then seats himself to look for and perceive the object he has thus placed in position. In such a case as this, for the plaintiff to recover damages, the court holds, he must show with reasonable certainty that, notwithstanding his gross imprudence in thus exposing himself to peril, the defendant's motorman could, by the exercise of ordinary care, have averted the accident.

CAN ASSUME THAT CHILD WILL NOT DELIBERATELY RUN INTO CAR.

Adams v. Nassau Electric Railroad Co. (N. Y.), 58 N. Y. Supp. 543. June 6, 1899.

Children early learn that contact with some things will produce pain and injury, and their education with respect thereto proceeds with considerable rapidity. While they lack judgment to act with care and circumspection in respect of such matters, yet they are quite sensible of the necessity of avoiding contact with objects which experience has taught will inflict harm. A child will not usually place its hand in the fire, as it early learns that if it does it will be burned, and it will not voluntarily run into a moving car, being sensible that pain will follow. A child of sufficient maturity to play about the streets, and of the age say of nearly 6 years, may be assumed to know that injury would result to him from such an act. These well-known facts, the second appellate division of the supreme court of New York holds, people engaged in traffic upon the streets may reasonably and fairly take into consideration in operating their vehicles thereon. So, in this case, the court thinks that the motorman had the right to assume that an infant of such

age would not voluntarily leave the walk at the side of the street, and deliberately run into the car. Consequently, it holds, he was not, in the exercise of reasonable and ordinary care, required to operate his car in contemplation of such a contingency, although he was undoubtedly required to be upon his guard against the heedless action of immature children. And, as the fact was that the child did not reach the track until some part of the car had passed the child, the court declares itself unable to see that any act was required of the motorman to check his speed, as at no time was the child on the track in front of the car. That the car was stopped within a distance of 20 feet after contact with the child, the court considers showed that it was evidently under reasonable control. Judgment for the plaintiff reversed.

RESPONSIBILITY FOR OBSTRUCTION OF HIGHWAY WITH PILE OF RAILS.

Slayton v. West End Street Railway Co. (Mass.), 54 N. E. Rep. 351. June 30, 1899.

The fact that the plaintiff by her own admission did not notice the pile of rails over which she fell, the supreme judicial court of Massachusetts holds, would not alone require it to be held, as matter of law, that she was negligent as the presence of the rails was a temporary condition which she was not bound to anticipate.

But be that as it might the street railway company argued that the evidence adduced was not sufficient to warrant a verdict against it for the plaintiff, because the work of substituting new for old rails was being done by a firm of contractors. Nevertheless, the court overrules the company's exceptions to a judgment for the plaintiff. It points out that it was to be noticed that the railway which was under repair was in actual use for the transportation of passengers, and that it was more natural that the control of the work of repairs, which would unavoidably affect the safety of operation, should be retained by the company than committed to independent contractors, whom the company could not control. Moreover, it says that whether the relation of the firm to the defendant company was that of an independent contractor or that of an employe was a matter peculiarly within the knowledge of the company, and, when the latter rested its case without introducing evidence upon the subject, some inference might be drawn from this conduct. Again, it insists that the fact that the rails were used to repair the defendant's railway had some tendency to prove that they were its property, and placed in the gutter for its convenience and by its servants.

So, even if each separate piece of the evidence was so consistent with the defendant's nonownership and lack of control as with its responsibility, the court holds that the state of the whole evidence at the close of that part of the trial, in view of the fact that the defendant introduced no evidence as to the true relation of the contractors itself, justified the submission of the issue to the jury.

RIGHTS OF DELIVERY WAGONS VERSUS STREET CARS.

Black v. Staten Island Electric Railroad Co. (N. Y.), 57 N. Y. Supp. 1112. May 8, 1899.

A man driving a wagon for the delivery of groceries, after following the street car tracks until he came to within about 100 feet of his destination, looked behind, but could discover no approaching car. It was about 8 o'clock in the evening, and somewhat dark and misty, but he could probably have seen the headlight of a car for a distance of about 300 feet. The street at the point where he stopped was about six feet and six inches wide from the curb to the first rail of the track. There he turned from the track, hung up his lines on a hook in the wagon, and stooped down to pick up the packages he was to deliver, when a car, approaching from the rear, struck his wagon. He said that he supposed he was clear of the track, but did not look to see, feeling perfectly safe in the place he stopped the wagon. The motorman testified that the hind wheel of the wagon was over the track for a distance of about three inches. The main contention of the company was that the driver was guilty of contributory negligence in failing to look back and observe the approach of the car, and also in failing to make such observation as was necessary to make sure that he was clear of the track sufficiently far to enable a car to pass without coming into contact with the wagon.

So far as the first proposition was concerned, the second appellate division of the supreme court of New York holds that the jury was authorized to find that the driver made such observations as a prudent person would ordinarily make under the circumstances, to discover whether any car was approaching, and therefore acquit him of negligence in that regard.

Upon the other question, it pronounces the case somewhat closer, yet it thinks the evidence presented a question for the jury in that regard. It says that it is to be borne in mind that, while the right of the railroad company to have its cars move over its tracks is paramount to the right of use by the public, yet such rule is not an absolute one in all cases. The railroad company has no paramount right of use, as against persons having occasion to make use of the street for proper purposes.

People with vehicles, engaged in the delivery of merchandise, continues the court, have an equal right with such railroad company to occupy the street, for a reasonable time, to insure such delivery, even though it prevents, for the time being, the operation of the cars thereon.

Where a street is so narrow that a vehicle may not be stopped upon it for the purpose of delivery of merchandise without obstructing the tracks of the railroad company, such persons have the right of reasonable use, for the purposes of their business, equal with the railroad company; otherwise, it might well be that the street could not be capable of use by any one with vehicles, save the railroad company. Under such circumstances, the court thinks that their rights are equal, and that one may not exclude the other.

In this case, the court says, the plaintiff was lawfully using the street for the purpose of delivering his commodity; and if, in the accomplishment of such purpose, it became necessary to obstruct the railroad track, the defendant company was required to yield to such necessity, and give the plaintiff reasonable opportunity for such delivery.

Even if the street were wide enough to admit of the delivery wagon standing between the curb and the rail and permit the car to pass, of which the court is by no means sure, it holds that if the plaintiff exercised reasonable care in looking for the approach of a car, he had the right to stop for a time necessary to make delivery of his goods; and it was for the jury to say whether, in view of the width of the street, and of the space between the rail and the curb, the observation which he made for the approach of the car was such as a person in the exercise of ordinary prudence would have taken.

The defendant company was chargeable, equally with the plaintiff, the court holds, with knowledge of the space between the curb and the rail, and in the operation of its cars upon such street it was required to exercise due care in passing vehicles thereon, and not to so operate them as to come into contact with such vehicles; and if it could not pass a vehicle standing upon the street, or if the vehicle was necessarily upon the track, then the obligation of the company required it to suspend operations for the time necessary to enable the person so standing to make delivery of his merchandise.

Taking into consideration the width of the space between the rail and the curb, the width of the plaintiff's vehicle, the overhang of the car, and the obligations of each to the other, the court finds itself unable to say that the plaintiff in this case was guilty of contributory negligence, as matter of law, in permitting his vehicle to come to rest at the time and under the circumstances disclosed by the evidence. On the contrary, it thinks that the question was one of fact, and was properly submitted to the jury.

Judgment for the plaintiff affirmed.

NEW MAINE ROAD OPENED.

The Westbrook, Windham & Naples (Me.) Electric Railway was formally opened to the public on August 17th, which was the occasion of a general celebration all along the line. The directors and their friends were given a royal reception in the form of a celebration. Extra cars kindly furnished by the Portland Railroad Co. were put on the line and were busy all day.

An elaborate banquet was prepared and afterwards congratulatory speeches were made by a number of the townsmen; a band concert, fireworks and illumination concluded the evening.

UNIFORMS.

The late Emepror William of Germany was a great stickler in matters of apparently small concern. On one occasion he was reviewing troops, when suddenly he ordered one of the soldiers to step from the ranks and thereupon proceeded to administer a most scathing censure. When he had finished, he remarked to the officer in charge: "It is the leaving one button unbuttoned that spoils the discipline of an army."

While in street railway service there is certainly no such occasion to narrow instructions down to the buttoning of a certain number of buttons on a pleasant or stormy day, it cannot be denied that a missing, or battered or rusty button, does greatly detract from the appearance of the rest of the uniform, and it is much more noticeable than the loss of a button from a citizen garment. The very word uniform means "all alike," but where one man wears a single-breasted coat and the next a double-breasted garment there is obviously a wide difference. We think the roads of the east generally give more attention to uniform matters than do our western lines; but both east and west there is a growing tendency to raise the standard of the appearance of the men.

It is difficult to tell exactly just wherein lies the benefit which certainly results from a thorough uniforming, but there can be no doubt of the effect. A western steam road a few months ago decided to extend its uniforming into all departments, including brake-

MILWAUKEE ELECTRIC RAILWAY & LIGHT CO.

men on freight trains, depot and baggage men, and even the crossing flagmen. In short, all employes who come into public view. The president of the road reports the result as both highly satisfactory and surpassing. An employe of the road in citizen's clothes standing on a depot platform may be inclined to return a careless or even uncivil reply to some traveler; the same man in uniform is not only recognized as belonging to the road, and hence easily singled out when information is needed, but he is more careful in his conduct and treatment of others, for the inquiring stranger may be an officer or director of the road. The men also are less free to visit saloons when on duty and in uniform. On this road the extension of the uniform service brought a radical improvement in the general discipline, which was considered good before.

We believe that on many street railways the question of the uniform is not appreciated, and the management is satisfied with a general order specifying a certain uniform. Our observation and experience in this work leave no doubt that to be effectively done requires a good and frequent system of inspection and a firm insistance on keeping up to the regulations. It may not be necessary to issue a blanket order that on May 1st and November 1st every man shall procure a new suit, though nearly all steam roads and police departments require the wearing of the summer and winter uniform in season. The work of a conductor especially is particularly hard on aparel, but the same man at the wages paid for conducting would not expect, as a clerk in a store, to appear in the decidedly shabby outfit we frequently see him wear on a car. The conductor is certainly sufficiently well paid to warrant the company in expecting him, as the principal representative of the company before the public, to present himself in attire at least whole and clean. Yet time and again we have seen men on duty on a car clad actually in rags. What impression of the management that allows such things is made upon the public and strangers in the city needs no comment, and yet that road may be—otherwise—well managed and conducted.

The daily press frequently comment in severe terms on the arbitrary order, as they term it, of a road when it issues a uniforming order. They never do for a police department or a military company. Any yet the prices which companies secure for their men for uniforms are extremely low and almost always several dollars less than the employe could get the same garment made elsewhere. Uniform makers, like other business men, can afford to make a lower price per suit on 100 or 1,000 uniforms than tailors can, making an occasional suit out of the same materials.

Naturally some men wear their suits longer and take better care of them than others, but there are few conductors who can get along and still look presentable with less than two suits in one year, or three suits in two years at longest.

With a strict system of inspection and a firm enforcement of rules it is less difficult than many suppose to bring the standard up where it should be. We have known cases where men reported as in bad uniform when called in for inspection to borrow a good suit for the occasion, and when returned to work don the old garments. But a simple system of records showing when the order was last issued for a suit readily throws light on the subject.

There are several ways in which the standard may be kept up; inspection at car depots is one placing the responsibility entirely on the depot master or car house foreman for the appearance of his men, or by an order and record system. A plan adopted by one company will suggest its application anywhere. Bids are received for furnishing a garment in accordance with the company's specifications. When a man needs a uniform he goes to the uniform clerk, who issues the order on the maker. The man presents his order, which is in duplicate; one coupon he retains and attaches to his monthly bill to the company, the other he fills out and returns each day stating that John Smith, conductor No. 300, has been measured for his uniform. By checking these coupons against his order book stub, the uniform clerk knows the garment is being made. This prevents the men from accepting an order and not using it. A transfer of the reading of the stub into simple record book gives a complete history of a man's uniforming for any term of years. In the case of the road just mentioned the company pays for the uniform and deducts the amount from two pay days, thus making it easier on the men.

Many street railways do not find it necessary to use different weights of cloth summer and winter. The steam roads frequently do; the New York Central, for instance, use a 16-oz. single breasted suit in summer and a 25-oz. double breasted in winter. The Metropolitan Traction Co., of New York, which is a well uniformed road, uses two weights for conductors and a double breasted coat for motormen.

The reflex action on the man wearing a uniform is beneficial. It gives him an added dignity and authority. New men going on to a uniformed road quickly discover that the public recognize them as green and take advantage of them. The new man is always glad to get into his regulation suit. On some roads a man is not required to uniform for two weeks pending his acceptance. On others the "student season" is less; on others he is not allowed to take a car until in dress, and must take his chances on proving satisfactory.

The series of three photographs shows the uniforms worn by the employes of the Milwaukee Electric Railway & Light Co. The first two are of a conductor with and without his overcoat and the third represents a motorman with a fur-lined overcoat, which is found to be a great protection in that latitude. Aside from the lining in the overcoat the conductors and motormen are uniformed alike. On account of the cold nights at all seasons of the year, due to the proximity of Lake Michigan, uniforms of the same weight and texture of cloth are worn winter and summer.

The suit is made of 20-oz. blue uniform cloth. The coat is double breasted with lappel collar and 10 buttons in front and 2 on each sleeve. There are 10 pockets in the coat, as follows: two skirt pockets, 2 ticket and 1 breast pocket on the outside, and on the in-

side 2 skirt pockets, 1 ticket and 2 breast pockets. All outside pockets with the exception of the breast are leather corded or all leather throughout, and made of kangaroo calf. The inside pockets are made of heavy twilled pocketing, and all are hung, stayed and fastened in the best possible manner. The vest has 6 buttons, no collar and 1 inside and 4 outside pockets.

The conductors' uniform overcoat is made of 30-oz. blue overcoating, is double breasted, with lappel ulster collar 6 in. wide. On the outside there are 2 skirt, 2 hand and 2 ticket pockets and 2 on the inside. These are made of drab corduroy and are bound and corded with leather. The coat is cassimere lined and interlined with blanketing, and extends 6 in. below the knee. The overcoat for the motormen is the same as for the conductors except that the buttons are nickel instead of gilt; it extends 8 in. below the knee, and is lined with black Colorada sheerling fur.

The uniforms complete with buttons cost $17 each, $7 of which is deposited with the company's tailor at the time of trying it on, the remainder being paid on delivery of the suit. The cost of the conductors' overcoats, blanket lined, is $17, and the motormen's, lined with fur, $22. The caps worn are made with a flexible top stiffened with horse hair linings and covered with cloth to match the uniform. The price is $1.75, c. o. d., and is very serviceable as well as presenting a natty appearance. The cap used by the conductors has a straight peak and gold plated badge, having the word "Conductor" and the initials of the company stamped in, and the conductor's number cut out, thus throwing the numbers in relief with the blue cloth of the cap as a background. The motorman's cap has a visor peak to protect the eyes. The cap badge is silver plated and stamped "motorman." The badge and buttons are gold for the conductors and silver for motormen.

The Wilkesbarre (Pa.) & Wyoming Valley Traction Co. prescribes light weight, blue uniforms with a black silk cap for summer, and heavy weight uniforms with navy blue cloth cap for winter service. The company pays for the summer and winter caps, which are furnished twice a year, and are returned on leaving the company's employ. The uniforms are ready made and cost from $10 to $15, which is paid by the employe at the time of purchase. The standard uniform is the same for conductors and motormen.

The Twin City Rapid Transit Co., of Minneapolis, specifies that the coat shall be cut in cadet style and be worn buttoned at all times. Any neat cloth overcoat may be worn, but fur coats are not permitted. The conductors and motormen are dressed alike. The suits are made to order and cost $15 for summer and $18 for winter, and are paid for by the employes in $5 instalments, deductions being made each pay day, which comes twice a month.

The Nashville Street Railway Co. requires that the motormen and conductors wear single breasted sack coats made of heavy blue cloth for winter and of lighter cloth in summer. These uniforms are ready made and cost $10 and $12 respectively and are paid for when purchased.

The Cleveland City Railway Co. prescribes the style and allows the employes to get the uniforms where they can do the best. The uniforms are of blue cloth, light for summer and heavy for winter. The suits are either ready made or made to order, costing $10 to $13 for summer and $14 to $16 in winter.

The series of five figures show the uniforms adopted by the Chicago City, the North Chicago and the West Chicago Street Railway companies, and these are made in large numbers by C. F. Orr & Co., Chicago. By a simple and effective system of measurements under standard specifications these garments are made to order and cost but little more than the ready made uniforms. The high grade cloths for these uniforms are supplied by the Warrenton Woolen Co., through its agent, Theo. A. H. Weinz, of New York.

The Union Traction Co., of Philadelphia, asks for bids for uniforms from reliable firms and awards the contract to the lowest responsible bidder. The employes are required to make their own financial arrangements. A sample uniform is kept at the office of the general superintendent, and in case of any dispute the sample coat or uniform is used to decide the question. The coat of the summer uniform is a single breasted, four-button sack with straight front. The edges are double stitched and the seams plain. Each sleeve has two buttons with eyelets and rings. Good, substantial-wearing sateen sleeve lining, same as approved sample, must be used. The facing is loose, piped narrow with Italian cloth. There are four buttons below the roll put on with eyelets and rings. The coat lining is of double warped Italian cotton, closed at bottom with 1½-in. plait and to extend to the front edge of the coat. The outside of the collar is cut whole and the under collar is the same goods as the coat and well padded. The cash pocket is on the right side and is 3¾ in. wide and 3½ in. deep; the punch pocket on the left is 3¾ in. wide and 5 in. deep and the lower pockets are made not less than 6¾ in. at the opening. These pockets are faced with shields not less than 1¼ in. wide on each side of the pocket mouth with the edge turned in and single stitched. The outside and inside breast pockets are of unbleached drill and all others are of heavy duck.

The vest is single breasted with notch collar. There are six buttons put on with eyelets and rings. The edges of the vest are double stitched with facing loose. The back of the lining must be of double warped Italian cotton with the inside of good, substantial sateen. There are four outside pockets with welts and one inside breast pocket. In the trousers there are the usual top and hip pockets and the side seams are made with a narrow welt. The legs are to be made with a narrow welt and not less than 18½ in. at the knee and 17½ in. at the foot. All goods throughout are of 15½-oz. Middlesex cloth and all sewing is of silk.

UNIFORMS FOR THE LARGE CHICAGO ROADS.

The uniform overcoat is a double breasted ulster, made of "traction overcoating," weight 30 oz., manufactured by Sullivan, Vail & Co., 329 Broadway, New York. It is to come within 11 in. of the ground for motormen and 14 in. for conductors. There are two rows of six buttons and three on each sleeve, of the company's design, with eyelets and loose facings piped with Italian cloth of good quality. All buttons are put on with rings and button stays. A deep storm collar coming above the ears when turned up is provided with a tab. The two muff pockets are made of velveteen, the two cash and two lower pockets of 8-oz. duck and the one inside breast pocket of heavy unbleached drilling. The cash pocket is to be at least 4½ in. wide with shield of the same cloth not less than 1½ in. in width when finished. The horizontal edge of the coat and all seams are double stitched ¾ in. The body of the coat is lined throughout with warm material and well wadded down below the waist and well stitched. All garments are sewed with pure dye sewing silk, finished in a workmanlike manner and from goods thoroughly shrunk.

A simple, but neat and handsome uniform, as may be seen from the half-tone cut, is worn by the employes of the Lindell Railway Co., of St. Louis. These are ready made and are of light-weight blue cloth for summer and heavy weight for winter, costing from $12.50 to $14, the cash being paid at the time of delivery. There is no difference between the uniforms of the conductors and motormen.

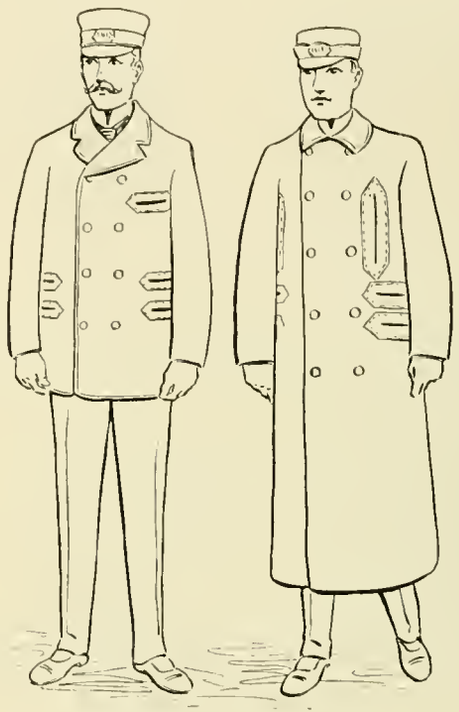
The following regulations regarding the uniforms of the emergency crews are enforced by the Boston Elevated Railway Co. The full regulation uniform consists of a coat of corduroy made single breasted with turndown collar and buttoned close to the chin. The vest and trousers are of the same material. A service stripe of scarlet cloth shall be worn on each coat sleeve for each five years of

LINDELL RAILWAY, ST. LOUIS.

service. Buttons are of gilt of the company's standard design. The badge is always worn on the left breast of the outer garment. The caps are of the same cloth as the uniform with cloth badge in front of same. The full uniform must be worn at all times when on duty, except at such times when the work renders other clothing proper. When off duty full uniform or none must be worn.

The uniforms for the conductors and motormen are of dark navy blue cloth and the coat is double breasted sack with ¾-in. double stitched edge, and cut to fit the form rather full. The cutaway collar is of the same material as the coat. There are 10 large buttons in front and 2 small ones on each sleeve. The regulation buttons and badges are furnished by the company and always remain its property, a deposit being required to insure their return. In the coat there are two side hand pockets, two outside cash, one outside breast, two inside breast and two inside ticket or cash pockets. All pockets are made of ticking or heavy drilling and the outside pockets are reinforced with the same material as suit. The vest is single breasted, with six buttons and four outside and one or two inside pockets. The pants are cut with medium large knee and bottom and have ¼-in. welt on the sides. There are the usual side or top, one watch and two hip pockets.

The overcoat is of heavy weight stock blue kersey or beaver, lined



BOSTON ELEVATED RAILWAY.

with flannel. It is double breasted, with 10 large buttons in front and cut to fit the form rather full and to extend half way between the knee and instep. The collar is 3½ in. wide with step and of the same material as the coat. There are two muff, two outside cash, two side hand, two inside breast and two inside cash pockets made of ticking or drilling. The outside pockets are reinforced with the same material as overcoat or piped with leather. Leather or velvet patches, facings or button holes or velvet collars are not permitted.

The caps are made of navy blue cloth with bell top, leather visor and leather band on front fastened at either side by the official button. On the upper side of the band is a ¼-in. gilt lace stripe on the conductors' caps and a silver lace stripe on the motormen's caps. The winter caps are of blue Scotch havelock, the upper side of the lappel having the stripe. The general order for employes wearing service stripes, issued last fall by C. S. Sergeant, second vice-president of the company, was published in the "Review" of December, 1898.

The company specifies that the uniforms shall be made of dark navy blue woolen cloth, but does not specify the weight of the goods or where they are to be purchased. Uniforms of the starters and inspectors are similar to those of the conductors and motormen, the difference being only in the trimmings. The chief inspector in each division constantly watches the uniforms of all employes and reports thereon to the superintendent, who takes the matter up with the employe in question and requires new uniforms when necessary.

There are several excellent manufacturers who make a specialty of the production of woolens especially for street railway use. Among them may be mentioned the Burlington Woolen Mills, whose product is handled by Dudley, Battelle & Hurd, 53 Worth St., New York. Mr. Charles Bowler, one of the most experienced uniform men in the country, is in charge of this department.

Another established concern whose woolens are in use on a large

number of street and steam railways is the Warrenton Woolen Co., whose excellent output is handled exclusively by Mr. T. A. H. Weinz. Mr. Weinz has also had a long experience in this line and a wide and favorable acquaintance among street railway men.

The Waterloo Woolen Manufacturing Co. operates an extensive plant, the product being handled by Patterson & Greenough, of New York and Chicago. Several grades and weights are made to suit the varying climatic conditions of the country and the goods have an extensive sale throughout the states.

The cap is by no means the least important feature of a uniform, although in manufacture a specialty by itself. Hohenadel Bros., Chicago, make a neat and very serviceable cap which is largely used. This cap was illustrated and described in our issue of March, 1899.

The cap illustrated herewith is made by F. H. Newcomb, Brooklyn, who has a large street railway patronage. Carefully selected materials are used to give long service under the trying conditions of all kinds of weather, and the cloth of a character which will not fade. Skilled workmanship is employed, and the result is a cap which never fails to give satisfaction.

A large eastern uniform house is that of Hackett, Carhart & Co., whose establishment is at 422 Broadway. The concern is always glad to receive inquiries and will freely reply to any questions from managers who are having trouble with their uniforms. They have earned a wide and favorable reputation for perfect and serviceable garments, and are supplying many street railways.

POWER HOUSE OF THE TOLEDO & MAUMEE VALLEY RAILWAY.

The Toledo & Maumee Valley Railway Co., which has heretofore rented all its power from the Toledo Traction Co., is now building a power house of its own on the west bank of the Maumee River, about midway between the city limits and the southern terminus of the loop. The plant will be operated by water power with a steam engine in reserve. Water will be taken from the Erie & Miami Canal, which runs from Toledo to Cincinnati.

The power plant is a brick building, 60 x 150 ft., with a steel roof. It is situated near the foot of the river bank, within 15 ft. of the water. The highway on which the railway is laid passes along the bluff and is about 190 ft. from the building. The bulkhead and floodgates are to be on the far side of the track from the river, and the water carried under the track and down to the wheel through a 6-ft. steel pipe. The bulkhead will be 55 ft. long, 4 ft. thick and 14 ft. high. The available head is 60 ft. The power house equipment is to comprise one 600-h. p. turbine built by James Leffel & Co., a Lombard governor, one twin unit of two 300-kw. G. E. generators, one 150-kw. booster giving a maximum pressure of 725 volts, one 500-h. p. Hamilton-Corliss compound condensing engine, and four Shaw & Kendall water tube boilers, carrying 120 lb. steam pressure.

The wheel pit is at the north end, outside of the building proper; it is covered over and access is had through a door from the generator room. The wheel is coupled to an 8-in. shaft 58 ft. long, extending along the east wall of the engine room. Belted to this shaft are the twin unit, with couplings each side of the driven pulley so that either or both of the generators may be driven, and the booster. The generators are wound for 500 volts at no load and 550 at full load. At the south end of the generator room is the engine with a clutch for connecting it to the line shaft.

The boiler room is at the south end of the building, and is 45 x 60 ft. The stack is 5 ft. in diameter and 65 ft. above the grates.

Between the boiler and the engine room is a space 30 x 60 ft., which will be equipped for a repair shop.

The stock of the Montreal Street Railway Co. is quoted at 320.

TROLLEY MAIL CARS LOADED DIRECT.

Postmaster Wilson, of Brooklyn, has arranged a plan to load the trolley mail cars direct at the Post Office by means of a siding to be built alongside of the building. A piece of property was purchased by the Government for the sum of $20,000, and at present the matter of proving the title is under way. When the legal matters have been adjusted the work of putting the property in shape for Post Office uses will be begun at once.

The present building is to be razed to the ground and a solid roadbed is to be erected flush with the street.

On this two tracks are to be laid, so that the trolley mail cars can be run in over the sidewalk and upon the space now occupied by the building. The mail cars will be run close to the mailing division on the main floor, where doors are to be built so that the cars can be loaded direct from the mailing division.

Besides the saving of time and labor, the sum of $1,200 a year will also be saved in carting.

STATION STREET INDICATORS.

One of our contemporaries, the Electrical Engineer, of London, describes a plan for informing travelers concerning the movements and stopping places of electric cars which is to be tried by the Liverpool Tramways Committee. What are called station street indicators will be placed on one route; they are described as follows: "These indicators consist essentially of an ornamental and conspicuously colored pavement, 4 ft. square, formed of red granite concrete, surrounded by a border of white ornamented with an incised foliated design. The artistic square is conspicuous from a distance, and must almost inevitably be seen by every pedestrian. Each indicator contains (first) the name of the street or road legible under all conditions of weather and at all times of day and night. An arrow indicates the direction of the cars. 'Tramcars stop here on request' appears on those indicators other than those at which 'All tramcars stop,' as at terminal and a few other fixed points on the route. This is followed by a clear and precise statement of the destinations of the various cars—for example: 'For Dingle and Aigburth,' 'For Prince's and Sefton Parks,' and 'For Smithdown-road.' The whole of this lettering is in snow-white characters on a dark-red background, so that the wording can be read with ease."

NEW SCALE OF WAGES IN ATLANTA, GA.

The directors of the Atlanta Railway & Power Co. have declared a substantial increase in the wages of conductors and motormen both in the employ of the above named company and the Atlanta Railway Co. The increase was unsolicited and came in the nature of a surprise to all the men.

The order was issued August 15th, as the result of a meeting of the board of directors held during the first of the month and for the first time in the history of the company a rising scale of wages was adopted in the recent order.

Heretofore the wages of motormen and conductors who have been in the employ of the road for a certain length of time has been 12 cents an hour, while formerly new men just beginning have been paid 10 cents an hour. Under the new scale, the pay of motormen and conductors who have been in the service of the road for three years has gone up to 15 cents an hour. The employes in the service from one year and less than three years are increased to 14 cents an hour, and those who have been with the company less than one year, receive under the new scale 13 cents an hour.

The new order extending over the lines of the Atlanta Railway and Atlanta Railway & Power Co. affects practically 500 men, the number employed on the two roads in the capacity of motormen and conductors. The lines of the two roads at the present time, counting those in operation and those actually in the process of construction, amount in all to nearly 100 miles.

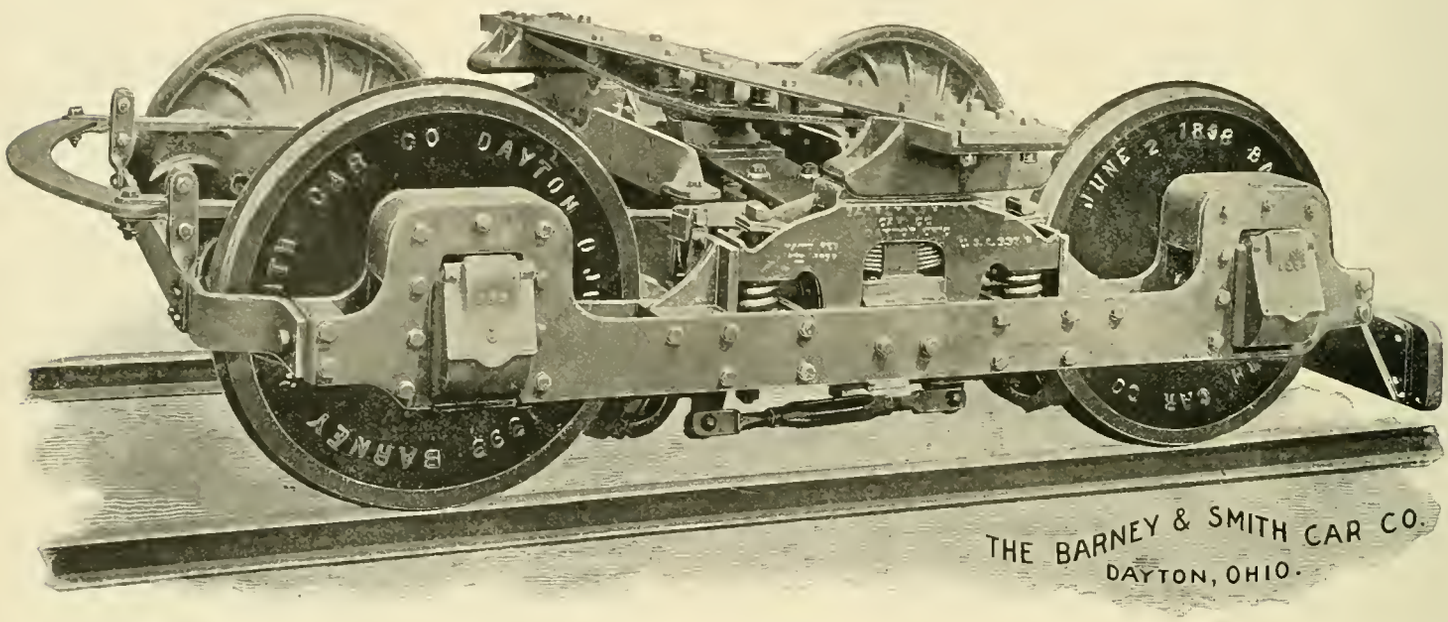
A number of the employes have since held a meeting at which resolutions thanking the company for the increase in wages were adopted.

The Reading (Pa.) & Southwestern Electric Railway Co. has increased the wages of its employes.

BARNEY & SMITH CLASS "H" TRUCK.

The accompanying illustration shows the improved pivotal truck made by the Barney & Smith Car Co., Dayton, O., especially for suburban and city service where double truck cars are used. The marked feature is that it is so designed that the car body may be carried very low as compared with many other trucks of the pivotal type and thus obviate one of the objections to their use.

The side plates of the frame are made of steel in one piece without welds of any kind, and the two plates on each side frame are securely bolted together with distance castings between. Over each journal box and between the side plates of the frame is a coil spring. On each side of the side frame at the center are the side bearings, securely fastened to the end of the truck transom, which is made of 8-in. wrought iron plates, and to which are fastened the center plates. The truck transoms and side bearings, upon which rests the body bolster of the car, is carried by an arrangement of springs, clearly shown in the illustration. This combination gives an easy and uniform movement to the body of the car. These trucks are so arranged with proper connection to the body bolster



CLASS "H" TRUCK.

of the car as to allow the trucks to swivel freely and pass around the shortest of curves without difficulty.

At the center of the truck are two cross bars, to which are fastened the motor supports; this can be adapted to any kind of motor used. The brakes on these trucks are inside hung, as will be remarked. The brake mechanism is very simple and easy to keep in repair; the brake head and brake hanger bracket are so arranged that by drawing up a wedge in each of them by means of a nut, all the slack or play in the brake hanger and pin can be taken up. The advantages claimed for an inside hung brake is that it overcomes the chatter, which is very annoying at times on the old style outside hung brake, and also that the brake is thoroughly equalized.

REPAIRING THE CHILKOOT TRAMWAYS.

A gang of men are now busy repairing the Chilkoot, Alaska, tramway, and it is the intention of the railway company to keep the road in order for emergency use in winter. Two of the towers are being replaced and some of the wire cable is being replaced where it is worn. Snow sheds are being constructed where there is a likelihood of a snowslide coming down next winter or spring. The engineers have been retained at the power station to keep the machinery in condition.

There is little travel in winter and most of the freight will be light stuff, for such can be carried to an advantage on the trains.

ELECTROLYSIS SUIT AT SPOKANE.

In December last we gave an account of the status of a suit then recently brought by the Spokane (Wash.) Gas Co. against the Washington Water Power Co., which operates the Spokane Street Ry. The judge of the Superior Court, in which the suit was brought, has prepared his findings of fact, and issued an injunction to prevent the use of any except cast-weld joints in paved streets and any except Chicago rail bonds in other streets. The defendant will appeal the case, as to observe the injunction would entail great expense.

The suit was begun last October, and many electrical experts examined as witnesses, among whom were Prof. E. Darrow, of the Washington Agricultural College, and Bert L. Baldwin, of Cincinnati.

The court's findings are briefly as follows:

The only method of absolutely preventing stray currents of electricity is the double trolley system.

The best single trolley is the cast weld joint system.

The best wire bond is that known as the Chicago bond.

That it is not practicable to use cast weld joints except where street is paved with such material as asphalt, brick, macadam, wooden blocks or similar material.

That it is shown by the evidence in this case that gas pipes of plaintiff have been injured by electrolysis.

That such injury has been caused by defective bonding of street railway system and an injunction is granted to prevent defendant from injuring plaintiff, and ordering defendant to use the cast weld system on all paved or macadamized streets, and Chicago bond on all other streets.

COLUMBUS RAILWAY MEN'S OUTING.

The Columbus (O.) Street Railway Co. gave its employes their annual outing on August 23d, and a general good time was provided for all the employes and their families. As it was impossible for all the men to spend all day at the outing the car runs were so arranged that every man could spend a part of the day in the enjoyment of Olentangy Park and its places of amusement. The company had 1,600 badges made, which were distributed among the employes.

The badges served as pretty souvenirs of the day and were useful at the park, for they admitted the holder to the Casino and every other place of interest at Olentangy, through the courtesy of the theater company.

TOLEDO, FREMONT & NORWALK R. R.

The Comstock Construction Co., of Detroit, Mich., is now engaged in building an electric line to connect Toledo and Norwalk, O. Messrs. Riggs & Sherman, 613 The Nasby, Toledo, are the chief engineers in charge of the work, and they have completed surveys and estimates. Mr. W. A. Comstock, secretary of the Comstock Construction Co., sends in the following concerning the enterprise:

"The proposed road will run from Toledo in a generally southeasterly direction, going through the following cities and villages: Genoa, Woodville, Hesseville, Fremont, Clyde, Bellevue, Monroeville and Norwalk. The distance traversed will be 60 miles, 31 miles of which is on the Maumee & Western Reserve Turnpike in Sandusky County.

"It is the intention of the company to build the road in a thoroughly first-class manner throughout, sparing no expense to make the construction modern and up to date in every particular. In fact, the road is to be built to keep, not to sell. The whole system will be in operation by May 1, 1900, but only the first half, as far as Fremont, will be pushed hard this fall.

"Contracts have already been let, for the ground construction as far as Fremont, to the Chase Construction Co., of Detroit, for everything except steel in bridges, masonry and ballasting. The Ohio Brass Co. has the order for the overhead material. Westinghouse, Church, Kerr & Co. are to furnish the steam and electrical machinery. The Carnegie Steel Co. is under contract for the rails through Fremont. These are to be 75-lb. per yard. Copper bonds, spikes, bolts and angle splices are also purchased.

"The road will be equipped with the three-phase system. The central power house will be in Fremont, O., seven substations being used. The operating offices will be located at Fremont, and the head office probably in the Majestic Building, Detroit."

The Comstock Construction Co. has been organized to build the road. Its officers are: W. B. Comstock, president; S. F. Angus, vice-president; A. W. Comstock, treasurer; W. A. Comstock, secretary; Henry A. Haigh, general counsel.

"A railroad corporation known as the Toledo, Fremont & Norwalk Railroad Co., will be organized under the laws of Ohio, with a capital stock of $1,500,000. Its officers will be S. F. Angus, president; W. B. Comstock, vice-president; A. W. Comstock, treasurer; W. A. Comstock, secretary; Henry A. Haigh, assistant treasurer and general counsel.

PROTECTION OF WIRE ROPES.

Wire ropes for transmitting power are used under a great variety of conditions and many efforts have been made to secure a satisfactory protective coating which would answer equally well for ropes used in a dry atmosphere, where the tendency is towards a rapid oxidation and sloughing off of the coating, for those exposed to acid vapors, and for ropes running in damp conduits, or even submerged in water. The Ironsides Co., of Columbus, O., has succeeded in perfecting a coating for wire ropes which it submits as perfectly satisfactory and possessing the desirable qualities of being tenacious, pliable, water-proof and free from destructive acids and also acting as a lubricant. This compound is known as "Wire Rope Shield," and has been used, we are advised, on ropes for all sorts of service, from office buildings to mines and dredging machinery. The illustration shows a section of wire cable protected externally by the "shield" and filled with another of the Ironsides products, which is known as "Wire Rope Filler." This latter is to effectually seal the cable against water and acids, and also prevent abrasion of the strands by surrounding them with a lubricant. The company states that many of the prominent makers of wire ropes use this filler in their wire cables, with the result that the life of the product is greatly increased.

Some trips were made last month over the lines of the New Bedford, Middleboro & Brockton (Mass.) road, which is nearing completion. It was expected that the road would be finished by September 1st.

SITUATION IN ATLANTA.

August 21st the city council of Atlanta, Ga., passed an ordinance providing for a close supervision and regulation of the street railways of that city. A bitter contest over the granting of franchises led Joel Hurt, representing the Atlanta Railway & Power Co. and the Atlanta Railway Co., to make the proposition published in the August "Review", page 522, for a payment to the city of a portion of the gross receipts in consideration of exclusive franchises; this the city refused to accept, but one of the provisions of the ordinance adopted grew out of it.

The ordinance contains the following principal provisions:

The city reserves the right to regulate the location and construction of all tracks, wires, conduits, etc.

The tracks of all companies, for a distance not exceeding five blocks, may be used by other companies upon the payment of just compensation.

On the expiration of the original grants to the Atlanta Consolidated Street Ry. (in 1921) all companies shall pay the city a portion of their gross receipts not exceeding 5 per cent per annum. If any of the present companies consolidate, the 5 per cent tax on gross receipts is to become effective at once; but the reciprocal use of transfers shall not be construed to be a consolidation.

The maximum rate of fare for one continuous trip between 5 a. m. and 12, midnight, to be 5 cents, and between 12, midnight, and 5 a. m. 10 cents.

BRIDGE WRECKING BY ELECTRICITY.

On August 18th a wooden bridge over the Wabash river at Clinton, Ind., was wrecked by electricity, the plan of operation being that of Mr. H. N. Mills, of Clinton, and described in the Western Electrician. The bridge was 735 ft. long and consisted of three spans with a 70-ft. draw over the channel; it was desired to remove the bridge without injury to the piers. This was the only toll bridge remaining in Indiana and the approaches, piers and abutments had been purchased by the county, which had contracted for a new steel structure. The late owner had agreed to remove the wooden structure within 30 days but could find no one to undertake the work in this short time. Finally Mr. Mills suggested the use of electricity, and his plan was adopted with success.

Each span was cut through in two places, about 20 ft. from each pier, by burning through the timbers, of which there were 27, with loops of iron resistance wire heated by electricity. The loops, 54 of them, were of No. 12 iron wire with sash weights attached at the bottom to pull the loops down as they burned their way through the timber. Alternating current at 50 volts was used, the wires being heated to a cherry red. The spans were cut one at a time, 1 h. 40 min. being required for each. Current was turned on at 5 a. m. and the last span fell at 2 p. m.

PROPOSED ROADS.

Mr. E. W. Taylor, 85 Commercial Block, Salt Lake City, advises us that he has under consideration several propositions for the building of roads of from 25 to 50 miles each.

A street railway company has been organized at Mankato, Minn., with officers as follows: President, H. A. Patterson; vice-president, S. J. Stanwood; secretary and treasurer, John B. Meagher. No subscriptions to stock have been offered as yet, but the company proposes to do so before January.

The Dayton & Northern Electric Railroad Co., with general offices at Dayton, O., is now making surveys for an electric road from Dayton to Toledo, 162 miles. The company has an authorized capital of $20,000, which will be increased to $1,500,000; the officers are: President, Mr. Randall; vice president, general manager and purchasing agent, A. E. Townsend, Cambridge, O.; treasurer, M. F. Laviness; secretary and superintendent, Samuel Stewart; general consul, Benjamin S. Henderson; chief engineer, Robert Gamble. At the present time the surveys for 20 miles of the route have been completed, and on August 28th the contract for rails was let to a Canadian firm for November delivery.

PLAN OF EXHIBIT HALL, AMERICAN STREET RAILWAY ASSOCIATION CONVENTION.

CURB SPACES. WEST SIDE OF BUILING.

Taunton Locomotive & Manufacturing Co....90 ft. x 10 ft.
McGuire Manufacturing Co.....50 ft. x 10 ft.
Taylor Electric Truck Co.....50 ft. x 10 ft.

Mr. Jas. R. Chapman, chairman of the committee on exhibits, 444 N. Clark St., Chicago, advises us that the foregoing list of exhibitors is practically complete. A few of those whose names are on the list may decline to use the spaces allotted to them, still having the matter under advisement.

Gallery spaces have been offered to some late applicants, but they have not yet been accepted.

The Committee hopes to secure permission from the city to fence in the portion of the street occupied by exhibits. It is possible that the curb space for the entire length of the building may be taken, but those assigned to date are given in the diagram.

OTHER PREPARATIONS FOR THE CONVENTION.

The general committee having charge of the arrangements for the convention of the American Street Railway Association met on August 14th and chose Mr. J. M. Roach, general manager of the Chicago Union Traction Co., as permanent chairman. The committees on hotels and entertainment were consolidated and Mr. Roach chosen chairman in place of the late Mr. Bowen.

All the committees are now at work on their respective assignments, and there is every indication that the next convention will surpass all previous ones in attendance and interest.

Exhibitors sending goods should see that they are marked with the consignor's name and addressed to Tattersall's, Chicago, care of H. W. Smith, successor to Anderson Transfer Co., 1618 State St. The bill of lading or advice that the goods have been shipped in his care should be sent to Mr. Smith, giving particulars. Goods will be delivered to the proper assigned space as shown on the diagram of the exhibit hall. An early shipment, with all charges prepaid, should be made to insure delivery at the hall in time. Exhibitors must pay for delivering goods at the hall, but the local committee has made arrangements with H. W. Smith, successor to the Anderson Transfer Co., to deliver all shipments to and from the building at low rates if sent in his care. Electrical connections for power and extra lights must be made at the expense of the exhibitor. The committee on exhibits will make contracts for labor and materials at regular prices, so that exhibitors may not be over charged.

September 1st an announcement was made by the Association, which is in part as follows:

The eighteenth annual meeting of the American Street Railway Association will be held at "Tattersalls," State and 16th Sts., Chicago, Oct. 17, 18, 19, 20, 1899.

We will have a large exhibition of street railway supplies, every foot of space in the hall having been applied for.

At a meeting of the Executive Committee, held in Chicago, Feb. 6, 1899, the following resolution was adopted:

Resolved, That the last day of the convention, Friday, October 20th, be set apart for the systematic and careful inspection of exhibits by the delegates and that all street railway managers be urged to send delegations from their mechanical, operating and accounting departments to inspect them.

The annual banquet will be held Friday evening, when the officers elect will be installed.

The headquarters of the association will be at the Auditorium Annex. The Auditorium is across the street and managed by the same parties. Chicago is noted for its good hotels, so no trouble will be experienced in securing good accommodations.

HOTELS AND RATES.

Auditorium, American plan, $5 per day each person.
Auditorium Annex, European plan, $2 to $4 per day.
Wellington, European plan, $1 50 and upwards.

All of our leading hotels are within a radius of one-half mile. They include the Victoria, Wellington, Great Northern, Grand Pacific, Palmer, Tremont, Sherman and Clifton, and all are within 10 minutes' ride of the hall.

Railroad rates will be as before, one and one-third fare for the round trip on the certificate plan. Be sure and get a certificate from the agent when you purchase your ticket and leave the same with the clerk when you register at the hall; it will be signed and ready for you on Thursday, October 19th.

Our Chicago friends intend to make your visit a pleasant and profitable one, so that you will not regret attending this convention.

Please make your arrangements to be present, if possible.

T. C. PENINGTON,
Secretary-Treasurer.

Approved: CHARLES S. SERGEANT,
President.

The program of papers will be found on another page.

THE TACOMA-SEATTLE AIR LINE.

The Tacoma-Seattle Electric Railway Co. filed on August 10th its acceptance of the franchise for an electric railway recently granted by the city councils. Accompanying the acceptance was a certified check for $2,000, deposited by John Collins, the president of the company, to guarantee the performance of the conditions imposed by the franchise. The company has been assured that the right of way through the Puyalop Indian reservation will be forthcoming, and the franchise rights both in Seattle and Tacoma have been agreed upon. The contractors will first devote their attention to the bridge work and grading along the right of way. The roadbed will be laid with 70-lb. steels rails, which are necessary to insure the rate of speed at which the cars will run. The maximum grade, when the line is completed, will not exceed one-half per cent on any portion traversed, and trains will be able to easily maintain a schedule of 40 minutes between the two cities.

The road will tap the towns of Des Moines, Sunnydale, Buenna and Stones Landing. There are three lakes contiguous to the right of way, and once in operation the line is expected to become a very popular resort for campers and summer pleasure seekers.

Work upon the road is expected to begin in less than 30 days, and it is expected to establish communication between the two cities not later than next April.

The Municipal Assembly of New York has fixed September 18th as the date for a public hearing on the application of the Manhattan & Jersey City Railway Co. for a franchise for a double track tunnel railway from New York City under the Hudson river to the Jersey state line.

MECHANICAL DEPARTMENT

MAINTENANCE AND REPAIR OF ROLLING STOCK.

Editor "Review": In following up the articles on the "Maintenance and Repair of Rolling Stock," by Mr. Greer, of the Yoakum Improvement Co., the thought suggests itself, that the most important thing is whether the ideas that are therein set forth are based on actual results in running a hundred-car road. If there are any hundred-car roads running in the country with a force of seven men, the fact is not well known.

In the first place, what is a hundred-car road? We think it can only mean a road that operates 100 cars.

Mr. Greer speaks as one of the humbler experts who made electrical railroading successful, and success must certainly have been attained if it were possible for 100 equipments to be maintained with the men and appliances mentioned in his article in the "Review" of August 15th. A "humble expert" is certainly a misnomer for the manager of such a road.

Coming first to the painting. If the cars are re-painted every two years, and re-touched twice a year, that means that this painter and apprentice will have to paint one car a week and touch up four cars per week. This makes no allowance for repairs due to accidents and collisions. To properly do this work is impossible, with the force named, unless that apprentice is a freak; two painters could not do it.

We will not speak of that lone car builder, as we dislike to speak ill of the dead, and there is certainly no such man living. But the blacksmith that can help both the machinist and the car builder, besides doing the blacksmith work on 100 equipments, ought to live forever, especially, if he gets that air pipe to his furnace, as recommended by Mr. Greer.

A man that can do all the armature, and other electrical repairs, on 100 cars is something we have read of but never seen; but we reserve our sympathy for that one machinist and the apprentice who do the repairs and keep the equipments clean.

A hundred-car road will average about one pair of wheels per day, if the cars are running, and make the mileage that most managers want them to make.

In the distribution of labor there is no provision made for babbitting bearings, and all such work, unless the machinist incidentally does that work between times, and there certainly is no provision made for repairs to trucks. The only way to avoid these repairs, so far as we know, is to let them stay in the house. How does Mr. Greer propose to take care of the truck repairs? No one (except in his mind) has been able to do this without help.

After attaining such remarkable results, it is surprising that Mr. Greer should not advocate manufacturing all supplies necessary. He says he does not believe in street car companies doing this work, but in this same article he has a drawing of a simple and inexpensive lift, which may be made in your own shop. By the way, that air hoist is a dandy! The statement that air can be admitted to all four cylinders simultaneously is true, but the idea that a hoist so connected can be practically used is ridiculous, and has never been done under the circumstances, as stated.

We won't say anything about the selection of tools, but that son of Vulcan, who prefers a pneumatic hammer in place of a helper, certainly ought to be on exhibition at the next convention in Chicago.

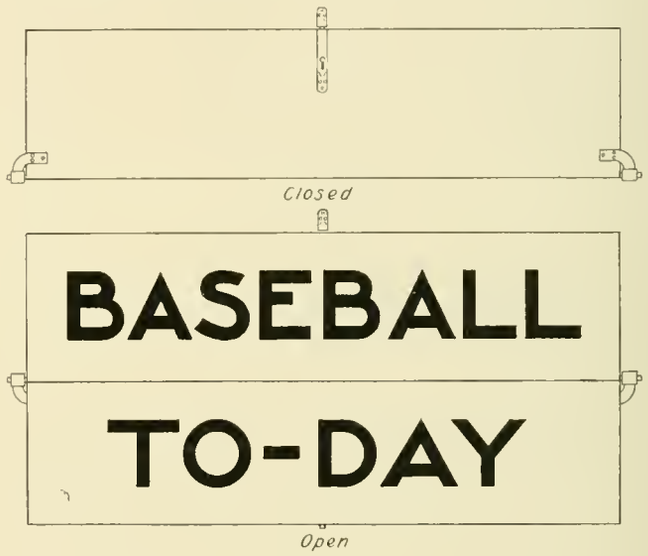
If the results claimed have actually been obtained and can be duplicated then there are several hundred-car lines in this country that waste thousands of dollars every year. If it is ordinary day dreaming, then it has no place in the "Review."

THOS. ELLIOTT,
Chief Engineer Atlanta Consolidated St. Ry.

Atlanta, Ga.

OPEN AND CLOSED CAR SIGN.

The Metropolitan Elevated in this city carries a large number of passengers to the baseball park, and to encourage this business have had all the cars supplied with a sign which is fastened on both sides of the car about the middle and above the windows. To save

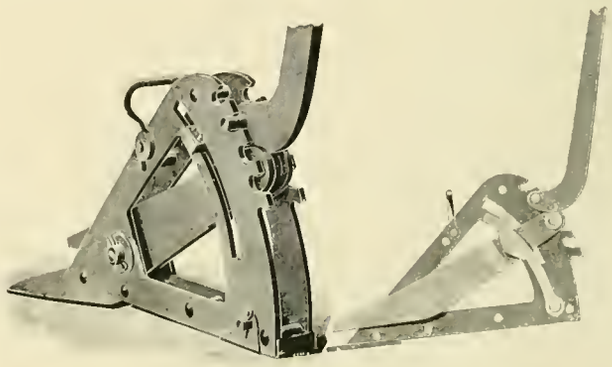


the trouble of putting them on and off the sign is made in two parts, hinged in the middle, and when open carries the notice, and when closed is scarcely noticeable.

Our illustration will readily explain the manner in which the sign is made.

RAIL LIFTER.

The accompanying illustrations show a new rail lifter of European design which is described in Engineering of June, 1899. The illustrations showing the tool in perspective and in section are suffi-



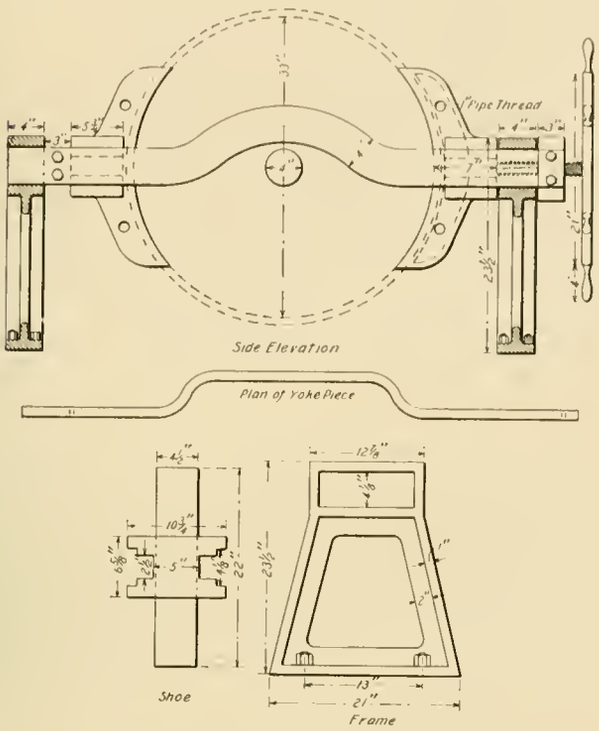
RAIL LIFTER.

cient to explain its operation. The handle lever which is put into the successive notches on the frame pushes the lifting lever down a certain distance, thus raising the track. The lifting lever is held in place while the handle lever is being changed to the next notch by means of the stop pivoted on the lifting lever as shown, which

bears against a locking lever pivoted below. It will be seen that the back of the locking lever is out of center with the fulcrum of the lifting lever, and hence the latter having been forced down cannot fly back when the pressure is taken off, as the follower-piece sliding down in its slots takes up all slack and keeps the locking lever in close contact with its stop. To raise the lifting lever again, it is only necessary to lift this follower-piece, thus allowing the locking lever to move back.

FOR TESTING MOTORS.

The different car equipments at present used by the Chicago City Ry. require that five motors be mounted for testing armatures. Accordingly Mr. C. E. Moore, the master mechanic, has designed



BRAKE FOR TESTING MOTORS.

a special arrangement for convenient testing. The five motors have been mounted with the axle bearings in line and a 4-in. shaft 21 ft. long placed in them; in addition to the 10 bearings thus provided by the motor cases, there are two bearings which are in brackets bolted to posts which are part of the building. These five motors are: G. E. 800, Walker, Westinghouse 12A, Westinghouse 49 and Westinghouse 3. In case another type of motor should be used in the future the main shaft may be readily extended. In the proper place beside each motor a gear wheel is fixed to the main shaft which in this testing machine corresponds to the car axle.

In order to provide a resistance for the motor to work against two car wheels are keyed on the shaft between the third and fourth motors, and a pony brake applied to them. The two wheels are placed close together, the flanges being outside, and give a surface about 5 in. wide to which a brake can be applied, the flanges acting as a guide for the brake shoes.

The brake shoes and the yoke and supports in which they are mounted are shown in the sketch. Each shoe is a large casting presenting a friction surface 4½ in. wide by about 24 in. long, with side flanges to guide its horizontal motion in the yoke; the shoes are hollow with holes tapped for 1 in. pipes to provide for circulating water through them. The yoke is forged from 1 x 4-in. bar iron, offset up to pass the shaft and out to pass the wheel hub, as shown in the sketch; the two sides of the yoke are held apart by two distance pieces. At one end the distance piece is a cast iron block 3 x 4 x 8½ in.; at the front end it is 8½ in. long, but the central portion is circular with a recess in one side to hold a brass nut in which works in form the 1½-in. screw for setting up the brake shoes. This stress is applied by a hand wheel about 30 in. in diameter.

The yoke is supported in two cast frames, shown in detail in the sketch, bolted to the floor. There are no arrangements for measuring the work absorbed by the brake.

A switchboard with the necessary switches and Weston voltmeter and ammeter is located near the side wall; near this board is a series-parallel controller for manipulating the motors.

The testing room is on the third floor of the shops and adjoins the armature winding shops; an overhead traveler system enables the armatures to be run from the shop directly to the motor in which it is tested.

NEW YORK BRAKE TESTS.

In the "Review" for May, page 336, was published the announcement of the Railroad Commissioners of New York inviting the makers of brakes for street cars to submit them for an official test. In response to this invitation, 21 different systems of brakes were submitted for tests, and six of these were to be tested on August 29th and 30th.

The tests were made on the Lenox Ave. line of the Metropolitan Street Ry., between 146th St. and 135th St., in New York City, this portion being approximately level. Fourteen speed and distance curves were taken for each brake, three each at initial speeds of 8, 12, 15 and 16 miles per hour and two at 16 miles per hour using sand. The brakes were all fitted to long cars mounted on Brill maximum traction trucks.

The apparatus for registering the speed, distance and time was designed by Mr. C. R. Barnes, the comissioners' engineer. For

ARMATURE TESTING ROOM—CHICAGO CITY RAILWAY.

recording the speed there are two wooden wheels mounted on an axle and held against the rails for springs; the axle is geared to a shaft which in turn is connected to a screw by friction gearing. On the screw is a carriage with the recording pencil. The pencil has a weight attached to it and is carried downward at a rate determined by a clock mounted on the carriage. A Boyer speed recorder is mounted in the usual manner and an adjustable stop placed so that on reaching a given speed the dial pointer makes contact with it. This contact closes an electric circuit and the action of the current simultaneously throws into gear the friction clutch driving the carriage, releases the escapement controlling the vertical motion of the pencil and rings a bell, which is the signal for the motorman to stop.

The first test, August 29th, was that of the electric brake of the General Electric Co., and this was followed by a test of the Delvin brake; because of rain and a misunderstanding of the method of applying the brakes, these tests were not made a part of the permanent record.

August 30th and 31st and September 7th the first series of tests were concluded, satisfactory records being secured. These brakes tested were the Price momentum brake, controlled by the Peckham company, the Christensen air brake, the Standard air brake, the G. E. electric brake, the Devlin brake. Tests of a brake submitted by the Columbia Electric Car Lighting & Brake Co., and scheduled for September 7th, were postponed, the company not being ready.

PENNSYLVANIA STATE ASSOCIATION.

The eighth annual meeting of the Pennsylvania Street Railway Association will be held at Lancaster on October 4th and 5th, and promises to exceed in point of interest, instruction and entertainment any meeting heretofore held by the association.

The association will meet on Wednesday at 11 a. m. at the Stevens House. Addresses will be delivered and scientific papers on different subjects of interest to the members of the association will be read and discussed, including addresses by Hon. James C. Beck, of Philadelphia; Frank Sillman, jr., of the Scranton Railway Co.; W. P. Mackenzie, of the Harrisburg Foundry & Machine Works, and others.

The addresses to be delivered and papers prepared by practical street railway men will be a feature of unusual interest and instruction to the convention.

The second day will be devoted to a series of entertainments and excursions, including a trolley ride over the system of the Pennsylvania Traction Co., and luncheon at Chickies Park. The indications point to a more largely attended meeting than any that has yet been held by the association. The list of papers to be presented at the meeting has not yet been completed, but programs will shortly be mailed furnishing a detailed statement of exercises for the first day and the entertainments offered for the second day of the convention, which will be both as instructive and enjoyable as any meeting that has yet been held by the association.

By provision of the by-laws of the association not only street railway companies in the state of Pennsylvania, but all manufacturers of street railway supplies, are eligible to membership in the association, the fee for membership in each case being $25 and annual dues $10.

Members of the association are urged to send as many representatives as possible to the convention, and others who have not yet joined the association are also cordially invited to join and become acquainted with the advantages of membership with the association.

For further information address the secretary, S. P. Light, Lebanon, Pa.

About half a ton of trolley wire was cut down and carried off by thieves upon the line of the Norristown (Pa.) & Chestnut Hill road on August 23d. This is the fifth robbery of the kind within a month, and no trace of the thieves has been discovered.

Burglars attempted to break open a safe with nitroglycerin in the office of the Chicago & Milwaukee Electric Ry. on August 28th, but were evidently frightened away. The door of the safe was bent but did not give away. There was about $1,200 in the safe.

CINCINNATI, NEWPORT & COVINGTON EARNINGS.

President Ernst sends us the following figures concerning the operation of the Cincinnati, Newport & Covington Street Ry. for July, 1899:

Gross receipts	$68,703.99
Operating expenses	24,204.53
Gross earnings	44,499.46
Tolls, damages, taxes, etc.	12,062.36
Net earnings	32,437.10
Increase over July, 1898	11,210.96
Ratio of expenses to earnings with tolls	45.92 per cent
Ratio of expenses to earnings with tolls, July, 1898	62.78 per cent
Ratio of expenses to earnings without tolls	35.22 per cent
Ratio of expenses to earnings without tolls, July, 1898	52.86 per cent

AMERICANS SEEKING LONDON FRANCHISES.

A trolley line from London, Eng., to Brighton, one of the principal seaside resorts, has been projected by Albert Johnson, of Brooklyn, N. Y., who until recently was one of the principal owners of the Nassau lines of the latter city. To secure a railway franchise in England it is necessary not only to survey all the territory covered, but furnish the city with lithographed maps illustrating exactly what is to be done and how you are going to do it. The maps are being prepared and should be lithographed at the close of this month. On October 1st Mr. Johnson's company will make its application and hopes to get it without any trouble.

In speaking of the projected road Mr. Johnson says: "The distance between London and Brighton is 45 miles. That distance we will travel over a private way, going over or under all intersecting roadways and interfering and touching no public thoroughfare. The tracks will be 110-lb. T-rails. No grade will be over 1½ per cent. This will enable us to maintain an even speed, so that with the motors we will use the distance between London and Brighton will be covered at an average speed, including stops, of a mile a minute. We have been surveying the ground from London to Brighton and expect to have that work done by the end of this month. A score or more surveyors have been at work since I was over in the spring."

The fares which it is proposed to charge over this route will certainly appeal to the people. The present fare from London to Brighton is $1.50, or 6 shillings. The fare for the trolley route has been fixed at 6 pence. Within the city limits the fare will be 2 pence, which it is expected will attract considerable traffic.

The franchise, of course, depends entirely upon the municipal government. At present most of the electric railways are owned by the city, although they are leased to private corporations, which run them. The capital for the enterprise is ready whenever the requisite permission is obtained.

BOYCOTT AT CHATTANOOGA, TENN.

On August 1st, a number of the employes of the Chattanooga (Tenn.) Electric Railway Co. organized a local division of the Amalgamated Association of Street Railway Employes. The company was convinced that the object of the association was to foment discord and notified the men that those of them who wished to retain membership in the union could not remain in the company's employ. In accordance with this rule 15 men were discharged on August 6th, and their places filled by new men who had been taken on in anticipation of there being vacancies. The company employed 67 men, 26 of whom joined the union; 11 of that 26 afterwards withdrew.

The union organized a boycott against the company, but this movement proved a failure, the sympathy of street car patrons being alienated by the riots and the stoning of cars by which the men sought to injure the company's property. By August 28th the boycott was reported to have petered out.

The new electric road in Fond du Lac was opened on August 21st with a trolley ride of the business men of the town that evening.

SOME NEW TYPES OF STREET CARS.

The car shown in Fig. 1 is of considerable interest since it seems to be the first open car of purely American type ever sent to Europe. It is from the shops of the Brill company, and is of the standard 12 bench type and is mounted on "Eureka" maximum traction trucks. The length over the end posts is 34 ft.; it is 43 ft. 8 in. over the buffers, but the limitations of French streets, however, come in and a width of only 5 ft. 10½ in. is permitted at the sills. This is increased to 6 ft. 5 in. at the posts, but the extreme width at any part had to be kept down to 7 ft. 8¾ in., and for this reason, although the car has 12 benches, its seating capacity will not exceed 48 persons, allowing the American standard of 17 in. each. The platforms are 4 ft. long and are separated from the body of the car by bulkheads in the usual manner. Only two sashes are placed in these bulkheads, and the peculiar form of the grab handles seen on the posts is also made necessary by the narrowness of the body and the limiting width. The openings between the seats are closed by leather covered hook chains and the interior finish is of bird's-eye maple for the head linging, and ash for the trimming over the openings.

FIG. 1—THE FIRST AMERICAN TYPE CAR FOR EUROPE.

The trucks have 30-in. and 20-in. wheels, with a 4-ft. wheel base of standard gage, and are furnished with G. E. 1,000 motors. These cars without motors weigh 15,275 lb., and the weight of one truck is 3,000 lb. The steps are 18 in. from the ground with a 15-in. riser, and the openings are closed by curtains which come to the floor, the round corner seat end panels enabling this to be done easily.

Shipment was effected after the car was entirely completed by taking it apart in sections and packing it closely in boxes. The great length of the car is particularly noticeable, showing that the French street railway people at least are waking up to the advantages of as large a car as can be used on their streets and are beginning to use them.

Another new type of car is the convertible car of the Norfolk Western Street Railway Co., from the Brill Works, which differs materially from any which have hitherto been put in operation. As will be seen from Fig. 2, it is completely vestibuled, giving it the same protection in winter as cars designed for the most extreme northern service. The body of the car is 22 ft. 11 in. long, and the platforms are 4 ft. 6 in. long, giving a total over the dashers of practically 32 ft. It is mounted on a heavy pattern of No. 21-E truck which has an 8-ft. wheel base of standard gage. The wheels are 33 in. in diameter and the car is to be fitted with two G. E. 1,000 motors. The vestibules are arranged so as to have as much window surface as possible and thus give the motorman a clear view in all directions. The windows are fitted with sash and panels which lift out. These panels are of cherry and are finished in the natural color of the wood. When they are removed the car becomes practically an open one. The curved panels below the seat not only strengthen the body but greatly add to the safety of the car in case of accident. It is so low that the passenger has all the advantages of the side entrance type. There are fourteen seats with reversible backs and four stationary seats. The total seating capacity of the car is 36. The seats are upholstered in red plush, the interior finish over the windows is of cherry, and the head lining is of maple veneer highly decorated. The drop platform and a step with a 13-in. riser brings the tread of the step within 15⅞ in. of the head of the rail. It has Sterling brakes, electric headlights and eight lights within the car.

FIG. 2 NEW BRILL CONVERTIBLE CAR.

FOREIGN FACTS.

Siemens & Halske are preparing plans for a projected railway in the city of Coburg, Germany.

Ben Clench, the highest mountain in Scotland, will have an electric road to its summit and a sanitarium.

A new electric line has been put in operation in the City of Como, Italy. The road is only a mile long but will be extended later.

It is proposed to construct a light railway between Beverley, England, and the Hull & Barnsley Railway, a distance of about eight miles.

All the street car lines of Lisbon, Portugal, are to be equipped with electricity. A delegation of Portugese is coming to the United States to study the subject.

The Austrian Government has granted a concession to the city of Prague to construct an electric railway system through the city and suburbs, the line to be completed within two years.

The Sheffield Car Co., of Three Rivers, Mich., has received two orders for a carload of hand cars for both the Russian government railroad in Siberia, and President Kruger's railroad in South Africa.

U. S. Consul Hugh Pitcairn writes that Hamberg, Germany, has the most complete trolley system operated on the Continent, the whole plant being constructed by a local corporation controlling American patents.

The London County Council has voted £10,000 for preliminary plans and surveys for an electric tramway from Westminster-bridge to Tooting. A report on the plan from Prof. Kennedy recommended the conduit system.

The Loraine Steel Co., of Johnstown, Pa., is the successful bidder for furnishing 50 miles of steel rails for a trolley road to be built by the Honolulu Traction Co. in the Hawaiian capital. The road will be completed by the end of next year.

Three rival railway companies in Tokio, Japan, who have unsuccessfully sought street railway franchises, have combined and organized a company capitalized at 15,000,000 yen. It is understood that the concession will be granted to this new company.

The street railways of Paris now have 12 different motive power systems in use operating 31 lines. Of these, six use accumulators, two a combination of accumulators and overhead lines, one an overhead conductor and conduit, one surface contacts and others compressed air, steam, etc.

All the northern part of Italy is covered with a network of steam tramway lines, many of which have now been converted to electric roads. Milan is the center of this system. It is possible to go from that city enormous distances by the "vapore," and it furnishes an ideal means for seeing the country.

For some years rival projectors have unsuccessfully applied for permission to build electric railways in Yokohama, Japan. The council has now authorized the construction, provided the applicants form one company, and throw open its subscription books to all applicants. Such a company is being organized.

The first electric line in the United Kingdom was built in Ireland from Portrush to the Giant's Causeway, and it is now undergoing extensive improvement. The metal center poles which are being put in came from Ohio, and the wire from Massachusetts. The new electric system now being installed is after the design of Sir William Siemens.

The first electric railway in China was opened June 24th between the Peking station at Machiapu and the south gate of the city of Peking. Eventually it is proposed to extend the line inside the city. The barrier at present in the way is the necessity for breaking a new gate through the city walls. It is thought that the authorities will yield this privilege.

Catania, Sicily, has recently introduced electric railways (about 24 miles in length), the concession for which, together with the electric lighting of Catania and district, have been granted to German capitalists. The population of Sicily is rapidly increasing, and the introduction of the electric light in the principal towns is likely to be a feature of the near future.

Meran, in the Austrian Tyrol, was recently the scene of a serious catastrophe. An inclined railway runs up the Schneeberg, and as a party of tourists were making the ascent the cable by which the car was moved broke, the brakes or the safety appliances did not appear to work, and the car was dashed to pieces in the valley below and several of the passengers were fatally injured.

The tramway bill of the Corporation of Sunderland, England, has received the royal assent, and the council has agreed to purchase the undertaking from the Sunderland Tramways Co. at a cost of £35,000. The whole of the old and new routes are to be electrically equipped by August 31, 1900, the total expenditure being estimated at £126,618. The contract has been placed in the hands of Messrs. Dick, Kerr & Co.

The Corporation of Limerick, Ireland, has appointed a committee to consider a new proposal from the Limerick Electric Tramway Co., under which the company proposes to proceed without asking the Corporation to give any guarantee whatever. The company propose to lay six or eight miles of tramways, the cost to be about £70,000, of which £40,000 would be spent in the city, in addition to the company employing permanently a staff of 300 men.

The San Juan and Rio Piedras Railway Co. has been incorporated at Albany, New York, to operate an electric railway and furnish electric light at Porto Rico. The company will operate the first electric railway and electric power plant on the island. It has purchased a steam road eight miles long and electricity will be substituted as a motive power, the overhead trolley system being used. The work of reconstructing the road has already begun.

Consul-General J. G. Stowe writes from Johannesburg, South Africa, that concessions for electric railways are wanted in that city but are refused by the Government believing that they would stop the sale of forage and horses. The streets are wide and the city is a busy one, but the motive power of the street railways consists of horses and mules. He states that electric lines should also be built in Kimberley, East London, and Durban. The horse cars still run in these cities, and the length of the present roads is great.

Nelson, B. C., was en fete on July 31st, the occasion of driving the first spike of the electric street railway. The spike, which was a gold one, was driven by Mr. C. S. Drummow, managing director of the Duncan Mines, and a director of the British Electric Tramway Co., which has lines in various parts of the world. A banquet was held in the evening, at which representative men from all parts of the Kootenay were present. This Nelson railway is the first street railway in Kootenay, and the population of Nelson has reached 6,000.

The British Tramways Co., of England, has contracted with the British Thomson-Houston Co., Ltd., for four 500-kw. tramway generators, coupled direct to vertical cross compound engines of the corliss type, together with three 30-kw. motor generators and two 50-kw. lighting machines; also a complete switchboard for this machinery. Also for 150 single truck double deck cars. The British Thomson-Houston Co. is to act as English representatives for the General Electric Co. Not having the facilities necessary for building the machinery embodied in this contract, everything pertaining to the electrical part of the order, the amount of which is estimated at quite $100,000, will be constructed in the American works of the General Electric Co.

AMERICAN ELECTRICAL WORKS CLAMBAKE.

An event of interest to electrical men throughout the country is the annual clam bake given by the manager of the American Electrical Works, Mr. E. F. Phillips, and the bake of this year, which was held on the 9th of September, was the most noted and enjoyable; it was more largely attended than on any previous year, there being present 360 whose names were registered. Cards of invitation to the number of about 8,000 has previously been sent out to street railway, electric light, and electrical supply men throughout the country, and to the representatives of these industries in Canada, Mexico and some of the South American countries. The cards were unique, in that they consisted of plates of pure sheet copper, 4 x 6 in., on which the invitations to the 21st annual bake were engraved in script.

More than 800 letters were received in reply to the invitations, all couched in cordial terms and many of them very flattering to the management of the company, and all emphasized the importance of the line of goods made by this company.

At 10:30 on the morning of the 9th a number of electric cars waiting at the Narragansett Hotel were quickly filled and an enjoyable ride of five miles brought the guests to the home of the Pomham Club, a most delightful location overlooking the river and bay.

On registering, each guest was provided with a badge, and a crash uniform cap, upon the front of which was printed in large letters "Twenty-first Annual Clam Bake of the American Electrical Works, Providence, Rhode Island, Pomham Club, September 9, 1899."

At 11:30 lunch was served, following which the guests passed the time in social intercourse, and in singing and dancing, until the bake was ready. In the meantime a photograph of the entire company was made, the guests being seated upon the sloping bank facing the south.

Tables were spread with plates sufficient to accommodate the entire number, the main or middle table being reserved for the speakers and press representatives, at the head of which Mr. Phillips presided.

The menu cards were also printed on sheet copper, enclosed in an engraved cover. The feast was a very enjoyable one, the chowder and bake being especially fine; the flavor is peculiar to this region, and it is claimed that no other clam bakes in the country can approach the menu provided by the Rhode Island chefs.

Following the banquet Mr. Phillips made an address of welcome, referring in happy terms to this particular date, saying that the company had become of age, it being the 21st anniversary, and that he wished to make it a family affair, and invited every one present to feel as if they had returned home after a long absence, or come back to their boyhood days and enjoy a ramble over the house, as they would if they had returned to their own homes. In closing his address he introduced Mr. R. S. Brown, of the Westinghouse company, whom he invited to act as toast master, and who filled the position very acceptably, introducing himself and the speakers in a humorous manner, and was followed by an address from Congressman Capron, Mr. Wendall, of Wendall & McDuff, New York, Frank Ridlon, of Boston, one of the oldest representatives of the electrical industry in the country; next by C. B. Fairchild, of the "Street Railway Review", and others.

During the banquet a local band played popular airs, and the whole affair was one of the most enjoyable that it has ever been the privilege of the writer to attend.

Among the other representatives of the technical press were: J. B. Bennett, Street Railway Journal; E. Wood, American Electrician; Frank Perry, Western Electrician; E. P. Shaw, Electrical World.

The engineers of the Brooklyn Elevated roads suffered a cut in wages from $3.50 a day to $2.50. They are now called "motoneers." The surface car motormen receive $2 a day and the Brooklyn Bridge motormen $2.25 per day.

The Denver City Tramway Co. is to get a return of $2,000 in war taxes. On the consolidation with the old cable company revenue stamps were affixed to both the mortgage and the bonds, although they were merely two features to one transaction. Congress passed a law to return one-half of the war tax thus paid in.

NEW PLANT OF THE SARGENT CO.

The increase in the business of the Sargent Co., of Chicago, because of the American Brake Shoe Co., made it necessary for it to increase its shop capacity, and accordingly contracts have been made and buildings are now being erected at Chicago Heights, 27 miles south of Chicago. The site is near the lines of the Michigan Central, Chicago, Joliet & Eastern, Chicago & Eastern Illinois, and Chicago Terminal railroads.

The plans, as prepared by Huehl & Schmidt provide for buildings to cover an area 250 x 260 ft.; the total cost of the buildings, exclusive of machinery and equipment, is estimated at $40,000. The iron foundry is to be 200 x 110 ft. The iron cupola room is 30 x 33 ft.; storage room, 30 x 110 ft., core room, 35 x 110 ft., steel foundry, 50 x 200 ft.; steel melting room, 32 x 30 ft.; work shop, 30 x 200 ft.; cleaning shop, 52 x 200 ft. The steel foundry is to be two stories. The buildings are to be of brick, stone and steel and equipped with machinery of the latest design.

The company fully expects to have the brake shoe department of the new plant in operation by December 1st, and the steel foundry by January 1st. The present plant at 59th and Wallace Sts. will be continued, and the output of steel castings greatly increased when the foundry is removed to the new works.

We extend our best wishes to the company and hope that its phenomenal growth will continue so that other additions may be necessary in the near future.

NEW PUBLICATIONS.

GRANITE STATE SCENERY in and about the Capital City is the title of a handsomely illustrated pamphlet published by the Concord (N. H.) Street Railway Co. The handsome residences of the city, its factories, public building, institutions, etc., are described and illustrated in connection with the lines of the street railway company. The work is handsomely got up, and comprises an interesting souvenir of the city.

CASSIER'S MAGAZINE for August presents a special number devoted exclusively to electric railway literature. The issue is called the Electric Railway Number, and contains 292 pages of reading matter, with over 200 engravings. There are 18 articles prepared by as many well-known engineers and authorities in railway matters. From the historical survey of the subject to its business aspect, every intermediate phase has been carefully considered, and every noteworthy detail has been worked out by a competent authority, and presented in a masterly manner.

"COMPOUND ENGINES" is the title of a new book on this subject by James Tribe, member of the American Society of Mechanical Engineers. It differs from most other works having a similar title in that it is of small size, being a hand or pocket book of 140 pages bound in flexible covers with round corners. There are a large number of steam engineers whose duties make it desirable for them to have a knowledge of the principles and methods of computing the proportions of compound engines, but who are not sufficiently familiar with algebra and calculus to easily follow the discussions of the subject as found in most works on the steam engine. Mr. Tribe has undertaken to present in a compact and simple form the principles underlying the subject so as to make them of service to the practical man; he has carefully avoided higher mathematics, and put the results of formulas in the shape of rules, tables and diagrams, adding many numerical examples to explain their use so that the meaning and application are made very clear. The book is divided into 15 sections; the first five sections, some 38 pages, discuss preliminary matters, the next six sections cover 64 pages and are devoted to multiple expansion engines, the next two treat of condensing apparatus and cylinder oils, and the last two consist of tables and definitions. In the section on definitions we note some errors and ambiguous statements; thus for adiabatic expansion it is the vessel and not the gas which must possess the property of not suffering heat to pass; momentum is the product of mass and velocity, and not "the work stored up in a moving body"; power is the rate of doing work and not "force multiplied by distance, multiplied by time." These misstatements will doubtless be corrected in future editions. Published by James Tribe, Racine, Wis. Price, $1.50.

PERSONAL.

MR. T. E. MITTEN, general superintendent of the Milwaukee lines visited the "Review" on his way east a few days ago.

MR. ENGLUND, of Mayer & Englund, Philadelphia, is justly proud of a fine little daughter who arrived on August 16th.

DR. W. E. BELL has been appointed surgeon of the Terre Haute Street Railway Co., to succeed Dr. T. C. Stunkard.

MR. E. J. LAWLESS, eastern representative of the American Car Co., spent several days renewing acquaintance with his many Chicago friends recently.

MR. E. H. MULLIN, in charge of the publication bureau of the General Electric Co., New York, visited Chicago in connection with the company's printed matter for the coming convention

MR. ROBERT F. FOX recently resigned his position as manager of the Wilmington (Del.) City Railway Co. He was presented with a handsome gold watch by 21 employes of the company.

MR. PHILIP H. WOOTAN, of Boonton, N. J., sailed for China last month, to be absent five years. He is employed by the American Traction Co., of New York, and will represent the company at Shanghai.

MR. CHARLES T. YERKES was last month chosen president of the Chicago Consolidated Traction Co., succeeding Mr. John M. Roach, resigned. Mr. L. S. Owsley succeeded Mr. W. F. Furbeck as vice-president.

MR. MAHLON D. ORDE has been selected to succeed L. S. Owsley as assistant secretary and treasurer of the Chicago Union Traction Co. Mr. Orde was formerly a teller in the Northern Trust Company Bank.

MAJ. RUSSELL B. HARRISON, formerly president of the Terre Haute Street Railway Co., has been critically ill with yellow fever at Santiago de Cuba, but is now convalescent. Major Harrison has been isolated, but was not taken to the fever hospital.

MR. E. L. BEMIS, who has lately been elected to the presidency of the Richmond (Va.) Traction Co., is also president of the Virginia Electrical Railway & Development Co. Mr. Bemis is a native of Louisiana, but for several years has been a well-known resident of Richmond.

MR. WM. CANHAM, president of the Port Huron (Mich.) City Electric Railway Co., has retired from the office and disposed of his one-fourth interest to the firm of F. Saunders & Co. Work on the proposed extension to Marine City will be commenced as soon as practicable.

MR. A. W. LYNN resigned his position as superintendent of construction and maintenance of way of the Milwaukee Electric Railway & Light Co. on August 30th, to become general manager of the Milwaukee Rail Joint & Welding Co., to which position he has been elected. Mr. Lynn has been connected with the Milwaukee street railways since 1886.

THE DIRECTORS of the Logansport, Rochester & Northern Traction Co., of Indiana, have organized by the election of the following officers: President, J. T. McNary, of Logansport; vice-president, L. W. Welker, of Albion; secretary, George Holman, of Rochester; treasurer, B. F. Keesling, of Logansport; civil engineer, Walter Osmer of Logansport.

MR. J. H. SIMMS, for the last year the general superintendent of the Staten Island Electric R. R., has resigned. In his place R. J. Carnahall, of West Brighton, has been named as superintendent of traffic and H. M. Kemp as superintendent of maintenance. The business of the line has doubled within the last two months, and the division of labor was thought desirable.

MR. C. W. FOOTE, manager of the Zanesville (O.) Electric Railway Co., tendered his resignation, to become effective September 1st. Mr. Foote will leave that city for Hamilton to assume the office of general manager of the Cincinnati & Miami Valley Traction Co., owning an electric railway line running between Dayton, Miamisburg, Franklin, Middleton and Hamilton.

MR. FREDERICK LENOIR, superintendent of the Gardner (Mass.) Electric Street Railway Co., has been chosen to fill the same position for the Gardner, Fitchburg & Westminster road. Although the road will not be in running order for over a month, it was found necessary to choose a superintendent to look after matters partaining to the road. He will continue in his present position.

MISS MABEL B. JOHNSON, who was chief clerk to Auditor Smith, of the Lynn & Boston, and one of the most expert lady accountants in the country, has been promoted to auditor to fill the vacancy occasioned by Mr. Smith coming to the Union Traction Co., this city. Miss Johnson has been sought after by several large roads to take charge of the accounting department, but decided to remain in Lynn.

MR. GEORGE M. ELLIS, formerly the superintendent of the General Electric Warehouse, Chicago, for a number of years, is now with the Gregory Electric Co. and the Charles E. Gregory Co., 52-64 South Clinton St., Chicago. Before leaving the General Electric Co. Mr. Ellis was tendered a banquet by the employes and presented with a meerschaum pipe set with sapphires and diamonds, and a handsome gold watch, as a token of the high esteem in which he was held by them.

MESSRS. CHARLES A. RICHARDSON, GEORGE A. MURCH AND W. B. FERGUSON have resigned as directors of the Torrington & Winchester (Conn.) Street Railway Co., and James Alldis, George B. Alvord and A. P. Hine, all of Torrington, were elected in their places. The other directors are Henry Gay and S. A. Herman, of Winsted, and E. H. Hotchkiss and F. F. Fuessenich, of Torrington. James Alldis was elected president and S. A. Herman, secretary and treasurer.

MR. A. J. GIFFORD, who has been connected for the past 10 years with the General Electric Co., in St. Paul and Chicago, left the latter city on August 18th to take charge of the company's transportation department in Schenectady. In his new position Mr. Gifford will have charge of all the company's shipments from the Schenectady factory, a similar position to the one he has previously held, but covering a much larger field.

MR. W. F. FURBECK, long associated with the Yerkes' interests of Chicago, has resigned his position with Mr. Yerkes and will be associated with A. L. Dewar & Co., private bankers.

THE NEW YORK METROPOLITAN COMPANY'S CONDUITS.

Since the introduction of its underground trolley system in New York the Metropolitan Street Railway Co. has put in a great many more ducts alongside of its track than are necessary for the railway feeders. It has laid 36 electrical conduits in Broadway, and is expected to use only four of them in operating electric cars. It is supposed that the other 32 conduits are to be used for electricity which the company will sell to customers along Broadway.

The Birmingham (Ala.) Railway & Electric Co. increased the pay of the motormen and conductors, and in addition to this distributed about $1,000 in cash prizes among them. One hundred and sixty-six men received awards, which were offered at the beginning of the year to the conductors keeping clean cars, the motormen having no accidents, etc.

SOUND VIEWS OF PHILADELPHIA'S MAYOR.

Early this month professional agitators visited Philadelphia and endeavored to work up a strike among street railway employes, taking advantage of the meeting in that city of the G. A. R., as a time when a strike would be particularly undesirable. Two meetings were held, at which 17 were present at one and 21 at the other, out of 4,000 employes. The Philadelphia Times has the following:

Mayor Ashbridge was seen and spoke freely on the subject of a prospective tie-up at this time. As is well known, the chief executive is an out and out friend of the workingman, and has probably done more than anyone else in the city to secure employment for conductors and motormen. Hence an expression of opinion from him on a subject such as this will have exceptional weight with the classes affected.

"No one," he said, "is more anxious to see the laboring man get ahead than I, but I have no patience whatever with these professional labor agitators, who, at salaries of $25, $30 and $50 a week, spend their time in fomenting trouble for the ones who pay them. Of course, we all want to get as much money as possible and work as few hours as possible for it, but when conditions are such that we cannot take as much time to ourselves as we would like, we should not shirk our duty.

"Certainly, if the men want to commit suicide, let them strike on Monday, or at any time during the Grand Army encampment. There isn't a citizen of Philadelphia who would be in sympathy with them.

"But I blame the men who make a business of strikes and labor troubles for such rumors. Naturally, if harmony always prevailed between labor and capital the men would see that they were useless appendages, and so they seize every opportunity to bleed their victims by making all the trouble they possibly can, magnifying grievances, and even manufacturing them, and levying the usual assessment.

"What do they care for the starving men who accept their inflammatory utterances as gospel? What do they care for the suffering families, the disgrace following the violence which their words incite? Nothing, so long as their own salaries are regularly paid. For this class of men I have nothing but unmitigated contempt."

CENTRAL ELECTRIC TROLLEY EAR.

All work is troublesome, but it is more than vexatious not to be able to secure results. In placing the overhead parts of electric railway construction in proper shape, it is important that the parts easily fit and remain fitted; a clip that does not clip and a clinch ear that will not clinch are abominations. Much of the trouble in assembling parts of a whole comes through inherent faults not manifested on the surface; but attributable to the methods of casting. Malleability, to produce pliability and eliminate brittleness, is the salient point in overhead material, where the difficulty of assembling parts is a positive factor and the complex whole is at all times liable to severe strain.

The "Type W" clinch ears are cast in the same position as shown in the illustration, the lips being formed by the prints in the regular

moulding sand. This process of moulding is a secret known only to the makers. Wherever a core is used in casting, the metal coming in contact with it becomes chilled and gains undesirable crystalline properties with resultant brittleness. The method of casting followed by the Central Union Brass Co. leaves the clinching lips of the trolley ear entirely pliable and in condition to readily clinch about the trolley wire, and when once hammered into place to so remain. Installation and maintenance are made more economical by saving of time and no trolley wires will sag by the opening or breaking of the lips of this car.

The Central Electric Co., Chicago, carries these reliable articles in stock, as well as a complete line of railway material.

AN INSULATED THIRD-RAIL SYSTEM.

Experiments which have been carried on for some time on a ½ mile section of the Long Island R. R. by Messrs. Cox and McDonnell to test an improvement in the third rail system have been brought to a satisfactory conclusion, and the system has been pronounced an unqualified success by several prominent railroad men who witnessed the experiments. Messrs. Gould and Sage of the Manhattan Elevated System, President Baldwin of the Long Island Railroad Co., and President Clarke and other managers of the New York, New Haven & Hartford, with representatives of the New York Central and other prominent railroads have visited the place and taken a trip over the half mile of track, and it is said, have all been convinced of the practicability of the system for trunk and elevated railroads.

In this system the third rail consists of a hollow wooden trough on top of which is fastened an iron cap. Inside this trough runs a large copper wire for the transmission of electricity. A smaller iron wire lies loosely on top of this and this wire is lifted as the train passes along by a powerful magnet to the top of the rail, which thus becomes electrified for the length of the car. A short distance behind or ahead of the car the third rail is dead.

It is claimed that the loss from leakage and the danger of short circuiting in wet weather is entirely obviated by this system, which was found to be perfectly reliable on the experimental section during the heaviest storms.

President Baldwin said about the system:

"The only hindrance to our at once taking hold of this matter is the fight over the validity of the patent. There are several others who claims title to the invention. As soon as this is settled we are ready to go ahead."

FIRE AT NIAGARA FALLS, ONT.

The power house of the Niagara Falls Park & River Ry., on the Canadian side at Niagara Falls, was destroyed by fire on the night of September 4th. The first intimation of trouble was when the attendant noticed a short circuit on the alternating current line in the basement. He had hardly time to shut down the water wheels and throw the switches before the interior was ablaze. The building was of stone, and only the walls remain. The station was the property of the International Traction Co. and contained three generators for the railway service, and two 750-kw. generators of the Canadian Niagara Power Co. The damage to the building is placed at $10,000, and to the apparatus about $75,000. It will be recalled that the road has another power station at the foot of Queenston Heights, and this gave a partial service until connection was made across the upper steel arch bridge with the trolley wires in Niagara Falls, N. Y. The Niagara Falls Park & River Ry. will be run by current from the central station of the Niagara Falls Power Co. until other arrangements are perfected.

RAILWAY NEGOTIATIONS IN MOBILE, ALA.

Negotiations are in progress looking to the purchase of the two Mobile street railways by outside capitalists and their consolidation into one system. Mr. W. H. Patterson, of Atlanta, who is connected with the Consolidated Street Railway Co. of that city, has been in Mobile inspecting the property of the street car companies, and has had several conferences with Manager Semmes, of the Mobile Street Railroad Co. and with Manager Wilson, of the Mobile Light & Railroad Co.

Mr. Patterson stated that if he could reach an agreement with the street railway owners he would get capitalists to purchase and consolidate the roads. He expected an agreement would be reached within two or three weeks.

One of the rumors in Chicago is to the effect that the Chicago Union Traction Co., the Chicago Edison Co., the Commonwealth Electric Co. and the Illinois Vehicle Co. are to be consolidated.

The Belleville Electric Railway Co., of Belleville, Ill., has petitioned to have its franchise extended for six years. The present franchise has 14 years to run, and the company wishes to issue some 20-year bonds.

HUBBARD ELECTRIC BRAKE CO.

The Hubbard Electric Brake Co. has been incorporated for $1,000,000 and began the manufacture of electric brakes in its own shops, at Chester, Pa., on September 11th. The inventor, Mr. Hubbard, and the vice-president, G. E. Pratt, are both well known to street railway men. The works are at Nos. 126 to 130 Sixth St., Chester.

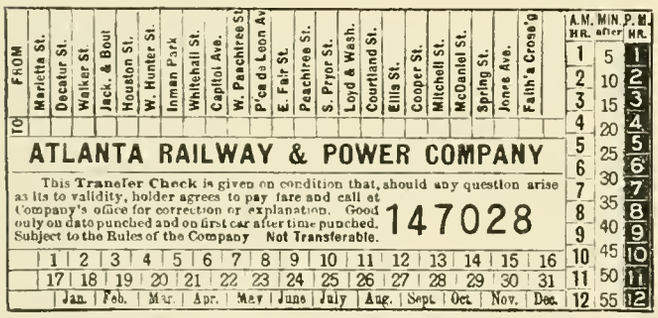
The company calls attention to the following points: The first cost is reasonable, bringing it within the reach of all roads; its simplicity in construction and operation make its use easy by any motorman; sliding and skidding of wheels is prevented, and brake may be operated from either platform by either line or motor current; the braking force works from a jam cylinder under the center of the car, with fulcrum and brake levers working uniformly on all wheel treads; absence of any rigging on the axles and no necessity for additional motors, piping or machinery.

The company has been making some tests which are said to be very interesting, and which will be announced at the coming convention.

ATLANTA TRANSFER CHECKS.

We show herewith the transfer check now used by the Atlanta Railway & Power Co. The original is 2 x 4¼ in., printed in black on olive green paper, excepting the serial number, which is in red. On the back is a copy of the city ordinance relative to the misuse of transfers. The ordinance reads as follows:

"No transfer ticket or written instrument giving or purporting to give the right of transfer to any person or persons from a street railroad car or route to a street railroad car operated upon the same or another line of route of said street railroad in said city, shall be issued, sold or given away, except to a passenger



lawfully entitled thereto and by or from a duly authorized agent of said street railroad company.

"Any person, other than a duly authorized agent of the aforesaid street railroad company, who shall in said city issue, sell, exchange or give away such a transfer ticket with intent to have the same used for passage, and any person or persons not lawfully entitled thereto who shall offer for passage such a transfer ticket, shall be guilty of an offense for each and every act, and on conviction thereof shall be punished by imprisonment not to exceed 30 days, or fined not exceeding $100, either or both, in the discretion of the recorder's court, for each and every such offense."

NEW BADGES FOR THE TRI-CITY EMPLOYES.

The motormen and conductors of the Tri-City Railroad Co. were provided with new coat and cap badges last month. The insignias are very neat and the cap badges designating the office of the wearers, are so arranged that they are interchangeable. On occasions when through rush of business or otherwise a motorman may perform the duties of conductor, or vice versa the badge may so designate, and the advantage of the new scheme will be shown in all the men, extras as well as regulars being properly badged at all times when on duty. The coat badge, an immense button, bears the man's number and the name of the company, but does not indicate his position.

CONSOLIDATION OF THE NASHVILLE, TENN., RAILWAYS.

The City Council of Nashville, Tenn., passed an ordinance last month permitting the consolidation of the three railway companies in that city. This gives the consent of the mayor and city council of Nashville to the acquisition by the Nashville Railway Co. of the franchise, rights and ways, properties and assets of the Nashville Street Railway Co., the Nashville & Suburban Railway Co., and the Citizens' Rapid Transit Co.

The roads are owned by the Hambleton company, of Baltimore, and considerable opposition was made to putting the three franchises in the possession of a single company, but after considerable discussion the measure passed the council by a vote of 15 to 5.

TAMPERED WITH SIGNAL BELLS.

By representing himself as an electrical inspector on the street cars in Cleveland, Walter Bertram, an electrician, managed to put the electric signal bells on 40 cars out of order last month. Bertram's scheme to do injury to the railroad company's property was interesting. He stationed himself at the corner of Perry and Prospect Sts. and boarded every passing car. He would represent himself as one of the company's electricians, and would try all the push buttons in the car. He also worked around some of the electrical apparatus with a screw driver. He worked on a number of cars until he came in contact with a non-union conductor. The latter refused to let Bertram meddle with the electrical apparatus until he displayed his credentials. As he could not do this he jumped from the car and disappeared.

He was soon seen to board another car, and while at work on the electrical apparatus of the latter was arrested.

SANS SOUCI PARK A GREAT SUCCESS.

In previous issues we have described Sans Souci Park, the new South Side Chicago summer resort, and now as the season draws to a close we note the fulfilment of every promise made of its high class and popularity. That Chicago people appreciated the filling of this long felt want has been attested by the 800,000 who have visited the beautiful grounds and witnessed the many pleasing features presented. Under the able management of Mr. W. H. Carter the park has proved to be a great family and pleasure resort, and has been patronized by the most fashionable and discriminating people of this city. During the season first-class vaudeville and out-door attractions have been presented. The electric fountain has proved the most beautiful attraction ever offered for out-door pleasure, and has been a leading feature. It has been the aim of the management to keep the social atmosphere of the park of the purest quality and we congratulate it on its success in an undertaking which will make the park more popular next year than this, if there is any superlative of success. Extensive improvements will be made on the buildings and grounds before the opening of next season. Experience has suggested many changes, and when these are completed along the lines contemplated the rough edges of newness will be removed and Sans Souci Park will present a paradise for the patronage of prosperous people when the season of 1900 opens. We predict even greater results than attained this year, as Chicago people are always ready to lend the stamp of approval to everything good in the line of summer resorts.

TROLLEY PARTIES TOO NOISY FOR PHILADELPHIA.

The order has gone forth in Philadelphia that the noises which attend trolley parties in that quiet city must cease. President Parsons, of the Union Traction Co., has ordered all conductors to maintain quiet and order upon their cars.

When the electric cars were introduced and trolley parties became a fad, the authorities complained of the noise made by some of the riders. The traction companies were asked to suppress these noises and orders to that effect were issued. Now, in time the rules against too much noise on cars were overlooked, hence the new order.

ECHOES FROM THE TRADE

LITTLEFIELD & MYSENBURG, Chicago, agents for the Lorain Steel Co., secured an order for 100 du Pont trucks for the Indianapolis Street Ry.

THE E. P. ALLIS CO. has recently published a handsome pamphlet of nearly 200 pages, descriptive of improvements in its engines. There are numerous fuel page illustrations of its latest types of engines

THE E. P. ALLIS CO., of Milwaukee, was among the bidders for the engines for the new power plant to be erected by the Glasgow Tramway Committee, and its tender was accepted, the price being £114,544.

THE PITTSBURG REDUCTION CO. last month shipped to the Russian Government, at St. Petersburg, 200 cases of aluminum to be used as a conductor line for an electric railway controlled by the Imperial Government.

JOSEPH LOCKWOOD, of the Michigan Electric Co., Detroit, is acting as the representative of the J. G. White Co. in building the power house of the Lake Orion road. This station is nearing completion and will be a model plant.

CHARLES B. HAZARD, manager of the New York office of the Electric Storage Battery Co., of Philadelphia, advises us that the New York office has been removed from 20 Broad St. to the 15th floor of the American Surety Bldg., 100 Broadway.

THE SIEMENS & HALSKE ELECTRIC CO. OF AMERICA has removed its St. Louis office from No. 6 Laclede Building to No. 116 Laclede Building; W. R. Mason is the company's sales agent in that city. Long distance telephone, Main 2212 M.

THE GOLD CAR HEATING CO., of New York, has taken orders during the past month which surpass all former records. Among the most prominent orders for electric heaters is that of the Boston Elevated Railway Co., which has ordered heaters for 100 new cars.

THE KUHLMAN CAR CO., of Cleveland, O., has secured the contract to furnish 12 new cars for the Detroit & Northern Electric Ry., the new line now under course of construction between Detroit and Pontiac, via Farmington. This line will start running through cars about January 1st.

WENDEL & McDUFFIE, of New York, have received since August 1st orders for 50 snow plows and sweepers. The orders for these machines are being placed much earlier than usual and will tax the capacity of the Taunton Locomotive & Manufacturing Co., for which Messrs. Wendel & McDuffie are agents.

THE ELMER P. MORRIS CO., of New York, has added to the list of concerns for which it is agent, the following: Wagenhals Manufacturing Co., Cincinnati; Mundel Electric Works, Springfield; Spiral Journal Bearing Co., St. Louis. The company has recently received a number of large orders, both foreign and domestic.

ROBERT W. BLACKWELL & CO., LTD., has just been incorporated for the purpose of taking over the business of engineers and contractors heretofore carried on by Messrs. Robert W. Blackwell & Co., at 39 Victoria St., Westminster, London, S. W.; 133 Bermondsey St., London, S. E.; 20A Chapel St., Liverpool; 50 Boulevard Houssmann, Paris, and 120 Liberty St., New York. The directors of the new company are: Robert Winthrop Blackwell, Philip Dawson, Benjamin Hunting Howell, Sir Charles E. Howard Vincent, Francis Henry Barker.

A. O. SCHOONMAKER, 158 William St., New York, the extensive dealer in mica, reports a good demand for solid mica segments, and is filling an order for 10,000 for one of the largest street railways in the country, this being a duplicate of an order given last spring. Mr. Schoonmaker is ready to furnish samples to anyone wishing to give his goods a trial.

THE BADT GOLTZ ENGINEERING CO., formerly Meysenburg & Badt, Incorporated, advises us that Mr. Edward A. Meysenburg has resigned as treasurer and retired from the active management of the company, and that the name of the company has been changed as above to indicate the work the company is doing and the active members of the firm.

THE SWARTS METAL REFINING CO., Chicago, with office and works at 20 to 32 North Desplaines St., is buying large quantities of trolley wire from street railways which are tearing down old lines, or have short pieces of wire which cannot be used on the line. The same concern also purchases at the highest market price other metals worn out in car and other service.

THE STARR BRASS WORKS, of Kalamazoo, Mich., has recently doubled its capacity and increased its capital stock from $10,000 to $20,000. This has been made necessary by the success which the company is meeting with in the sale of its long distance trolley wheels and harps. Large orders have been placed with them by many of the leading roads in the country.

F. W. KELLY, general manager of the Consolidated Car Heating Co., Albany, N. Y., announces important changes in his selling department. H. N. Ransom, who has been general agent at New York, has resigned to accept the office of purchasing agent of the Buffalo Railway Co., and the vacancy has been filled by the appointment of J. N. DuBarry, jr., whose headquarters will be in the Havemeyer Bldg.

COL. BONNER, of the Bonner Rail Wagon Co., Toledo, O., was in Douglas and Laxey, Isle of Man, last month when the Isle of Man Tramways Co. inaugurated a freight service on its lines, using the Bonner rail wagons. The company and its patrons are well pleased with the new service, and the manager of the company, Mr. Alexander Bruce, has been warmly praised by the public for his enterprise in introducing the wagons.

ROBERT H. DERRAH, of Boston, is meeting with great success in the promoting of trolley excursions in Eastern Massachusetts, which business he began developing last spring when he severed his connection with the Boston Elevated Ry. During the past summer Mr. Derrah has arranged with the street railways of suburban Boston for special cars, which make trips several times each week; on these trips the excursionists pay the expense, Mr. Derrah does the rest.

THE WESTERN ELECTRIC CO. is agents for hot wire ammeters and voltmeters made by the Stanley Manufacturing Co. These instruments are either direct or alternating current and are of two types, for switchboard work or for portable use. They are accurate, dead beat, possess a wide range of adjustment, and are invaluable for general central station use. The Western Electric Co. has recently placed upon the market the marine type of its "Petite" lamp suitable for shipyards and lake vessels.

ADAM COOK'S SONS, 313 West St., New York City, who are the sole makers of the celebrated "Albany" lubricating compound and compound cups for all lubricating purposes, send us the following extract from a letter from F. M. Sprague, 213 W. Seventh St., New York: "The cups came all right, too. They are doing the work to a T and are filling 'a long felt want.' We have

ordered 50 lb. more of your No. 3 grease." This is a reflection of the usual experience of engineers who use the "Albany" compounds.

THE J. G. BRILL CO. has sent us a pamphlet entitled "Fifteen Months of Experience with a Perfect Passenger Truck," which treats of that company's No. 27 double truck. The experience has shown the special advantages of this truck to be: greater safety, not easily derailed by obstructions, easier riding under all conditions of track, steadiness of the truck itself, no tilting of truck upon applying the brakes, less danger at frogs and switches, less adjustment of shoes where air-brakes are used, equal loads on all wheels at all times, load, not leverage, on wheels.

BULLOCK ELECTRIC APPARATUS continues to find favor, especially among the more exacting users. Sales reported by the company for August embrace 52 machines, ranging in size from 2¼ kw. to 800 kw. capacity. The orders were widely distributed throughout the United States and two were from Great Britain. The latter were for the celebrated "Teaser" equipment, for operating large printing presses, one for a 50-h. p. equipment coming from the Free Press, of Aberdeen, Scotland, and four 50-h. p. equipments from the Scottsman, of Edinborough. We are advised that the company has just issued Bulletin No. 3,432, which will be forwarded to any one applying for it at the general office, Cincinnati.

THE AMERICAN VITRIFIED CONDUIT CO., with general offices at 39-41 Cortlandt St., New York, has issued a new catalog descriptive of its vitrified, salt-glazed underground and interior conduits. The company has developed these ducts from the results of extensive and practical experience, and its present products are admirably adapted to the requirements of trunk, feeder and distributing lines for all kinds of electric transmissions. The joints of these conduits are aligned with dowels, giving the smoothest possible interior surface, and they are made so as to be practically indestructable. They are made up in a number of different styles and sizes, which are illustrated in this catalog, together with views of a number of places where ducts are being installed for electrical purposes.

"WESTINGHOUSE GAS ENGINES" is the title of a new trade catalog of the Westinghouse Machine Co., and it is by far the most complete and instructive catalog of such engines that it has been our pleasure to see; in fact, the avowed purpose of the company was to publish a book which would be a source of information to readers. The pamphlet contains 70 pages, profusely illustrated with views of the engines and details, and the descriptive matter clearly sets out the principles and method of operation. The company makes very strong claims for its method of regulation which consists in varying the volume of mixed gas and air according to the load; the proportions of gas and air in the mixture remain constant, and a charge is admitted at every stroke. The company builds two-cylinder engines in sizes from 10 h. p. to 70 h. p., and three-cylinder engines in sizes from 15 h. p. up. The largest yet built is 650 brake h. p.

"DIXON'S GRAPHITE PRODUCTIONS" is the title of a 6 x 9 pamphlet of over 60 pages recently issued by the Joseph Dixon Crucible Co., of Jersey City. It treats of over 60 different classes of graphite products made by this company. We quote a portion of the preface as follows: "A carefully written history of graphite — its nature, its formations, its sources of supply, its uses in the past and at present, and its possible range of uses in the future — would be alike interesting to the scientific man and the layman. Such a history has never yet been written, although the Dixon company has given publicity to much valuable, and about the only, information on the subject.

"Joseph Dixon, the founder of the Dixon company, was the originator of the graphite industry, and in 1827 began the manufacture of Dixon's plumbago or blacklead crucibles and Dixon's "Carburet of Iron" stove polish. His invention of the blacklead crucibles revolutionized the crucible business, and all plumbago crucibles today, wherever made, are manufactured after his methods.

"Graphite is sometimes called plumbago, oftener blacklead. The three names mean the same thing. Graphite varies largely in its constructure, and the value of graphite for its many mechanical purposes depends not alone on its purity, but quite as much upon a careful selection and preparation of the proper kind for the work intended."

THE NATIONAL WATER TUBE BOILER CO., New Brunswick, N. J., which organized 52 years ago under the name of the National Iron Works, has been recently reorganized and enters the field with the best of prospects. The new owners are all business men of this city of high standing who realized when the concern was to be sold that it augured well. The directors of the company are Hugh McKeag, Philip Weigel, jr., Robt. J. Smith, P. M. Welsh, P. G. Polhemus, C. A. Schenck and Hugh Boyd. The officers are: President, Hugh McKeag; vice-president, P. G. Polhemus; secretary and manager, C. A. Schenck; treasurer, Philip Weigel, jr. Mr. Schenck has been with the National Water Tube Boiler Co. for 11 years. During the latter part of that time he has been acting as manager. Mr. Schneck is a man of ability. He is thoroughly acquainted with the workings of the business as a result of his wide experience and will no doubt do much to improve the condition of the concern.

THE WESTERN ELECTRIC CO. carries in stock some very neat novelties in the way of portable battery lamps. The "Emergency," "Search," or "Flash" light is made in three sizes, cylindrical in form, the diameter of all being the same, and their length being respectively 8½, 11 and 13 in. These lights give from six to eight thousand flashes before the battery requires renewal. They are extremely useful where a light is wanted quickly. The company is distributing a catalog descriptive of this device. This catalog also illustrates the "Ever Ready" electric walking cane, interior search light, electric gas lighter, surgical and dental lamp, electric bicycle lamp, "Ever Ready" night lamp, electric candle, ornamental banquet lamp, electric ruby lamp, for photography, portable reading lamp, the "Ever Ready" scarf pin, and other battery novelties. If any of our readers have not received a copy of this catalog the same will be sent to them upon request.

GEORGE E. FISHER, president and treasurer of the Chase Construction Co., general contractors, Detroit, Mich., has secured the contract for his company for constructing the Toledo, Fremont & Norwalk Ry., from Toledo to Fremont, O., which includes all work outside of the power house and bridges. The company will employ a force of 200 or more men on this contract, when the work is fairly under way, preliminary work having been started last week. Mr. Fisher states his company have had a very busy season and are now completing the large municipal electric lighting plant for the city of Grand Rapids, and the construction of the Cleveland & Eastern Ry. at Cleveland, O. This road runs from that point 36 miles east to Chardon, O., being the second interurban line running out of Cleveland constructed by the Chase company. It has also just completed and turned over to the owners, quite an extensive lighting and power plant, operated by water power, at Belding, Mich., this being a high tension, multiphase alternating system.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING CO. recently received a letter from Pres. A. D. Claflin, of the Commonwealth Avenue Street Ry., Newtonville, Miss., which in substance is as follows:

"We have 16 15-bench cars equipped with Westinghouse 12-A, 30-h. p. high speed motors; these cars are now running their third season over our main line, making the regular schedule of 11 miles in 54 minutes. The traffic on these cars, particularly in the summer season, is very heavy, as they constantly carry from 130 to 160 passengers per trip; our record is 203 passengers on one of these cars at one time. Our road has many curves and several long grades as steep as 5 per cent, two in particular being nearly a mile long each. We have never been obliged to pull a car off the line while in service on account of any trouble with the electric motive apparatus. We have never lost either an armature or a field, and in fact, have had no trouble whatever with your motors running under these trying conditions. We believe this to be an exceptionally satisfactory record for service."

PROVIDENCE FENDERS have been ordered for the cars of the Tri-City Railway—Davenport, Moline, Rock Island—after several months' tests of various makes.

THE CLONBROCK BOILER CO., of Brooklyn, N. Y., has opened a western office at 1457 Monadnock Bldg., Chicago, which will be in charge of Mr. H. B. Ham.

THE MORDEN FROG & CROSSING WORKS has completed the contract for the electric railway at Seoul, Korea, and during August shipped a consignment to Honolulu, Hawaii.

THE AJAX METAL CO., of Philadelphia, extends a cordial invitation to all railroad managers, motive power and other officials, to pay it a visit at Section M-13, Main Building, of the National Export Exposition, which is now being held in Philadelphia. The company will have representatives there at all times, and will take pleasure in offering its services to all visitors. It will provide ample facilities for correspondence, and will give them every attention.

WELLINGTON HOTEL, CHICAGO.

One of the best known and most popular hotels in Chicago, and which we can recommend as enjoying the reputation of having the best chef in the city, is the Wellington, situated conveniently in the down town district. It is at the corner of Jackson Boulevard and Wabash Ave. convenient to the retail shopping district, and within easy walking distance of all the theatres. It is one block from the Lake Front, and cars for the convention hall pass the door. The building is constructed on a fire-proof principle, the walls and cross-walls all starting 3 ft. thick in the basement and continuing up to 12 in. at the roof. These cross walls or partitions surround every space 25 ft. square through the building. The floors are 14 in. deep in fire-proof material, so that, with the side halls and stairways from each floor, the iron bridge across the alley connecting the Michigan Ave. annex, the question of safety is settled beyond argument.

The Wellington is conducted on the European plan, with handsome cafes on the first floor, and a very popular grill room.

BRITISH COLUMBIA ELECTRIC RAILWAY CO.

The second annual report of this company has been issued for the year ending March 31st, from which the following data are taken: In November, 1898, 1,200 shares of non-cumulative 5 per cent preferred stock of a par value of £11 per share, were issued, out of which issue the £60,000 non-cumulative 6 per cent income bonds have been paid off at par. Most of the extensions and improvements previously recommended by the general manager and chief engineer have been acted upon and it is expected that they will all be completed by September 1st, from which time the increase in profits should commence to accrue. Owing to delays in some of these improvements no financial benefit was realized from them during the year covered by the report. The installation of the plant for utilizing the water power from the falls of Goldstream, Victoria, has but recently been put in running order, after experiencing many difficulties. This machinery was started in September, 1898, but various troubles arose which were not overcome until the end of March, 1899, since when it has been in satisfactory service.

The gross profit for the year amounts to £30,188 14s. 1d. From this the directors have paid interest charges and dividend on preferred stock, which leaves £15,550 13s. 1d. available for distribution. From this sum the directors have decided to write off 20 per cent of the preliminary expenses, to pay a dividend of 4 per cent on the common stock, absorbing £8,000. To transfer to reserve account £6,148 19s. 10d. and to carry forward to the next account £189 4s. 9d. In addition to the amount mentioned above, the directors have transferred to the reserve account the surplus of premium received over the expenses of the preferred share issued, £1,349 5s. 2d., bring the reserve fund up to £12,000.

The disastrous fire at New Westminster in September only affected the company by the burning down of about ½ a mile of track equipment. The company donated £2,100 to the relief fund. Owing to the large number of sightseers carried at the time, and the large amount of building materials and general freight carried since, the receipts of the Westminster branch have suffered comparatively little, notwithstanding that the return fare between Vancouver and Westminster has been reduced from 75 cents to 60 cents.

In reference to the state of the company's lines, the report states that the roadbed and track on the Vancouver and Westminster branches have been maintained in excellent condition, and on the Westminster branch work has been commenced with a view to replacing the four small bridges by culverts and a permanent railway embankment. This will reduce the cost of maintenance in future. The directors have decided to entirely relay the roadbed of the Victoria branch, as it is not in good condition, and the rails are light, and they have decided that it will be more economical and wiser to put the track in first-rate permanent condition at once than to follow the system of improvement which was commenced last year, by which the roadbed and track were to be renewed over a period of several years.

A consolidation of the power houses of the Vancouver and the Westminster branches has been commenced and the new plant is expected to be finished by September next. When this is accomplished, with the new installation just completed at Victoria, the company will have throughout thoroughly efficient machinery of the latest type, with all the most recent economical improvements, whilst the old plants at Victoria and Westminster will, as heretofore, carefully maintained for the purposes of reserve. Beyond the regular lighting extensions, the installation of a storage battery, and the reconstruction of the roadbed at Victoria already referred to, there are no new improvements or extensions at present proposed or needed.

The officers of the company in Canada are: General manager, J. Buntzen, Vancouver; chief engineer and general superintendent, J. M. Campbell, Vancouver; assistant engineer and superintendent, R. H. Sperling, Victoria; assistant comptroller, E. H. Wilcox, Vancouver; local manager, A. T. Goward, Victoria; superintendents of traffic, H. Gibson, Victoria, D. A. Shiles, Vancouver.

TROLLEY EXPRESS DISCONTINUED.

The trolley express which has been running for some time between Manchester, N. H., and Rockville, was withdrawn last month. The street railway company's charge for running the express car over its line was one-third of the gross receipts. It has not been a paying venture for the street railway, but the express company had a good thing. The rate was recently raised to 15 cents a mile for each mile that the express car was run. The daily average of the car is about 85 miles, and the express company would not agree to the change, so the car was withdrawn. The trolley express did a good business from the first and the business was steadily increasing. The greater portion of the goods carried would come under the head of freight, rather than express matter.

THE PHILADELPHIA-ATLANTIC CITY LINE.

From the description of the promoters the new line to be run from Philadelphia to Atlantic City will contain numerous points of novelty. A forfeit of $104,000 has been put up with the treasurer of the state, which practically insures the building of the line. The road will be built for through passengers only. There will be no local stops. This clears the road of local trains and leaves the track clear for high speed traffic.

The extra conductors and motormen in the employ of the Middletown (Conn.) Street Railway Co., went out on strike August 12th.

A RAILWAY ORDINANCE CONTESTED.

An ordinance in Brooklyn requires the Brooklyn Rapid Transit Co. to stop its cars before crossing certain specified streets, which are asphalted, and are used by bicyclists. Bicyclists complain that the company has persistently violated the ordinance which was passed by the City Assembly, because of the large number of wheelmen and wheelwomen injured by the trolley cars.

Evidence of these violations has been collected by the police and turned over to the corporation council for prosecution.

The company does not deny the facts charged, but has confined its defense to an endeavor to prove that the ordinance is unreasonable and that, therefore, under a ruling of the Court of Appeals, is not binding upon it.

Judge Van Wart, before whom the cases were tried, has received the company's briefs and reserved his decision.

PRIVATE TROLLEY CAR STRUCK BY LIGHTNING.

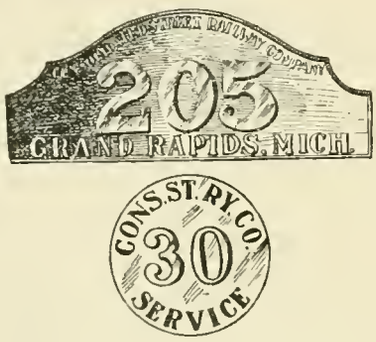
While a party of 13 prominent business men of St. Louis were enjoying a ride in the "Electra," the private car of President Spencer, last month, the car was struck by lightning, causing considerable fright and some injuries to the party.

After enjoying a pleasant trip and a dinner at the other end of the line, the party started to return to the city. All went well until Osage was reached, at midnight, when the occupants found themselves in the midst of one of the worst electrical storms they had ever witnessed, and even the brilliant lights in the car failed to hide the vivid flashes of lightning that continually played about them.

Suddenly there was a deafening crash, accompanied by a blinding flash, and the car seemed to be in a blaze. The occupants were stunned for an instant; when they recovered they saw that the brass lamp fixtures of the car had melted and the molten metal had scattered over several of their number, painfully burning some of them.

NEW BADGES FOR RAILWAY MEN.

The Grand Rapids (Mich.) Consolidated Street Railway Co. has just provided its employes with new badges upon which figures alone are used to designate the men. The old badges bore the words "Conductor" or "Motorman," but as the company frequently uses motormen to collect the fares and sometimes has used conductors to operate the motors, the result has been a con-



fusion of labels and it has been decided to designate the men hereafter by numbers only. The figures on the new badges are of nickle fastened on a background of hard rubber.

The numbers from 30 down are reserved for the use of the company's officers and the service men who are not regularly employed on the cars. The general manager and secretary have small gold badges lettered in black enamel with the name of the company and the office of the person wearing it.

A new style of roadbed has been adopted by the Brooklyn Rapid Transit Railroad Co. Heavy girder rails are being laid upon beds of concrete 10 in. wide and 12 in. deep. No ties are used. The rails are held at proper distance by steel braces running crosswise. These in turn are kept in place by the granite paving blocks.

TAUNTON & BROCKTON LINE SOLD.

The Massachusetts Electric Companies, which has absorbed most of the important electric railways of that state, recently purchased the Brockton & Taunton Street Ry. The price paid was not officially announced, but is generally thought to be $150 per share. When the other roads in the city of Brockton were bought, the majority of the stockholders of this road asked $175 and until the present deal was made, held out for that price. The road is one of the most important in that section and possesses excellent rolling stock. It connects Brockton and Taunton by a direct route.

The plan of the syndicate is to use this road for a direct route from Brockton to Providence, doing away with the Brockton, Bridgewater & Taunton as part of the Providence road. This will make the trip from Brockton to Providence much shorter than at present.

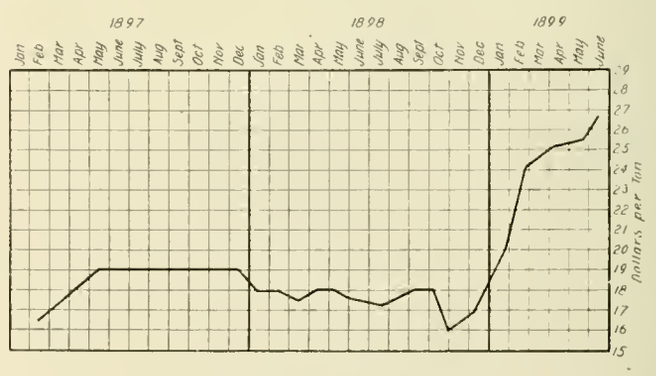
NEW RAILWAY PARK FOR AUGUSTA, GA.

Col. D. B. Dyer, president of the Augusta Railway & Electric Co., of Augusta, Ga., has announced that his company has perfected plans for a handsome 15-acre park in the village of Summerville. The park will be located at the present terminus of the Monte Sano track and the railway company expects to spend a large sum of money in improving the park property.

The pavilion will be commodious, ornamental and presentable. It will have a basement designed for car storage. Walks are to be laid out, shrubbery planted, water arranged and fountains put in.

FLUCTUATION IN STEEL RAILS.

The sudden rise in the prices of crude and finished iron and steel products has been very marked and the following diagram taken from the Iron Age shows the fluctuations in steel rails for the last two years. During 1896 the price of steel rails remained



PRICE OF STEEL RAILS.

stationary at about $28 per ton, but at the dissolution of the rail pool in 1897 the price dropped to a point shown where the diagram commences. Since the beginning of July prices have advanced still farther, so that the upward course of the curve continues.

TRAFFIC ARRANGEMENT DISCUSSED.

A traffic arrangement between the Manhattan Elevated system of New York and the elevated and surface roads of Brooklyn has been under consideration for some time, and there seems to be a prospect of its early consummation. A similar agreement between the Manhattan and the Third Avenue systems, whereby transfers are given for 8 cents, has been in operation for several months and has proved so advantageous as to encourage the management of the Manhattan to extend the same to the Brooklyn roads. President Rossiter, of the Brooklyn Rapid Transit system, and General Manager Skitt, of the Manhattan, have a favorable opinion of an exchange system and have had several conferences on this subject. Neither Mr. Rossiter nor Mr. Skitt will say what exchange rate is under consideration. It is generally supposed among street railway men that the 8 cent rate in force between the Third Ave. and Manhattan systems is the basis of negotiations.

THE CHICAGO CONVENTION.

Eighteenth Annual Meeting of the American Street Railway Association in Chicago, October 17, 18, 19 and 20, 1899 Attendance Will Be the Largest in the History of the Association Hotel Facilities Ample Delegates Can Study Every Type of Motive Power Horse Cars, Cable Cars, Trolley, Third-Rail, 3-Phase, Storage Battery and Compressed Air Systems All Are in Operation Here Strong Program for the Meetings Unprecedented Display of Exhibits A Genuine Chicago Welcome Awaits the Guests.

The American Street Railway Association is getting along in years, and the Chicago meeting will make the eighteenth annual gathering. Chicago invites the street railway fraternity of the world and will endeavor to see that every visitor is royally entertained. Its central location with regard to railroad travel makes it especially easy of access, and with hotel facilities sufficient to care for the population of a good sized city, we believe the attendance will be larger than at any of the previous conventions.

The convention opens Tuesday morning, October 17th, and continues during the succeeding three days. The papers to be presented promise to be unusually valuable and interesting, and abundant time will be allotted to discussions.

The Executive Committee has felt that the excursions and entertainments should not encroach upon the regular work and purposes of the meeting, but the program has been so arranged that work and pleasure will be suitably alternated. The entertainment committee will discharge its duties in a manner which, we believe, will be pleasing and interesting.

One whole day will be devoted to the Exhibition. This is an innovation, but one which delegates and supply men alike will appreciate. The meetings and display will be under the same roof in Tattersalls, which is at State and 16th Sts. It is easily reached by several lines of surface cars without change and requiring only a few minutes' ride.

Chicago affords exceptional facilities for studying the various methods of motive power. We still enjoy (!) a number of horse cars, and the cables and trolleys, the third rail of the elevated roads, with the storage battery line and compressed air in night car service, leave little to be desired by the earnest student of the several methods of propulsion.

The steam raods have made the usual concession of one fare and a third for the round trip. Purchasers must, however, be sure to get the special ticket and receipt when buying in order to avail themselves of the reduction. The ticket must also be stamped for return, by the authorized agent of the traffic association, who will have an office at the convention hall.

The Chicago ladies have organized a large committee and propose to look after the wants and comfort of the visiting ladies in every way. It is earnestly hoped the number of ladies in attendance will be as large as possible.

The Accountants' Association anticipates a large gathering of its members and a very interesting meeting. This association has grown very rapidly and accomplished a vast amount of important work in a short space of time. Its efforts have commanded the endorsement of state railroad commissions and the managements of our largest and best roads. The Accountants will meet at the same place and time but in its own quarters.

As the evenings during October are usually cool in Chicago, visitors will do well to bring with them garments of fairly heavy weight, although the days are usually warm and bright, and light overcoats are not always necessary.

There will be much to interest the visitor in the line of power plants and repair shops. The successful operation of the 3-phase system of long distance transmission of the Chicago & Milwaukee line affords a working demonstration of what undoubtedly will be widely copied for roads of this class. We have described quite fully in this issue the more interesting features of our local power stations and repair shops to enable the reader to select in advance such points as he specially wishes to visit and examine while in attendance at the convention.

The territory now embraced in the State of Illinois has furnished material for an interesting history, which in its early days was full of tragedy, with a chain of thrilling events to mark the aggression of the white man and the recession of the Indian. The picture is aptly painted in the familiar words of William Wirt:

"Not many many generations ago where you now sit circled with all that exalts and embellishes civilized life, the rank thistle nodded in the wind and the wild fox dug his hole unscared. Here lived and loved another race of beings; beneath the same sun which rolls over your heads the Indian hunter pursued the panting deer; gazing upon the same moon which smiles for you, the Indian lover wooed his dusky mate."

Before coming into the hands of the United States this section, in common with all the rest of the country, belonged by right of discovery, to Spain. Then came the French, who were driven out by the English, and who, in turn, surrendered the land to the United States government. But before all these it was the home of the Indian. The Algonquin family extended from Canada, along the St. Lawrence River, west to the Mississippi. In this family were many tribes, and among them was one called the "Illini," an Algonquin word which signifies "superior man;" our present spelling, "Illinois," is said to be a French corruption of the Indian plural, "Illinuk." The main settlements of this tribe were in the middle and northern part of this state. In what is now La Salle County was a thriving Indian village called La Vantun, which in 1680 contained 800 inhabitants. Within the limits of the present state there were 20 other villages. The region was rich and fertile, and attracted the attention of the other tribes of Algonquins, and they began clamoring for a division. Family troubles ensued, which were bad enough, but when the outsiders, the Sioux, the Sac and Fox, the Kickapoos, the Pottawatomies and the Iroquois came in for a share, matters grew serious for the poor Illini. The Iroquois were by far the strongest and most persistent of the enemy. They kept up a constant warfare and nearly wiped the Illini out of existence, until finally a crisis was reached. The Iroquois had made one of its periodical raids and plundered a village, driven away its people and began indulging in a wild and beastly orgy in honor of the victory. The Illini braves were entirely cowered, and from a distance watched the revelries of their enemies. Then uprose an Indian Joan of Arc. It was Watseka, a maid of the Illini. She begged the men to rally and make one more effort to drive out the Iroquois, but the braves were brave no longer. Then Watseka turned to the women and one and all they flocked around her. They armed themselves with bows and arrows and stood ready for the word. This shamed the men and they too prepared for fight. They all, Indians and squaws, rushed upon the Iroquois and not only drove them from the village, but followed them in their retreat and very nearly exterminated them. In honor of this Indian maid the place where this fierce battle was fought is still called Watseka, and it is the county seat of Iroquois County.

Jean Nicolot, a native Canadian, who had lived among the Algonquin Indians for years, discovered Lake Michigan on July 4, 1634. He then called it Lake Illinois. He was the first white man to put foot on Illinois territory, but Louis Joliet and Pere Marquette were the first white men to reach the "Land of the Illini" or to touch the site of Chicago. These two explorers left Mackinaw in May, 1673, paddled down to Green Bay and up Fox River to the Wisconsin River, on which they floated to the Mississippi.

La Salle had become enthusiastic over what Joliet told him, and he organized an exploring expedition. His chosen friend and companion was an Italian, Chevalier de Tonti, and these two men played the most important part in the history of Illinois. It was about 1680 they reached the "Chekogona" River, probably the present Calumet and pushed on to the interior. La Vantum was then a large and flourishing village and just previous to the appearance of La Salle the Iroquois, the old enemy of the Illini, had made a successful raid and completely annihilated it. The village was somewhere in the vicinity of the present city of La Salle, where is an immense rock 185 ft. high, completely isolated, and with a level top surface of nearly an acre in extent. It is inaccessible, except by one narrow, steep path. It now bears the name of "Starved Rock." Here in 1682 La Salle created a fortification, which he called Fort St. Louis. For some years all the region about was thickly populated with Indians and Frenchmen, and La Salle was the governor.

His several expeditions through the country had resulted in the forming of numerous settlements and these have been the nucleus from which the state has grown. Kaskaskia was the most important, and later became the capital of the state. In 1765 this settlement passed into the hands of the English. Then came the revolt of the colonies against English rule, and in 1778 George Rogers Clark obtained from Patrick Henry, governor of Virginia, permission to attempt the capture of the Illinois territory. He was successful and since 1779 the entire northwest territory has been in the possession of the United States. All this section was then considered as a part of Virginia. In 1818 Illinois was admitted to the Union, with Kaskaskia as the capital. Later it was removed to Vandalia, and in 1836 to Springfield. In 1720 slaves were introduced to work the newly discovered coal mines at Ottawa, but slavery was abolished in 1823 by a popular vote of 4,972 for and 6,640 against it.

The Indian era in Illinois ended with the Black Hawk war. Black Hawk was a Sac chief and resisted the demand to relinquish his land to the whites. A war ensued, which lasted for several years and cost more than a thousand human lives. Inch by inch the red men were driven to the Mississippi, and the waters of that river were made red with the blood of the last remnant of the Black Hawk warriors, shot by the soldiers in the effort to escape.

As early as 1673 Louis Joliet had conceived the idea of a canal to connect Lake Michigan and the Mississippi. In 1821 a conference was held in Chicago, attended by many Indians of the Pottawatomie, Chippewa and Ottawa tribes, to discuss the proposition of granting sufficient land for a canal "to connect Buffalo with New Orleans." There were 64 chiefs present, representing the tribes interested, and on Aug. 29, 1821, the treaty was signed transferring to the United States 5,000,000 acres.

Work on the Illinois & Michigan Canal was not begun, however, until July 4, 1836; it was completed in 1848. The cost of the construction from Chicago to La Salle was $6,557,000 to which should be added nearly $3,000,000 spent by the City of Chicago in deepening the canal between Chicago and Joliet to the lake level, which was refunded by the state in 1871. This canal is the only reminder of the internal improvement scheme authorized in 1837 to give every part of the state a railway or canal.

The richness of the soil, the mineral products, the climate and the influence of Chicago, have all combined to make Illinois one of the richest and most prosperous states in the Union. Its growth has been rapid. In 1819 it contained but 12,282 people. Each census since has given the following figures: 1820, 55,162; 1830, 157,445; 1840, 476,183; 1850, 851,470; 1860, 1,711,951; 1870, 2,539,891; 1880, 3,077,871; 1890, 3,826,351. Since 1890 it has made great strides and 1898 there were 5,686,915. As a state it has produced a number of great men. Lincoln and Grant were elected to the presidency from Illinois, and Adlai Stevenson to the vice-presidency. Stephen A. Douglass was also an Illinois man, though born in Vermont. Sheridan and Logan were residents of Chicago for many years.

During the rebellion Illinois sent over 259,000 men to the Union armies, 10,000 of whom were killed or mortally wounded and 24,000 died from other causes connected with the war.

SOME CHICAGO OFFICE BUILDINGS.

1837~1899 Chicago THE MAGIC CITY

The full and perfect history of the city of Chicago has never been written—can never be written. The growth from a trading post among the Indians, in an unsettled wilderness to a city among the first of the earth in commercial importance, all within the memory of men still living, has been too rapid for the historian to keep pace and the best recitals of Chicago's rise and progress are but fragmentary glimpses of the stirring events of the years within which this has all come about. Herewith are given a few facts that will serve as an outline of what would be possible in the way of a historical sketch of the "Magic City by the Lake."

The first building to be erected where the city now stands was a rude log cabin, built in 1790 by a refugee negro, who had fled from San Domingo. In 1804 the government erected Fort Dearborn, which in 1812 was destroyed by the English allies of the Indians, who were then conducting a predatory warfare on the scattering settlers, who had been attracted to the fertile prairies of Northern Illinois. In 1816 the fort was rebuilt and continued to be occupied with a garrison until 1837, when it was abandoned. By this time all danger from the Indians was over, the removal farther west

CITY HALL AND COURT HOUSE.

of almost all of them having been effected. The fort stood, however, until 1856, when it was demolished. A tablet at the intersection of Michigan Ave. and River St. marks the place where it stood.

The first impetus to trade came in 1836, when work on the Michigan Canal was started, and this date properly marks the beginning of Chicago's commercial history. A school with twelve pupils had been opened four years previously, and the little settlement rapidly grew into a village. In the same year, 1832, a post office was established and communication with the outer world assured. In March, 1837, incorporation took place, and in the same year Congress appropriated $30,000 for the purpose of establishing a lake harbor. From this period the growth of Chicago was phenomenal, unprecedented in the history of this or any other country, and has been the wonder, as well as the admiration of the world. People flocked from the four quarters of the globe. All nations and all tongues have sought this city as a Mecca, and the last census disclosed the fact that twenty-five distinct and separate nationalities are represented in the population in large numbers, while several thousand foreigners from many different climes are not classified. Among the principal foreign countries represented in Chicago's population are the following: Germany, with 490,542; Ireland, with 248,142; Sweden, with 111,190; Poland, with 90,858; Bohemia, with 89,280, and Norway, with 45,090. England, Russia, France, Denmark, Holland, Hungary, Switzerland, China, Belgium, Greece follow in the order named, with many other countries of both hemispheres.

At the opening of the present year Chicago covered an area in excess of 187 square miles, almost 120,000 acres. The population was estimated by the school census and the count made by the police early in the present year at almost 2,000,000. The equalized value of the property in the city, for purposes of taxation, aggregates more than $300,000,000. The streets and alleys in the city aggregate 3,940 miles, of which about one-third is paved. Western Ave. extends as a continuous street for 22 miles, and Halsted St. is but two-thirds of a mile less in length. The pupils in the public schools number 230,239, housed in 650 school buildings. Other than public schools report 114,180 pupils. The cost of the public schools for 1898 was almost $7,000,000, and 5,268 teachers were employed. In 1898 the expenditures for all municipal purposes were $33,316,184.

In the matter of water supply this city is fortunate to have at its door Lake Michigan, one of the purest of the great inland seas. The water system of Chicago is one of the largest and best in the world. Water is taken from the lake at points from two to four miles from shore, conveyed through tunnels to pumping stations and distributed throughout the city. The great drainage channel, now nearing completion, which has cost almost $30,000,000, will insure water absolutely free from contamination. This canal is one of the greatest works of its kind, and will well repay an inspection.

Chicago leads the world in many lines of trade and commerce, among which may be mentioned grain, lumber and live stock.

The trade of Chicago for 1898 is summed up as follows: Produce, $469,000,000; wholesale, $618,000,000, and manufactures, $613,085,000, making a total of $1,700,085,000. This was an increase over the business of 1897 amounting to $176,568,000.

As illustrating the growth of the city, there are many men still in business who came to Chicago when it was a city of only 20,000, and men of 40 remember the time when as boys they went swimming in the lake where Michigan Ave. now is, at a point directly in front of the Auditorium Hotel.

The Big Fire.

The most important event in the history of the city is the big fire, which broke out at 9 p. m. on the night of Oct. 8, 1871, and burned for two days and three nights, with resistless fury. The weather for days had been extremely dry, and the frame buildings and roofs were like tinder. Driven by a high wind the conflagration swept east from the starting point at Clinton and Van Buren Sts., across the river and made a clean sweep to the lake. It also moved south to 12th St. and north to Lincoln Park, with but one building that escaped in all this territory. It burned over an area of 2,100 acres, including the entire retail and wholesale business district, and rendered homeless nearly 100,000 people, and destroyed $196,000,000 of property. Insurance to the amount of $44,000,000 was paid. It was necessary to place the city under martial law for a time and General Sheridan took command. The scenes during the fire baffle description. Thousands were driven before the flames into the lake, and remained there for hours up to their necks in water. The wooden pavements took fire and added to the difficulty of travel. Teams commanded fabulous sums per hour; thousands saved only what they could carry in their arms. The response of the entire world with measures of relief was immediate, $7,000,000 being contributed, and without parallel, and placed Chicago under a debt of gratitude it can never forget. The fire was at last stopped by a heavy rain, and because there was little left to burn. The rebuilding of the city began next

day, and the thousands of loads of debris went a long way toward bringing streets to uniform grade. In rebuilding care was taken to erect largely of fire-proof construction, and the event, while a great temporary loss, and one which ruined hundreds of business men, was a lasting benefit to the city.

Railroads.

The unexcelled transportation facilities enjoyed by Chicago have doubtless contributed more to the city's growth than any other one element. The railroad is a product of the 19th century. Within the memory of men now active in business life it has made its appearance and revolutionized the world. In 1830 there were but 23 miles of railway in operation in the United States. During the next decade this mileage was increased to 2,818, and in 1850 it had grown to 9,021. In 1860 there was a total of 30,626 miles, and in 1870, 52,922 miles. The return of mileage in 1880 showed 93,296, and in 1890 this had reached a total of 166,000. It is estimated that by the close of the present year there will be nearly 200,000 miles in operation in the different states. The year of

STATE STREET IN 1865.

greatest railway construction was 1887, when 12,878 miles of new track were laid.

Illinois easily leads the states of the Union in railroad mileage with a total of 10,726, Pennsylvania being a close second with 9,965 miles. As a railroad center Chicago leads the cities of the world, the total number of separate lines entering the city being 39, leading, with their branches and connections to all sections of this country and extending into Canada and Mexico. These roads

WABASH AVENUE.

have 1,515 miles of track within the corporate limits of the city, but this by no means represents the needs of the separate lines, many being compelled to use leased track, by reason of lack of terminal facilities. The entrance to a crowded metropolis by so many lines has been a serious problem and has required engineering skill of the best ability to solve. The lake shuts off all approach from the east, thus further complicating matters.

The first road built from this city was begun in 1847, on a line extending toward Galena, of which 42 miles had been completed in 1850. The first road to reach the city from the outside was the Lake Shore & Michigan Southern, in February, 1852, the Michigan Central coming in later in the same year. From this time on railway building was rapidly promoted, the business interests of the city readily recognizing the vast importance of such connection and contributing liberally in the way of donations and purchase of stocks.

Running into the very heart of the best grain producing sections of the United States, as many of the roads entering Chicago do, their freight traffic in these lines is enormous. Last year five the leading main roads brought in as follows: Chicago & Northwestern, 61,000,000 bushels; Illinois Central, 37,000,000; Chicago, Rock Island & Pacific, 37,000,000; Chicago, Burlington & Quincy, 57,000,000, and the Chicago, Milwaukee & St. Paul, 44,000,000.

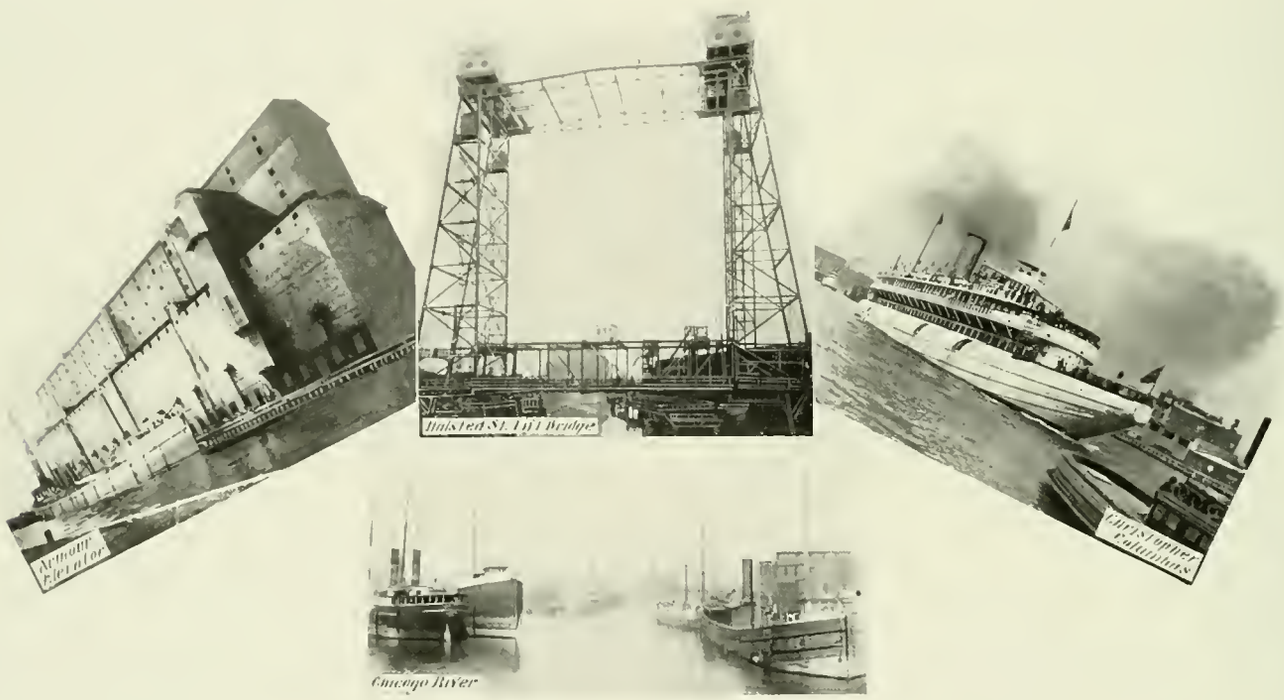
All lines of road entering Chicago are intercepted before reaching

STATE AND WASHINGTON STS.—AFTER THE FIRE – CLARK AND ADAMS STS.

the thickly populated section by a belt line that encircles the city on its three sides and thus enables cars to be transferred from one road to another with small loss of time. This belt system is a separate corporation.

One very important feature in connection with the majority of the roads is the suburban service. By this means rapid transit and frequent trains are assured and many thousands of persons daily avail themselves of this excellent service, some living as far out as 30 miles and daily coming to the city, where their business interests are.

Within recent years the city has became so congested in many parts that it has been necessary to require elevation and depression of tracks. In the past two years more than 200 miles of tracks within the city have been elevated and some 57 miles depressed, abolishing by this means 270 grade crossings. This has been a great saving to life and limb, and at the same time has enabled the roads to make much faster time. The track elevation has necessitated heavy expenditures on the part of the railroads, but the saving in time, in the annual expense of maintaining crossing gates and watchmen, and in damage claims has in a number of instances more than paid the interest charges on the investment.



SCENES ON THE RIVER.

Marine.

The vast importance of Chicago's marine service is but little understood. In no way can the magnitude of this business be better illustrated than to give a comparative statement of the total entrances and clearances of a year at the principal seaports of the United States, with the total at this city.

Baltimore	5,770
Boston	5,793
New Orleans	2,717
New York	14,445
Philadelphia	3,057
San Francisco	2,509
Totals	34,891
Chicago	19,193

The Suez Canal carries much of the commerce of a hemisphere; much, indeed, of the exchangeable products of the world, and is open throughout the year. The canal at Sault Ste. Marie, known as the "Soo," was only open for vessels about eight months in 1898. Yet the traffic via the "Soo" was 21,234,664 tons, and that via the Suez during the entire twelve months about 9,000,000 tons. The internal waterway commerce of the United States during eight months exceeded in tonnage the commerce between Asia and the Western world, through the Suez canal, by 12,000,000 tons. While all of this American tonnage does not come or go from here, yet the figures go to show the immensity of lake traffic.

During last year 9,428 vessels arrived at the port of Chicago, representing a tonnage of 7,557,215 tons, and the 9,502 vessels clearing represented 7,686,448 tons. Of these 179 arriving were vessels engaged in the foreign trade, their total tonnage being 235,790, and 457 vessels engaged in the same trade cleared the port, their tonnage amounting to 401,138.

A record of arrivals and clearances for the past 20 years shows a wonderful increase in the tonnage of the vessels engaged in the local trade. In 1870 the combined arrivals and clearances amounted to more than 25,000 vessels, but their combined tonnage was scarcely 6,000,000, more than 1,500,000 tons less than the 9,428 vessels arriving during 1898. Engaged in the Atlantic and Gulf coasts, and in the Pacific coast trade there are but 299 steam vessels of 1,000 tons and over, and their combined tonnage is but 654,816. On the northern lakes 401 steam vessels of 1,000 tons and over are engaged, their tonnage aggregating 780,296.

During 1898 the following shipments were made by lake from Chicago: Lard, 33,949,200 lb.; oil cake, 46,138,900 lb.; millstuffs, 86,466,060 lb.; tallow, 6,009,300 lb.; hides, 2,145,900 lb.; wool, 3,829,225 lb.; flaxseed, 2,212,560 bu.; timothy seed, 1,432,528 lb.; other grass seeds, not including clover seed, 7,196,957 lb.; wheat, 26,594,263 bu.; corn, 97,166,944 bu.; oats, 28,019,617 bu.; rye, 3,667,659 bu., and barley, 2,815,043 bu.

Traffic on the great lakes has not been as large in many years as during the present season and at no time during the past 10 years have carrying charges been as high during the midsummer months. Taken in all of its aspects the lake commerce of Chicago was never in a more prosperous condition, and it bids fair to not only remain one of the great sources of the wealth of the city, but to increase with the years and the inevitable growth of the great inland metropolis.

At South Chicago are extensive shipyards, where some of the largest of the lake steam craft have been built. The Christopher Columbus, a whaleback excursion steamer, belongs here; has a carrying capacity of 5,000 passengers and sails daily during the summer season.

Elevators and Grain Trade.

To properly handle the immense shipments of grain annually arriving in Chicago has required the investment of large sums of money in elevator warehouses. Much improvement has been made in this class of buildings within recent years, necessitated by the constant increase in receipts of all kinds of grain, and the demand for safe storage and economy in handling. To attain the first the buildings are constructed in a style peculiarly their own, combining great strength with every known precaution to avoid fire and to quickly extinguish it should it originate. To meet the demand for cheapness in handling the grain many devices have been installed so that it is possible to unload both cars and ships by a system of suction pipes and to transfer the grain from place to place within the building by an endless belt, on which the grain falls and travels, and also by the more primitive bucket elevator. Cars are unloaded now within a few minutes after arriving at the elevator, and ships give or receive a cargo with but little loss of time.

Of the elevators in Chicago there are 18 that the Board of Trade recognizes as regular, to be used for the storage of grain and flaxseed under the rules of that organization and the regulations and requirements of the board of directors. The combined capacity of these 18 elevators is 28,050,000 bushels.

On all grain and flaxseed received in bulk and inspected in good condition the storage rates are three-quarters of one cent per bushel for the first ten days or part thereof, and one-fourth of one cent per bushel for each additional ten days or part thereof, so long as it remains in good condition. On grain damp or liable to early damage, as indicated by its inspection when received, two cents per bushel is charged for the first ten days or part thereof, and one-half of one cent per bushel for each additional five days or part thereof. No grain is received in store until it has been inspected and graded by authorized inspectors, unless by special agreement. The inspection of all grain arriving in the city is done under the supervision of the Chief Grain Inspector, who is an officer of the state.

The volume of grain stored in warehouses of class "A," as defined by the statutes of Illinois and recognized as regular warehouses under the rules of the Board of Trade, at the close of 1898 aggregated 11,706,912 bushels. The elevators of Chicago are largely utilized for the storage of flaxseed, the receipts of which for 1898 reached 5,481,173 bushels.

The receipts of grain and of flour in its grain equivalent, for a number of years, cannot but be of interest. The following are the official figures, as given out by the Board of Trade; the totals are bushels.

1898.	1897.	1896.
320,436,357	296,767,115	253,802,134

The receipts of the different kinds of grain during the same period were:

	1898.	1897.	1896.
Wheat	35,741,556	28,087,147	19,933,402
Corn	127,426,374	110,747,389	92,722,348
Oats	110,293,647	118,086,662	109,725,689

The quantity of grain and flour in its grain equivalent at Chicago during 1898 was more than 5,000,000 bu. in excess of like receipts at Minneapolis, Duluth, Milwaukee and St. Louis combined, being, as above stated, 320,436,357 bu. During the single month of October the receipts of grain were more than 42,000,000 bushels.

It is interesting to note the growth of this immense grain business, which is really beyond the average comprehension. In 1838, one year after the incorporation of Chicago, 38 bushels of wheat were received, and this jumped the next year to 3,678 bushels. In 1840 the receipts were 10,000 bu.; in 1850, 883,644 bu.; in 1860 they had increased to 12,402,197 bu.; in 1870, 16,432,585 bu.; in 1880, 22,796,288 bu.; in 1890 only 11,075,276 bu. were received, but in 1891 the grand total aggregated 38,000,169 bu.

As wonderful as this growth is it has been similar in all kinds of grain, until today Chicago leads the world in this branch of commerce.

Chicago Board of Trade.

The influence of the Board of Trade of Chicago has been one of the potent factors in promoting the commercial growth of the city. The early life of the board was simple and unpretentious. Annual dues were at first but $2, and the yearly rental of the building occupied only $110. The membership slowly increased as the years went by, and when the new charter was obtained in 1859 the roll of members aggregated 625. Quarters were taken in 1865 in a building located at the corner of Washington and La Salle Sts., and this continued to be the home of the Board until the great fire of 1871. Immediately rebuilding on the same location the board remained here until 1885, when the present handsome edifice on Jackson boulevard was completed and occupied. At this time the list of members was almost as great as at the present, and the transactions of the Chicago Board of Trade had attracted the attention of the world. The rules and regulations adopted by the board relative to grain and provision dealing were accepted as the standard in all civilized countries and still remain operative. Composed, as it is, of the highest type of representative business men, of capitalists whose names are known in all lands, of financiers whose operations affect the great arteries of commerce, Chicago's Board of Trade daily transacts business amounting to many millions of dollars, and holds one of the highest positions obtainable by any similar body and the confidence of two continents. The great majority of the operations

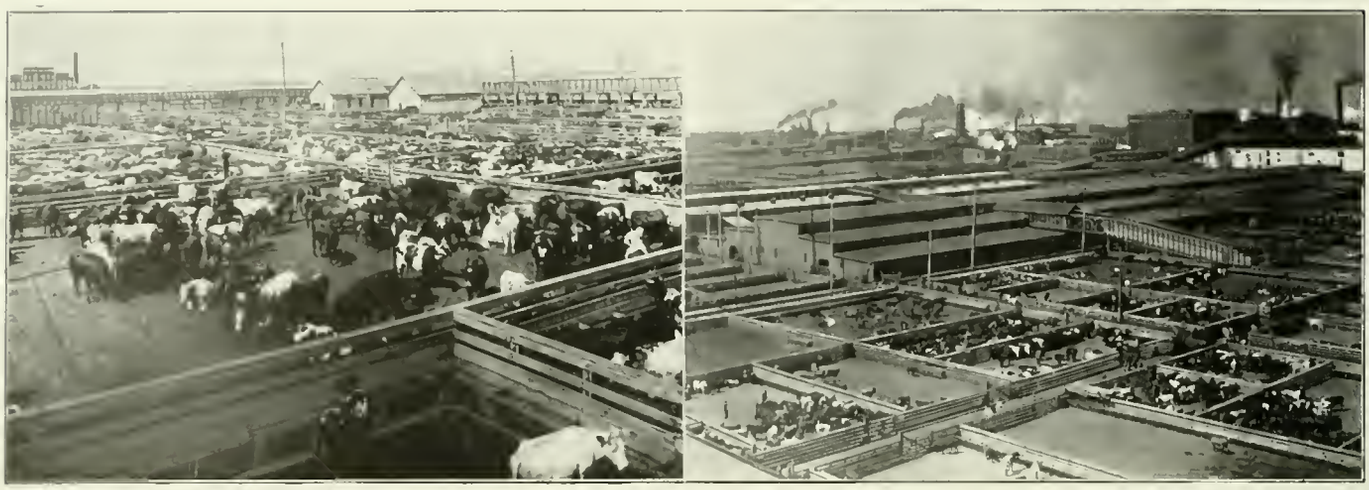
WHEAT PIT, BOARD OF TRADE.

on the Board are founded on mere verbal understandings, a nod of the head or the holding up of a hand often binding members in transactions running into the hundreds of thousands of dollars, yet so high is the standard of honor that seldom in the history of the board has any trouble arisen through a violation of such contracts.

Spacious galleries for visitors are provided, and during trading hours a visit to the Board, with its animated scenes in the wheat and corn pits, and a small army of telegraph employes at work forms one of the most interesting sights in the city. The best time to visit the Board of Trade is about 11 o'clock and strangers in the city should avail themselves of this opportunity.

The transactions on the Board are in no sense of the word gambling, as is supposed by many not familiar with the operations there conducted, and the highest courts in the land have repeatedly decided that the deals come strictly within the lines of legitimate business, and the contracts, whenever questioned on this score, have been invariably upheld. A strong feeling exists among the members against any species of speculation not entirely "regular," as defined by the rules and regulations, and a relentless warfare has been waged against bucket shops, with such success that they have been almost entirely driven out of business in this city. Many of the firms carrying on this vicious form of speculation have, within recent years, been sentenced to long terms of imprisonment and heavily fined.

During the half century of its existence the Board has generously responded to all calls for charity, and whenever and wherever flood, famine, fire or epidemic has caused want, misery or suffering the generous hand of the Board has been extended in no stinted measure.



CATTLE PENS, THE CHICAGO STOCK YARDS.

The Stock Yards.

Chief among the manifold industries of Chicago is the live stock and meat business, conducted almost exclusively at the Union Stock Yards. They are located in the south-central portion of the city, and so situated that a belt system of railway gives connection with all roads entering the different sections without transfer of the stock from cars. The yards afford unequaled facilities for the conduct of the immense business; occupying 475 acres of land, 230 acres of which are covered with plank flooring. The pens for live stock are admirably arranged, both for convenience of unloading from the cars, egress when the stock is to be moved and comfort of the animals while detained and facilities for watering and feeding. These inclosures number 13,000 and occupy some 50 acres.

An idea of the magnitude of the yards may be gleaned from the statement that there can be fully accommodated at one time 75,000 head of cattle, 50,000 head of sheep, 300,000 head of hogs and 5,000 horses. To properly comprehend the magnitude of this industry a visit is necessary, and a study must be made of the methods employed in the management of the enterprise and the regularity with which each department is conducted must be observed to be at all understood. Transactions involving millions of dollars occur daily, and receipts and shipments each 24 hours involve equally large amounts of money. Forty lines of railroad, branching out into the majority of the states of the Union, bring in the stock and take out meats and kindred lines of food products consigned to the four quarters of the globe.

The name and fame of the Chicago Union Stock Yards are world-wide, and there is constantly a stream of visiting strangers bent on investigation. This inspection is facilitated by the concerns engaged and every opportunity is afforded to visitors to see and examine the process by which so many millions of live stock are annually converted into food products.

In addition to the supply of water by the city works the Stock Yards are provided with six artesian wells, varying in depth from 1,250 to 2,250 ft. These furnish an unlimited amount of pure water, much superior in quality to the water of the lake, which at present is more or less impregnated with sewage. The daily consumption during the hottest months of the year, reaches 7,000,000 gallons. Within the grounds embraced in the yards there are 90 miles of water pipes, and the water-troughs with which the stock pens are supplied would, if placed end to end, measure 38 miles in length.

The official returns for 1898 will show the yearly business. In hog packing 18 concerns had an estimated capital invested exceeding $20,000,000; employed almost 25,000 workmen and turned out products aggregating $75,000,000 in value. In beef canning and packing 11 concerns had over $6,000,000 invested, utilized the services of more than 11,000 workmen and produced nearly $50,000,000 worth of goods. In the lard, lard oil and stearine industries four firms, with a capital of $2,000,000, employed 3,000 people and turned out $7,500,000 of finished products. The six firms making butterine had a capital of $2,500,000, worked nearly 2,000 hands and produced $4,500,000 worth of this article. Fifteen firms were engaged in the manufacture of sausage, their combined capital was $2,000,000, the number of workers 1,800, and the value of the product reached $4,000,000. The best estimates obtainable place the total wages paid to the workmen employed as above stated at $24,000,000, in addition to which there is an army of men regularly working in the yards, amounting in all branches of labor to fully 5,000 more than those who are enumerated above.

Some of the largest commission houses in the world have their offices located at the Stock Yards and transact a business there

SHEEP PENS.

A "STREET."

TWO GREAT MARKET PLACES.

that ramifies throughout the West and Southwest, numbering their branches and customers by the thousands. The business done by these firms in 1898 was the largest in the history of the yards. The receipts of all stock aggregated 15,700,000 head, of a valuation of $230,000,000. This was fully 1,000,000 head of stock more than had ever been received in a single year.

A detailed explanation of the many processes of manufacture and the wonderful system under which the work is carried out would require pages. We therefore leave that to be the better understood and appreciated by a visit to the yards, which many of our readers will doubtless desire to inspect. The entertainment committee will provide for all who wish to make this interesting and instructive trip.

"Water Street."

The greatest produce market in the world is to be found on Water St., and should be visited at very early hours in the morning to be seen at its best. Trading begins at 4 a. m., and the several thousand delivery wagons which come from all parts of the city throng the place until 9 o'clock. After that shipping orders are filled, and by 3 o'clock the business of the day is practically over. Commission merchants representing many nationalities and the food products of many climes and countries are here. The district has long since outgrown its limits, but there seems no available place to which to move and the congestion continues, and is constantly becoming worse. Great warehouses are filled from top to bottom with every sort of fruit, vegetable, fish, game and poultry, and the sidewalk piled high with crates, barrels and boxes.

Banks.

Chicago has 36 national and state banks, with numerous private banking houses. The deposits last year amounted to $301,203,931; loans and discounts were $170,771,307; surplus and profits, $20,157,457. The First National and Illinois Trust & Savings occupy the largest, and the latter the finest, banking establishment to be found anywhere.

And so we might go on with added pages of history and reports of the varied business interests of the city, but will pass with only a brief reference to others of those many interests of importance. It is the largest center for the manufacture of farm machinery; one firm alone employing 6,500 men in its works. Its lumber interests are of great magnitude and occupy the "lumber district" on the south branch of the river. In iron works there is a large and diversified line of manufacture, and in certain lines of shoe and furniture trade it also leads the country.

ILLINOIS TRUST & SAVINGS BANK.

It is a pleasure, however, to turn from figures and commerce to those things which stand for culture and higher thought, and in these matters the new city of the prairie has distanced many a city of the East.

RIVER SCENE—SLOOP THAT CROSSED THE ATLANTIC TO THE WORLD'S FAIR.

The Art Institute.

The Art Institute of Chicago is housed in a magnificent stone building in the Lake Front Park, facing on Michigan Boulevard, directly opposite Adams St. The Institute was known originally as the Chicago Academy of Design, its beginning dating from 1866, when New York and Philadelphia were the only cities in the United States claiming similar associations. Many vicissitudes were encountered up to 1882, when the academy became known by its present title. In that year Mr. Charles L. Hutchinson was elected president, and from his induction to office, contributed much of his valuable time to the active management and gave liberally of his means. Mr. Hutchinson has been re-elected to the position annually since that year, and the wonderful growth of the institution may be attributed, in great measure, to his efforts in behalf of it. The Hon. Lyman J. Gage, Secretary of the Treasury, has been the treasurer during the entire career of the Institute.

In 1892, when the World's Columbian Exposition was in its beginnings, the opportunity offered for the Art Institute to combine with the Exposition management and erect a building on the lake front, which was to be used for sessions of the World's Congress of Religions. Upon its close, the property reverted to the Art Institute, and cost it a little less than half a million dollars. The ownership of the building is vested in the city of Chicago, while the right of use and occupation is given to the Institute so long as it shall fulfill the purposes for which it was organized. It must be open free to the public on Wednesdays, Saturdays, Sundays and legal holidays, however, thus being in effect a gift to the people. The building is of Bedford limestone and is thoroughly fire proof.

THE ART INSTITUTE.

The Institute has a number of fine collections of sculpture (both of originals and reproductions), a department of Egyptian antiquities and relics of the Pharoahs. Prominent among these collections are the Elbridge G. Hall plaster casts from representative original sculptures; the H. N. Higinbotham collection of Naples bronzes, which include reproductions of objects found in Herculaneum and Pompeii. The Egyptian antiquities were the gift of Messrs. H. H. Getty, N. W. Harris and C. L. Hutchinson, and all of them are real. They have been collected and presented to the Institute as illustrative of the more usual applications of art in ancient Egypt, aside from architecture. One coffin displayed antedates the period of decorated mummy cases, and is undoubtedly of the time of Abraham, that is, about 2,000 B. C. Another is part of the famous discovery of the final burial place of the Pharoahs at Deir El Bahari.

One of the collections which should prove of interest, not solely to the Egyptologist is that of the scarabs or seals in the form of the sacred beetle. This is one of the rarest and most complete in existence, surpassed only by that in the Boulak Museum, Egypt. It is almost a complete series from the time of Mena, the earliest known earthly potentate, down to the Christian era, when ancient Egypt passed out of history. The scarabs are made of a great variety of stones and gems, and bear the signet of the monarch whom they represent.

The classical antiquities, presented by Messrs. M. A. Ryerson, C. L. Hutchinson, P. D. Armour and others, consist chiefly of Greek and Roman specimens, and are real. They include prehistoric American vases (terra cotta) from New Mexico and Arizona, Greek and Roman coins, Graeco-Italian vases, Greek glass, bronzes, etc., Roman lamps and terra cotta masks of rare value.

On the second floor of the Institute are the paintings. The Henry Field Memorial Collection comprises 41 original oil paintings by 20 of the most esteemed modern painters, including canvas by Carot, Millet, Rousseau, Diaz and others. Breton's "Song of the Lark" is also there on exhibition. The room is splendidly arranged, every facility being at hand for viewing the works with the proper light and shade. The Munger collection embraces 63 paintings, including oil and water colors, and was the private collection of the late Albert A. Munger of this city. While it contains very important examples of some of the most noted modern painters, such as Meissonier, Bougereau, Gerome, Munkacsy, Michetti and Troyon, it has but one specimen of each, and represents not only the French and German schools, but also the Belgian, Italian, Austrian, English and Swedish.

Thirteen of the most important art paintings by old and modern masters, which were purchased in June, 1890, by the Institute from the famous Demidoff collection in Florence, are now on exhibition. They include several by Van Ostade, Rembrandt, Hals, Rubens, Van Dyck, Murillo (The Immaculate Conception), Titian, Goyen, Von der Neer, Hobbema, de Keyser and others. In the collection lent by Mr. Cyrus H. McCormick are landscapes by Daubigny, Corot, Troyon and the late George Innes. Charles Sprague Pearce's magnificent "The Beheading of John the Baptist," which was painted in Paris in 1881, attracts the attention of all visitors. Among the modern oil paintings, perhaps none are more interesting than those lent by Mrs. P. C. Hanford. This

CHICAGO PUBLIC LIBRARY.

NEWBERRY LIBRARY.

collection embraces more than 50 paintings, among which are some by such well known artists as Rosa Bonheur, Breton, Corot, Meissonier, Millet, Munkacsy, de Neuville, Troyon, Verboeckhoven and others.

Nowhere in the city could one's leisure hours be more profitably spent than in the Art Institute, where everything displayed is alike interesting to both layman and connoisseur.

In the instruction department 1,200 students are enrolled.

and judiciously had it been framed that nearly every western state has since patterned after this admirable law. Provision is not only made for the establishment and maintenance of public libraries by taxation, but also for their proper management. The law recognizes the fact that such collections are for the public good, and as such may be justly established and maintained at the expense of the tax payers.

It is not possible to give more than a passing glance at the

ART INSTITUTE—MAIN ENTRANCE HALL.

Public Libraries.

Prior to the great fire Chicago had no public library, and there was no law, either state or municipal, authorizing the establishment and maintenance of such institutions. The nucleus of the present system and the one great incentive to the upbuilding of the public library of today was the contribution by the people of London, England, of some 5,000 volumes immediately after the destruction of all existing collections here by the fire above referred to. Following this magnificent donation the Chicago Public Library sprung into an active existence, Germany, France, Bohemia and other foreign countries contributing many and valuable works. In 1872 the Legislature passed the public library act, and so wisely

public libraries of Chicago in this article. There are within the limits of the city many libraries that rank among the best of their class in the United States, and but few cities can number so many fine collections of books of every kind open to the people without money and without restriction, save such as are wisely intended for the preservation of the works.

The Public Library stands at the head of the local list; it has the greatest home circulation of any library, over one million books having been withdrawn in a single year. Manchester, England, Boston, Mass., and Birmingham, England, rank next in order in this respect, a showing especially creditable to Chicago as indicating the literary aspirations of those so generally believed to be engrossed entirely with the details of trade and commerce.

DISTRIBUTING ROOM, CHICAGO PUBLIC LIBRARY.

The edifice, occupying the site of Dearborn Park, is one of the most imposing, well arranged and costly of public library buildings. Free delivery stations to the number of 50 are maintained throughout the city, and from them 744,995 volumes were circulated during 1898. The scope of the library is very comprehensive, constituting rather a library for the people than one for the scholar.

Classical in its composition, this beautifully reared pile of marble is one of which Chicagoans all are justly proud. The foundations were laid in 1893, and the greater part of four years were spent in bringing the structure to completion, at a cost of $2,125,000. It is the opinion of experts that this library is the most economically constructed of any in the city. The cost per cubic foot enclosed is 48 cents; the average office building costs from 35 to 40 cents, and one, at least, in the city, ran to 55 cents, while the average cost of the government buildings is as high as 65 cents per cubic foot.

The building is on Michigan Boulevard, between Washington and Randolph Sts. There are two entrances to the building; one leads into the lobby and staircase and the other into the G. A. R. memorial corridor and staircase, both being done in pink and white marble. The marble quarries at Carrara and Sienna were worked for six months to fill the orders necessary for the lobbies and two grand staircases. Throughout the structure are 10,000 sq. ft. of glass mosaic—the greatest area of glass mosaic placed in a building since the time of Constantinople's Sancta Sophia or the famous cathedrals of Italy.

Many characteristics make it comparable only with the Congressional library at Washington. It is certainly one of the best things of which Chicago can boast, as being genuine and artistic. There is no painted wood in it. Where it was necessary to use wood of a cheaper grade than mahogany, the best of American woods was used, and in such cases there is no sham in the matter of stains and varnishes. All that looks marble is marble; all that seems bronze is bronze, and all the iron looks like iron. In constructing such an ideal building, it was a matter of infinite care on the part of Architect Coolidge, who also planned the Art Institute, to keep all the small points in keeping with the large features. There were over 1,200 drawings made in the architect's office, in addition to almost innumerable sketches and studies. This took the time of twenty-five draftsmen for a year.

The ground upon which the library stands dates from the time of the Indians; the building from about 16 years ago. It was really started in 1883, when a committee from the Grand Army posts and the board of directors went jointly before Congress and sought the passage of an act giving them the right to erect a building as a soldier's memorial, an academy of design and a library. They asked this right, because they wanted to use as a site a part of the Fort Dearborn reservation—the particular part which had been fixed by the lettering of the first plat as "public ground forever, to remain vacant of buildings." Congress, however, did nothing for nearly 10 years.

There is no doubt but that Chicago has builded for the future in its library. It is estimated that at least 2,000,000 books can be housed under its roof without trespassing upon the reading rooms.

NEWBERRY LIBRARY.

DELIVERY DESK, CHICAGO PUBLIC LIBRARY.

CHICAGO HISTORICAL SOCIETY BUILDING.

as now arranged, although there are now 300,000 volumes on the shelves and at the disposal of the student and bookworm. The delivery room, a picture of which accompanies this sketch, extends clear across the building, being 130 x 49 ft.

Ranking next in importance is the Newberry Library, located on Walton Place, facing Washington Square. The building, composed of steel and granite, was erected 1891-93, and has at the present time an estimated capacity of one million volumes. Ultimately the building is to cover the entire block, and will then accommodate about three million volumes. This institution was founded July 1, 1887, under a provision of the will of the late Walter L. Newberry, whose name it bears. It is maintained as a library for reference exclusively and a specialty is made of music, medicine and religion. The number of books consulted daily is in excess of one thousand.

By the will of the late John Crerar, who died Oct. 19, 1889, the sum of $2,500,000 was devoted to the establishment of the library which bears his name. It is a library of specialties, like the Newberry, and treats of the natural, the physical and the social sciences. The Crerar building has not yet been erected, and for the present the collection occupies the entire floor at 87 Wabash Ave.; it numbers some 50,000 volumes.

The library of the University of Chicago is an adjunct to that celebrated institution of learning; it was founded in 1891, and already has 300,000 volumes, for the most part works on biblical literature, church history, homiletic and systematic theology, political economy, sociology, history, science and ancient classics.

The Chicago Historical Society Library is devoted to books, manuscripts, charts and collections bearing in the main on local history. Twice since its foundation it has been entirely destroyed by fire, but is now housed in the beautiful home of the society at Ontario St. and Dearborn Ave.

The Chicago Law Institute Library, consisting now of more than 30,000 volumes, was also entirely destroyed in the fire of 1871, losing at that time over 7,000 volumes, valued at $30,000.

The Armour Institute Library consists of about 15,000 volumes, chiefly works of reference, and is maintained, as is the college, by the founder, Mr. P. D. Armour.

NEWBERRY LIBRARY.

GRAND STAIRCASE—CHICAGO PUBLIC LIBRARY.

The library connected with the Chicago Academy of Sciences, twice destroyed by fire, is now safe from further like calamity, in its present home the handsome structure standing in Lincoln Park

Other prominent free libraries of Chicago are the Theological, Hammond, McCormick Seminary, Jesuit College, with many smaller collections in all portions of the city.

The University of Chicago.

In the fall of 1888, Mr. John D. Rockefeller conferred with Prof. William R. Harper regarding a new university for Chicago, finally entering into communication on the subject with the American Baptist Education Society, which immediately took steps toward the founding of a well equipped college. This was made possible through a proposition on the part of Mr. Rockefeller to subscribe $600,000 toward an endowment fund, conditioned on the pledging of $400,000 additional before June 1, 1890. This was accomplished, and the nucleus of what is now known as the university, was obtained. Further liberal donors, including Messrs. Marshall Field, Charles T. Yerkes and others, added to its permanency by their generous subscriptions. The total endowment is in excess of $7,000,000. Sept. 10, 1890, the university was incorporated and at the first meeting of the board of trustees Prof. William Rainey Harper, of Yale, was elected president, entering on his duties July 1, 1891.

Before any particular building was projected, however, a general plan was prepared of the entire group, as it would appear after all the buildings should be erected, and in consequence the erection of the first building was not commenced until Nov. 26, 1891. The recitation buildings, laboratories, chapel, museum, gymnasium, library—the public buildings of the institution—are the central figures of this plan, while the dormitories are arranged in quadrangles on the four corners. The material used in construction for the entire group is blue Bedford stone.

Oct. 1, 1892, the doors were first opened to students. The first year more than 900 matriculated; the second year in excess of 1,100. The third year the attendance rose to 1,750, and the fourth year to above 2,000.

The University grounds front south on the Midway Plaisance, having Ellis Ave. on the west and Lexington Ave. on the east, and comprise about 35 acres. The location is one that but few cities the size of Chicago could offer; the Midway is a beautiful lawn, terminating at the east in Jackson Park and at the west in Washington Park, both of them almost within a stone's throw of the University.

Cobb building is the gift of Mr. S. B. Cobb, for many years president of the Chicago City Ry., and the Yerkes Observatory, which with its building and equipments (located at Lake Geneva, but belonging to the University) and costing $1,000,000, was the gift of Mr. Charles T. Yerkes. Five other buildings and halls on the campus bear the names of persons who have been largely interested in Chicago surface lines, showing the interest street railway people have taken in the institution. The donations of Mr. Rockefeller, however, equal those of all others combined.

UNIVERSITY OF CHICAGO—SOME OF THE BUILDINGS.

Armour Institute of Technology.

The Armour Institute of Technology dates back only to Sept. 14, 1893, when it was first opened to students. For several years previously, however, Mr. Armour had been planning for an institution of its character. Mr. Armour is believed to have gained his inspiration from the mission which his brother, the late Joseph F. Armour, endowed in 1881, with a bequest of $100,000.

The task of carrying out the latter's purpose in establishing the mission was intrusted to Philip D. Armour, to whom the greatest measure of praise is due. Since 1886 the sum of $3,000,000 has been added to the original bequest, and the scope of the institute has been wonderfully enlarged. The mission was built at 31st and State Sts. in 1881, and so marked was its effect on the neighborhood that Mr. Armour was led to erect the buildings known as the Armour flats. These apartments drew a better class of people to the vicinity of the mission, and a school was planned, which would give to boys and girls a practical industrial training at a nominal cost.

Mr. Armour thereupon placed at the disposal of the Institute $1,500,000, this sum being represented by the apartment buildings and their revenues, and the institute building itself. The original plan, which partook more of the manual training school idea, soon developed into the technological institute as it stands today. Preparatory to the working out of the scheme, Rev. Frank W. Gunsaulus, D.D., then pastor of the Plymouth Congregational Church, was made president of the Institute in 1892. Dr. Gunsaulus drew about him the members of the original faculty.

The original plan of the Institute included some higher tech-

nical training, the scope of which was not at first precisely defined. But the importance to the community of this branch of education was strenuously urged by persons whose opinions were entitled to consideration, and demonstrated by the many applications for extended courses of engineering which were received as soon as this purpose of the Institute became known. Accordingly, full four-year courses were planned, and in 1895, after the Institute had been in successful operation for two years, its corporate name was changed from "Armour Institute" to Armour Institute of Technology. In 1898 the course in science was added, and this year civil

ARMOUR INSTITUTE.

engineering was included. The courses now offered in mechanical engineering, electrical engineering, architecture, science and civil engineering are leading to the Bachelor of Science degree.

The growth of the Institute is on a parallel with that of Chicago. When the school was launched in 1893 there was naturally much speculation on the part of those interested as to the number of applicants for admission, and estimates of from 300 to 500 were deemed extravagant. During the first year 2,500 applications were received, and 1,050 students enrolled; the second year there were 1,087; the third, 1,122, and the fourth year, 1,200 students.

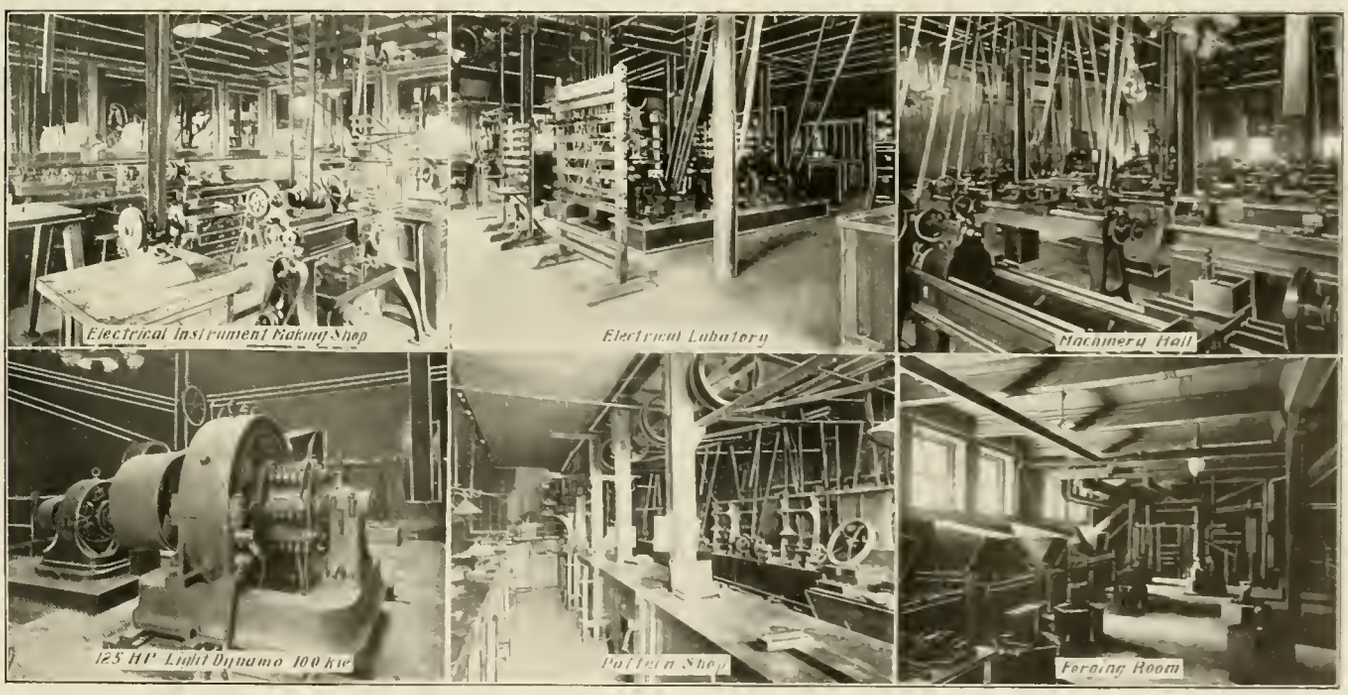
River, Bridges and Viaducts.

The Chicago River, one of the best known in the country, though only a few miles in length, is both serviceable and notorious. It was once little more than a good sized creek draining the marsh lands upon which the city has been built, but the millions of dollars which have been expended in its improvement and for structures along its banks have given it a commercial value of great importance. The river divides the city into three divisions, north, west and south, although none of the branches anywhere near approach the corporate limits. It is as much a created river as the foundations upon which the city stand are artificial.

The Chicago River is celebrated for its density and odor, and for the curious habit it has of flowing "up stream" one day and out into the lake the next. This is occasioned by off shore winds, which lower the lake level, or by the work of the pumps at the end of the south branch, where the water is lifted and poured into the Illinois Canal. When the Drainage Canal is in operation a constant volume of pure water will flow through it from the lake. While the river will not support a person who tries to walk upon its surface, its appearance would often justify the belief that it might. During the past summer the river was on fire and burned fiercely for several hours, requiring several steamers and fire boats to extinguish the flames, which destroyed some $6,000 worth of piling and bridge approaches. All the shipping which comes into Chicago proper is unloaded along the river, and its commercial value to the city has been inestimable. Numerous plans have been proposed for filling it up and either laying railroad tracks or making streets. The Drainage Canal has, however, settled such ideas. The river is lighted with arc lights by the city, and movements of vessels are directed by a boat dispatcher, who is a city official. During the rush hours, morning and night, when thousands of suburban passengers are crossing to take their trains, the bridges are kept closed.

The river is spanned by 61 bridges, whose length aggregate 2 1-3 miles, and no other city has so extensive a system of bridges and viaducts as Chicago. Thirty-seven bridges and viaducts cross railroad tracks to accommodate team and pedestrian travel. The length of these is 3½ miles.

While the river itself, as a highway for commerce, is under the jurisdiction of the Federal Government, the bridges spanning it are erected and maintained at the expense of the city. There is a Division of Bridge and Viaduct Construction, under the immediate management and control of a bridge engineer, who is an official of the Bureau of Engineering, and also a Division of Bridge and Viaduct Maintenance.



INTERIOR VIEWS, ARMOUR INSTITUTE OF TECHNOLOGY.

TYPICAL CHICAGO SKYSCRAPERS.

By reason of the extension and growth of the street railway systems of this city in recent years they have required, in many instances, the use of bridges and viaducts where the original structure was not substantial enough to meet the needs of this additional service. They have, in consequence, met all, or a considerable portion, of the expense required to place the structure in proper condition. The Lake St. Elevated has utilized one of the bridges by laying tracks on top of the original structure, it having been strengthened.

The most modern of the bridges of the city is the one at North Halsted St. It is of the Scherzer rolling lift type, similar ones having been constructed at Van Buren St. and for the Metropolitan Elevated road. The North Halsted St. structure with a 50-ft. plate girder deck span constitutes the continuation northward of the Chicago Ave. and Halsted St. viaduct. The bridge is 34 ft. between centers of trusses, with two 6-ft. sidewalks. The trolley tracks are in the center of the roadway, with team space on both sides. It is operated by electricity and compressed air and combines the most advanced and modern ideas in bridge construction.

The department of bridges has under its supervision 1 lift, 2 bascule, 40 swing, 2 jack knife, 1 pontoon and 15 fixed bridges. All of the more important of the heavy movable bridges are being equipped with electricity, as a motive power in turning, as rapidly as possible.

The opening of the Drainage Canal, confidently set for December 1st of the present year, will eventually necessitate the removal of all center piers from the river, and there is little room to doubt but that the bascule will be the type of bridge universally adopted when this great highway that is to connect the lakes with the Mississippi River is ready for operation. The cost of the North Halsted St. bridge was about $114,000, of which amount the city paid 75 per cent, and the North Chicago Street Railway Co. paid 25 per cent.

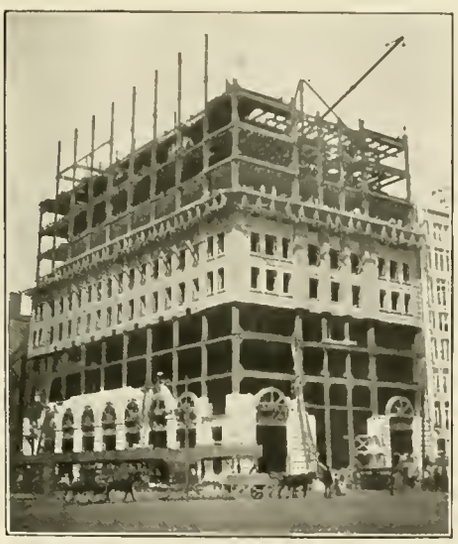
Another recent and modern structure of great public utility is the South Halsted St. viaduct, the entire expense of building which, $83,594, was paid by the Union Stock Yards & Transit Co. and the Chicago City Railway Co. This viaduct spans the tracks of the Union Stock Yards & Transit Co. at 40th St. and consists of three double roadway spans 60 ft wide; two spans 136 ft. and one span 100 ft. Perhaps the most important viaduct in the city is that at Clark and 16th Sts. This is a double roadway plate girder over

the depressed railroad tracks, and was opened to traffic Nov. 16, 1898. It was built by the Joint Track Elevation Commission, and the total cost of the work was paid by the railroad companies interested. When a crossing at grade, as it was before the construction of the viaduct, it was, perhaps, the most dangerous in the city, if not in the United States, and fatal accidents were frequent. This viaduct is used by the Chicago City Ry.

A City of Skyscrapers.

The skyscrapers no longer cause wonder, and in all parts of the country they have gone soaring heavenward, in the effort to get as many acres as possible under one roof, and incidentally to outdo some other city. But it was here in Chicago that the skyscraper received the seal of approval and where the example was set. Most of the tall buildings in Chicago are built upon piling, but in some instances a platform of railroad iron and I beams laid up cob house fashion and filled in with concrete was built, this platform resting on the clay subsoil.

Allowance is made for these buildings to settle and the plans adopted to ensure uniform settlements are often very interesting. The new Great Northern Building adjoins the old Great Northern on one side, while on the other are comparatively small structures. Thus a portion of the ground was compressed by the tall building already erected and it was to be expected that the settlement of the new one would be quite uneven, accordingly one side of the new structure is carried on a set of jacks which can be moved and so keep the building plumb. The rapidity with which many of these



IN PROCESS OF ERECTION.

tall buildings have been erected is really surprising. In one instance by the use of electric light 15 stories were put up in as many days, and one story in two days is frequent. The shell or outside cover of the framework is generally of terra cotta, and this often is of different styles for different parts. It often occurs that the material for say the first three or four stories fails to arrive as soon as that for the stories above, but this does not delay the work, and several times it has occurred that a building has been completed so far as the exterior was concerned in all above the third story, and from a distance the appearance was given of having begun to build from the top down. One office building has over 6,000 tenants, representing in numbers the population of a good sized town, and the business force of quite a large city. We illustrate several of these structures.

Fire and Police Departments.

The costly lesson of the great fire resulted in providing against a repetition of a like calamity by creating a department which is second to none in the world, either in equipment or efficiency. It has 18,000 fire hydrants, with all Lake Michigan to draw from. In its equipment are 92 steam fire engines, 5 fire boats, 2 water towers, 25 chemical engines, 4 hand engines, 52 hose wagons, 26 hose carriages, 30 hook and ladder trucks, 9 chemical extinguishers, 101 portable pumps and almost 200,000 ft. of hose. At the opening of the current year the department owned 475 horses, the best that money could buy, and highly trained to the difficult service. The

FIRE BOAT "ILLINOIS."

buildings, land and apparatus of the department, as shown by the report of the chief for 1898, were of a total valuation of $1,979,385. The entire force consisted of 1,126 uniformed men. The city is divided into 16 battalion districts, the companies in each district comprising a battalion in charge of an assistant fire marshal. The expense incident to the maintenance of the department for 1898 approximated $1,500,000, a per capita tax on the inhabitants of Chicago of about 84 cents.

In 1898 the number of alarms responded to was 6,581, which involved 5,048 fires. The value of the buildings and contents was $91,922,210. The loss was $2,651,735. The loss over insurance only amounted to $105,270.

Chief Dennis Swenie is considered the most experienced fire-fighter in the world, having spent his entire life in the department, and is now past 60 years of age, but as active as ever.

The police department numbers 3,304 members; 77,440 arrests were made last year and $372,034 worth of stolen goods recovered. To run the department cost $3,360,601. The ambulance division is well officered; it cared for 9,584 persons last year, traveling 53,000 miles in doing so.

Both the fire and police departments are under civil service and all appointments below commanding officers are made on the merit system, thus taking these public servants as much out of politics as possible. Each department maintains a pension fund and members are retired after 25 years of service with one-half pay of the rank held at the date of retirement, and families of deceased members are taken care of where the death occurred in the line of duty.

Service stripes—one for each five years—are worn on the arm.

"ILLINOIS" IN ACTION.

Parks and Boulevards.

Few of the other great cities compare favorably with Chicago in the matter of parks and boulevards. To the 38 parks located within the limits of the city there is given over 2,232 acres. The parks are divided among the three divisions of the city as follows: North side, 8 parks, with a total of 324 acres; west side, 17 parks, covering 625 acres, and the south side, 12 parks, contain 1,281 acres. The parks in each division of the city are under the management and control of a separate board of park commissioners, who are appointed by the governor of the state. The cost of the maintenance of these places of public resort is paid out of state funds, the city being thus relieved of a large annual expense. There

FLORAL PIECE.

are, however, 18 small plots of ground dignified with the name of parks, which remain under city control, and although comprising only about one acre each, on an average, they cost by way of annual maintenance in excess of $10,000.

The largest and most prominent of the parks of Chicago are as follows:

North side, Lincoln Park, 320 acres.
West side, Humboldt Park, 200 acres.
West side, Garfield Park, 185 acres.
West side, Douglas Park, 179 acres.
South side, Washington Park, 371 acres.
South side, Jackson Park, 586 acres.
South side, Lake Front Park, 210 acres.

Vast sums of money have been expended in bringing the parks to their present state of beauty and attractiveness and that they are appreciated by the residents of the city is shown when on holidays and Sundays during the summer months tens of thousands of the people of all classes and conditions seek their shade, rest and quiet. To the visiting stranger they are shown with pardonable pride, and the time expended in viewing them is well spent and amply repaid. The Lake Front Park adjoins the business center of the city on the east and has been, for the most part, made by filling in the lake. It is as yet uncompleted, but the progress made and the promises of the South Park Commission lead to the belief that it will be unsurpassed for beauty. The Art Museum stands on the grounds of this park, and ultimately the Field Columbian Museum is to find a home within its confines. In quite a number of the public parks of the city the skill of the landscape gardener and the ingenuity of the decorative florist seem to have been exhausted. Many fine statues adorn the parks, noticable among which are those of Lincoln and Grant in the park named for the former, in which is also located a well selected and quite extensive zoological garden. The collection of wild animals from all quarters of the globe form an interesting feature, and one of which the public seems never to tire. An unusual fact in such collections is the constant breeding of wild animals not usually multiplying in captivity, the sale of the young of which constitutes a large source of revenue, providing means for the constant expansion of the collection. One feature of special interest is the herd of American bisons, improperly called buffaloes, which is one of the very few droves of this almost extinct animal now in existence. Jackson Park, the scene of the never to be forgotten World's Columbian Exposition, presents a scene of rare beauty, enhanced by its extending along the lake front and containing several mementoes of the great fair.

The boulevard system of Chicago is admittedly the most extensive and finest of any of the large cities of the world. The principal parks are connected by a continuous system or chain of boulevards, and a drive of about 35 miles completes a visit to every one of importance. Within the city, and under the direct control of the several boards of park commissioners, are 43 different boulevards, aggregating more than 66 miles in length.

Of these the most important are Lake Shore Drive, Sheridan Road, Diversey Ave. and Ridge Ave. on the north side; Humboldt, Washington and Jackson Boulevards on the west side, and Michigan Ave., Grand, Drexel and Garfield Boulevards on the south side. The first named, Lake Shore Drive, follows the very edge of the lake for over two miles, and strong efforts are being exerted by citizens of both Illinois and Wisconsin to have it made a connecting boulevard driveway between this city and Milwaukee, 80 miles.

SCENES ON CHICAGO BOULEVARDS.

The Street Railways of Chicago.

The street railways of Chicago (and under this head are included the elevated roads as being within the definition, "railways laid in, on, under or over, streets to facilitate the use of those streets by the public") comprise nearly 1,100 miles of track, with nearly 6,000 cars and are operated by 15 companies. Of these 15 companies only three have histories, or had predecessors which have histories, extending back prior to 1889. One of these is the South Chicago City Ry., which was chartered in 1883; the other two, the Chicago Union Traction Co. and the Chicago City Ry., operate systems which had their beginnings over 40 years ago.

Chicago City Railway Co.

The first street railway franchise granted by the council was in 1856 to Roswell B. Mason and Charles B. Phillips for street car lines in both the north and south divisions of the city; 1857 was a panic year, no money could be raised, and the franchise was allowed to lapse. In 1858 another ordinance was passed by the council, but not until the promoters had bought four horse cars and hauled them from the station to the corner of Randolph and

D. G. HAMILTON.
President Chicago City Railway Co.

States Sts. over the corduroy roadway which laid in the middle of State St. to enable Frank Parmelee's buses to ply in that very muddy thoroughfare. Mr. Parmelee had started his first bus line (the Parmelee transfer system still continues) in 1853; this was originally intended for the transportation of passengers between the hotels and railroad depots, but later a bus line was operated on State St. between 12th and Randolph. After the four street cars had stood for a short time as an object lesson and evidence of good faith the council, Aug. 16, 1858, acted and Frank Parmelee, Henry Fuller and Liberty Bigelow received a grant to operate street cars on State St., Cottage Grove Ave., Archer Ave. and Madison St. Ground was broken Nov. 1, 1858, Henry Fuller and William Bross using a pick and shovel to inaugurate the work.

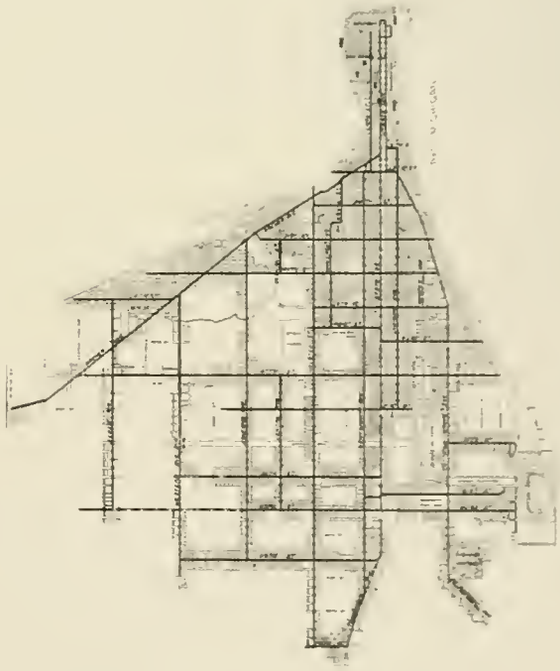
In April, 1859, the four cars mentioned began running over a single track of strap rails spiked to the planks of the corduroy road in State St.; by April 25th the line extended as far south as 12th St. The grant of the city council was confirmed by a special act of the legislature, approved Feb. 14, 1859, and the Chicago City Railway Co. was incorporated, by the three gentlemen mentioned and David A. Gage. The grant was for 25 years, and covered the south division of the city.

Mr. Parmelee withdrew his State St. omnibuses when the street car line was finished, but rival omnibus companies were organized, and rate wars cut the prices of rides from 12 for 50 cents to 40 for a dollar, or less. In the end the street cars won and the competing omnibus lines ceased operating in 1864.

It would be tedious to enumerate the extensions made from time to time, as the horse car lines kept pace with the growing city. The Madison St. line of the Chicago City Railway Co. and other West Side lines built under a franchise granted May 23, 1859, were about Aug. 1, 1893, sold to the Chicago West Division Railway Co., and the Chicago City has since continued in operation to the South Side.

Chicago was the second city in the country to build cable roads. The first cable road here was in the State St. line from Madison St. to 39th St., four miles of double track of the Chicago City Railway Co., the portion thus rebuilt had been the first street car line that the company built. In the language of Mr. C. B. Holmes, who was at that time president of this company, Chicago claims no credit for the invention of the system, that belongs to San Francisco, which had for nearly 10 years experimented with cables for climbing the steep hills in that city; but Chicago did undertake the serious task of demonstrating that the system was practicable in a region of severe winters with deep snow and intense cold and that it was an economical means for moving heavy traffic.

Work on the Chicago City's first cable line, four miles of double track, was commenced Aug. 12, 1881, and the line opened for traffic Jan. 28, 1882. The first train consisted of 10 cars drawn by a single grip car, and carried over a thousand passengers from the down town terminus at Madison St. to the company's general offices at 20th St. This first construction cost $105,000 per mile of single track; the company raised the street grade 3 ft. on that portion of the cable line north of 12th St. and lowered it 18 in. south of that point. The construction was attended with engineering difficulties of the most extreme character. Blocks of streets were open for months at a time, and it became necessary to invent machinery for facilitating the work. At certain points thousands of wagon loads of rock and gravel went into apparently bottomless pits, and it required intense energy and courage on the part of the president to bring the work to completion. Months before the line was finished it seemed as if nothing could save the company from complete bankruptcy. When the line was opened, however, engineers from all parts of the world came to Chicago by hundreds to study the new motive power. Even after the cable cars started troubles continued. The manufacturers



LINES OF THE CHICAGO CITY RAILWAY CO.

of wire ropes had never had experience in making cables for such severe service, and for two years there were frequent "strandings" of the ropes, which caused shut-downs for several hours at a time. On such occasions horses from the other lines were rushed out and drew the cars until the rope could be spliced. For the past 10 years such delays have been of very rare occurrence.

ROBERT McCULLOCH,
General Manager

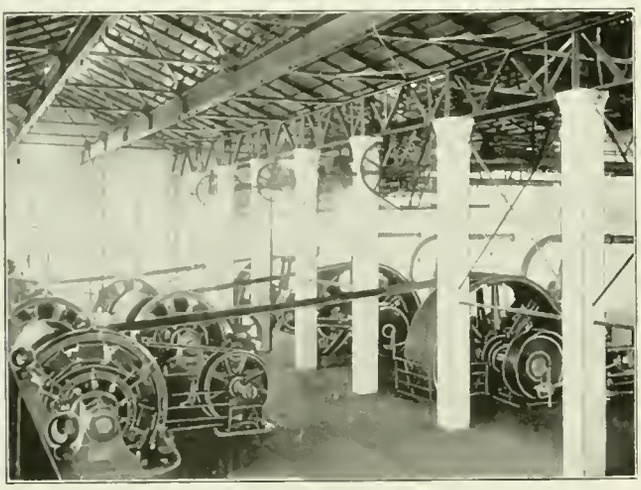
GEO. O. NAGLE,
Asst. Gen. Mgr. and Supt.

FRANK R. GREENE,
Secretary.

C. N. DUFFY,
Auditor.

Immediately upon the construction of the first line another was laid in a similar manner on Wabash and Cottage Grove Aves., from Lake St. to 39th St., making, with that built the previous year, 20¼ miles of cable track, and all operated from one central power station.

During the summer 1886, the State St. line was extended to 63d St., making a continuous double track cable line over seven miles



52D ST. AND WABASH AVE. STATION, CHICAGO CITY RY.

in a straight line, and adding six miles to the cable system. This new line was, however, operated from a power station situated midway between 39th St. and 63d St., and was also converted from a horse line to cable.

In 1887 the Wabash and Cottage Grove line was extended south to 71st St., with a branch running east to Jackson Park in 55th St.; the next spring the main line was extended a few blocks farther to give more ready access to Oakwood Cemetery. This addition increased the total cable mileage to 34.75 miles measured as single track.

The first franchises for electric traction were secured in 1892, and all except the cable lines equipped as rapidly as possible; at the present time the company's lines comprise 196.85 miles, measured as single track, 157.36 electric, 34.75 cable and 4.74 horse.

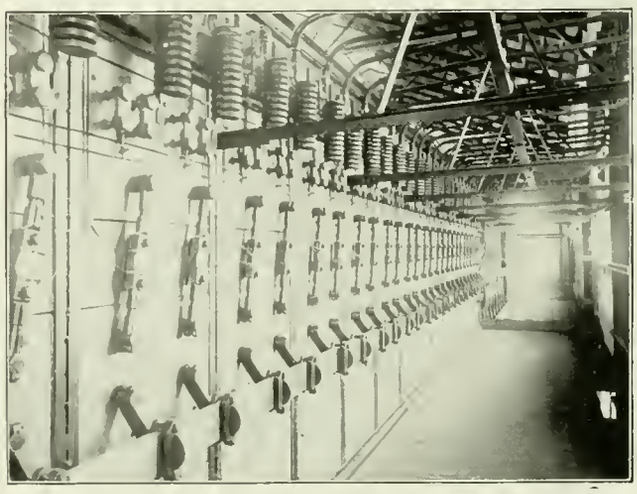
The company has five power houses—three cable and two electric. The first cable station is that at 21st and State Sts., which was built in 1881. Its equipment comprises 10 boilers aggregating 2,800 h. p., and six engines aggregating 3,900 h. p. From this station are driven four cables: North on State St. 26,400 ft.; south on State St. to 39th St., 23,800 ft.; Wabash Ave., north, 24,300, Cottage Grove Ave., 27,500 ft. During the past summer foundations under one of the engines and the cable driving gear have been rebuilt; solid have been substituted for differential drums, and the foundations were moved so that fewer gears and pinions are required to transmit motion from the main line shaft to the cable drums.

The other two cable stations were built in 1887. That at 52d and State Sts. has two 500-h. p. engines and three Hazelton vertical boilers, but they are used only in winter; during the summer a 600-h. p. Westinghouse motor operated by current from the electric power station at 52d St. and Wabash Ave. is used instead. Two cables are driven from this plant; one from 39th to 52d St., 19,175 ft. long, and one from 52d St. to 63d, 14,500 ft. long.

The cable station at 55th St. and Cottage Grove Ave. has two 1,200-h. p. engines and three 500-h. p. boilers. It drives three cables: 39th St. to 55th St., 21,300 ft. long; 55th St. to 71st St., 22,400 ft.; on 55th St., 12,800 ft.

The first electric power station built by the Chicago City Ry. is that at 52d St. and Wabash Ave., which was completed in 1893 in time to furnish power during the World's Fair, and enabled the company to carry millions of passengers that it could not otherwise have handled. This building is 130 x 147 ft., of red pressed brick, with terra cotta and stone trimmings. The boiler room is 56 x 128 ft., with 19 tubular boilers 72 in. by 18 ft., rated at 200 h. p. each. They are all equipped with Murphy smokeless furnaces, which are fed with coal from a bin overhead. The stack is 175 ft. high, with a 10-ft flue. Between the stack and engine room are two 1,000-h. p. Baragwanath feed water heaters. The coal conveyor built by the Link Belt Engineering Co. was illustrated in the "Review" for July last.

There are 10 improved simple engines, with 24 x 48-in cylinders designed to run at 100 r. p. m., with 100 lb boiler pressure. Each pair of engines has an 18-ft. built-up fly-wheel weighing 25 tons, which is connected to a 72-in. pulley by a 21-wrap compound wound rope drive. The driven pulley is between two 700-h. p. Westinghouse generators, which are driven through friction clutches. The driven pulley has grooves for 32 wraps of rope, 21 of these passing around the engine fly-wheel, and 11 around the "compound multiple winder," which is 72 in. in diameter and situated between the engine and generator; the tightener is overhead. This winding is a combination of the Dodge, Hitzroth, Williams, Macdonald and Hoadley patents. The pulleys in this plant were made by the



REAR OF SWITCHBOARD

Acting General Counsel.

G. W. KNOX,
Electrical Engineer.

C. E. MOORE,
Master Mechanic.

C. J. REILLY,
Chief Engineer.

Dodge Manufacturing Co., of Mishawaka, Ind., and the clutches by the Eclipse Clutch Works, of Beloit, Wis. The switchboard is equipped with Weston instruments.

Interesting data on the performance of this station were published in the "Review" for November, 1893.

The second electric plant of the company was built in 1896 at 49th St. and Oakley Ave. under the supervision of Robt. J. Hill, who was at that time the company's chief engineer. The building is built of brick, but with a steel frame; in general arrangement it is similar to the Wabash Ave. station. At the present time only one-half the equipment it was designed to receive is installed.

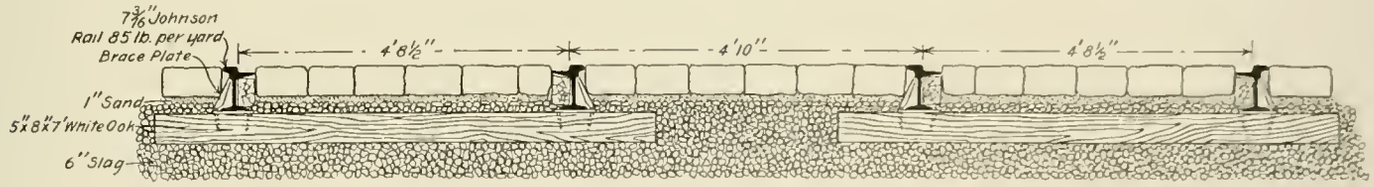
The boiler room is 99 x 266 ft. with 24 return tubular boilers 78 in. by 20 ft., rated at 300 h. p. each. Coal is delivered to tanks running the entire length of the boiler room by conveyors made by John A. Mead & Co. All the boilers are fitted with smokeless furnaces. There are three 2,000-h. p. Baragwanath feed heaters in the station.

In the engine and generator room are three pairs of 36 x 60-in. simple engines. Each pair of engines has a 20-ft. fly-wheel connected to a short jack shaft by means of a rope drive. Sweet separators are used. On each end of each jack shaft is an 800-kw. Walker generator. The switchboard was built by the Walker Co. and the design contemplated 112 feeder panels. The instruments are all Weston and among them is a 20,000-ampere ammeter.

The foundations in this plant were built by Clift Wise, who has also done much of the other construction work for this company.

The company has the following car barns: At 39th St. and Wabash Ave., a two story building, with capacity for 331 cars; at this barn is a stable with 40 double and 16 box stalls. At 39th and State Sts., a three story building, with capacity for 310 cars. At 61st and State Sts a three story building, with capacity for 398 cars, and stable room for 26 horses. At Archer Ave. and Putney Ct., a building partly one and partly three stories high; only the ground floor is used for storing cars, and has capacity for 134; a portion of the second floor is used as club room by the employes. At 69th St. and Emerald Ave., a one story building, with capacity for 195 cars. At Cottage Grove Ave. and 39th St., a one story building, with capacity for 415 cars and stable room for 35 horses.

The car equipment comprises 409 open motor cars, 522 closed motor cars, 258 grip cars, 303 closed trailers, 375 open trailers and 2 mail trains of a grip car and trailer each. These were built by the Brill, Stephenson, St. Louis, Wells & French and Pullman companies, and in the shops of the Chicago City Ry. These cars



CROSS SECTION OF STANDARD ROADBED—CHICAGO CITY RY.

are from 26 ft. to 30 ft. over all, except grip cars, which are 19 ft. The company has 503 double equipments, of Westinghouse 3, 12 and 49, G. E. 800, and Walker 5 motors, which are mounted on McGuire and Moore trucks. The latter trucks, designed by C. E. Moore, were built in the company's shops. The motor cars are all to be equipped with the Price momentum brake, designed by W. G.

Chief Supervisor.

Price, formerly the company's mechanical engineer and now with the Peckham Co. The cars are heated with Columbian stoves, made by the McGuire Manufacturing Co. Meaker fare registers are used exclusively.

The Chicago City employs about 3,500 men.

The shops of the Chicago City Ry. are at 21st and Dearborn Sts., directly in the rear of the power station and office building. The building has two floors, with an area of 45,000 sq. ft. each, and a monitor third story, having an area of 20,000 sq. ft. The shop machinery is driven by a 75-h. p. engine, taking steam from the power station across the alley. A 13 x 13-in. Ideal engine drives a Brush 50-lamp and an Excelsior 45-lamp machine used for lighting; there are 350 incandescent and 88 arc lamps in the building. The building is heated by exhaust steam from the cable station. In the shop power plant is also a Pedric & Ayres double air compressor, with a capacity for 120 cu. ft. per minute. A pressure of 80 lb. is carried in the storage tanks and a piping system carries the air to all parts of the building, where it is used for various purposes.

The machine shop contains 7 engine lathes, 1 turret lathe, 6 drill presses, 1 turret drill, 1 planer, 1 shaper, 1 milling machine, 1 boring machine, 1 hydrostatic press, 1 car wheel grinder, 1 Q & C cold metal saw, 1 power hack saw, 1 tool grinder and 4 air lifts. In the wood room are 1 planer, 1 jointer, 2 molding stickers, 2 rip saws, 1 cross cut saw, 1 band saw, 2 shapers, 2 mortising machines, 1 tenoning machine, 1 sandpapering machine, 1 turning lathe and 1 emery wheel. The blacksmith shop is especially well equipped with labor saving tools; there are 1 small Bradley hammer, 1 steam hammer, 1 belt-driven drop hammer, 3 furnaces and 8 forges. When there are more than 500 pieces of one kind to be made the foreman designs a swedge or die for forging them under the drop hammer. An elevator takes cars to the second and third floors; on the second floor 58 cars can be repaired at one time, and on the third floor 17. On the ground floor are five tracks for 12 cars, four pits and two extra ones for emergencies. On the third floor are the pattern shops and store rooms, the armature shop, armature testing room, upholstering department, etc.

Visitors to these shops will be particularly interested in the special machines, tools and other apparatus which have been designed by Mr. C. E. Moore, master mechanic. Among these are the armature coil taping machine, the washing machine, the cane splitting machine, the rail bender, the trolley wheel cutter and the cushion cleaning machine; all of these effect great saving in both time and labor. These machines, as well as the armature testing room have been described in detail in previous numbers of the "Review."

The standard roadbed construction of the Chicago City Ry. consist of 7 3-16-in. Johnson 85-lb. girder rails laid on 5 x 8 in. x 7 ft. white oak ties which are laid in slag, as shown in the cross section. There is, of course, a great deal of track laid with rails of other sections, but the 7 3-16-in. girder is used in new work.

All joints are cast-welded by the Falk process, the company having a welding plant and doing its own work. The first cast-weld joints were made in 1895; at the present time there are over 33,000 welded joints on the system. The breakage of these joints has been about one-half of one per cent per year and is growing less each year, which is taken to be an indication that defective casting has been the cause of the failures. The percentage of breakage has been less in unpaved than in paved streets.

The accompanying engraving is reproduced from a series of pho-

tographs taken in the track department museum of the Chicago City Ry. and shows the molds, rail sections, and finished joints, and the tables give the dimensions, weights and other data. It will be noted that two of these joints are used at railroad crossings only.

Another engraving shows views of two interesting pieces of track work; one is the crossing over the Fort Wayne railroad tracks at 26th St., and the other the new cable curve and crossing at 22d St. and Cottage Grove Ave., built by the Falk Co.

In its electrical construction the company uses the insulating material of the Albert & J. M. Anderson Co.

The presidents of the Chicago City Ry. have been as follows: Liberty Bigelow, Mar. 28 to Sept. 20, 1859; B. F. Carver, to Apr. 8, 1861; William H. Waite, to Aug. 11, 1863; D. A. Gage, to August, 1864; Samuel M. Nickerson, to Aug. 1, 1871; Albert Crosby, to Jan. 11, 1872; M. D. Hennessy, to Jan. 8, 1874; S. B. Cobb, to January, 1882; C. B. Holmes, to January, 1891; G. H. Wheeler, to January, 1898; M. K. Bowen, to April, 1899.

The present officers and operating staff are: President, D. G. Hamilton; vice-president, Joseph Leiter; secretary, Frank R. Greene; treasurer, T. C. Penington; general manager, Robert McCulloch; assistant general manager and superintendent, George O. Nagle; auditor, C. N. Duffy; chief engineer, C. J. Reilly; master mechanic, C. E. Moore; electrical engineer, G. W. Knox; assistant superintendent, A. C. Heidelberg; purchasing agent, G. I. Bergen; superintendent of time tables, Leon Jewell; acting general consul, M. B. Starring; chief supervisor, J. J. O'Keefe.

D. G. Hamilton, president of the Chicago City Railway Co., has for many years been prominently connected with street railway interests. He was born in 1843, in Chicago and has lived in his native city nearly all his life, a large portion of his considerable wealth being invested here. He began the practice of law, shortly after his graduation from college, meeting with unusual success in this profession. Of late years he has given much of his attention to real estate matters and the financiering of new projects of various kinds, but has always found time to devote to the interests of the Chicago City Railway Co., of which he has been a large stockholder and director for a number of years. Early in 1899 he was elected second vice-president of this system, succeeding Joseph Leiter, and on the death of M. K. Bowen, a short time ago, was made president. Mr. Hamilton was for many years president of the National Railway Co., of Chicago, which company owned extensive street railway properties in St. Louis. He is a prominent club man, a trustee of De Pauw and the Chicago Universities, and a director in a number of local enterprises.

Capt. Robert McCulloch, who became general manager of the Chicago City on September 1st., is probably better known, and has more genuine friends, than any other man connected with the street railway industry; for to know him at all, is to recognize at once those dignified, yet kindly and genial attributes that have always commanded the respect and honor of mankind. Descended from a sturdy Scotch ancestry, but reared and educated under the softening influences of a refined Virginia home, the finer qualities of the man have been developed to an extent not often reached by the average business man. Capt. McCulloch was born Sept. 15, 1841, in Rockbridge County Va., and was educated at Lexington, Va. At the opening of the civil war, he volunteered his services in the confederate cause. He went to St. Louis in 1869, and in 1871 entered the employ of the Bellefontaine Railway Co., of that city as superintendent, was afterward made secretary, and then vice-president and general manager. In 1889, he was made vice-president and general manager of the National Railway Co., leaving this office in August last.

T. C. Penington, who has held the office of secretary and treasurer of the company for the past 18 years, was born in Wilmington, Del., Sept. 14, 1844. His parents moved their home to Illinois in 1860, just before the war broke out, and Mr. Penington, although but 18 years old, enlisted in the 36th Illinois at the commencement of hostilities and remained in the service until peace was declared. He has been connected with the Chicago City Ry. continuously for the past 27 years, beginning as clerk and by his own efforts, securing promotion in a few years to his present position. He organized the splendid system now in operation on this road. Mr. Penington has acted as secretary and treasurer for the American Street Railway Association since 1895, and has brought into this work, the same systematic and satisfactory methods he has employed for so long in his official connection with the Chicago City Ry. This, together with his genial personality, has made his administration of the office, particularly pleasing to the members and executive committee of the association.

Frank R. Greene, secretary of the Chicago City, is a native of Newport, O., and was born June 8, 1859. He served in various capacities as bank clerk, bookkeeper and cashier, in Marietta, O., Indianapolis, Ind., St. Paul, Minn., and Chicago, until in April, 1890, he was made auditor of the Chicago City Railway Co. He was appointed secretary in January, 1891.

C. N. Duffy, auditor of the company and one of the best-known authorities on methods of street railway accounting, was born Aug. 14, 1859, at St. Louis. In 1873 he accepted a position as shipping clerk in a mercantile establishment, and at once commenced the systematic study of the theory of keeping accounts, which he has continued all his life. He remained in the mercantile line for 12 years, but in May, 1886, was chosen secretary and treasurer of the Union Railroad Co., of his native city, and since that time has devoted himself exclusively to the perfecting of a system of accounts suited to the requirements of street railway companies. His efforts in this line have been most successful and the aid he was able to give in the recent work of the Street Railway Accountants' Association, has won for him the gratitude of the entire fraternity. When the Union R. R. was absorbed in 1889, by the National Railway Co., Mr. Duffy was made secretary and treasurer of the entire system. This position he held until shortly after the recent consolidation of all the lines in St. Louis, when he resigned to become auditor of the Chicago City Railway Co. Mr. Duffy is chairman of the permanent committee on Standardization of the Street Railway Accountants.

George O. Nagle, assistant general manager and superintendent of the Chicago City Ry., is a native of Milton, Pa. He was born Dec. 31, 1868, and early in life moved to Lima, O., where he was educated in the public schools. Moving to Chicago in 1886, he attended the Chicago Atheneum for a short time and then entered the employ of the Cragin Manufacturing Co. He left this company in a few months and began work with the Chicago, Burlington & Quincy R. R., leaving this connection in February, 1891, to go with the Chicago City Railway Co., in its claim department. Six months later he was promoted to the position of private secretary to the superintendent, which he held until appointed superintendent on Jan. 18, 1898. Sept. 1, 1899, he was appointed assistant general manager.

Chicago Union Traction Co.

The North Chicago City Railway Co. was incorporated by the same act of the Legislature (Feb. 14, 1859) which incorporated the Chicago City Railway Co. The original incorporators of the North Chicago were William B. Ogden, John B. Turner, Charles V. Dyer, James H. Rees and Valentine C. Turner. May 23, 1859, the city council authorized the construction of tracks in a number of streets in the North Division of the city and within a few years the company was operating lines on Clark St., from North Water St. to Green Bay Road; on Division St., from Clark to Clybourn Ave., on Clybourn Ave. north of Division; on Wells St. from North Water to Division, thence west and north on Sedgwick to Green Bay Road, and on Chicago Ave., from Rush St. to the Chicago River. Extensions were made from time to time till in 1886 the company had 18 miles of track. The North Side lines were financially successful, as were all the city horse car lines, but the system, solely by reason of animal traction being used, had practically reached its limit of growth in 1886, when Mr. Yerkes secured control of it.

The officers of the North Chicago City Railway Co., were: John B. Turner, president from 1859 to 1867; V. C. Turner, secretary and treasurer from 1859 to 1865, vice-president from 1865 to 1867, president from 1867 to 1885; H. N. Towner, secretary and treasurer from 1865 to 1873; Hiram Crawford, secretary and treasurer from 1873 to 1885; Lucian Tilton, vice-president from 1875 to 1877; George Dunlop, vice president from 1879 to 1887.

The Chicago West Division Railway Co. was incorporated by special act of the Illinois Legislature on Feb. 21, 1861, the incorporators being Edward P. Ward, William K. McAllister, Samuel B. Walker, James L. Wilson, Charles B. Brown and Nathaniel P. Wilder. In 1863 this company bought the tracks which the Chicago City Ry. had built on Randolph and Madison Sts. The great fire of 1871 caused many people to move to the West Division of the city and the west side road found it necessary to make great extensions of its tracks. Keeping growth with the population the company in 1884 operated 75 miles of track, having a daily average of 3,246 horses in service. In 1885 there were 3,733 horses and 655 cars in service, the daily mileage being about 22,500. It is quite interesting to note that the number of round trips was 3,029, on an average round trip of only 7½ miles. The Chicago Horse & Dummy Railway Co. was incorporated Feb. 12, 1883, and secured franchises for west side streets; this company, which soon passed under the control of the Chicago West Division, changed its name to the Chicago Passenger Railway Co. Later the two properties were consolidated, both being leased for long terms to the West Chicago Street Railroad Co. The officers of the Chicago West Division Railway Co. before the lease to the West Chicago were: President, J. Russell Jones; vice-president, Benjamin F. Campbell; secretary and treasurer, George C. Webb; general superintendent, De Witt C. Cregier. In March, 1886, Charles T. Yerkes and other gentlemen of Philadelphia organized the United States Construction Co. and in its name bought a controlling interest in the North Chicago City Railway Co.

On May 18, 1886, Mr. Yerkes and his associates organized the North Chicago Street Railroad Co. and it acquired all the property of the old company, and formed the nucleus of the great Yerkes System which was developed in the north and west divisions of the city in the next 13 years.

Mr. Yerkes and his associates secured a majority of the stock of the west side companies and July 19, 1887, incorporated the West Chicago Street Railroad Co., and shortly afterwards the older companies leased their property to the West Chicago.

Immediately on securing the north side lines Mr. Yerkes set about providing better down-town terminals, and installing cables for operating the trunk lines. The La Salle St. tunnel under the Chicago River was rebuilt by the North Chicago Street R. R. in 1887 and the north side cable lines built; these cable lines comprise 17 miles (measured as single track) and were, together with the down-town loop, completed in March, 1888.

As soon as possible after the organization of the West Chicago Street Railroad Co. the work of improving the west side lines was

begun. The Washington St. tunnel was rebuilt in 1890 and the cable system installed on Madison and Halsted Sts. and Milwaukee and Blue Island Aves. In 1893 a tunnel under the south branch of the Chicago River at Van Buren St. was completed and that line cabled. The total cable construction for the West Chicago amounted to 30.24 miles (measured as single track) and included three down-town loops. What was 10 years ago called the "deadly trolley" met with bitter opposition in the city of Chicago, and no franchise for down-town electric lines could be secured until after nearly all the suburbs had enjoyed the advantages of the new motive power for several years. An ordinance permitting the equipment of the Yerkes lines was passed in April, 1894, and within 16 months 210 miles of electric roads had been completed. All of this work was done by the electrical department of the north and west side roads under the management of Mr. J. R. Chapman, and it established a long-distance record for quick construction of city lines. The electrically operated lines of these companies in 1898 aggregated 250 miles.

Over 200 miles more of electric street railways were built in the north and west divisions of the city and its suburbs as feeder lines, but the recent change in the management of the North and West Chicago lines makes it more proper to take up the feeder lines in connection with the Chicago Consolidated Traction Co. rather than with the system of which they originally formed a part.

On July, 1, 1899, the Chicago Union Traction Co. assumed control of the North Chicago and the West Chicago Street Railroads by virtue of leases executed the previous day. The officers and staff are: President, Jesse Spalding; vice-presidents, R. A. C. Smith, of New York, and Walter H. Wilson, of Chicago; secretary, J. C. Moore; treasurer, J. H. Eckles; assistant treasurer, M. B. Orde; auditor, F. E. Smith; general manager, John M. Roach; assistant manager, G. A. Yuille; electrical engineer, J. R. Chapman; division superintendent, T. A. Henderson; master mechanics, F. T. C. Brydges and John Millar; chief engineer in charge of West Side power stations, J. Z. Murphy, chief engineer North Side power stations, John Gleason.

The power houses of this company are 11 in number, of which nine are cable plants and two are electric stations.

For operating the north side cables three power stations were built; one at La Salle Ave. and Illinois St., just north of the river, for hauling the cable through the tunnel and around the down-town loop; one at Clark and Elm Sts., for the Clark St. and Wells St. lines, and one at Lincoln and Wrightwood Aves. All of these have been enlarged from time to time as the traffic increased.

The loop station was completed in 1887 and its present equipment comprises two engines, one 300-h. p. and one 250-h. p., seven boilers and one set of driving machinery, and a motor and two dynamos, one arc machine for the tunnel and one incandescent machine.

The North Clark St. cable station was built in 1887, an old building formerly used as a swimming school and skating rink being remodeled. In the engine room there were originally four 500 h. p. simple non condensing engines with 28 x 60 in. cylinders, but, in 1890 two of these were replaced by larger engines having 36 x 60 in cylinders. At this station is a Siemen Halske 500 volt motor driving a Siemen Halske 110 volt dynamo for lighting the plant; current for the motor is taken from a trolley circuit. The boiler plant comprises nine return tubular boilers 72 in by 18 ft. which carry steam at 100 lbs. Coal hoppers are provided above the boilers, but have not been used for several years, as oil is the fuel. The oil is delivered in the tank wagons of the Indiana Pipe Line Co.

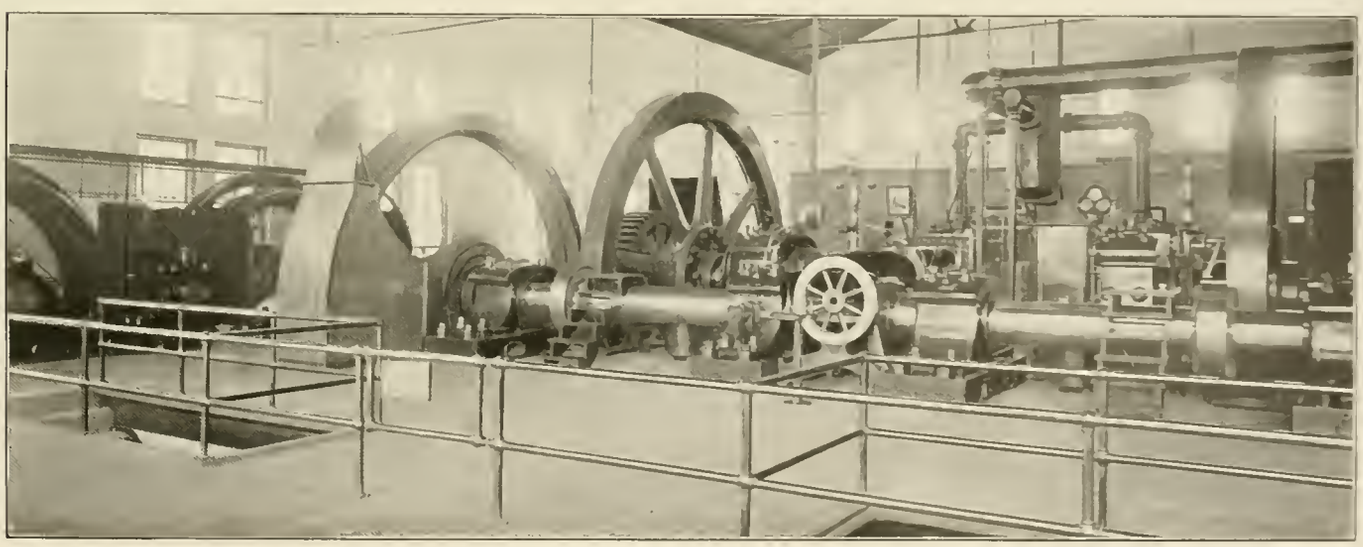
JOHN M. ROACH,
General Manager Chicago Union Traction Co., President Suburban Railroad Co.

and emptied by gravity into storage tanks which have an aggregate capacity of about 800 barrels. The pressure on the fuel oil piping system is about 10 lbs. The building is of brick, one story high, except at the north end; the stack is 125 ft. high above the grates.

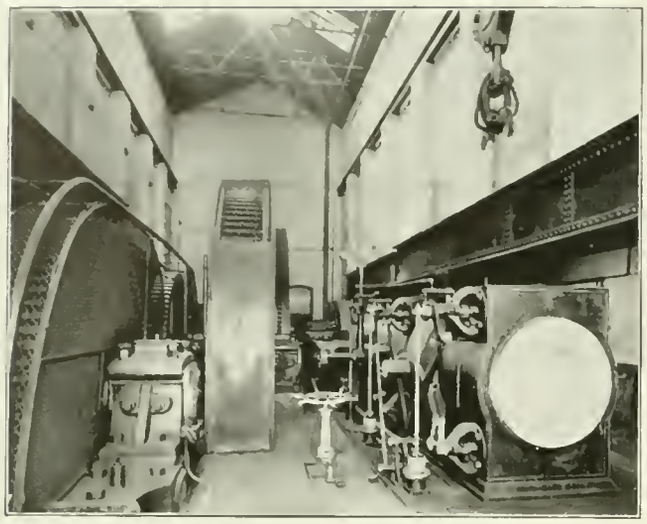
The Lincoln Ave. Station contains two 300-h. p. corliss engines, 4 boilers and 2 sets of driving machinery, and drives the cable, 18,000 ft. long, from Center and Clark Sts. to Wrightwood Ave.

On the West Side are six cable stations. Three of these were built to operate the Madison St. cable system which was installed during the summer of 1889, and are all of similar design.

The Washington St. cable station is located at the corner of Washington and Jefferson Sts., a portion of this building being



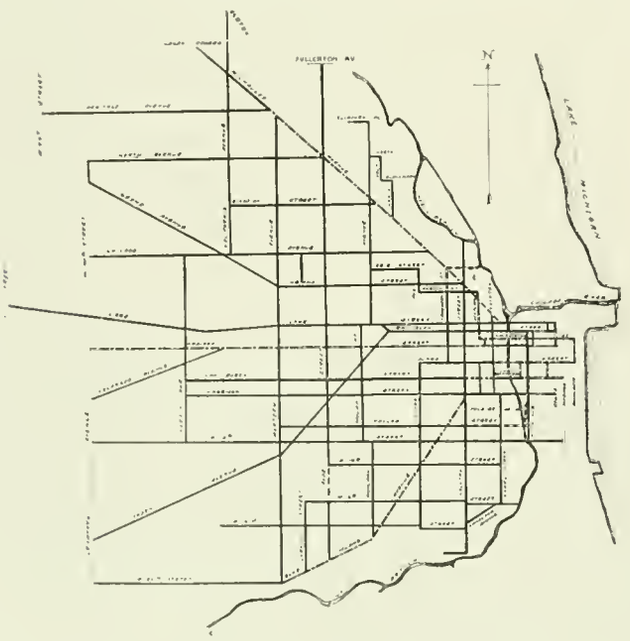
ENGINE ROOM, MILWAUKEE AVE. STATION, CHICAGO UNION TRACTION CO.



DESPLAINES ST. CABLE STATION.

formerly occupied by the general offices of the company. This station operates the down-town loop, and lights the tunnel and building. There are two simple non-condensing engines of the corliss type with 36 x 60 in. cylinders conected by a rope drive to the cable machinery. The engines are rated at 1,000 h. p. each; one is sufficient for the work. There are six horizontal tubular boilers 72 in. x 18 ft. The oil for fuel is stored in a 4,000 gallon tank in the basement. The lighting plant mentioned is in the basement and consists of two high-speed Russell automatic engines, 12 x 18 in., driving a jack shaft from which are driven by wire ropes three arc machines and three 135-volt, 135-ampere Siemens-Halske dynamos.

Adjoining this station is a very interesting plant, built as an auxiliary. It was desired to install an additional engine and the only land in the vicinity that could be bought was a lot 25 x 150 ft. The equipment comprises one 1,000 h. p. simple non-condensing Corliss engine, six vertical tubular boilers aggregating 1,200 nominal h. p. each and a complete set of winding machinery. This



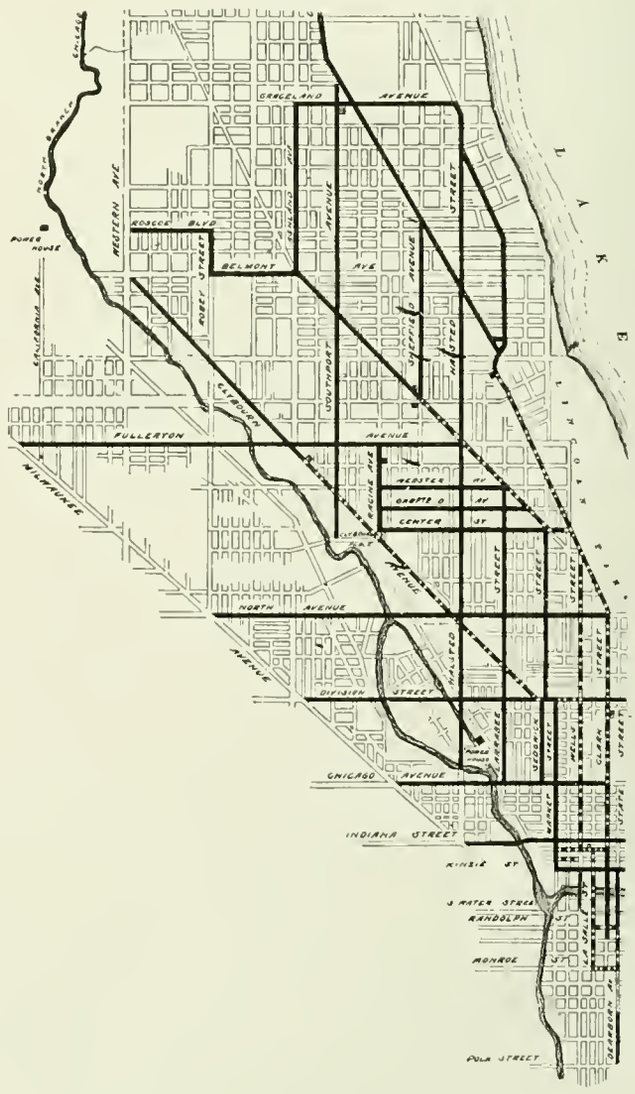
WEST SIDE LINES, CHICAGO UNION TRACTION CO.

is known as the Washington and Desplaines Sts. station as it fronts on the latter.

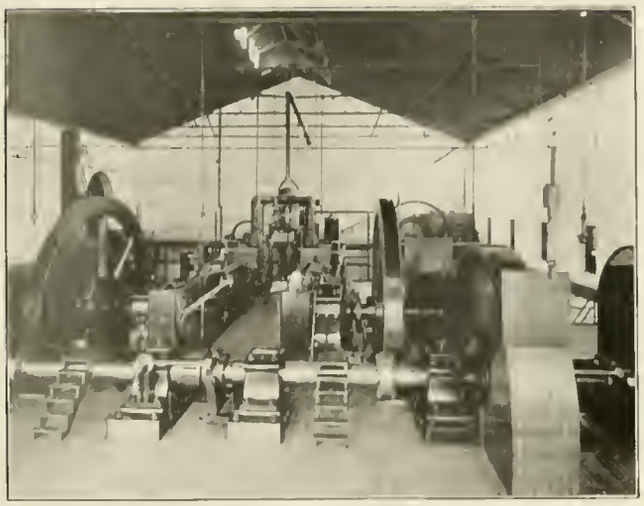
The second of the older cable stations is that at Milwaukee Ave. and Cleaver St. and drives two 1⅝ in. cables, each 21,000 ft. long; one has speed of 10 miles per hour and extends to the corner of Washington and Jefferson Sts. and the other with a speed of 12 miles per hour out Milwaukee Ave. to Armitage Ave. This building is of red brick 250 x 208 ft.; there are two simple non-condensing corliss engines with cylinders 30 x 72 in. built. The engines are of very massive construction and look heavy for their rating, which is 1,500 h. p. each; one engine suffices to drive both cables. The separators and piping are drained by Westinghouse steam loops. In the boiler room are eight horizontal tubular boilers 72 in. by 18 ft. carrying steam at 100 lb. Oil is now used for fuel. The stack is octagonal in section and 175 ft. high; the internal diameter is 7½ ft. At this station cement lined tanks are provided under the boiler room floor for storing a 30 hours' supply of feed water; this precaution was deemed necessary to guard against the possibility of a failure in the city supply. The Milwaukee Ave. station is still used, but the traffic on the line is light; trolley wires are strung over a considerable portion of the cable line on this division.

The third of the West Side cable stations which dates back to 1889 is that at Rockwell and Madison Sts. and it is an almost exact duplicate of the Milwaukee Ave. plant; it drives two cables 20,000 ft. and 18,000 ft. long respectively. There are two 1,500-h. p. Greene engines geared to the main shaft, one or both being used as may be necessary and a 150-h. p. corliss engine which is used to drive the cable for a loop encircling the power station which is used for turning a portion of the cars, traffic on Madison St. west of the power house being light. A 25-h. p. Russell automatic engine rope connected to a 25 arc light dynamo is provided for lighting the building. There are two batteries of four boilers each, similar to the boilers in the other cable stations mentioned; oil is used for fuel. The separators are drained by Westinghouse steam loops. The traffic on the Madison St. branch of this system is still heavy, electric lines not having seriously cut into it as yet.

The Blue Island cable station at Blue Island Ave. and 12th St. was built in 1893. It is of pressed brick with stone trimmings, and



NORTH SIDE LINES, CHICAGO UNION TRACTION CO.



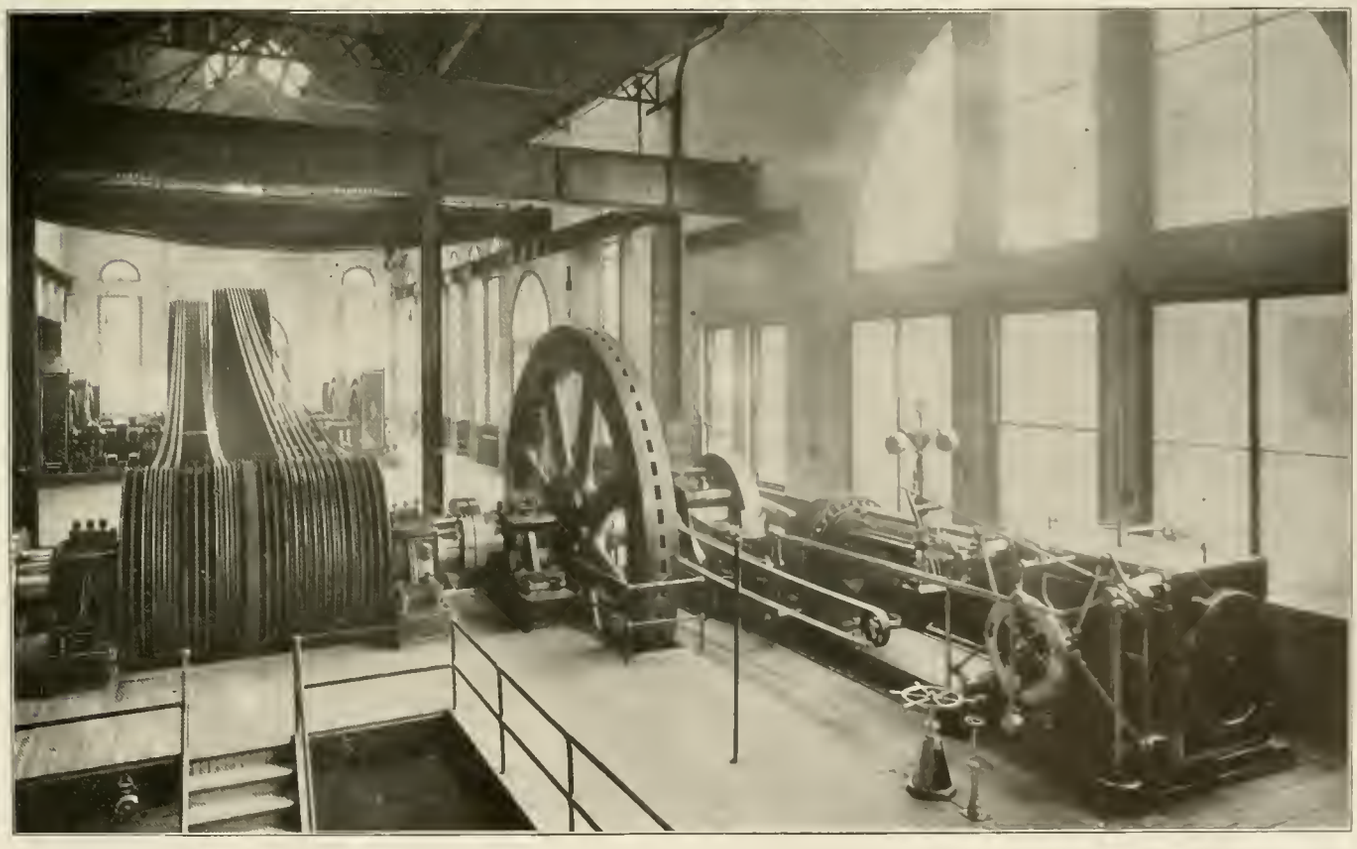
ENGINE ROOM, ROCKWELL AND MADISON STS.

includes as part of the structure a six-story office building. The portion where the machinery is located is 116 x 100 ft. In building the foundations quicksand was encountered and the excavations had to be carried down 40 ft. below the street level. Some 800,000 brick laid in portland cement were used in the engine foundations. Three cables are operated from the station. On Blue Island Ave. from 12th St. to Jefferson St., 12,400 ft.; on Blue Island Ave. from 12th St. to 26th St., 24,600 ft.; on Halsted St., 25,000 ft. All of these cables were made by the Roebling company and are 1 5-16 in. in diameter. In the engine room are two simple Allis engines with cylinders 40 x 72 in. rated at 1,800 h. p. with steam at 100 lbs. Each has a 24-ft. fly-wheel weighing 50 tons. These two engines are at either end of an 18-in. line shaft which carries the winding drums between them; pinions 5-ft. in diameter on the line shaft mesh with 14-ft. gears on the winding drums of which there are four, three 13½ ft. in diameter and one of 16 ft. In case of a drum breaking its cable can be shifted to the spare drum. One engine only is needed for operating the station, the second being held in reserve. There are eight horizontal tubular boilers 72 in. by 20 ft., in this station. The boilers are carried on iron columns, and the space underneath is utilized for the tension carriages; these are of the Root pattern, which are used in nearly all the cable plants in this country. A Westinghouse steam loop is installed at this station; the separator is beneath the floor.

The newest cable station in Chicago is that at Van Buren and Jefferson Sts., which was completed late in 1893. The building is 50 x 175 ft., of red brick, trimmed with Bedford stone. The marked feature of this plant is the rope drive, which is 75 ft. from center to center, being one of the longest in the country. The equipment comprises two simple non-condensing Allis engines, with 30 x 60 in. cylinders, and rated at 1,300 h. p. each. The fly wheels are 20-ft. in diameter and weigh 50 tons each. The boiler room contains eight tubular boilers of 225 h. p. each. A Westinghouse steam loop is used for draining the separator. The boilers are provided with grates for coal burning in case of emergency, though oil is the fuel commonly used. Two sets of cable driving drums are provided; one being always in reserve. The Van Buren St. loop cable is operated from this house; the rope is 1,300 ft. long.

The tunnel used by the Van Buren St. cable line was begun in 1891 and completed in 1894. It was built on private property at a cost of $1,600,000. It consists of one elliptical span of 30 ft., the length from entrance to entrance is 1,514 ft. and from portal to portal 920 ft. The east approach begins at Franklin St. and is 278 ft. long on a grade of 10 per cent; the western approach begins at Clinton St., and is 316 ft., with grades of 7.93 and 5.46 per cent. In order to construct the tunnel it was necessary to support adjacent buildings on jacks, while the foundations were undermined; the work was so carefully done that not even an elevator in any of the buildings was stopped. The two tracks through this tunnel are 15 ft. c. to c. The tunnel is built of brick in seven rings, giving a total thickness of 32 in.; the river section is concreted, covered with asphalt mortar and laid with flagging. At the time of its construction the arch of this tunnel was the largest ever built in tunnel work and we believe the distinction still holds good.

The electrical power houses of the Yerkes system have ever since their construction been considered among the most interesting

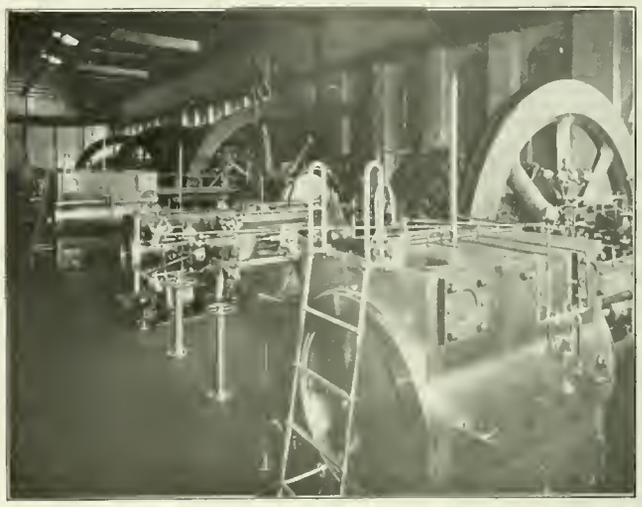


CABLE STATION, VAN BUREN AND JEFFERSON STS., CHICAGO UNION TRACTION CO.—ALLIS ENGINES.

of the power plants of Chicago, and it is quite safe to say that few engineers visiting the city have failed to inspect one or more of them. Those passing to the Chicago Union Traction Company are the ones known as the Western Ave. and the Hobbie St., or Hawthorne Ave. These stations supply the same lines as before the lease of the two roads to the Union Traction Co., the Union Traction and the Consolidated Traction renting power from each other.

The electrical power station of the West Chicago lines is at Western Ave. and Washington Boulevard, three miles west of

WESTERN AVE. STATION.



ENGINE ROOM, WESTERN AVE. STATION.

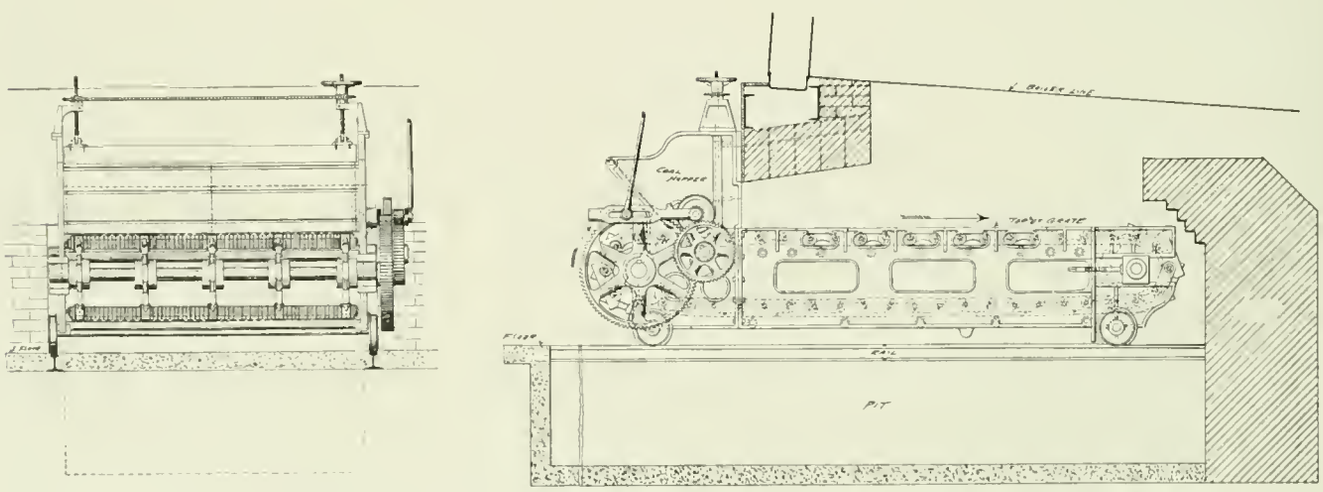
State St., quite near the center of distribution of the system. When designed it was intended that the ultimate capacity of this station should be 12,000 h. p., and it is interesting to note that it was then the largest electrical power house that had ever been designed. Construction was begun in 1894, and by the summer in 1895 it was supplying about 7,000 h. p.

This plant now contains five engine and dynamo units of 1,500 kw. capacity and one of 750 kw. The engines are cross compound. The cylinders of the 2,000-h. p. engines are 34 and 54 in. x 60 in. stroke. Those of the 1,000-h. p. engines are 26 and 40 in. x 48 in. stroke. The diameter of the fly-wheel is 25 on the 2,000-h. p. and 20 ft. on the 1,000-h. p. The 25-ft. wheel weighs 80 tons. The revolutions per minute are 75 on the 2,000-h. p. and 80 on the 1,000-h. p. engines. The generators were made by Siemens & Halske, and are the usual internal field type built by that company for direct driving. The armature winding consists of copper bars and the surface of the armature is turned off to form the commutator. These machines perform their duty in a very satisfactory manner, as is always the case with the large direct-connected units built by this company.

The engine room of this station is 57 x 250 ft., and has an iron floor and basement similar to the California Ave. plant, except that there are no condensers in the basement. As in the other station all piping and wiring is run under the floor so as to give full swing to operation of the two Walker 35-ton electric cranes which span the engine room. There are four steam loop and separator systems in this plant, which were furnished by Westinghouse, Church, Kerr & Co.

The switchboard is made up of General Electric panels. The feeder board in the gallery has 70 panels. The generator panels are on the main floor. Two Thomson recording wattmeters measure the output, one serving each half of the generator board. The generator panels have in addition to the regular General Electric apparatus a Siemens & Halske device for opening the shunt field circuit. This is an arrangement whereby the final break of the field circuit is made by gradually separating two carbon points until the arc gets so long that it breaks the circuit. This method, it is claimed, gets rid of the dangerous inductive kick when the field circuit it opened. All the feeders leave the station from one corner of the engine room basement. From the switchboard they pass straight down and then run along a rack on one wall of the basement to the manhole of the underground conduit on Western Ave.

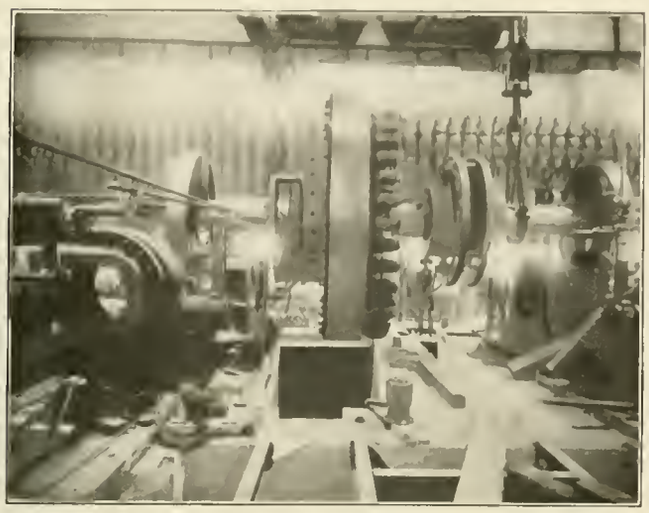
The boiler room contains 20 400-h. p. Stirling water tube boilers. This was said to be the largest single order of the kind ever placed at the time it was made. Oil was used as fuel and no provision made for burning coal until the present summer, when the company became convinced that coal would be cheaper, and contracted with the Green Engineering Co., of Chicago, to equip all the boilers with its traveling link grates.



GREEN TRAVELING LINK GRATE.

The accompanying illustrations show end and side elevations of

the type of grates which are now being installed. Each of the 20 grates is over 10 ft. wide, which is about 20 per cent wider than it has heretofore been possible to make traveling grates that would operate successfully, from 8 ft. to 8 ft. 6 in. being considered the limit. The effective grate surface is 84 sq. ft. for each boiler; 9 ft. long by 9 ft. 4 in. wide; each grate weighs about 3,500 lb. and the whole mechanism is mounted on wheels which run on a track as



ERECTING A 2,500-H. P. UNIT, WESTERN AVE. STATION.

shown in the drawing, so that when desired the grate may be rolled out of the furnace.

The elements or links of the grate are a little less than 12 in. long and the surface which forms a portion of the grate surface is about 7/8 in. wide, the web or body of the link being thinner. Through the web are two circular holes, 6 in. c to c., and these are slotted on the under side. The links are connected by transverse joining bars which are oval in cross section; the long diameter is such that they turn easily in the circular holes in the grate links, and the short diameter so that they slip through the slots mentioned. This design enables a defective link to be easily removed and a new one put in its place; it is only necessary to turn the two joining bars so that the slots may slip over them, remove the link, put a new one in place, and turn the bars again. The joining bars are held in a position such that the links cannot slip off by outside binder links, in which the holes conform to the cross-section of the bar; these binders are held in place by cotter pins. The links are spaced so as to give the desired air spaces (about 30 per cent) by the bosses which are cast around the holes in the webs of the links.

The arrangement of joining bars is one of the principal features of the design; a second important feature which permits the grate to be made of any width that may be desired is the supporting of the chain. The supports are made of heavy steel piping mounted in roller bearings at the ends; the bearings are housed and fully protected from dust and ashes.

The driving links are in pairs, the bosses on the two coming together and forming the "tooth" which meshes with the driving sprocket. The chains of driving links are placed 14 in. apart. The driving mechanism is at the front end, and is worked by a ratchet which is actuated by a rod from an eccentric on an independent shaft. In the Western Ave. station there will be two 20-h. p. motors installed to operate the driving shafts; one of these is ample for the work, the other being in reserve.

At the rear end of the furnace the grate is carried on sprockets on a horizontally adjustable shaft.

A coal hopper is included with the gate apparatus. The regulating gate is lined with fire brick and moves in vertical guides. The roof of the fire-box at the igniting arch is made of fire brick of special design, which slip over steel channel bars.

These grates may be adjusted to give a surface travel ranging from 3/4 in. to 5 in. per minute.

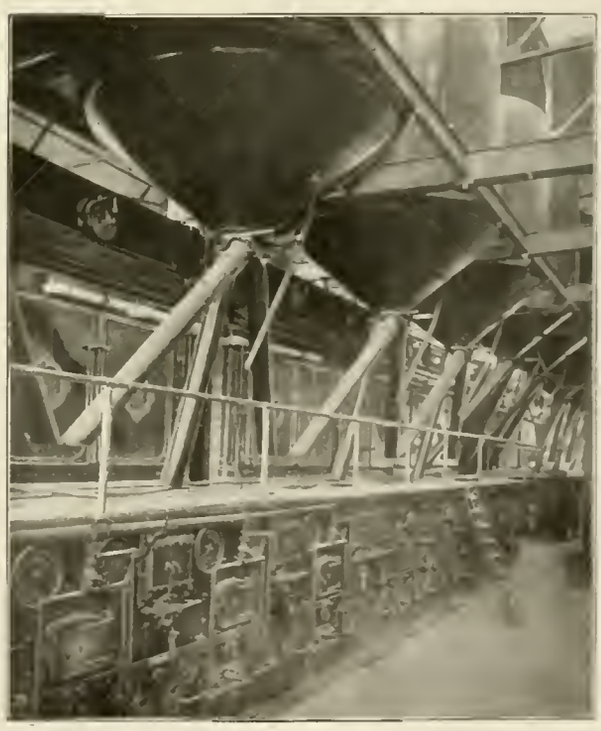
Six 2,000-h. p. exhaust steam heaters are ranged around the base of the stack, near which are also the two boiler pumps and the pumps for the fuel oil system. A simple gravity system of oiling is employed. The building is heated with exhaust steam. The main exhaust of the station is 40 in. in diameter, and passes up alongside the stack. The stack is 235 ft high, 10 ft. flue, 27 ft square at base and on a foundation 48 ft square

The third large electric house built for the Yerkes system is that at Hawthorne Ave and Hobbie St It is located on the Chicago River about two miles from the business center of the city.

It furnishes current for the North Chicago lines south of North Ave. and to the down town end of the Lake Street Elevated road It is without doubt the best located of the large stations in Chicago. It is on the river so that there is plenty of free water for condensing, and is on a railroad siding so as to get cheap coal It is also near the center of the district it supplies. The station is planned for a capacity of 4,000 h. p. in four units of 800 kw each. Three of these are now in place, leaving the fourth to be installed at some future date. The engines are cross compound condensing horizontal corliss, built by the E. P. Allis Co., of Milwaukee. The cylinder dimensions of these engines are 24 and 46 x 48 in. The speed is 80 r. p. m. The main shafts are 22 in. in diameter and each carries a 50-ton fly-wheel and the armature of an 800-kw generator. The generators are of the 10-pole railway type made by the General Electric Co. They were guaranteed to have 94 per cent efficiency and not to heat to exceed 50 C. above the room. The switchboard is in a gallery; it has 20 panels.

In the boiler room are 10 "Standard" water tube boilers of 350 h. p. each which supply steam at 130 lb. The boilers are all equipped with smokeless furnaces. There are automatic stokers and a complete coal and ash conveying apparatus made by the Link Belt Machinery Co., of Chicago. A hopper holding 5 tons is put over each boiler. The conveying apparatus is arranged so that coal can be taken in or ashes discharged at either end of the boiler room; that is, on the river side or on the switch track side.

The independent Blake condensers are from the Allis works, and a Reynold's feed water heater is operated in connection with them. The cold feed water is first put through these heaters, and then



BOILER ROOM, HOBBIE ST. STATION

through an exhaust heater, which is supplied from the exhaust of the condenser air pumps and boiler feed pumps. A Westinghouse steam loop installed by Westinghouse, Church, Kerr & Co., drains the separators and returns the water to the hot well.

The feed water is taken from the Chicago River, but is filtered before using, so that the heaviest of the sediment is removed There is not, however, as much sediment in the water as it comes

from the river as would seem from the surface appearance, and after being filtered through sand it has nothing more than a slightly milky appearance.

There is a basement under the entire building. The steam main is put under the boiler room next to the engine room wall. This leaves the engine room basement free for the condenser mains and piping. The steam main is drained by Westinghouse steam loops running straight up the wall between the engine and boiler rooms. The building and details are after the general plans of other power houses mentioned.

These electric stations which have just been described, and also those to be mentioned in connection with the Consolidated Traction Co. and the Union Elevated Railroad Co., were all designed and erected under the supervision of Mr. S. Potis, jr., for many years chief engineer of the North and West Chicago roads, and Mr. J. R. Chapman, head of the electrical departments. Both of these gentlemen are well known to the street railway men of the country by reason of their work in Chicago. Mr. Potis left Chicago in 1896 and went to Mexico, where he remained until last spring, when he returned to Chicago and became chief engineer for the Illinois Telephone Construction Co. Mr. Chapman is now at the head of the electrical department of the Chicago Union Traction Co.; his latest power house is that for the Northwestern Elevated; he is also electrical engineer of the Consolidated Traction Co.

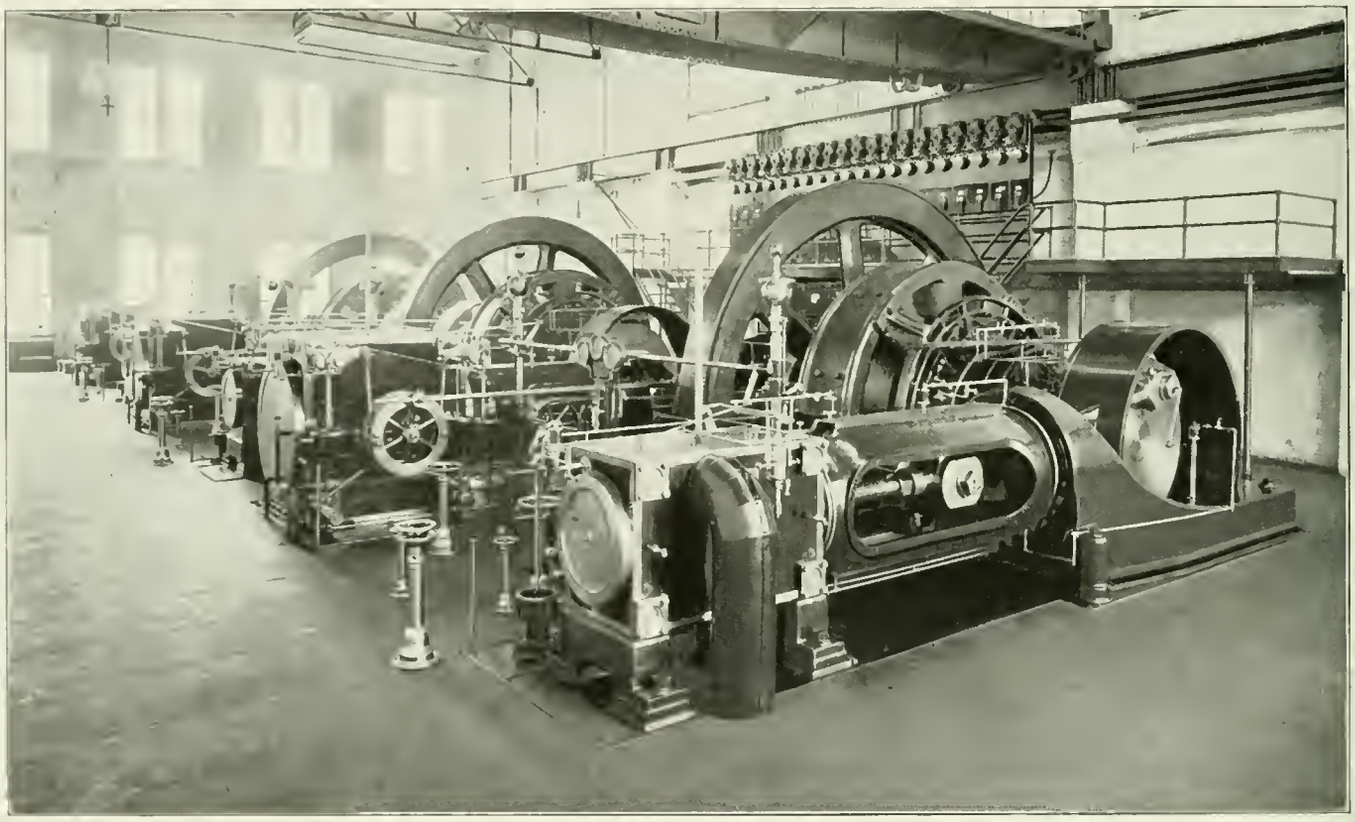
The lines of the Chicago Union Traction Co. comprise 249.68 miles of electric, 47.42 miles of cable and 6.6 miles of horse road, a total of 303.7 miles; of this two-thirds is on the west side.

The company has about 12,000 cast-welded joints in its track; part of which were made by the Falk Co. and part by the American Improved Rail Joint Co. Quite recently the company bought two of the Falk welding outfits and will, as soon as practicable, weld all of its tracks. So much has been said, pro and con, concerning the cast-weld joint as an electrical conductor that we are quite justified in again citing the testimony of Mr. Chapman on this point, published in our issues of January and May, 1898. In January, 1898, Mr. Chapman tested a new joint cast by the American Improved Rail Joint Co. and found that it had 97 per cent of the conductivity of the rail with a current of from 115 to 120 amperes per sq. in. of rail section. In May, 1898, another test was made after two years of service of a joint cast in 1895 by the Falk process; the drop in a 5-ft. length, including the joint with 500 amperes flowing was .048 volt, as against .040 volt for 5 ft. of solid rail; with 730 amperes the drop with the joint was .065 volt, and with 758 amperes without the joint, .069 volt. It is almost needless to say that in view of these tests cast-welded joints are not bonded.

No one standard type of overhead construction is found on the system of the Union Traction Co., different methods being employed in different portions of the city. On a number of the down town streets phosphor bronze wire is used for span work, with No. 0 trolley wire, while in the suburbs a large amount of galvanized steel span wire, with No. 00 trolley wire is found. Anderson insulation is used exclusively, however, and heavy iron poles have been erected throughout, the minimum weight for these being 913 lb.

The West Side car barns and storehouses are as follows: Storeroom for general supplies, Western Ave. and Warren St., two story brick, 125 x 96 ft.; car barn, Campbell and Armitage Aves., two story brick, 400 x 254 ft.; car barn, Division St. and Western Ave., 337 x 258 ft.; car barns, Grand Ave. and N. Leavitt St., two story brick, 295 x 296 ft. and 139 x 120 ft.; car barns, 12th St. and Ogden Ave., two story brick, 270 x 125 ft. and 125 x 235 ft.; car barn, Van Buren and Throop Sts., two story frame, 50 x 120 ft.; car barns, Western Ave. and Harrison St., two story brick, 125 x 296 ft. and 125 x 72 ft.; car barn, Rockwell and Madison Sts., power house, barn space, 120 x 247 ft.; car barn, Blue Island Ave. and Leavitt St., two story, 267 x 203 ft.; car barn, Clybourne Place and Wood St., two and three story brick, 438 x 266 ft.; car barn, Van Buren St. and Kedzie Ave., 234 x 326 ft.; car barn, O'Neill and Halsted Sts., two story brick, 255 x 244 ft.; car barn, Western Ave. and Washington boulevard, two story brick, 365 x 309 ft.; cable barn, West Madison St. and Crawford Ave., one story brick, 322 x 212 ft.; car barn, Lake St. and Park Ave., 114 x 162 ft.

The rolling stock of the West Side lines comprises 1,842 cars, 20 snow sweepers and 40 plows. Of the cars 400 are closed and 316 open motor cars, made by the American and Pullman companies, 258 grip cars, 863 trail cars and 5 mail cars. The grip cars were built by the Brill and American companies, except 50 combination cars, which were built by the Brownell company; the trailers



ENGINE ROOM, HOBBIE ST. STATION, CHICAGO UNION TRACTION CO.—ALLIS ENGINES.

were made by the American and Laclede companies. The motor cars are, for the most part, 21 ft. and 22 ft. bodies, with 4½ ft. platforms. The company has 400 double equipments of G. E. 800 motors and K2 controllers.

The snow sweepers were built by the J. G. Brill Co., each has two G. E. 800 motors for traction and one G. E. 800 for driving the brooms. The snow plows were made in the company's own shops.

The motor cars are mounted on Brill trucks, and the trail cars on American and Bemis trucks.

The minor car equipment includes 900 Lewis & Fowler improved

ENGINE ROOM, 12TH ST. AND BLUE ISLAND AVE.

fare registers, 200 Meaker fare registers, and cable car headlights. The cars on one line have self-oiling trolley wheels.

All the cars, except grip cars, have side bars made in the company's shops; another interesting safety device is the set of springs, invented by Mr. Roach, between the dashers of the grip and trail cars.

The shops of the West Side lines are located at Washington St. and Warren Ave., and comprise a carpenter shop, 332 x 125 ft.; wood working machine shop, 115 x 75 ft.; iron machine shop, 115 x 75 ft.; blacksmith shop, 64 x 32 ft.; brass foundry, 32 x 21 ft.; paint shop, 332 x 159 ft.; store rooms, 56 x 82 ft. and 33 x 52 ft.; office and stock rooms 58 x 33 ft.

The shops are equipped for general car repair and rebuilding work and constitute what are believed to be the largest street railway repair shops in the country, the total floor space under cover being nearly 1,600,000 sq. ft. In the wood machine shop are 3 circular saws, 1 shaper, 1 planer, 1 boring mill, 1 jig saw, 1 band saw, 1 molding machine, 1 router and 1 lathe. In the iron machine shop are 8 lathes, 2 boring mills, 2 drill presses, 3 planers, 2 nut and bolt machines, 1 punch and shear, 7 drills, 2 shapers, 1 wheel press and 1 Q & C rail saw. A large portion of this machinery was furnished by J. A. Fay & Egan.

A 50-h. p. 500-volt Siemens & Halske motor is installed for driving the iron working machinery and a similar motor for the wood shop. In the blacksmith shop are 9 forges, 2 blast furnaces and 2 steam hammers. Fans driven from the machine shop motor furnish air for the forges and furnaces. The brass foundry has four furnaces and here are made all the bearings and brass fittings used on the entire system. The tool room is very compact, and with the convenient checking system in use it is very easy to keep track of all the tools; the tool room is in charge of a man who makes light repairs and also electrical repairs.

All of the shops are lighted by electricity, except the paint shop, where gas is used; all of the buildings are heated by steam. The steam plant comprises four boilers and a 200-h. p. engine, which is not used since the motors have been installed.

Light running repairs are made at the operating car barns, of which there are 10, but all of these sub-stations are supplied with material from the main shops as occasion requires. This shop also makes all the power station machine repairs and supplies the labor and material for car house repairs. The track crossings used are also made here, but not the special work involving curves.

The superintendent of the shop is Mr. F. T. C. Brydges, who has designed a number of special tools and methods which enable work to be handled rapidly with a small force of men. An evidence of the efficiency of the management is the fact that only four men are required to make all the armature and field repairs in the 400 double motor equipment.

Recently the blacksmith shop has been kept busy making fenders. The method adopted for shaping the elements of the fenders is to heat the iron in the blast furnace and bend it around a former, where it is held in place by tongs till cool. Two men do this work very rapidly.

On the North Side there are six operating car barns and four storage barns. The operating barns are as follows: Clark St. and Sherman Place, Lincoln and Wrightwood Aves., Clybourn Ave. and Cooper St., Larrabee and Center Sts., Graceland and Southport Aves., Kroger and Center Sts. The storage barns are located at Center and Racine Sts., Sedgwick and Menominee, Belden and Racine and at the Clybourn Ave. station.

At the Larrabee St. barns is a gas plant, where the company makes the gas used for lighting its cable cars on the Pintsch system.

There are two repair shops, one at Fullerton and Sheffield Aves., occupying two buildings 246 x 150 ft. and 48 x 120 ft., and one near the Clark St. "Limits" station, at Clark St. and Dewey Court. The latter is the machine and iron working shop, where truck and motor repairs for the entire system are made. It is well equipped with the machine tools ordinarily found in shops, and in addition there are a number of special tools designed by Mr. V. T. Lynch, who has the supervision of this shop. Among these tools may be mentioned those for cutting and drilling gears and pinions, which are all made in this shop, and the key seating machine; these machines were illustrated in the "Review" for August, 1897. Visitors to these shops will also be interested in the cranes used for lifting motors from cars on the transfer tables. The equipment of these shops comprises: 6 drill presses, 1 planer, 6 lathes, 1 pattern lathe, 1 bolt machine, 1 milling machine, 1 shaper, 1 band saw, 2 gear cutting machines, 1 key seater, 1 armature testing machine for G. E. 800 motors, 1 7 x 12-in. air compressor, 1 fan, grindstones, emery wheels, etc. Much of this machinery as well as that in the wood shop was furnished by Fay & Co. The gear cutters, key seater and air compressor were made in the shop. The machinery is driven by electric motors.

The Fullerton Ave. shops comprise three buildings equipped with machinery for general carpenter work and car building; paint

BOILER ROOM, 12TH ST. AND BLUE ISLAND AVE.

shops and car washing and storage rooms occupy the lower floor of one building and the second stories of two. There is also a machine shop. The equipment comprises: 2 planers, 1 shaper, 1 band saw, 1 self-feed rip saw, 1 molder, 1 tenoning machine, 1 mortising machine, 1 cut-off saw, 1 double saw table in the wood shop; 4 lathes, 1 boring mill, 1 car wheel borer, 1 shaper, 1 bolt cutter, 3 drill presses, punch and shears, emery grinders, and air compresser in the machine shop; a complete outfit of tinsmith's tools in the tinshop; 3 forges and tools in the blacksmith shop and 2 furnaces in the molding room. There are four electric motors for driving the machinery; one 50-h. p. in the wood shop, one 40-h. p.

JAMES H. ECKLES,
Treasurer.

F. E. SMITH,
Auditor.

J. C. MOORE,
Secretary.

J. R. CHAPMAN,
Electrical Engineer.

in the machine shop, one 20-h. p. for the car elevator and one 1-h. p. for the blower.

The North Side lines have an equipment of 900 cars made by the Brownell, Stephenson, American, Wells & French and Pullman companies. There are 140 closed motor cars mounted on Brill and Peckham trucks and equipped with two G. E. 800 motors; 130 open motor cars mounted on Brill trucks with two G. E. 800 motors; 80 grip cars and 550 trail cars. The controllers used on the motor cars are the General Electric K2 and K11. Meaker fare registers are used.

There are some interesting pieces of special work to be found in the lines of the Union Traction, among which may be mentioned the double track acute angle crossing at Halsted and Clark St., which was built by the Johnson Co., and the loop at the "Limits" station, which was put in by the Paige Iron Works. At the corner of Washington and Jefferson Sts., two cable routes using the Washington St. tunnel diverge, and a switch operated by compressed air is installed; a single movement of a lever in the switch tower throws both the rail switch and the cable switch; this switch was built in 1890 by Wm. Wharton, Jr. & Co.; the compressor is driven from a shaft in the cable vault.

Jesse Spalding, who was chosen president of the Chicago Union Traction Co., in July, 1899, was born in Bradford County, Pa., April 15, 1837. His early life was spent in the lumber trade, first in rafting logs, then in buying timber for his employers, and finally in buying and shipping for himself. He was very successful in this business, soon acquiring considerable capital, which he invested in the formation of various lumber syndicates and navigation companies. In the counsels of the Republican party, Mr. Spalding has always taken a prominent part, and has several times been a candidate on the Republican ticket. He has also been closely connected with the mercantile and social interests of Chicago, is a director in the Commercial National, Garden City and Hibernian banks, and president of the Spalding Lumber Co.

John M. Roach, who has been the right-hand man of Mr. Yerkes in his many Chicago railway enterprises, needs no introduction to the street railway fraternity. For over a quarter of a century he has been associated with railway interests in Chicago, advancing rapidly from one position of trust to higher ones, until now he fills the office of manager of one of the largest and best developed systems in the country. He commenced his career in 1872, as a conductor on the North Chicago City Ry., but his ambition and ability allowed him to stay in this lowly position but a short time. His qualities were recognized at once by his superiors, and he was rapidly advanced to cashier, purchasing agent, superintendent and finally general manager. He has retained this office through all the change of administration, and as new extensions were built and new lines taken in by consolidation, they were at once put under his charge. He is now general manager of the Chicago Union Traction Co., and president of the Suburban Railroad Co.

Geo. A. Yuille, assistant general manager of the Chicago Union Traction system is a native of Wisconsin, born in 1861. He has been a resident of Chicago for 18 years, and associated with the West Side street railway lines since January, 1894.

F. E. Smith, auditor of the Chicago Union Traction Co., was born at Norwalk, Conn., Mar. 15, 1857. His first railroad experience was as chief clerk at the local freight station of the New York & New England R. R. at New Britain, Conn., in 1882. He afterwards filled positions as contracting agent of the Union Pacific Ry. in the Boston office; as auditor of the Connoton Valley Railway Co. at Canton, O.; as chief clerk in the auditor's office of the Cleveland, Akron & Columbus Ry. at Akron, O., and as auditor of the Zanesville & Ohio River Ry. at Zanesville, O. On May 1, 1894, he was appointed auditor of the Lynn & Boston Railroad Co., which position he occupied until this property was taken over by the Massachusetts Electric Companies. June 1st of this year he was appointed auditor of the Massachusetts Electric Companies, which position he resigned July 1st to accept his present duties. Mr. Smith was one of the prominent organizers of the Accountants' Association, and holds the office of 3d vice-president in that organization.

James R. Chapman, was born and educated in Boston, Mass. In 1872, having taken a course in civil engineering, he commenced his practical work, as rodman on the Portland & Ogdensburg R. R. He followed steam railroad construction for 16 years, but in 1888 went to Kansas City, and became interested in street railway work; in 1891 he went to Grand Rapids, Mich., to superintend the changing of the cable and horse lines to electricity. Mr. Chapman's Chicago career began in 1894 and since that date he has been very closely identified with the development of the transportation systems of the city, as chief engineer not only for the North and West Side surface lines, but also for three of the elevated roads. The electrical equipment of all these lines was installed under his supervision. He is now electrical engineer for the Chicago Union Traction Co., the Suburban Railroad Co., the Lake Street Elevated, the Union Elevated and the Northwestern Elevated.

MOUTH OF CHICAGO RIVER.

Chicago Consolidated Traction Co.

In developing the transportation systems of Chicago Mr. Yerkes found it convenient to prosecute the work by organizing a number of suburban companies. Eight of these companies were consolidated in February, 1899, and the properties are now operated by the Chicago Consolidated Traction Co. This company was chartered Jan. 28, 1899.

The companies thus consolidated have an aggregate of 203.97 miles of track and are:

The Cicero & Proviso Street Railway Co., chartered Feb. 15, 1899, which operated lines in the towns of Cicero and Proviso, connect

CHARLES T. YERKES,
President Chicago Consolidated Traction and Union Elevated Railroad Cos.

ing with the West Chicago at West 40th and Madison Sts., and also had lines on Lake St., Fifth Ave., Chicago Ave. and other streets in Chicago; this company had about 50 miles of track.

The Chicago & Jefferson Urban Transit Co., chartered Oct. 8, 1890, which owned lines from Canal and Monroe Sts. (just west of the river) to Fulton St. and Western Ave., and on Chicago Ave., between Kedzie and Crawford Aves., making in all 7.7 miles of track; this road went into operation March, 1896.

The Chicago North Shore Street Railway Co., chartered Apr. 15, 1891, to build a line from Chicago to Evanston; it owns 17 miles of track. The property was leased in October, 1894, to the North Chicago Electric Railway Co., the road was opened for traffic June 10, 1894, and connects with the North Side cable lines.

The Ogden Street Railway Co., incorporated Oct. 1, 1891, which operated 15 miles of track in the western part of the city connecting with the West Chicago at Madison and West 40th Sts., and Ogden Ave. and West 40th; this company had 36 miles of track.

The Chicago Electric Transit Co., chartered Apr. 26, 1893, and opened for traffic Dec. 26, 1894; this company owned 37 miles of single track electric lines in the northwestern part of the city.

The North Chicago Electric Street Railway Co., incorporated June 19, 1893, which had about 42.5 miles of track in the northwestern portion of the city. As stated, this company leased the Chicago & North Shore property.

The Evanston Electric Railway Co., incorporated Oct. 1895, which owned 2.75 miles of track in Evanston.

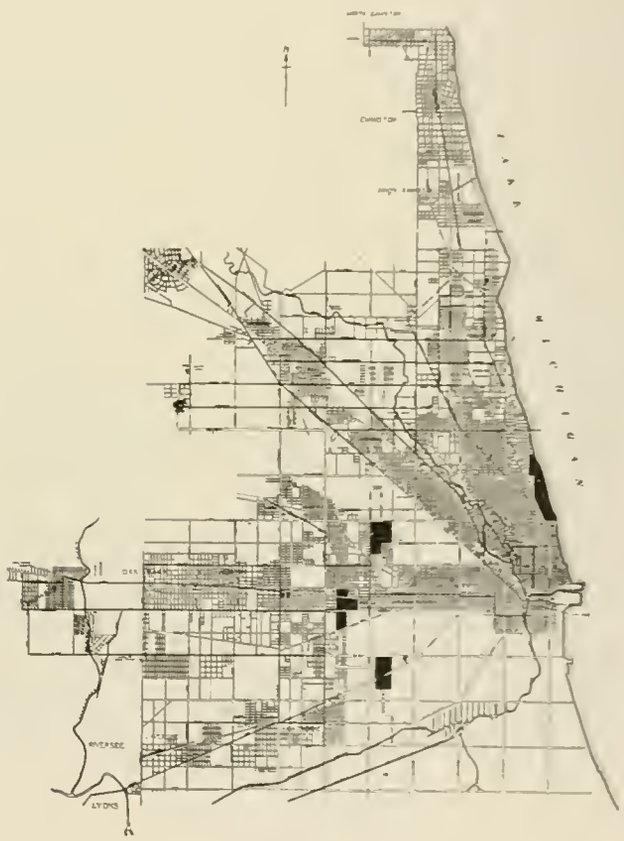
The North Side Electric Street Railway Co., incorporated Feb. 28, 1894, and began operating Jan. 16, 1896, which had 7.63 miles of track extending northwest near the Chicago River, from Kinzie St. to Clybourn Place.

The power houses of this company are three in number, the largest being the California Ave. plant at California Ave. and Roscoe Boulevard. This station was the first of the three large Yerkes electric power houses to be completed; work on it was begun in June, 1894, and current supplied to some of the North Side lines by January, 1895. This plant is 7½ miles from the heart of the city and supplies all the lines in the northwest portion of the territory covered, down to within three miles of the down town district. It was built by the Chicago Electric Transit Co., one of the subsidiary Yerkes companies, but now may be considered as belonging to the Consolidated Traction. It is the first direct connected electric railway plant built in Chicago. The building is a handsome brick structure, trimmed with stone and is fireproof. The roof is of corrugated iron; the boiler room is of concrete carried on brick arches and the engine room floor is of steel plates.

The main dimensions are 245 x 122½ ft., and it is 36 ft. from floor to eaves. Half the building is boiler room and the other half engine room, making the dimensions of each 245 x 61 ft. Originally there were four 1,000-h. p. direct connected engines. A 1,200-h. p. compound engine was removed from the power station of the Chicago North Shore road in 1898 and is now in this station, making five engines. There is room for one more unit.

The building has a basement 10 ft. deep under the entire floor, that under the engine room being taken up by pipes, wires and condensers, and that under the boilers receiving the ashes. The steam plant consists of ten 300 h. p. water tube boilers and these are equipped with 20 smokeless furnaces. In connection with the furnaces there are storage bins, conveyors and chutes, which deliver the coal into the furnace magazines from which it is fed automatically into grates, and the furnaces are so arranged that the ash and clinker is sifted and ground automatically into the ash pits which also are fitted with conveyors, so the process of supplying the coal feeding the furnaces and cleaning out the ash and clinkers is constantly going on automatically.

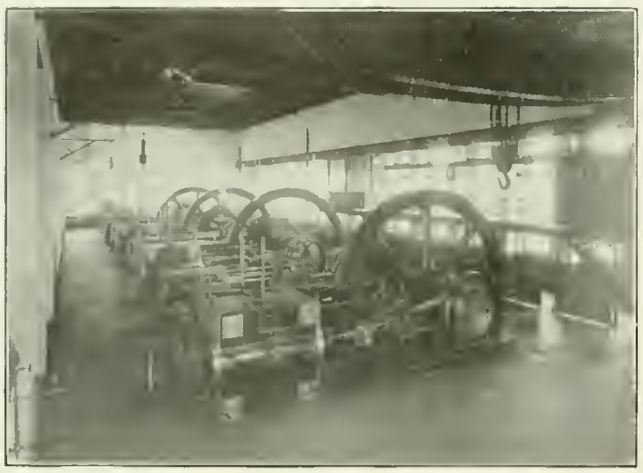
The coal conveying system was put in by the Borden & Selleck Co. of Chicago and is the first plant of the kind in the west. In connection with this a 2,000-ton coal storage house, 200 x 20 ft. and



LINES OF THE CHICAGO CONSOLIDATED TRACTION CO.

20 ft. high is built some distance back of the parallel with the boiler room. Each wagon of coal is weighed on entering the yard and is then driven to one corner of the coal storage house. Here arrangements are made for dumping it. The load when dumped takes one of two courses. It either is raised and distributed by conveyors along the length of the storage, or it is raised 20 ft. and taken across the alley and distributed in bins above the furnaces. From the

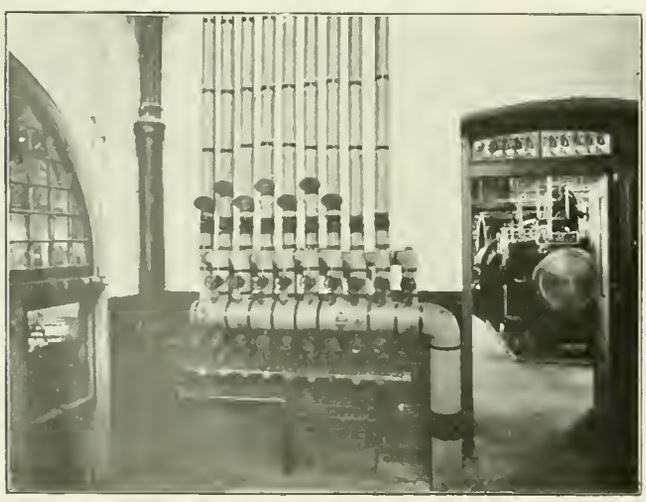
latter place it is fed by chutes to the furnaces. These bins have 400 tons capacity. Of course arrangements are made for conveying from the storage to the boiler room bins. The whole set of conveyors is run by a 40-h. p. electric motor. The capacity of the conveying system is 40 tons per hour. The Harrison noiseless conveyor is used.



ENGINE ROOM, CALIFORNIA AVE. STATION.

An oil burning equipment is also provided and there are tanks for storing 1,000 gallons of oil. To feed the boilers Admirality feed pumps are supplemented with Metropolitan injectors and exhaust feed water heaters. All steam piping is under the floor and 17 Westinghouse steam loops installed by Westinghouse, Church, Kerr & Co. act as separators, and return to the boilers water condensed in the steam piping. One of the illustrations shows the loop at the Cicero & Proviso station.

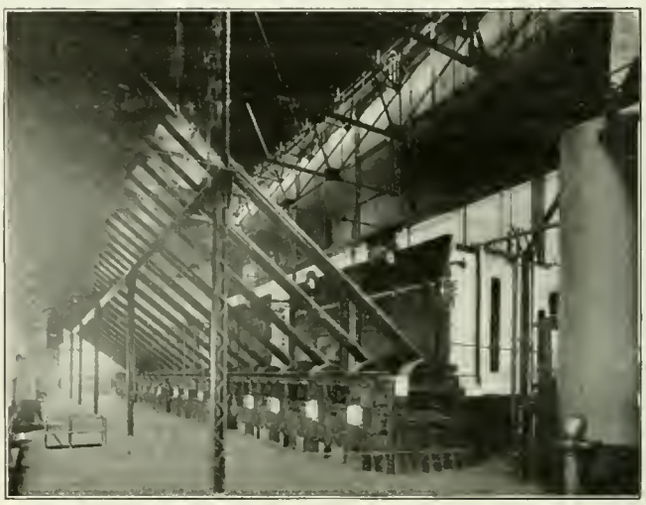
The station is located on the Chicago River and jet condensers are employed. There are four 1,000-h. p. cross compound condensing engines with 24 and 40 by 48 in. cylinders. They are direct connected to Siemens & Halske generators. The armatures of these machines revolve outside the fields. The weight of the armatures is 12 tons. The fly-wheel is 20 ft. in diameter. The piping is, of course, arranged to run the engines condensing or non-condensing and to run high pressure in both engine cylinders in emergency



WESTINGHOUSE STEAM LOOP MANIFOLD, CICERO & PROVISO STATION.

cases. The stack is 14 ft. square inside and 200 ft. high. As the Chicago River is a navigable stream at this point the feeders running east had to be put through a tunnel under the river. The tunnel is 12 ft. high, 6 ft. wide and 289 ft. long, the feeders entering it through the vertical shafts at each end. Feeders going south and west leave the station on very heavy overhead lines. The switchboard panels are the General Electric standard railway type. The generator board is on the main floor, and the feeder board of 40

Compressed air is also used for cleaning armatures and switchboard panels on a gallery. A 20-ton Walker hand power crane travels the length of the engine room. An automatic air pressure oiling system furnished by Wilson, Whiting & Davis, of New York, is used whereby the oil is forced to the bearings on the various machines by compressed air. One valve controls all the oil cups on a unit.



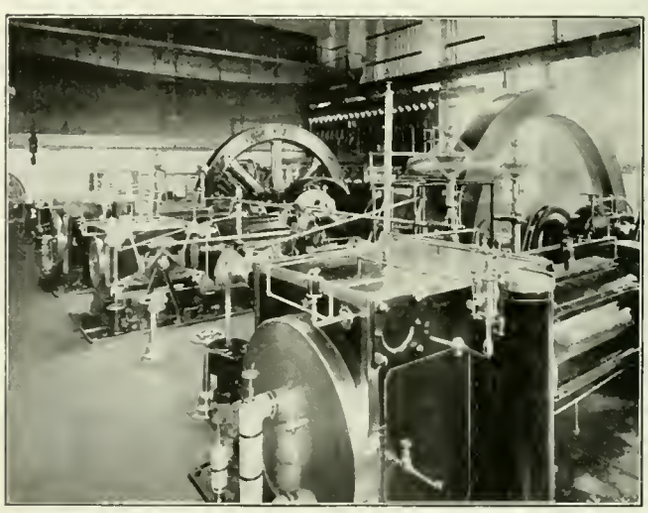
BOILER ROOM, CALIFORNIA AVE. STATION.

Air pumps made by the Crane Co. of Chicago furnish the supply.

The Cicero & Proviso station on the corner of Lake St. and Harvey Ave., midway between Austin and Oak Park was originally built in 1890 and was equipped with one 250-h. p. high speed engine and one 250-h. p. corliss belted to four 80-kw. dynamos; afterwards a 500-h. p. Corliss engine and two 200-kw. generators were added. This plant was soon outgrown and in 1894 a new building was erected adjoining the old one, and the latter no longer used. This station was built for an ultimate capacity of 5,000-h. p. There are now two 1,000-h. p. Allis compound engines with cylinders 24 and 40 x 48 in. These are each direct conected to 750-kw. Siemens-Halske generators.

There are eight 300-h. p. boilers set with smokeless furnaces. Feed water heaters are used.

The power house of what was formerly the Chicago North Shore



ENGINE ROOM, CICERO & PROVISO STATION.

road is located at Edgewater and was built in 1892. Originally three simple engines were installed; one of 600 h. p. with cylinder 24 x 30 in. running at 110 r. p. m. with steam at 80 lb., connected by a rope drive to a 300-kw. four-pole generator, and two 400-h. p. engines connected to one shaft on which is mounted a fly-wheel with rope drives to two 300-kw. generators. In 1896 a 1,200-h. p. compound engine with cylinders 24 and 48 x 48 in. was added, but in 1898 this unit was removed to the California Ave. station. This

engine is direct connected to a 12 pole Siemens-Halske generator.

The boiler room at this station has four water tube boilers. The boilers are fitted for using either coal or oil as fuel; which is used is governed by the market.

The outside dimensions of this building are 150 x 220 ft., the south portion of it is divided into two large rooms for the storage of cars. This station is now operated only on heavy days or in emergencies.

The track and overhead work of these lines, being under the direction of the same men is similar to that of electric lines of the Union Traction. The company has recently bought a cast-welding outfit from the Falk Co. and will weld all of its track.

The officers of the Chicago Consolidated Traction Co. are: President, Charles T. Yerkes; vice-president, L. S. Owsley; secretary and treasurer, Charles F. Marlow.

Charles T. Yerkes, who is perhaps, entitled to be called the foremost street railway financier of the world, was born in Philadelphia, June 25, 1837, of Quaker parents, and his early life was spent in that city under Quaker influences. Until 1881, he devoted his energies exclusively to a banking and brokerage business, but at that time, having opened a branch of his Philadelphia banking establishment in Chicago, he conceived the idea of gaining control of the street railway transportation systems of the latter city, the possibilities of improvement and extension appealing to him with irrestible force. In 1886 he succeeded in gaining control of the North Side lines and reorganized the company as the North Chicago Street Railroad Co. In spite of powerful opposition he carried out his plans for changing the motive power from horse to cable and also gained permission to use the—until then—almost useless La Salle St. tunnel, which he rebuilt to conform to the requirements of his cable system. Two years later he obtained control of the west side lines. Next came the substitution of cable and electricity for the horse on all trunk lines and the extension of lines out across the prairies. After these lines had all been completed and perfected, Mr. Yerkes still sought new fields to conquer, and turned his attention to the elevated roads. His fight for the elevated loop, which has given the residents of Chicago the finest service of the kind in the world, is unique in transportation annals. And these achievements are all the more remarkable when it is remembered that there is probably not a man in Chicago who has been so much maligned and opposed by the press and hindered in his work by political schemers as Mr. Yerkes. Hardly one of his projects for the improvement of the street railway facilities of the city has been allowed to go through without a storm of protest from press and public. Yet through all this Mr. Yerkes has maintained a dignified and unshaken position, quietly carrying his plans through, in spite of obstacles, and he now has the satisfaction of knowing that Chicago is beginning to realize what he has done for the city.

Charles F. Marlow, secretary and treasurer of the Chicago Consolidated Traction Co. and treasurer of the Suburban Railroad Co., was born in Philadelphia Jan. 15, 1864. In September, 1896, he came to Chicago, becoming associated upon his arrival with the Siemens-Halske Electric Co. as assistant secretary and treasurer. In December, 1898, he resigned to become auditor of the Yerkes system of surface and elevated lines, taking his present position with the Consolidated in February last when the consolidation of the various companies was effected. Prior to coming to this city Mr. Marlow had been for a number of years in the freight claim department of the Pennsylvania system at Philadelphia. In July last, owing to the resignation of Mr. L. S. Owsley as treasurer of the Suburban Railroad Co., he succeeded that gentleman.

L. S. OWSLEY,
Vice-President.

C. F. MARLOW,
Secretary and Treasurer.

Chicago General Railway Co.

The Chicago General Railway Co., was incorporated Oct. 21, 1893, under the general railroad law of Illinois and soon thereafter leased all the property of the West & South Towns Street Railway Co., which had been incorporated by the same parties Aug. 22, 1891, as the West & South Towns Horse Railway Co., under the horse and dummy law. In May, 1897, the two companies were formally consolidated.

The General Ry. at the present time owns 26½ miles of track (measured as single track), including the right, under leases, to operate its cars over the East 22d St. lines of the Chicago City Ry. and also the Stock Yards line south of Archer Ave.

The power plant, car house and shops are at 30th St. and Kedzie Ave.; the yards and buildings cover 6 2-3 acres and the buildings were all designed with the idea of providing for future as well as the present requirements. In the power house are two 400-kw. General Electric generators, Bates engines aggregating 1,200 h. p., boilers of 1,200 nominal h. p.

The rolling stock comprises 30 motor cars and 2 horse cars; of these 20 are mounted on single and 10 on double Peckham trucks. The company has 25 double equipments of 50-h. p. General Electric motors.

This company recently introduced a graded fare system by selling 12 rides for 25 cents on branch lines without transfer and 6 rides for 25 cents on all lines with transfer, the single fare being 5 cents.

The officers and operating staff of the company are: President, J. H. Witbeck; vice-president, Chas. L. Bonney; secretary, J. I. Jones; treasurer, Lawton C. Bonney; purchasing agent, C. L. Hull; electrician, Geo. W. Botham; engineer, John W. Ewald.

C. L. BONNEY,
Vice-President.

L. C. BONNEY,
Treasurer.

J. I. JONES,
Secretary.

Calumet Electric Street Railway Co.

The Calumet Electric Street Ry. is one of the most promising street railway properties in the country, as it covers a very large area in a portion of the city that is rapidly increasing in population. While we have classed the Calumet as an interurban line, out of compliment to Pullman, West Pullman, Washington Heights, South Chicago and the 24 other towns which it connects with 63d St., Chicago, nearly all the territory served by the road is within the present city limits of Chicago, except the town of Roby, Ind. The road may properly be called an interstate line.

The company was incorporated May 17, 1890, the organizers being N. K. Fairbanks, J. D. Harvey, Samuel E. Gross, W. V. Jacobs and O. S. Gaither, and acquired franchises for the principal streets south of 63d St. A great deal of construction work was done between 1892 and 1895, and the necessary bond issues were carried by the National Bank of Illinois, which at the time of its failure in December, 1896, held nearly all the outstanding obligations of the Calumet company. In April, 1897, John C. McKeon, receiver of the bank, was appointed receiver of the Calumet; in January, 1898, Mr. McKeon resigned both positions, and was succeeded by Gen. John McNulta, in whose hands the road now is.

The road has 80 miles of single track and leases three miles from the Chicago Electric Traction Co.; the territory covered is 65 square miles. It has 137 motor cars and 85 trail cars built by the American, Pullman, Lamokin and St. Louis car companies, 90 double motor equipments, G. E., T. H., Steel and Detroit, and 175 McGuire and 5 Peckham trucks; the minor car equipment includes New Haven double fare registers. For handling snow the company has a Brill plow and a McGuire sweeper.

The power house at 93d St. and Drexel Ave., has a capacity of 1,500 kw. The equipment comprises one Buckeye compound condensing engine direct connected to a General Electric 500-kw. generator and four Ball compound condensing engines belted to Walker 250-kw. machines. One of these machines is utilized as a booster when needed. The boilers comprise eight water tube boilers, five equipped with mechanical stokers and three with shaking grates.

For cooling condensing water for re-use there is a reservoir 80 x 200 ft. and 6½ ft. deep with wooden cooling tables, giving an area of about 25,000 sq. ft.

On property contiguous to the power house are three car barns which, with sheds adjoining, have capacity for all the cars. At the rear of one of the large barns is the repair shop with nine tracks.

The road connects with the South Side Elevated and the Chicago City lines at three points on 63d St. At one of these, Stony Island Ave., a large and handsome terminal station equipped with elevators for transportating passengers to the elevated road has been erected.

The officers and staff are: Receiver, John McNulta; president, John Farson; general manager, H. M. Sloan; secretary, H. B. White; auditor, E. H. Harrison; engineer, G. H. Binkley; master mechanic, W. A. Harding.

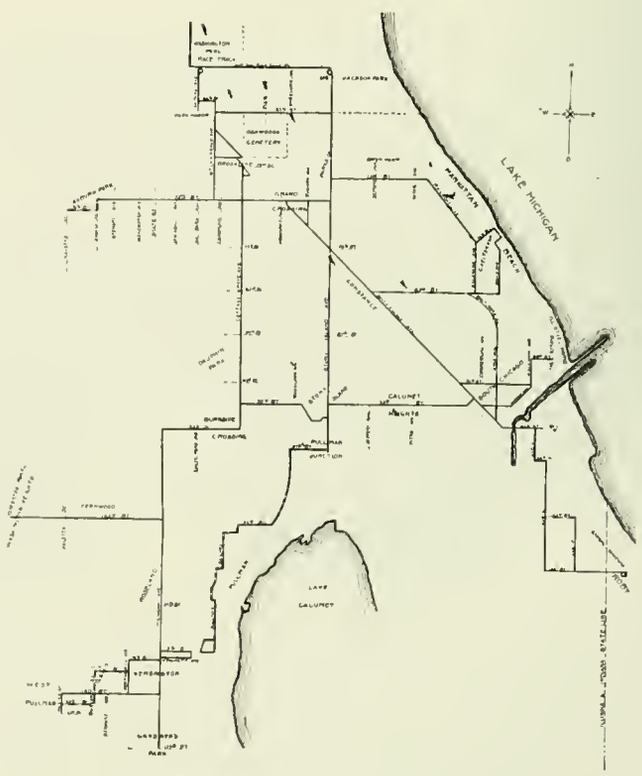
John Farson, president of the Calumet Street Railway Co., was born in Union City, Ind., Oct. 8, 1855. He went to Chicago in 1877 and studied law; was admitted to the bar in 1880, but soon gave up his practice and entered the banking business, accepting a place with Preston, Kean & Co. Mr. Farson remained with this firm until 1889, when he organized the firm of Farson, Leach & Co., of which he is now the head. He is a member of the Chicago Board of Trade and Stock Exchange, and a director and member of a number of prominent social and educational clubs.

H. M. Sloan, general manager of the Calumet Electric Street Ry., was born in 1857, at Pemberton, N. J., but his parents moved to Philadelphia when he was a child. He attended public schools until he was 18 years of age and afterward attended and was graduated from a Quaker seminary at Philadelphia. After graduating he entered the mill business, but in 1883, went west to Montana and engaged in cattle raising; while living in that state, he was elected to the legislature. In 1888 he went to St. Paul, accepting a position as inspector of cable road construction, and after this work was completed, he was made first foreman of cable lines, then assistant superintendent and then superintendent, which position he held when the road was equipped with electricity. Mr. Sloan left St. Paul when the systems in St. Paul and Minneapolis were consolidated and accepted an office with the street railway company at

JOHN FARSON,
President.

H. M. SLOAN,
General Manager.

W. A. HARDING,
Master Mechanic.



CALUMET ELECTRIC STREET RAILWAY.

West Superior, Wis., continuing this connection for 18 months, when in September, 1895, he became general manager of the Calumet Electric Street Railway Co.

William A. Harding was born in Bristol, England, in 1864, and was educated as a mechanical and electrical engineer in London. In 1882 he came to America and went into business in the Northwest Territory of Canada, in partnership with his father. A few years later he went to the Pacific Coast and engaged in electrical engineering work. In 1890 he became master mechanic and electrical engineer of the Calumet Electric Street Ry.

Suburban Railroad Co.

The Suburban Railroad is another of Mr. Yerkes' roads, a controlling interest having been acquired by him in July, 1897. The company was organized May 8, 1895, and a contract made with a specially organized construction company for building the road. Financial difficulties prevented the execution of this contract and the work was let to Naugle, Holcomb & Co., of Chicago, in November, 1896; this firm completed the construction of 17 miles of double track in July, 1897, and in the same month it was secured by the Yerkes' interests.

The company leased for 50 years from the Chicago & Northern Pacific R. R. 9 miles of double and 5¾ miles of single track and from the Wisconsin Central 1.7 miles of single track, which gives it two routes from the city west to the Desplaines River, and a line from the western terminal of the elevated roads southwest to the town of La Grange. A portion of the leased lines was equipped for electric traction and the company now operates 56 miles.

The future of this company is very promising, there being a population of about 200,000 people within easy reach of the road; there are three large cemeteries and a number of picnic grounds on the lines which further greatly increase the traffic. Power is supplied by one of the power houses of the Chicago Consolidated Traction Co. The company's own power house, which is not used at the present time, however, is at Harlem Ave. and 22d St.; the equipment of this station includes three 250-h. p. Stirling boilers, carrying steam at 125 lb., and two tandem compound condensing engines, 17½ and 33 by 48 in., and 12 and 22 by 48 in., direct connected to Walker generators of 250 kw. and 400 kw. capacity, respectively. The boilers are fitted with Mesner stokers. Deane jet condensors and pumps are used.

This station is the second street railway power plant at which a reservoir and cooling tables were installed to enable the condensing water to be used over and over again. The reservoir is 100 x 200 ft. and provides, including the tables, 36,500 sq. ft. of cooling surface. The water for the station is drawn from an 8-in. well, 185 ft. deep by a Pohle air lift; this is motor driven. The car house is near the power station and is a brick building 114 x 124 ft., with 10 tracks; at one end are the repair shops.

All of the new track was laid with 7 in. 70 lb. T rails in 60 ft lengths; cedar ties were used on tangents and oak ties on the curves. Much of the track is paved between the rails with cedar blocks, though it runs through open country. The trolley wires are No. 00 furnished by Washburn & Moen; the insulators, cars, etc., are all of the Ohio Brass Co. make.

The rolling stock of this road consists of 14 motor and 10 trail cars made by the Pullman company. The motor cars are 42 ft. 6 in. long, with closed vestibules at each end; the trailers are of the same dimensions, but not vestibuled. Each car has 24 double seats of the Hale & Kilburn walk-over pattern, spring-edged and rattan covered. The Gold hot water heaters are used.

The cars are mounted on McGuire No. 26 trucks with 5 ft. 6 in. wheel base, and 23 ft. between centers. The motors are Walker 50-h. p. one to each truck; the motors drive the forward axle of the forward truck and the rear axle of the rear truck. Each car has two trolley poles, the rear one only being used. The cars are equipped with air brakes and air compressors made by the Christensen Engineering Co., of Milwaukee; part are motor driven and part axle driven compressors.

C. S. LEEDS.
Secretary.

The officers of the Suburban Railroad Co. are: President, John M. Roach; secretary, C. S. Leeds; treasurer, C. F. Marlow; superintendent, J. J. Linden.

Chicago Electric Traction Co.

The Chicago Electric Traction Co. is the successor to the Englewood & Chicago Electric Railway Co., which was incorporated Jan. 11, 1893. In 1894 the company built about 1⅝ miles of track in 63d and 67th Sts., and connecting avenues, which is used jointly by the Calumet under a lease. Control of the bonds issued by the company was acquired by parties interested in the Electric Storage Battery Co., of Philadelphia, with the understanding that storage battery cars would be used. Nearly all the tributary territory is sparsely settled and the company became insolvent, and in January, 1897, G. Herbert Condiet, who had charge of the construction work, and later was general manager, was appointed receiver. The receiver operated the road until Oct. 12, 1897, when it was sold to J. S. Bache for $260,000; a reorganization was then effected under the name Chicago Electric Traction Co.

The company has 29½ miles of track, extending from South Park Ave. and 63d St., where it connects with the South Side Elevated and the Chicago City roads, south to Englewood, Washington Heights, Blue Island and Harvey, and a branch runs west from Morgan Ave. through to Morgan Park. There are several summer resorts and three cemeteries on the lines; a large summer traffic results from the former, and for the latter a special funeral car is operated. On the Morgan Park line is a grade of 9.3 per cent for 371 ft., and as this could not be surmounted with a 50-h. p. motor geared to one axle only, a Bronsdon counter weight system was installed similar to those at Providence and St. Paul, which have been described in the "Review."

The track was built by C. E. Loss & Co., and is of the very best construction, as this was essential to long life of the battery plates. The rails are 7-in. 80-lb. Johnson girders, laid on oak ties spaced 2 ft. c. to c. Tie plates are used; the joints are made with 6-bolt fish plates and a tie-rod is placed at every joint.

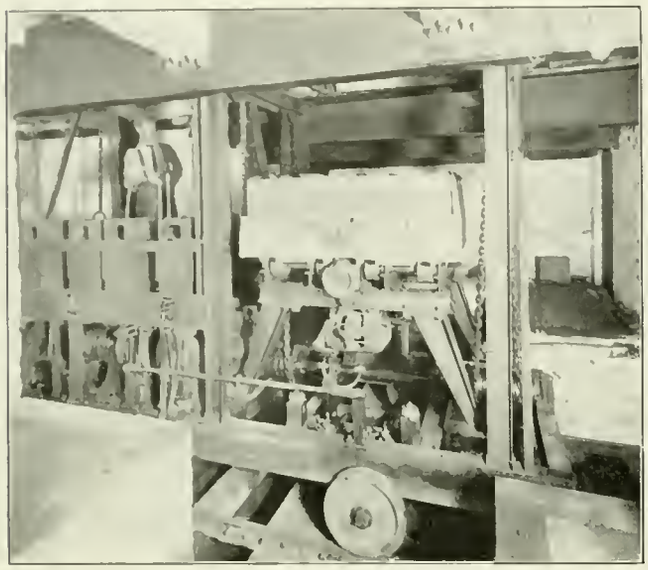
The rolling stock comprises 50 motor cars and 26 trailers, built by the St. Louis Car Co., and mounted on du Pont trucks, made by the Lorain Steel Co. Each motor car carries a battery tray containing 72 cells, 8 x 5 in. and 18 in. high; the batteries weigh 3½ tons, and can deliver 400 ampere at 150 volts. There is one 50-h. p. Walker motor suspended on the outside of the car axle.

The power station and car house are at 88th St. and Vincennes Road; this is convenient to the Rock Island tracks, over which coal is delivered to the station.

The car house first built is of brick, 175 x 102 ft., and at the front end is two stories high, the offices being on the second floor. Last summer a new car house of iron and steel construction, 100 x 100 ft., was built in the rear of the old one. The power station adjoins the brick car house, and is 73 ft long; the engine room extends across the front side of the building, and is 30 ft. wide; the boiler room back of it is 37 ft. wide.

The plant differs from other street railway stations in that the generators are not all of the same voltage, as it is necessary to have three circuits of different potential to charge the batteries properly. Four 6-pole, 190-kw. shunt wound Walker generators, with a variable voltage between 160 and 190 were installed. This

is the ultimate dynamo capacity of the station, the fourth machine being held in reserve. The dynamos are direct connected to two 250-h. p. Willans engines, built by the Bullock Manufacturing Co. These two engines are at either end of the room, and the design contemplated a third one, of 500 h. p. in the center. To give the most flexible arrangement the Arnold system, invented by Bion J.



BATTERY ELEVATOR.

Arnold, president of the Arnold Electric Power Station Co., was adopted. A solid shaft with couplings extends from one engine to the other. The armatures of the generators are fixed to quills, which are free to rotate about the solid shaft. This makes a very complete and compact engine generator installation, a 1,000-h. p. plant occupying a floor space only 12 x 50 ft. Each engine has two sets of cylinders, the cranks being at 180 degrees. The steam, entering the high pressure cylinder, from the steam chest, expands through the hollow piston rod into the receiver space below, ready to act on the following piston. An air cushion takes up the momentum of the moving parts and permits a speed of 380 r. p. m. without excessive noise or vibration. The speed is regulated by a throttle valve in the steam pipe controlled by a centrifugal shaft governor.

Just to the rear of the power units is the white marble switchboard, consisting of five panels, one for each generator and the

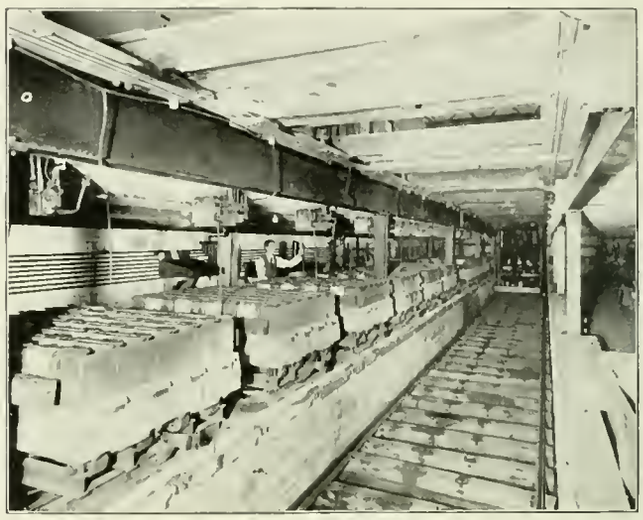
E. R. GILBERT,
General Manager.

A. E. DAVIES.
Superintendent.

fifth for the motor and auxiliary switches. There are four bus bars, the three lower ones being for the high, medium and low voltages and the top one the common negative bar.

Each panel has two switches, one for the negative lead of the generator after it has passed through a recording ammeter and circuit breaker, and the other switch can be turned through a semicircle making connection with any of the three positive bus bars. Weston illuminated dial ammeter and voltmeter and a resistance box for controlling the voltage are attached to each generator panel.

In the boiler room are three 200-h. p. Heine boilers fitted with Roney stokers; there is room for three more. A Green economizer with 102 tubes is installed. A Worthington cooling tower 12 ft. in diameter and 30 ft. high is located near the stack; in warm weather a large fan driven by a Siemens-Halske motor is operated in connection with the tower.



CHARGING TABLES.

One of the most interesting features of this road is the method of handling the car batteries. The charging tables are located in the basement of the car house; a traveling carriage with an elevator at each end runs in an alley way between the two charging tables. The elevators, the carriage and the shifting rolls for moving the battery trays about are driven by electric motors and the whole operation of removing a discharged battery and placing a fresh one under a car can be done in 50 seconds.

Each battery cell has nine plates 7¾ in. wide by 14⅜ in. long; five of these are negative of the "Chloride type, ¼ in. thick, and four positive of the "Tudor" or "Manchester" type 5-16 in. thick. The battery tray is covered by a loose fitting rubber crate, which prevents the electrolyte from splashing out of the jars. In charging the discharged battery is first connected to the 160-volt main with a current of 150 amperes flowing. The current decreases as the counter electro-motive force increases, and when the current diminishes to 30 amperes the battery is switched into the 172-volt circuit. The current jumps to 150 amperes and diminishes again, and then the terminals are transferred to the 176-volt circuit. This operation can be accomplished in about 40 minutes, although a slightly better battery efficiency is shown when the time is longer. For a more detailed description of this plant and data on performance see St. Ry. Rev. Feb., 1898, p. 73.

A sub-station was recently built at the Harvey terminus of the line, which is 13 miles from the 88th St. power station. The round trip of 26 miles is more than the batteries should be required to make in regular service, and the sub-station is for partially charging them at Harvey. This plant comprises a 50-h. p. Nash gas engine, using gasoline, a 40-kw. Eddy generator and a station battery. In the basement are charging tables and elevator.

The operating expenses of this road for 1898 were reported as 8.75 cents per car-mile, and we are advised that this figure has not shown any increase for the nine months of 1899.

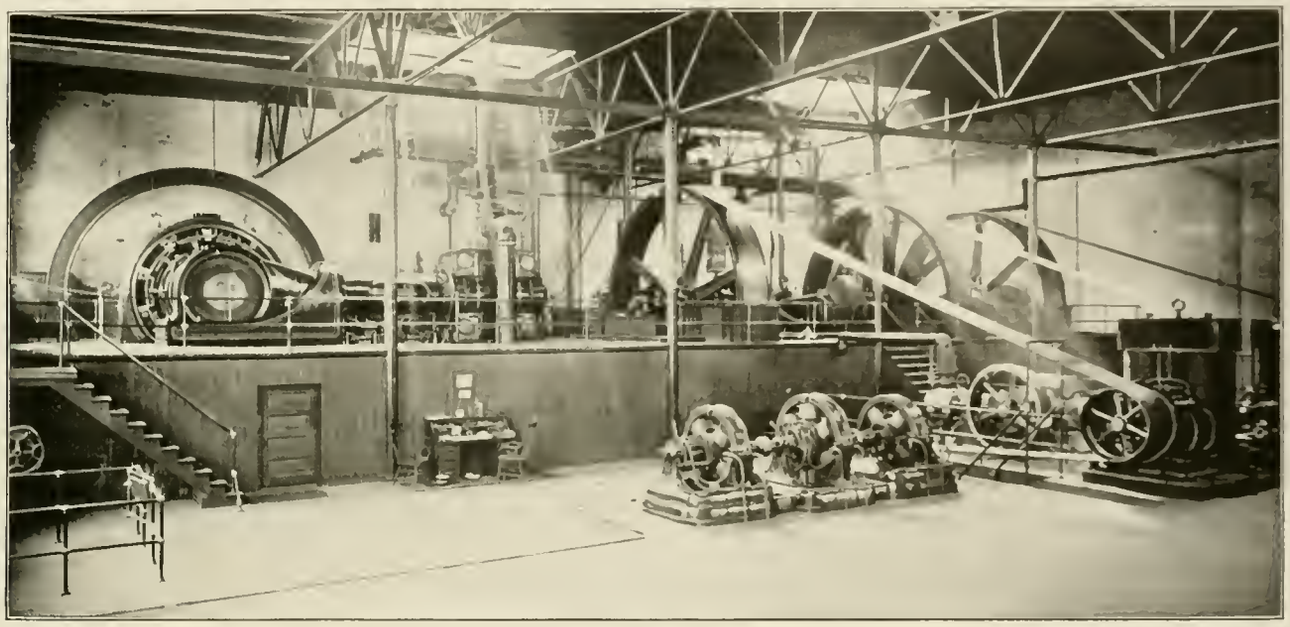
The officers of the company are: President, I. L. Rice; vice-president, H. Atkinson; general manager, E. R. Gilbert; treasurer, J. S. Bache; superintendent, A. E. Davies.

E. R. Gilbert, general manager of the Chicago Electric Traction Co., has been connected with electric street railways almost from the beginning of his business career, paying particular attention in recent years to the application of storage batteries to street car locomotion. He began work as a shop hand in the factory of the Eddy Electric Manufacturing Co., of Hartford, Conn., his native city, but soon pushed himself forward to more responsible positions. He was finally made manager of the Boston office of this

concern. Receiving an offer from the Hartford Street Ry., he resigned from the Eddy company, taking up the duties of purchasing agent for the Hartford system, and continuing in this capacity until asked to go to Philadelphia as manager of the Holmesburg, Tacony & Frankford Electric Street Ry., which he did. When Mr. Conduct resigned as manager of the Englewood & Chicago Electric Railway Co. Mr. Gilbert was called to Chicago to fill his place with the reorganized company, and has remained in this position ever since, the road under his management enjoying a period of marked prosperity.

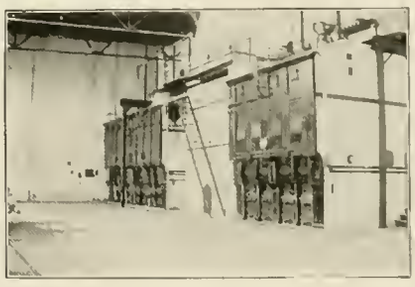
South Chicago City Railway Co.

The South Chicago City Railway Co. was incorporated May 31, 1883, as the Ewing Avenue Horse Railway Co., the name being changed in 1885. The old company had a few miles of track in South Chicago which was operated by horses until permission to use electricity and also franchises for a large number of other streets were secured in 1891 and 1892. This company now has 35 miles of electric road with a northern terminus at 63d St. and Madison Ave. where connection is made with the Chicago City and the South Side Elevated; its principal line runs from 63d St. to Roby, Ind., eight miles, and is quite close to the lake shore.



ENGINE AND DYNAMO ROOM—SOUTH CHICAGO CITY RAILWAY CO.

The Hammond, Whiting & East Chicago Railway Co. was chartered in 1892, to build an electric road connecting these Indiana towns; 12 miles of single track was built, including a line from Roby to Whiting. In 1896 a controlling interest was bought by parties controlling the South Chicago City road, and the two have since been operated as one.



BOILER ROOM.

The combined mileage of these two companies is now 57½ miles, all operated from the power house of the South Chicago City company at South Chicago. This plant is on Ewing Ave. near the 92d St. Bridge, and is equipped with three Allis engines, 22 x 48 in. belt connected to three Edison 200-kw. generators, one compound engine, 20 and 48 x 48 in., direct connected to a 500-kw. Westinghouse generator and one Ideal engine direct connected to a 65 kw. Mather generator; in the boiler room, which is 60 x 100 ft., are three 350 h. p. Stirling boilers. The large engine has jacketed cylinders and a superheating receiver, all of them, except the Ideal, have belted condensers. Between the low pressure cylinder and condenser of the compound is a closed feed water heater. There is also a Green economizer. There is also an interesting booster installation at this station; two 50-kw. General Electric multipolar, series boosters are direct connected to a 150-h. p. multipolar shunt-wound motor. These three machines are well shown in the illustration. The Hammond end of the line is 9½ miles from the power station.

The rolling stock comprises 74 motor and 53 trail cars built by the St. Louis, Brownell and Pullman companies. The motor cars are mounted on McGuire and Peckham trucks and fitted with Westinghouse motors.

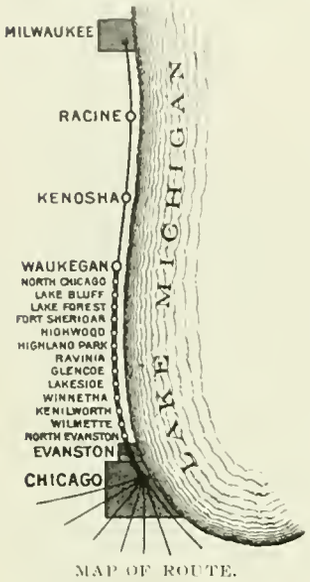
WILLIAM WALMSLEY.
Superintendent.

EDWIN JOWETT.
Chief Eng'r of Station.

The officers and staff of the company are: President, D. F. Cameron; vice-president, D. M. Cummings; secretary, treasurer and purchasing agent, O. S. Gaither; superintendent, William Walmsley; chief engineer of power station, Edwin Jowett.

The Chicago & Milwaukee Electric Railway.

The opening a few weeks ago of the entire section of the Chicago & Milwaukee Ry. between Evanston and Waukegan, a distance of 27 miles, marks the introduction of a new system of electrical distribution for long-distance interurban railways combining both direct and alternating current transmissions and auxiliary storage batteries to take care of the temporary heavy loads. This system was worked out by Mr. Bion J. Arnold four years ago while acting as consulting engineer for a long-distance, high-speed line, and may be summarized as follows: The road is divided into sections and at about the middle of each section, except that one contiguous to the power house, is located a sub-station containing an equipment of transformers and rotary converters and a storage battery auxiliary. These sub-stations receive their energy through a 3-phase transmission line from high tension alternating current generators in the main power house, which also contains sufficient direct current machinery to feed the section of the road adjacent to it. This arrangement presents so many economies over the ordinary direct current system of distribution for long distances that when Mr. Arnold was called in as consulting engineer for the Chicago & Milwaukee Electric Railway Co. he advised this system, and the first section of the road, which was built between Highland Park and Waukegan, by C. E. Loss & Co., was equipped according to this plan. For this section a power house was built at Highwood containing one 5,500-volt alternator, and a sub-station at North Chicago containing one rotary converter and without a storage battery. The equipment of this first section was of a temporary nature and was more or less incomplete. The line was about 15 miles long with a single track, but it proved successful and thoroughly convinced Mr. Arnold of the advantages of this system.



MAP OF ROUTE.

With the extension of the railway to Evanston and the completion of the plans came a change of management of the road, and considerable opposition to the alternating current was evinced by the new management, and in order to complete the work along the lines originally laid out the Arnold Electric Power Station Co. submitted a proposition to carry out the work under a guarantee that the operation of the road would reach a certain specified efficiency. It was under this condition that the Arnold company was awarded the contract for the extension of the road with the exception of the rolling stock and track.

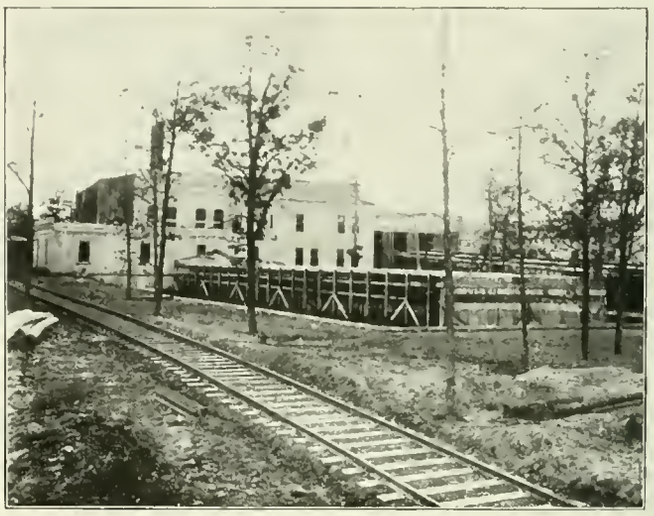


FIG. 1—POWER HOUSE, HIGHWOOD.

This included engine, batteries, direct current and alternating current generators, switchboards, transformers, rotary converters, economizer, pumps, mechanical draft apparatus, condensers, piping, cooling table and reservoir, power house building, two sub-station

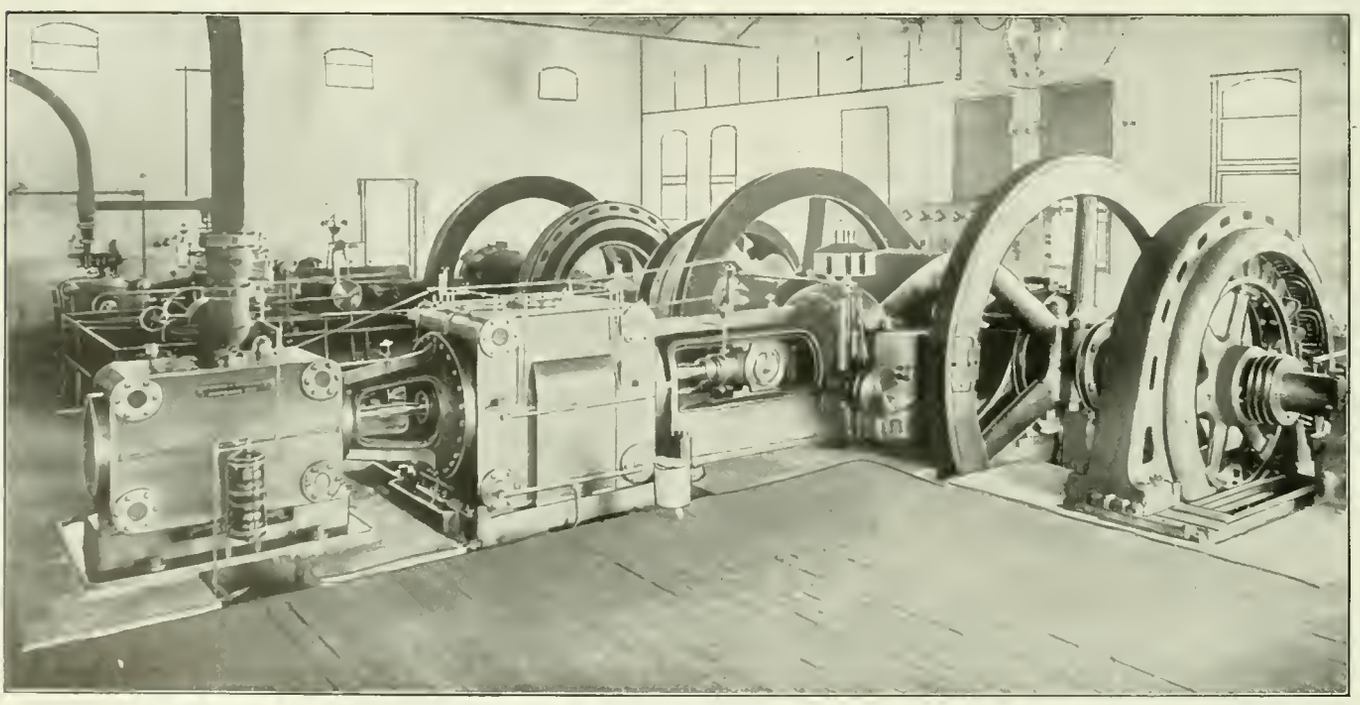

FIG. 3—ENGINE ROOM, HIGHWOOD—FILER & STOWELL ENGINES.

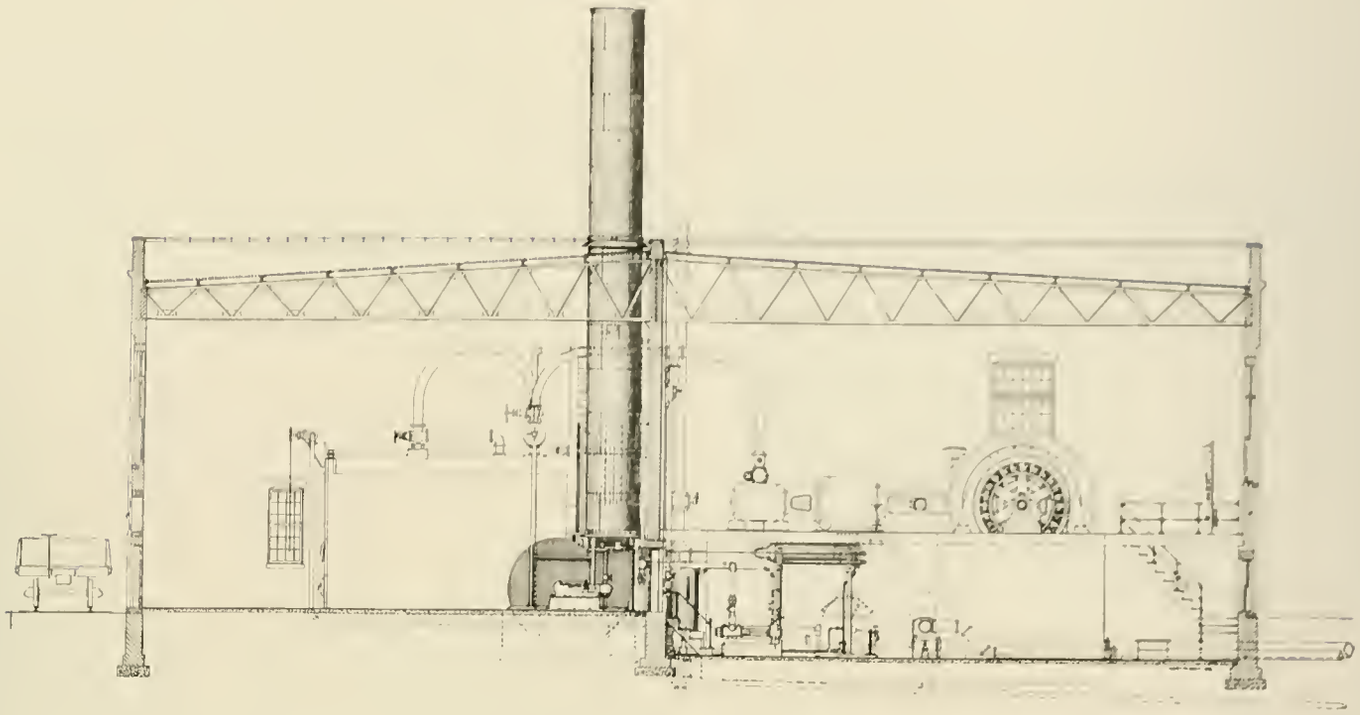

CROSS SECTION OF POWER STATION.

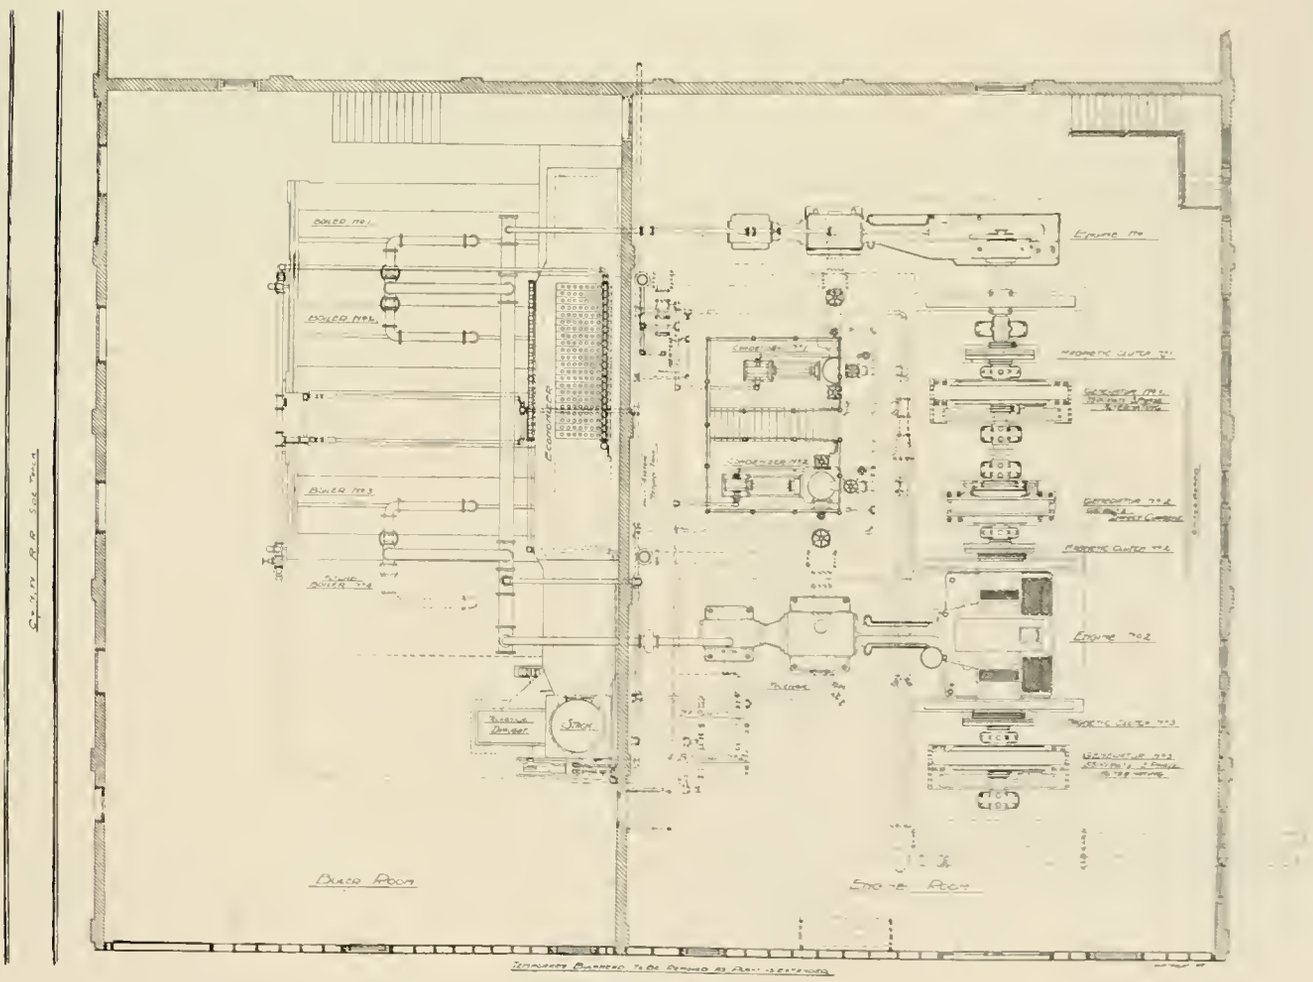

FIG. 2 PLAN OF POWER STATION AT HIGHWOOD.

buildings, car barns, offices and overhead equipment, all to be complete ready for operation.

The policy of the Arnold company of working out its own solution of the engineering problems and submitting plans and specifications with its proposition, together with an economy guarantee covering the entire installation, makes this contract a notable one;

and it is to be remarked that throughout the work upon this road the most pleasant relations have existed between the officers of the road and the Arnold company.

The route of the Chicago & Milwaukee road runs through a chain of charming suburban towns and country residence districts lying along the lake shore north of Evanston. Starting at the latter place the line runs practically north throughout its entire length, and after reaching Wilmette, the first town north of Evanston, the road makes a detour to the west where it approaches the tracks of the Chicago & Northwestern R. R. and from here passes over its private right of way through Kenilworth, Winnetka, Lake Side, Glencoe, Ravina and Highland Park, at which place it emerges upon the public highway. This section is double tracked and comprises the extension which has recently been completed. Continuing from Highland Park the single track line passes through Highwood, Fort Sheridan, Lake Forest, Lake Bluff, North Chicago and Waukegan, its present terminus, the entire line closely paralleling the tracks of the C. & N. W. R. R.

The roadbed was built by the North American Railway Construction Co., of 65 lb. rails of the American Society of Civil Engineers' section, laid upon wooden cross ties, except in passing through the towns, where girder rails were required. The rails are joined with 4-hole 24-in. fish plates and are connected with Atkinson rail bonds. The turnouts on the 15 miles of single track are provided with spring switches.

The overhead work is span wire construction on the double track section and bracket construction on the single track line. In passing through the towns the franchises which were secured required the use of iron poles. These are made of pipe 5, 6 and 7 inches in diameter of the different sections and are set in concrete. The remainder of the poles are wooden and carry 4-pin cross arms, three of the insulators carrying the wires of the 3-phase system and the fourth insulator the direct current feeder. The insulators are the ordinary double petticoat glass pattern and no trouble has developed with their use for the high tension lines. The trolley wire is a No. 00 B. & S. gage hard drawn copper wire furnished by the American Steel & Wire Co., and is fed from a No. 0000 feeder, which runs almost the whole length of the road. The general arrangement of the wiring is as follows: From the power house at Highwood near the center of the road three lines of No. 4 wire run south to the sub-station at Winnetka and three lines of No. 8 wire run north to the sub-station at North Chicago. These lines carry the high tension 3-phase currents. The road is divided into six sections of 4½ miles each, two sections being fed from each station. The two middle sections are fed from the power house by a direct current from the station generator and the two sections opposite each sub-station are fed by the current from the rotary converters. The direct current feeder is tied into the trolley line at five points in every mile, except that there are no connections to this feeder for one mile each side of the station in order not to obtain too high a voltage at this point. Each of these sections is separated by section insulators which in cases of emergency permit any section of the road to be cut out, but by-pass switches are placed on the poles opposite the section insulators which permit the current to shunt around them, and in general they are closed so that the current from the rotaries is connected in parallel with the direct current generator at the power house. From this description it will be seen that the direct current feeds nine miles in the center of the road and each sub-station feeds nine miles at each end of the road. The line material was furnished by the H. W. Johns' Manufacturing Co.

POWER HOUSE.

The general arrangements of the power house and sub-stations of this road have already been outlined in the "Review" for August, 1898, page 500, but with the completion of the system additional data are available which will make a more detailed description of the plant of interest. The power house at Highwood is built of yellow pressed brick and its general appearance is shown in Fig. 1. The plan and elevation in Fig. 2 show the details of the building and the location of the machinery. The engine equipment consists of two Filer & Stowell tandem compound condensing engines of the corliss type, one having cylinders 17 and 30 x 36 in. and the other 22 and 38 x 42 in. Both engines run at a speed of 125 r. p. m., which is a rather unusual speed for engines of this type. The generators are three in number, two being alternating and one a direct current machine, and these are direct connected to the engines by means of the "Arnold System." The large engine normally drives one alternator and the direct current generator, and the small engine the other alternator, but the quill system permits considerable flexibility in the connections of the machines.

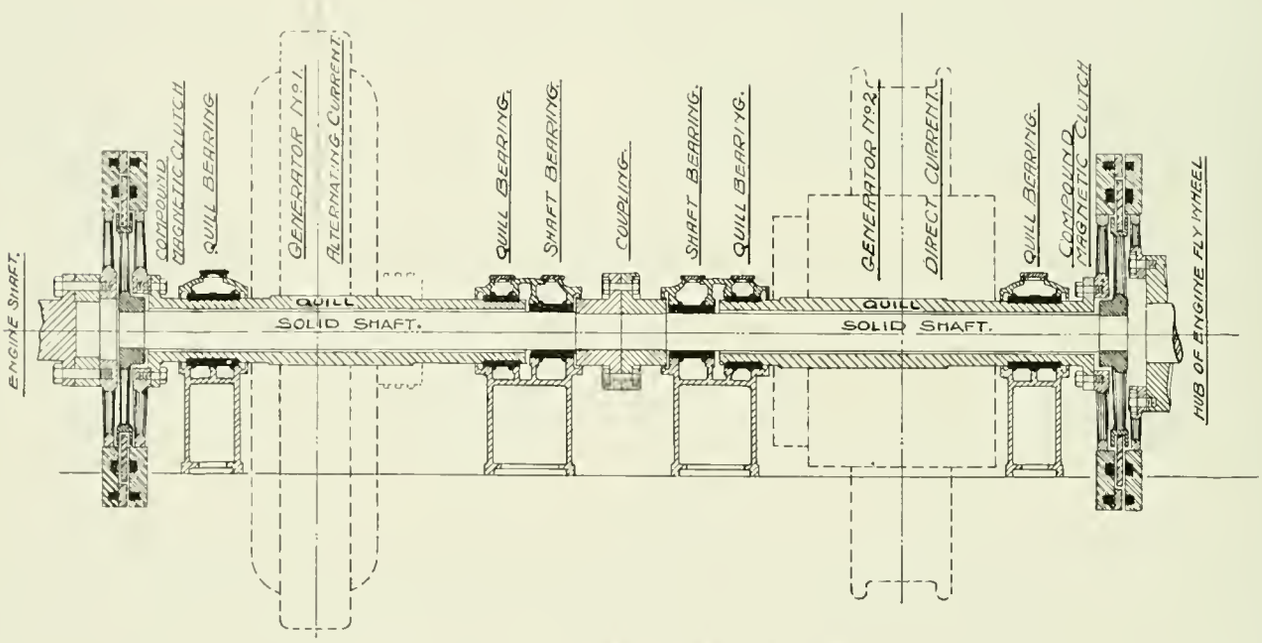

FIG. 4—CROSS SECTION OF "ARNOLD SYSTEM."

The alternators have 24 poles and have a capacity of 250 kw. They generate a current of 5,500 volts initial pressure and of 25 cycles. The direct current generator is a 6-pole machine of 250 kw. capacity and generates a current of from 600 to 650 volts pressure. All of the electrical equipment is of the General Electric Co.'s manufacture, and a general view of one of the alternators and the large engine is shown in Fig. 3.

The small engine is provided with a special arrangement of piping by means of which its capacity may be doubled in case of a break down of the large engine. A separate high pressure steam pipe is connected to the low pressure cylinder of the small engine

so that the low pressure cylinder can take high pressure steam through a reducing valve. When this is done the high pressure cylinder is arranged to exhaust directly into the condenser instead of into the low pressure cylinder. By means of this arrangement the small engine, would be able to temporarily run the road in case of accident to the large one, while the latter is of sufficient capacity to economically run the road alone. The engine and boiler room piping is fitted with Crane valves.

From the diagram, Fig. 2, it will be seen that the basement of the engine room forms an open pit between the engines in which two Deane jet condensers are situated, each being sufficient in capacity for the engine to which it is adjacent. These condensers are furnished with water from a cooling table and reservoir in front of the building, shown in Fig. 1. The table is 132 ft. long by 30 ft. wide and contains three shelves, one above the other about a foot apart. The table stands over a reservoir 150 ft. x 60 ft. in area and 8 ft. deep. Hot water from the condensers is discharged onto the top shelf of the table near the building and runs to the further end where it falls onto the second shelf and back along this to the third shelf, from which it falls into the reservoir at the further end, the intake pipe for the condensers being near the building and at the op-

FIG. 5—SUB-STATION, WINNETKA.

posite end of the reservoir from that in which the hot water from the table falls. The bottom of the reservoir is built of cinder concrete from which the sides slope upwards at an angle of 45 degrees for 4 ft., this part being built of stone concrete. On top of the slanting walls is a vertical brick retaining wall which brings the height of the reservoir up to 8 ft. An important feature of the engine room is the system of connecting the generators and engines referred to above as the "Arnold System." This device is shown in the plan in Fig. 2 and also in detail in Fig. 4. In this system each generator is mounted upon a quill or hollow shaft having a solid shaft inside with a half inch of space between them. These hollow shafts are held in position in the bearings into which they enter half way. Magnetic clutches are attached to the engine shafts which may be connected to either the solid shafts or the hollow shafts by means of switches upon the switchboard. By means of this system the large engine usually drives an alternator on one side and the direct current generator on the other side, while the small engine drives the other alternator. The large engine, however, may be connected to drive all three generators or the small engine may drive an alternator and the direct current machine. As the two middle generators may be driven together or separately from either engine the system has much more reliability than an equal number of independent units. It has in fact all the advantages of a belted countershaft connection without the corresponding friction and belt losses.

The switchboard is of blue Vermont marble and is in the front of the engine room as shown in Fig. 2. It consists of nine panels. The first two panels to the left are feeder panels, each containing a circuit breaker, an ammeter and a single pole feeder switch. Next is a battery panel with two single pole switches and a 1,000-ampere double reading ammeter with readings each side of zero according to whether the batteries are being charged or discharged. One direct current generator panel contains a circuit breaker, ammeter, two single pole switches for the generator circuit and one lighting switch for the building. One exciter panel is equipped with an am-

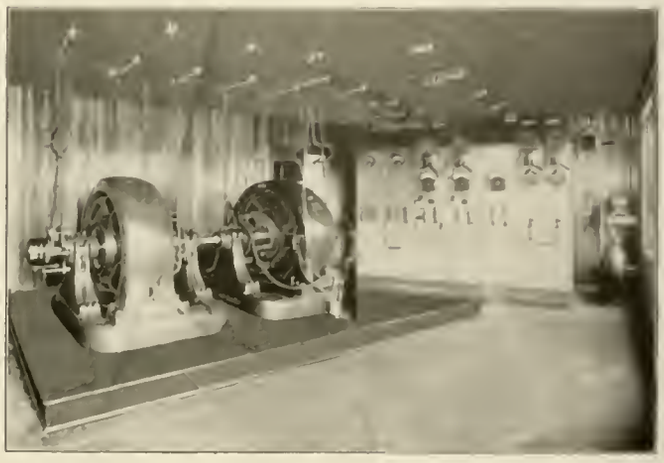

FIG. 6—ROTARY CONVERTER ROOM, WINNETKA.

meter and a voltmeter, two field switches (one for each exciter) and a rheostat. The four remaining panels are one alternating and a No. 1 sub-station panels and the second alternating and a No. 2 sub-station panels. The two alternating generator panels are alike and each contains one Thomson inclined coil ammeter and an inclined coil voltmeter, one 3-pole snap switch working in oil on the rear of the board with the handle in front, one 2-pole single throw switch for the field circuits of the alternators, and one field rheostat. There is also a synchronizing set consisting of a pilot lamp and switch and six plug connections for reading the voltage on the different legs of the 3-phase line.

The two sub-station or line panels each contain one 3-pole switch, one inclined coil voltmeter and one inclined coil ammeter.

At present the fields of the alternators are run from two exciters, belted to the main shaft, which are wound for 125 volts, which is the standard practice for the General Electric alternators. This arrangement was adopted temporarily to get the road running on time and the fields of these machines, however, are to be rewound for a 600-volt circuit and will then be energized from the storage batteries, doing away entirely with the exciters and all belted connections. The switchboard equipment is all of the General Electric

FIG. 7—STORAGE BATTERY ROOM, WINNETKA.

manufacture, except the direct current instruments, which are of the Weston type.

The boiler room is situated directly in the rear of the engine room, from which it is separated by a brick partition wall, as

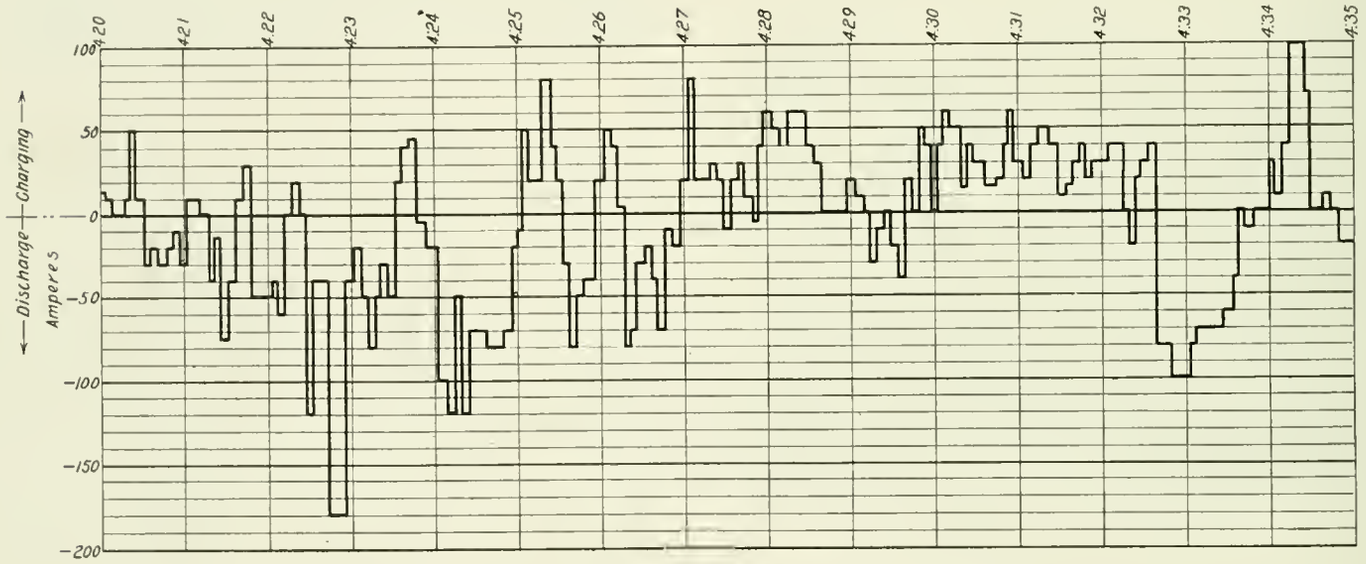
shown in the diagram, Fig. 2. This room contains three Cahall boilers of 250-h. p. capacity each, made by the Aultman & Taylor Machinery Co., and fitted with down-draft furnaces. The firing is done by hand labor. At the back of the room and over the rear of the boilers is located a Green fuel economizer of 750 h. p. capacity, which will deliver the feed water at 275° F. An induced draft is also provided by means of a Sturtevant fan, and the arrangement of the draft is such that the gases from the furnaces may be delivered to the stack either with or without passing through the economizer and with or without the use of the induced draft. Indiana egg coal is used in the boilers, and this is delivered directly to the boiler room floor from a spur track from the C. & N. W. R. R., which runs close to the side of the building, making any special coal handling devices unnecessary.

There are two Deane feed water pumps, 5 in. and 4 in. x 9 in. provided for feeding the boilers.

Directly in front of the power house is a long, narrow building containing the company's offices in front and a storage battery room in the rear. The front portion has two stories, both floors being devoted to the clerical force of the company, while the storage battery room is only one story high. The storage battery

static transformers and convert it into a direct 600-volt current. The machines are 4-pole, with one armature, taking the alternating current on a collector at one end and delivering the direct current at the commutator at the other end. Carbon brushes are used at the commutator end. The rotaries are self starting, and will operate when the current is turned on at the power house without attendance, but as an attendant is always at the sub-station, having a six room living apartment over the converter plant, a switch is provided for starting these machines. The rotaries run at a speed of 750 r. p. m.

The location of the switchboard is shown in Fig 6. It comprises seven panels, and is built of marble. At the left are two alternating current panels, each containing three single pole switches, one Thomson alternating current ammeter and a pilot lamp and switch, which constitute the synchronizing set for starting the machines. The third panel is for the storage batteries, and is equipped with two single pole switches and a 1,000-ampere double reading ammeter. Two feeder panels each contain an ammeter, two single pole switches and a switch for lighting the building. The two direct current panels each have a 600-ampere ammeter, one field switch, two single pole switches, one rheostat, one circuit breaker and one



POWER HOUSE STORAGE BATTERY RECORD, JULY 4, 1899, 4:20 TO 4:35 P. M.

rooms at the sub-stations and at the power house are all alike, and will be described together.

SUB-STATIONS.

Sub-station No. 1 is located at Winnetka, a general view of the building, which is 100 ft. x 30 ft., being given in Fig. 5. This station is divided into three rooms, one for the static transformers, one for the rotary converters and switch board, and one for the storage batteries. The static transformer room is a narrow room, 8 x 19 ft., containing six General Electric static transformers arranged in a row along the front wall of the building. These machines receive the 3-phase current from the power house at 5,500 volts, and reduce it to a tension of 380 volts. Each transformer has a capacity of 42 kw., making the total capacity of the sub-station 252 kw. On the partition wall opposite the transformers are six single pole switches which control them. These are arranged in two rows of three, each switch being surrounded by an open marble box about a foot deep to avoid the possibility of arcing. The six transformers are connected in two multiple series of three each, and the six switches are connected one to each end of the two primary coils in series. When all of these switches are closed a delta connection of the three phase circuit is made, or by opening the two switches connected to one primary circuit the load will be carried on the two other sides of the system.

Directly behind the transformer room is the rotary converter room, 19 x 24 ft., a view of which is given in Fig. 6. This room contains the rotary converters and the sub-station switchboard. There are two rotaries on one side of the room, each of 125 kw. capacity, which take the 380-volt alternating current from the

voltmeter. At one side of the switchboard is a 1-h. p. induction motor, which operates a small blower. This is used for forcing air through the static transformers under about ½ an ounce pressure for cooling purposes. The storage battery plant occupies the remainder of the ground floor of the sub-station.

Sub-station No. 2 is located at North Chicago in a building identical with that at Winnetka, except that it contains an extension along one side, 30 ft. in width, which is used for a car barn. The interiors of the two sub-stations are also identical, both having been built after the same plans and specifications. The equipment at North Chicago is only one-half of the capacity of that at Winnetka, but as the apparatus and its arrangement is the same in both cases no description of this station is necessary. It contains but three static trasformers and one rotary converter.

STORAGE BATTERIES.

The accumulator plants of which there is one at each station form an important adjunct of this equipment. The three batteries are the same in each case except that the number of plates varies, the cells at Winnetka containing 15 F plates, those at the power house 11 F plates and at North Chicago 7 F plates, all of the type made by the Electric Storage Battery Co., known as chloride accumulators. A general view of the Winnetka storage battery room, which is identical in appearance with the other two, is shown in Fig. 7. Each battery contains 288 cells, which are arranged in rows of two cells, with wide aisles between the rows, giving easy access to any point in the room. The room is also of ample size, well lighted and has excellent provision for ventilation. The cells are of glass and are considerably larger than is

needed for the present number of plates used, the idea being to allow for a considerable increase in the capacity of the battery by adding extra plates. These cells are set on the standard insulators of the Electric Storage Battery Co., which are two part glass insulators, the bottom part forming a flat tray containing oil, in which the upper part stands. The batteries are in constant service, being charged when the load is light and discharging on the heavy loads. The operation of the batteries is shown on the double reading ammeter on the battery panels of the switchboard described above. The rate of discharge is shown on a scale one side of the zero point, and the rate of charging on the other side of the scale. The accompanying diagram made from the ammeter readings showing the operation of the battery during a heavy load was taken between 4:20 and 4:35 p. m. on July 4th, the area of the curve above the zero line showing the periods of charging and the area below zero the periods of discharging of the battery. The battery either charges or discharges according to the voltage of the line, thus equalizing the load on the engines, which in this case are probably about one-third less in capacity than would be required without the batteries. The energy delivered by the batteries during heavy load periods and stored by them during light loads is clearly shown in the diagram. The amount of charge in the batteries is told approximately by hydrometer readings of the specific gravity of the electrolyte in the cells. During the readings given there were 263 cells in series.

The rolling stock consists of 20 motor cars and 18 trails cars, built by the J. G. Brill and Pullman companies. The cars are all vestibuled and have center aisles with cross seats, the seats extending about two thirds of the length of the car. The remainder of the car is partitioned off, making a baggage room and smoking compartment at one end, having side seats and sliding doors on the side for receiving baggage. The car bodies are mounted on Peckham trucks, of which there are eight of the 14 A type, extra strong. These are double trucks, and each car is equipped with two General Electric 50-h. p. motors. Each car is also fitted with Christensen air brakes, for which the air is supplied from a rotary air compressor driven by an electric motor.

The company also has one Ruggles rotary snow plow, made by the Peckham Co., and has recently ordered a McGuire sweeper.

Since the opening of the road over its entire route the traffic has been most satisfactory, and on several occasions it has taxed the entire rolling stock to handle it. The engineering details have also proved entirely effective, and it is confidently expected that the efficiency test, which will soon be made, will fully meet the expectations of the engineers. The road is run more on the style of a steam road than a street railway, as the company now owns considerable private right of way along its line and is acquiring more from time to time, as it can be purchased.

The officers of the Chicago & Milwaukee Electric Ry. are: President, G. A. Ball; vice-president, A. C. Frost; secretary and auditor, George M. Seward; treasurer, J. W. Maneck; general superintendent, R. S. Ives.

The Elevated Railroads of Chicago.

The elevated railroads of Chicago that are in operation aggregate almost 75 miles and the Northwestern Elevated, of which a considerable portion is already completed will bring the total up to 100 miles. The territory covered by the five elevated roads is well shown by the accompanying map.

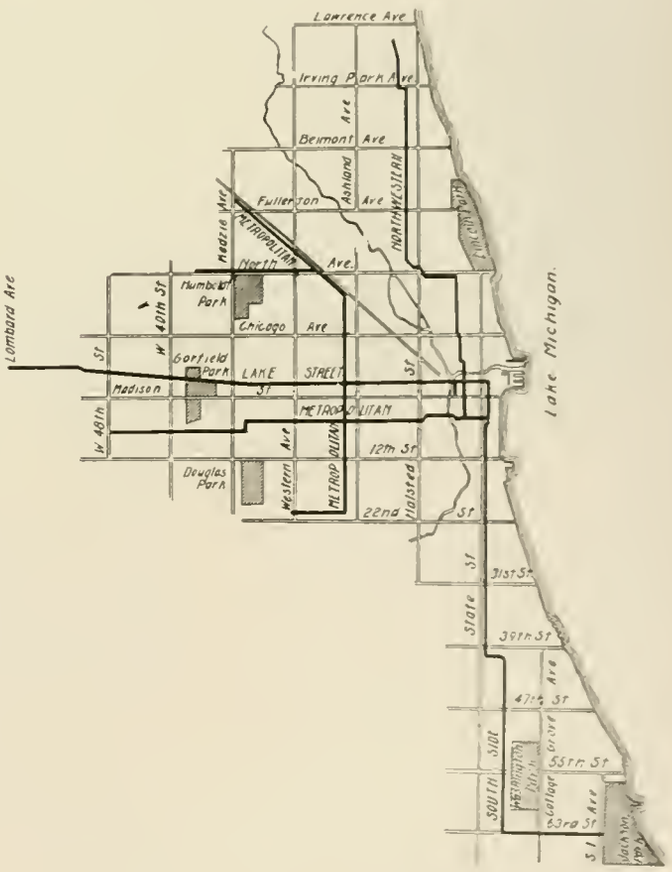
South Side Elevated.

The South Side Elevated, which is known also as the "Alley L" from the fact of its being built on a private right of way adjacent to the alley between State St. and Wabash Ave., was opened for regular traffic to 39th St., June 6, 1892, and to Jackson Park on May 12, 1893. The Chicago & South Side Rapid Transit Railroad Co. was incorporated Jan. 4, 1888; after many financial difficulties, the construction company having the contract to build the road turned the property over to the railroad company in December, 1892, and the latter completed the road to Jackson Park. This road, then operated by steam locomotives, handled an enormous traffic during the World's Fair, but early in 1894 it became evident that it could not earn fixed charges. The surplus from 1893 carried the company so that no default was made on bonds till 1895. In September, 1895, foreclosure proceedings were instituted by the trustee for bondholders and Marcellus Hopkins was appointed receiver. Mr. Hopkins operated the road as receiver until January, 1897, when a reorganization was effected, and the South Side Elevated Railroad Co., assumed control. Oct. 10, 1897, the company began operating its cars around the Union loop and there was at once a 50 per cent increase in the traffic.

This road is particularly interesting for the reason that it is operated on the Sprague multiple-unit system. The first six cars to be equipped with this system, were taken from service and shipped to Schenectady, June 11, 1897, to have the necessary electrical apparatus placed in position. These were returned October 17th of the same year, and were immediately put in operation on the Metropolitan Elevated for the purpose of thoroughly testing them and remedying any defects that might develop. These cars ran on the Metropolitan until June 5, 1898, when they were transferred to the South Side Elevated. During 1897 the Electrical Installation Co., was given the contract by the Sprague Co. to equip 114 additional cars belonging to the South Side Elevated R. R. with the Sprague system and this work was carried out at the shops of the Wells & French Co. The last cars of this lot were delivered Mar. 19, 1898, and on May 15, 1898, the first regular passenger train was run with current taken from the third rail. The elevated company during the last three months of 1898 equipped in its own shops 30 more cars.

Since January, 1897 the company has been paying 3 per cent on its stock and it is believed will soon be put on a 4 per cent basis.

The Sprague system as installed on this road has been fully described in the "Review" but the essential features may be briefly recapitulated. For the most part each car is independently lighted, heated, driven and braked; there are some trail cars. But all the



THE CHICAGO ELEVATED RAILROADS.

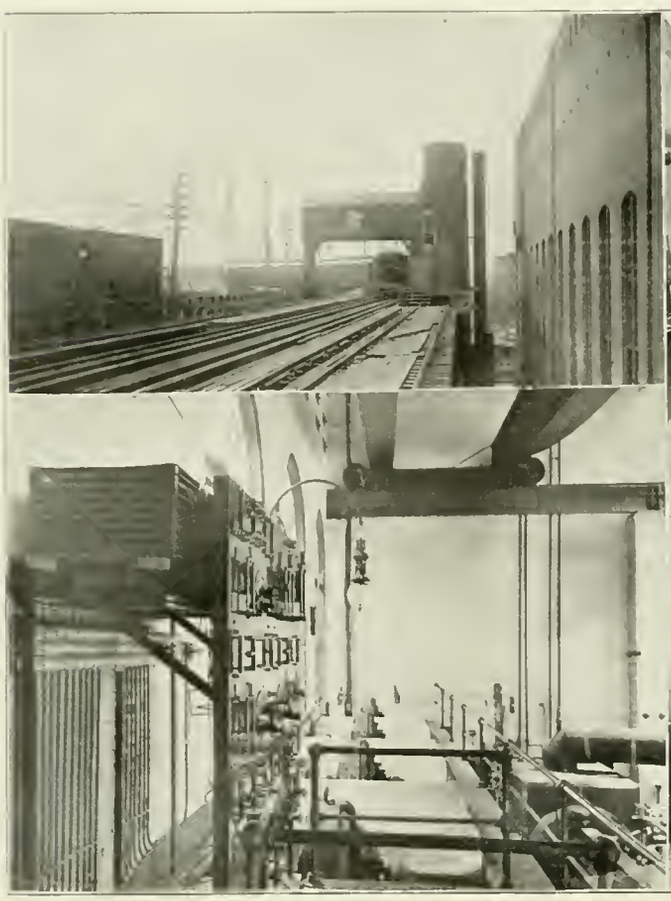
cars in a train are controlled by one motorman. The apparatus comprises a "master" controller on each end of each unit; master controller and train line cables; removable sections of the train line, called jumpers, which correspond to the air hose couplings used with air brakes; the main controller, which consists of relays and a throttle, pilot motors with automatic limits, a rheostat cylinder, and a reverser.

The equipment of the road includes 150 motor cars and 30 trailers. The motor cars are the passenger cars of the original steam equipment; under one end of these cars the old truck was retained, but at the other end a motor truck was added. The McGuire Manufacturing Co. furnished the first 120 motor trucks which are fitted with a swing bolster, and the Peckham Truck Co. the last 30. Each motor truck has two G. E. 57 motors of the ironclad four pole type with single reduction gears. The cars are all equipped with the Christensen air brake system, each car having a Christensen motor-driven compressor; the motors have the General Electric automatic regulators. The Gold electric street car heaters are used on all cars.

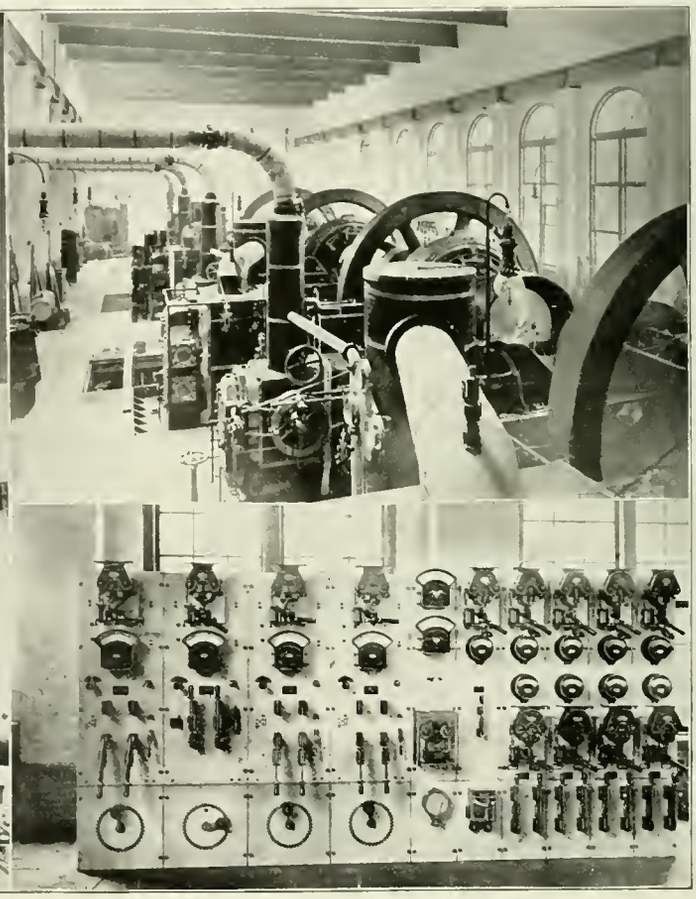
The power house is located at 40th and State Sts., on the line of the Lake Shore & Michigan Southern, and was designed by Messrs. Sargent & Lundy, consulting engineers for the company.

The building is 200 ft. long and divided lengthwise into large rooms; the engine room is 59 ft., and the boiler room 48 ft. wide. The engine equipment comprises four cross compound, condensing Allis-Corliss engines with cylinders 26 and 54 x 48 in.; speed 80 r. p. m. Each engine will develop normally 1,200 h. p., but will carry a 66 per cent overload. The direct connected Westinghouse generators are of 800-kw. capacity, giving 1,280 ampers at 625 volts, although the generators are capable of running under temporary overloads of 100 per cent. A Reynolds condenser receives the exhaust steam from each engine. Water is taken from a tank under the cooling tower outside the station and discharged into the top of the tower through a 20-in. pipe. Five motors drive 10 fans for the cooling tower. These motors are 6-pole, 600-volt and run at 150 r. p. m. A 30-ton electric crane spans the engine room and is equipped with General Electric motors. Piping from the compressed air system extends to each generator for cleaning the armatures, etc., the air being furnished from a Westinghouse air pump. Oil is supplied by a gravity system, pipes running to all the bearings from a tank placed near the roof of the station. After being used the oil is filtered and two pumps return it to the tank.

The switchboard is of white marble and is unusually compact for so large a station. The four panels to the left are each for a generator. Each panel has a General Electric circuit breaker and switches, a 2,500-ampere Weston ammeter and field rheostat controller, the resistance of which is under the floor. The next panel to the right receives the entire current of the station and is designed to carry 8,000 amperes. It has a 750-volt voltmeter and an 8,000-ampere ammeter, a General Electric wattmeter, and a Bristol recording voltmeter. The next panel supplies current to the station. This goes to the five cooling tower motors, the two motors running the coal handling machinery, the crane motors, 200 incandescent lamps and 20 enclosed arc lamps. A recording wattmeter keeps a record of all the energy so used. The four panels to the right are for the eight feeders running out of the station. Each panel has two single pole switches, two circuit breakers with the two ammeters between them.



STRUCTURE AT 40TH. ST.
FAN MOTORS AND SWITCHBOARD.



ENGINE AND GENERATOR ROOM.
MAIN SWITCHBOARD.

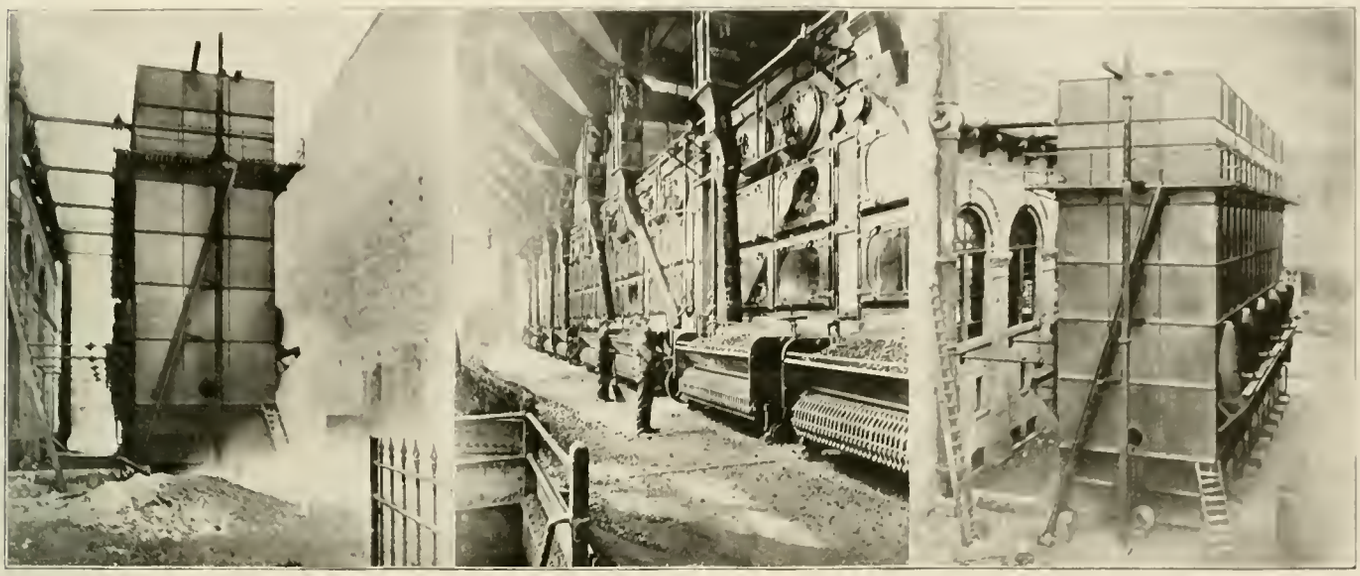
The five motors mounted in the engine room are connected by shafting to the 10-ft. fans of the Barnard cooling tower, which is notable for its great size; it is 64 ft. long, 16½ ft. wide and 34 ft. high; beneath it is a tank 6 ft. deep.

There are 12 Babcock & Wilcox water tube boilers tested for a pressure of 300 lbs., the pressure of the station being only 160 lb. All the high pressure steam valves were furnished by the Crane Co. Two vertical oscillating engines drive the chain grates, the exposed furnace surface of each being 7 ft. 6 in. x 8 ft. 6 in.

The boiler feed water is pumped by three Blake compound feed pumps, 10 and 7 x 12 in. from either the city mains or the condenser discharge. Each boiler has a hot water meter attached and two meters register the water which is supplied to the station

from the city water mains. The steel plate stack is 200 ft. high and 13 ft. 8 in. internal diameter at the top. The plates are ½ in. at the bottom and ¼ in. at the top, with a fire brick lining from 9 in. to 4½ in. built up in the interior. There are two flues extending from the boilers to the stack, one containing two Green fuel economizers, the hot gases being drawn into this one from a point near the middle of the bank of boilers. This flue is closed when the economizers are not in use.

The station has complete equipment of coal and ash handling machinery. The coal is delivered from the cars into a hopper



COOLING TOWER. BOILER ROOM. COOLING TOWER.

and passes through a motor driven crusher. It is delivered by a McCaslin conveyor, made by the John A. Mead Co., New York, to a second conveyor, and is carried to the coal bins and tanks above the boiler room. The coal is delivered from the tanks to the mechanical stokers as shown in the interior view of the boiler room. The ashes are collected by the same conveyor that handles the coal. They drop into a pit beneath the boiler and are dampened before removing. There are three feeders extending north of the station, two of 1,000,000 c. m. cross section and one of 500,000 c. m. To the south there are two of 1,500,000 c. m., two of 1,000,000 c. m. and one of 500,000 c. m., cross section.

At two points on the line, at 61st St., where the shops are located, and at 12th St., the last passenger station north before entering the business district, storage batteries have been installed for the purpose of acting as equalizers for the central station, reducing the drop in potential on the line, adding to the reliability of the power supply, and to some extent they carry the peak of the load. Each of these two batteries consist of 248 "chloride" cells made by the Electric Storage Battery Co., of Philadelphia; each cell has 26 pairs of plates, with room in the tanks for 26 pairs more. Each battery has a capacity of 535 kw. h. at the hour discharge rating and may be discharged 60 per cent above this with safety. With the batteries connected in multiple it is found that the morning and evening generator load peaks are from 500 to 1,500 amperes lower than without the battery. The peaks occur at 8:15 a. m. and 5:45 p. m., and the low points in the load curve at 1 p. m. and 3 a. m. The current consumption for motors and lights on this road is about 2.1 kw. h. per car-mile.

The hardest test on the capacity of the system was on Oct. 19, 1898, when the car-mileage was increased 80 per cent above the normal. With 148 cars and a total trackage of nearly 20 miles, 240 cars per hour were sent into and out of the loop for several hours. This load was carried by six 400-h. p. boilers with two men in the fire room.

The shops and yards of the company are located at 61st St. and Calumet Ave., the former occupying a rectangular two story building, having a frontage on 61st St., of 152 ft., and on Calumet Ave., 162 ft.

The main machine shop where all the machine work for the entire system is done, is on the ground floor, and is 50 ft. square. Here is found a full set of metal working tools and labor saving devices for turning out work expeditiously and economically, the collection including: 1 bolt cutter, 1 saw lathe, 2 large lathes for turning up armature bearings, commutators, shafting, etc. One of these has a 33 in. swing and takes work up to 9 ft. 6 in. in length; the other has room for a 20-in. swing, and takes work 6 ft. in length. One lathe for truing up wheels. This machine has 44 in. swing, 8 ft. between centers. One "Universal" milling machine. One grinder, for grinding tools used on the milling machine. Two ball-bearing drill presses, one with a 25-in. table, made by J. A. Fay & Co., of Cincinnati, and one with 16-in. table. One planing machine. One grind stone. One Featherstone emery wheel. A number of these machines were purchased through J. A. Fay & Co., as agents. All of the tools are run by belting from shafting, which is driven by a 25-h. p. motor, taking current from the line circuit.

In the machine shop is also placed a large Smith-Vaile pump for furnishing water for fire and other purposes throughout the shops and yards. This has a capacity of 720 gallons per minute, and from the end of a 3-in. pipe 1,200 ft. long, supplied with a three-way nozzle, has thrown three streams at once to a height of 75 ft. The pump is direct connected through gears to a 75-h. p. motor. All current taken from the line for power purposes in the shops first passes through a storage battery, thus preventing fluctuation in the line voltage from affecting the speed of the tools.

J. F. MORRISON,
Superintendent.

The shafting in the shop is supported on upright timbers entirely independent of the walls. In this way vibration of the building is avoided, and even when all the tools are running full speed the noise cannot be heard in the next room. Five machinists and two helpers take care of all the work in this department.

Opening from the machine shop is the blacksmith shop, where two forges, supplied with a motor driven fan are in operation. Two smiths and a helper do all the blacksmith work required on the road. In the same room with the forges are two Heine safety boilers for operating the heating system. From these, direct steam is led through mains to all parts of the buildings and yards.

Adjoining the machine shop on the south is a large "general utility" room. At one end of this are benches for mending rattan

seats, and floor mats, varnishing blinds, repairing air brake valves, etc. One man repairs all the rattan seats on the system, weaving in new pieces where holes have been made, and thus often avoiding the expense of an entire new covering. This would cost from $2.00 to $5.00, but by the present arrangement the seat is made practically as good as new in two hours by a man who receives 15 cents an hour. One man also does the regrinding and repairing of all the Westinghouse air brake valves.

In the center of this general room is a small air compressor, driven by belting from the same motor that drives the pump in the machine shop. The compressor has a capacity of 210 cu. ft. free air per minute, and is provided with an automatic device for cutting out the compressor valves when the pressure in the storage tanks reaches about 75 lb. per sq. in. This enables the compressing piston to work without load until the pressure falls below the predetermined point, when the valves are again cut in and the pressure raised. The air is stored in nine cylinders, having a capacity of 21 cu. ft. each. Pipes lead from these to the yards for cleaning out the cars with compressed air, and to the motor repair shop on the floor above for operating a pneumatic armature lifting jack.

A small room adjoining this larger one is devoted to armature winding and repairing. Here the 300 railway motors, all pump motors, pilot motors and fields are kept in order, and in addition considerable work is done for the 40th St. power house. But two winders and two helpers are employed. This speaks well for the small amount of repairs necessary.

The rest of the ground floor is taken up with store rooms, of which there are two; one for iron and steel in bars and other rougher supplies, and one for the smaller and more expensive parts. In these two rooms are kept everything that is likely to be called for by the men in the different repair and inspection departments.

An electrically driven elevator runs from the ground floor to the second story for raising all heavy parts and apparatus. This has a capacity of 10,000 lb., and is operated by a 15-h. p. motor.

The oil room is situated in a separate building, apart from the shops to avoid risk from fire. All lamps are cleaned and filled in the same building.

The second floor is divided into paint and carpenter shops, motor repair room and offices for the foremen, assistants, etc.

The paint and carpenter shop will accommodate 12 cars at a time and here 20 cars are thoroughly overhauled, repaired and repainted every month.

The motor repair shop has three tracks, holding two cars each, or six in all. This room is well equipped with labor saving devices, including two cranes and a pneumatic lifting jack, designed by Mr. Allen, the general foreman, for removing and shifting armatures. This latter apparatus is mounted on a truck, and with it a damaged armature can be taken from the motor, carried to the elevator and the new one picked up and placed in position in a very few minutes.

The motor repair shop opens directly onto the elevated yards, where cars are cleaned and stored. The third rail in the yards is in sections, and knife switches are placed at convenient points for cutting out any section upon which men may be working. This avoids the possibility of accident from touching the live rail, while the employes are at work.

In one corner of the yards is placed one of the most important features of the whole system. This is the testing building. In this place, every car on the road is thoroughly examined and tested in every detail once every three days. Trucks, motors, car bodies, controllers, etc., are gone over step by step by men assigned to special lines of inspection. Thus there are two men looking after controllers alone, one man on platform switches and reversers, two men on motors, a man on oiling, one man on resistance boxes and cables, three men on air brakes and adjustments and a man on relays. These men also make minor repairs. The building is about 400 x 35 ft., with large windows the entire length of each side. The walls and ceiling are whitewashed and the floor is covered with lime to absorb the waste grease. There are two pits, each accommodating eight cars. Advantage is taken of the time required to inspect the rolling stock to clean windows, transom lights, etc.

The officers and heads of departments of the South Side Elevated are: President, Leslie Carter; vice-president, A. A. Carpenter; general manager, Marcellus Hopkins; superintendent and master mechanic, J. F. Morrison; purchasing agent, Alonzo Nelson; general foreman, in charge of motive power, Andrew J. Allen; chief engineer of the power station, Alex Hadin.

J. F. Morrison, superintendent and master mechanic, was born in 1860, and his railroad career commenced in 1878, when he entered the service of the Manhattan Elevated R. R. of New York as train dispatcher. He continued in the employ of this company until 1892, when he resigned to accept the position of superintendent of transportation for the South Side Elevated R. R. of Chicago. In 1893 he was appointed to his present position.

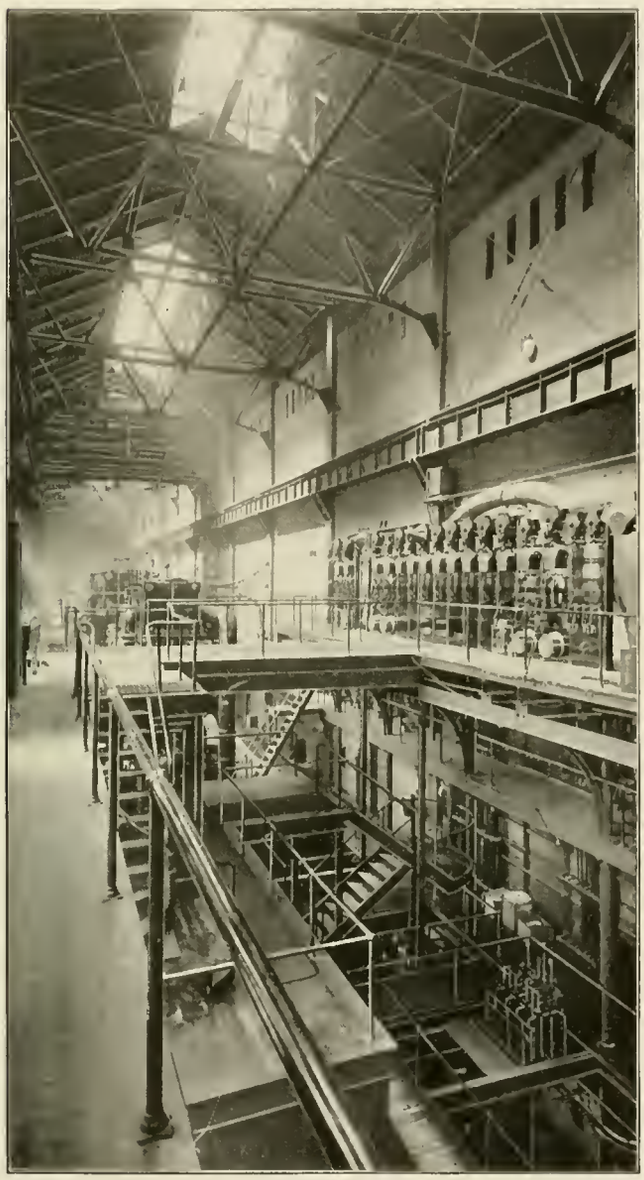
The Metropolitan Elevated.

The Metropolitan West Side Elevated Railroad Co. was incorporated Mar. 9, 1892, being organized by A. F. Walcott, who was then at the head of the construction company building the South Side Elevated. The capital was subscribed by London, New York and Boston capitalists. The company bought outright its entire right of way save, of course, at the street crossings. The construction work was done by the West Side Construction Co., of which E. W. Eckart was chief engineer. The territory served by this system is shown on the map. From the Union Loop to Market St. is a double track structure; from Market St. to a point

SCHERZER ROLLING LIFT BRIDGE—METROPOLITAN WEST SIDE ELEVATED.

1½ miles west of the river is the main line, with four tracks; from this latter point three double track lines diverge, to the south, west and north; the northern branch again divides into two double track branches. From Market St. to each of the terminals is about six miles; the total of (single) track is 30 miles. Trains were started from Canal to Robey St. May 6, 1895; from Franklin to Robey St. May 15th; from Franklin St. to Logan Sq. May 25th; on the Garfield Park line June 19th; on the Humboldt Park line June 29th; on the Douglass Park line August, 1896.

The success of the Intramural Ry. at the Columbian Exposition led the Metropolitan to adopt electricity as the motive power



INTERIOR OF METROPOLITAN POWER HOUSE.

and Mr. W. E. Baker, general manager of the Intramural, was made general superintendent of the Metropolitan. The General Electric Co. received the contract for all the electrical apparatus June, 1894. The example of the Metropolitan was followed by the other elevated roads in Chicago and they are all now electrically operated.

The structure was designed to carry 30-ton locomotives and was the heaviest built up to that time. The minimum height above the street is 14 ft., the usual height being 15 ft. The girders are of the plate type 4 ft. deep, and vary from 30 to 50 ft. in length. The posts rest on foundations of concrete 8 ft. square and 7 ft. deep. The most notable feature of the structure is the Scherzer rolling lift bridge over the Chicago River; this consists of two double track bridges placed side by side. The span from center to center of bearings is 114 ft. There are also three notable viaducts, the longest spans a clear space of 254 ft. over the Chicago & Northwestern tracks near Paulina St.; at the Union Depot yard is a viaduct of two spans, one of 227 ft. and one of 178 ft.; the third viaduct is at Rockwell St. over the tracks of several railroads.

The running rails are of 5-in. 80-lb. T-section rolled by the Illinois Steel Co. The conductor rails are 42-lb. and the feeders are 75 lb. rails made by the same company. The conductor rail is supported at one side of each track, 7 in. above the running rail, by insulating blocks. The conductor rail is fastened to these supporting blocks by clips. The conductor rail bonds are flexible copper

DICKINSON MACALLISTER.
President Metropolitan Elevated.

strips 3-16 in. thick and as wide as the rail base plate under the joints and riveted to the lower flanges. The feeders are 75-lb. T-rails laid between the tracks and boxed over. At a few points there was not sufficient room to use feeder rails and copper wires were hung under the structure. These wires and the copper for joining the feeder rails were furnished by the Washburn & Moen Co., the Simplex Electrical Co., and the John A. Roebling's Sons Co. For the return, the track rails are bonded to the structure near the middle point of each rail. At the river, where the continuity of its structure is broken by the bridge four Simplex rubber and lead covered, armored submarine cables of 500,000 c. m. and 14 of 235,000 c. m. capacity were laid on the river bottom.

A complete system of interlocking signals was installed by the National Switch & Signal Co.

The power house is located on the main line a short distance east of the intersection of the east and west and the north and south lines. It was originally 305 ft. long by 90 ft. wide, two tracks of the structure passing on each side of it; during the last year an addition was built, making the building 450 ft. in length.

When the station was built there were four vertical cross-compound engines, built by the E. P. Allis Co. Two of these have cylinders 36 and 72 x 48 in. and are direct connected to General Electric 1,500-kw. generators; they are guaranteed to work satisfactorily with a load of 3,100 h. p. each. The two smaller engines are direct connected to G. E. 800-kw. generators. This summer two additional Allis engines were installed; each is a vertical cross-compound, with cylinders 38 and 76 x 48 in., and is direct connected to a 1,650-kw General Electric generator.

Each of the engines has a separate governor controlling a butterfly valve in the main steam pipe. An electric crane, made by the Morgan Engineering Co., travels the entire length of the engine room.

The boiler room is on the north side of the building and now contains 20 Babcock & Wilcox boilers in batteries of two each; 12 of these constitute the original installation. Green economizers are used in this station. The coal handling machinery in this station is very complete. Coal is thrown into storage bins in front of the boilers by being dumped through doors in the roof from

cars on a siding of the elevated structure which passes directly overhead, or it can be hauled by teams to the alley in front of the boiler room and thrown in through the window. Coal cars can be run up onto the structure at the terminus of the Garfield Park line where it connects with the Chicago & Western Indiana Belt line. The boilers are all equipped with Babcock & Wilcox automatic stokers. Ashes fall into a conveyor in the basement of the boiler room.

the motorman's cabs. "Straight" air brakes made by the New York Air Brake Co. are used; an electrically operated air pump placed in one of the cabs furnishes the air for the train. Each motor car has electric headlights and markers, or destination signs.

The trail cars are 47 ft. over all of the standard elevated railway type; all cars have electric heaters made by the Central Electric Heating Co., of New York. The car couplers used were made by the W. T. Van Dorn Co., of Chicago.

H. M. BRINCKERHOFF,
Assistant General Manager.

GEO. HIGGINSON, JR.,
Secretary and Treasurer.

A. S. JONES,
Superintendent of Transportation.

A 5 ft. tunnel extends to the power house from the Chicago River and water for condensing is drawn from this source.

The switchboard is in a gallery which is level with the elevated structure.

The first car equipment consisted of 55 motor cars built by the Barney & Smith Car Co., Dayton, O., and 100 trail cars made by the Pullman Car Co. The company now has 65 motor and 168 trail cars.

The motor cars are 47 ft. 2¾ in. over all, and 40 ft. over the sills; the width at the sills is 8 ft. 7 in.; the roof is 12 ft. 10 in. above the rails. The motorman's cabs occupy two corners of the car, half of the cab being within the car and half on the platform. These cars weigh 40,000 lb., exclusive of the motors, and about 62,000 lb., including everything when loaded to their maximum capacity. They are used as smoking cars, and have side seats only.

The motor cars are mounted on swing bolster trucks, with 34¼-in. steel tired wheels, made by the Baldwin Locomotive Works, after designs of the Metropolitan company. The motor cars are equipped with two and four G. E. 2,000 motors and with two G. E. 55 motors.

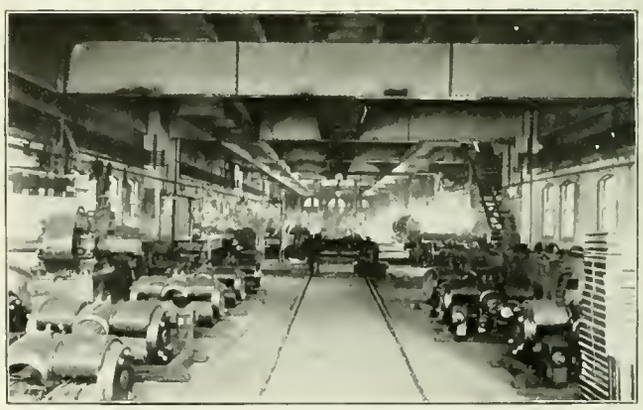
The motors are operated by series parallel controllers placed in

The company's shops are in a two story building adjacent to the structure and lying between Throop St. and Center Ave. The second floor is on a level with the tracks; all work on the car bodies and light repairs are made on this floor. For heavy repairs the trucks and motors are taken to the lower floor on a hydraulic elevator.

On Feb. 1, 1897, the company defaulted on its bonds, and foreclosure proceedings were at once instituted, Dickinson MacAllister being appointed receiver. In 1898 a reorganization was effected and the Metropolitan West Side Elevated Railway Co. took charge of the property in February, 1899.

The last two years have shown a very large increase in the traffic of this road, and the daily average of passengers carried increased from 44,434 for January and February, 1897, to 77,200 in December, 1898; the increase for July, 1899, was 26 per cent over July, 1898. For 345 days in 1897 the total of passengers was 16,085,547; for 365 in 1898 it was 23,887,667.

EXTERIOR METROPOLITAN SHOPS.



INTERIOR METROPOLITAN SHOPS.

The officers of the company are: President and general manager, Dickinson MacAllister; secretary and treasurer, George Higginson, jr.; assistant general manager, H. M. Brinckerhoff; superintendent of transportation, A. S. Jones; auditor, C. W. Hillman; purchasing agent, D. L. Budd; chief engineer, William S. Menden.

Lake Street Elevated.

The Lake Street Elevated Railway Co. was organized in April, 1888, under the Elevated Ways and Conveyers act, and the first sections of the structure were set at Lake and Clinton Sts., Dec. 18, 1889. There was a great deal of litigation connected with the early history of this company; it had to fight five other companies before it secured franchises, and financial difficulties compelled

the suspension of work after three miles of the structure had been completed. In 1892 the Illinois Supreme Court rendered a decision which cast doubt upon the sufficiency of the incorporation, and a new company, called the Lake Street Elevated Railroad Co., was chartered, its stock being exchanged for that of the old company. Messrs. F. L. Underwood and Willard R. Green, the contractors for the structure, secured control of the company in 1892 and negotiated its securities so that the road could be pushed to completion. At this time ex-Mayor John A. Roche was president of the company and Col. M. H. Alberger, the principal subscriber to the stock of the old company, was general manager.

The road was first opened for traffic Oct. 28, 1893; the formal opening was Nov. 4, 1893, when five trains of four coaches each carried a large party of invited guests from the down-town terminus to Homan Ave. and back.

The operation at this time was by steam locomotives. The company had 25 two-cylinder compound locomotives built by the Rhode Island Locomotive Works, and 125 passenger cars built by the Gilbert Car Co., Troy, N. Y. The locomotives weighed 60,000 lb. each; the drivers were 44 in. in diameter; the cylinders were 13 and 21 x 18 in.; steam pressure, 180 lb.

One of the most interesting features of the structure is the bridge crossing the Chicago River. Working jointly with the city, the old bridge at Lake St. was rebuilt with an upper deck on the draw span. The structure is 48 ft. wide, posts being set at the curbs, and was designed for three tracks. Up to the present time only two tracks have been laid, save where a third one was needed for car storage or switching purposes; it is intended to complete the third track from W. 52d St. to Campbell Ave. at an early date, and give an express service making no stops between those points.

In 1895 the Lake Street road was equipped for electricity, the third rail and feeder systems being installed under the direction of Mr. J. R. Chapman, electrical engineer for the Yerkes system. The work was under the immediate charge of Mr. C. E. Collins. The third rail on this road is supported on insulators placed 6 ft. apart. These insulators are made up of three pieces; a base casting bolted to the ties, a bolt covered with insulating compound screwed into the base, and a cast top piece with flanges to grasp the rail. The only machine work done on the insulator was cutting threads for the joint between the bolt and the base; a tight joint between the bolt head and the rough cast cap was made with sulphur. This insulator was designed by Messrs. Chapman and Hanson; the insulating compound was furnished by Albert & J. M. Anderson Manufacturing Co. The rails are protected by wooden guards.

The feeders are 1,000,000-c. m. and 1,500,000-c. m. copper cables made by the John A. Roebling's Sons Co. They are held in place by iron brackets, lined with Anderson insulating compound bushings, spaced 100 ft. apart. At intervals of 10 ft. between the iron brackets are clay insulators made by the H. B. Camp Co., of Aultman, O., which serve as supporters for the feeder cables.

Since September, 1896, the road has been operated by electricity, though the first trial of electric traction was in June of that year.

The rolling stock consists of 37 motor cars and 87 trail cars, these being the passenger cars of the original equipment. The motor cars are mounted on trucks made by the Baldwin Locomotive Works; each truck has one G. E. 57 motor. The controllers are of the General Electric L 4 type. Westinghouse air brakes are used, an electrically driven pump in the cab of the motor car furnishing the air for the train.

The elevated structure extends from the northwest corner of the Union Loop out Lake St. a distance of 7 miles, a spur in Fifth Ave. used as the terminal before the completion of the Loop, and the third track bring the total trackage up to 17 miles, measured as single track.

D. H. LOUDERBACK,
President Lake Street Elevated and Northwestern Elevated.

West of W. 52d St. there is an incline to the surface, and Lake St. trains run out to the junction of Wisconsin Ave. and Randolph St. in Oak Park, a distance of 9½ miles from the Loop.

The company has no power house of its own, and buys power by meter from the Union and the Consolidated Traction companies. Power is furnished from the Hobbie St., the Western Ave. and the Cicero & Proviso stations. For the month of July, 1899, the average power per car-mile run was 1.95 kw. h.; the motor cars weigh 52,000 lb. and the trail cars 32,000 lb.

The shops and car house are at Lake St. and Harding Ave. The building is on the surface level and is 450 ft. long and 60 ft. wide. Four tracks extend the entire length of the buildings; cars are brought down from the structure over an incline 550 ft. long on a grade of 2¾ per cent. The machine shop occupies the south

INCLINE OF LAKE STREET ELEVATED AT WEST 52D ST.

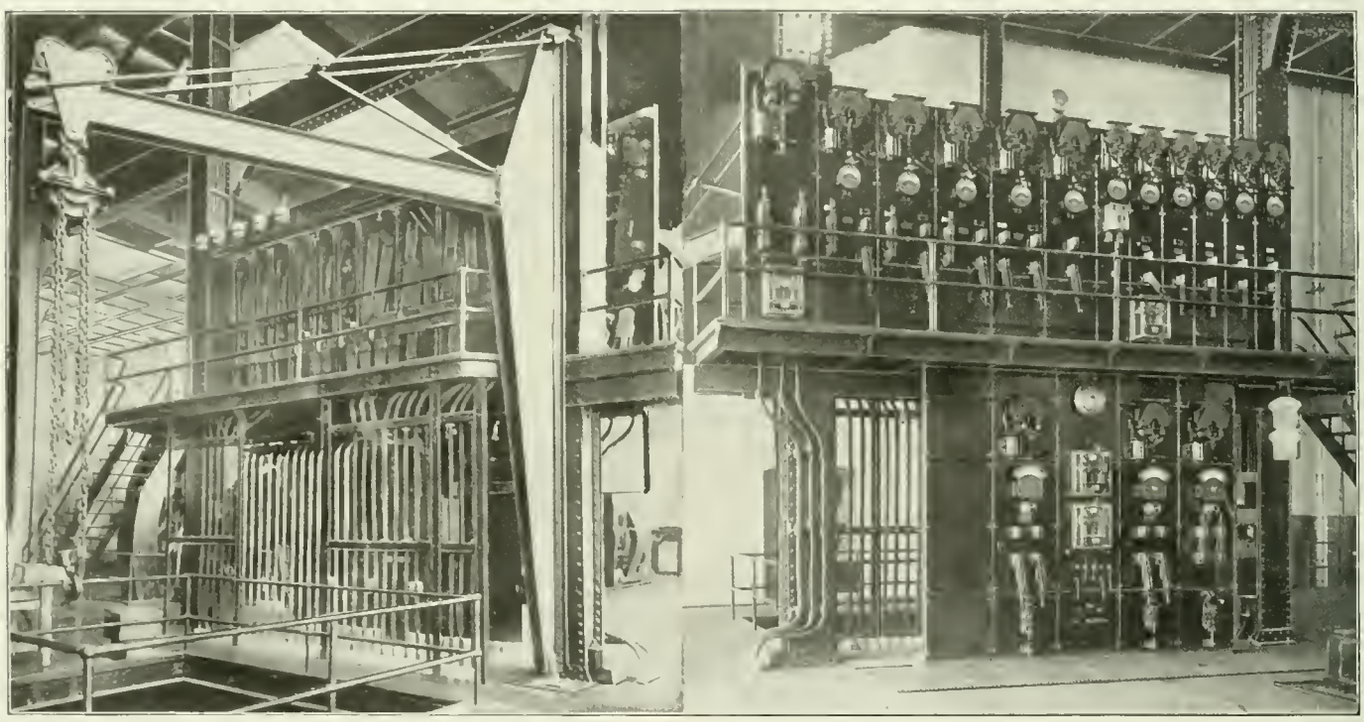
end of the building. An electric crane, made by the Wm. Sellers Co., of Philadelphia, runs along the west half of the building.

The operating offices are in rooms on the second floor of the shop buildings, and the general offices in the Royal Insurance Building.

The officers of the Lake Street Elevated Railroad Co. are: President, D. H. Louderback; vice-president, A. S. Littlefield; secretary and treasurer, Howard Abel; general superintendent, Frank Hedley; engineer, Charles V. Weston; electrician, J. R. Chapman.

The Union Elevated.

The Union Elevated Railroad Co. was incorporated in November, 1894, by Mr. Yerkes and his associates for the purpose of building a down-town loop terminal for all the elevated roads in the city. The Loop is a double track structure, 11,150 ft. long, with 11 stations. By a lease dated Oct. 1, 1897, the road is granted to the four elevated railroads for their sole use for so long a period as under present franchises or extensions thereof they may be permitted to operate; the lessees pay the Union company a guaranteed minimum rental of $250,000 and all expenses, but pay one half cent for every paying passenger carried on their respective lines, and in addition pay all the expenses of operation and maintenance, including taxes and ground rent of the power station building when the ½ cent compensation amounts to more than $250,000 and expenses. The Union company pays the city a per centage of the net earnings, after deducting $250,000 a year bond interest; the payment to the city increases from 5 per cent prior to 1902 to 25 per cent after 1933.



SWITCHBOARD, UNION LOOP POWER HOUSE.

Work on the Loop was begun during the winter of 1895 and completed in the summer of 1897. The Lake Street began using the Loop tracks as far as the Adams and Wabash station in October, 1896, and to make the complete circuit Oct. 10, 1897; the Metropolitan began using the Loop Oct. 11, 1897, and the South Side on Oct. 19, 1897. The effect of the loop connection in increasing traffic on the roads using it has been little short of marvelous, the figures for the month of September, 1897, and September, 1898 for the South Side and Metropolitan are:

	1897.	1898.
Metropolitan	1,144,096	1,813,464
South Side	902,010	1,397,280

The road is operated on the third rail system, the conductor rails being placed between the two tracks, at the sides of the wooden box carrying the feeders along the center of the structure. The feeder box is covered and serves as a footpath for employes. The method of supporting and insulating the conductor rails and feeders does not differ from that employed on the Lake Street. The insulators were made by the Albert & J. M. Anderson Co., of Boston, after the design of J. B. Chapman, the electrical engineer of the Loop, who designed the electrical equipment. For feeding purposes the Loop is divided into four sections, the north and west and the east and south sides of each track constituting the sections. There are 11 feeders carried from the power house to the structure through a conduit laid in Market St. Each of these feeders is of stranded copper and has an area of 1,500,000 c. m. At stations and special work the bare cables are replaced by insulated cables carried under the structure. While the feeder system in general outline is very simple, the detail drawings showing connections to the conductor rails at special work resemble geometrical puzzles. In spacing the contact rails at crossovers and switches, the method of making the car bridge the two connections was adopted.

About 1,100 32-c. p. lamps are required for lighting purposes, and they are all on the same circuit, the cables being carried in the feeder box. A 30-pair telephone cable is carried around the structure and connected to switchboards in all the stations and signal towers. A very complete interlocking switch and signal system has been installed.

A great deal of special track work was necessary and it was all done by the Paige Iron Works, Chicago.

The company has no rolling stock, but owns a large power plant on Market St. opposite Congress St. The building is of brick and irregular in shape, the longest dimensions being 142 ft. front and 164 ft. deep. It is a double-deck station, the boilers being placed in the second story; a hanging floor below the boiler room floor carries the smoke flues and provides room for coal and ash handling machinery.

There are 16 Babcock & Wilcox 400-h. p. water tube boilers arranged in batteries of two; they are all equipped with grates and "Acme" automatic furnaces for coal burning and with fuel-oil circulating apparatus installed by the National Supply Co. Oil is received at the station in tank wagons. As oil is used for fuel the

coal handling machinery contemplated in the original design has not yet been put in place.

All the steam accessories for this plant are placed in the basement. Three Wheeler surface condensers with marine type air pumps, are installed. The water for condensation is obtained from the river, the circulating pumps being of the centrifugal type. The water for boiler feeding, however, aside from that obtained from the condensers, comes from the city mains. It is expected that the early completion of the drainage canal will so improve the river water that it may be used for the boilers. The feed-water pumps were made by the George F. Blake Manufacturing Co., and are vertical, duplex and piston packed. The feed water passes through horizontal heaters located between the low-pressure cylinder and condenser of each engine; thence it passes into vertical heaters supplied with exhaust steam from the auxiliary machinery, and from these heaters it goes to the boilers at a temperature of about 210 degrees. All the heaters were made by the Wheeler Engineering Co.

The steam piping is arranged so that the risk from damage on account of breakage is reduced to a minimum. Three main vertical supply pipes from the boiler room to the basement pass through the engine room, back of the engine cylinders and close to the brick wall, and these are the only steam pipes to be seen on the engine-room floor. The separators are located in the basement, as well as the reheating receivers, operating valves, grease extractors, etc. The return of all water of condensation is effected by a Holly return system. All piping from which any heat could be lost is covered with the H. W. Johns asbesto-sponge material.

The engine room is on the first floor, and contains three cross-compound condensing slow speed engines, with cylinders 30 and 60 x 60 in.; mounted on the main shaft of each engine is a Siemens & Halske internal-field type of generator. The generators have 16 poles and turn at 75 r. p. m., the nominal capacity of each being 1,500 kw. The engine shafts are hollow-forged, fluid-compressed steel made by the Bethlehem Steel Co. For handling machinery in the engine room there are two hand operated overhead traveling cranes made by Pawling & Harnischfeger, of Milwaukee, and three post cranes over the basement hatchways.

The switchboard is built between two of the steel posts supporting the girder for the overhead cranes; it is of slate and two sections high.

The generator panels are on the level of the engine-room floor and the feeder panels are on the gallery above, which is provided with a railed balcony on all sides. The leads from the generators are laid under the floor to the switchboard, and the feeders from the latter are conducted from the power house to the elevated structure in ducts underneath the surface of Market St.

Five panels make up the lower board—a wattmeter panel in the center and two generator controlling panels on each side. Each generator panel has a positive and a negative switch, having a carrying capacity of 3,500 amperes. Beside these large switches there is a Weston ammeter, a General Electric circuit breaker, and a Siemens field switch on each generator panel. The wattmeter panel carries two instruments, each of 7,000 amperes' capacity, and also the switches controlling the lighting circuits in the building. Two voltmeters are mounted on an insulated swinging frame on one side of the board.

The feeder panels in the gallery are as follows: Four, of 3,500 amperes' capacity each, for the Loop proper; one, of 700 amperes, for the lighting surface on the structure, including lamps for ticket stations, platforms, street intersections, signal towers, etc.; five, of 800 amperes each, with wattmeter, that may be used for supplying current to surface electric railway lines controlled by Mr. Yerkes and operating in the business district. In addition to the 10 panels named a special "emergency panel" has been recently installed. It is equipped to carry 5,000 amperes to supply the South Side Elevated beyond the Loop in case of interruption of that company's power from its station at 40th St. For this purpose a special emergency feeder is in position on the Van Buren St. side of the Union Loop. Each of the feeder panels has a Weston ammeter and a General Electric circuit-breaker.

BOILER ROOM, UNION LOOP POWER HOUSE.

The maximum load on the Loop station up to the present has not exceeded 4,000 h. p. Ordinarily one unit is sufficient for the midday load, while there is a light load for two engines during the rush hours. The variation in load is from a maximum of 6,000 amperes at 6 p. m. to as low as 250 amperes in the hours after midnight. The fluctuations in load are excessive, a swing from 250 to 3,000 amperes having been observed at 4:30 p. m. within a period of 20 seconds.

This station was built after the designs of Mr. Potis and Mr. Chapman.

The Loop is also connected with the Hobbie St. station of the Union Traction Co., and with the power stations of the Metropolitan and South Side roads. The equipments of the latter stations are such that in summer when there is no current required for heating it is more economical to operate the Loop from them and shut down the Loop station. The north and east sides of the Loop take current from the South Side station, and the others from the Metropolitan. The result is that these two stations have a better load factor, giving a lower cost for power, and the lessees save the expense of operating the Loop station.

The officers of the Union Elevated Railroad Co. are: President, C. T. Yerkes; vice-president, J. Charles Moore; general manager D. H. Louderback; secretary and treasurer, Howard Abel.

The Northwestern Elevated.

The Northwestern Elevated Railroad Co. was organized in October, 1893, Mr. Yerkes being the moving spirit, for the purpose of building an elevated road through the North Division of the city. The work of construction began May 19, 1895, and the first of the superstructure was placed Jan 27, 1896. After 3¼ miles of structure had been built the financial panic of 1896 caused a suspension of the work which was not resumed until the spring of the present year; during the past summer the progress has been rapid, and it is confidently expected that the line will be in operation by March, 1900. In all there will be 25.45 miles of track, of

WORK ON THE NORTHWESTERN ELEVATED.

which 23.92 miles will be used for running trains, and the rest for car storage.

From Institute Place to Wilson Ave., a distance of a little more than 5½ miles, the road will be four track, and it will be two track from Institute Place to its connection with the Union Loop at Fifth Ave. and Lake St. Express trains will be run, which will make stops only once in each mile between Wilson Ave. and Institute Place. These trains will run from Wilson Ave. into the heart of the business district in a little more than 25 minutes. The contract for the rails, ties, special work and everything above the structure was let to the North American Railway Construction Co., of which A. S. Littlefield is president.

The terminal station will be at Wilson Ave. This building is to be constructed of brick and steel, and will be 400 x 65 ft. in size. It will have a capacity for housing 40 motor cars, which will be put in operation when the line is open for traffic. The work on the viaduct at Wells St. was recently completed.

The Pullman company has the contract for building 147 cars for this road, and nearly half of them have been completed. These cars are 46 ft. long over the end plates, and 8 ft. 7 in. wide at the sills. As the road is to be operated left handed the motorman's cabs are at the left forward corners of the motor cars. The cars are to have Hale & Kilburn seats, covered with rattan of small mesh, and "Pantasote" curtains, with Forsyth fixtures.

Trucks for the motor cars are to be of the swing bolster type, with 6-ft. wheel base, designed by Mr. Hedley, general superintendent of the Lake Street Elevated, and made by the McGuire Manufacturing Co.

The power station building, at Fullerton and Southport Aves., is well under way. This is the latest of the stations designed by Mr. Chapman, and embodies all the improvements that his extensive experience with the Yerkes lines could suggest. The plant is about midway between the two extremities of the road, and is a little over half a mile west of the line. The building now erected is 112 x 255 ft.; it occupies less than half of the lot, the design contemplating an addition of 175 ft. to the present building, so that the ultimate capacity of the station will be 14,000 h. p.

The first equipment will comprise 12 Babcock & Wilcox boilers, arranged in batteries of two, equipped with Murphy automatic smokeless furnaces and four engine and generator units, besides the auxiliary apparatus. There are three 30 and 60 x 60-in. cross-compound Allis engines direct connected to 1,500-kw. Siemens & Halske generators, operating at 75 r. p. m. The smaller engine is of the same type, with 23 and 46 x 48-in. cylinders, operating at 80 r. p. m. and direct connected to a 750-kw. Siemens & Halske generator.

For handling coal, there are to be storage bins, chutes and conveyors of the gravity bucket type.

There is a basement 12 ft. 4 in. high under the entire building; on the engine room side are steam and exhaust piping, receivers, separators, and the electrical cable connecting with the switchboard; on the boiler room side are the ash conveyor, the smoke flues and the feed and blow-off piping systems. The boiler feed pumps are three in number, of the Admiralty type, made by the Henry R. Worthington Co.; the feed is taken through one of two 2,000-h. p. heaters.

The steam header, carried overhead in the boiler room, is of wrought iron pipe, 28 in. diameter, with welded flanges; the maximum boiler pressure in the station is to be 160 lb.

The station has a Weiss counter-current type of central condenser built by the Southwark Foundry & Machine Co., which will condense the steam from all the engines in the station. The condenser vessel has a capacity of 14,000 h. p. The condenser pumps comprise a dry air pump for removing the air from the system, and a Bibus rotary pump for supplying the cold injection water; these two pumps are driven from the same engine, the air pump tandem and the circulating pump belted. The hot water flows from the condenser through a "water leg," which is merely a barometic column, the lower end of the pipe being submerged The action of the circulating pump is positive, and the amount of water it handles automatically regulated according to the load, because of the speed of the auxiliary engine being governed by the action of the air pump.

C. V. WESTON,
Chief Engineer.

Condensing water is taken from a 12-ft. brick tunnel built by the city, extending from the lake to the river, which is laid in Fullerton Ave., in front of the power house.

The stack at this station is at one side, opposite what will be the center when the building is extended. It is 27 ft. square at the base, 203 ft. high above the street, and has a 10-ft. flue; it rests on a pile foundation topped with concrete 31 ft. square and 5 ft. thick.

The officers of this company are: President, D. H. Louderback; vice-president, C. D. Hotchkiss; secretary and treasurer, Howard Abel.

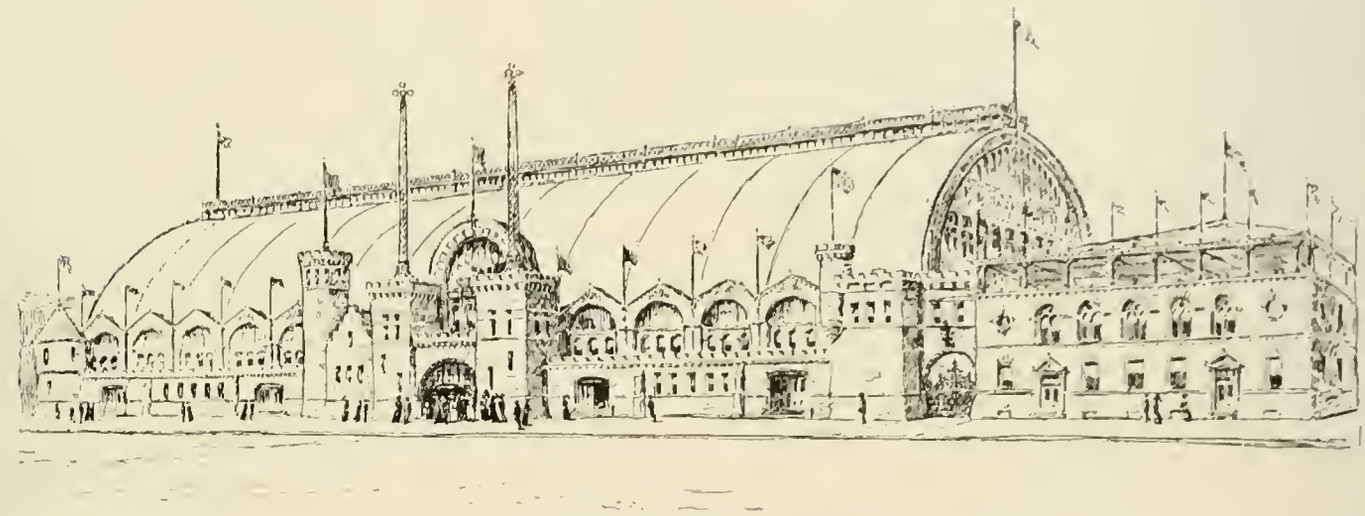
NO MUNICIPAL RAILWAY FOR DETROIT.

The street railway fight in Detroit is ended, at least so it is announced. Elliott G. Stevenson, Eli B. Sutton, J. G. Hutchins, Tom L. Johnson and R. T. Wilson held a long conference in New York on September 9th, relative to the reopening of the Detroit municipal street railway campaign, and after the meeting Mr. Stevenson stated that as a result of the conference the entire street railway deal contemplated under the McLeon act and later under the plan proposed by the Municipal Railway Co., is permanently and absolutely abandoned. The reason given is that Mr. Wilson refused to tie up his property with another option, and that he also increased the asking price of the roads from approximately $15,000,000 cash to $17,000,000.

THE CONVENTION HALL.

The convention will be held in the buildings known as Tattersalls, which extends from 16th St. to 17th St., between State and Dearborn. It is reached from the down town hotels by taking any car on either the Wabash Ave. or State St. lines of the Chicago City Ry. Passengers should alight at 16th St. and walk west, (away from the lake) the one or two blocks.

Chicago, much to its discredit, has not at present any suitable or adequate building for gatherings of this kind. The immense Coliseum at 63d St., with a seating capacity the largest in the country, burned about two years ago. During the present year a strong company was organized, and had in process of erection a magnificent building, both as to its capacity and appointments. It was to be the finest of the kind in the United States. While Tattersalls was selected for the convention on the visit here of the executive committee, it was confidently expected then that the new Coliseum would be far enough along so that the meetings and exhibits could be held there. Up to August 31st work was progressing rapidly day and night, and arrangements were practically closed to transfer the convention to the new structure, which it



PROPOSED CHICAGO COLISEUM.

CHICAGO COLISEUM WRECKED AUGUST 31ST.

was promised by the builders, would be ready by the time required. On the date named, however, a terrible disaster occurred in which nine workmen were killed by the falling of the immense trusses which formed the arch of the roof. It is an occasion of deep regret and disappointment to the local committees, that they are obliged, after all, to locate the meeting in a building which, while perfectly safe, and of fairly good size does not possess the interior appointments they would gladly have secured were another building of sufficient size to be had. They have, therefore, been obliged to make the best of an unfortunate and unexpected situation, which they are powerless to help.

The new Coliseum would have been 382 ft. long by 172 ft. wide, which is 69 ft. longer and 41 ft. wider than Madison Square Garden. We illustrate the design of the Coliseum as it would have been, the accident, to show what we expected to offer our guests. We also desire to express the great disappointment of the local committee.

BUREAU OF INFORMATION.

This important feature of the Exhibit Hall is in charge of an active committee, whose title is that of Publicity and Information. The office of this committee will be found at the main entrance of the building. Here are provided telephone and telegraph facilities, railroad time tables of all roads running into Chicago, diagrams of the theaters, city and railroad directories, and other general information usually desired at such times.

A force of stenographers will be provided, with machines, to handle dictation of guests promptly and accurately. Complete facilities also are provided for checking garments or packages which visitors may not wish to carry with them in the building.

Another feature which is new and which will be greatly appreciated by the exhibitors, especially, is the post office department. A special carrier will be detailed from the Chicago post office and stationed at the Bureau during the entire convention week.

Mail addressed care Tattersalls will be delivered promptly to the proper person in his exhibit space, and six deliveries per day will be made. Mail for delegates will be carried to convention hall with the same promptness. Stamps and postal cards will also be provided.

The committee has prepared an extremely complete reference book of pocket size, which is a miniature Chicago directory specially compiled with reference to the wants of street railway people.

The Bureau will open at 8 a. m. and remain in operation until late at night.

"REVIEW" HEADQUARTERS AT TATTERSALLS.

The headquarters of the "Review" at the convention hall will be found at the first space on the right of the main entrance to the exhibit hall—Space No. 2.

We invite visitors to drop in and rest, or use it for office or meeting purposes. There will be an abundance of comfortable chairs and a hearty welcome.

PLAN OF EXHIBIT HALL, AMERICAN STREET RAILWAY ASSOCIATION CONVENTION.

LIST OF EXHIBITORS.

No. of Space.	Exhibitor.	Sq. Ft.
1.	C. F. Orr & Co.	100

HOME OF THE "STREET RAILWAY REVIEW."

The "Review" will be pleased to have its readers visit its establishment at any time during convention week, and to have its friends make use of its office.

The business and editorial offices of the Windsor & Kenfield Publishing Co. occupy the thirteenth floor of the Monon building. In the adjoining building are our mechanical departments. The "Review" is one of the few trade and class journals which operates its own printing establishment. This is divided into two departments: the composing room, where a battery of typesetting machines operate day and night; and the press room. The latter contains five presses, three of which were built to order specially for high grade printing. Two of these presses are among the largest and fastest of their class in the city. Our friends are invited to call and inspect the operation of these machines. Our establishment is convenient to all the down town hotels by a few minutes' walk, and the street number is 324 Dearborn—near Van Buren. In telephoning call for Harrison 754.

Announcement is made by an official of the Grand Rapids & Indiana Ry., a steam road running from Richmond, Ind., to Mackinac, Mich., that if the proposed electric line is built from Grand Rapids to Kalamazoo, to compete with its service, it will immediately equip its division between those two cities with electricity.

LAKE SHORE AND ROCK ISLAND DEPOT.

LOCATION OF RAILROAD DEPOTS IN CHICAGO.

We give for guidance of visitors a list of the railroad depots, some of which are used by several roads. Also the convenient means of reaching them from Wabash Ave. and Jackson St., which is a central down town point easily determined.

CENTRAL STATION: Lake Front and 12th St.; reached by Wabash Ave. cars going south.

NORTHWESTERN DEPOT: Fifth Ave. and the river. Take Dearborn St. car, so marked.

UNION DEPOT: Adams St. and Canal (just across the bridge) take Adams St. cars bearing depot sign.

LAKE SHORE and ROCK ISLAND DEPOT: Van Buren and Sherman Sts., four blocks west of Wabash. Walk, take cab or Lake St. Elevated.

POLK ST. DEPOT: Foot of Dearborn St.; Wabash, State or Dearborn St. cars.

GRAND CENTRAL STATION: Harrison and Fifth Ave.; cars so marked from Van Buren and State Sts., or cab.

SPECIAL TRAIN FROM THE EAST.

A special train to the Chicago convention will be run from Boston over the Boston & Albany, and from New York over the New York Central, merging at Albany and from there continuing over the New York Central and Lake Shore & Michigan Southern. It will be a vestibule train of Wagner sleepers with dining car. Fare is one and one-third for the round trip. Passengers taking train at New York or points on New York Central should address Milton C. Roach, general eastern passenger agent, N. Y. C. R. R., 413 Broadway, New York. Passengers from Boston and points on the B. & A. communicate with J. L. White, passenger agent, B. & A. R. R., 266 Washington St., Boston.

Leaving time from principle points is as follows:

Lv. Boston	B. & A.	10:30 a. m.	Sunday, Oct. 15.
Lv. Worcester	B. & A.	11:42 a. m.	Sunday, Oct. 15.
Lv. Springfield	B. & A.	1:14 p. m.	Sunday, Oct. 15.
Lv. New York	N. Y. C	1:00 p. m.	Sunday, Oct. 15.
Lv. Albany	N. Y. C.	4:35 p. m.	Sunday, Oct. 15.
Lv. Utica	N. Y. C.	6:52 p. m.	Sunday, Oct. 15.
Lv. Syracuse	N. Y. C.	8:15 p. m	Sunday, Oct 15.
Lv. Rochester	N. Y. C.	10:05 p. m.	Sunday, Oct 15.
Lv. Buffalo	L. S. Ry.	12:00 midnight.	Sunday, Oct. 15.
Ar. Chicago	L. S. Ry.	2:30 p. m.	Monday, Oct. 16.

OFFICERS A. S. R. A.

President, Charles S. Sergeant, second vice-president Boston Elevated Railway Co., Boston, Mass.

First Vice-President, Henry C. Moore, president Trenton Street Railway Co., Trenton, N. J.

Second Vice-President, Ernest Woodruff, president Atlanta Railway & Power Co. and Atlanta Railway Co., Atlanta, Ga.

Third Vice-President, Walton H. Holmes, president Metropolitan Street Railway Co., Kansas City, Mo.

Secretary and Treasurer, T. C. Penington, treasurer Chicago City Railway Co., Chicago, Ill.

Executive Committee, the president, vice-presidents and—

Albion E. Lang, president Toledo Traction Co., Toledo, O.

G. A. Yuille, assistant general manager Chicago Union Traction Co., Chicago, Ill.

Frank Jones, vice-president and manager Memphis Street Railway Co., Memphis, Tenn.

John I. Beggs, general manager Milwaukee Electric Railway & Light Co., Milwaukee, Wis.

Ira A. McCormack, general superintendent Brooklyn Rapid Transit Co., New York.

A complete list of the cities where the conventions have been held and the presiding officer is as follows:

Boston	Moody Merrill	1882
Chicago	H. H. Littell	1883
New York	William H. Hazzard	1884
St. Louis	*Calvin S. Richards	1885
Cincinnati	Julius S. Walsh	1886
Philadelphia	*Thomas W. Ackley	1887
Washington	Charles B. Holmes	1888
Minneapolis	George B. Kerper	1889
Buffalo	Thomas Lowry	1890
Pittsburg	Henry M. Watson	1891
Cleveland	John G. Holmes	1892
Milwaukee	D. F. Longstreet	1893
Atlanta	Henry C. Payne	1894
Montreal	Joel Hurt	1895
St. Louis	H. M. Littell	1896
Niagara Falls	Robert McCulloch	1897
Boston	Albion E. Lang	1898
Chicago	C. S. Sergeant	1899

*Deceased.

PROGRAM.

TUESDAY, OCTOBER 17th.

10 a. m. Meeting called to order by President Sergeant.
Address of welcome.
Calling of the roll.
Invitation extended to join the Association.
Address of the president.
Report of the executive committee.
Report of the secretary and treasurer.
Paper: "Investments in Street Railways: How Can They Be Made Secure and Remunerative?" By Charles T. Yerkes, president Chicago Consolidated Traction Co. and Union Elevated Railroad Co.
Reception at Auditorium Parlors, 8:30 p. m.

WEDNESDAY, OCTOBER 18th.

Convene at 10 a. m.
Paper: "Maintenance of Car Equipment." By J. H. Vanderveer, Brooklyn Heights Railroad Co.
Paper: "Modern Street Railway Shops; Their Design, Machinery and Shop Practice." By B. L. Kilgour, electrical engineer, Cincinnati Street Railway Co.
Appointment of Committee on Nomination of Officers and selection of next place of meeting.
1:30 p. m. Trip to Drainage Canal. Train leaves depot at 1:30 sharp; return at 5 p. m.

THURSDAY, OCTOBER 19th.

Convene at 10 a. m.
Paper: "Construction and Maintenance of Street Railway Track." By Edward Butts, Metropolitan Street Railway Co., Kansas City, Mo.
Paper: "Tram Service and Its Practical Application." By Ira A. McCormack, general superintendent Brooklyn Heights Railroad Co.
Election of officers for ensuing year.
1:45 p. m. Tallyho ride through Jackson Park.
2:00 p. m. Trolley ride to stock yards. Attendants will be on hand to show all the points of interest.
8:00 p. m. Theater party. Tickets will be distributed at the hotel. Those intending to go will make up their own parties and get tickets accordingly.

FRIDAY, OCTOBER 20th.

The entire day to be given to the examination of exhibits.
Ladies will be taken to the principal stores, the Art Institute and Lincoln Park; carriages will be in waiting at the hotel at 10:00 a. m.
7:00 p. m. Banquet at the Auditorium.
Installation of officers-elect at the banquet.

LOCAL COMMITTEES FOR CONVENTION.

Following are the local committees on arrangements for the convention:

GENERAL COMMITTEE.

John M. Roach, chairman
Geo. A. Yuille, secretary and treasurer.
H. M. Sloan. — Geo. O. Nagle.
F. L. Fuller. — H. H. Windsor.
T. C. Penington. — J. R. Chapman.

EXHIBITS.

James R. Chapman, chairman.
Geo. W. Knox. — C. E. Moore.
F. T. C. Brydges. — John Millar.
W. F. Carr. — A. C. Heidelberg.
N. C. Noe. — W. A. Harding.

ENTERTAINMENT.

J. M. Roach, chairman.
Frank R. Greene. — T. M. Henderson.
Geo. C. Bailey. — A. S. Littlefield.
Geo. A. Yuille. — Harry Keegan.
F. W. Edmunds. — F. S. Kenfield.

HALLS AND HOTELS.

Geo. O. Nagle, chairman.
A. S. Littlefield. — T. M. Henderson.
F. H. Clark. — H. A. Higgins.
W. H. Forsyth.

TRANSPORTATION.

F. L. Fuller, chairman.
W. W. Bean. — Wm. Walmsley.
T. D. Miles. — W. J. Cooke.
J. M. Atkinson. — J. J. O'Keefe.
Clift Wise. — H. W. Falk.

BANQUET.

J. M. Roach, chairman.
M. B. Starring. — D. G. Hamilton.
H. H. Windsor. — B. E. Sunny.
G. C. Bailey. — C. S. McMahon.

FINANCE.

Geo. A. Yuille, chairman.
J. C. Moore. — C. R. Penington.
H. B. White. — W. S. Bell.
F. H. Fitch.

RECEPTION AND LADIES.

H. M. Sloan, chairman.
L. S. Owsley. — F. L. Fuller.
C. K. Knickerbocker. — T. P. Bailey.
G. A. McKinlock. — J. C. Moore.
C. N. Duffy. — Robt. McCulloch.
T. C. Penington. — F. E. Smith.
F. R. Greene.

OFFICERS OF THE AMERICAN STREET RAILWAY ASSOCIATION.

C. S. SERGEANT,
President.

T. C. PENINGTON,
Secretary.

HENRY C. MOORE
First Vice-President.

ERNEST WOODRUFF,
Second Vice-President.

WALTON H. HOLMES,
Third Vice-President.

A. E. LANG,
Executive Committee

G. A. YUILLE.

FRANK JONES.

JOHN I. BEGGS.

IRA A. McCORMACK.

Members of the Executive Committee.

LADIES' RECEPTION COMMITTEE.

Mrs. J. M. Roach.	Miss Maude Pennington.
Mrs. Frank R. Greene.	Mrs. C. R. Pennington.
Mrs. J. Chas. Moore.	Mrs. Z. E. Knapp.
Mrs. J. W. Buell.	Mrs. W. J. Cooke.
Mrs. M. B. Starring.	Miss M. E. Cooke.
Mrs. J. R. Chapman.	Mrs. Clay Crawford.
Mrs. W. A. McGuire.	Miss Estelle Johnson.
Miss M. A. McGuire.	Mrs. Geo. A. McKinlock.
Miss E. B. McGuire.	Mrs. W. Worth Bean.
Miss M. Willowby.	Miss Keith Bean.
Miss Frances Byrne.	Mrs. F. S. Kenfield.
Mrs. H. H. Windsor.	Mrs. J. N. Hobbs.
Mrs. J. Samuel Sheahan.	Mrs. R. E. Richardson.
Mrs. Clift Wise.	Mrs. H. A. Marsh.
Mrs. R. H. Prince.	Mrs. H. M. Sloan.
Mrs. Robt. McCulloch.	Mrs. W. A. Harding.
Miss Bessie Felton.	Miss Edna Kimmell.
Mrs. George A. Yuille.	Mrs. G. W. Knox.
Mrs. Theo. P. Bailey.	Mrs. C. N. Duffy.
Mrs. B. E. Sunny.	Miss Clara Cunningham.
Mrs. T. C. Penington.	Mrs. J. C. Shainwald.

PUBLICITY AND INFORMATION.

H. H. Windsor, chairman.

J. A. Hanna.	C. J. Reilly.
Arthur Hartwell.	C. A. Brett.
D. B. Dean.	C. S. McMahon.

CHICAGO STREET RAILWAY MAIL SERVICE.

The street railway mail service on the Chicago lines is quite important. Four railway post office routes were established Nov. 11, 1893, and were operated by the railway mail service bureau of the Post Office Department until recently when they were placed under the jurisdiction of the Chicago post office.

During the fiscal year ending June 30, 1898, the Chicago & North

FIRST STREET RAILWAY POST OFFICE IN CHICAGO.

Clark St. route, 3.61 miles, with two cars and four clerks, made 22,996 miles, and handled 24,320 pieces (estimated) of mail matter per day; the Chicago & Milwaukee Ave. route, 3.07 miles, two cars and three clerks, made 34.64 miles, and handled 10,800 pieces per day; the Chicago and Madison St. route, 4.07 miles, two cars and five clerks, made 34,701 miles, and handled 24,320 pieces per day; the Chicago & Cottage Grove Ave. route, 7.73 miles, two cars and four clerks, made 53,971 miles, and handled 20,060 pieces per day. The first three routes are over the Chicago Union Traction lines, and the last over the Chicago City Ry.

The opening of an extension of the Cleveland & Chagrin Falls Electric Ry. and the completion of the Cleveland & Eastern Ry., makes a through electric line from Cleveland to South Newbury, a distance of 30 miles.

OFFICERS STREET RAILWAY ACCOUNTANTS' ASSOCIATION.

President, J. F. Calderwood, auditor Twin City Rapid Transit Co., Minneapolis, Minn.

First Vice-President, E. R. L. Tighe, accountant Brooklyn Rapid Transit Co., New York.

Second Vice-President, R. Lancaster Williams, treasurer Richmond Traction Co., Richmond, Va.

Third Vice-President, F. E. Smith, auditor Chicago Union Traction Co., Chicago, Ill.

Secretary and Treasurer, W. B. Brockway, secretary Toledo, Bowling Green & Fremont Railway Co., Toledo, O.

Executive Committee, the officers and—

H. L. Wilson, auditor Boston Elevated Railway Co., Boston, Mass.

H. C. Mackay, comptroller Milwaukee Electric Railway & Light Co., Milwaukee, Wis.

H. E. Babcock, auditor Elmira & Horseheads Railway Co., Elmira, N. Y.

J. D. Fraser, secretary and treasurer Ottawa Electric Railway Co., Ottawa, Canada.

PROGRAM.

MONDAY, OCTOBER 16th.

7:30 p. m. Annual meeting of the Executive Committee.

TUESDAY, OCTOBER 17th.

10:00 a. m. Meeting room in Tattersalls.
Address of welcome.
Annual address of the president.
Annual report of the executive committee.
Annual report of the secretary and treasurer.
Appointment of convention committees.

WEDNESDAY, OCTOBER 18th.

10:00 a. m. Meeting room in Tattersalls.
Report of Permanent Committee on "A Standard Classification of Accounts." By C. N. Duffy, auditor Chicago City Railway Co., Chicago, Ill.
Paper: "Car Mileage." By H. C. Mackay, comptroller Milwaukee Electric Railway & Light Co., Milwaukee, Wis.

THURSDAY, OCTOBER 19th.

10:00 a. m. Meeting room in Tattersalls.
Report on the Department of Blanks and Forms. By W. B. Brockway, secretary Toledo, Bowling Green & Fremont Railway Co., Toledo, O.
Paper: "How Should Supplies Accounts be Kept?" By W. M. Barnaby, chief accountant Brooklyn Rapid Transit Co., New York.
Unfinished business.
Report of convention committees.
Election of officers.
Adjournment.

FRIDAY, OCTOBER 20th.

Devoted entirely to the examination of the exhibits.

POST OFFICE AT CONVENTION HALL.

The Bureau of Information will provide excellent post office facilities at Convention Hall. A special carrier will be detailed from the Chicago post office, who will deliver direct to exhibitors or delegates in the building, all mail matter addressed in care of Tattersalls. Exhibitors who in past years have not found it convenient to return to their hotels during the day can get their mail with least possible delay by having it addressed as stated. Frequent collections of mail will be made, stamps and postal cards will be provided, and the convention post office will be made as effective and complete as possible.

The new Detroit, Rochester, Romeo & Lake Orion Electric Ry. was opened September 26th.

OFFICERS OF THE STREET RAILWAY ACCOUNTANTS' ASSOCIATION OF AMERICA.

E. R. L. TICHE,
First Vice-President.

JOHN F. CALDERWOOD,
President.

F. E. SMITH
Third Vice-President

H. L. WILSON,
Executive Committee.

W. B. BROCKWAY,
Secretary.

H. C. MACKAY,
Executive Committee.

H. E. BABCOCK,
Executive Committee.

JAMES D. FRASER,
Executive Committee.

ENDORSEMENT OF THE STANDARD SYSTEM OF ACCOUNTS.

The Accountants' Association has good reason to be pleased with the endorsement which the Railroad Commissioners have given its standard system of accounts. Chairman Duffy recently received the following letter from the Connecticut Railroad Commissioner:

Dear Sir: Mr. Seymour has received a communication from Commissioner Cole in which he advises that he presented the report in relation to street railway accounting; that it was received with marked favor, and was adopted unanimously upon the reading of the preliminary report of Mr. Seymour. This is about all that is now necessary, I believe, to warrant us in going ahead and having the necessary number of copies printed, and I would therefore thank you to forward to me at your convenience the copy I last sent you, making such notations thereon as will enable me to place your order.

Mr. Cole adds (and I take a great deal of pleasure in communicating the same to you out of courtesy to Mr. Seymour):

"You were also complimented twice during the proceedings for having prepared and presented so complete a report—the only complete report upon any subject, except that upon legislation, which was presented by Mr. Brown of Pennsylvania. It was a great convenience to the delegates to have your report printed in pamphlet form, and that fact was also commented upon by members on the floor as well as by the chairman, officially."

With kind regards, and trusting to hear from you in due season, I am,

Yours truly,

HENRY F. BILLINGS

Hartford, Conn.

Entered at the Post Office at Chicago as Second Class Matter.

VOL. IX. OCTOBER 15, 1899. NO. 10.

Delegates and others attending the convention will find in the Daily Edition of the "Street Railway Review," to be issued during convention week, full information concerning the program for the day and an account of the previous day's sessions of the two Associations.

The present tendency toward concentration and consolidation is probably nowhere more marked than among the street railways. Chicago furnishes a good example; a year ago there were 17 operating street railway companies in the city and suburbs; by the two consolidations of the Yerkes interests this number has been reduced to nine.

This year the American Street Railway Association holds its annual convention in Chicago for the second time, the first visit of the Association having been in 1883. That meeting was nominally the second, but in reality was the first convention, the previous meeting at Boston in 1882 having been only for the purpose of organizing. Each of the sixteen years that have elapsed since 1883 has seen the Association broadening its scope and increasing its influence as its growth kept pace with the expansion of the street railway industry, and at no time has the Association been in a more prosperous condition. Last year we published the membership statistics, which showed an increase from 35 members in 1882 to 205 in 1892; from 1892 to 1896 there was a decrease to 160 due to consolidations; since 1896 there has been an increase in numbers, to 161 in 1897, 165 in 1898 and 171 in 1899.

This convention promises to be an unusually interesting one; every effort has been made by the officers and executive committee to provide an excellent program, and the street railway men of Chicago have through their committees prepared for the reception and entertainment of the delegates and other visitors.

It is somewhat amusing to note the seriousness with which the public in some of the English cities have anticipated difficulties in connection with proposed electric railway construction. And yet these fears are evidently sincere and honest. We refer to questions which were once live issues here, but which have been proven years ago to be unfounded. At present the Liverpool public are greatly exercised over the interference with vehicular traffic which the proposed tramways are to induce.

When the cars are once in operation the demonstration will be both effective and satisfactory. The same anxiety was general here in Chicago in 1880, when it was proposed to install the cable system, and objectors were loud in their predictions that the presence of cable cars in the streets would cause confusion and practically drive teaming from the streets so occupied. The cables had been in operation scarcely a week before these fears were found groundless. Instead of chaos it was seen that the mechanically operated cars gave to the moving mass upon the street a definite current which moved up one side and down the other, and that instead of being any detriment, it was a positive advantage. There is no reason why the rule which has prevailed in this country upon the introduction of cable and electric cars should not be found to work the same in foreign cities.

Two years and seven months ago the Street Railway Accountants' Association of America was organized at Cleveland with 25 companies as members, and one of the best indications of the necessity of such an association for the accounting officers of street railways is the growth in the membership roll. Nov. 25, 1897, after the Niagara Falls Convention, there were 52 companies reported as members; Oct. 1, 1898, after the Boston Convention, there were 76; Mar. 31, 1899, there were 93, and since then six other companies have joined, making the total at the present time 99. The many consolidations effected during the past year will no doubt cause a marked reduction in the number of members of this Association, just as consolidations in the past have affected the roll of the A. S. R. A. But this will not detract from the influence of the Association, but rather increase it because the same interests will be represented but controlled by fewer men. The name of this Association has not prevented British companies from desiring to avail themselves of its work, and two of the recent additions to the roll are the Glasgow Corporation Tramways and the Central London Railway.

At Cleveland, at Niagara Falls and at Boston, papers on various subjects of interest to accountants were presented, but the most important work of the Association has been that done through its committees looking to a standard system of street railway accounting. The scheme and classification recommended at Boston, with a few minor changes, in August last, received the official endorsement of the Convention of State Railroad Commissioners, as was noted in our August issue. It has been the policy of the

Association to work in harmony with the Railroad Commissioners or other state officials to whom reports must be made, and, as we have seen, the result has been most satisfactory.

Second only to the standard system of accounts is the Department of Blanks and Forms, and the records of this department when exhibited at the convention will be a great surprise to those who have not kept in close touch with this work. Secretary Brockway has had the blanks arranged in large scrap books, and the collection now comprises the forms used by over 80 per cent of the companies which are members of the association. There are 15 books, 20 x 30 in. and 1 book, 30 x 30 in.; the collection has a complete index so that one may turn instantly to any particular forms he wishes to inspect.

It is seldom that so young an organization can show so much in the way of results accomplished, and the increasing attention given to street railway accounts leads us to predict an even more rapid growth of this Association in the immediate future.

It is the function of associations of all kinds to promote in every way the interests they represent, and the presidents of such associations often (and, we may say, generally) recognize that one of the best means to that end is to encourage the younger members by pointing out to them what great things have been done and the path they must follow to reach the goal. This position of the president in such matters has been so long recognized, and his chair is so hedged about with dignity, that he can afford to laugh with the rest when a little fun is poked at him, as was done by Mr. J. W. Alvord in his interesting paper on "Getting Jobs," which we publish in another part of this issue.

Mr. Alvord is a distinguished member (perhaps one less eminent than he would not have written the paper) of the engineering profession, which the presidents point out has for its work that of "harnessing the forces of Nature." The author, believing that the literature treating of "how to harness" will be well taken care of by his professional brethren, devotes his paper to showing how the "hostler" gets his job.

The engineer who has successfully withstood the ordeal of having his ribs poked will enjoy the distinctions between theory and practice that Mr. Alvord so aptly states; the one who is undergoing the operation will keenly appreciate if he does not enjoy. The whole paper should appeal to everyone because the three rules laid down are equally sound for one who aspires to be a commercial "robber baron" or a traction "magnate" or anything else.

It is sixteen years since the American Street Railway Association met in Chicago. This city at that time had but three street railway companies and the aggregate of their lines was about 160 miles measured as single track; at the present time there are nine surface roads in Chicago, including the interurban lines, which operate almost 1,000 miles and elevated roads with 100 miles more. In 1883 horses furnished the motive power for all the street railways in the city except the then recently completed cable lines of the Chicago City Railway Co. Today nearly all of the well-known systems of street railway traction may be found in Chicago. Leading the list is the overhead trolley with about 875 miles; then come the cables with over 80 miles, the storage battery road with 35 miles, and horses with 11 miles. The third rail system has been in successful operation on 75 miles of elevated road for several years and the Northwestern Elevated with 25 miles more will soon be completed. The South Side Elevated is operated on the multiple unit system—every car being a motor car; the Metropolitan and the Lake Street use trains having a single motor car and trailers.

The electric street railways here present interesting examples of different methods of current distribution; the Calumet and the South Chicago City have boosters for feeding their longest lines, the Chicago & Milwaukee is the latest installation employing a three-phase transmission line and sub-stations with static transformers and rotary converters.

The owl-car problem on the cable lines is solved in two ways, horses and compressed air furnishing the motive power. Apropos of animal traction probably every visitor to Chicago is greatly surprised to see horse cars in the down-town district; this is the fault of the city and not of the companies, which would be very glad to operate trolley cars in Dearborn and Adams Sts., were they permitted to do so.

In the power houses of the various lines there is a wide difference in practice. In the cable stations of the Union Traction simple non-condensing engines are installed, and horizontal tubular boilers with the exception of the auxiliary station at Desplaines St., which has vertical tubular boilers; there are three methods of connecting the engines to the cable driving machinery, belts, gears and rope drives, the latter method being used in the Washington and Jefferson and in the Van Buren and Jefferson stations. The Chicago City cable plants have simple non-condensing engines; the engines in these stations are belted to jack-shafts which drive the cable drums through gearing.

The eight large electric power stations have nearly all been built within the last six years and with two exceptions we find the equipment comprising compound engines and water tube boilers. Four of these stations have horizontal cross-compound condensing engines direct connected to the generators; another one is so situated that condensing water was not convenient and has no condensers. The Metropolitan Elevated power house is the only large station with vertical engines, having vertical cross-compound condensing engines direct connected to the generators; water is brought from the river through a tunnel.

In marked contrast to the other stations comparable in size, the two electric power houses of the Chicago City Ry., one built in 1893 and one in 1896, have simple non-condensing engines connected to the engines by rope drives and return tubular boilers.

Only one of these larger stations, the South Side Elevated, has a cooling tower, though a cooling tower is used at the power plant of the storage battery road, and three companies, the Calumet, the Suburban, and the Chicago & Milwaukee, have reservoirs and wooden cooling tables.

On the whole, it is doubtful whether another city in the country offers such an opportunity as does Chicago for managers who desire to examine and compare the different systems of electric traction.

The Roadmasters' Association of America at its convention in Detroit last month discussed the relative merits of 30-ft. and 60-ft. rails, and went on record as opposed at the present time to a greater length than 33 ft. An abstract

of the committee's report will be found on another page. The three principal objections to long rails are: They are not properly straightened at the mills. They require more labor to properly maintain the track than where shorter lengths are used. They require an increased opening at the joint to allow for expansion. The advantages claimed for long rails are: The reduction in the number of joints, a smoother riding track and decreased cost of maintenance.

The first of these objections is doubtless a serious one for the steam railroad man because the majority of rail mills were designed for rolling 30-ft. to 33-ft. rails, and 60-ft. lengths can be handled only with greatly increased trouble and cost. In street railway work the 60-ft. rail has almost come to be the standard length, and the mills which make a specialty of rolling street railway rails have overcome any difficulties that may have at first been experienced in handling the longest rails. The experience of street railways in cities with long rails has been most satisfactory and within the last two years a considerable portion of the interurban electric lines, which are built more in accord with steam road practice, have been laid with 60-ft. rails, with, we believe, equally satisfactory results. More care in loading, unloading and laying the longer rails is required, but the advantage of reducing the number of joints one-half more than compensates for this.

As to the second objection, that the cost of track maintenance is greater with long than with short rails, the testimony of the members of the Roadmasters' Association is conflicting, and it cannot be taken as established.

In discussing the proper allowance to leave at joints for the expansion of the rails, the Roadmasters' committee presented some data of experiments made by it which showed that the linear expansion by heat of 56-lb. T-rails was nearly twice that of 85-lb. T-rails; also that the linear expansion per degree difference of temperature was nearly twice as much between — 20° F. and + 5° F. as between + 5° F. and + 70° F. The committee explained its work in a modest manner and expressed the regret that more exact methods could not have been employed, closing with the recommendation that further experiments be made.

One of our contemporaries takes occasion in reporting this convention to sneer at the methods and results and rejoices in its "faith in the permanence of physical constants." We believe that the sneer is ill-timed, and that though the results may at first seem a little startling, it is by no means certain they are incorrect.

Messrs. Lavoisier and Laplace found the coefficient of linear expansion between 32° F. and 212° F. to be about 15 per cent greater for steel tempered yellow than for untempered steel. It is the practice, in some mills at least, to roll all weights of rail from ingots of the same size and it is quite possible that the different amounts of work done on the different sections may affect the coefficient of linear expansion in a manner similar to the tempering.

Messrs. Dulong and Petit found the cubical dilation of iron between 0° C. and 100° C. to be .00003546 per degree, and between 0° C. and 300° C. to be .00004405 per degree, so that it does not appear that the different coefficients for different temperatures found by the Roadmasters are necessarily wrong.

Neither is there anything essentially absurd in 30-ft. and 60-ft. rails when in the track having different coefficients of linear expansion.

This question of the openings to be left at joints to allow for the expansion and contraction of rails is one which has ceased to be of importance to the management of a street railway having its tracks altogether in paved streets—the continuous rail, either with cast-welded or electrically-welded joints is the best solution for such cases. When the continuous rail was first suggested it was predicted that it would kink in summer and break in winter; after the experiment was made and this prediction turned out to be false two reasons were found to explain the facts; these were that the rail being nearly all underground the changes in temperature were not as great, and the skin friction prevented the movement of the rail longitudinally and the lateral support of the pavement prevented kinking. Experiments made by Mr. A. J. Moxham, who communicated his results to the American Street Railway Association in a special report at the Pittsburg meeting in 1892 (see Proceedings, p. 195) showed that for all practical purposes the whole of the rail may be taken as being at the temperature of the air. Mr. Moxham had a piece of track 1,160 ft. long laid with 78-lb., 6-in. girder rails; these were on ties spaced 11 to 30 ft. and held to gage by tie-rods spaced 10 ft. apart; the joints were made with fish plates 13⁄4 x 4 x 64 in. with 18 bolts 1 1⁄4 in. in diameter; the bolt holes were drilled and reamed and the bolts turned to make a driving fit. The roadway was of macadam. Observations extending over a period of several months with a range of temperature from 10° to 81° F. showed no motion of the rails.

This experience has been repeated on a number of street railways—the track does not kink in summer and does not break in winter. In May, 1897, we described a section of track one mile long with cast-welded joints laid by the Chicago City Railway in an unpaved street; the rails were 7-in. girders weighing 83 lb. per yard and were laid on ties 28 in. between centers with tie-rods every 7½ ft. This track, after a year's service, was in excellent alinement, although the soft mud could have given the rail but little lateral support. We understand that this company has found the percentages of broken cast-welded joints to be smaller in unpaved than in paved streets; in the paved streets the breakage is believed to be entirely due to faults in the casting, as the number of breaks decreases each year.

In August, 1898, we published an illustration from a photograph of the tracks of the street railway at Ft. Wayne, Ind., which showed the rails very badly kinked, the track having been uncovered on a a hot day. We have recently been advised that this track did not kink until it had been jacked up.

The late Mr. M. K. Bowen, after his experience in welding the tracks of the Chicago City, was of the opinion that the rails should be welded when they were at a comparatively high temperature, thus putting them in tension and not compression by heat changes.

To managers of interurban electric roads, however, the questions discussed by the Roadmasters are as important as to the steam road men, and the results of the proposed investigation would prove interesting.

The "I Will" design on our first page has generally been adopted as the most characteristic of Chicago, and was the design for which a valuable prize was awarded by the Daily Inter-Ocean.

The Marinette (Wis.) Gas, Electric Light & Street Railway Co. has commenced laying pipes for the purpose of furnishing heat to the City Savings Bank and other buildings. A new 200 h. p. engine is being added to the power station equipment.

FUEL ECONOMY OF RAILWAY ENGINES.

BY PROF. R. C. CARPENTER, CORNELL UNIVERSITY, ITHACA, N. Y.

(This paper was prepared for the Ithaca meeting of the New York State Street Railway Association, but owing to the unavoidable absence of Prof. Carpenter, was not presented at that time.)

In the following paper are given the results of 35 tests of electric railroad power stations, which have been made during the past eight years under my supervision, by especially trained students in advanced work in Cornell University.

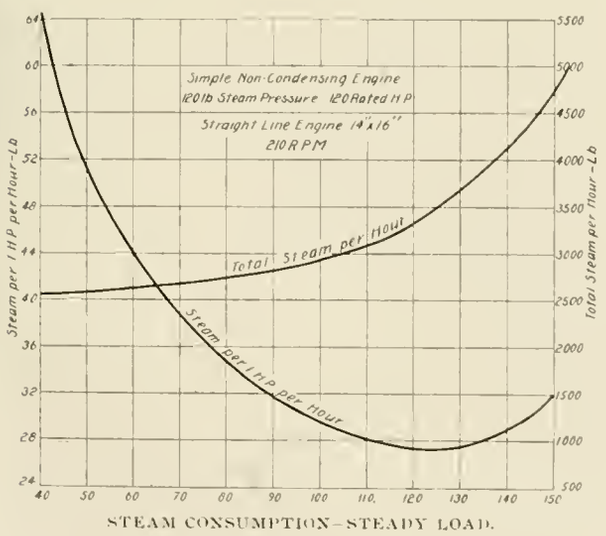
The tests which are cited were made under the ordinary conditions of operation peculiar to the system referred to. In every case the results were doubtless affected by the machinery employed, the method of operating the station and by the varying and continually changing load produced by irregularities in loading and moving of cars.

The tests show the fuel consumption of several classes of engines, operating under the usual condition of power house work. There is shown a variation in the fuel economy by engines of the same class, operating in different stations, which in some instances is of considerable amount. This is probably to be expected, for it is well known that the economy is affected to a great extent by variation in load, since an engine fully loaded is in general much more economical than one partly loaded; no duty throws on an engine a more variable load than street railway work. A certain amount of the variation in coal per horse power as shown by the tests, may be accounted for by individual differences due to poor or good firing; this may and often does make 20 per cent or more difference in fuel economy, and this condition affects the uniformity of the results about in the same proportion. The effect of employing different classes of engines is also well marked. The fuel consumption of different classes of engines is doubtless the most interesting and practical part of the investigation. If we can learn from the tests the probable fuel consumption of each class of engine, we can draw conclusions as to the saving which might be produced by change of power, and we can also predict with certainty the fuel charges for different classes of stations.

SIMPLE NON-CONDENSING ENGINE—SLIDE VALVE AUTOMATIC.

The summary of the tests of the simple non-condensing engine shows on the whole an economy of steam and coal nearly equal to that usually attained with engines of this class in any work. The most probable values indicating an average consumption of 34.3 lb. of steam and 4.63 lb. of actual coal per i. h. p. per hour.

In tests made by the writer, with an engine of this class operating with a steady load, the best result at the normal load corresponding to about ¼ cut-off, was slightly over 27 lb. of steam per i. h. p. per hour; the steam consumption was greater either with a lighter or heavier load. As an illustration, the following diagram



STEAM CONSUMPTION—STEADY LOAD.

exhibits the results of a series of tests made on an automatic slide valve engine running non-condensing. Each test was continued sufficiently long at a given load to obtain the water consumption for that condition. The results are shown in the accompanying diagram, by employing horizontal distances to represent horse power, and vertical distances to represent steam used per horse power per hour. The scale on the left corresponds to the curves showing steam, that on the right to curves showing total steam per hour.

The curves show graphically how the steam used changes with change in load. When the load is light the steam per horse power per hour is very great, when the load is normal the steam consumption is lowest, when very high, the steam consumption per i. h. p. is increased. The total steam per hour increases faster than increase of load. The curve indicating steam per i. h. p. per hour shows slightly over 27 lb. at 120 h. p., nearly 30 lb. at 150 h. p., 44 at 60 h. p. and 64.3 lb. at 40 h. p.

Thus it is seen that a comparison of the results of the tests of the automatic simple non-condensing engines in actual power house work with those obtained under best conditions, is in many respects favorable. The average results of all the tests show a steam consumption only about 25 per cent higher than obtained with this class of engine working under most favorable conditions. This corresponds, by the diagram, to the results obtained with the engine tested at about 80 h. p. or at two-thirds its rated capacity. The average load as compared with the capacity of the engines in the various power house tests, was 54.2 per cent, which would correspond by the diagram to a steam consumption of 31 lb. per horse power.

The following shows in tabular form the results of the tests of simple engines in a power house.

TABLE I.

SUMMARY OF TESTS OF SIMPLE NON-CONDENSING SLIDE VALVE ENGINES.

No.	H. P. of Engine	Steam per i. h. p. hour	Actual coal per i. h. p. hour	Mean observed i. h. p.	Per cent observed h. p. to capacity	Boiler Evaporation per lb. combustible from and at 212°	Kind of coal
6	200	34.8	4.47	110	55	11.50	Pea A
1	405	34.5	a 6.54	257	63.4	a 9.11	Culm, East
7	1975	35.7	4.60	862	51	9.46	Ohio
11	300	37.3	4.49	90	44	12.20	Bit. W. Pa.
11	300	34.3	4.72	95	46.7	10.20	Bit.

Average		35.1	5.07		54.2	10.24	
Neglecting c		34.3					
Neglecting a. b. c.			4.63				

Engine in test (31) in bad condition.

Probable average coal per i. h. p. hour, when using anthracite or eastern bituminous, 4.63 lb.; anthracite culm, 6.54; western bituminous, 5.38.

Coal per kw. h. output averages 50 per cent higher or 6.94, 9.81 and 8.07 respectively.

Probable error for any given case not over 10 per cent.

Steam pressure 90 to 120 lb.

NON-CONDENSING SIMPLE CORLISS ENGINE.

Three stations only were tested which were using non-condensing simple corliss engines. These three stations show fairly uniform results, both as to steam and coal consumption, and as was the case with the simple slide valve engine, the results closely approximate the best results to be obtained with that class of engine. Thus, while this class of engines might produce a horse power under favorable conditions of loading for an expenditure of 23 to 25 lb. of steam used, the tests show an average steam consumption of 28.3 lb. of steam per i. h. p. per hour, the average load being slightly over one-half of the rated capacity.

The coal per i. h. p. per hour average 3.45 lb., the evaporation per pound of combustible varied considerably, which was due in part to the variation in calorific value of the coal used. The summary of the results of the test is shown in the following table:

TABLE II.

Summary of Results of Tests of Simple Non-condensing Corliss Engine

No.	H. P. of engine	Steam per i. h. p. hour	Coal per i. h. p. hour	Mean Observed i. h. p.	Per cent observed h. p. to capacity	Boiler Evaporation per lb Combustible	Kind of coal

Average		28.3	3.45		50.3		

NON-CONDENSING COMPOUND ENGINE.

The data obtained relating to this class of engine are limited, and probably insufficient to draw any general conclusion; four tests of power stations were made in which such engines were used, these tests are numbered respectively 2, 4, 21 and 24.

The power house tests Nos. 2 and 4 were made when both simple and compound engines were running; the results do not differ essentially from those obtained with simple engines and previously recorded.

Tests Nos. 21 and 24 were made on non-condensing compound engines, working under fairly favorable conditions. Test No. 21 does not show better coal or steam consumption than many of the tests recorded for simple non-condensing engines; compared with No. 24 it shows a better coal record due principally to the fact that in test No. 21 the coal used was from western Pennsylvania, while that used in test No. 24 was from Illinois. The difference was due principally to the quality of fuel used.

It would hardly be safe to draw a general conclusion from the results in the table regarding the compound non-condensing, as compared with the simple non-condensing engine for railroad purposes, but such conclusion as could be deduced would be but slightly in favor of the compound non-condensing engine.

Some additional information was obtained on this question by a test (24) which was made on both simple and non-condensing compound engines, each kind being tested separately and so as to give an opportunity of comparison. The test on three simple engines showed an average steam consumption of 31.8 lb. per i. h. p. per hour and a fuel consumption of 5.38 lb. of coal. The test on one compound non-condensing engine, 24 x 48 x 48 in., 1,200 h. p., showed a consumption of 30.37 lb. of steam and 4.93 lb. of coal per i. h. p. per hour. The actual evaporation per pound of combustible from and at 212 degrees being in the test of compound 7.75 and in the tests of the simple engines 7.83 lb. of steam. Reducing the results for uniform evaporation, the two tests would indicate that the compound as compared with the simple non-condensing was 0.4 per cent more economical in use of coal, and about 5.5 per cent more economical in use of steam.

The compound non-condensing engine is much less economical, as shown by these tests, when employed in power house work where the load is variable than when used for a steady load. Thus I have tested a compound non-condensing engine of this class working with a steady load and with about the same steam pressure as in the cases cited and found a steam consumption under the best conditions of loading of 22 to 23 lb. of steam per i. h. p. per hour, which is nearly 33 per cent better than shown by the same class of engines in power house work.

TABLE III.

Summary of Results of Tests of Compound Non-Condensing Engine.

No.	H. P. of Engine.	Steam per i. h. p. per hour.	Coal per i. h. p. hour.	Mean observed i. h. p.	Per cent observed h. p. to capacity.	Boiler evaporation, lb.	Kind of coal.
2	1000	30.5	4.22	603.5	60.3	9.03	Bit.
4	1250	36.8	4.33	674	53.8	9.92	3 parts Ant. Culm 1 part Bit. slack.
21	400	34.20	4.17	205.	51	10.23	Bit. Pa.
24	1200	30.37	4.93	754	62.7	9.01	Bit. Ill.
Ave. 21 and 24		32.28	4.55				

Test No. 2 was made on three simple engines 150 h. p., one cross compound 250 h. p. and one triple 300 h. p.

Test No. 4 was made on three simple engines 250 h. p. each and one compound of 500 h. p.

Steam pressure 100 to 125 lb.

We have seen that the simple non-condensing engine performs its work in a railway power house under conditions of varying load with an average steam consumption only about 25 per cent higher than the best average record for its class of engines with a steady load. The compound non-condensing engine requires on the other hand, however, nearly 40 per cent more steam than when working under best conditions with a steady load. From these limited data it would appear that the compound non-condensing engine is only slightly better than the simple non-condensing, and except under extreme conditions not sufficiently better to warrant its use.

COMPOUND CONDENSING SLIDE VALVE OR HIGH SPEED AUTOMATIC ENGINE.

The average results of the tests which were made in power stations using automatic engines of the slide valve type, show a steam consumption of 23.96 lb. and a coal consumption of 3.41 lb. per i. h. p. per hour. If we reject the three highest values as given in tests 3 (a), 18 and 21, and the lowest result as given in 8 (b) we shall have for the average 22.7 lb. of steam and 3.25 lb. of coal per h. p. per hour, which can doubtless be assumed to be most probably correct for this class of engine.

Most of the makers of engines of this class will guarantee them to produce a horse power hour for a consumption of 18 lb. of steam under favorable conditions of loading, and engines of this class have in several instances produced a horse power hour for less than 15 lb. of steam. It will be noted that the best results with engines of this class was 16.7 lb. of steam per i. h. p. per hour, and 2.4 lb. coal per h. p., which was obtained with an engine of 400 h. p. of the four valved type.

The effect of the variable load and other conditions due to railway work is to affect the economy adversely by 30 to 40 per cent, as compared with the best results with a steady load.

COMPOUND CONDENSING ENGINE.

The average results of the tests made on the compound condensing corliss engines and other engines with similar valve gear, including McIntosh & Seymour and Greene, show a steam consumption of 18.8 lb. and a coal consumption of 2.6 lb. per i. h. p. per hour. Omitting test No. 10, for the reason that the coal was of a poor quality, and the evaporation low, the average becomes 18.25 lb. of steam and 2.36 lb. of coal per i. h. p. per hour. The steam consumption of this class of engines working with a good load can safely be taken as 15 lb. or less per i. h. p. per hour, in

which case the actual results in power house practice exceeds the results when the load is steady, by slightly over 20 per cent.

A study of these latter tests shows a higher evaporation per pound of coal than was obtained in power houses using the cheaper grade of engines. This is probably to be explained by the fact that a better grade of engineers and firemen are employed to operate stations of this class, as compared with those using cheaper machinery, although it may possibly be an accidental variation, due to the fact that only a limited number of stations were tested in each class.

The average evaporation from and at 212 per pound of combustible was found to be as follows: For stations using the simple non-condensing engine, 10.26 lb.; for stations using the compound condensing slide valve engines, 9.82 lb.; for stations using corliss compound condensing engines, 10.54 lb. of steam. It is not easy to explain why the evaporation is better from stations using simple engines than from those using compound engines of the same class, as the average grade of employes is rather better in the stations using compound than simple engines; probably the variation is an accidental one, due to the limited number of stations of each class tested. The average range in the variation of results of the evaporation tests for the stations employing the three classes of engines does not exceed 7 per cent, and whether it can be accounted for or not, it will not seriously affect the conclusions.

TABLE V.

Summary of Results of Tests of Compound Condensing, Corliss, Greene, McIntosh & Seymour, and Similar Valve Motions.

Summary of results: A summary of the average results of these various tests is given in Table VI in such manner that the various classes of engines may be readily compared. The best results with each class of engine when sufficiently well marked is also given.

A column giving the proportional value of the engine on the basis of coal consumption with a corliss compound condensing engine placed at 100 is also given. A column giving the probable coal consumption per kilowatt-hour is also appended.

TABLE VI.

Summary of Average Results.

Class of engines.	Steam per i. h. p. lb.	Coal per i. h. p. lb.	Steam per i. h. p. lb. Best load.	Proportional value of engines.	Probable coal per k. w. h. lb.

Best result	14.5	1.80			2.70

RELATIVE ECONOMY OF VARIOUS TYPES OF ENGINES.

Assuming that the results of the tests which have been cited give average and best results for engines of the different classes tested when working under the conditions of street railway work, it is easy to compute the probable yearly cost of each class of engine and by this means determine the relative value from a financial standpoint.

From the table last given it will be noted that the steam consumption per i. h. p. per hour varies from 31.3 lb. to 14.5 lb. A boiler horse power under the conditions of steam pressure supposed to exist would be about 30.4 lb. of steam, although this amount would vary slightly, depending upon the temperature of feed water and upon the steam pressure. The computation would show that 1.13 boiler horse power would be required in case a simple slide valve non-condensing engine were used, while 0.6 of a boiler horse power only would be required for furnishing steam for the compound corliss engine or engines of its type in order to supply them with the same relative amount of steam. This indicates that a considerably less amount of boiler power would be needed for the more economical engine than for the more wasteful one, and this fact tends to equalize the cost of a power station on employing the different classes of engines.

From actual prices which have been quoted within the last six months the writer feels certain that an engine of 500 h. p. capacity, of good quality in its respective class can be purchased and, under ordinary conditions, can be erected complete on foundations for the figures which are given in the following table. A boiler horse power is considered as worth $12 when erected for each class of engines. In view of the recent rise in prices this may be somewhat low, but the results are comparatively true for each class of engine. The figures in the table do not consider real estate, building or chimneys, which would vary largely with different conditions. Despite the fact that engines, pumps, heaters and piping will cost more per horse power for the condensing than for the non-condensing engines, the total cost per horse power does not differ greatly for the various classes of engines employed; this is due largely to the fact that a smaller boiler plant is needed with the more economical engine.

Table VII shows the cost per horse power and also the total cost of the machinery for a power plant of 500 h. p. capacity. It may be remarked that the cost of engines of larger units would be somewhat less and the cost of those with smaller units somewhat greater per horse power than the results shown in the table.

TABLE VII.

Cost per Horse Power of 500-H. P. Plant.

	Boiler h. p. per engine h. p.	Cost per Horse Power					Cost for 500-h. p. plant
		Engine	Boiler	Pumps and heaters	Piping, etc.	Total per i. h. p.	
Non-Condensing Engines							
Simple slide valve	1.135	$8.00	$13.60	$2.00	$5.00	$28.60	$14,300.00
Simple Corliss	0.933	12.00	11.20	2.00	5.00	30.20	15,100.00
Compound slide valve	1.00	11.00	12.00	2.00	5.00	30.00	15,000.00
Condensing Engines							
Compound slide valve	0.75	11.00	9.00	4.00	6.00	30.00	15,000.00
Compound corliss	0.602	16.00	7.25	4.00	6.00	33.25	16,625.00

Taking the fuel consumption as shown by the average results and also the best results in the various tests mentioned, we can compute the yearly requirements in tons per horse power for each class of engine. This has been done in the following table, which is arranged to show the number of tons of 2,000 lb. each required per horse power per day for a day of 12 hours, of 18 hours and of 24 hours. The fuel cost at $2 per ton per horse power year for a day of 18 hours is taken as a basis of comparison of fuel costs of the various engines which have been tested. A day of 18 hours is believed to represent fairly well the average length of time which railroad engines are required to operate. It is also believed that $2 per ton is not far from the average price paid for coal by railway stations in New York state. If anything, it is rather below than above the average price and consequently lessens rather than exaggerates the proportional saving made by the most economical engine.

To the fuel cost of each engine must be added fixed charges of sufficient amount to cover interest and repairs and this has been assumed to be in each case 8 per cent of the cost. No account is taken of that portion of the operating expense chargeable to en-

ployes and oil for the reason that there is no known reason why such charges should be essentially different for the best or for the poorest engine. The following table shows these various quantities computed for the different classes of engines. The last column in the table shows the sum of fuel costs and fixed charges and is one which may be taken to represent the proportional yearly cost of each class of engine.

By a study of the results in the latter column some interesting conclusions may be deduced.

First, as to the saving due to condensing water; we have only two results which can be compared to show the value of the condenser; these results are the cost of the compound slide valve non-condensing compared with the average value for the compound slide valve condensing. The results are respectively, $20.54 and $23.76; the saving due to condenser is $5.78, which is 19.5 per cent of the cost of running a non-condensing and 24.4 per cent of the cost of running a condensing engine. The saving would seem to be nearly 20 per cent and, for reasons which have been already mentioned, would probably be more.

STREET RAILWAY LOAD CURVE.

Second, the average yearly cost of engines of the compound condensing type with the Corliss, McIntosh and Seymour, or Greene valve gear as compared with the simple slide valve engines, show a yearly saving of $14.69 per h. p.

The difference in costs of the power plant considered is $4.65, which is the excess in cost of the compound condensing corliss type over the simple slide valve non-condensing. The saving in fuel and fixed charges is thus seen to be sufficient in a single year to pay 3.15 times the difference in cost between the cheapest and best power plant. Comparing in the same way the average yearly costs of fuel and fixed charges for the compound slide valve condensing engine and the compound corliss condensing type, we find a yearly saving of 5.64 in favor of the better grade of engine. The difference in costs of the two plants is 3.25 in favor of the compound condensing slide valve engine. Thus, in a single year the saving on the fuel and fixed charges of the better engine as compared with the poorer will pay 1.73 times the difference in costs.

Third, these figures would show that no station can afford to purchase and operate the simple non-condensing engine of any type as compared with the compound condensing engine, and fourth, that the compound condensing engine of the best type and with improved valve gear such as the Corliss, McIntosh & Seymour and Greene, and one or two other makes, although costing somewhat more, is so much more economical to operate that, taking all things into consideration, it gives much better financial returns than an engine of any other class. These financial returns are so much in their favor that unless other conditions are exceedingly unfavorable these latter engines are the only ones which should be considered in purchasing machinery for power house work. This general conclusion, that the compound condensing engine of slow rotative speed and with the improved valve gear is much more economical to use than any other type for power house work, even when fixed charges are considered, is certainly the only one which can be adopted from the average results of the tests which I have quoted. This conclusion is noticeable from the fact that in a comparison of costs of different types of railway engines made by Dr. Charles E. Emery, he concluded that the compound condensing engine of the slide valve type and with cylinders arranged in tandem was, when fixed charges were considered, the more economical engine to use. The tests which I have referred to point to a different conclusion and indicate that the saving of the better type of engine will many times repay the extra expenditure of costs. In brief the tests indicate that the engines of the best class are much the better investment.

TABLE VII.

Fuel and Interest Charges for the Different Classes of Engines.

	Coal per i. h. p. lb.	Tons per horse power per year. Day 12 h.	Day 18 h.	Day 24 h.	Fuel cost per year, 18 hrs. per day, $2.00 per ton.	Interest and depreciation, 8 per cent.	Total cost per year per h. p.

BRITISH JOTTINGS.

From our London Correspondent.

The main incident of September in the British tramway world was the fixing of the contracts for the main engines for the power station of the Glasgow Corporation electric tramways. As is well known, with the exception of one route, all the lines in Glasgow are worked by horses. The decision to adopt electricity universally throughout the city was taken some time ago, and the municipality, which owns and operates the system, is now actively engaged in installing electric power and in making large extensions. When the work is completed the lines will cover about 55 miles of streets, nearly all double track; power is being provided to operate eventually 600 cars. All the generating machinery will be in one large power station, from which current will be distributed on the three-phase system to sub-stations, where it will be transformed and converted. It is calculated that by this method the voltage drop in the rails will never exceed 3½ volts, so that gas and water pipes should be very safe from electrolysis. Round the letting of the contract for the main engines of the power station, controversy raged during the latter part of August and the beginning of September, and the matter was finally fixed at a meeting of the Town Council on September 7th, when it was decided to give the contract for two of the engines to the E. P. Allis Co., of Milwaukee, and for the other two to John Musgrave & Sons, Bolton, England.

The engines, it should be mentioned, are vertical compound three-cylinder machines, each capable of developing from 4,000 to 5,000 i. h. p., and fitted with fly-wheels weighing about 100 tons each.

In August the Corporation's committee recommended that the offer of the Allis company be accepted for all four engines, the price to be £114,564—say $570,000. This excited a great deal of local feeling, as it was maintained that British engine builders could turn out as good machines as American firms, though it was admitted that the home manufacturers had not yet produced any large slow-speed engines for electric traction purposes. The

specification had not laid down dimensions of main parts as essentials, but certain leading dimensions were suggested as being considered about what was required. The British tenderers regarded these dimensions as excessive and unnecessary, and tendered upon their own ideas, which are based upon marine and mill engine practice. They said, however, if the dimensions suggested were to be regarded as essential they were prepared to conform to them. The suggested sizes were more in accordance with American practice, and the Allis company conformed to them.

The Town Council sent the matter back again to the committee and the latter body, after conference with representatives of four of the tendering firms, in which the British offerers expressed willingness to modify their designs, recommended that two of the engines should be given to the Allis company, at a total of £57,282, and two to the Musgraves, at a total of £47,788. Delivery within a specified time was made an essential, as the Corporation wishes to have as great a length of the tramways as possible working by electricity when the Glasgow 1901 exhibition opens. As already mentioned, the Council on September 7th confirmed this proposal. The result should prove of great interest, because it will give engineers and tramway people an opportunity of comparing the performances of engines built by two of the most noted engine-building firms of the world, one American and the other English.

The following were the contracts let at the same meeting of the Council:

Two main engines, E. P. Allis Co.	£57,282
Two main engines, J. Musgraves & Sons	47,788
Exciter engines, W. H. Allen & Co., Bedford	3,054
Boilers, Babcock & Wilcox Co.	21,280
Three-phase generators, British Thomson-Houston Co.	25,670
Anxiliary generators, British T. H. Co.	5,343
Exciter generators, British T. H. Co.	1,711
Transformers, Westinghouse Electric Co.	19,983
Rotary converters and boosters, Westinghouse Electric Co.	39,216
Surface condensers and air pumps, the Mirrlees Watson & Yaryan Co., Glasgow	15,000
Total	£236,327

Contracts were also let for centrifugal circulating pumps and boiler feed steam pumps with local firms, the amounts of which are not stated. The contract for auxiliary engines has not yet been let.

These are the largest electric traction contracts which have yet been given in this country.

The opening of new electric lines in various towns goes on merrily. In Dublin some additional routes will soon be ready. Coventry has just opened extensions of a track length of seven miles, making a total of 12¾ miles. Sheffield recently started up its electric lines to the extent of 12 miles of route, mostly double track, and it promises to go on till there will be 36 miles. The electric machinery in both these cases is of American make, the Westinghouse company having been successful in Coventry and the Thomson-Houston Co. in Sheffield. The electrifying of the Liverpool tramways is also being pushed rapidly forward. In Edinburgh the only example in this country of an extensive application of cable traction is nearing completion, and it is probable that a large proportion of the system will be running before the end of the year. The first route is to be opened early in October.

The report by the directors of the Glasgow District Subway Co. for the half year ended July 31st last, which has just been issued, is interesting because the line is the only underground cable railway in the country, if not in the world. It is roughly a circle 6½ miles in circumference and serves the central and western districts of Glasgow. It commenced operation in the beginning of 1897. Dividends were paid on the preference shares from the start, and six months ago the first dividend on the ordinary shares, 1 per cent per annum was declared. A similar distribution is now made for the past half year. As the line was expensive to construct, the capital is large in proportion to the total receipts, the capitalization being £1,300,000, and the amount raised by loans £177,000. Trains of two cars each are run, the train weighing empty 13¾ tons. The total receipts for the half year were £35,977, and the working expenses £17,520. The receipts per train mile were 15.78 d., and the expenses 7.68 d., giving a ratio of 48.67 per cent. The train-miles run were 547,083, and the number of passengers carried 6,505,221. The details of the expenses per train mile in pence and decimals were: Maintenance of way, works, etc., .82; locomotive power, 3.16; repairs and renewals of cars, .24; traffic expenses, 2.47; general charges, taxes, etc., .99; total, 7.68 d. The total is about a half penny higher than the average of previous half years, and the increase seems to be mainly on the items of coal and wages. The fares for passengers are a penny or twopence, according to distance, and there is one halfpenny stage.

In the latter part of September important decisions were reached by the tramway committees of the town councils of Manchester and Leeds. The former committee considered an offer by the Manchester Tramway Co. to pay £50,000 a year for the lines on a 10 years' lease instead of £23,333 a year which it has been paying on the lease now expiring. The committee resolved, having regard to the town council's decision, to municipalize the tramways and to the arrangements entered into with adjoining local authorities for the working of their lines in conjunction with the city tramways, that it could not contemplate the extension of company's lease. The committee subsequently decided to recommend the council to obtain borrowing powers for £250,000 for the construction of the permanent way, £150,000 for overhead equipment, £360,000 for the purchase of 600 electric cars, £90,000 for lands and car sheds, and £10,000 for preliminary expenses; total, £860,000. The lines which have hitherto been operated by the Manchester Tramway Co. comprise 100 miles of track on 80 miles of streets.

The Leeds town council tramway committee agreed to recommend the expenditure of £160,000 for the electrical equipment of all the lines in the city which have not already been electrified, namely 17 miles of street length, all double track. The existing electric lines extend to 12¾ miles, also double track. When the whole scheme is complete 200 cars will be required. The output of the plant already installed is 1,900 kw., and the consulting engineers (Messrs. Hopkinson & Talbot) recommend engines and dynamos to give 1,500 kw. more, making a total of 3,400 kw. A storage battery of 750 kw. h. capacity is to be provided to take care of the fluctuations in the load. The estimate of £160,000 covers boilers, engines, dynamos, boosters, switchboard, battery, overhead line work, laying underground feeders and 125 cars.

HOLLOW-FORGED STEEL SHAFTS IN CHICAGO.

It is not so very long ago since the first hollow-forged and annealed steel shaft was introduced in the West. Since that time, however, the superiority of this type of forging has become so well established a fact that at this date almost all of the street railways in Chicago have in their power houses shafts made of fluid-compressed open-hearth steel, hollow-forged on a mandrel and thoroughly annealed. In some instances, where a still higher quality of steel was required, the shafts have also been oil-tempered.

The methods and processes employed by the Bethlehem Steel Co., which owns the largest works in this country equipped for the manufacture of such forgings, are too well known to need discussion here. Suffice it to say, in brief, that a shaft made by the Bethlehem Steel Co. has undergone the following processes during its manufacture:

1. It has been made from an ingot approximately twice the diameter of the finished forging, in order that the metal might be worked properly.

2. The ingot has been subjected to hydraulic pressure, up to 7,000 tons if necessary, during the cooling process, thereby preventing blow-holes, piping and other defects apt to occur at this critical stage.

3. If a solid shaft, the ingot has been forged down under a hydraulic press, of which the Bethlehem Steel Co has several ranging in capacity from 3,000 to 14,000 tons.

4. If a hollow shaft, a hole has been bored through the ingot through which a mandrel has been placed; the ingot is then forged under a hydraulic press on the mandrel.

5. Every forging, before leaving the works, is carefully and thoroughly annealed to relieve it of forging and cooling strains. No forging is considered finished until after it has undergone this treatment.

As already stated, hollow shafts made by the Bethlehem Steel Co. can be found in almost all of the Chicago traction companies' power houses. To enable delegates in attendance at the convention to readily ascertain where these power houses are located, the Bethlehem Steel Co. has prepared a very interesting and elaborate souvenir for free distribution, giving the exact location of each of Chicago's power houses, with full directions how to reach it, a brief description of its engines, boilers, generators, etc. As this souvenir contains also the official program directory of the exhibitors, and is profusely illustrated, showing views of the Auditorium (the Association's headquarters), Tattersall's, exterior and interior views of Chicago power plants, etc., no visitor should fail to ask for a copy.

The main office and works of the Bethlehem Steel Co. are located at South Bethlehem, Pa., 89 miles from New York and 57 miles from Philadelphia. Its officers are: President, Robert P. Lindermann; vice-president, E. M. McIlvain; treasurer, C. O. Brunner; secretary, Abraham Schropp. The company has offices at 100 Broadway, New York City, in charge of Wm. H. Mitchell; at 421 Chestnut St., Philadelphia, in charge of R. R. Haydock, and at 1433 Marquette Building, Chicago, in charge of E. Nelson. The Chicago office was opened, shortly after the World's Fair, at 1025 Monadnock Block, by Messrs. Fischer & Porter. On November 1st, 1895, Messrs. Fisher & Porter having dissolved their partnership, H. F. J. Porter continued the Bethlehem Steel Co.'s Chicago office at 1433 Marquette Building, where it has been located since that time. The territory covered by this office embraces all states west, south and north of the Alleghany Mountains. In 1897, Mr. Porter was transferred to the main office and was succeeded in Chicago by his assistant, Mr. Nelson, who has been in charge of the office since then. The Chicago office employs a number of agents in western cities, including St. Paul, Minn., Cleveland, O., Cincinnati, O., St. Louis, Mo., and arrangements have recently been perfected with C. S. Burt Co., Ltd., 726 Gravier St., New Orleans whereby matters in the south will be efficiently looked after.

The product sold by the Bethlehem Steel Co. in the West consists in the main of high-grade steel forgings of every description. Builders of engines are not slow to grasp the fact that by using a stronger quality of steel they can reduce the dimensions of their forgings. Builders of marine engines and owners of navigation companies, especially, appreciate the fact that by using hollow forgings they secure not only a grade of forging which insures them immunity from breaking, but increase their carrying capacity as well. Consulting and designing engineers, having carefully investigated the product of the Bethlehem Steel Co., specify it. Railroads use nickel steel for their locomotive forgings such as crank pins, axles, connecting rods, side rods, etc. Broken shafts, made of wrought iron or hammered unannealed steel, are being replaced by forgings made of fluid-compressed open-hearth steel or nickel steel, hydraulically forged and thoroughly annealed. Chicago's water works are equipped with Bethlehem forgings, and they can also be found in a number of power plants of private corporations in Chicago, such as Swift & Co., Illinois Steel Co., Chisholm, Boyd & White Co., Armour & Co., and many others.

SOME RECENT ENGINEERING WORK.

Sargent & Lundy, engineers, at 1140 Monadnock Block, Chicago, have prepared the plans for some of the largest electrical plants installed during the past year. Prominent among these is the South Side Elevated R. R., of Chicago, the entire electrical equipment of which, including the power station, was in the hands of this firm. The success of this installation as regards low cost of operation and adaptability to conditions of traffic, is clearly demonstrated by the recent operating reports of the company.

Additional plants built under the supervision of this firm during the past twelve months are the new central station for the Cincinnati Edison Co. and the enlarged station for the Milwaukee Electric Railway & Light Co. An important installation now on hand is the power plant and line equipment of the Union Traction Co., of Anderson, Ind., owning 160 miles of track. This is a three-phase road, with one central station, containing three 1,000-kw. Westinghouse generators, and eight rotary converter sub-stations, containing 14 250-kw. Westinghouse rotary converters. Storage batteries will be placed at the central station and at each sub-station to carry the peak of the load. The line pressure will be 15,000 volts.

Sargent & Lundy are consulting engineers for the Boston Elevated R. R., Atlanta (Ga.) Railway & Power Co., United States Electric Light & Power Co., of Washington, D. C., Chicago Edison Co., Consolidated Street Ry., of Grand Rapids, Mich., South Chicago City Ry., and the Virginia Improvement & Development Co., of Richmond, Va.

Mr. Frederick Sargent, the senior partner, was formerly engineer for the Edison General Electric Co. of New York, and later chief engineer of the electrical and mechanical engineering work at the Columbian Exposition in 1893. Mr. A. D. Lundy, before his present connection, was chief engineer of the Sprague Electric Equipment Co.; later district engineer for the Edison General Electric Co., in the Southern States. The firm of Sargent & Lundy was formed in 1890.

THE W. R. GARTON CO.

This company was organized in 1898 and was recently incorporated; W. R. Garton is president and Ray P. Lee secretary. Mr. Garton is well known to the railway world as the inventor of the lightning arrester which bears his name. The company is exclusive territorial agent for a large line of important supplies made by some of the best concerns in the country; and as a large stock is constantly carried prompt shipments are made. In fact the large business which has been built up in a short time is in no small measure due to the policy of always shipping goods on the day promised. Among the houses represented by it may be mentioned: The Electric Railway Equipment Co., of Cincinnati, maker of all kinds of railway supplies, line material, tubular iron and steel poles and brackets; Billings & Spencer Co., Hartford, drop forgings, B. & S. commutator bars, Kelsey ratchet brake handle; the General Equipment Co., Camden, N. J., automatic circuit breakers; Keystone Electrical Instrument Co., Philadelphia, voltmeters, ammeters; Massachusetts Chemical Co., Boston, insulating paints, tapes, cloths, paper; the Multiplex Reflector Co., Cleveland, all kinds of reflectors and headlights; the Eureka Tempered Copper Works, North East, Pa.; the McLaughlin rail bonds; the Graphite Lubricating Co., Bound Brook, N. J., Bound Brook trolley bushings; Pittsburg Steel Holloware Co., pressed steel gongs; A. O. Schoonmaker, N. Y., all forms of amber and India mica; E. F. DeWitt & Co., Lansingburg, N. Y., common sense sand box; Miller Knoblock Co., South Bend, assembled commutators, refilled armatures, and armatures rewound; the Lea Manufacturing Co., all kinds of inclosed arc lamps; National Carbon Co., all kinds of carbons; Garton lightning arresters; Van Dorn & Dutton, gears, pinions and track scrapers. All these manufacturers will be represented at the exhibit of the W. R. Garton Co., at the convention.

PRIZES FOR EMPLOYES IN BIRMINGHAM.

As announced in the "Review" for January, 1899, page 47, J. B. McClary, general manager of the Birmingham (Ala.) Railway & Electric Co., at the beginning of the present year, offered cash prizes to the conductors and motormen keeping the cleanest cars and having the least number of accidents, the prizes to be distributed on July 1st and January 1st of each year. On July 1st, last, over $1,000 was distributed to the men, and the system has had such a marked effect in the decrease of accidents and in the neatness of the cars, that the company has decided to still further increase its scope. Hereafter prizes will be distributed once a month instead of every six months, as follows:

Motormen on cars having no conductors will receive $3.33 1-3 for keeping clean cars and $6.66 2-3 for avoiding accidents.

Motormen on cars having conductors will receive $6.66 2-3 for avoiding accidents.

Conductors on cars having motormen will receive $3.33 1-3 for keeping cars clean.

The prizes for the months of July and August were distributed on September 20th, and 90 per cent of the men received some amount over their regular pay, showing the interest manifested by them in the company's efforts to better its service.

The managers of the street railways in St. Louis report they are having great trouble in securing men for repairing tracks and laying new rails.

A SUCCESSFUL ELECTRICAL HOUSE.

If there is still a lurking doubt in the mind of any visitor to Chicago that the "times of orders" are really here, if he will but step into the headquarters of the Central Electric Co., at Nos. 264 to 270 Fifth Ave., he will very soon have that doubt turned into a full assurance that an era of business activity such as has not been known for years has come to at least a portion of the electrical trade. For here he will see a small army of clerks, each with a handful of the company's regulation order forms, hurrying to and fro, giving shipping instructions, asking at different departments for certain lines of goods, all in seeming confusion, but all following closely the rules of a well developed system for filling orders promptly and correctly; customers coming and going in an almost constant stream; and best testimony of all, if the visitor will glance into the shipping room, any further question that might still remain in his mind will vanish. The Central Electric Co., for one, is crowded with orders.

The supplies handled by this company need no introduction. They include such well known specialties as Okonite wire, Westinghouse lightning arresters and arc lamps, Westinghouse alternating fan motors, Wagner transformers and switchboard instruments, Hill switches and switchboards, and the products of the Central

SHIPPING ROOM, CENTRAL ELECTRIC CO.

Union Brass Co., Columbia Incandescent Lamp Co., The Bullock Electric & Manufacturing Co., and the Ziegler Electric Co. A large assortment of sizes and shapes is constantly on hand and the company numbers as one of its most valuable assets the good name it has with its customers for prompt shipments.

The business of the Central Electric Co. was established in March, 1887, at 38 and 40 La Salle St., but these quarters were quickly outgrown, and after various changes the present location was secured in 1898.

Geo. A. McKinlock, the president, and to whose energy and business ability the present prominent position of the company is due, was born in Oswego, N. Y., Dec. 27, 1857, and has been associated with electrical enterprises since 1877, when he was appointed manager and cashier of the American District Telegraph Co. at Detroit. In 1880 he became one of the incorporators of the Detroit Electrical Works, and remained with this concern until 1887, when he resigned to seek a wider business field. He went to Chicago and started the enterprise now known as the Central Electric Co. Charles E. Brown, the secretary, has been with the company for 10 years, and although still a young man, brings to bear upon his work an executive ability which compels success in anything he undertakes. M. M. Wood has charge of the street railway supply department, and is widely known to the trade, many of the specialties made by the Central Union Brass Co. and handled by the Central Electric Co., being of his invention.

PARRISH SIGNAL SYSTEM.

Although the Chicago & Milwaukee Electric Railway is now double tracking, it had an exceptionally fine system of block signals installed upon its line from Highland Park to Waukegan, protecting the single track line against head end collisions, as well as using it to insure the quick operation of the cars. The system used was the Parrish block signal system, made by the Parrish Signal Co., of Jackson, Mich. Although the newest in the field, it was one that has given splendid results and perfect satisfaction. The system is very simple, consisting of semaphores of the banjo type, placed at one end of each switch or turnout; the operation is by a trip contact operated by the trolley wheel, and the protection given is perfect. When a car enters upon a block the switch automatically gives a release signal to the motorman, showing that the track is clear and allows him to proceed, while at the same time a signal is given at the outlet of the switch, a mile or so in advance of the car, blocking that switch and preventing a car from entering in the opposite direction upon this stretch of track. Had the second car already entered the block, the first car would have found the danger signal set against it upon entering the switch.

The system gave great satisfaction, and upon all single track roads where protection and speed are desired the block signal system of this nature is invaluable. The maintenance of this signal costs practically nothing, a point that is important.

PAINTING STREET CARS.

The United Railways Co., of St. Louis, has decided upon yellow as the standard color for all its cars. This company was recently formed by the consolidation of all the street railway companies in St. Louis, and naturally had from the former roads a great collection of cars painted in over a dozen different colors and styles. To remedy this as much as possible and reduce all the cars on the system to a uniform standard, the entire rolling stock will be passed through the paint shops as quickly as possible, and the coloring and lettering altered to suit the new conditions.

The middle panel and all the upper part of the cars will be painted in Tuscan yellow, and the lower or concave panel and the dashboards in lemon yellow. On the sides in the middle panel in 6-in. letters of block character, will appear the name "St. Louis Transit Company." In the upper left-hand corner of the dashboards will appear the number of the cars, and on the left side of the platform door, 6 ft. from the floor will be painted the initials of the old company, as "L. R." for "Lindell Ry.," "C. R." for "Citizens' Ry.," etc. This is intended only for employes, and is simply a private mark to indicate to which branch of the system the car belongs. Aluminum leaf is used for lettering, this having been found less expensive than gold or silver leaf, and more durable.

In numbering the numbers in the even hundreds are given to open cars and in the odd hundreds to closed cars; different series of numbers are also assigned to different divisions, so that the number alone indicates to the employes the type of car and its location on the system.

The paint shops of the various systems have been consolidated, and there are now but three, namely the Lindell, the Union Depot and the Citizens.

CAR PLANT FOR SWITZERLAND.

Locomotive Engineering gives details of the formation of a syndicate to establish a large car and locomotive manufacturing plant in Switzerland. The works will be able to turn out annually, 600 locomotives, 1,000 steam railway passenger cars, 1,000 electric railway cars and 10,000 electric switches and signals. The officers will be: President, George Burnham, president of the Baldwin Locomotive Works; vice-president, John A. Brill, of Philadelphia; secretary, Werner Siemens, of the Siemens & Halske Co., of Berlin; treasurer, M. de Neuflize, director of the Paris, Lyons & Mediterranean Ry.; managing director, Corneille Barbey, general manager of the Yoverdam & Ste. Croix Ry.

PERSONAL.

LIEUT. FRANK J. SPRAGUE, of the Sprague Co., was a passenger on the first westward trip of the "Oceanic."

MR. CHARLES A. COFFIN, president of the General Electric Co., has returned with his family from an extensive European trip.

MR. EDWARD D. PAGE has succeeded Mr. Frank Brewer, resigned, as president of the South Orange (N. J.) & Maplewood Traction Co.

MR. ERNEST WOODRUFF, president of the Atlanta (Ga.) Railway & Power Co. and of the Atlanta Railway Co., was a caller on the "Review" last month.

MR. HENRY SCHNITZER, formerly superintendent of the Davenport (Ia.) & Rock Island Ry., now the Tri-City Ry., died at Oklahoma City, September 16th.

MR. E. C. FELTON, president of the Harrisburg (Pa.) Traction Co., has been succeeded by Mr. Edward Bailey, president of the Harrisburg National Bank and of Harrisburg Trust Co., and a director in the traction company.

MR. C. J. FIELD has severed his connection with the American Vitrified Conduit Co., and in addition to his practice as a consulting engineer, will devote his time to the management of the United States Motor Vehicle Co., of New York.

MR. H. S. COOPER, who was for many years superintendent of the Schenectady (N. Y.) Railway Co., has accepted a position with the Ithaca (N. Y.) Street Railway Co., as general manager.

MR. DON A. CLAY has been elected treasurer of the Haverhill (Mass.), Georgetown & Danvers Street Railway Co., in place of Mr. James F. Shaw, resigned. Mr. Clay is also treasurer of the Georgetown, Rowley & Ipswich Street Railway Co.

MR. J. S. HAMLIN sailed last week for Paris, where he will represent the Christensen Engineering Co. The demand for the air brakes of this company has become so large abroad a foreign office has become a necessity. His address is No. 50 Boulevard Hausman, Paris.

MR. W. WORTH BEAN, in addition to his duties as president and general manager of the St. Joseph & Benton Harbor Electric Railway & Light Co., is operating the Benton Harbor & Eastman Springs Electric Street Ry., running 2½ miles east of the former company's track in Benton Harbor, Mich.

MR. DANIEL A. HEGARTY has assumed his duties as general superintendent of the Railway Co., General, with offices in the Drexel Building, Philadelphia. Mr. Hegarty has held the position of superintendent of the Norfolk (Va.) & Ocean View Ry., and also superintendent and chief engineer of the Hestonville, Mantua & Fairmount Ry., of Philadelphia.

MR. H. WHITLEY, vice-chairman of the Borough Tramway Committee of Halifax, England, and Mr. H. F. Street, borough electrical engineer, called on the "Review" when in Chicago last month. They are particularly interested in securing information concerning three-phase transmission for electric railways and counterweight cable systems for heavy grades, and made an extended trip, visiting most of the important cities east of the Mississippi.

MR. F. L. FULLER, for the last six years general superintendent of the West Chicago Street Railway Co., and more recently superintendent of the west division of the Chicago Union Traction Co., has recently resigned from the service of that company and accepted a position as assistant to the president and general superintendent of the United Power & Transportation Co., of Philadelphia, with headquarters in Philadelphia. This system embraces about 400 miles of track, and the lighting plants of the cities of Wilmington, Trenton, Chester, Wilkes Barre, Reading, Lebanon, and also one Philadelphia line known as the Roxbury, Chestnut Hill & Norristown Street Railway Co. We have heard it remarked by a number of those who have had the best opportunity of watching Mr. Fuller's methods of discipline and management in connection with the West Chicago system, that they regarded him as one of the best operating men in the country, and his many friends congratulate him on his advancement to so responsible a position, and their best wishes go with him for abundant success in his new field of labor. The "Street Railway Review" joins in the good wishes, and congratulates the president and managers of the system on their good judgment in selecting one so competent to fill the position.

ELECTRIC CARS IN PLACE OF CABLE.

The first car propelled by the underground electric system over the 125th St. line of the Third Ave. road, New York, was run on Thursday, September 28th. The next day, Friday, 16 electric cars were put in operation, sandwiched in between the horse cars, which were all retained, on account of the extra traffic due to the Dewey parade, and on Sunday the full complement of 20 electric cars was put in operation.

The work of changing the cable line on Tenth Ave., to be operated by the underground trolley, will begin at once, and the line will be operated by horse cars while the change is being made, as was the line on 125th St., temporary tracks being laid outside the present cable track, on which to operate the horse cars.

It is expected that the Third Ave. line proper will begin operating by electric cars by the end of the present month. The work on the 42d St. system is also approaching completion.

The new 8-wheel cars which are to replace the cable cars on Third Ave. have been received from St. Louis and the bodies are being mounted on the trucks, which are of the Peckham make, and will all be equipped with the Standard air brakes, the operating cylinders being placed between the wheels as in locomotive practice.

STREET RAILWAY TRUCKS AT CORNELL UNIVERSITY.

Delegates and others in attendance at the New York State Street Railway convention at Ithaca last month were interested to note in the mechanical museum in Sibley College a number of street railway trucks of different types, made by the J. G. Brill Co. On inquiry it was learned that the authorities of the university, thinking that it would be of advantage to the students to have an opportunity to study the construction and design of trucks for electrical cars, wrote to the J. G. Brill Co., of Philadelphia, and suggested that the company furnish the university for use in the mechanical and electrical engineering department, different types of its latest pattern. The company considered the proposition favorably, and realizing the advantage it would be to both the students and to the company, shipped immediately three trucks, comprising one No. 27 "Perfect" passenger truck, one "Eureka" maximum traction truck, such as is the standard of the Metropolitan Street Railway Co., of New York, and also the standard of some of the Brooklyn roads, and one of the No. 21E solid forged frame trucks. These trucks occupy a prominent position in the museum among the numerous other machines and appliances, and furnish an interesting object lesson, so that students cannot help but be familiar with the general construction of street railway trucks, even from the superficial observation that would be given them during the years required for completing their course of study.

The new extensions of the Coventry, Eng., electric railways have been recently opened for public traffic.

Superintendent Duncan, of the Pottsvile (Pa.) Union Traction Co., a consolidation of several street railway lines, centering in Pottsville, has issued the following letter to all union employes on the system: "You are a member of a labor organization in Pottsville. If you want to remain in the service of the company, you must sever your connection with that organization at once."

ON THE THEORY AND PRACTICE OF GETTING JOBS.

Read before the Illinois Society of Engineers and Surveyors by J. W. Alvord, Chicago.

In recently looking over a mass of pamphlets in one of our society libraries for the purpose of ascertaining their relative values for preservation and indexing, I became impressed with the lack of attention to the very practical subject which I have chosen as the title of this paper.

It is a cause for congratulation to note the completeness and care with which professional brethren have been willing to lay before us, in all possible detail, the methods which they have adopted, the researches which they have made, and the conclusions to which they have arrived after long and laborious study, in the performance of jobs which they have already secured, but of the important and interesting problem, how to obtain such jobs, such writers are usually more than modest, and if perchance they hint at that phase of the subject at all, it is with the lightest and airiest touch or the breathing of some such unsatisfying and elusive ritual as:

"The committee having placed the matter in my charge," or "being consulted by the president of the company," or to use a still more common and unsatisfactory expression: "The writer being called in at this juncture to undertake the work," etc.

Now I have enjoyed reading such phrases as these for many years. They appeal to my imagination. In my mind's eye I could see a committee of solid and influential citizens after long and profound consultation coming to my professional brother's office in a body, and solemnly almost, one might say, reverently "placing" the matter in his charge unreservedly and fully, and with that simple and childlike confidence that in so doing they had by that one act fully insured the brilliant success of the proposed undertaking.

Or again, my imagination has pictured the aged and gray haired millionaire president asking for a consultation on some of the problems presented by the works, and gravely appearing at the office of my brother engineer at the appointed time followed by his own engineer with roll of plans, and patiently waiting his turn for admission to the inner sanctum.

Nor have I failed to catch the inspiration afforded by the seductive phrase, "Having been called in at this juncture." I could well see the anxious inquiries on the part of various members of the company as to whether we can get X to take this matter up, and the mutual friend making personal inquiries as to whether X's time was fully occupied just at present, and finally at the culmination of the diplomatic process when subterranean understanding had been duly reached, that X could afford the time and would "be willing" on certain captious and exacting conditions to take the matter up, resolutions being immediately passed at the meeting of the board of directors "That whereas," etc., the effect of which would be to duly employ X forthwith, without so much as ever mentioning the word "compensation," or even hinting but that any sum which X might name would be perfectly satisfactory. And indeed, the general tone of the resolution being to the effect that the company would consider it a perfect boon to be permitted to employ the said X at all.

In the course of years of anxious expectancy and fond yearning for jobs and more of them, I must admit that such delightful experiences as these have been somewhat few and far between in my own career, and when the remotest similarity to the examples given have actually occurred, the experience has left me in such a stunned and unnatural condition of mind as to be truly pathetic.

In earlier years I naturally felt with humility that I was only clinging to the outskirts of the profession, hanging on to its extremities, as it were, and when I lost my first important salary and tried to get another, I felt a good deal as a cat does when thrown out of an upper window, and goes down with a rush, clawing, yowling, and grabbing at everything in sight in vain attempt to ease the situation.

The inability at that time to get my claws into anything tangible made a serious impression on me, which has only deepened with the lapse of time and the accumulation of experience.

Now in the course of resulting reflections on the subject, it has often occurred to me to wonder how I came to be possessed of such high ideals on the art of job getting. I must admit that these ideals seem to come as much from my own wild flights of imagination as from the literature of my brother engineers. They always formed a bright and beautiful dream hovering just above, reality luring me with boundless hope. They always intensified too by the passing greetings of the profession. Who has not observed in the midst of the bitter struggle for existence the cheering influence of these passing greetings with our fellow engineer, especially with a rival in our own line of business. "Hello, Jones, how goes it," and then Jones grasps your hand and leads you to the curb to one and pours into your ears a glittering story of major success he has had of late; how he was chosen among twenty applicants at "Three Corners," what the mayor of Gingerville had said of the successful test of his latest water works. How busy he was, and how much work he had been obliged to refuse recently, perhaps mentioning in this connection in an airy way a job which you yourself might have just received after the hardest kind of work, and, if after listening to this optimistic account with growing envy and longing, you should venture, just as Jones starts, looks at his watch and mentions an important engagement with the harbor committee, if you should venture to detain him just a minute and tell him that you were not very busy and would like to help him in some of his work, how confidently Jones would explain that his practice just at present time was nearly all consulting matters and special reports, which really necessitated his own personal attention, that he would be glad when anything came along to remember you, etc.

It must be admitted that it certainly has a very wine like effect upon a man to actually get a job, but I have often thought that it would be well if men like Jones could go off somewhere after such an experience and secrete themselves for a day or two until they were fit to appear in public. I think the worst thing that can be said of them is that they age the rest of us rapidly. We unconsciously lose our freshness and trustfulness in meeting with them.

Quite the opposite in character are the men, young for the most part, I take it, who confide their disappointments to the correspondence column of the Engineering News. These letters from young men who have failed and tell about it, always fill me with great interest. They are so ingenuous and disinterested in relating their story of the business ignorance and general low practices of town councils, bridge commissioners or other trustees employing talent. We are all familiar with their treatment of professional ethics. They have been degraded by being forced into a competition by callous and unfeeling boards who give no thoughts to the advancement of the engineering profession at all, and after the applicants have named compensation (and possibly failed to verify their qualifications) they have been subjected to the mortification of seeing their professional knowledge weighed up and measured like a lot of hay or potatoes, and perhaps found wanting. It is indeed a cruel experience, this having the cold outside world size up our professional attainments instead of taking our own measure of ourselves for comparison, and the hard cruel fact that these worldly and greedy trustees are looking for the largest knowledge for the least money, comes upon a sensitive and confiding nature like the blighting breath of a simoon upon a gentle flower.

Possibly I am wrong in reading all this between the lines in such letters. What they actually tell makes an entertaining and often humorous story from a business standpoint. And the editors (shrewd fellows) know that it is "soothing reading" for most of us, and generally comment upon the letter in a comforting way.

Far be it from me either to suggest that such mournful stories are not often, too often based upon sad facts. Indeed, should I take occasion to doubt them, I am too often reminded of a worthy old uncle of my own who had conquered a living with arduous toil for many years among the rugged hills of western Connecticut. Upon a visit to him I confessed blushingly from time to time my many triumphs over the forces of nature. The old gentleman eyed me suspiciously for a day or two in the evident attempt to determine my species, and finally asked confidentially: "Now 'sn't this engineering business a kind of fancy business anyhow?" I doubt if the worthy man during his lifetime was ever fully convinced that I earned my living legitimately.

I do not wish in this paper to throw discouragement in the way of those who are about entering this noble profession of ours by the discussion of the subject I have undertaken, and if any of my professional friends in salaried positions feel that the world is yearning for an opportunity to push them to the front, by all means let them open an office and give the yearning world a chance. It is at this particular point that I desire to contrast the theory with the practice.

You open an office and insert your business card in the technical papers. Then you brace yourself for a flood of business. Your professional rivals drop in one by one to ask "how it comes on," and incidentally to see how much your office furniture cost you, and otherwise assure themselves that you are not likely in the remotest way to get a job away from them.

A few book agents vary the monotony of life, and once and a while a well-dressed life insurance agent makes your heart jump into your mouth as you lead him into the inner office with every nerve braced to keep the joy out of your face and assume a bored and indifferent air. I know of few more trying, soul wrenching moments than come with the disclosure of the life insurance man's business in that inner sanctum. It is for this, then, that those pumping engine details have been scattered over the table, and books on deep and abstruse subjects placed where they meet his eye. A man who can pass through these experiences without the freshness of his hope being perceptibly withered has fitted himself for a better land.

But yet the theory seems to be all right. You are a professional man. Your work is such as to require confidence in you on the part of your clients. Consequently it is indelicate on your part to push your claims to their notice. You feel competent to do their work. You have done it before over and over again successfully, but you must not intrude this fact to their notice, but wait for them to come to you.

These are the conclusions I have been led to after long years of perusal of engineering literature. I take delight in the theory. It accords with my own sensitive nature and my retiring disposition. I always read articles on the "Standing of the Engineer" and "Ethics of the Profession;" I am especially fond of "Presidents' Annual Addresses," I consider them delightful reading. I well remember seven years ago returning from a $75 trip to Braceville where I had been at my own expense to see another engineer receive a job, being much comforted by reading the annual address of our worthy president. It seemed to relax the strain of the Braceville episode to read of the great achievements of the engineer along the different lines of his profession throughout the world, and to know once more that his was the opportunity to "harness the forces of nature to the use of man."

I have been familiar with that sentiment for many years, but it never seemed to have the same weight and swing as it did on this occasion. It calmed my nerves and filled me with a glow of hopefulness. I felt once more a man. I think we cannot set too great a store on these presidents' addresses. I like to hear about the Forth bridge, the Nicaragua ship canal and the new battleships and realize that I belong to such a glorious fraternity who are truly conquering nature. It may be inferred from my reference to the Braceville episode that I have sometimes gone out after jobs. It is with some reluctance that I am compelled to admit here, confidentially, that once or twice I have "run over" to a town or two to see if there was any interesting and instructive work going on. I very well remember the first time I did this. I thought it a little singular that I should find near the bait the plain footprints of several distinguished professional brethren versed in that particular specialty. Some of them I was told had "stopped over" on their way to important work at other points further on. Some had been invited by a particular friend who was extremely anxious to see the important work in the proper hands. Nearly all happened to have fortunately with them some copies of testimonials of former work which they would leave. The engineering of this particular job was finally let on proposals. I remember that at the letting several of us who happened to be in town were interviewed by the council one by one behind closed doors, sized up, so to speak, much as racing men get out a trotter to see him make a turn or two, punch his ribs, feel of his legs, and look at his teeth. Perhaps the comparison is a little vulgar, but I felt less pleasant about it than the trotter probably does, as a usual thing. I also remember while waiting for my turn to trot, being called aside by a mysterious man with a wandering eye and a sinister smile, and being informed in a highly secretive manner, that the firm of Tripod & Sight-pole had three of the council for them, and there would be no show for me unless I would leave the matter with him, that he had a good deal of influence with the council and wanted to see me get that work. I remember being much touched by his sympathy and solicitude in my behalf, and saying to him earnestly that if awarded the work I would endeavor to do it well and faithfully, together with much more in the same strain, the net result of which, much to my surprise, seemed to cool his interest wonderfully. I noticed afterward that Messrs. Tripod & Sight-pole got the work, and I remember particularly being struck with the fact that there was a difference of some 3,000 per cent between the highest and lowest bid. It is natural to abuse the wily councilman for his lack of appreciation of engineering ability, but it is hard to see how he can form a very high opinion of a profession that has such a variable estimate of themselves.

After my arrival home, I watched eagerly for next week's technical papers. Now, thought I, we will have this disgraceful competition exposed by an able editorial on "the folly of treating brains as merchandise," or "low depths of ignominy to which some town councils are sunk." I was disappointed; after searching vainly all through the news columns, I found the following brief item in the next issue: "The services of Messrs. Tripod & Sight-pole, the well known engineers of Metropolisville, have been secured by the city of," etc.

After this my confidence in the theory of getting jobs began to wane. I laid the theory on the shelf, as it were, and found myself compelled by urgent necessity to discover the practice. In the course of a number of years of heartrending experiences I have, I think, discovered a few simple rules for getting jobs which, after much reluctance, I have concluded to give to the profession in absolute confidence. They have not always worked as well as I would like, but they at least give one a fair chance with other professional brothers, and they are as follows:

1. Find your job.

This is quite necessary. I have completely discarded the theory on which I started in, that your job should find you. It may work once in a while, but as a rule a needy engineer out of work is a great deal keener hunter than a lonesome job is. After you have found jobs for a good many years it is possible that some stray jobs may find you, but I wouldn't count on it. They are only the few bright beams Heaven sends to illumine our dreary pathway, and should be so considered and accepted.

2. Know a great deal more about how that job ought to be done than anybody else around.

There is no doubt at all but that this is a very important requirement indeed, in the practice of getting jobs, but it is one which I feel almost ashamed to mention, and indeed would have forborne to speak of had it not been that occasionally I have met enthusiastic and confident engineers eager and willing to lend a hand in the great work of harnessing the forces of nature, but a little uncertain as to the difference between the breeching and bellyband.

One enthusiastic friend of mine who had offered to design and construct a $25,000 waterworks for $25, confided to me that it was his intention to read up on the subject nights and get into that line of business. He seemed disappointed when the waterworks committee intimated their unwillingness to "place" the matter in his hands because he had heard of waterworks men who charged $50 per day and expenses, and thought it might be a lucrative business.

This delightful trait of ambition in our profession should be commended, could it only be turned into proper channels, but the greatest problem we have is how to direct the energies of such would-be members into ethical discussions on the standing of the profession or society resolutions upon the unsatisfactory condition of the remuneration of engineers.

3. Know the men who have the jobs to give.

This last rule seems also to be one of those delightfully simple propositions in theory which are found so difficult in practice. The theory of the thing is that an engineer's reputation ought to precede him everywhere. In practice he is usually exceedingly glad if it will only follow him at a respectable distance.

People with jobs to give want to see you, poke your ribs, and put you through your paces, as I have elsewhere intimated. And if you would like to be their "hired man," which is the plain but unused name for it all, it is best for you to go and submit yourself to the process as gracefully as you can.

I believe, however, that it is quite possible to do all this and still be modest. There is no money in being bashful, but to be suitably modest at the proper time and in the proper amount is an art whose worth to the fortunate possessor cannot be overestimated.

Long years of harrowing experiences have frayed the edges and removed the bloom from my own early attempts to be modest. Yet I can not refrain from referring with pride to one attempt, which, though disastrous to me at the time, may prove instructive in this connection.

In the first year of my apprenticeship the city directory man called at the office in which I was engaged and asked for my name and designation. Naturally I did not feel at that time that I stood more than upon the threshold of our great and noble profession, so I informed him simply that I thought I might be entitled to be called an "engineer's assistant." I am at loss to determine even to this day whether this was an act of true modesty or mere bashfulness, but this classifier at the central office of that directory evidently had no difficulty whatever in placing me. He had met pretentious people before in his line of business, and when the directory was duly printed and issued I was dumbfounded to observe the appellation of "fireman" following my name and address.

It is pretty evident that the business world makes but little allowance for ordinary modesty, but it doubtless has distinct difficulty of its own in designating and classifying a profession which expects a man to drive stakes in a sewer or paint landscapes in the office, corner the elusive bacillus in the laboratory, or throw off a literary gem in the shape of a financial prospectus between meals.

In closing this paper I cannot but regret that I have taken up so much time in elucidating the theory rather than the practice of getting jobs. I cannot help but feel, however, that if read between the lines the diligent enquirer in this interesting field will find some hints which if they do not guide him in his hard and toilsome pathway will at least cheer him with the reflections that it has been trodden before.

MERRICK AIR-ELECTRIC SYSTEM.

BY ASA L. MERRICK.

Why compressed air is used instead of electricity to propel a car may not at first be apparent. To some persons this combination may seem like folly when it is understood that in compressing air by electricity fully 25 per cent of the electric power is lost. But the advantages gained in using compressed air more than counterbalance this loss, and makes it possible to save a still larger percentage in other ways, thus saving that which is now wasted by the present system. It reduces the great wear and tear of the electric motor. It lessens the percentage of accidents, as this car is started and stopped with ease and rapidity, and it obviates the objectionable unbalancing of passengers who may be standing or walking in the car when it is started or stopped.

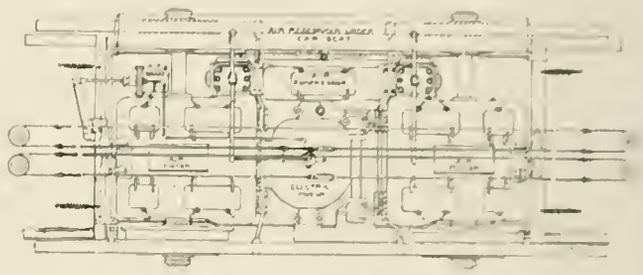
The device for starting and stopping is so simple and effective that the ordinary motorman can operate it instantly in times of need. There being but one crank instead of two the chances of confusion in cases of emergency are consequently lessened one-half. Where two cranks are employed, in the hurry to stop, there is sometimes failure to turn one in the right direction, thereby causing an accident. The air motors that propel the car are convertible, being arranged so that when the pressure is shut off from the cylinder (there being two in each motor), they are converted into air compressors, so that the momentum of the car can be utilized to compress air until the car is stopped.

The electric motor, which is used only to compress air, is not subjected to sudden strains, as is the case when connected to the axles of the car. The greatest strain on electric motors occurs when starting the car, and when power is suddenly applied they often burn out, causing a great expense for repair. Many electric railway companies have had a large experience in this line, and the cost of repairing electric motors and power plants is so great the problem of how to overcome this is a serious one.

By the application of an air compressor it is overcome effectually, for there is no resistance to be overcome at the instant current is turned on the electric motor. The instant power is shut off the piston of the compressor moves away from the end of the cylinder which is compressing air (for it has been released by shutting off the power) and the compressed air drives it back until the pressure has become equalized, or down to the atmospheric pressure, so the motor when started has no resistance until the piston is resisted by compressed air, which does not occur until the piston has traveled a portion of its stroke, and the interval which occurs between the starting and resistance allows the electric controller to be turned on at all times and under any conditions without the slightest injury to the motor. Thus there is no more expense attached to a railway plant under air system than there is to an electric light plant.

How to prevent the loss which is often occurs from the motorman applying the brake when the electric power is on in order to stop the car quickly is another question of importance. There being two independent forces which can be applied together intentionally or carelessly, the loss of electric power is therefore enormous. With our mechanism the difficulty is overcome for only one crank is used to start the car change the motors to compressors and operate the brake. By moving the crank through one eighth of the circumference of a circle the air pressure is shut off from the brake cylinder, which releases the brake and turns on the air power to the motor; a reverse motion of the crank reverses the operation.

When it is stated that we have four motor cylinders, whose combined piston area is 50 sq. in., that these cylinders are geared to the axle three to one, and are in combination with an air brake cylinder



AIR-ELECTRIC SYSTEM.

whose piston area is 33 sq. in., the air pressure ranging from 60 to 100 lb. per sq. in., it will be understood that we have a great force to stop the car in an emergency. This force is used only to avoid accidents. In ordinary cases the motor cylinder when converted into an air compressor will bring the car to an easy stop without any inconvenience to the passengers.

As electricity is the best and most convenient power that can be applied to railway service the device has been designed to overcome all objections to the present electric system, and reduce the running expenses as much as possible. The air motors are like ordinary types of steam engines, with convertible device attached. The air compressor is also the same as the ordinary compressor, except in the cooling device. Every part of this mechanism is simple and strong and will be found well adapted for hard and continuous service.

CINCINNATI, NEWPORT & COVINGTON.

For the months of August, 1899, and August, 1898, the receipts, expenses, etc., of the Cincinnati, Newport & Covington Street Ry. were as follows:

	1899.	1898.
Gross receipts	$70,144.55	$63,952.09
Operating expenses	24,383.20	28,312.91
Net earnings	45,731.29	35,039.18
Tolls, damages, taxes, etc	12,062.35	30,478.55
Net profit	33,668.04	839.37
Ratio of expenses to earnings, with tolls	45.25 p. c	54.27 p. c.
Ratio of expenses to earnings, without tolls	34.77 p. c	44.27 p. c.

For the first eight months of 1899 the gross receipts were $464,410.49, an increase of $31,272.98 over the corresponding period for 1898; and the operating expenses, $190,190.80, a decrease of $19,414.86. For this period the operating ratios are 53.30 and 40.95 per cent, as against 59.50 and 48.39 per cent in 1898.

Permission has been granted by the Secretary of War to the West End Traction Co., of Pittsburg, to lay a wire cable for ferry purposes in the bed of a branch channel of the Ohio River from a point about 2,000 ft., east of Chartiers creek, from the south shore to Brunots Island.

The South Park Board on September 13th passed an ordinance granting the Chicago City Railway Co. the right of way through Gage Park, thus enabling the company to continue its extension on Western Ave. The ordinance was passed on condition that grooved rails would be placed on boulevard crossings.

NEW INDIANA ROAD.

The contract for constructing the interurban road of the Indianapolis & Greenfield Rapid Transit Co. has been given to the Kirkpatrick Construction Co., of Greenfield, Ind. This line is to run from Greenfield to Irvington, a suburb of Indianapolis, where connection will be made over the Indianapolis Street Ry. into the heart of the city of Indianapolis. All financial arrangements have been made and preliminary steps taken to commence construction work. The road is to be completed Sept. 1, 1900. The proposed route is 17 miles long, passing through Irvington, Cumberland, Gem and Philadelphia, and there are practically no curves or grades throughout the entire length.

The officers of the company are: President, John J. Cooper, Indianapolis; vice-president, George C. Webster, Indianapolis; secretary, L. E. McDonald, Greenfield; treasurer, William C. Dudding, Greenfield. Mr. C. M. Kirkpatrick of Greenfield is president of the construction company.

THE AMERICAN STEEL & WIRE CO. MAKING ELECTRICAL GOODS.

The American Steel & Wire Co., contrary to the impression which might be created by its name, by no means confines itself to making iron and steel wires or their products. By the absorption of the Washburn-Moen Manufacturing Co., the larger organization secured one of the world's most important manufactories of bare and insulated copper wires in various forms and for all electrical purposes.

With the immense plant at Waukegan, Ill., only 35 miles north of Chicago, at which much of the copper wire is produced, the American company enjoys exceptional facilities for catering to the wants of the trade in the west, giving as it does to the organization the same prestige in occupying the western field that is enjoyed by the Washburn-Moen department at Worcester, Mass., in eastern territory.

We make these statements on the assumption that they will be news to many of our readers, the recent changes in the commercial and manufacturing world having been so numerous and kaleidoscopic that many, even among the large users of their products, have not become familiar with the new scope of their operations.

In every line of production certain names come to stand out in bold relief as synonyms for some forms of superiority or for some characteristics of excellence. In the production of electrical wire, bare and insulated, the introduction of improvements calculated to secure best results and in uniformity of excellence, no name has ever stood higher than that of Washburn-Moen. The merging of this company into the American Steel & Wire Co. means simply a further step in the lead whereby with unlimited resources, continued investigation and improvements and a still greater superiority are assured in the production of all forms of electrical wires, rail bonds, etc.

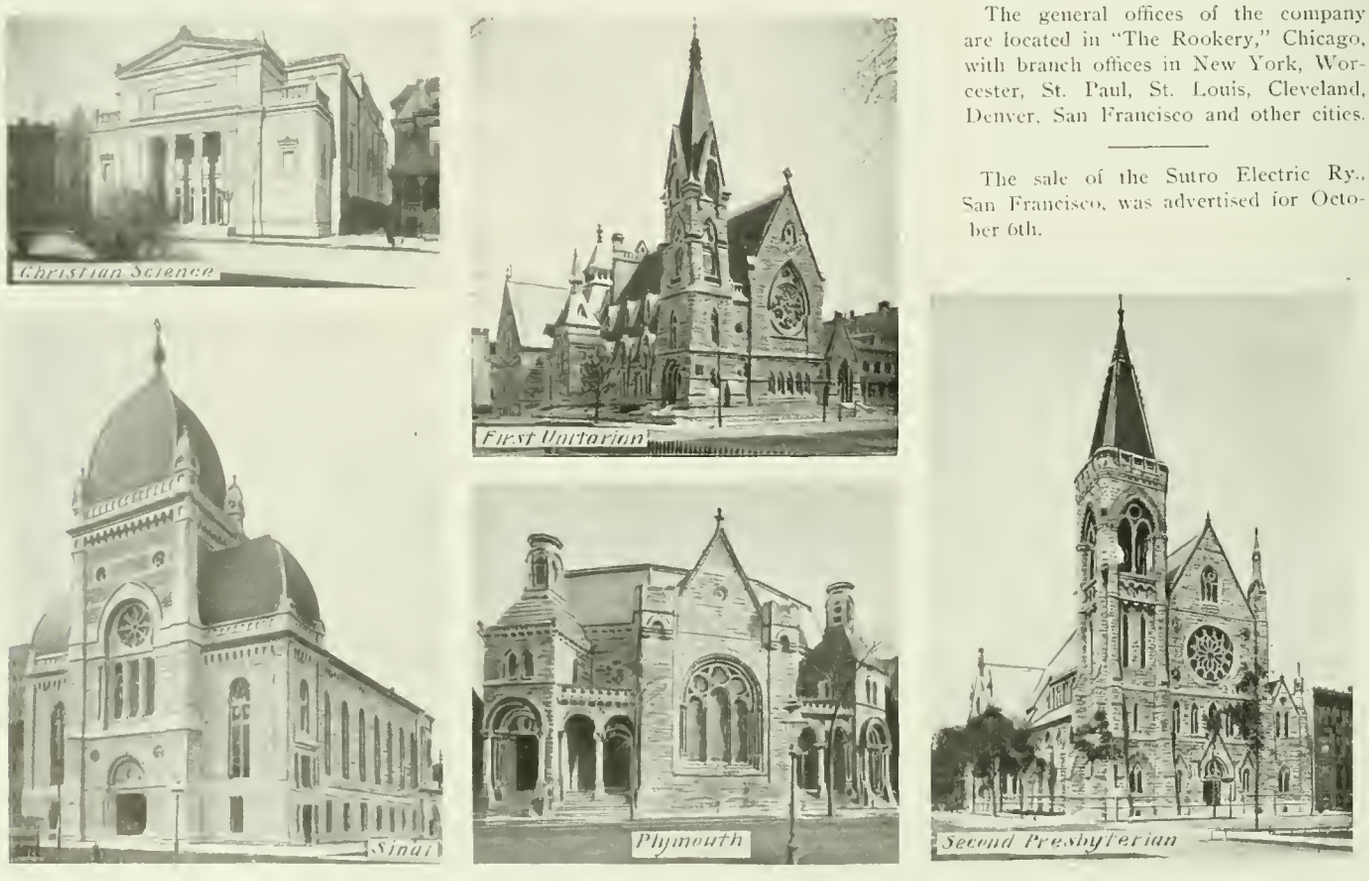
At the Waukegan plant special attention is given to the manufacture of the well known "Extra BB," and "Steel" telephone and telegraph wires and copper wires for electric lighting and street railway plants in all their various forms; and the system of tests at every stage of the manufacture of these goods is at once so unique and rigid that the high standard set for all the products of this company is always maintained. Purity, conductivity, tensile strength, finish and uniformity to gage, are all given due attention, resulting in the output of millions of pounds, distributed among all the nations of the earth in the operation of the great telephone, telegraph and electrical traction systems.

In the production of copper rail bonds, either solid or flexible, the prestige of the Washburn-Moen name has been increased since the formation of the American Steel & Wire Co., and the output of solid and flexible "Crown" bonds in a variety of patterns and for adjustment to the rails in various positions has been marvelous. This is equally true of the manufacture and sale of copper trolley wire, in which this company has earned a commanding position.

In the department of insulated wires, the entire line, including every form of magnet wire, office and annunciator wire, weather proof wire, feeder wires, lead encased wires and cables, and submarine cables is thoroughly covered, the rubber insulating, taping, braiding, lead encasing, armoring and weather proofing being carried on under the supervision of the most expert scientific skill and experience that can be secured.

The general offices of the company are located in "The Rookery," Chicago, with branch offices in New York, Worcester, St. Paul, St. Louis, Cleveland, Denver, San Francisco and other cities.

The sale of the Sutro Electric Ry., San Francisco, was advertised for October 6th.



WELL-KNOWN CHICAGO CHURCHES.

THE ARNOLD ELECTRIC POWER STATION CO.

The Arnold Electric Power Station Co. was organized in 1896 to make and sell the parts peculiar to the "Arnold System" of power station construction, and acting in this capacity it has supplied a number of plants with magnetic clutches, shafts, quills, box stands and coplings. Among these plants may be mentioned the Ft. Dodge Light & Power Co., Ft. Dodge, Ia.; Chicago Board of Trade; Englewood & Chicago Electric Railway Co.; Land Title & Trust Building, Philadelphia; University of Michigan, Ann Arbor, and W. B. Conkey Co., Hammond, Ind.

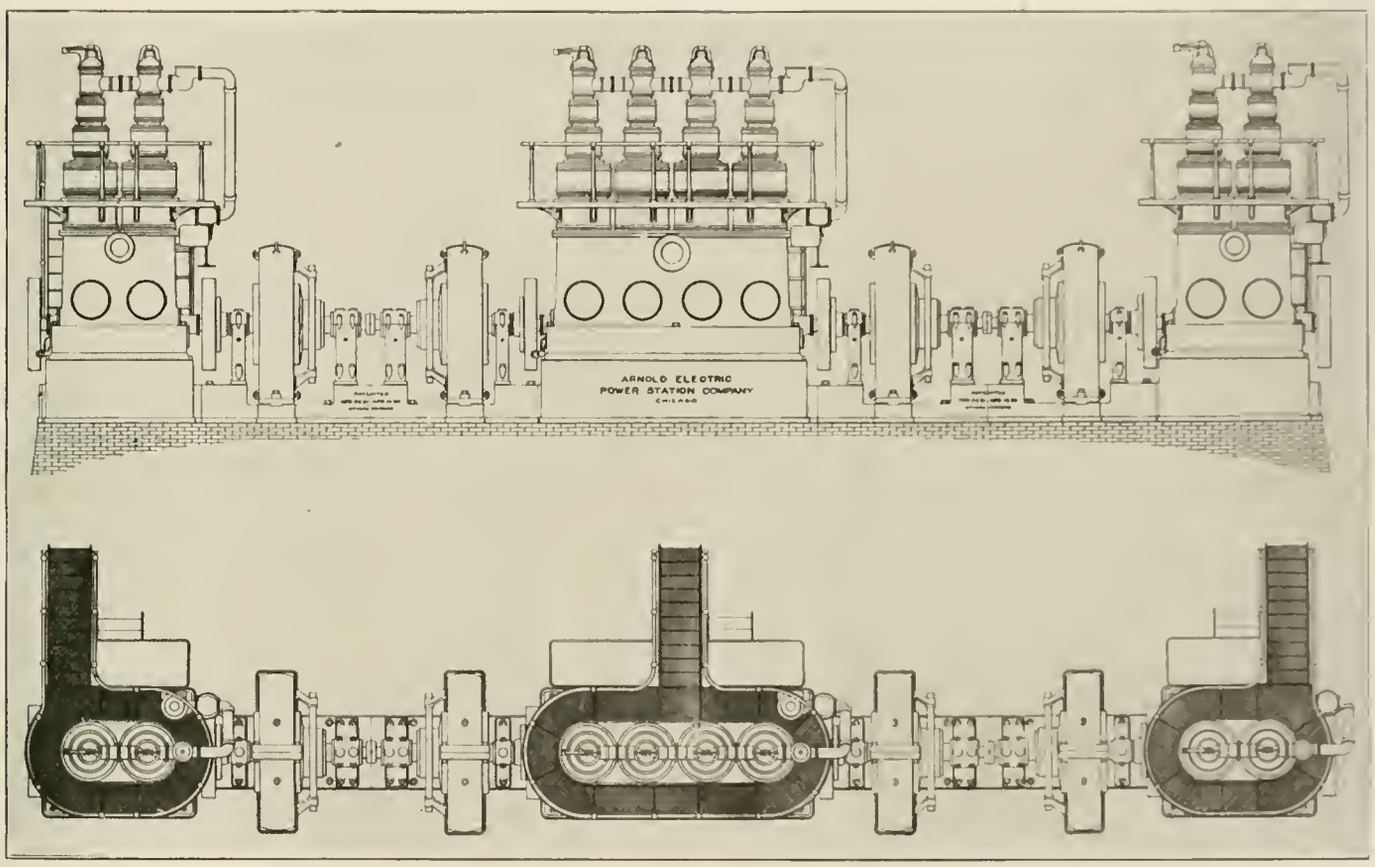
Through natural development this company has gradually broadened the scope of its work until it is now in position to make a proposition for furnishing and erecting in place entire electrical properties, and it already has an enviable record along this line.

Four years ago Mr. Bion J. Arnold, as consulting engineer, worked out a plan of electrical generation and distribution for a long distance high speed electric line, which comprised a central station containing direct current generators for supplying one section of the line, and alternators generating current at high potential for transmission to a number of sub-stations, each equipped with a storage battery and rotary transformers and converters. When the Chicago & Milwaukee Electric Railway Co. retained Mr. Arnold he advised the use of this system, and it was adopted for the first section, from Waukegan to Highland Park. A change in the management of the road resulted in some opposition to the alternating current system, but the Arnold company proposed to equip the road according to the original plans and guarantee the efficiency. The company received the contract for everything except the track and rolling stock, and the work has recently been completed, as described elsewhere in this issue.

The position of the Arnold company is unique among contractors; it works out the solution of the engineering problems involved in an undertaking and submits a proposal for doing the work, with guarantees as to the efficiency. Being in no way connected with any manufacturing concerns it is perfectly free to buy and use any make of apparatus.

The entire power plant and building of the Imperial Electric Light, Heat & Power Co., at St. Louis, Mo., was constructed by the Arnold company. The plant is a large central station, using 500 volt generators working in parallel with a storage battery auxiliary. By dividing this battery into two parts a distribution system was devised which allowed the use of 220 volt incandescent lamps, arc lamps, and power motors off the same mains—a decided departure from central station practice. This system has been adopted for another large central station since the erection of the Imperial plant.

The Arnold company was also given the contract for the complete light, heat and power plant erected in connection with the new railroad shops of the Chicago Great Western R. R. at Oelwein, Ia. This contract comprised not only the heating and lighting of the shop buildings, covering many acres from a central plant, but also the application of a large number of motors for various uses. This has been the first plant to adopt the Arnold magnetic clutch for line shaft work, though these clutches have been used for some time in connection with the three way couplings, which are a part of the Arnold system of power station construction.



THE ARNOLD SYSTEM AS DESIGNED FOR THE CHICAGO ELECTRIC TRACTION CO.

Another notable installation recently completed is the isolated plant for the Garrett Building, Chicago, which is occupied by a large wholesale grocery establishment. This contract included a complete system of lighting and power wiring for 45 motors, a storage battery auxiliary with booster and switchboard, and three generators connected by means of the Arnold system to two high speed engines. The plant is remarkable for the small amount of space occupied.

A history of the Arnold Electric Power Station Co. would hardly be complete without some reference to its energetic president, Mr. Bion J. Arnold. For 10 years Mr. Arnold has held a high place among electrical engineers. As technical representative of one of the large manufacturing companies he built a number of electric railway plants, which stand today as monuments of his skill. He has been connected with pioneer engineering work in more than one field. He was consulting engineer of the first electric elevated railway—the Columbia Intramural Ry. at the World's Fair, and also the first successful storage battery railway in the

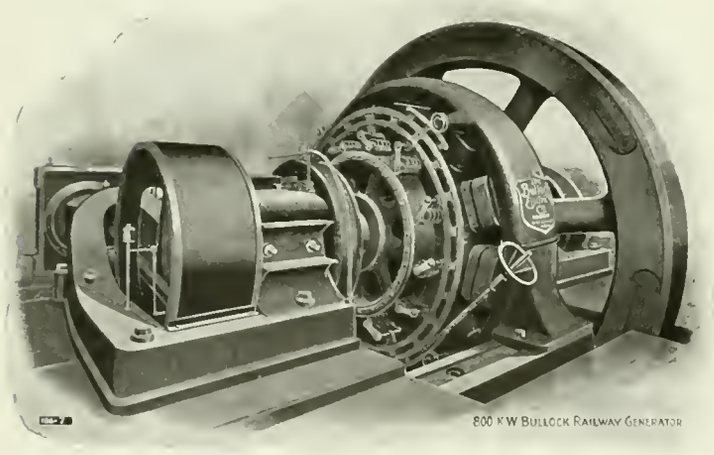
United States, now the Chicago Electric Traction. He was an early advocate of the use of the storage battery and backed up his judgment by entering into the manufacture of accumulators in such a manner as to gain considerable profit for the company which he formed for that purpose. Mr. Arnold has always had the courage to carry out his solutions of engineering problems, even when confronted with considerable opposition, and has had the pleasure more than once of seeing the methods which he has introduced become accepted practice. It is easy to predict that many railroads will be built upon the plan of the Chicago & Milwaukee Electric, and that the Arnold magnetic clutch and the Arnold system of power station construction will become well known features in power station work.

The advent into general electrical contracting work of the Arnold Power Station Co., prepared as it is with an organization capable of handling the largest contracts and willing to guarantee the operation and the economy of a completed plant or installation is a development which promises to bring about new methods in building extensive electric properties.

A NEW STREET RAILWAY GENERATOR.

The Bullock Electric Manufacturing Co., of Cincinnati, has, throughout the 10 years of its existence, faithfully adhered to the maxim that "what is worth doing at all is worth doing well," and the natural result has been the building up of a reputation which has made the Bullock generators famous for excellence at home and in many foreign lands. After a series of additions to the original plant it became necessary in 1898 to erect entirely new works, and although these buildings were not ready until January of the present year, the rapid increase in the business is such that further enlargement will be necessary.

The company has intended for a long time to bring out a railway generator which should embody all the excellent features of its smaller generators, and is now building railway generators up to



NEW STREET RAILWAY GENERATOR, BULLOCK ELECTRIC MANUFACTURING CO.

800 kw. Among the important features of these new machines may be mentioned a scheme for oscillating the brush holder mechanism in a direction parallel with the shaft. The movement is very slow and results in constantly changing the line of travel over the commutator face and thus removes all tendency to cut or groove the latter. The action is the same as secured by the end play of an armature in a belted generator or that produced by the electro magnetic device used at the end of shaft on rotary transformers, and which is recognized by engineers as a means of greatly prolonging the life of the commutator.

The pole pieces and coils may be removed without disturbing the yoke or armature, and with two of them removed, it is possible to remove one or more armature coils should repairs be necessary.

The armature coils are made of continuous bars of copper without joints between the commutator connections which materially adds to the life of the machine. These coils are all thoroughly insulated, pressed and baked before being placed on the core, no additional core insulation being necessary. All armatures are thoroughly ventilated by slots perpendicular to the shaft through which the air rushes when the machine is in operation. A liberal rating permits of constant operation at full load with low temperature rise.

One of the 800-kw. machines has been sold to the Oakland Rapid Transit Co., of Oakland, Cal., and is shown in the engraving. This machine operates at a speed of 80 r. p. m., and at this speed develops 550 volts at no load. It is over-compounded for a rise of 50 volts at full load, making the full load voltage 600.

Bullock railway generators are well worth the careful investigation of every railway manager, and full praticulars and details of construction will be found in the new Bullock catalog, No. 3434, which will be mailed anywhere on request.

WM. D. RAY.

Mr. William D. Ray, the general manager of the McGann Air Brake Co., Detroit, has been in the electrical business for the past 11 years. In 1890 he was electrician's assistant of the Cicero Electric Light Co., this city, then for two years electrician of the Grand Central station in charge of the lighting plant, and four miles of electric and block signals. In 1892 he became electric light inspector of the Chicago & Northwestern, and in 1893 was an inspector and foreman in the electrical department of the World's Fair. From here he became assistant consulting electrician of the Standard Electric Co., Chicago, leaving that position in November, 1894, to become superintendent and later manager of the Everett (Wash.), Railway & Electric Co. He is an associate member of the American Institute of Electrical Engineers, and Association of Railroad Air Brake Men.

W. D. RAY.

During the past year he has had the management of the McGann air brake, and has introduced this system on the following roads: Kansas City & Leavenworth, 10 equipments; Cleveland & Eastern, 8; Mahoning Valley, 3; Sandusky & Interurban, 3; Detroit, Rochester, Rome & Lake Orien, 6, and Detroit and Northeastern, 12.

Mr. Ray will have a fine exhibit at convention hall, and demonstrate the system he has been chiefly instrumental in bringing before the public.

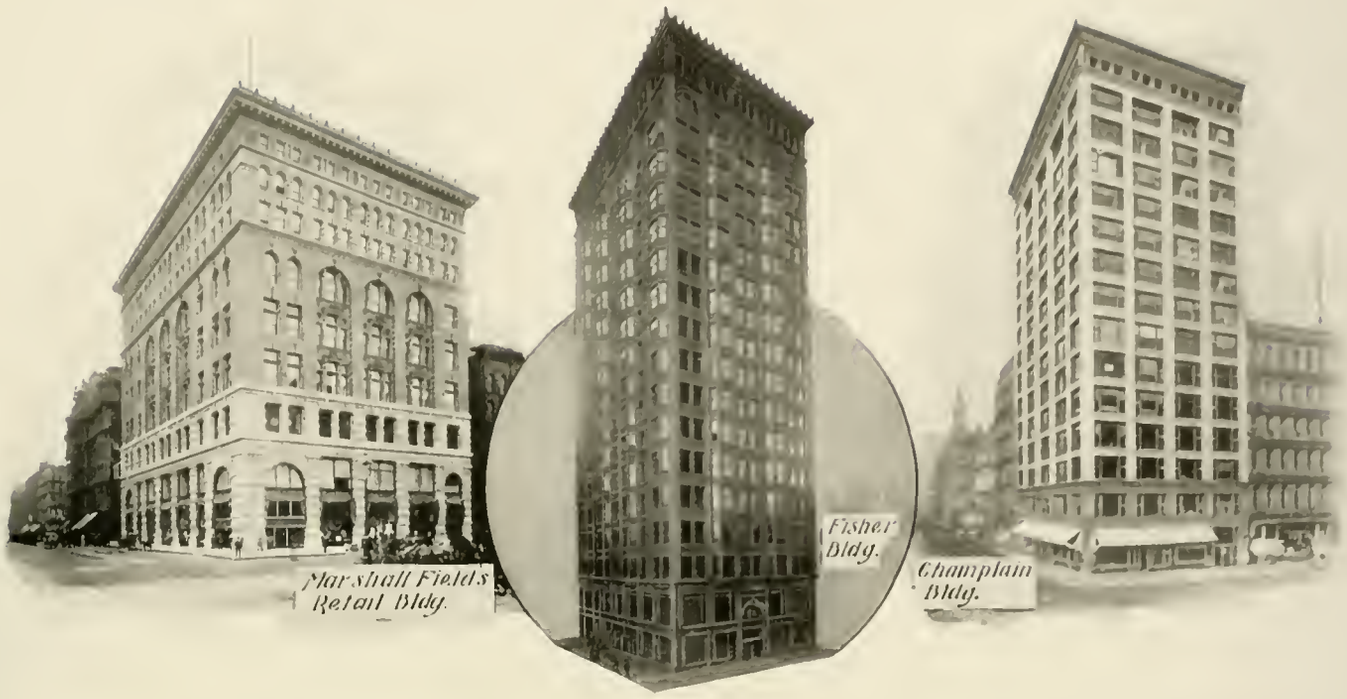
ELECTRIC TRAMWAYS IN NICE.

U. S. Vice-Consul Piatti advises the State Department that the new electric tramways at Nice which were to be opened about October 15th will be operated until December 15th by horse power.

The reason given is that it was necessary to replace the existing overhead telephone wires by underground cables so that they might not be affected by the overhead wires of the railway, and that no concern could be found in France that was willing to contract for the delivery of the necessary cables before November 1st.

Mr. Piatti adds: "This, in itself, may not be a fact of paramount importance; but, reverting to the continuous attempts made by this consulate to induce our manufacturers to cultivate the very considerable opportunities offered by the port of Nice for a direct trade with the United States, it may not be out of place to say that in this instance an American firm might have competed with success in furnishing the necessary electric cables."

VOL. 1, STREET RAILWAY LAW.



NORTH AMERICAN RAILWAY CONSTRUCTION CO.

One of the best known railway construction companies in the country, and which has executed very large and important contracts, is the North American Railway Construction Co., of this city. Its headquarters are in the Monadnock building, and its officers are widely known to street railway managers. They are: A. S. Littlefield, president; E. J. Evans, secretary and treasurer, and E. M. Fry, general superintendent.

The work at present under way includes some of the most important of the year in the entire country, foremost among which is that on the Northwestern Elevated of this city, where the contract includes all above the structure—timbers, ties, track and special work. This road is, for the most part, a 4-track line aggregating 25 miles of single track. As the rail is 80-lb. A. S. C. E. T-section in 60-ft. length, it will readily be understood that no small degree of skill is required to place this iron. To do this work special mechanical devices were necessary, and on another page in the description of the Northwestern Elevated will be found an illustration of the hoisting machine. The 60-ft. rail on the Union Loop was also laid by this company.

Another important contract is that at Indianapolis, where 25 miles of track are being entirely rebuilt. The new rail is 9-in. girder, made by the Lorain Steel Co., which is also furnishing all the special work of its "guaranteed" type. The track is being cast-welded by the American Improved Rail Joint Co.

At Kansas City the work involves a large amount of track work in which 103-lb. girder is being laid, some in concrete trenches and the balance with wooden tie construction. The Lorain Steel Co.'s "guaranteed" special work is also being used here, and the joints cast-welded.

Having completed the double track extension of the Chicago & Milwaukee Electric between Highland Park and Evanston, the North American forces are now engaged in completing the second track for the same company between Ft. Sheridan and Lake Forest; the rail used being standard T-section 65-lb. and 60-ft. long.

Altogether the year has been one of the busiest and most prosperous in the history of the construction company, which has had all the work it could handle to advantage.

Closely allied to the North American company in its work is the American Improved Rail Joint Co., the officers of which are the same as of the other concern, and whose cast welding of rail joints has been attended with great success. Among the important welding contracts of the year is the 25 miles at Indianapolis and several thousand joints at Kansas City.

Mr. Littlefield is also head of the firm of Littlefield & Mysenburg, who for years have had the general agency of the Johnsen Co., now the Lorain Steel Co., during which time they have sold hundreds of thousands of tons of girder rail. The sales of girder rail the past season has been the largest in six years, and the largest ever of Lorain special work. The firm also handle the Du Pont single and double trucks.

NEW CASUALTY COMPANY.

The Pennsylvania Casualty Co., with a capital of $100,000 and a surplus of $50,000, was recently organized.

The stockholders of the company, who are gentlemen prominent in financial and business circles in Scranton, Philadelphia, Mauch Chunk and elsewhere, elected the following board of directors: Thomas R. Brooks, coal operator, Scranton; William Connell, coal operator and president of Third National Bank, Scranton; A. C. Fuller, treasurer Scranton Stove Works, Scranton, Pa.; Fitch Gilbert, capitalist, Eau Claire, Wis; Alfred Harvey, silk manufacturer, Scranton, Pa.; Edward S. Jones, coal operator, Scranton Pa.; F. H. Johnson, superintendent Enterprise Powder Manufacturing Co., Gracedale, Pa.; John L. Kemmerer, attorney-at-law and capitalist, Scranton, Pa.; E. P. Kingsbury, vice-president Tribune Publishing Co., secretary and treasurer Enterprise Powder Manufacturing Co., Scranton, Pa.; Elmer H. Lawall, vice-president International Correspondence School, Scranton, Pa.; Thomas R Patton, vice-president Union Trust Co., Philadelphia, Pa; Thomas M. Righter, president Mt. Carmel Banking Co., and coal operator, Mt. Carmel, Pa.; W. C. Teter, insurance, Scranton, Pa; W. B. Whitney, Whitney & Kemmerer Co., Philadelphia, Pa.; Dr J. S Wentz, coal operator, Mauch Chunk, Pa.; James J Williams, president Merchants' and Mechanics' Bank, Scranton, Pa.; W. W. Watson, attorney-at-law and vice-president Traders' National Bank; C. H. Zehnder, president Dickson Manufacturing Co., Scranton, Pa.

The officers are: W. W. Watson, president; John L. Kemmerer, first vice-president; Thomas R. Brooks, second vice-president; F H. Kingsbury, secretary; E. P. Kingsbury, treasurer; W. C. Teter, general superintendent.

This company has been organized to carry on the business which the American Mutual Indemnity Co. has so successfully conducted during the past two years.

According to reports the Canadian Government is to subsidize electric lines, as it now does steam roads.

LONG RAILS.

At the annual convention of the Roadmasters' Association of America, held in Detroit last month, a report upon the "Advisability of Increasing the Length of Rails and Using Miter Joints; the Difference in Expansion of Light and Heavy Rails," was made, signed by Mr. V. T. Douglas, of the Chesapeake & Ohio, and Mr. G. W. Merrill, of the Norfolk & Western. We present the following abstract:

There are about eight railroads in the United States who have purchased and are using 45 and 60-ft. rails. The use of rails over 30 ft. in length was commenced experimentally about nine years ago, and while results in some instances have proven quite satisfactory, it may be said that not enough time has yet elapsed to fully develop either the advantages or disadvantages.

The advantages claimed for the 60-ft. rails are the reduction of 50 per cent in the number of joints, better riding track and that it is maintained with less labor. From the information gathered it appears that the objections to 60 ft. rails are:

First—That they are not properly straightened at the rolling mills. While this would seem to be a question of mechanical skill, yet the complaint is general, and indicates that the mills are not prepared and are unable to straighten 45 or 60-ft. rails as well as the 30-ft. rails.

Second—Complaints are made by trackmen that more labor is required on 60-ft. rails, in order to secure good surface, than on the same length of track laid with the 30-ft. rails; this on account of rails springing and not raising to a uniform surface.

Third—Another objection offered is the increased opening required to allow for expansion.

It may be mentioned that it is claimed by many track men that not to exceed 50 per cent more expansion is required for 60-ft. rails than for 30-ft. rails; but as few roads have used less than 50 per cent with satisfactory results, and not having been able to establish the fact scientifically, your committee cannot vouch for its truth.

Inquiries at the leading rolling mills in this country reveal one or two significant facts, namely:—That rails 45 and 60 ft. in length have not yet proven satisfactory, or that purchasers are still watching the results, as few roads have placed a second order for such rails. We believe that until a more perfect workmanship can be attained in the straightening of 45 and 60-ft. rails, they are not likely to be favorably received however satisfactory they may be in other particulars. We believe the subject a fruitful one, and one that should receive continued investigation, as the introduction of any means by which 50 per cent of rail joints can be successfully reduced will be a boon to railroads generally.

After careful consideration your committee can see no objections to 33-ft. rails, and would recommend their use. The advantages to be obtained are greater convenience in handling, transporting and maintaining, and a reduction of 10 per cent in joints.

While your committee recommends the use of 33-ft. rails, we have strong hope that further trial and improvement in manufacture and appliances may at no distant day render it practicable to recommend 45 and even 60-ft. rails.

Your committee regrets that from present information we cannot recommend miter-cut rails. The point of contact between wheel and rail is so slight that an opening at any practicable angle will cause a blow, and as the mitred points are unsupported by the web of the rail, we believe that the depression or flattening at the joints will be about as rapid as the square-cut rails.

Evidence from two prominent roads where mitred rails cut at an angle of 55 degrees have been in hard service for four and five years show fairly satisfactory results. Other roads, after nine years' trial, are not placing any orders for mitred rails. We are satisfied, from information gathered, that in some instances, at least, the unsatisfactory condition of the rails has been caused by too great expansion space having been allowed.

Your committee was under the disadvantage of having no means at hand of making entirely accurate measurements. Our experiments in determining the difference in expansion in different weights were made by constructing a timber platform (wood being used because little affected by extremes of heat and cold), and on this platform, when the temperature of the air registered 5 degrees above zero, were laid one 30-ft. 56-lb. rail, one 30-ft. 75 lb. rail and one 30-ft. 85 lb. rail, the length of each rail at that temperature being registered. At the temperature of 20 degrees below zero the lengths were again carefully taken, when it was found that the 56-lb. rail had contracted 3-16 in., the 75-lb rail had 2-16 in. and the 85-lb. rail 2-20 in.

At a temperature of 70 degrees above zero these rails were again measured, and it was found that between the temperatures of 5 degrees above and 70 degrees above zero the 56-lb. rail had expanded 1-12 in., the 75-lb. rail 1-16 in. and the 85-lb. rail 1-17 in. From this your committee concluded that heavy rails are less affected by the extremes of heat and cold than light rails, and in this we are borne out by the experience of practical trackmen.

The data, reduced to a more usual form of decimal coefficients per 100 degrees F. are:

Contraction from +5 degrees to —20 degrees F.		Expansion from +5 degrees to +70 degrees F.	
Rail.	Coefficient.	Rail.	Coefficient.
56-lb.	.00208	56-lb.	.00107
75-lb.	.00139	75-lb.	.00060
85-lb.	.00101	85-lb.	.00065

The importance of the work may be better appreciated when we take into consideration the fact that the amount of expansion space, to a great extent, determines the life of the rail. In view of the importance of determining definitely the space necessary to be allowed in laying rails of different weights, your committee would recommend that a committee be appointed with authority to employ methods and appliances necessary to make an accurate record and report of the expansion and contraction of rails varying from 60 to 100 lb. per yard, at temperatures of as wide range as practicable; also to ascertain definitely the difference in expansion of 30 and 60-ft. rails.

In the discussion on this report the three objections to long rails were dwelt upon. It appeared that the majority of mills cannot straighten 60-ft. rails save at the expense of much time and labor. Mr. P. E. Carhart of the Illinois Steel Co., believed that a 30-ft. rail could be straightened with fewer blows than any other length, and that consequently the steel was less injured. A number of members stated that long rails would not kink if properly loaded. Mr. D. Foley, of the Michigan Central, was of the opinion that, contrary to the report of the committee, 60-ft. rails could be surfaced with less labor than the same length of 30-ft. rails; on his road he had 500-ft. lengths made up rails riveted at the joints, expansion joints being placed every 500 ft., and believed these long lengths gave better results than 60-ft. rails.

On motion the Association went on record as opposed to the use of rails longer than 33-ft. at this time.

PRIZE FOR POPULAR FIRE COMPANY.

The park manager of the Wilmington (Del.) City Railway Co., in order to increase public interest in the company's theater at Shellpot Park, offered to present the sum of $100 to the most popular fire company in the city, the prize to go to the company receiving, during the month of August, the largest number of votes from patrons of the theater. The charge for all seats at matinee performances was 5 cents, but in the evening the orchestra row was 10 cents and the family circle 5 cents. Purchasers of 5-cent tickets had the privilege of casting one vote for their favorite company, and the 10-cent tickets entitled the holders to two votes.

The Phoenix Fire Co. came out ahead and immediately decided to use the $100 in placing rubber tires on its ambulance.

COMMUTATOR COMPOUND FREE.

Believing that a trial of the Gale commutator compound means an order for more and its continued use, the makers, K. McLennan & Co., 100 Washington St., Chicago, will send free to any street railway man on request, a sample of the compound. In sending for the sample readers are requested to mention the "Street Railway Review."

As the result of recent drouths the City Electric Co., of Austin, Tex., which depends entirely on water power for its operation, and which supplies current to the street railways of the city, has been compelled to shut down, with the result that all the car lines are tied up for an indefinite period.

THE OSHKOSH 3-PHASE ELECTRIC RY.

The Citizens' Traction Co., of Oshkosh, Wis., which has for several years operated an electric railway within the city limits, has recently completed an interurban line connecting the cities of Oshkosh and Neenah, which, following the trend of the most modern practice, is operated on the 3-phase alternating current system. The urban lines, which aggregate 16 miles of single track, are somewhat peculiarly laid out to serve the entire city, there being in the first place a belt line encircling the city and from different points on this belt branches run into the heart of

FIG. 1 ON THE INTERURBAN LINE.

the city, forming several loops, some of the belt line being included in each division. The interurban line is 16 miles in length, starting from the Athearn Hotel in the center of Oshkosh, and running out over what is called the north loop to the northern limit of the city, and from here there follows 10 miles of track without a curve, and the remaining 6 miles have but four slight curves, making an ideal road for high speed service. Figs. 1 and 2 show views along the interurban line, the former being a view of the straight track and the latter showing one of the curves near Neenah.

Oshkosh, within the last few years, has become a flourishing city, largely on account of the numerous manufacturing interests which have located there. It contains about 32,000 inhabitants, and is located at the mouth of the Fox River and on the shore of Lake Winnebago. The river banks within the city are lined with factories, which lend considerable business activity to the city, while the residence portions are handsomely built up with detached dwellings surrounded by well cultivated grounds. The traffic on the 16 miles of urban electric lines for last year amounted to 1,526,408 passengers. Neenah and Menasha, with which the new interurban line connects, contain about 17,000, making the population from which the future traffic of the road will be drawn about 50,000. The road between these cities runs through a highly cultivated farming district, from which considerable traffic will be realized, and the roadbed is located close to one side of the highway, so as not to interfere in the least with wagon traffic, and for the greater part of the way there are no road crossings. The lines, both urban and interurban, are single track, with turnouts, and this necessitates, especially in the city, a particular running schedule, which is closely adhered to. It is noticeable that, although entirely a single track and with cars running at frequent intervals, the schedule is so closely followed that delays at the turnouts are of rare occurrence. The turnouts are placed at intervals of 3,000 ft. along the road.

The road is laid with 60-lb. T-rails, made by the Illinois Steel Co., 30 ft. in length, laid on ties 6 x 7 in. and 7 ft. long, with 2 ft. between centers. The foundation for the roadbed is gravel, of which the company owns two pits along the line. The rails are held to gage by tie rods and are cross bonded every 300 ft. Within the city the company is required to pave between and 12 in. outside of the rails. The road is practically level, the maximum grade not being over 2 per cent.

The overhead work is upon cedar poles, 7 in. in diameter at the top and 30 ft. long, 6 ft. being in the ground. They are set 120 ft. apart, and with a 7-in. rake. In the city span construction is used, while most of the interurban line has side brackets. The trolley wire in the city is No. 00 B. & S. gage, and on the interurban No. 000 drawn to a figure 8 section. The trolley hangers and insulators are of the patterns made by the H. W. Johns Manufacturing Co., the Ohio Brass Co. and Albert & J. M. Anderson. The brackets are built of light angle iron. The feeders vary from 100,000 to 500,000 c. m. in section. Fig. 3 shows the methods employed for stringing the overhead wires. An old flat car was used on one end of which the platform for the wiremen was built, and arrangements were also provided for holding several reels of wire on the car, which paid out as the car was drawn along the track by a small engine. The construction work was all done by the Falk Co., of Milwaukee.

The company owns 15 open cars and 21 closed cars, including 6 cars 46 ft. in length, for use on the interurban line. The city cars are 22 ft. long, the closed ones having vestibules with side seats and center aisles, and have single trucks with double equipments of motors. The interurban cars are very commodious, and are plainly but neatly finished. They are vestibuled at each end, the vestibules having five drop sashes. They are equipped each with four motors and Christensen air brakes. The car and equipment complete weighs about 47,000 lb. The seats are rattan covered "walk-over" type, 12 on each side of the center aisle, giving a seating capacity for 48 persons. An air whistle is used instead of the usual gong, for a warning signal. The cars are heated with Baker hot water heating apparatus, the same as used on steam roads, and are lighted inside by 22 incandescent lamps. One end of the car is partitioned off by sliding doors, with glass sashes, making a smoking compartment, with seats for 10 persons. In some of the cars the space used for the smoking compartment is utilized as a baggage compartment, and the latter have outside sliding doors. The heater for the hot water apparatus is contained in this compartment. All the cars are equipped with fenders of the company's own make and with Van Dorn track scrapers. The company uses a McGuire rattan snow sweeper.

The car barns and power house are situated alongside of each other on the lake shore, at the mouth of the Fox River, and both are yellow brick buildings, the former being 40 x 160 ft. in dimensions and containing five parallel tracks. The power house is 73 x 42 ft., the front of the building containing the engine room and the rear the boiler room, the latter being 4 ft. lower than

FIG. 2 CURVE NEAR NEENAH.

the former, and the two separated by a brick partition wall. There are three boilers of the Babcock & Wilcox make, having 96 4-in. tubes each and drums 36-in. x 16 ft. The furnaces are 6 x 8 ft. and steam is generally carried at 140 lb. The boilers are fed by two Worthington pumps, 6 x 4 x 6 in. Coal storage for 75 tons is provided, and this room also contains the condenser and a Wheeler feed water heater. Water for condensing is pumped from a crib 240 ft. out in the lake.

There are two Hamilton-Corliss engines, made by the Hooven, Owens & Rentschler Co., located in the engine room, with 20 x 42-in. cylinders and running at 90 r. p. m. They have 16-ft. fly-wheels mounted on 12-in. engine shafts, each wheel weighing 16 tons. There are three generators in this room, two being 225-kw. direct current generators of 550 volts pressure, which are run in

tandem from one engine, one belt running on top of the other. The other generator is a 6,600-volt 3 phase revolving field machine of 300-kw. capacity, and is belted to the second engine. This is excited by a 4 pole 13½-kw. exciter, and the 3-phase circuit is led to six 50-kw. air blast transformers, three being at the power house and three at the sub-station on the line of the interurban road, 12 miles distant. The plant also contains two 4-pole rotary converters, one at the power house and one at the sub-station, each being 150 kw. capacity and of the G. E. type. The power house switchboard is located in the front of the building 5 ft. from the wall, is 15½ ft. long and made of white marble. It contains the standard G. E. equipment. The direct current machinery at the

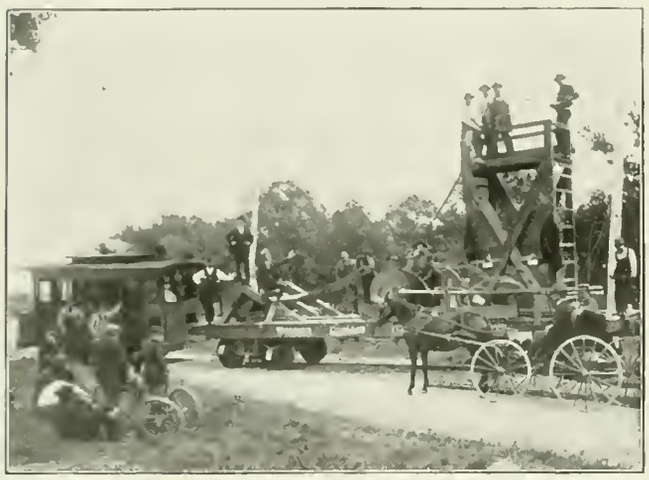


FIG. 3. STRINGING OVERHEAD WIRES.

power house ordinarily takes care of the urban portions of the road and the alternating current the interurban portion. In times of light load, however, both divisions of the road may be run together on either the direct or alternating machines, and in general the two parts of the road are electrically connected so that the generator current and the converter current are in parallel. The two divisions may also be kept separate by means of section insulators.

The sub-station is shown in diagram in Fig. 4. This is located on the line of the interurban road towards Neenah, and besides the room for the machinery contains dwelling apartments for the attendant. The converter room contains three static transformers, a 150 kw. rotary converter, a switchboard and a motor and blower

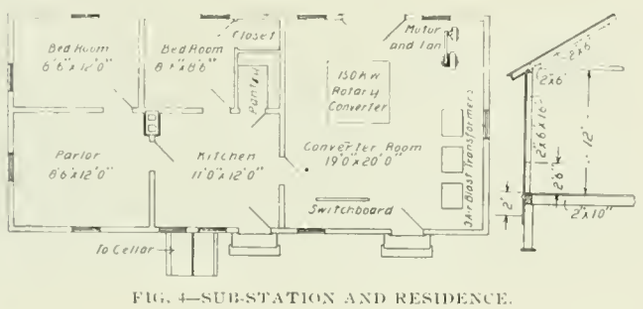

FIG. 4—SUB-STATION AND RESIDENCE.

for supplying air to cool the transformers. The current from this rotary feeds about one-half of the interurban line.

This line, which has just been opened to traffic, connects at Neenah with the Fox River Valley road running to Appleton, and which is to be ultimately extended to Green Bay. The Oshkosh-Neenah road will then form a link in the chain of trolley roads commencing at Green Bay and eventually running through Kaukauna, Appleton, Neenah, Oshkosh, Fond du Lac, Oconomowoc, Milwaukee, Racine, Kenosha and Chicago.

The Citizens' Traction Co. was organized, and the city lines were built in 1897, the capital stock of the company being $500,000. The officers are Geo. J. Kobusch, president; E. E. Downs, vice-president and general manager; Otto U. von Schrader, secretary and treasurer.

CINCINNATI STREET RY. AND THE EMPLOYES' ASSOCIATION.

September 6th the Street Railway Employes' Mutual Protective Association received the following communication from the Cincinnati Street Railway Co.:

Gentlemen—The directory of the Cincinnati Street Railway Co., desiring to show its appreciation of the benefits derived by the employes, and to assist in the support and maintainance of your organization, trusting it is, and believing it to be, in the interest of the employes members of the association, at a meeting of the board, held on Sept. 5, 1899, unanimously adopted the following resolutions:

Whereas, The Cincinnati Street Railway Co. is desirous of contributing to the relief of its employes and to aid in the support and maintenance of the association organized by the employes, believing said organization to be in the interest of the employes; now, therefore,

Resolved, That the sum of $5,000 be and same is hereby appropriated from the surplus of this company, and directed to be paid by the treasurer to the Street Railway Employes' Mutual Protective Association, which said sum is to be under the control of the management of said association.

Resolved that we recommend, subject to the discretion of your association, the following amendments to the constitution:

Article x, Section 1, to read as follows: Any member who shall become sick or disabled shall receive 75 per cent of his daily salary or wages for each day so sick or disabled, provided he has been a member in good standing for three months, and has fully complied with the constitution and by-laws.

Article x., Sec. 9. No benefits shall be paid for a fractional part of a week, or less than seven days. (To be repealed.)

Article xiv., Sec. 13. Every member shall pay to the financial secretary, at the first regular meeting of each month, 25 cents dues. (To be repealed.)

Check for the above amount is herewith respectfully enclosed.

The principal object of this donation is to enable you to lessen the burden and increase the benefit derived by your members. If this action is taken, members will be relieved from paying dues, and their benefits in case of disability will be increased and their families properly provided for; and, in case of death, their families will receive an amount that will place them above want. If these suggestions are concurred in by your association, it is the expectation that a similar amount will be annually donated by the Cincinnati Street Railway Co.

LARGEST IN THE WORLD.

The advertising in all lines on the North and West Sides in Chicago is controlled by the well known firm of George Kissam & Co., which is entering on its fifteenth year of occupancy, and reports business in its line as being good for the first time since 1893. This firm, the largest of its character in the world, is extremely popular with street railway officials by reason of its manner of conducting the street car advertising business, prompt payments of all rentals and a thorough understanding of street railway requirements.

All through the period of business depression subsequent to 1893, this firm went right along, though losing heavily, and that the personality and methods are popular is shown by the continuous occupancy of the car systems of Chicago and other large cities. Mr. George Kissam will be in attendance at the convention, not having missed one in 10 years.

An assistant from the Railway Post Office Department has been inspecting the system of the Ohio Central Traction Co., of Galion, O., with the view of establishing a mail service over the line between Bucyrus and Galion. It is probable such a service will be commenced in the near future.

Through electric cars between Milwaukee and Chicago are to be put into operation next year, unless present plans miscarry. There is practically a through line between the two cities, and the Milwaukee Electric Ry. & Light Co. has gone so far as to purchase sites for interurban stations along the route.

McGUIRE COMPANY'S SPECIAL TRAIN.

The McGuire Manufacturing Co., of Chicago, has arranged for the month of October, a rather novel method of advertising. It will have a special train of 43 platform cars, each car carrying one of its snow sweepers, decorated with banners and mottos. The train will leave Chicago during the convention, after being exhibited for one day on a side track at a point nearest the convention hall. It will then proceed on its way to New York via Washington, delivering sweepers enroute and stopping at places where the company thinks sweepers are likely to be sold, where a representative of the company will invite the railway officials of the place to review the train. When the train reaches Washington it will be reduced to 17 cars. Leaving 10 there for the Columbia Ry., it will proceed to New York, dropping one at Chester, Pa., and completing the trip by delivering six at New York City for the Metropolitan Street Railway Co.

This will undoubtedly be the largest train of this sort of freight that has ever been made up in any country. Sixty sweepers are now being constructed in the shops of the McGuire company for shipment in the month of October. To accomplish this and at the same time take care of the large truck business of the company, about 350 men are working night and day. It is an interesting fact that it has sold sweepers as far west as Portland, Ore., south to Augusta, Ga., and east to New York City.

IMPROVEMENTS AT ST. JOSEPH.

The St. Joseph & Benton Harbor Electric Railway Co., of St. Joseph, Mich., has in the last nine months completed an additional brick boiler room at its station, and has installed one 300-h. p. Babcock & Wilcox water tube boiler, one 250-h. p. tandem compound condensing engine, made by the New York Safety Steam Power Co.; one 120-light Brush arc dynamo; one 2,000-light G. E. alternator, and one 300-h. p. Worthington condenser. The rolling stock has been increased by the addition of six open trail cars, three open motor cars, each seating 50 persons, and one electric sweeper, and the company is now engaged in laying one mile of 13 lb. 7 in. Johnson girder rail. A 5,000 gallon water tank, 50 ft. high, with automatic sprinklers for fire protection at the barn, has also been erected.

This company has, within the past few months, secured a three year contract to light and heat the county court house and jail, situated about 300 ft. from its St. Joseph power house. The contract was granted after the street railway company had succeeded in demonstrating to the Board of Supervisors, from their own reports and figures, that the railway company could do the work for three years at $1,100 less than it would cost the supervisors to do it from the county's own private plant.

TELEPHONES IN RAILWAY SERVICE.

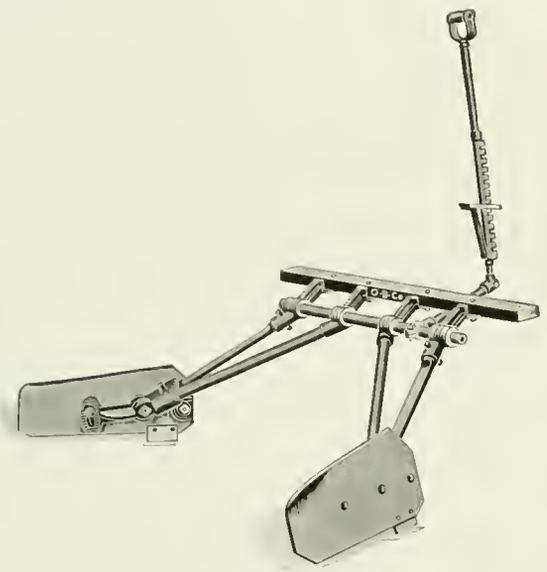
There was a time when telephones in street railway operation were looked upon more as a luxury than as having any real necessity. Now their efficiency and assistance are such that few roads can afford to do without them. The construction of trolley lines has also simplified the matter, as obviating the necessity of erecting special pole lines for the wires. Once used the manager would as soon think of running his road without gongs or head lights, as without telephones.

An excellent system of telephones designed exclusively for street railway work, is that manufactured by the Garl Electric Co., of Akron, O. For interurban work where it is desirable to have frequent telephoning points, and without the expense of installing as many complete telephones, a connection box is provided which can be attached to the poles and plugged into by the car crew using a portable receiver and transmitter. These connecting boxes are so constructed that the connections are 3 in. apart, which prevents short circuiting the line. Where it is desired the box may be placed above the reach of persons on the ground, in which case the employes cut in with a pole of suitable length. By carrying extra joints to the pole, connection may also be made without the connecting boxes by reaching to the telephone wires overhead and making contact with the two wires. This permits use of the line everywhere on the system, regardless of boxes or stations. The Garl company will have a complete exhibit, at Tattersalls, of its different telephone specialties.

SOME OF THE PRINCIPAL CHICAGO HOTELS.

THE MONARCH TRACK CLEANER.

Any article which has to do with keeping the track clear of ice and snow is of particular interest at this season of the year to nearly all the operators of electric railroads, and the track cleaner illustrated is no exception. This is distinguished from other scrapers by the name of "Monarch" and is the product of the Ohio Brass Co., Mansfield, O., which has recently made arrangements with the patentees for its exclusive manufacture and sale. This form of track cleaner has many points of originality which have given it a preference. A number have been in use for the past one or two seasons and have given universal satisfaction. It affords the greatest possible strength with the least possible weight, being one-third lighter than any similar device now on the market. It has a wide range of adjustment and adaptability to all styles of cars. All the wearing



MONARCH TRACK SCRAPER.

parts are quickly and inexpensively replaced. The cross bar and compression braces are made of gas pipe with connections and fittings of malleable iron, and the tension bar, which holds the blade in bearing upon the track, is made of the best quality of spring steel, which in turn is firmly clamped to the cross bar by malleable iron fittings. The two blades operate independently of each other, and both are under the entire control of the motorman by means of the handle and lever which adjust them either "on" or "off" the track at will. Ample range of adjustment to adapt the scraper to all heights of car platforms is obtained by special malleable fittings bolted to the blades, which act also as a substantial backing to resist the strains upon them. The blades are provided with steel shoes, which bear directly upon the rail and take all the wear. These may be readily replaced when worn out without removing the scraper from the car. They also serve to keep the scraper blades above the roadway or brick pavement and other obstructions. The features of this scraper which are peculiar to itself are covered by letters patent.

OIL TESTING DEVICE FREE.

A very neat, compact and serviceable oil testing device has been sent us by the Famous Filter Co., 316 North Main St. St. Louis. It is the same as is furnished with every Famous filter. With the aid of this microscopic device any minute impurities are easily detected in new oil, cylinder oil, and filtered waste oil. The company will send one of the indicators free to any manager, purchasing agent or engineer who, in writing for same will mention the "Street Railway Review." Full directions for its use—which is a simple matter—accompany each indicator.

A pleasant outing was enjoyed by the employes of the Bay Cities (Mich.) Consolidated Railway Co., at Wenona Beach on September 6th.

ROCKFORD RAILWAY, LIGHT & POWER CO.

By courtesy of Mr. T. M. Ellis, general manager of the Rockford Railway, Light & Power Co., of Rockford, Ill., we have received a statement of the operation of this company's electric street railway for the month of July, 1899, which is published herewith. This road comprises 22 miles of track; the rolling stock consists of 35 motor cars with double equipments of 15-h. p. and 27-h. p. General Electric and Walker motors. In the power house are 400 kw. of General Electric generators driven by Ball and Ide engines.

BALANCE SHEET.

Cash from passengers	$6,346.40
Ticket sales	1,055.00
	$7,401.40
Operating expenses	3,715.03
Net earnings	$3,686.37

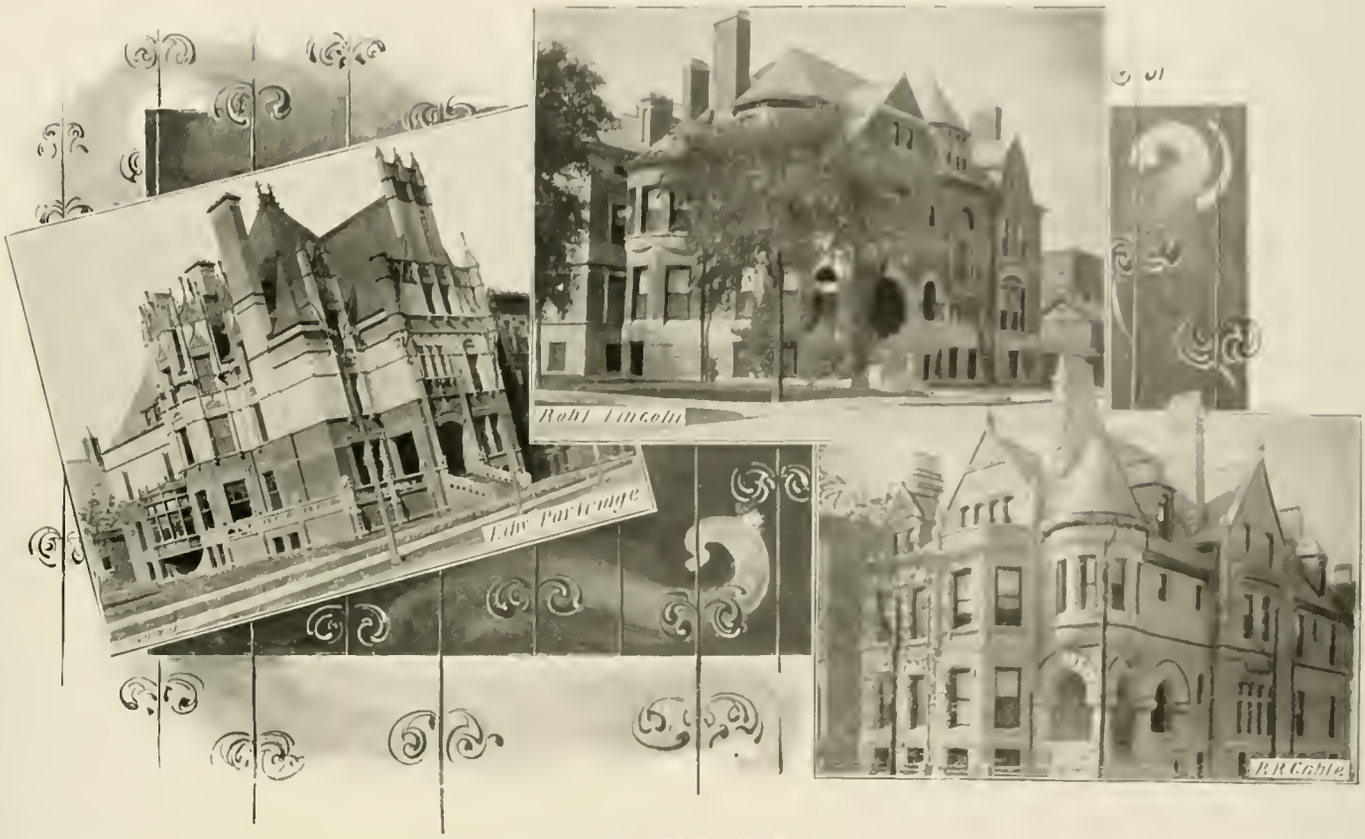
OPERATING EXPENSES.

General Expenses:	
Salaries of officers and clerks	$ 265.00
Stationery and printing	65.50
Legal expense	2.50
Feed, etc	38.27
Contingent expense	55.84
Park expense	167.01
Leased lines and buildings	50.00
Total	$ 644.12
Transportation:	
Wages, motormen and conductors	$1,452.48
Wages, power house employes	215.00
Lubricants and waste for cars	18.76
Fuel for power house	630.56
Water rents	22.81
Cleaning and sprinkling track	74.01
Miscellaneous	26.45
Barn expense	14.51
Total	$2,454.50
Maintenance of Way and Buildings:	
Repairs on track	$ 108.25
Repairs on poles and overhead line	49.50
Repairs on buildings	14.05
Repairs and renewals of paving	39.69
Total	$ 211.49
Maintenance of Equipment:	
Repairs on car bodies and trucks	$ 171.75
Repairs on electrical equipment of cars	150.02
Repairs on power house equipment	83.07
Total	$ 404.84
Total operating expenses	$3,715.03

SUMMARY.

Passengers carried	163,222
Average earnings per day	$238.75
Average cars operated per day	11¾
Earnings per car per day	$20.32
Operating expenses per day	$119.84
Operating expenses per car per day	$10.20
Total motor car-mileage	54,457.5
Mileage per day	1,756.7
Mileage per car per day	149.5
Earnings per car-mile	13.59 cents
Operating expense per car-mile	6.82 cents
Net earnings per car-mile	6.77 cents

It should be noted that the various items "repairs" include the labor necessary to do this work. The item for fuel is large because nothing but high-priced lump coal could be obtained.



CHICAGO RESIDENCES.

THE LORAIN STEEL CO.

The Lorain Steel Co., successor to the Johnson Co., which was the first manufacturer of rails to make a specialty of 60-ft. girders for street railways, has an immense business and the Johnson rails are known everywhere that street railways are operated. All of the Chicago surface railway companies have Johnson rails in their tracks and the standard roadbed specifications used for new work call for 60-ft. girders. The Du Pont trucks made by this company are used on the cars of the Chicago Electric Traction Co.

A LIQUID PRIMER AND SURFACER.

It is an axiom with the up-to-date general manager that his cars must be kept clean and attractive in appearance, no matter what the conditions. An unkept, unpainted street car not only does not encourage traffic, but it goes further and often keeps passengers from riding. Therefore a good paint that will hold its color and surface is an absolute necessity. But to secure such a paint has not been entirely easy. A passenger car operated in crowded streets is being continually run into and scraped by trucks and wagons of all kinds; it must run in all sorts of weather, and while on the road and in the car barn is subjected to rapidly changing temperatures and different degrees of moisture in the atmosphere. Therefore a paint, to meet street railway conditions, must possess superior qualities.

The Cartime Surfacer Co., of Chicago, has had on the market for some time a liquid primer and surfacer that, it is claimed, are perfectly suited to this severe service. These compositions are sold ready for use, and do not require oils or other additions. The claims made for them are: They fill the pores of the wood completely, permitting a fine finish; they produce a smooth and elastic surface; they will not crack, peel or blister; they enable a car to be painted in half the time required under the old methods, and are less expensive. Another strong point is they can be put on over old paint without burning off the old coating. The headquarters of the Cartime Surfacer Co. are at 1654 Monadnock Building.

Reports still come in from all parts of the country of work held up on new roads through inability to procure rails.

PIERCE & RICHARDSON, CHICAGO.

This well known engineering company divides its special work into five departments: electrical, mechanical, heating, ventilating and sanitary. Unlike many engineers, it confines itself to consultation, expert opinions, examinations and preparing plans and estimates, but does not undertake contracting. The company was incorporated in 1894, and the present officers are: R. H. Pierce, president; R. E. Richardson, treasurer, and S. G. Neiler, secretary. Among the complete plans recently prepared are those for the street railway plants at Natchez, Miss., and Jackson, Tenn. It is also consulting engineer for the Chicago City Ry., and laid out the work for the recent extensive renewals of the cable machinery at the cable station, 2020 State St.

Heating and ventilating of large buildings under difficult conditions has constituted a large share of the company's work the past two years. It also does a large amount of inspection and making examinations of roads and plants for eastern trust companies.

A NOVEL WHOLESALE ARREST.

A southern city recently was the scene of a most unusual wholesale arrest, when 40 drunken negroes, men and women, were made prisoners in a trolley car and taken in a body to the police barracks. The crowd had been visiting the city park, where they had raised a serious disturbance by firing off pistols. They finally took possession of a trolley car and started for the city. As soon as they boarded the car two policemen, with drawn pistols, stepped to each platform and told the mob they were under arrest. The prisoners offered but little resistance, and the motorman ran his car without stop through the city to the police station.

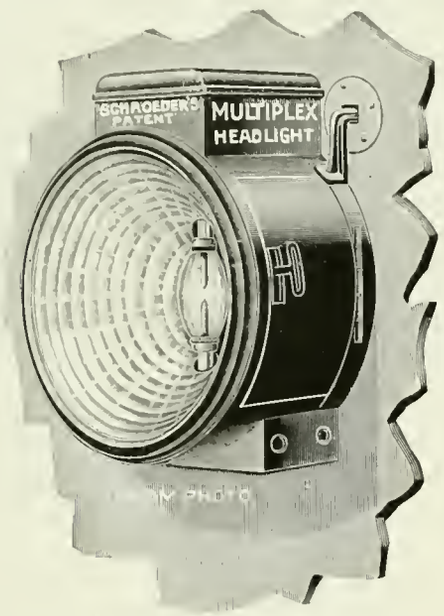
The Cataract Power Co. has purchased a controlling interest in the Hamilton Street Ry., the Hamilton Radial Electric Ry. and the Hamilton & Dundee Street Ry., of Hamilton, Ont.

The Cincinnati Street Railway Co. has been directed by the Board of City Affairs to remove the slot rails and yokes remaining from the old Vine St. and Walnut Hills cable roads.

A NEW FEATURE IN HEADLIGHTS.

An important improvement in headlights was accomplished when the Multiplex Reflector Co., of Cleveland, brought out its novel and original design for headlight reflectors. These are spun out of a heavy gage of brass, and their form consists of a series of convex or concave corrugations of shape, size and radius according to the kind of light to be used with it. They are polished, heavily silver plated and then burnished to maintain a lasting brilliancy. Each corrugation is not only a reflector, but the effect is cumulative, concentrating and intensifying the light to a remarkable degree. The beams from one corrugation merge with those of the next.

These reflectors can be applied to any form of headlight at



MULTIPLEX HEADLIGHT.

present in use by a railway company. The manufacturers, however, make and carry in stock a large variety of headlights complete. No. 75 B is a type which is inserted in a hole in the dash, with a front projection of only 1½ in. and a rear projection of 3¼ in. It has become very popular with the many roads using it. A special hood light and detachable dash lights are also made in several sizes and styles. The recent demand for arc headlights for interurban use where high speed is desired has been met with an excellent arc type, which is not only self regulating, but is not affected by any amount of jarring or vibration. Rheostats accompany each headlight, and the manufacturers will be glad to send a light of any size or type on trial without charge, their experience having been that where they are once tried an order is certain to follow.

STREET RAILWAY OPERATIONS IN THE CAUCASUS.

The municipal council of Tiflis, the chief city of the state of Tiflis, which is situated in Transcaucasia, Russia, has invited bids for the street railroad concession of the city and suburbs. The successful concessionaire must conform to the following conditions:

The concessionaires must pledge themselves to continue the exploration of the railway line, now being constructed by the Societe Anonyme Belge under the contracts of 1881 and 1885 of an approximate length of 21 versts (13.92 miles).

The concessionaires must agree, in addition, to construct and operate the new lines known as the Didoube, Sololac, Vardissoubane, Avlobare, Navellouge, Sadovia and Bazar Armenian lines, the purchase of the private properties along the new line to be made by the concessionaire. The Ortotchali line shall be prolonged to the government prison, and the Olguinskaia line three versts beyond the gardens of Vera. The total future length will be about 15 versts.

If the construction of these lines is found to be impracticable the concessionaire shall substitute other routes approved by the city. The construction of lines not mentioned shall be at the option of the city.

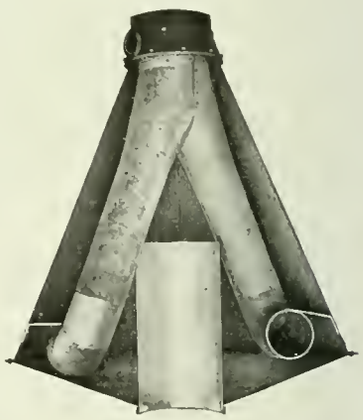
The concessionaires shall substitute upon all the lines electric for horse traction.

At the termination of the term of the convention all the lines of railway, with all material and appurtenances, shall become the property of the city, to which the concessionaire shall deliver them free and in good order.

All other conditions, such as the term of the concession (which shall not exceed 30 years from the day of the signing of the contract), the security offered by the concessionaire, the conditions of the possible repurchase of the railway by the city before the end of the term of the contract, the question of rates, etc., etc., shall be set forth in the application for the concession. The bids are to be handed to the municipal council not later than October 14th.

THE STURTEVANT EXHAUST HEAD.

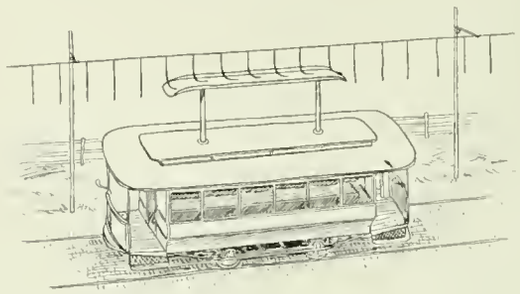
As indicated by the illustration, this exhaust head, built by the B. F. Sturtevant Co., Boston, is designed to separate by the utilization of centrifugal force. The head is attached directly to the end of the exhaust pipe from which the steam passes up to the branch pipes and is discharged tangentially within the case. It is thus given a vigorous whirling motion and the entrained water—likewise the oil—is thrown outward with great force, strikes the cool sides and trickles down to the outlet at the bottom. The steam, now perfectly dry, finds ready escape through the central opening above. As water weighs nearly 1,600 times as much as exhaust steam, and as centrifugal force is proportioned to the weights of the bodies in motion, it is evident that the force acting upon the water is nearly 1,600 times that exerted upon the steam, and that the action is both positive and absolute.



These heads are built in sizes to fit pipes from 1 in. to 20 in., all sizes above 10 in. being flanged. The case and pipes are of heavy galvanized iron, 16 to 20 gage, according to size, all external joints are riveted and soldered, and the internal pipes are double braced.

AN INSULATED TROLLEY LINE.

Among the startling inventions which appear from time to time in the electric railway field comes one from Ft. Myers, Fla., in the shape of an insulated trolley wire, which, according to its inventor, Capt. W. O. Rew, possesses manifold merits of the highest



THE REW INSULATED TROLLEY WIRE.

order, and which has elicited the most flattering comment on the part of electrical engineers and street railway men wherever the model illustrated herewith has been submitted to expert criticism.

On top of the car is a metal trough making contact with pendant wires from the overhead line; the pendant wires are to be insulated to within a few inches of the lower end.

THE SPEER CARBON CO.

The carbon trust will find a vigorous competitor in the Speer Carbon Co., of Saint Marys, Pa., whose new works are now completed and in running order. The business which has already come to this concern not only indicates the general desire to find relief from trust methods, but an appreciation of the quality of the product of the company. The concern is capitalized for $200,000

J. S. SPEER,
General Manager.

ANDREW KAUL,
President.

ANDREW KAUL, JR.,
Secretary and Treasurer.

and has erected a plant with all the latest and best facilities for this special work, and has placed the management in experienced hands, having secured the services of Mr. J. S. Speer, who was formerly a member of the firm and secretary and treasurer of the Partridge Carbon Co. He brings to the new company a highly qualified experience.

The Speer company not only has its own plant, but owns a

OFFICE OF THE SPEER CARBON CO.

private natural gas pipe line 25 miles in length. This secures the greatest possible economy in manufacture, and also that uniformity of heat in the baking ovens so desirable in carbon manufacture. Another great advantage lies in the ownership of its own coal mines, thus insuring the highest grade of coal for its raw product. The factory is fire proof and covers over half an acre. Nothing has been omitted nor any expense spared to make it the best equipped in the country.

The officers are all men well known in their own state, with a financial backing which provides an abundance of capital to push and increase the business. The president is Andrew Kaul; secretary and treasurer, Andrew Kaul, jr.; general manager, J. S. Speer; vice-president, Louis Streuber, and B. E. Cartright and J. G. Wertz are directors.

BEES HOLD UP A RAILWAY.

A queen bee with a numerous swarm of retainers recently established temporary headquarters in the box used by the flagman at the crossing of 16th and Curtis Sts. in Denver. The flagman was quickly routed and for an hour or more was constrained to do his signaling from the curbstone instead of from the middle of the street. The appearance of the bees at the most crowded corner in the city caused numerous unpleasant surprises. Several lines cross at this point and each passing car caused the bees to rise from the flagman's box which they had utilized for a hive. Men passengers pulled up their coat collars and women protected themselves from the swarming insects with handkerchiefs and parasols. A number of passing bicyclists inadvertantly ran into trouble at this point and were obliged to scorch vigorously to escape their undesirable companions.

Later the police were called upon and a policeman with a broom attempted to dislodge the swarm but was soon forced to retire precipitately. Meanwhile the crowd thickened to watch the fun. After

WORKS OF THE SPEER CARBON CO.

an hour and a half the bees began to thin out and a fall of rain aided in driving them away. By evening only a few straglers remained hovering around the flagman's station.

AN EXPERIMENTAL ROAD FOR RICHMOND, VA.

An experimental road is to be built in Richmond, Va., within the next two months which will be one-quarter of a mile long. It is to be equipped with the Jenkins underground trolley system, and is merely an experiment of that system with a view to demonstrating the feasibility and commercial value of Mr. Jenkins' invention. The details of this system are not yet made public.

WORKS OF THE SIEMENS & HALSKE CO.

The extensive works of the Siemens & Halske Co., of America, are located at the extreme western limits of the City of Chicago, near Garfield Park, on the site formerly occupied by the Grant Locomotive Works. The grounds are rectangular in shape, cov-

C. S. KNIGHT.

ering about 35 acres, and there are 12 acres of floor space in the eight buildings included in the plant. All of the shops are equipped with the latest tools and appliances, and the company is constantly adding new and improved machinery for increasing the capacity of the works and keeping them thoroughly up-to-date. The buildings are fitted with high windows, furnishing excellent light in day time; are heated by steam in winter, and lighted by electric arc lights at night. Three spur railroad tracks, running the full length of the grounds, and through the principal buildings, furnish the best of shipping facilities. At present, the plant is running night and day, and the company is carrying over 800 employes on its pay rolls.

Entrance to the grounds is secured through the office building, a two story brick structure 45 x 130 ft. On the lower floor of this are the executive and engineering offices and the bookkeeping department, and in the second story are the drafting rooms, where the drawings and blue prints for all the work that comes to the plant are made.

To the right of the office building is the foundry, 80 x 260 ft. Here three large furnaces are in constant operation, turning out at times 60 tons of work a day. One 25-ton and one 15-ton traveling electric crane, and two 5-ton post cranes, facilitate the handling of heavy material. Some of the important pieces of work now passing through the foundry are several 200-kw. and 400-kw. generator fields and one 1,500 kw. alternator field. This latter ring is cast in two pieces, each half weighing 40 tons.

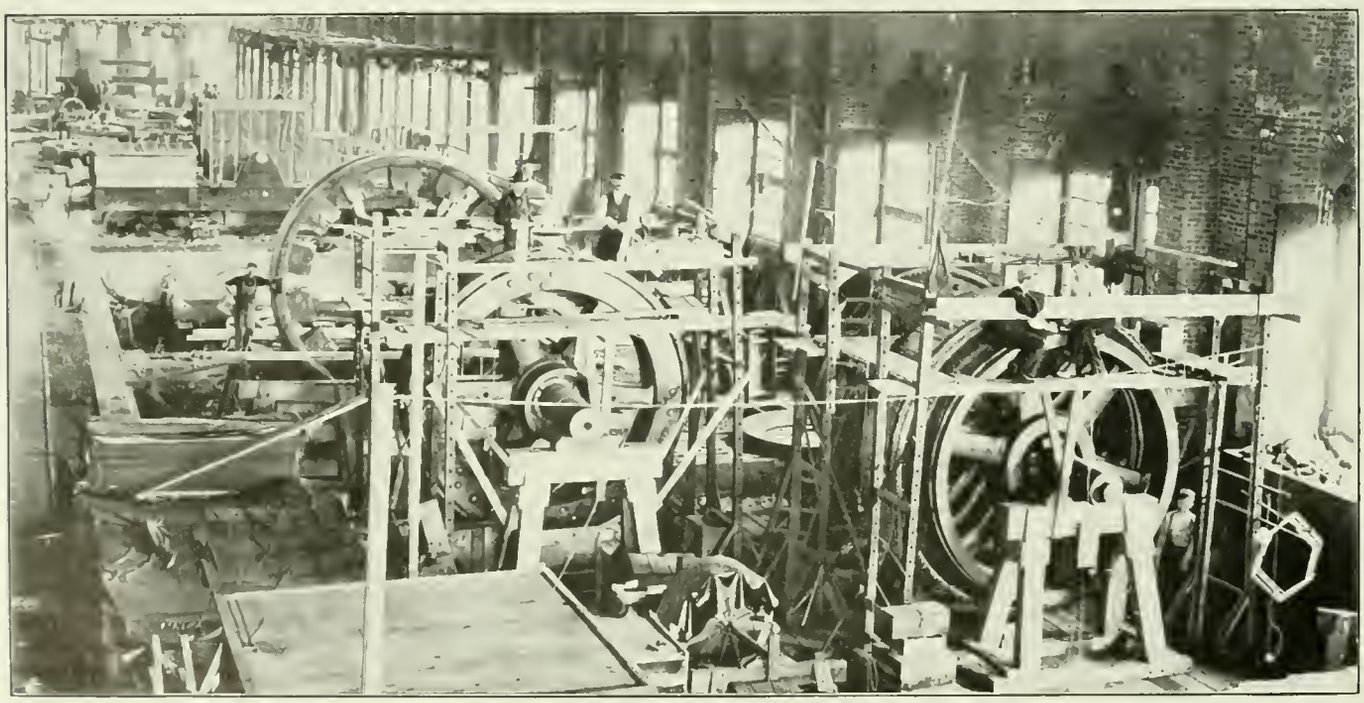
One large division of the foundry is devoted exclusively to the manufacture of automobile motor frames; in fact every department of the entire works now have several men working exclusively on automobile motors, one order alone for 1,400 of these having been received recently from the Electrical Vehicle Co., of New York, for which the Siemens & Halske Co. acts as manufacturing agent. These small motors are built of laminated iron, after entirely new designs, to secure the greatest possible strength with least weight and greatest magnetic flux. That the company's engineer has succeeded in developing something new in this line is shown by recent tests, when automobile motors, rated for 20 amperes were suddenly reversed several times while carrying 100 amperes of current, without the slightest signs of injury. The rise in temperature at full load is guaranteed not to exceed 17° C.

At the back of the foundry and under the same roof, are the core rooms, the carpenter shop, and the brass foundry, where all kinds of brass castings are made. There are six furnaces for this purpose, and these are being worked to their total capacity. A hydraulic press for shaping commutator bars, etc., occupies one corner of the brass foundry.

To the left of the foundry building is the pattern shop, 60 ft. wide and 130 ft. long. This building is provided with large suction pipes for carrying off shavings and dust, connection being made for this purpose with each machine. All the tools are run from shafting, driven by electric motors. A general store room, 70 x 230 ft., for keeping old patterns is located near the pattern shop.

At the right of this store room is the paint shop, 70 ft. wide by 170 ft. long, and immediately behind this, the boiler shop, 100 x 250 ft. This latter building is one acquired from the Grant Locomotive Works, and is not utilized to any extent at present except for doing a little heavy shearing and punching work.

Taking up the greater portion of the northern half of the grounds are the erecting and machine shops, 110 x 370 ft., and the hammer

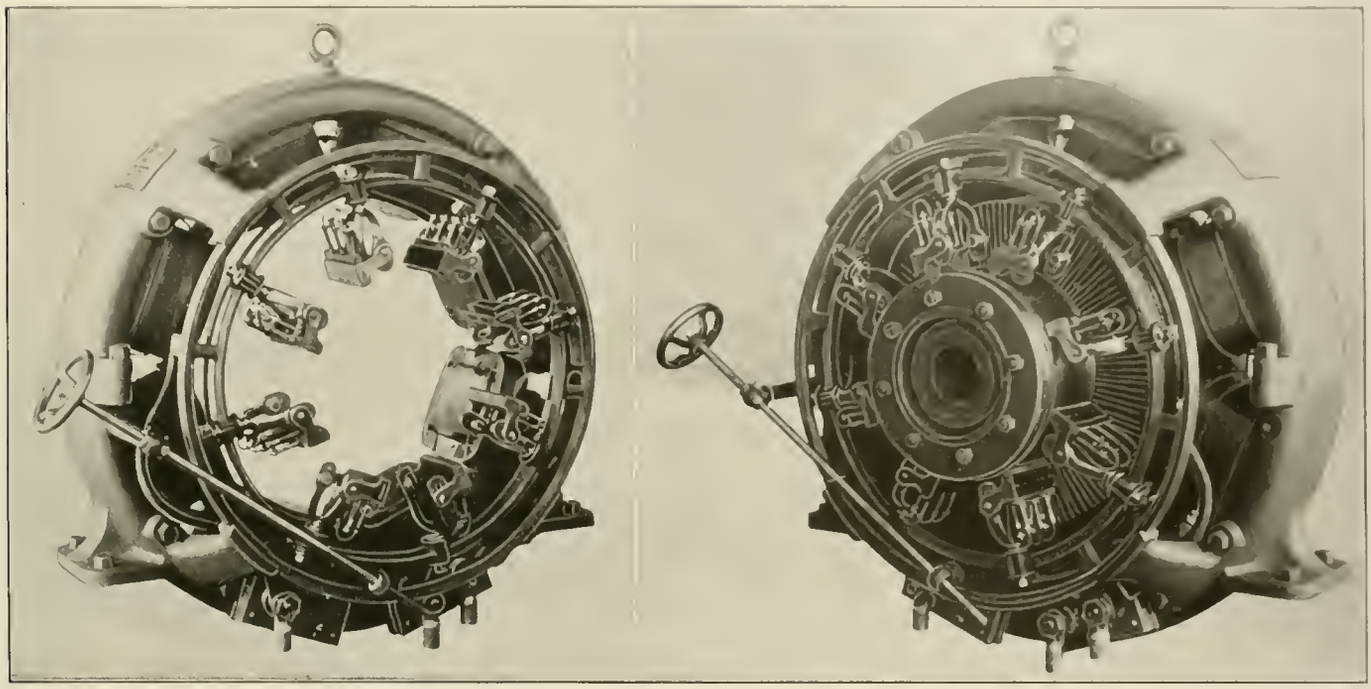


VIEW IN ERECTING SHOP.

and blacksmith shops, 80 x 125 ft., and 80 x 250 ft., respectively; these are in two L shaped buildings, and here are found tools and labor saving devices too numerous to mention, for performing quickly and accurately the different operations of drilling, forging, planing, assembling, etc. On the upper floors of these buildings are the coil winding department, and the switch, switchboard, meter and arc light departments. All oils are stored in a small outhouse.

attending strictly to its own affairs, depending on the satisfaction which its apparatus has everywhere given to make its name known. Our illustrations graphically explain the perfectness and magnitude of its work. The company has important plans in hand which will shortly be announced and which will greatly interest street railway interests.

The Siemens & Halske Electric Co. of America is one of the



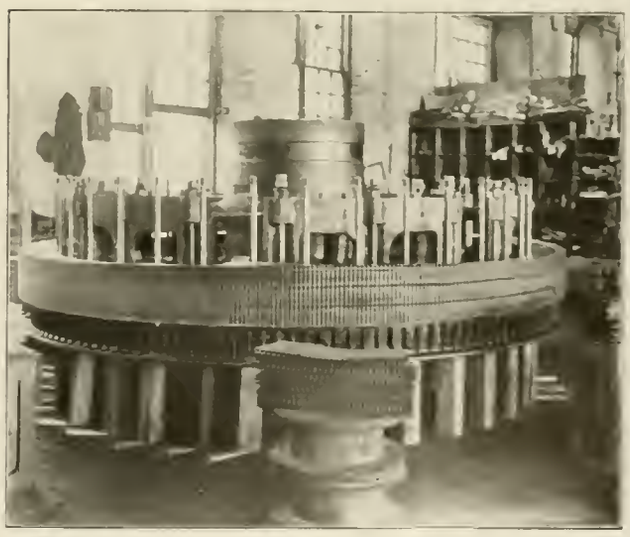
ENGINE TYPE GENERATOR WITH AND WITHOUT ARMATURE.

A power station for furnishing light and power to the buildings, and an artesian well 2,100 ft. deep, complete these well arranged works, which enable the Siemens & Halske Co. to turn out with the least possible delay direct and alternating generators of any capacity, rotary convertors, transformers, etc., as well as its well known line of electrical specialties.

Two important features distinguish Siemens & Halske generators, and are worthy of particular mention. These are the arrangement of the field and the formation of the brush holders. The feature of the field structure is what is known as the shoeless pole construction, designed to prevent sparking under the most adverse conditions, the reversing field being so arranged that the coil to be reversed enters in gradually and is not distorted under any circumstances. The patent brush holder guarantees excellent contact, the current being taken directly from the brush, rubbing contact not being relied upon.

Among the companies in Chicago and vicinity using Siemens & Halske generators may be mentioned the following: Chicago & Western Indiana Railway Co., one 42 kw. and one 95 kw. generator; Chicago Union Traction Co., one 700 kw., one 1,500 kw., one 20 kw., one 16 kw. and four 500 kw. generators; Chicago Consolidated Traction Co., three 750 kw. generators; Union Loop, two 1,500 kw. generators. In addition these companies are using about 200 latest type Siemens & Halske motors, ranging in sizes from 30 h. p. to 50 h. p.

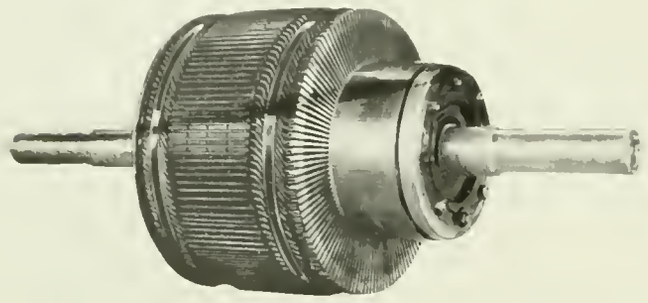
No electric concern in the world bears a higher reputation than the parent Siemens & Halske Co. No new device is ever allowed to go out until the management is ready to endorse it fully, and in arriving at this conclusion two years of experiment and severest test under every possible condition is rigidly required. The result is the products of this company, one of the largest of its kind in the world, carry an unquestioned reputation. The same regard for perfect machinery has been adopted by the Siemens & Halske Electric Co. of America, and easily explains the remarkable success which has attended its operation. The policy of the company has uniformly been not to indulge in publicity as to its sales, which have reached to all parts of the country and include many of the most important plants in the United States. Its history has been one of pioneers in the manufacture of electric machinery, the company having been originally formed in 1892 and being a branch of the Siemens & Halske Co. of Berlin, of which Dr. Von Siemen is the founder. The Grant Locomotive Works plant was taken over in 1895, and the manufacturing headquarters moved to their present location. The officers of the company are: President, Isaac L.



PARTIALLY COMPLETED 50-KW. ARMATURE.

Rice; vice-president and general manager, C. S. Knight; secretary and treasurer, W. T. Block; engineer in chief, Alexander Churchward. Mr. Knight, under whose general supervision all the work is turned out, has had many years' experience in the building of electrical apparatus and is well known in electrical circles. His work in this line commenced in 1881, when he became interested in

the Ft. Wayne Electric Co. of Ft. Wayne, Ind. When this company was placed in a receiver's hands in June, 1894, Mr. Knight was chosen a director in the new company formed, for the purpose of carrying on the business of the Ft. Wayne Electric Corporation. This connection continued until February 1st of this year when he accepted his present position. Messrs. Churchward, Sessions, Duncan and many others of the Fort Wayne Electric Cor-



COMPLETED ARMATURE.

poration, at the same time joined the forces of the Siemens & Halske Electric Co. of America; the Siemens & Halske Co. thereby securing such patents as were owned or controlled by the parties above mentioned in addition to the many furnished by the parent company; it is also bringing out many new designs and types to meet special conditions, etc. The general sales offices of the company are in the Monadnock Building.

A BELT HOSPITAL.

The Leather Preserver Manufacturing Corporation has its main offices and establishment at 27 West Monroe St., this city, and aptly terms it a "belt hospital." In these days, when managers desire to economize in all proper directions, great savings are possible in having old belts overhauled, instead of throwing them away the moment they become unfit for use. By the system em-

J. F. SMITH.

ployed every trace of oil and grease is removed without injury to the leather or glue. A treatment is then given with amber dressing, which renews the life of the belt, makes it soft and pliable and prevents slipping.

The company also manufactures various compounds for preserving belts, which have met with a large sale and proved very satisfactory.

The company makes a standing offer to customers to ship in belts which it examines and names a price for repairing and renewing, and if not satisfactory the company will return the belts and pay the freight. It also buys old belts. The manager is Mr. J. F. Smith, who will be glad to have street railway managers call and inspect the plant.

STREET-CAR STRIKE IN NANTES.

Mr. Joseph I. Brittain, United States consul at Nantes, under date of Aug. 7, 1899, writes the State Department as follows:

Three weeks ago, all the employes of the tramways of Nantes quit work and demanded an increase in wages, an opportunity for promotion, three holidays during each month, and a decrease in the daily hours of service. After a week's idleness, work was resumed, the men having been conceded nearly all they demanded.

The cars are propelled by compressed air. The men who manipulate the machinery from the front platforms of the cars are called conductors, and those who collect the tickets and punch the same are known as receivers. The fare is not uniform for all distances, as is the case in most American cities, but passengers are charged so much per section—2 sous, or about 2 cents, for one section, a distance of nearly a mile; 3 sous for two sections; and so on until 6 sous are charged, which is the maximum price for the entire route, being a distance of about four miles. The cars are not so well patronized as those in American cities, and the service is poorer, persons being obliged to wait 10 or 15 minutes for a car.

Previous to the strike the men were obliged to work 12 or 15 hours per day. The conductors received 4 francs (77 cents) per day, and those of the first grade 4.50 francs (87 cents) per day. Receivers were paid 3 francs (58 cents) for the second grade, and 3.50 francs (68 cents) for the first grade. The tram cars stop running at 9:30 in the evening, and resume business at 6 in the morning, the same men being on duty during the entire time. After several conferences between the company and the employes, the service was resumed, the company agreeing to pay the following prices:

Class of labor.		Wages	
		Francs	
Switchmen:			
First class	per month.	115.00	$22.19
Second class	do	110.00	21.23
Third class	do	105.00	20.26
Track cleaners:			
First class	do	90.00	17.37
Second class	do	80.00	15.44
Third class	do	75.00	14.47
Firemen:			
First class	do	120.00	23.16
Second class	do	115.00	22.19
Third class	do	110.00	21.23
Conductors:			
First class	per day	5.00	.96
Second class	do	4.50	.87
Third class	do	4.00	.77
Receivers:			
First class	do	4.00	.77
Second class	do	3.75	.72
Third class	do	3.00	.58

The men have been granted three holidays during each month, but without pay, and 12 hours are considered a day's work. During the strike no riots occurred, but no attempt was made to start the cars, although the company claimed that new men could have been procured for the service.

A NEW YORK-WASHINGTON TROLLEY LINE.

A rumor to the effect that the Pennsylvania Railroad Co. has a project on hand to connect New York City and Washington has been widely circulated. The company already controls most of the trolley lines in Jersey City and Newark, and is negotiating for the purchase of a line from Newark to Elizabeth, already in operation. This line will be continued to Trenton, 56 miles distant from Jersey City, and will pass through New Brunswick and Princeton.

The formal opening of the new Ypsilanti (Mich.) & Saline Electric Ry., occurred September 5th. A special car, containing 50 Ypsilanti officials and prominent citizens, made the run to Saline, where the authorities of that township were met and conveyed in a second special car back to Ypsilanti. Here the party enjoyed an elaborate banquet.

CONSTRUCTING BY CONTRACT.

So long as there are new railways to be built or old ones to be rebuilt there will doubtless be railway contractors. As in all other lines of trade there are in the railway construction line contractors with responsibility, organization and equipment, and others without these qualifications. It is with the former we deal in this article. As to the policy of letting work to contract: Each side of the question has its partisans, the negative side being usually taken by officers who have either been badly dealt with by some contractor, or have mistaken ideas of economy. As a rule where the railroad company is not large enough to warrant a permanent construction department, new work, if not contracted, is carried on at greater expense than if let to a responsible contractor for many reasons, among them being the following:

First, The incentive to push work is not as potent in the railway employe as in the contractor.

Second, If construction work is carried on by a temporary organization, inexperienced men, indifferent as to results, must of necessity be employed; the man or men in charge having regular duties to perform in the operating department, will be unable to properly look after both construction and operation; hence either or both departments must suffer.

METROPOLITAN, KANSAS CITY.

Third, By contracting, the cost of a piece of work is determined prior to commencement instead of after completion.

Fourth, The purchaser relieves himself from responsibility. In short, by contracting work the purchaser fixes in advance the cost, gets a quicker and better job, shifts the responsibility and at the same time saves money.

The Electrical Installation Co., of Chicago, has gained the confidence of engineers and its customers by the execution of only the highest class of work. The intent of the engineer in the specification is realized, and the spirit of the contract given fullest consideration. Disputes, delays and extra claims are avoided by a broad comprehension of the engineer's purpose. These business methods result in a satisfactory and permanent piece of work. Mr. J. I. Case, the manufacturer of Racine, Wis., is president of the company, and devotes considerable time to the management of its affairs. The name J. I. Case is favorably known the world over.

Mr. Fred H. Fitch, vice-president, is also the general manager of the Sioux City Traction Co. of Sioux City, Ia.; was formerly connected with the Chicago City Railway Co., and is a man expert in railway financing, construction and operation.

Mr. J. A. Brett, general manager, has been constructing railways since the use of electricity as a motive power, having first served with the Sprague Electric Motor Co. in 1886.

Mr. A. M. Howes, secretary and treasurer, was formerly in the stock and grain brokerage business, has been with the company since its incorporation and has had years of experience in financial matters.

The Electrical Installation Co. during the last six years has com-

FEEDERS, SOUTH SIDE ELEVATED, CHICAGO.

pleted work under 112 contracts for electric railway construction and equipment. Some of its most important work is shown in the accompanying illustrations. We give a depot scene on the Wellston & Jackson Belt Ry., a part of the Hocking Valley system, operating between Wellston and Jackson, O. The Hocking Valley Ry. was one of the first steam roads to adopt electricity as a motive power on branch lines. The Electrical Installation Co. not only constructed and equipped this road under contract, but designed the power plant, and did all of the construction work under its own specifications. That the work was thorough is evident from the following letter written a few weeks ago by Chief Engineer Sheldon, who says:

"It affords me pleasure to testify to the stability and satisfactory performance of the electric plant of this company, which was designed and installed by you in Jackson County, O., in 1895-6. All of the equipment furnished and construction work done by you is in first-class condition after a continuous operation since Mar. 1, 1896, during which time there has not been a single stoppage or delay in our traffic, which begins at 5 a. m. and runs till 11 p. m. The record is one of which your people may well feel proud, as we certainly do."

Another view of this company's work shows track construction of

CAR ON WELLSTON & JACKSON BELT LINE, HOCKING VALLEY

the very highest class, for the Metropolitan Street Railway Co. of Kansas City, Mo., which is known to contractors throughout the West as most exacting in its requirements for high quality of construction. The Electrical Installation Co. has completed work for

this company under 10 separate contracts, and new work has been awarded them this year, which will detain one of the large construction forces in Kansas City probably until April, 1900.

Another view shows a part of the feeder work on the South Side Elevated, Chicago. All of the electrical construction work on the elevated structure and the entire electrical equipment of the 180 cars was done by the Electrical Installation Co. in 1897-8. The drilling for track bonding was done while trains were operated on three minutes' headway, and with but very few delays of not more than 10 seconds. In fact all of the work was done under the most extraordinary and unfavorable conditions, and the contractors have often been complimented for the careful manner in which it was prosecuted, as well as for its high quality and permanency.

The company is in the field for the financing and complete construction and equipment of electric railways and lighting plants. Its organization is thorough, efficient and constantly maintained, and the volume of business done by this company has given it an experience valuable to those having work in its line. The general offices are located at 1517 Monadnock Building, and attendants upon the American Street Railway Association convention are extended a cordial invitation to call.

NEW PLANT OF CHRISTENSEN ENGINEERING CO., MILWAUKEE.

That this company has practically and satisfactorily solved the problem of air braking on street cars is strongly emphasized by the fact that twice within the past year the company has found it necessary to double the size and output of its manufacturing plant, and that the demand has so rapidly increased that it is now imperative to again increase its capacity 100 per cent. The management believes that the very satisfactory results obtained by all the roads using the company's devices, has thoroughly demonstrated that the apparatus is now reduced to a condition of efficiency and durability which insures its success. The amount of business already done, together with the large amount on hand and in sight, fully warrants the investment of sufficient capital in special machinery and modern appliances to insure not only prompt deliveries, but to admit of the manufacture of goods at a cost which will enable it to supply the demand at the lowest possible price consistent with first class material and workmanship. A factory site of seven acres has been purchased, conveniently located as to railroad facilities, combined with features of beautiful and healthful surroundings, which would make it desirable, even for handsome residences. On this site the company is erecting a modern plant, consisting of foundry and machine shops, which will give sufficient capacity to insure its ability to fill orders promptly. The plans for the new shops have been drawn with great care, and all the latest conveniences known to the trade will be incorporated. Compressd air will be used in the many capacities for which it has been proved the most suitable power, and machine tools will be run by electric motors arranged in small units for convenience.

The works are so arranged that there is ample space between the buildings, giving plenty of light, and the spaces not occupied will be devoted to well kept lawns. The power house will be located centrally, so that the electric transmission to the motors located in various parts of the works will be effected with the least possible amount of loss.

The boiler room is immediately adjoining a railroad track, and is slightly lower than the latter, so that coal is easily unloaded.

The power house will, besides the boilers, contain direct connected generators in units of 100 h. p., and various dynamos for giving voltages of 80, 110, 220, 250, 450, 550, 650, 750 and 1,000 volts for testing purposes, as well as power.

The foundry will be located near the power house and the coke bins and a store house for pig iron will be immediately alongside the track, within easy reach of the cupolas. The foundry will be fitted with the latest improved machinery, having electric traveling cranes and compressed air cranes for the lighter work. The method of molding will be in accordance with the latest improved practice, compressed air being used for tamping, and wherever practical to use it. This foundry building is connected with the main buildings by means of compressed air cranes, with tracks arranged in such a way that the product can be transferred readily. The machinery in the foundry will be operated by electric motors throughout, in fact no steam will be used anywhere in the plant, except in the power house.

The main machine shop will be arranged with electric traveling cranes to handle the heavier work. The lighter work will be handled by compressed air cranes arranged to cover practically the whole area occupied by machine tools, in which articles weighing over 50 lb. are being finished. The machines will be so arranged that when the parts are finished, they will be near the department where the complete equipments are assembled, immediately adjoining this department is the testing room, in which also are arranged cranes of various capacities for handling the machines and after testing, the equipments are either shipped or deposited in the warehouse, which is arranged with a railroad track immediately in its center. The warehouse is likewise fitted up with cranes for conveniently handling the goods, and is also provided with wood working machinery for making packing boxes, both for domestic and foreign shipment.

WORKS OF THE McGUIRE MANUFACTURING CO.

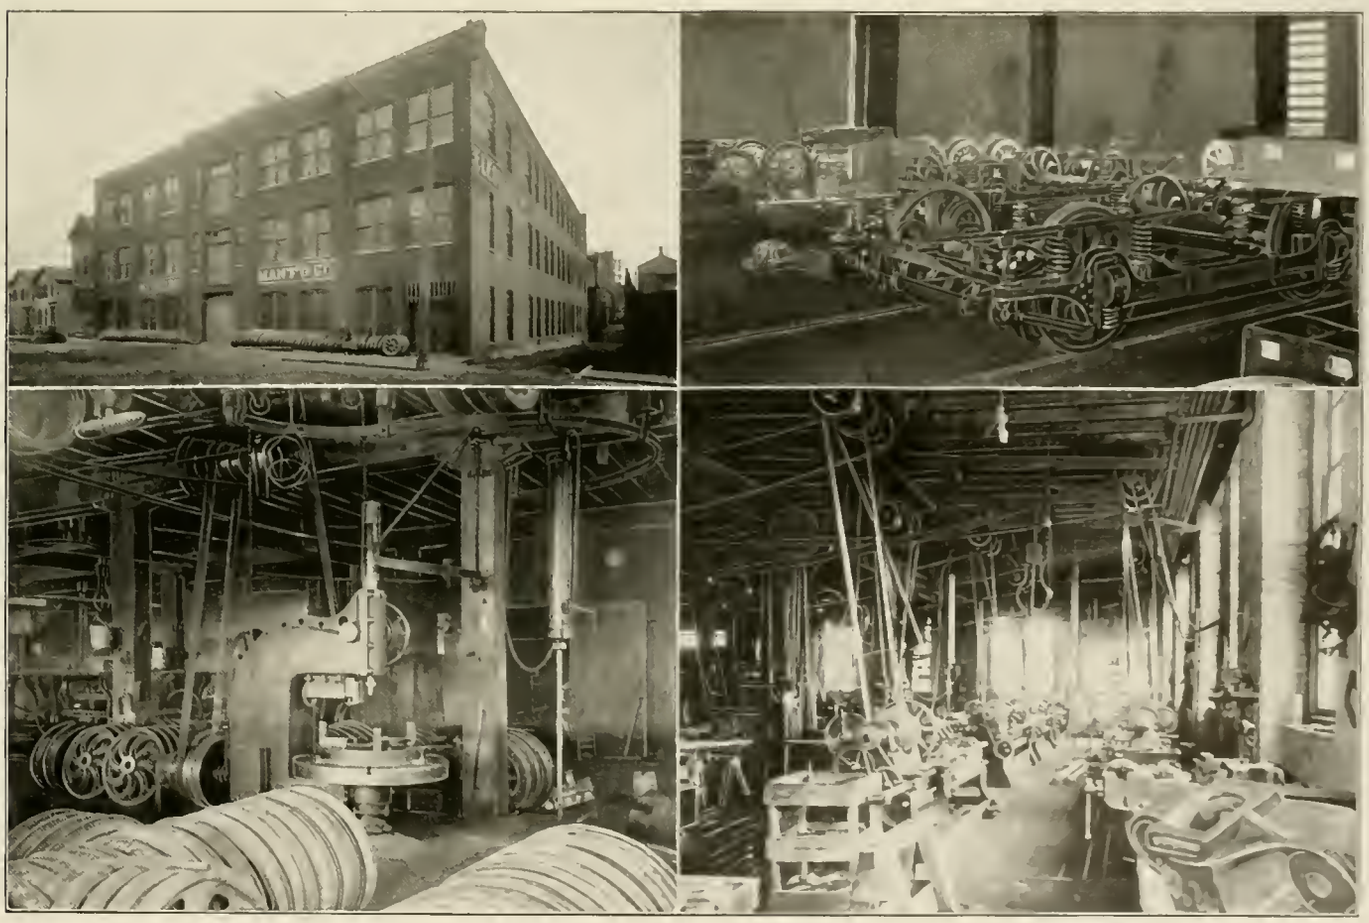
The McGuire Manufacturing Co., of Chicago, was among the first in this country to take up the manufacture of electric trucks for street railways, and it is the owner of a large number of the most valuable patents covering important features in truck construction, and is believed to have produced more original designs of trucks than all the other makers put together. Many of its designs have been copied in this country and throughout Europe, especially in Germany.

W. A. McGUIRE.

W. J. COOKE.

The trucks made by this company are in use in all the large cities of America, and, indeed, there is hardly a road in the country where some sort of the product of this company is not in use. The designs and workmanship are of the highest order, and can be found in operation on lines where safety to the traveling public is the first consideration. In fact, the company boldly advertises that it does not pretend to rival competitors in the question of price—or rather, the original cost of the truck—but claims that its trucks, while costing a trifle more in the first place, in the long run are the cheapest trucks made.

While the company has sold large numbers of trucks abroad,



WORKS OF THE McGUIRE MANUFACTURING CO.

but little attention has been given to that market, being perfectly satisfied with the trade it has had here. It certainly has had a most successful career, and has always maintained the very highest credit. Having an abundance of capital, it has always been able to purchase its raw material at the very best market and has always taken the advantage of discounting its bills.

Besides the truck business, the company has made an enviable reputation as builders of snow sweepers. A very interesting item about snow sweepers will be found in another column, which illustrates the magnitude to which this branch of the business has grown. It also makes a car heater, called the "New Columbia." It is a very superior design, and as well as being a heater it is an ornament to the interior of the car. This branch of the business has also been very successful.

McGUIRE HANGER.

Mr. W. A. McGuire, the originator of the company, who has been its president and general manager from the first, is the principal owner, and besides being entirely responsible for the financial part of the company, has given much of his attention to designs and inventions, which cut a prominent figure in the business of the company. He has accumulated a comfortable fortune and might have retired years ago, but takes a great pride in the company bearing his name and is exceedingly jealous of its reputation. He is sharp in a business way, but upright and honorable in all his dealings. Mr. W. J. Cooke is the vice-president of the company, and has been since it was organized. He has had charge of the sales department from the first. He is the Chesterfield of salesmen in the railroad line and thousands of railway people are always glad to see his smiling face whether they need his services or not. He is a heavy owner in the company and has acquired an independence, which, however, has no effect upon his graceful manners.

The works are located on a valuable piece of ground owned by the company, about one mile from the court house, bounded on the west by Morgan St., on the south by Kinzie St. and on the east by Sangamon St. While the plant is quite large—covering several acres—it is entirely too crowded for such a business as is being done at present, as the accompanying cut will show, every particle of floor space being covered with material or machinery. There is not much question but that the near future will find the company compelled to extend its plant. In fact, an option has already been secured on a large property in the southern part of the city.

We add a list of a few of the patented features of the McGuire trucks which are now being sold in large quantities to railway companies to be applied on all makes of trucks: The elastic brake hanger, safety brake shoe, double acting brake rigging, three-quarter elliptic spring, ratchet brake handle, method of cushioning frame on axle, and adjustable traction feature in bicycle trucks. About 5,000 of the McGuire brake hangers have been sold to railway companies during the past year for use on the trucks of other makers.

The following paragraph heads a recent circular issued by the McGuire company:

"Since it has become a fact that cast steel can be made to equal rolled steel, and that it is susceptible of being worked in a forge in the same manner as the ordinary bar steel, and since the old difficulty with cast steel—of blow holes and shrinkage cracks—has been overcome, we have adopted this metal in the double and single trucks."

The solid steel Columbian truck, a cut of which is shown on another page, has in its construction all the advantageous features which have developed in the experience of the McGuire company, and it has fewer parts than any other truck in use. Its frame being made of cast steel, has all the spring seats, spring cap, housings, etc., cast into one piece, which must surely be a great advantage.

The No. 39 truck is especially designed to carry a long car body as low as possible. Its features are: Solid steel frame cushioned over each box (Cloud-McGuire patents), center bearing, swing bolster on elliptic and spiral springs, short wheel base (4 ft.), motors hung outside, car body carried as low as on a single truck; with one motor it is considered by many the best maximum traction truck on the market, and is the lightest weight for its strength of any truck manufactured.

These two are the latest productions of the McGuire company and its order books show that it is to deliver about 600 of them within the next three months. The following is what Mr. Cummings, superintendent of the Indiana Railway Co., South Bend, Ind., says about the No. 39 truck:

"Let me say right here, that this truck for high speed interurban service is highly satisfactory. It rides like a sleeping car. It is the simplest in its construction, and we do not hesitate to say that it is the best truck we ever saw. It has so many good points that it must be seen and used to be appreciated. Come down and see us and bring your friends and we will show you the very best equipped high speed service in the country."

It will repay a visitor to the convention to see this equipment on the Indiana Railway. The solid steel Columbian may be seen in use on the Chicago City Ry. on the South Side, or the Chicago Consolidated Traction Co. on the North Side.

The Northern Ohio Traction Co., of Akron, has notified the chief of police that police officers in the future will not be permitted to ride free on its cars unless in full uniform.

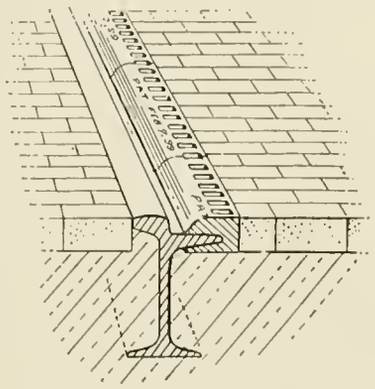
MONUMENTS IN CHICAGO PARKS.

TRANSFORMING TRAM HEAD GIRDER INTO GROOVED RAIL.

A decidedly novel method of producing a grooved rail has been invented by Mr. S. J. Buckland, of Springfield, Mass. He accomplishes this with any section of girder rail by fitting into the tram an iron paving block of special shape. This invention, like many others, was the result of a necessity. The city desired the railway company to use a grooved rail on one of its streets, and the proposed change from the old rail to a grooved was estimated to cost the company $8,000 for rail and the city $10,000 for paving. Mr. Buckland is one of the aldermen, and in his effort to accomplish the desired result at less expense, originated the iron paving block, which bears his name. By his system the estimates have been cut down with a saving of $7,000 to the city, and $6,000 to the company.

Our illustration conveys a good idea of how the block is shaped and used, and where laid in brick paved streets, as is proposed in Springfield, involves little disturbance of the pavement. City Engineer Moulton says of the track laid experimentally:

"I have examined the section of old rail track on Dwight St. in this city, which has been treated by the application of your blocks on the inside flange of rails, and, as far as surface indications show, it appears to answer all practical purposes as forming a safe piece of



BUCKLAND PAVING BLOCK.

track likely to cause no complaint from the public. There has been less chance to test the wear of the blocks from the wheels of the street cars than could be wished, although in track perfectly laid there should be no contact with wheel flanges, but as far as wear from nearly a year's traffic of ordinary vehicles is concerned, there is little evidence of it.

"It would appear that the close fitting of the block on both top and bottom of the inner flange or rail head, together with supplementary support obtained from concrete or paving tightly wedged under the blocks and extending to web of rail would, when the paving between the rails is well laid, render the blocks stationary, and as long as horizontal movement is restrained there can be no vertical movement and consequent looseness. The section of track before mentioned being well laid and the paving between the rails being brick, there is no evidence that any movement has taken place in any block."

Numerous tests were made with blows from a 15-lb. sledge, and inserting an iron bar in the groove and running a loaded sprinkling car over. No damage was occasioned by these and other severe tests. As shown in the cut no bolts are required, and the blocks are placed with ordinary labor.

EXPORT EXPOSITION AT PHILADELPHIA.

With imposing ceremonies and in the presence of a large party of distinguished guests, the National Export Exposition at Philadelphia was opened on Thursday, September 14th. The exercises included a large parade, in which the governor of Pennsylvania, the mayor of Philadelphia, numerous civic officers, Rear-Admiral Sampson and officers of the North Atlantic squadron, and many distinguished citizens identified with the promotion of the exposition, took part; orations were delivered by the governor, Congressman Hepburn of Iowa, Mr. Wilson, managing director of the exposition, the mayor and several others. Music was furnished by a chorus of 600 voices.

At night there was an illumination of the region surrounding the City Hall and the Avenue of Lamps, which consists of a colonnade along Broad St. for some hundreds of yards.

ATTACHMENTS FOR AUTOMATIC COUPLERS.

The W. T. Van Dorn Co., of Chicago, in addition to the developing of the well known Van Dorn coupling head, has paid considerable attention to the perfecting of attachments for connecting these couplers to the car.

In Fig. 1 is shown a No. 5 coupler, connected to the Van Dorn improved ball joint attachment. With this arrangement the head is

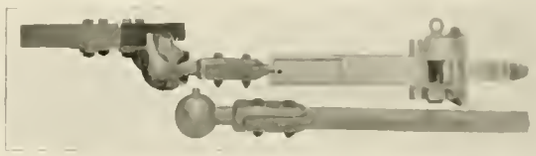


FIG. 1 WITH BALL JOINTS.

readily joined to the car body, either by using a block of wood or flat bar of iron, 1 x 8 in.; the length of the attaching bar can be easily regulated, and the lost motion is reduced to the minimum. An adjustment of $\frac{3}{8}$ of an in. to allow for wear has been provided.

In Fig. 2 is illustrated what the Van Dorn company calls the Barnes T-rail attachment, made especially for very heavy service, and particularly to meet the requirements of elevated roads. It is simply a T-rail, weighing 80-lb. to the yard, and swiveled on the body bolster. The coupling head is bolted on to the T-rail with four turned bolts with rimmed holes. This makes a very solid coupling, durable, easily adjusted and inexpensive to maintain. There are two springs to each attachment.

The Van Dorn couplers, in connection with these attachments, have effectually solved the problem of automatically coupling trail cars on street surface, and elevated railways. They are also of

FIG. 2 WITH T-RAIL ATTACHMENT.

great value, when two cars are to be used together for bucking snow in winter. An important advantage possessed by these devices is their ability to couple to other makes of couplers, as the draw bars make a common pin and link coupler, and the coupling bar can be placed in either of the draw bar heads as desired. All the elevated roads in Chicago and Brooklyn are employing Van Dorn couplers, as well as the leading street railway companies.

ELECTRICITY AT ILLINOIS UNIVERSITY.

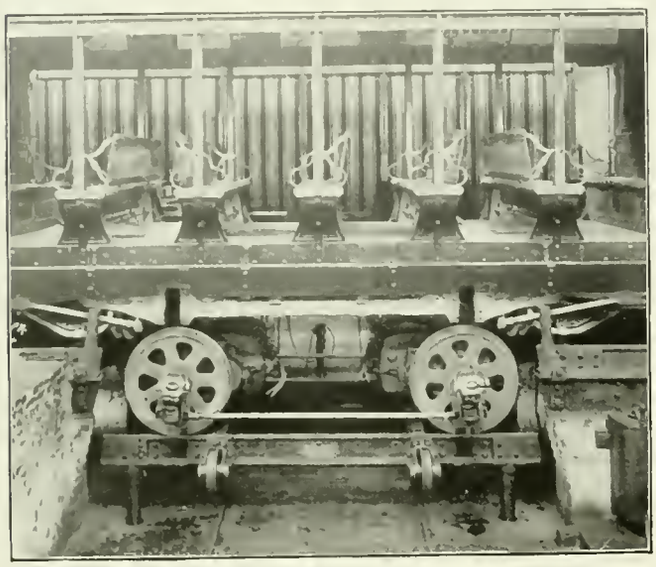
A number of new courses in the Department of Electrical Engineering have been added in the field of electro-metallurgy, alternating current working and polyphase testing, and electric lighting and power plants, at the University of Illinois, Champaign and Urbana, Ill. The equipment of the electrical engineering laboratory is being continuously increased for regular and advanced work in these branches.

The four years undergraduate course has been made elective for the last year and a half; that is, a student may elect his further work in the regular electrical course, in the electro-physical course or in the electro-chemical course. The degree of electrical engineer is given only after completion of five years. The fifth year is devoted entirely to special work.

THE BRYAN CAR DISMANTLER.

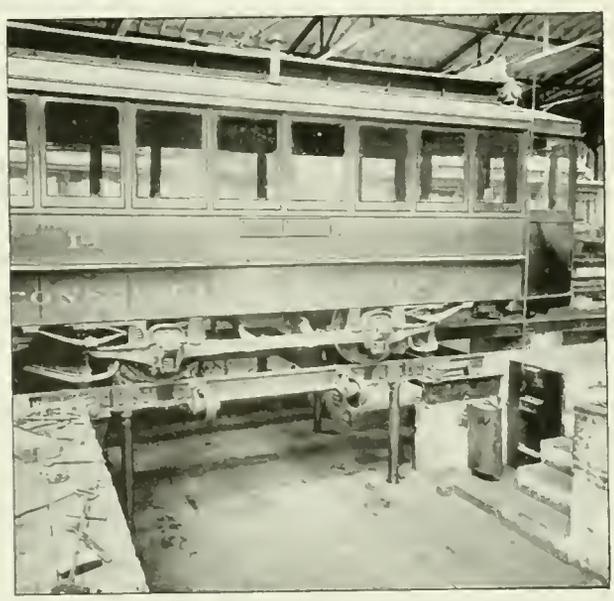
The manager who has once witnessed the operation of the device described in this article will hardly consider his shop equipment complete without it. Our illustrations show this system as installed in the Frankstown shops of the Consolidated Traction Co., Pittsburg.

The dismantling pit in which the device operates is extended sideways for a sufficient distance to allow for hoisting out the



BRYAN CAR DISMANTLER.

wheels and motors. On the floor of this are track rails placed at right angles with the car tracks above. A section of the track over the pits sufficiently longer than the over all dimension of the wheels, is removable, being made in the form of a truck with small wheels on each side as shown. The truck is provided with sliding plates, curved so as to fit the flanges of the wheels, and operated by screw



BRYAN CAR DISMANTLER.

handles, and which form, when screwed up against the wheel flanges a cradle that centres them.

On the I-beams tying the side rails together are provided pivoted supports for the motors. The pivoted supports have screw handles, so that when thrown in position they raise the motor to facilitate the removal of the suspension. The ends of the rails of these tracks or trucks are leveled so as to slide easily into position when being raised, and also to steady the truck when being used as a running track. This section of track or truck is mechanically raised or lowered by four massive screws, so placed as to support the four corners of the truck, and these are operated simultaneously by shafting carried on the frame of the machine under the pit floor, and arranged to operate the screws by means of bevel gears. The corner posts of the frame are threaded to suit the screws and form bearing for the bevel gears operating the screws. The power is supplied by a railway motor, in the latest design, arranged to gear direct into one of the line shafts. This motor is operated by an ordinary street car controller.

At the four corners and just outside the movable section, are pivoted arms with movable steel shoes which may be turned up vertically or folded away beside the rail when not in use supporting the car. The supports for these pivoted arms are carried on substantial cast iron columns so designed as to hold the brickwork of the pit walls in position.

In the operation of the device the car is run into position over the pit, the curved slides are screwed up against the wheel flanges, the motor supports screwed up, taking the weight of the motor off the suspension, the pivoted arms are turned up, bringing the shoes under the ends of the truck frame so as to support the weight of the car. The connections are then severed, the journal box bolts and brake rods are removed, then the wheels, axles, one or both, with the motors, are quickly lowered by means of the screws, till the side wheels of the movable section rest upon the rails in the bottom of the pit, when it is easily run to one side, bringing the wheels and motors into position so as to be readily picked up by a crane and placed in some convenient place on the shop floor, where the motors can be opened, inspected and repaired.

A new set of axles and motors can be rapidly replaced by reversing the process. The crane pickes up the extra set and lowers them into the movable section. The wheel flanges dropping into the curved cradles, and the motors resting on the motor supports, which effectually centres them. The movable section is then run under the car, and the motor being started, the screws lift the section into position and raise the car from the supports. The wheels are secured in place and the necessary brake and motor connection made.

With four men the whole operation of renewing both pairs of wheels and motors and replacing them with new ones ready for service requires from 20 to 25 minutes.

The device can be arranged so that the truck can be under the car lengthwise, and the wheels and motors taken out from the end.

This device was first designed for the Consolidated Traction Co., of Pittsburg, Pa., by Mr. J. Bryan, engineer, Park Building, Pittsburg, and is now manufactured under his supervision: all inquiries for particulars should be addressed to him.

McGILL, POMEROY & CO.

This firm is the successor to that of McGill & Pomeroy, which was dissolved on May 1st last. The present members are James H. McGill and John W. Porter. The place of business is 317 Dearborn St., Chicago, and the concern has some of the best railway agencies in the city. Among the prominent companies represented are the Ohio Brass Co., overhead material; Forest City Electric Co., commutator bars; J. M. Atkinson & Co., rail bonds; the Cutter Electrical & Manufacturing Co., circuit breakers and rheostats, and the Wagenhals Manufacturing Co., slow feed controller handle. All of these supplies are widely and favorably known. Goods are kept in stock at all times, and prompt shipments thereby insured. The house also handles a large variety of electrical mining supplies, and does a large business in this growing field.

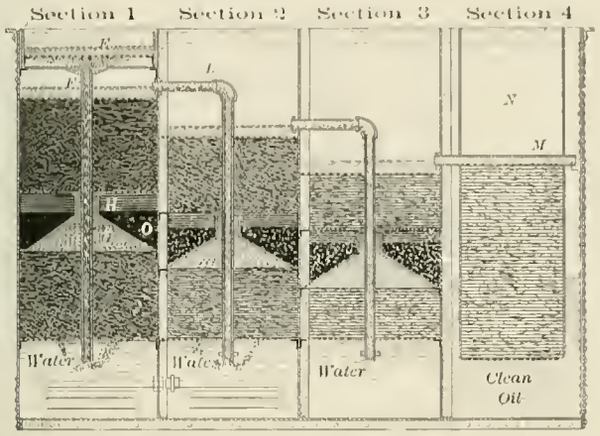
Mr. Jas. H. McGill, the senior member of the firm, has traveled extensively among street railways of the central west during the past five years and enjoys a wide acquaintance. Mr. John W. Porter, the new partner, is well known in electric lighting circles, having been connected for many years with this industry in Chicago. Mr. Edward R. Mason, formerly with the Mason Electric Equipment Co., is traveling salesman for the firm in Chicago and vicinity.

The Terre Haute (Ind.) Street Railway Co. has been ordered to put fenders on its cars within 90 days from September 8th.

TURNER OIL FILTER.

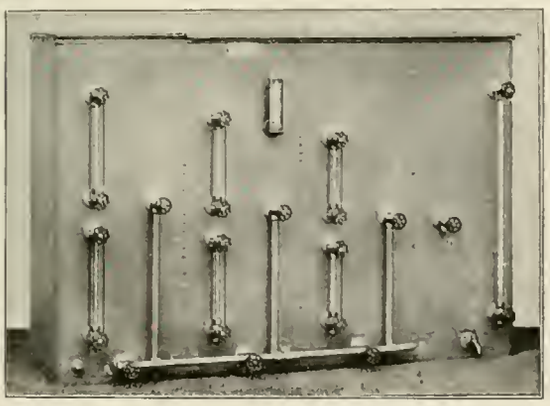
In many plants little attention is paid to the use of oil; in others a large saving is effected by the use of suitable and effective filters. Such a device is the Turner oil filter, made by M. V. Turner, 2777 North Lincoln St., Chicago. This filter is reliable, durable and efficient, and capable of giving absolutely clean oil in the minimum time of filtration.

The working and construction of the Turner filter may be readily understood from the accompanying illustration. The dirty oil is poured into pan E in section 1, and descends through pipe F, discharging into the water, below a perforated plate. The oil now rises through the perforations of the plate and passes up through filtering material and water into the cone G, escaping through perforations at the top of the collar of this cone. The oil now rises, passing through the second perforated plate and



SECTIONAL VIEW OF OIL FILTER NO. 9.

filtering material, while a certain amount of the heavy dirt settles in the dirt chamber, and should be drawn off. The partially filtered oil, having reached the pipe L, passes into section 2, repeating the same operation as in section 1, and so on until section 4 is reached, when it enters pipe M in cylinder N, descending through filtering material into the oil reservoir. The arrangements of the dirt chambers in sections 1, 2 and 3, as above described, is a great advantage over all other filters, as they do away with



EXTERIOR VIEW OF OIL FILTER NO. 9.

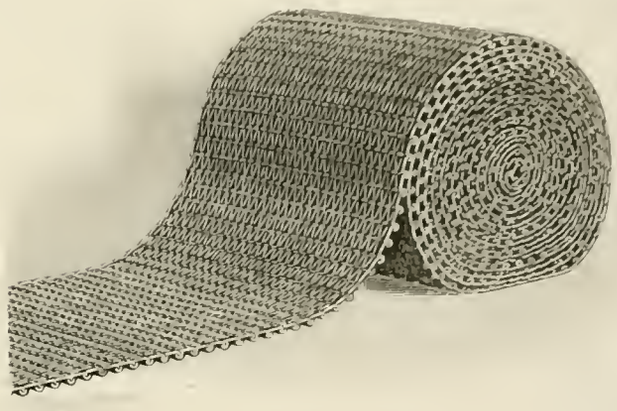
the passing of the oil through impurities left by previous filtrations. It is impossible for the dirt, after being deposited in the dirt chamber, to mix with the oil or water, as the chamber is packed with oakum at O. The filters are made in any desired size and of proper shape to conform to the engine or other rooms where they are to be placed. The directions for working the filters are simple, and involve little care and attention.

Hundreds of these are in use, and in Chicago many of the finest and largest plants in the city are equipped with them. Among such are the Auditorium, Pullman Co., Public Library, Calumet Electric, Crane Co., Cicero & Proviso Electric Ry., Metropolitan Elevated, Union Traction Co., South Chicago City Ry., Alley L. and Union Loop. Also Memphis Street Ry., Metropolitan, Kansas City, Toledo Traction, New Jersey Electric Ry., Omaha Street Ry., and many others.

The Turner waste cleaner by means of pressure under rollers and jets of hot water and steam recovers a large percentage of oil and waste. In the Chicago Edison plant (lighting) the weight of the cleaned waste and oil recovered represented 85 per cent of the dirty waste treated.

HOW TO KEEP CAR FLOORS CLEAN.

In the good old horse car days now rapidly passing into tradition, the car floor and its condition was a matter of little concern, and the traveling public patiently climbed over humps of soggy hay with never a suspicion that it could be improved. But



UNITED STATES WIRE MAT.

today one of the fundamental principles of good management is in the neat, cleanly and sanitary condition of the car. To accomplish these results various means have been employed; wooden seats in frames are nailed to the floor, hemp matting, and later wire matting. The latter seems to be the most practical solution. But here again we find degrees of wire matting, and the desirable one is that which will not curl at the ends; that is self-cleaning, and combines a neat appearance and lasting qualities with a first cost that is considered reasonable.

The United States Wire Mat Co., of Decatur, Ill., makes a wire mat which combines all these desirable features. Unlike all other wire mats it is one-sided, which allows dirt, cigar stumps, etc., to pass through, instead of sticking fast, to be removed by hand. The mat is made in any width desired, and in any length up to one mile. It rolls up like a roll of carpet, and the desired length for a one-piece mat to cover the entire car floor can be cut off and made ready to lay in five minutes. The mat is made of a special weave from the best galvanized steel or brass wire. It is being largely used in banks, offices, halls and public buildings, but nowhere with greater satisfaction than where adopted on street cars.

DEMAND FOR SAND BOXES.

The Ham sand box for motor cars, made by the Ham Sand Box Co., of Troy, N. Y., has been adopted as standard by a large number of the leading roads in this country and abroad, and the demand is constantly increasing. The company's works are overcrowded with orders, particularly duplicate orders from old customers. One of the largest car building concerns in Great Britain is using the Ham No. 4 box exclusively on all the cars it turns out, and has ordered this pattern in large quantities. The Glasgow (Scotland) Tramways has adopted the No. 3 style as standard.

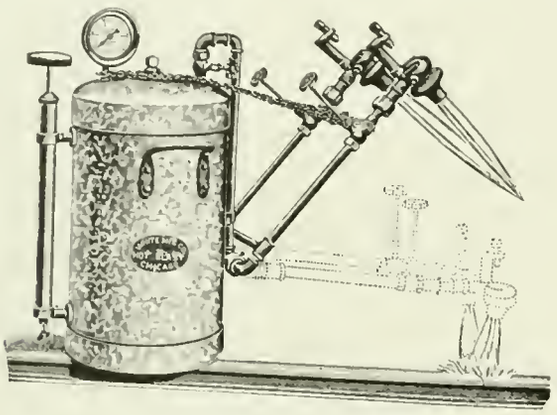
The Ham Sand Box Co. makes five different types of boxes to meet different conditions, and is just bringing out a sixth, which will be shown for the first time at the coming convention of the American Street Railway Association.

A telephone dispatching system will be installed on the lines of the Philadelphia & West Chester Traction Co.

RAIL JOINT HEATER.

With each new development in railway construction involving as it does new work and additional labor, comes shortly appliances for making this work both easy and less expensive. One of the important features in the process of cast welding rail joints is the proper preparation of the rail ends, and unless this is carefully and thoroughly done the succeeding work may be rendered useless by the breaking of the joint.

The rapid adoption by roads in all parts of the country of the welding system will make the rail joint heater, which we illustrate herewith, an appliance of interest to a large number of engineers, managers and contractors. The machine has two powerful



WHITE RAIL JOINT HEATER.

burners mounted on a 10-gallon tank. The burners are provided with a swinging motion both lateral and vertical, which permits of instant adjustment to any desired position. The burners produce a white heat with 10 minutes' application. The tank is powerfully constructed, the joints being brazed, and will stand a pressure of 500 lb., making its operation perfectly safe. It has already been adopted by nearly all the roads doing welding and is giving great satisfaction. It is made by the White Manufacturing Co., of 158 Indiana St., Chicago, and complete details and directions for use will be sent on application. The same concern also manufactures many other appliances used in railway shop and construction work.

THE Q & C CO.

The Q & C Co., of Chicago, maker of steam and street railway specialties, has gradually increased the scope of its business and added new appliances and devices to its list of goods, until it now handles over 40 distinct specialties. These include trolley and electric light poles, tie plates, metal saws, rail drills, jacks, street car steps, oil purifiers, pneumatic tools, steel rails, steel ties, frogs and switches, switch and signal stands, etc. One of the latest devices brought out by the company is its roadbed sprinkler for saturating the roadbed of steam roads and electric interurban lines with oil, for the purpose of eliminating vegetation, weeds and grasses, permanently laying the dust, preventing frost between the rails and in general increasing the comfort and safety of travelers. Oil sprinkling has already become popular with a number of steam roads, and the practice will soon be introduced on several high speed interurban roads.

The president of the company is Mr. Chas. F. Quincy. Mr. Quincy is a native of Boston, and has had many years' experience in the manufacture of railroad specialties. He is vice-president of the National Association of Manufacturers of Illinois. Mr. Frank W. Edmunds, who has charge of the Chicago office, has been connected with the company for eight or nine years, and during the last two or three years has taken an active part in its management. The general offices are at rooms 700-709 Western Union Building.

The Q & C Co. acts as western representative for the Pennsylvania Steel Co., the Maryland Steel Co., the Pearson Jack Co. and numerous other well known manufacturing concerns.

The Athens (Ga.) Street Railway Co. will build a new line to the rock quarry near the city, and haul stone for paving purposes direct to the streets where it is to be laid.

STEAM VALVES FOR HIGH PRESSURES.

In order to meet the requirements of modern extreme high pressure steam plants, the Crane Co., of Chicago, has designed a line of straight-way, globe and angle valves suitable to stand a working pressure of 250 lb., and tested to 800 lb. per sq. in. These valves are very massive, and care has been taken in their construction to distribute the metal, both iron and brass, in order to best meet the heavy stresses to which they are subjected, due to expansion and contraction, and to resist the unusual straining caused by the settling of the pipes. The body of these valves is very heavy, and has large and free openings. The seat in the body is made extra heavy, of hard metal, and in the globe and angle patterns is fitted with the Crane improved bridge to guide the swivel disk.

The swivel disk is made with a guide. Sizes up to six in. are made of solid hard metal. The larger sizes, eight in. and upward, are also made of hard metal, and are stiffened with a cast-iron plate, thereby making the disk very rigid. The combination of the guide on the disk and the bridge on the seat insures the square seating of the disk, and also prevents the rattling of the disk caused by the pulsation of the steam passing through a partly open valve.

All of the Crane valves are fitted with an improved disk nut, which enables them to be packed when open without steam escaping.

Part of the works of this company have been running 24 hours a day for the past six months, and all departments have been working overtime to keep up with orders. The volume of business carried on during the past year is nearly double that of the previous year. A new addition to the factory, 100 x 225 ft., and six stories high will soon be placed in operation and this will increase the capacity of the present works about 100 tons of iron a day.

Crane valves have gone all over the world; among recent customers may be mentioned the Central London Underground Ry.; Government Tramways, N. S. W.; Dublin United Tramways, Cork Electric Ry., South Side Elevated R. R., Chicago; Union Traction Co., Chicago; Chicago & Milwaukee Electric Ry., Chicago City Ry., Consolidated Street Ry., Grand Rapids, Mich.; Kansas City & Leavenworth Electric Ry., Metropolitan Street Ry., Kansas City, Mo.; Cripple Creek (Col.) Power Co., Milwaukee Electric Railway & Light Co.

The officers of the Crane Co. are: President, R. T. Crane; secretary, J. B. Murphy; treasurer, T. F. Gartz; manager engineering department, J. B. Berryman. Branch stores are maintained in New York, Philadelphia, Kansas City, San Francisco, Los Angeles, Portland, Ore., Omaha, Sioux City and St. Paul.

LARGEST SCRAPER ORDER ON RECORD.

The largest order for track scrapers ever given is that received last month by the Van Dorn & Dutton Co., of Cleveland, and was from the Boston Elevated Railway Co. for 1,188 pairs of the Clark patent. When this order is filled there will be upwards of 15,000 of these excellent scrapers in use in all parts of the country. The order was taken by Mr. Dutton, who reports the works as extremely busy all this year, and a large amount of work in hand and still more in sight.

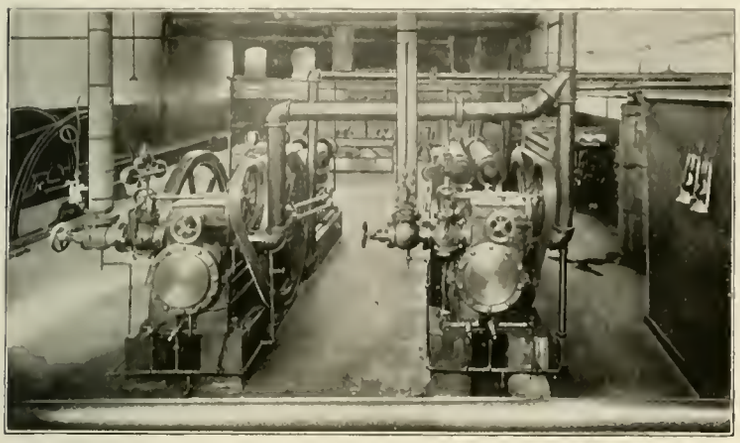
TO PREVENT LOOSE TROLLEY FROM INJURING OVERHEAD WORK.

An ingenious plan for signaling the motorman when the trolley wheel leaves the wire is used in Ithaca, N. Y. On all the cars of the Ithaca Street Railway Co. the rope coming from the trolley pole is fastened to the bell rope with a snap clasp. If the trolley wheel leaves the wire the pole jerks the bell cord, signaling the motorman to stop instantly and thus often preventing injury to the overhead work.

Wire thieves nearly compelled the Philadelphia & West Chester Traction Co. to suspend operation on September 4th by stealing the feed wire for a distance of several miles. The wire was cut down after the power had been shut off for the night on September 3d.

COMPRESSED AIR IN CHICAGO.

Early in the spring of the present year, the Compressed Air Motor Co., of Illinois, installed in the power house of the North Chicago Street Railroad Co., a plant for the operation of compressed air motor cars over the lines of the railroad company. The plant consists of two air compressors, and a bank of 20 Mannesmann tubes, the tubes being used as a reservoir to store the air as it is delivered by the compressors. The air is delivered



PLANT OF CHICAGO UNION TRACTION CO.

to the storage tubes by the compressors (only one of which is used, the other being held in reserve in case of accident), at a pressure of 2,600 lb. per sq. in.

Three motor cars were brought to Chicago, and two of them are now in regular service over the cable road, running from the "Limits" station to Clark and Washington Sts. and return. The first car leaves the barn at 12:40 a. m., and the last reaches the barn about 5:45 a. m., the two cars performing what is known as the "owl" service on North Clark St.

The cars present the same general appearance as electric or cable cars of the same size, and seat as many passengers. The

COMPRESSED AIR MOTOR CAR.

compressed air required to run the car is contained in Mannesmann tubes carried under the body and seats of the car. The mechanism which operates the car is of a modified steam locomotive type, and is all carried beneath the car body, nothing being visible except the controller, brake and reversing levers.

The storage capacity on the cars now being operated is sufficient to run the cars from 15 to 17 miles, but it has been the practice to charge the cars once every round trip. The charging is done in the open street opposite the power house at Elm and North Clark Sts. A copper pipe leading from the reservoir in the power house is connected with the car, and the air is delivered to the storage on the car. The whole operation, including stopping, connecting, charging, disconnecting and starting, does not consume two minutes, as air under this pressure flows very quickly. The motion of the car is very regular and smooth—there are no sudden jerks and no hissing of escaping air, the car being as nearly noiseless as it is possible for a street car to be.

In addition to the use of compressed air for running the car, the same air is used to operate a brake, which brake is pronounced by railroad men, and all who have observed it, to be as nearly perfect as an air brake can be. It is absolutely free from any noisy exhaust so common with other kinds of air brakes, and gives the motorman full control of his car.

There is no leak whatever in the storage of the air, either on the car or in the power house—the first trips of the cars being made with air with which the car was charged 18 hours previously. Air under pressure loses none of its elasticity, and will assume its normal condition whenever opportunity offers, no matter whether it be five minutes or five years after it is compressed, so that no matter how long a car may stand, the power is always there ready for use when required.

When one becomes familiar with all the details of the compressed air system, as demonstrated by this plant and cars, he is surprised at its simplicity and lack of complication. No especial training is necessary to operate the cars, instances having occurred where instruction was given to the motormen on only two trips, and they being given full charge of the car regularly thereafter.

In the installation and operation of a plant and cars of this system, it is not necessary to have a large number of high priced skilled workmen. A steam locomotive engineer of average intelligence can, in the course of a month or six weeks, become so familiar with the construction of these motors, as to be able to take full charge of repairs, maintenance, etc.

Since May 30, 1899, the date the air cars commenced running, they have traveled 5,033 miles and carried 62,428 passengers, counting only paid fares, and keeping no record of transfers, employes, etc. On numerous occasions one and two trailers have been attached to the motor cars, and on one occasion 267 passengers were carried on one single trip.

In this connection we think a word or two in regard to the Mannesmann tubes above mentioned is pertinent. These tubes are made in various sizes, those in the power house being 9 in. in diameter and 22 ft. long. They are seamless, weldless, and have only one opening in the neck. They are tested to a pressure of about 4,800 lb. sq. in. before leaving the factory, and, as they are never charged to more than 2,600 lb. working pressure, the factor of safety is a large one—in fact, tests have been made to ascertain the bursting point of these tubes, and it was found that it required a pressure of between 6,500 and 7,000 lb. per sq. in. to burst them.

MASSACHUSETTS STREET RAILWAY ASSOCIATION.

At a meeting of the Massachusetts Street Railway Association, held at Young's Hotel, Boston, September 13th, the following officers were elected:

President, John R. Graham, of Quincy; first vice-president, E. C. Foster, of Lynn; second vice-president, E. P. Shaw, of Brookline; secretary, Chas. S. Clark, of Boston; treasurer, F. H. Smith, of Quincy. Executive committee, John R. Graham, E. C. Foster, E. P. Shaw, P. F. Sullivan, of Lowell; Robt. Goff, of Fall River; Wm. A. Bancroft, of Cambridge; F. H. Dewey, of Worcester; H. H. Crapo, of New Bedford, and Wm. S. Loomis, of Holyoke.

It was voted that the president of the association attend the coming convention of the American Street Railway Association at Chicago as the official representative of the Massachusetts State Association.

Policemen have been stationed at the Olin Ave. bridge, spanning the Bronx River, in Williamsbridge, New York City, with orders not to allow the Union Railway Co. to put down tracks across it. It is thought by the Deputy Commissioner the bridge is not strong enough to stand the additional burden of car traffic.

FOREIGN FACTS.

The Pennsylvania Steel Co. is rolling rails for a new electric railway in Cuba.

The street railway line at Pueblo, Mexico, has recently been sold to an English syndicate.

A preliminary concession has been granted in Austria for a projected electric railway between Zabrzech and Schonbrunn.

The Corporation of Oldham, Eng., is putting in an extensive tramway system which will cost in the neighborhood of £250,000.

The Potteries Electric Tramway of England, recently described in the "Review" is about ready to open up two sections of lines to traffic.

Work has been commenced on the electric railway from Seaforth to Crosby, Eng., and it is anticipated that the road will be completed early in the spring.

The city authorities of Bath, Eng., have decided to apply for powers to construct a system of electric tramways. The cost is estimated at about £250,000.

The Electrical Corporation, Ltd., of Valparaiso, Chili, will soon let the contract for a large power plant on the Aconcagua River, and an electric road in that city.

The Leamington & Warwick (Eng.) Tramways Co. is desirous of introducing electric traction, and will probably obtain assistance from the British Electric Traction Co.

The Calcutta Tramway Co. has, after some difficulty, succeeded in making terms with the municipality and has now obtained sanction to operate its lines with electricity.

The Bombay Tramways Co. has asked sanction to change its horse lines to electricity. It also proposes to introduce the American system of a uniform fare for any distance.

The drivers and conductors of the Havana street car companies recently went on a strike for larger wages. Their places were filled with new men and the strikers became riotous and stoned the cars.

The council of Gateshead, Eng., has sanctioned important extensions of the tramways, for which powers have been obtained by the Gateshead Tramways Co. The total new mileage will be about 5½ miles.

Proposals are on foot for the utilization of the water power of the Kelso, Eng., flour mills for working tramways, electric lighting, and pumping the town's supply of water. At present about 100 h. p. is available from the turbines.

The first section of the new electric railway lines of Sheffield, Eng., was formally opened by the mayor last month. Sufficient cars are in service to provide a five-minute headway, and the novelty is attracting large numbers of passengers.

Ernesto Pugibet, of Mexico City, who is now in Paris, writes that on his return he will be accompanied by the representative of a strong French syndicate prepared to build electric railways in the Federal districts of Mexico and Tlalnepantla.

The London (Ont.) Street Railway Co. has served notice of an action against E. Jones Park, police magistrate, and John D. Wilson, mayor, to recover $20,000 damages claimed because of alleged illegal licensing of busses to striking employes.

The town council of Neath, Eng., has leased the Neath corporation tramways to the British Gas Traction Co., of England, for seven years. This company will pay a rent of $6,500 per annum, and will equip the tram lines with gas motor cars.

The mule car service of the city of Mexico which for many years has retarded the development of the suburbs of that city, is about to be replaced with electric traction. The new roadbed and track have been completed and the machinery is on the ground ready for erection.

A section of the new Dublin tramways has recently been opened to traffic. Work on a large new power house at Ringsend is approaching completion, and other sections of the road will shortly be opened. At present there are 65 trolley cars in service, and when the lines are all completed 250 cars will be required.

The Middlesex (Eng.) County Council has decided to apply to the Light Railway Commissioners for an order authorizing the construction of light railways through Isleworth, Twickenham, Teddington, Hampton, Hampton Court, and Hampton Wick, over the route originally proposed by the London United Tramways Co.

A proposal has been made by a local syndicate in Dundalk, Ireland, to construct and operate an electric railway system in this town and its seaside neighbor, Blackrock, and to combine with this plant one for the lighting of the town. Work on the railway lines is to commence within a month after the signing of the agreement.

The Compagnie Generale Francaise de Tramways, of Paris, is rebuilding the entire street railway system of Marseilles, and during this year the horse car lines will have been almost entirely converted to electric traction. The electric car trains are limited by law to 118 ft. in length and the speed cannot exceed 12½ miles per hour.

The electric tramways of Carlyle, Eng., will probably be in working order by the close of the year. According to the provisional order the system must be completed by Jan. 1, 1900, and efforts are being made to secure that end. A delay on the part of the contractors in commencing the work was caused by the difficulty in obtaining materials.

An early start will be made in the construction of the proposed tramways of Devonport, Eng. These will comprise 4½ miles of double track, 3 ft. 6 in. gage. Rails weighing 92 to 94 lb. per yard, and of the girder type will be used. The maximum gradient is 1 in 11, and the sharpest curve has a radius of 30 ft. Power is to be taken from the Corporation lighting station.

The Sao Paulo (Brazil) Railway, Light & Power Co. has contracted with the Stillwell-Bierce & Smith-Vaile Co., Dayton, O., for the construction of a water power plant on the Tiete River, 25 miles from Sao Paulo, which will cost $100,000. This will furnish power for 100 miles of electric railway. The electrical portion of the contract will be worth about $700,000.

The town council of Bradford, England, has resolved to obtain Parliamentary powers for the construction of extensive additions to its electric tramway system. The estimated cost of these new lines is about £160,000, being at the rate of about £8,000 per mile of single track. It is not proposed to construct all the lines immediately, and Parliament will be asked to grant five years as the term for completing the scheme.

The street railways of St. Petersburg are operated by horses, although on one of the lines owned by the city electrical equipment is being seriously considered. Double deck cars are used there, two and three being pulled in a train. Franchises are granted for a definite time, with the condition that at the expiration of the time the roadbed and track shall revert to the city. At present the government operates 10 miles and will soon acquire more.

The Griechische Elektricitats Gesselschaft has been formed at Athens, Greece, for the purpose of building an electric lighting and power station and constructing electric tramways. The works in Athens are estimated to cost about £300,000, and current will be supplied for lighting Athens, the Piraeus, the two Phalerums and their environs, and will supply motive power to the Athens-Piraeus railway, the tramways and the numerous factories of the Piraeus.

ELECTRIC RAILWAY IN BORDEAUX.

Consul Albion W. Tourgee writes from Bordeaux, France, that the Tram & Omnibus Co., of that city, having the exclusive right to operate street cars and omnibuses in the city, and whose charter had still several years to run, has recently sold to a new company, which will operate under a new charter. It is understood that the old company is to receive 12,000,000 francs ($2,316,000) for its property and rights for the unexpired term of its charter, stockholders being allowed the option of stock in the new company on favorable terms instead of cash. The former company was English, with headquarters in London; the new one is French. The chairman of the board of directors is M. Mercet, 10 rue de Londres, Paris. It is understood that the present managing director, M. Bretherton, will continue to hold the same position under the new management. As the legal formalities are not yet complete, the terms of the new concession can not be given. It is understood, however, that they require an immediate increase of the service in the city and vicinity, and that the new company will at once proceed to substitute electric power for horse power, which has been used heretofore. Information can be obtained by addressing M. Bretherton, managing director, Tram & Omnibus Co., rue Tivoli, Bordeaux, France.

NEW CLOSED CARS IN CLEVELAND.

The accompanying illustration shows a new type of closed car, built by the J. G. Brill Co., which is being put in service by the Cleveland City Railway Co. As loops are provided at the terminals of all the Cleveland City Ry. lines, these cars are built to run in but one direction, and there are openings for passengers on the right hand side only. The car body is 30 ft. long, 7 ft. 10 in. wide at the belt rails, and there is a 4 ft. 6 in. platform at the rear end. A semi-circular shaped vestibule at the front end adds 4 ft. more to the length of the car, making the total length over dashers, 38 ft. 6 in. The vestibule is sheathed in steel and has a folding door at the right hand side. To facilitate the entrance and exit of passengers, the doors are placed at the side nearest the platform opening, instead of in the center, the longitudinal seats being cut away for a short distance at each end for this purpose.

BRILL CLOSED CAR FOR CLEVELAND CITY RY.

The seats are spring upholstered, covered with plush carpeting; bronze trimmings are used throughout. Eleven windows on each side and three in the ventilating sash at each end guarantee good light and air. The bodies are mounted on No. 27-F trucks, which are equipped with four 12 A No. 30 nose suspension W. P. Westinghouse motors; these enable the cars to make the highest speed permitted in the city or suburbs. Each car is fitted with Brill angle iron bumpers, two sand boxes at the forward end and two Dedenda gongs. Signalling push buttons are placed at each post.

From the exterior it might appear as if these cars had regular steam coach hoods. This hood, however, is not framed as a part of the monitor deck, but is put in separately.

A new electric railway running from the city of Louisville, Ky., to Highland Park was opened early in September.

WELL-KNOWN BOILER COMPANY.

The Stirling Co., whose "Stirling" boiler has been extensively introduced in industrial and electrical fields, has recently organized a department for the manufacture of high grade water tube boilers for marine use, and its works are now turning out all the boilers required for the Russian cruiser "Varrag," the Russian battleship "Retvizan," the United States battleship "Maine" and the United States monitor "Connecticut."

The manufacturing plant of the company, including boiler and machine shops, foundry, etc., is located at Barberton, O., and is completely equipped with modern and improved tools and machinery for doing the required work. The general offices of the company are in the Pullman Building, Chicago. Sales agencies are maintained in nearly every city of prominence in the United States, and in addition the company has its own corps of salesmen in Japan, the Hawaiian Islands, Mexico, Brazil, Cuba and South Africa. The New York branch office is in charge of Mr. B. M. Barr, formerly with the Walker Co., and the Pittsburg office is under the management of Mr. W. S. Elliott, formerly with the General Electric Co.

Among the street railway companies that have ordered Stirling boilers during the past year are the following: Saratoga (N. Y.) Traction Co., Sedalia (Mo.) Electric Railway Co., Kansas City (Mo.) & Leavenworth Street Railway Co., Cleveland (O.) & Eastern Electric Railway Co., Wilkes-Barre (Pa.) & East Pittsburg Street Railway Co., United Railways Co., of St. Louis, Los Angeles Consolidated Street Railway Co., Los Angeles Traction Co., Wheeling (W. Va.) & Elm Grove Railway Co., Vicksburg (Miss.) Railroad & Power Co., Norfolk Southern Railway Co., Walpole, (Mass.), Worcester (Mass.) & Webster Street Railway Co., Wheeling (W. Va.) Railway Co., Mobile (Ala.) Light & Railroad Co., Akron (O.) Street Railway & Illuminating Co., Monongahela Street Ry., Pittsburgh, Cincinnati (O.), Hamilton & Dayton Street Ry., San Antonio (Tex.) Street Ry., Paducah (Ky.) Street Ry.

POOR'S MANUAL FOR 1899.

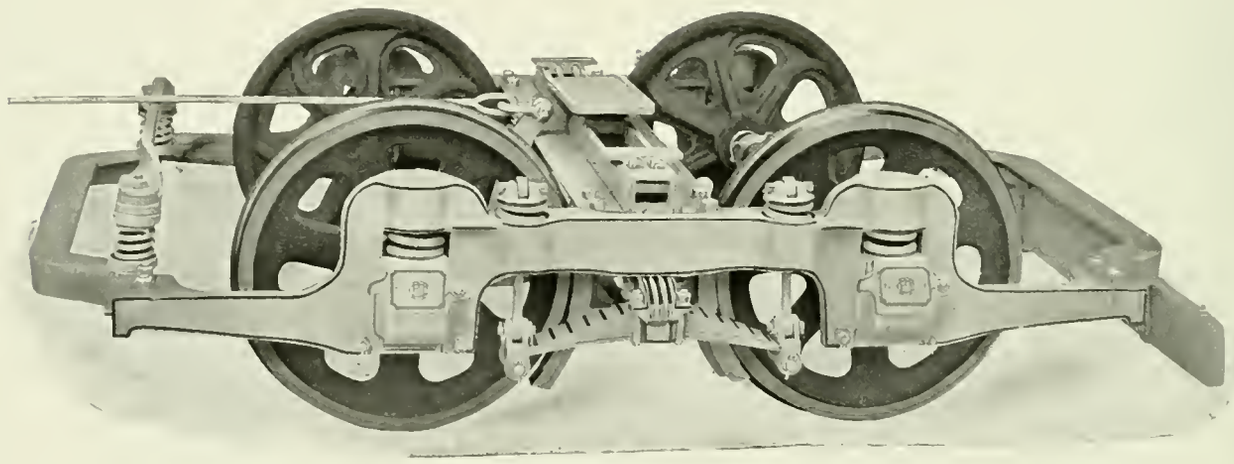
We have just received through A. C. McClurg & Co., Chicago, the 32d annual number of Poor's Manual of Railroads, published by H. V. & H. W. Poor, 44 Broad St., New York. This work has been before the public so long and has won so high a place among statistical books that nothing new can be said in praise of it; Poor's Manual is indispensable to anyone who wishes to keep in touch with the steam railroads of this country, and is a valuable reference book for those seeking information on street railway and other companies, state and municipal indebtedness, etc. We note with pleasure that each year the Department of Street Railways in Poor's is given more space. The present volume comprises 1,500 pages, but by reason of slightly larger pages and smaller type it contains matter that would fill 3,500 pages of some of the earlier editions. The introduction to the Manual for 1899 contains "A Study in Railway Statistics," which is a review of the development, finances, etc., of the railroads of the United States, with particular reference to the last 20 years. Price, $7.50, including cost of delivery in the United States or Canada.

THE PECKHAM NO. 14-B-3 SWIVEL TRUCK FOR KANSAS CITY.

The Peckham Truck Co. at its works in Kingston, N. Y., has now in process of construction 35 pairs of trucks of this type for a street railway company in Kansas City. These trucks as illustrated in the accompanying engraving are composed of cast steel side frames with cross sills and angles which form a transom between which the bolster plays, and these angles are secured to each side frame by two 7/8-in. turned bolts which are driven into holes reamed through the angle irons and castings after the frame has been erected, thus insuring an accurate and positive fit, and a construction that will remain square under all conditions. The side frames and all other parts are designed and proportioned to carry with safety a load of 30,000 lb. per truck.

The bolster, as will be noted, is carried upon two half elliptical springs which in turn are carried by coil equalizer springs. Large coil springs are also placed over each journal box so that there are three separate sets of springs between the rail and car body, insuring easy and steady riding. The journal boxes are unusually large and provide for a liberal amount of packing.

A special feature of this type of truck is the arrangement of the brake beams, which are placed between the wheels so that they are out of the way of the motors, which are carried outside of the axle, and by this arrangement the trucks are built with a wheel base of but 4 ft. The brake rigging outside of the shoes, bolts and hangers, consists of but eight pieces and the operation of the brake is quick and powerful; there is no lost motion to be taken up before the shoes are brought into action. In addition to this order for this type of truck the Peckham Truck Co. has received recent orders, some of which have been delivered and others still in process of construction, for 30 pairs for the Washington Traction & Electric Co., Washington, D. C.; 50 pairs for the North Jersey Street Railway Co., of Jersey City, N. J.; 15 pairs for the North Hudson County Railway Co. and a large number for several other roads. The works are running night and day to keep up with domestic and foreign orders and the trucks continue to maintain their reputation of durability and ease of maintenance.



PECKHAM NO. 14-B-3 TRUCK.

KNOX AUTOMOTONEER CO.

The Knox Automotoneer Co. has been organized to place on the market the "automotoneer" invented by G. W. Knox, electrical engineer of the Chicago City Ry. This device, which was described in the "Review" for September, 1898, page 703, is attached to street railway controllers and by automatically regulating the maximum velocity of the controller handle prevents its improper manipulation in starting. We are advised that the "automotoneer" has been used on many of the cars of the Chicago City Ry. for over a year and given excellent satisfaction.

The device will be exhibited at the convention by the Garten-Daniels Electric Co., space 32.

EXHIBIT OF NEW HAVEN REGISTERS.

The New Haven Car Register Co. will have a most interesting exhibit at the convention, and will show its new round single and double registers in addition to its well-known regular line of "New Haven" single, double and triple registers. It is claimed that these new round registers are the most complete and finest of the type ever made. They are made in a very thorough and workmanlike manner and have all the desirable features of other registers and additional ones of their own. The completeness of the double register which consists of two single registers in one case, is recognized at a glance, and the many valuable features, such as showing the number of the trip, as well as the direction, the number of each class of fare rung up on the trip up to 1,000, in large numerals, which can be read from the end of the longest car, the total number of each class of fares up to 100,000, and indicating the class of fare last rung up in prominent words, will be appreciated by all practical railway men.

Each machine is also provided with red safety shields and with automatic locking and controlling devices, preventing one side of register from being rung up while the other side is being operated. A locking device is also provided so that conductors can lock the register upon temporarily leaving car. This register is also adapted for use on two connecting roads, one side for each road, each conductor securely locking his side of register when leaving the car. It can also be arranged as two separate registers, each side operating and being reset to zero independent of the other side. All these different arrangements make this machine peculiarly adapted to meet the various conditions of registering fares on electric railways.

The round single registers are provided with very prominent numerals, and the safety shield is lettered "Not Registered"; this shield covers the figures instantly as the conductor begins ringing up the fare, and remains in view until after fare is rung up and registered. This machine has been adopted by the Third Avenue R. R., of New York, on its new equipment. Both of these registers, in addition to being very complete, strong and durable, present a very fine appearance with finely finished antique copper cases and ornamental aluminum dials, and will no doubt attract much attention at the convention at Space No. 77, where they will be exhibited.

THE "REVIEW DAILY."

One of the features of the convention will be the daily edition of the "Street Railway Review." The hearty and prompt response of advertisers leaves no room for doubt as to the desirability and necessity of a daily edition. Indeed, the assured success of the publication is such that the publishers have already decided to make it a permanent affair, and will hereafter issue a daily at future conventions, wherever they may be held.

Copies will be at all the leading hotels at daylight each morning for free distribution to convention people. If our readers should fail to find one in their mail boxes, please ask the hotel clerk for a copy. It will give full particulars of what has occurred the previous 24 hours and what is the order of the day.

ECHOES FROM THE TRADE

J. J. RYAN & CO., 68 West Monroe St., Chicago, report their foundry as extremely busy. They make a specialty of brass, bronze and aluminum castings of all kinds.

THE LORAIN STEEL CO. reports increasing demand for its Steel motor. This department is now in charge of Mr. R. T. Lane, with headquarters in Cleveland.

THE CITY OF WINNIPEG has adopted the Western Electric system of arc lighting and has now installed a complete plant for street lighting under municipal control.

GERARD SWOPE, formerly of the engineering department of the Western Electric Co., Chicago, now represents this company in St. Louis. The office is No. 10, Security Building.

THE PITTSBURG OIL CO., 307 South Desplaines St., Chicago, is now filling large orders for its winter motor grease, which has given general satisfaction. It also makes a boiler compound in both liquid and powder form.

THE CONSOLIDATED CAR FENDER CO., of Providence, R. I., following its usual custom of sending to the trade appropriate souvenirs on important days of the year, is mailing to its friends a neat placard commemorative of Dewey Day.

THE McGUIRE MANUFACTURING CO., is a concern not without honor in its own country. It has running at the present time in Chicago on the several roads 1,250 electric trucks, 21 combination snow sweepers and 725 Columbian car heaters.

THE PINTSCH SYSTEM of car lighting has been in use for several years on street railway lines in Chicago with perfect satisfaction. The cable cars of the North and West Side are so illuminated, as are also some of the lines of the Chicago City Ry.

THE DU PONT TRUCKS, made by the Lorain Steel Co., are meeting with steadily increasing favor, and recent contracts are for 35 single trucks for the Metropolitan, of Kansas City; 120 single trucks for Indianapolis, and 12 double trucks for the Detroit & Northwestern, of Detroit.

VISITORS INTERESTED in the process of making feed water heaters will have an opportunity to study the matter by a visit to the works of Wm. Baragwanath & Son, 44 West Division St., Chicago. The Baragwanath heaters are in use in all parts of the country, and in many of the railway power plants here.

ELECTRIC WELDING of rails has attracted recent attention on account of the work which has been done this summer in Buffalo, and described and commented on in the paper read before the New York State Association last month by Supt. R. F. Danforth, of the International Traction Co., of that city.

THE WHITING FOUNDRY EQUIPMENT CO., of Harvey, Ill., describes in a new 110 page catalog its many forms of electric, compressed air, hydro-pneumatic and belt power traveling cranes and hoists. Numerous reproductions from photographs of cranes actually in operation are shown in the pamphlet.

THE PAIGE IRON WORKS, Chicago, is experiencing the busiest time in its entire history. For months past the works have been running night and day and every man employed that could be given room to work in. Shipments have been prompt for these days when it is next to impossible to secure rail and iron.

THE WESTERN BANK NOTE CO., Chicago, is crowded with work on stocks and bonds. The steel engravings and lithographed work are unsurpassed anywhere, and the volume of orders from the East equals that originating in its immediate territory. The company occupies its own 10-story building on Michigan Ave.

THE ELECTRICAL INSTALLATION CO., Chicago, has closed a contract and is about to begin work on six miles of single track and three miles of double track construction for the Birmingham Railway & Electric Co., Birmingham, Ala. This is the third contract this company has had in Birmingham during the past two years.

THE JOSEPH DIXON CRUCIBLE CO., of Jersey City, is sending out two new pamphlets, one on Dixon's flake graphite and one on graphite wood grease for gears of electric railway motors. These catalogs are published in this company's usual artistic style and tell in a brief but forcible manner of the power of graphite to reduce friction.

THE MEAKER MANUFACTURING CO.'S works are at North Chicago, and visitors to the Chicago & Milwaukee electric line will be carried directly past the door. This ranks among the best designed and arranged fine machine work plants in the country, and as usual, is full of orders and very busy. The company's exhibit will be in charge of President Meaker, in space No. 40.

THE TURNER OIL FILTER will be found in use in the following railway plants in this city: West Lake St. plant of the Consolidated Traction (3); Metropolitan Elevated (3); Hobbie St. station Union Traction (3); South Chicago City Ry. (1); Alley L., State and 40th Sts. (2); Calumet Electric (1); Union Loop plant (2); and the Wabash and 52d St. station of the Chicago City Ry. (1).

ALBERT & J. M. ANDERSON, Boston, have shipped tons of their insulators to be used in railway construction work in this city. On the lines of the Yerkes' systems Anderson insulating material has been used almost exclusively, and to a large extent by the Chicago City Ry., the South Side Elevated and the South Chicago City Ry. The type generally used here is their well known Aetna brand.

H. W. JOHNS MANUFACTURING CO. will have a fine exhibit at the convention, which will be in charge of its western agent, the Manville Covering Co. Six representatives from the eastern office will attend, and among other features a working demonstration of its "inclosed fuse" will be given. This device is new and the makers state it is far in advance of anything previously attempted.

C. F. ORR & CO., Chicago, uniform tailors, will occupy space No. 1 at Tattersall's with an interesting display of uniforms and uniform cloths, buttons, etc. The company has had an extremely busy year and added many new roads as customers. The history of this concern has been that when once a road has its uniforms made here, it becomes a steady buyer. Every garment is made from exact and individual measurement.

THE ATLAS RAILWAY SUPPLY CO., Chicago, is meeting with steady and extremely gratifying success with its Atlas rail joint. The joint is in the nature of a truss, and provides a support which is intended to more than compensate in strength for the open section of the rails. It is specially adapted to suspended joints, but can be used with equal ease when it is desired to give the joint a tie support. The company prides itself on "an unbroken record of never a complaint."

THE GREEN FUEL ECONOMIZERS are highly appreciated in Chicago, having been installed in the following railway plants: Metropolitan Elevated, South Side Elevated, Chicago Electric

Traction Co., South Chicago City Ry., and the Chicago & Milwaukee Electric Ry. The system is working very satisfactorily in all cases. By this system the otherwise waste heat in the gases is taken out as they leave the boilers before reaching the chimney, and used to heat feed water, thus effecting a saving in fuel of from 12 to 20 per cent.

ONE OF THE NEATEST and most attractive booklets which will be distributed at convention is that compiled by Mr. E. Nelson, of the Chicago office of the Bethlehem Steel Co. It contains a large number of illustrations, specially made for the purpose, and showing every elevated and surface road power station in the city. Also directions as to what car line to take from Tattersalls to reach each plant. The cover design is in green and gold, and the album makes a collection of views which will be well worth preserving.

THE OHIO BRASS CO., of Mansfield, O., as a result of the increasing adoption of the third rail system, has supplemented its regular line of overhead trolley devices with a new and original design of third rail insulator, a patent for which has just been allowed. This insulator presents several new features, which cannot help recommending themselves to those who are familiar with the difficulties attending the use of third rail insulators in the past. This article appears in the new catalog, No. 4, recently published by this company.

THE REPUTATION of the Crane Co., Chicago, for high class, standard work is well known and applies to all its numerous products. To none more so, however, than to its high pressure steam valves, which are widely used in railway power plants throughout the country. In Chicago the power station of the South Side Elevated is completely equipped with these valves, which are also found in the plant of the Chicago Electric Traction, the Western Ave. station of the Union Traction Co. and in that of the Chicago & Milwaukee Electric Ry. at Highwood.

THE B. F. STURTEVANT CO., of Boston, Mass., describes in a new catalog what it calls its "steel plate planing mill exhausters," or in other words, exhaust fans for carrying off chips, dust and shavings in planing mills, spent bark in tanneries, waste wool and cotton in weaving mills, acid fumes in chemical works, and for use anywhere, where light material is to be transported from one place to another. Diameters, capacities, etc., are given in tables, enabling one to readily determine just what size fan and flue will be required to do a certain work.

THE DEARBORN DRUG AND CHEMICAL WORKS, Chicago, reports the largest business in the history of the company. The labratories are kept working to their full capacity continually, and the works equally so in making up the boiler compounds which are especially made for each case after analysis. The company prepares a special compound for each case, and states that its methods differ from those of other makers just as the prescription of an experienced physician after careful diagnosis differs from some patent medicine a patient may pick up.

HANNA & GRAY, Marquette Building, Chicago, territorial selling agents for Peckham trucks and Magann air brakes have had a remarkably prosperous year. The Peckham truck is well represented in this city. On the Alley L are 32 sets of the 14-A type. The Chicago & Milwaukee Electric has eight of the 14-A "extra strong"; and the Chicago General 20 "extra long" single trucks. The South Chicago City Ry. is using 12 single trucks and the Union Traction 10 single trucks. A Ruggles rotary snow plow built by the Peckham company is ready for the winter season on the Chicago & Milwaukee.

EUGENE MUNSELL & CO. and the Mica Insulator Co. of Chicago will make a combined exhibit at the street railway convention, having accepted a space of 200 sq. ft. near the entrance. This exhibit will consist of "Mica" in its natural state and in its various forms for electrical insulation, also stamped "Mica" segments and washers, both India and amber. Very large specimens of "Mica" will be shown, which will be of interest to all electrical engineers and street railway managers. The exhibit of the Mica Insulator Co. will consist largely of "Micanite" rings, segments, tubes, troughs, cloth, paper, etc. The exhibit will be in the hands of Charles E. Coleman, who has charge of the western business of these concerns. The companies' Chicago offices are located at 117-119 Lake St., where members of the electrical fraternity will be welcome during their stay in Chicago.

THE MORDEN FROG & CROSSING WORKS, Chicago, is among the largest builders in the country of street and steam railroad special work. The variety of this work turned out is great, and special facilities and men of long experience are provided to handle the most intricate and difficult work which arises. The company builds to order every kind of switch, switch stand, guard rails, clamps, frogs, crossings, rail braces, and in short every requisite for track work outside the rail itself. Its plant is large, and provided with every convenience and labor saving device, thus enabling it to fill orders as promptly as it does satisfactorily.

THE "GOLD SYSTEM" OF CAR HEATING is the title of the catalog for 1899-1900 just published by the Gold Car Heating Co., of New York and Chicago. The book comprises 80 pages, 9 x 12 in., and is handsomely bound in cloth. The various "Gold" systems of heating cars by steam, hot water, and electricity are illustrated and the apparatus described. Our readers will be most interested in that portion devoted to electric heaters. There are numerous letters testifying to the excelling satisfaction given by the Gold apparatus in service and an imposing list of users of the system. Copies may be had on application.

THE LOMBARD WATER-WHEEL GOVERNOR CO., of Boston, Mass., is sending out a little pamphlet giving full information regarding the new Lombard type "F" water wheel governor for regulating all makes of impulse water wheels and small turbines. This consists of a hydraulic piston, which exerts its thrust in either direction, through the mechanism of a rack and quadrant, to a rock shaft which is connected to the nozzle mechanism of the intake flume. The piston is actuated by water under flume pressure, and is of such area and stroke as to develop 5 ft. lb. per foot of head; this is sufficient to control all ordinary impulse wheels.

ADAM COOK'S SONS, 313 West St., New York, are making a liberal proposition to superintendents of motive power having trouble with motors by frequent stoppages, worn out babbitting in bearings, burnt out armatures, etc. They will furnish entirely free of expense, a sufficient quantity of their Albany electric motor compound (a barrel if need be) for a thorough test, confident that the result will prove it to be the ideal lubricant for this valuable class of machinery. The compound can be used on any kind of motor on the market today, and is meeting with splendid success on the electric train of the New York, New Haven & Hartford R. R., running at a speed of 50 miles an hour; also on other electric roads.

THE UNION STEAM PUMP CO., of Battle Creek, Mich., has published its new catalog for 1899-1900, describing its latest types of single valve steam pumps. While the field of a single valve pump is necessarily limited, its desirability under many conditions is evident, as for instance, owing to its ability to work at extremely low pressures, it makes an excellent boiler feeder, enabling the engineer to fill his boiler after the engine has been stopped, without extra fire. In designing the Moore valve movement the aim has been to require the piston to positively make one full stroke before it can recede or make another, thus adapting it to the successful handling of hot water condensations from steam radiating coils of all kinds. A full line of air, vacuum and special pumps of various types are illustrated in the catalog.

THE MORRIS ELECTRIC CO., of New York, has recently closed a contract to supply all the trolley, feed and span wire for the equipment of the lines of the Mexican Electric Tramway Co., Ltd., of the City of Mexico; also for all the ornamental brackets, fittings and appliances for the overhead work. In addition it has received an order from J. & O. Braniff Co., City of Mexico, for 650 ornamental electric light poles, one from the Havana Electric Railway Co., Havana, Cuba, for all the underground and overhead feeder cables and trolley wire to be used on that road, and several orders from the U. S. Government for material to go to

Manila and Cuba. During the month of September this company shipped goods to Africa, Italy, England, Brussels, South America, West Indies and Brazil, and on home orders to Texas, Indiana, Michigan, Alabama, New York, Connecticut and Pennsylvania. In this same month its sales of copper wire amounted to three quarter of a million pounds.

F. C. RANDALL, eastern sales agent for the Christensen Engineering Co., has changed his address from Park Avenue Hotel to No. 154 Arlington Ave., Jersey City, N. J.

THE DEWITT SAND BOX CO. has been formed to make and sell sand boxes and will succeed to the business of E. F. DeWitt & Co., Lansingburgh, N. Y. The company has offices at No. 30 Wall St., New York City.

THE GREEN ENGINEERING CO., 518 Western Union Bldg., Chicago, in addition to the grates for 8,000 h. p. of boilers at the Western Ave. station of the Chicago Union Traction Co., described on another page of this issue, has recently secured the order for 16 grates for the new plant to be built for the United Railway Co., of St. Louis. Other plants where the grates are installed are those of the Metropolitan Street Railway Co., Kansas City; United States Glue Co., Milwaukee; Armour Packing Co., Kansas City; Swift & Co., St. Joseph, Mo.; Brown Building, St. Louis; Cincinnati Edison Co., Cincinnati; Milwaukee Electric Railway & Light Co.

The company not only makes these grates, but contracts for complete power installations. The officers are: W. M. Green, president; John R. Gent, vice-president; P. A. Poppenhusen, treasurer; H. A. Poppenhusen, secretary.

THE WESTERN ELECTRICAL SUPPLY CO., of St. Louis, reports that in no department of its business have the effects of the good times been felt so much as in the street railway department. This branch of the business was added about one year ago, and by good management has so rapidly developed that it has become one of the largest in the country. The line of agencies includes the best known and largest makers in the country. Realizing that prompt shipments are the keystone to success, it stocked up liberally months ago, and now the factories are behind with orders, the advantages of such foresight are evident. The growth of this company during the past year has certainly been phenomenal, and proves conclusively what a combination of strict business integrity, prompt shipments, fair treatment of customers, and systematic and well directed hustling will do. The new catalog is strictly up-to-date, contains a very complete and carefully compiled line of supplies, embracing everything pertaining to the electrical business. The agency has just been taken for the "multiplex" reflector, described elsewhere in this issue. This company's exhibit at the Chicago convention will be made jointly with the Ohio Brass Co., space No. 17.

THE GREEN FUEL ECONOMIZER CO. reports recent sales of Green's economizers for the following plants: Third Avenue Railroad Co., Kingsbridge power station, N. Y., 32,000 h. p.; Swift & Co., Chicago; Botany Worsted Mills, Passaic, N. J., (6th order); Berkshire Cotton Manufacturing Co., Adams, Mass., (2d order); Wamsutta Mills, New Bedford, Mass.; Dominion Cotton Mills, Montreal, P. Q., (14th order); Hargraves Mill, Fall River, Mass.; Great Northern Paper Co., Millensocket, Me. (2 orders), and Madison, Me.; American Thread Co., Holyoke, Mass.; Webster Manufacturing Co., Suncook, N. H.; Societe Nestle, Fulton, N. Y.; American Hard Rubber Co., College Point, N. Y. (2d order); Washington Agricultural College and School of Science, Pullman, Wash.; Richelieu Woolen Mills, Chambley, Canton; New York & Rosendale Cement Co., Rosendale, N. Y.; Worcester City Hospital, Worcester, Mass.; Knoxville, Woolen Mills, Knoxville, Tenn.; Anniston Manufacturing Co., Anniston, Ala.; Revolution Mills, Greensboro, N. C.; Parker Mills No. 2, Warren, R. I.; Woonsocket Machine & Press Co., Woonsocket, R. I.; Metropolitan Water Board, Chestnut Hill Pumping Station, and Spot Pond Pumping Station; Schlichter Jute Cordage Co., Philadelphia, Pa.; Sir W. C. McDonald, Montreal, P. Q.; International Paper Co., Otis Falls, N. Y.; Nashua River Paper Co., East Pepperell, Mass. (2d order); Talbot Mills, North Billerica, Mass.

THE CAST WELD STEEL JOINT.

The Milwaukee Railjoint & Welding Co. has recently designed a new type of its cast weld steel rail joints for the work which it is now doing for the Rochester (N. Y.) Railway Co. The Milwaukee Railjoint & Welding Co. is the pioneer in this type of welding. Its success in welding exposed rail has been such as to excite surprise on the part of railroad men, who had not supposed it was possible to accomplish the result obtained. In 1898 the company welded eight miles of exposed rail between the city of Milwaukee and South Milwaukee. This track has been in constant use ever since, and subjected to the heaviest kind of interurban traffic. The breakage during the winter of 1898 did not amount to 1 per cent. Since the joints were repaired in the spring there had not, up to October 5th, been any further breaks, nor is it expected there will be; neither is there any kinking of the rails. In certain portions of the road slip joints were installed, but in other sections equally long the welding was made continuous, regardless of slip joints. The officers of the company state: "We find by experience that after the track is once adjusted after welding, it does not move a great deal, and there is not much necessity for a slip joint." The track referred to is certainly in first class condition, and will bear the closest inspection. As a result of the manner in which this welding stood the test of extreme temperatures the company received a second contract, for welding 15 miles of suburban track between Milwaukee and Wauwatosa on exposed rails.

Another notable contract is on a line of railway running through the main street of Milwaukee, which is believed to be the finest piece of street railway work and cast welding in the country. This is laid with 72-lb. T-rails on a 6-in. concrete foundation, with concrete between the ties; over this is asphalt paving. It is impossible in riding over this track to discern where the joints occur.

The company has recently arranged with the Calumet, of Chicago, for the latter company to do its own welding, using the steel jackets under license; similar agreements have been made with the Rochester Railway Co., and a road at Columbus, O. The contract now being carried out at Milwaukee with the Milwaukee Electric Railway & Light Co., is for 20,000 joints, which with the work done last year will make a total of 28,000 joints of the cast weld steel process on that road. The headquarters of the Milwaukee Railjoint & Welding Co. are in the Pabst Building, Milwaukee, and the officers are: S. C. Buchan, president; T. C. Buchan, vice-president; E. H. McVickers, secretary, and J. H. Kopmeier, treasurer.

INTERESTING LECTURE DURING CONVENTION.

The Political Economy Club, at the Chicago University, has arranged for a series of valuable lectures, and on October 10th H. F. J. Porter, M. E., of the Bethlehem Steel Co., will lecture on "The Development of the Art of Forging." The hour and place will be announced in the "Daily Review" of October 10th; delegates are invited to attend.

A MILE OF "AD."

The committee in charge of the advertising of the Street Carnival, held at Battle Creek, Mich., Sept. 4 to 9, 1899, hit upon a rather novel scheme for bringing the Carnival prominently before the public. People passing through the business district of Battle Creek Sunday morning, August 27th, were confronted by a poster neatly pasted on the pavement between the car tracks of the main thoroughfare, and stretching away in either direction nearly as far as the eye could see. The advertisement called attention to the principal attractions of the fair.

This huge poster was printed on a roll of paper containing 2,264,000 sq. in. in a continuous strip 35 in. wide and over a mile long. A repetition of the form used was made every 24 in.

According to plans, the new plant of the Richmond (Va.) Electrical Railway and Development Co. will be ready Mar. 1, 1900. Current will be supplied from this station for heating, power, lighting and street railways.

HALF FARES.

Reports state that storage battery cars will be introduced on the San Diego (Cal.) Electric Ry.

The sale of the Sutro Electric Ry., of San Francisco, Cal., was advertised to take place October 6th.

It is expected the first car will run over the recently built Detroit & Northwestern Ry. on December 15th.

The Westinghouse Electric & Manufacturing Co., has declared a regular quarterly dividend of 1¾ per cent on the first preferred stock.

The Pennsylvania R. R. will substitute an electric locomotive for steam service on its branch between Jeffersonville, Ind., and New Albany, Ind.

The Mahoning Valley Electric Ry., of Youngstown, O., on September 7th announced an increase of one cent an hour in the wages of all employes.

The electric railway to connect Ashland, Ky., and Centralia will be completed by December 1st. The road will not be opened for traffic before the early spring.

The General Electric Co. has declared a regular quarterly dividend of 1½ per cent on the common stock, payable October 14th, to stockholders of record October 3d.

The City Pasenger Electric Ry., the Logan Valley Electric Ry., and the Altoona Gas Co., of Altoona Pa., have been purchased by a New York syndicate for $1,000,000.

The Fond du Lac (Wis.) Street Ry. will soon be extended to the northwestern part of that city, in anticipation of the new Wisconsin Central car shops to be located there.

The People's Gas & Electric Light Co., of Defiance (O.), owning also a street railway system, offers tickets at the following prices: Six for 25 cents, 30 for $1.00 and 50 for $1.50.

The electric line from Kalamazoo, Mich., to Battle Creek, which is nearing completion, will be run by power from the water driven plant of the Kalamazoo Valley Electric Co., near Allegan.

Notice has been served by the Highway Commissioners upon the Long Island (N. Y.) Electric Railway Co. that it must pave the highways between its tracks and for a certain distance outside the rails or suffer a revocation of its franchise.

Special theater cars will soon be run at night on the East Taunton (Mass.) Street Ry. to Middleton and Middleboro, Mass., from Taunton, enabling residents of those two cities to attend the theaters at Taunton, instead of going to Boston, as they now have to do, on account of lack of transportation facilities.

Contracts for the construction of a new car barn have been let by the Pueblo (Col.) Electric Street Railway Co. The barn will be of brick, 52 x 140 ft., and will have storage capacity for 24 cars. The company is contemplating an increase in the number of its cars in the near future.

Compressed air as a possible motive power on the lines of the Cincinnati Street Ry., is being investigated by representatives of that company. If the trials now in progress on the 28th and 29th St. lines in New York warrant it one of the divisions in Cincinnati will probably be equipped experimentally with compressed air cars.

The Educational Department of the Harlem Branch Young Men's Christian Association at No. 5 West 125th St., New York, has added to its curriculum a course in electricity. The aim is to make this of practical value to all men who are interested in any branch of electrical work. Forty-eight lectures, illustrated with stereopticon views and practical demonstrations, are included in the course.

A new building, to contain a restaurant and cafe, a shooting gallery and a bowling alley, will be built by the Youngstown (O.) Park & Falls Street Railway Co., at its Terminal Park. The company, it is announced, is about to spend $100,000 in double tracking part of its line, buying new cars and motors and making several other improvements.

Mr. T. M. Ellis, gereral manager of the Rockford (Ill.) Railway, Light & Power Co., advise us that the wages of motormen and conductors, formerly 12½ cents per hour, were on September 1st changed to the following rates: First year, 12½ cents; second year, 13 cents; third year, 13½ cents; fourth and fifth years, 14 cents; after five years, 15 cents.

The promoters of the Jefferson (O.), Burton & Andover Electric R. R. promise to build the road if all the franchises and rights of way are given to them, and in addition $2,000 from each township along the route and $3,000 from each township containing an incorporated village, the money to be paid after the road has been constructed and in operation 90 days.

Some maliciously minded person, probably a discharged employe, badly crippled the service of the Chattanooga (Tenn.) Electric Street Ry. on September 13th by grounding the feed wire in one of the suburbs of the city. The work was evidently done by an expert electrician. President Warner, of the company, has offered $50 for the apprehension of the guilty party or parties.

Newspaper reports from Cleveland state that foreclosure proceedings against the Walker Co., on a claim for $175,000 bonds and $30,000, have been instituted by the Standard Trust Co., of New York. A receiver is asked for. This is said to be the final step in the efforts of the Westinghouse Co. to obtain absolute ownership of the Walker Co., which it now controls.

Two electric lines are being built between Xenia, O., and Dayton, and both have been making an effort to get into Dayton over Main St. On September 11th the Xenia Rapid Transit Co. stole a march on its opponents by having a meeting called and an old franchise which had expired several years ago, revived and renewed. The Dayton & Xenia Traction Co. will contest the legality of the proceedings.

The Birmingham (Ala.) Railway & Electric Co. has acquired the fee of all the properties of the Birmingham Traction Co., including the Highland Ave. steam dummy line of the Highland Ave. & Belt R. R., which was recently purchased by the Traction Co. It is further stated that the present officers of the Railway & Electric Co. will operate the consolidated system without change in personnel.

In order to meet the demands of the increased traffic on its lines, and also to enable it to supply power for the loop, the South Side Elevated Railroad Co., of Chicago, is doubling the capacity of its power station at 40th and State Sts. New Allis engines, two 1,500 kw. Westinghouse generators and Babcock & Wilcox boilers are being installed and will increase the output of the station by 4,800 h. p.

The Joliet (Ill.) Street Railroad Co., in accordance with its annual custom, on September 8th turned the entire street railway system of the city over to ladies, who acted as conductors. The receipts for the day went to the Silver Cross Hospital. Numerous entertainments were arranged by the ladies in different parts of the town to increase the receipts, among them being a baseball game and a band concert.

Cable trains are again running on the State St. line of the Chicago City Railway Co., the first train making the round trip on September 24th. When it became necessary to make extensive repairs at the 21st St. power house in July of this year, it will be remembered the Chicago City Railway Co. applied for and received permission to string temporary wires and operate this line by electricity for 90 days.

EASTERN OFFICE, 100 WILLIAM STREET, NEW YORK.

Entered at the Post Office at Chicago as Second Class Matter.

VOL. IX. NOVEMBER 15, 1899. NO. 11.

We call the attention of our readers to the fact that the "Street Railway Review" is the only paper to publish a verbatim report of the proceedings of the Street Railway Accountants' Association.

Our contemporary, the Street Railway Journal, in its monthly issue for November, attempts to make some reparation for the injustice it did us in its weekly news bulletins of October 14th and 21st, both of which carried announcements on the first page in display type that the first verbatim report of the convention would appear in its monthly isssue of November 1st. We are disposed to overlook the first announcement, but not the second, bearing date one day after the meeting had adjourned, and after the "Review" had issued five dailies, containing not only a verbatim report of both the American and Accountants' meetings the previous day, but all the other doings of the day previous. These dailies were not inaccurate, as our contemporary insinuates, and we shall be pleased to have our readers compare the Journal's report (12 days after the convention adjourned) with our report day by day.

Speaking of "inaccuracies" the shoe is decidedly on the other foot, for this same "news" bulletin, dated October 21st, takes the convention on a trip of inspection to the Alley L power plant and to the Chicago & Milwaukee road on Tuesday afternoon, October 17th. The trip to the elevated station did not occur until Friday afternoon, and the other, while talked of, did not take place at all. Mr. Kilgour is made to read a paper on Wednesday (three days previous), when in fact he not only was not present at any time during the convention, but did not send in any paper, and the subject was not discussed. This shows the danger of writing advance accounts of events scheduled on a program which is liable to change before the program has been carried out.

Every morning at daylight from Tuesday to Saturday inclusive, the "Daily Review" came out with an absolutely complete report of everything which transpired up to midnight of the previous day. The "Daily Review" also printed on Wednesday the name of every person registered on Tuesday. To copy and classify these names required the work of six persons for nearly six hours; on Thursday the Wednesday registrations were printed, making a list far more complete and much larger than has ever been previously printed. Our issue of Saturday morning gave the banquet toasts which ended at midnight Friday. To do this we employed a force of six expert stenographers and transcribers, whose work was completed in a few minutes after the last speaker had finished his remarks. Our same issue contained photographic illustrations of the exhibits, with descriptions, and made absolutely a complete history of the convention, leaving nothing unreported.

In reporting the Accountants' meetings we printed 12 pages of stenographic report, exclusive of the papers and reports read, as against five pages of long hand notes in the Journal. Our pages, moreover, were in brevier type, which measures 20 per cent more matter than that used in the Journal's long primer account.

The "Review" is not given to boasting of its own work, but after publishing what every one concedes to be the most complete and accurate convention daily ever issued by a trade journal, it does not believe the street railway fraternity will approve of this glaring mis-statement of fact by another paper in its frantic attempt to excuse its own lack of enterprise.

The treatment of employes with a view of increasing their efficiency and creating a spirit of loyalty and good will, is a question that is forcing itself more and more upon the attention of managers, and has received a new impetus by the paper bearing on this subject read before the Street Railway Association of the State of New York, at the Ithaca convention, and printed in the September issue of the "Review." As is usual with questions of this character, there is a diversity of opinion among managers as to the need of efforts in this direction, and also as to the method to be followed in securing better results where it is admitted that some means is desirable for decreasing accidents, increasing patronage and lessening the liabilities of so-called labor troubles. The paper in question treated the subject under five heads. But as there are only three of these heads, about which there could be any difference of opinion, it will suffice for the purpose of this discussion to quote these only. No. 3 reads: "By giving the men a careful education in the duties which they are to perform." No. 4: "By handling employes in such a way that they will feel that they are being treated as men and that they will not lose their loyalty to the company and to their immediate superiors on account of harsh and unjust treatment." No. 5: "By making them feel that intelligent service, loyalty to the company and a good record gives them a chance for promotion to a better position."

As to the first proposition, it is held by some, and the statement was boldly made in one of the papers read at the recent Chicago convention of the American Street Railway Association, "That the best motormen are often men who can neither read nor write and are found among teamsters, drivers on horse railways and the like." Again in the same paper, "The semi-technical man who is 'learning the business' makes the worst motormen of all; his mind is more active, he is interested in the performance of his motors and equipment and neglectful of his primary duties as a motorman. Moreover, he is a dissatisfied individual * * * not inclined to learn the business of motorman thoroughly."

Knowledge is power, but this must be coupled with a knowledge of one's own power and a knowledge of the governing laws of thought and how to apply them. It is difficult to understand why, if knowledge is power to do efficiently whatever one has to do, that the calling of a motorman should be an exception to this rule or principle. It is not usually claimed by the advocates of giving these employes a careful education as to their duty, and an explanation of the machines they are required to handle that it necessarily implies that they should be thinking more of the machine than their immediate duties on the street, or that they should attempt to remedy slight defects or attempt the adjustment or repair of the equipment while en route. In fact, the best trained motormen are not usually expected to do this. These things are left for men specially assigned to the work, properly clothed and equipped with the necessary tools. But the motorman cannot be too well instructed as to the handling of his car and apparatus by a careful and competent teacher. There is such a thing as not carrying these instructions far enough; in which case a little learning is a dangerous thing. But the question is one of thorough instruction, and if it is found that a motorman, whether thoroughly instructed or ignorant, is a "dissatisfied individual" it is prima facia evidence that he is not a proper person to handle the car, for his mind will go "wool gathering" and he will invite accidents and mishaps. Dissatisfaction, coupled with anxiety or fear of any kind will never produce a cool head to act wisely in any crisis. The failure of so-called semi-technical men as motormen is not that they know too much about the equipment, but that they are left to work their mental batteries the wrong way, and have not received proper instruction how to concentrate their thoughts and hold their attention to the thing in hand.

When a manager realizes that there are inherent potentialities in every man and that proper training will bring them out, he will find in his own hands the possibility of greater power and greater success. One's standard of so-called success with ignorant employes often blinds him to the fact that there was a greater and broader success which he failed to reach. The time has come when the laws and rules of success which have been known to a few who have been prepared for them, are now safe in the hands of the many. There is the dawn of a new cycle which will wrench from the grasp of ignorance the victims of its stultifying influence. A manager's success and that of his employes will hereafter be measured by the degree in which he avails himself of the power to think correctly and quickly.

Subjects 4 and 5 will receive attention in a subsequent article.

In the title of Mr. Yerkes' paper on street railway investments two questions were propounded. The first, how can they be made remunerative, was very briefly answered by saying that the matter lay with the management; the management of a street railway can exercise but little control over the receipts of the company and remuneration for the investors must be secured by economy of administration. The second question, how can street railway investments be made secure, was discussed at greater length. The author stated that the security of the investment depended more upon the term of the charter than anything else, and after comparing the cost of the horse car line, that received a 20-year grant from the city, with the electric railway of today, drew the conclusion that if the 20-year grant to the former was equitable then the latter should have a 200-year grant. To the objection that long-term grants would be bad policy, because preventing improvements in the means of transportation, it is answered that improved means of transportation would of themselves make the older franchises worthless. Mr. Yerkes believes that cities and companies should treat each other fairly; that street railways should pay a portion of their earnings to the city in return for the license to do business, and that they should be under the general supervision of commissioners appointed by the governor and holding office for a long term, say 15 years, so as to take them out of politics.

The proposition that the municipality should receive a portion of the earnings of the street railways located within it is one which will not be unanimously accepted by street railway men. It is an acknowledged principle that the consumer should in every case have some of the benefit which results from improved and cheaper methods of production, and in most fields this is obtained through the natural competition of the producers. The legislators of many of our states long supposed that competing street railways would give better service at lower fares, just as rival grocery stores make lower prices for provisions. While this idea is not entirely eradicated—Georgia still believes in it—it is now generally recognized that such things as supplying the public of a city with water, light, or transportation are natural monopolies. That is, the business can be done best and cheapest by a single company. The result has been that a demand has grown up for street railways to pave and light and clean the streets through which they run, for a percentage of the receipts to be paid the city, or for the municipal ownership of the industry.

The business, however, is one in which the local conditions have a most important bearing, and what would be reasonable in one city of say 100,000 inhabitants might be not only unjust, but physically impossible in another city of the same size. The volume of business carried is by no means the same in two cities of equal population, and the cost of fuel and labor is far from uniform.

When a permanent type of mechanical power is reached and it is no longer necessary to discard costly apparatus, not because it has worn out, but because improvements have displaced it, stockholders will be relieved of the large financial risk that, until then, must inevitably hang over their investments in street railway properties. Then, as construction is devised which will be of a much more permanent nature than has marked the history of track work until now, and with a definite limitation to construction and operating expense for a term of years, companies will be in position to share their earnings with the city, as few of them at present are warranted in doing. But even then, we are firmly of the opinion that that money, instead of being paid into the

city treasury, to be frequently squandered by politicians, should be used in improving and enlarging the car service. In this way only will those who have actually paid this money into the companies receive any direct benefit. The reduction in taxes to those wealthy citizens who use the cars seldom or not at all, is of vastly less importance than to increase the length of the ride that the workingman shall receive for a single fare, or the purchase and operation of additional cars, which otherwise would be run at a loss, hence not at all. The street car has emancipated the working people from tenement house life and has changed the social condition of hundreds of thousands. How much better that this work should be extended and enlarged than that a few millionaires should pay a few hundred dollars less tax than at present.

The care of the car equipment of a street railway involves a multitude of details, and as there is a best or a cheapest way of handling each one of these, men having charge of that department always find an interchange of ideas on the subject both interesting and profitable. This was well shown at the convention by the discussion which followed Mr. Vanderveer's paper on this subject. Everyone who spoke told of methods employed on his road whereby a saving of 25 per cent or of 50 per cent had been made in items of repair or maintenance of equipment, and the ideas developed undoubtedly furnished much food for thought. There has heretofore been no department of a street railway which has received more attention with a view to inaugurating economies than the power house. The results have well repaid the thought and labor expended, and it is now beginning to be recognized that the shops and car inspection department will also repay similar attention.

The subject of track construction and maintenance is not a new one before the Association, and in connection with Mr. Butts' paper it is rather interesting to review the recommendations that have at various times been made concerning this very important portion of a street railway. In 1883 it was believed that a track laid "with 40 or 45-lb. tram rails well spiked to stringers with good cast or wrought iron joint-plates at the ends of the rails" would fulfill all requirements. A year later the report adopted by the Association recommended, for heavy traffic, 60-lb. center bearing rails spiked to stringers which were laid on ties spaced 5 ft. between centers, with cast iron knees both outside and inside the stringers at each tie. In 1887 a report was presented which reviewed the history of the two types of construction, stringer and girder; the conclusion was that a rail weighing 55 lb. or 60 lb. per yard, supported by chairs on ties 4 ft. apart and having fish plate joints would be stiff enough to answer all purposes.

In 1892 the subject became more important than ever, and a report on "A Model Electric Railway Roadbed" recommended that the ties be placed about 27 in. apart, that the rail be deep enough to dispense with chairs, and that three-tie, six-hole fish plate joints be used. In 1896 the recommendation of a report on "Track and Track Joints" was for white oak ties 5 x 8 in. x 7 ft. spaced about 30 in. and 9-in. girder rails, held to gage by tie-rods spaced 6 ft. apart, with the joints cast-welded.

When this brief summary of what has been, at various times in the last 16 years, considered the best construction for street railway tracks is compared with that presented by Mr. Butts the changes are very marked. From the 40-lb. or 45-lb. rail of 1883 to the 80-lb. or 100-lb. rail of 1899 is a long step; from timber stringers to concrete beams surrounding the lower flanges and web of the rail is another, but the substitution of a cast-weld joint for the plate under the rail ends is probably the greatest difference, the other changes being in degree rather than in principle.

Mr. Butts agrees with all others who have previously presented reports on this subject to the Association, in advocating the center-bearing rail, but his road is one of the very few that are permitted to use this section. In most cities the municipal authorities prescribe either a tram or a groove rail.

The discussion on this paper brought out statements by a number of members concerning their experience with ties of different materials, rails of different sections, cast-weld joints and other points.

All the problems connected with a street railway do not lie in one department, and after the Association had considered the questions of investments, of equipment, and of track, Mr. McCormack read his paper on train service. He pointed out that a well arranged train service is essential to the commercial success of a street railway, and then entered at length into the ways and means of getting information concerning the conditions of the traffic, and then of meeting these conditions satisfactorily. Mr. McCormack treated his subject at greater length than any of the others who presented papers, and illustrated by concrete examples the application of the methods described and the results accomplished.

After having accomplished a task which he has undertaken a business man first wants to know what the results have been from a financial standpoint; then, having found what he has done or is doing, absolutely, he naturally wishes to know what the relative results are, that is to compare his work with that of others who are engaged in the same business. To get these absolute and comparative results, expressed in dollars and cents, is a part of the work of the accountant.

In the street railway field the wide variety obtaining in the methods of distributing different items of expense was such that one road given the monthly statement of another could tell but little about it, and comparisons were impossible. This led the Street Railway Accountants' Association to take up as its first work the development of a standard system of accounts according to which expenditures would be divided according to a uniform system. With the endorsement of the Railroad Commissioners given last August to the Accountants' "Standard System" this part of the Association's work may be said to be practically accomplished.

But assuming that in a short time all companies will keep their accounts in the same manner, the conditions under which they operate are so different that a comparison of results is difficult because there is no unit upon which accountants can agree as being a suitable basis of comparison.

Mr. Mackay presented the only paper read before the Accountants' Association at its last convention and advocated the "motor car-hour" as the most desirable unit for comparing performances, and particularly urged its superiority over the "car-mile." The lengthy and animated

discussion which followed showed the subject to be a very live one, and that the selection of a unit for comparisons is a work which the Association will do well to take up.

It is evident that the engineering trade of Great Britain and the Continent is now thoroughly aroused to the fact that something must be done and done quickly if American competition is to be met and overcome before it is too late. British and European firms have stood idly by and seemingly without much concern, have watched contract after contract go to American bidders, and have made no effort to determine why home establishments could not successfully meet this competition. But this apathy is rapidly developing into vigorous protestations against this condition of things, as is evidenced by the storm of disapproval raised at the letting of recent London and Glasgow tramway contracts and the building of the Atbara bridge in the Soudan by an American firm.

The foreign technical press is also awakening to a recognition of the conditions and in long, well-worded editorials is sounding its "note of warning." But it is almost amusing to see the different ways in which the various journals have sized up the situation. A few of them still persist in raising the feeble cry of favoritism, "outside influences" and lack of patriotism, and absolutely refuse to see that contracts for structural work, engines, electrical apparatus and tramway supplies are going to America, simply because American contractors can give better quality in shorter time and at cheaper prices. Of these no account need be taken.

But there is another class of papers which have succeeded in taking a broader view and whose opinions are worthy of consideration. Among these is Engineering, of London, and to show the real grounds upon which the coming battle will probably be fought we quote the following from an editorial in a recent issue of that journal:

"No industrial question at the present time has so keen an interest to British manufacturers as that connected with American competition. It has been brought prominently into public notice on more than one occasion during the last six months, but for several years past our manufacturers, merchants, and shippers have been unable to close their eyes to the fact that since the United States have recovered from the effects of the great panic of 1893, they have steadily become more dangerous antagonists, not only in this country (Great Britain), but in foreign markets, and especially in those markets which we have been accustomed to regard as our own. It is still urged by not a few persons that this competition is factitious; that in order to take away our customers, goods are supplied by enterprising Americans at a loss; that the articles forced on the markets of the world in preference to our own, are of inferior quality, and will not stand the test of time and use, and that the spurious phase of manufacture and commerce is but transient. But those who are able to take a broader view know that such statements are fallacious; they know that in many manufactured products the United States can beat us in price, and at least equal us in quality; they know that at present, and still more in the near future, the struggle of competition will grow keener, and that the advantages of this struggle do not lie with us." And again; "The manufacturers of Great Britain must either adopt new methods to cheapen production and increase the rapidity of the output or they must be content to see orders given wholesale to foreign contractors with whom they cannot hope to compete."

But in our opinion there is no great need of worry on the part of American manufacturers. The situation is one requiring simply watchfulness and a continuation of present efforts. Although foreign dealers may begin to recognize their deficiencies, it will take them years to bring their plants and their methods to such a state of perfection as to enable them to stem the tide of orders that is moving toward this country. At any rate this is not the first time that American pluck and genius have been pitted against the whole world, and there has never been but one result.

NEW INTERURBAN ROAD IN PENNSYLVANIA.

The Bethlehem (Pa.) & Nazareth Passenger Railway Co., which commenced operation on October 2d was incorporated at Harrisburg Feb. 6, 1899, with $150,000 capital stock. This is a single track road, with six turnouts running from Bethlehem to Nazareth, a distance of 10 miles, and is one of the best constructed roads in the state. The track is laid with 67-lb. T rails, furnished by the Scranton Steel Co., and is rock ballasted throughout.

The power house is built of brick 50 x 95 ft., with a slate roof. E. Keeler & Co., of Williamsport, as contractors, supplied all the machines for the station, consisting of two Hamilton-Corliss 300-h. p. engines, two 200-kw. Westinghouse generators, and three 500-h. p. boilers. The car barn is not yet completed, but will be 50 x 200 ft., and will contain space for storing 27 cars and 2 snow plows, a repair shop and machine shop. Five motor cars, built by the American Car Co., of St. Louis, will be operated for the present.

The officers of the company are: President, J. J. McKee; secretary, Robert B. Keys; treasurer, C. A. Wolle; superintendent, George H. Wolle.

TRAMWAYS OF BOMBAY, INDIA,

Wm. T. Fee, U. S. consul at Bombay, writing to the department under recent date gives the following report on the street car system of that city:

The company was chartered by the Bombay government in 1874, under the name of the Bombay Tramway Co., Limited. It has an invested capital stock of 30 lakhs of rupees, or about $1,000,000, and debentures of about two-thirds that amount. The stock is principally owned in the United States, and its main office is located in New York City. The road is a double track system, with about 17½ miles in operation.

It has in use 187 open cars, made by the company in Bombay. It employs 1,150 horses, each of which travels on an average 13 miles daily. They are well cared for and never abused, a sort of a hat or padded bonnet being fastened on top of their heads during the day as a protection against the sun. All animals, in fact, receive humane treatment in India.

About 1,100 men are employed by the company. The car drivers and conductors are paid by the trip, and the former receive about 18 rupees ($5.85) and the later 22 rupees ($7.15) per month. The track, barn, and common laborers receive the usual Bombay wages of 6 annas (12 cents) per day.

The rails are of the girder type, 30 ft. long and weighing 83 lb. per yard. They are laid on teak-wood ties and bedded in concrete. The road was opened to traffic in 1874, and its present cost is estimated at about 35,000 rupees per mile of single track. The total gross receipts of the road for the last financial year were $398,498 and the operation expenses during the same year were $257,821.

There is now a movement to convert the road into an electric line. In fact, the company has applied to the Bombay government to sanction the conversion. Electricity has but recently come into use in India, Madras being the only city where it is used on street railways as a motive power.

The Pittsfield (Mass.) Street Railway Co. has been notified to place one cent revenue stamp on all packages carried between Pittsfield and Dalton for its patrons. The company claims such service is in no sense that of an express company and has referred the matter to the department at Washington, D. C.

PRICE OF RAILS STRONG.

One of the questions which is disturbing managers is the immediate future of the rail market. It is understood that recently the rolling mills combined and notified the steam roads that immediate orders would be taken at $33 per ton, to be followed by an advance in price. It is given out that under this offer 1,500,000 tons were placed, amounting in value to nearly $50,000,000. This is about one-sixth of the entire possible output of steel for the next 12 months. The demand for structural iron shows no indications of decrease, which will further tend to strengthen prices. The necessities of the Russian Government in its railroad work will still further curtail the supply. As predicted, the mills have now advanced the price of T-rails two and three dollars per ton, and this of course governs the selling price of girders.

Many have held off in placing orders for next season's requirements, hoping there would be better prices available, but the present indications certainly do not favor any such good fortune for the buyers. Prices may not advance during the next 60 or 90 days, but we fail to note any indications that they will be any less.

We know of several companies which have extensions in contemplation, which have concluded to postpone the work another year, owing to the high price of steel and copper.

In this connection we also note the marked advance in price of motors and cars, but the demand is certainly sufficient to keep the factories running full time or better, hence no reductions can be looked for here. In fact, companies having necessities in these lines for next summer should lose no time in placing orders, for not only are prices certain to suffer no decrease, but as spring approaches it will be more and more difficult to count on prompt delivery. After December 15th every day's delay in placing order is likely to cause disappointment when the summer riding begins.

ANNUAL REPORT MONTREAL STREET RY.

The report of the Montreal Street Railway Co., a copy of which has been sent us by Mr. W. G. Ross, comptroller, for the year ending Sept. 30, 1899, shows the following results:

	1899	1898	1897	1896	1895	1894	1893	1892
Gross Receipts	$1,660,775.63	$1,471,636.65	$1,342,961.78	$1,265,505.29	$1,102,777.87	$896,090.59	$730,751.76	$544,106.61
Increase 1899 over 1898 12.85%	188,836.98							
Operating Expenses	912,849.06	768,584.55	730,423.60	710,544.70	652,911.74	637,068.14	593,041.71	465,647.99
Increase 1899 over 1898..18.56%	143,065.51							
Operating Expenses Per cent. of Car Earnings	55.23	52.14	54.66	56.48	59.20	71.16	78.00	82.68
Net Earnings	747,926.27	707,055.50	605,939.18	555,033.89	449,965.33	259,472.75	137,710.05	97,761.16
Increase 1899 over 1898 5.77%	40,770.63							
Net Income per cent. of Capital	13.16	15.00	12.41	11.56	10.21	8.00	6.17	
Passengers Carried	40,186,463	35,353,036	32,047,317	29,050,471	25,077,258	20,668,01[illegible]	17,127,9[illegible]	11,631,5[illegible]
Increase 1899 over 1898 13.67%	4,833,427							
Transfers	11,060,857	10,508,608	6,705,903	6,341,680	7,053,670	6,929,653	5,994,112	

The company's rolling stock has been increased since the last report by the addition of 64 closed motor cars, 100 open motor cars, 1 pay car and 12 electric sweepers, and there are under construction 36 closed motor cars. Large additions to the repair shops and car barns have been built.

During the year the company has paid to the city of Montreal the following amounts: Taxes on earnings, $70,811.42; on account of snow clearing, $60,456.; real estate and business taxes, $8,832.13, making a total of $140,099.55.

The Detroit (Mich.) Plymouth & Northville Ry., has been opened for traffic.

The Chicago Union Traction Co. has made a number of important changes in transfer arrangements, and the sale of tickets, as the result of several petitions presented by interested citizens.

ALUMINUM FEEDER CABLES ON THE NORTHWESTERN ELEVATED.

Although aluminum has been used for some time as a substitute for copper in the transmission of high voltages over long distances and in telephone and telegraph work, its first application to a direct feeder system is now being made on the Northwestern Elevated in Chicago. The Northwestern will be operated on the third rail system, the third rail conductor being fed from [illegible] in aluminum feeder cables, of which there will be more than 20 miles used. The cables are carried in a wooden trough between the up and down tracks, and are supported on vitrified clay insulators.

One of the chief drawbacks in the use of aluminum has been the difficulty of soldering or brazing joints, owing to the film of oxide always found on the surface of the metal and to its high heat conductivity. This obstacle has seemingly been overcome by the invention of a solder which forms a perfect amalgamation with aluminum, and makes a joint with a trifle higher conductivity than the cable itself. This solder is a secret composition, the parts of which are known only to the inventor, Henry Gronmu[illegible], of 9 Re[illegible] St., Chicago, who is making all the joints in the aluminum cables on the Northwestern structure.

The process of forming a joint is as follows: The ends of the cables are brought up into a movable canvas shanty, that can be erected in a few minutes at any desired point on the structure, and which shields the cable ends from the cold air and wind. It is found that by taking this precaution the joint can be made in about one-third the time. The ends of the cable are covered with fire clay and fluxed with a composition that is also kept a secret, after which they are brought to a white heat, or about 650 or 700° F. by means of gasoline brazers. A copper sleeve 6 in. long tinned on the inside and with an inside bore a trifle larger than the cables, is next slipped over the two ends and through a pour-hole left for the purpose, the melted solder is poured into the sleeve, finding its way between the strands of aluminum and making one solid piece of the copper, the solder and the aluminum. The joint has a conductivity of about 64 per cent and the aluminum cable about 62 per cent of that of fine copper. As copper is practically three and one-third times heavier and at present prices costs about 18 cents a lb., the saving in the use of aluminum at 29 cents a lb. is evident. The relative values of copper and aluminum as conductors for electricity will be found fully explained in the "Street Railway Review" for Mar. 15, 1899, page 157.

RAILWAY PROJECTS IN BERLIN.

The city of Berlin, Germany, is experiencing an unusual degree of activity in the construction and operation of street railways, which is described by D. B. Macgowan, correspondent of the Chicago Tribune, as so extensive that the city might easily be mistaken by a visitor for a street railway experimental station. Ten large systems are either in operation or under construction in that city. These are (1) the overhead "Ringbahn" constructed of brick, stone and iron, making a double loop around the outside and through the center of the city, (2) an elevated railway of steel construction nearing completion which will connect the eastern with the western suburbs, (3) a surface road on the underground trolley system, (4) an extensive system of horse, trolley and storage battery lines, (5) a storage battery line to Charlottenburg, (6) a surface steam railway in the western part of the city and suburbs, (7) a number of independent electric roads, one of which is being extended to Pottsdam, a distance of 20 miles, (8) horse and electric omnibuses and Siemens & Halske combination storage battery omnibus and trolley car, (9) a tunnel road connecting two suburbs separated by the Spree River, and which is to be extended, and (10) a complete system of underground railways which the city is planning to connect the railroad depots which are not situated on the Ringbahn loops. This will be an extensive system penetrating the most populous and busiest sections of the city.

The Newtown (Pa.) Electric Street Railway Co., was the victim of trolley wire thieves on October 16th. Over 1,500 ft. of the line between Newtown and Langhorne was torn down and stolen, completely disabling the road for several hours.

PENNSYLVANIA STATE CONVENTION.

The annual meeting of the Pennsylvania Street Railway Association was held in Lancaster on October 11th and 12th. The three papers read were: "Car Tracks," by W. H. Huelings, jr., of the J. G. Brill Co.; "The Electric Railway Engine of Today," by W. P. Mackenzie, of the Harrisburg Foundry & Machine Works; and "Track Construction Used in Scranton, Pa.," by Frank Silliman, jr., general manager of the Scranton Railway Co.

Officers elected for the ensuing year were as follows: President, W. B. Given, of the Pennsylvania Traction Co., Lancaster; first vice-president, E. C. Felton, of the Harrisburg Traction Co., Harrisburg; second vice-president, E. H. Davis, of the Williamsport Passenger Street Railway Co., Williamsport; treasurer, W. H. Lanius, of the York Street Railway Co.; secretary, S. P. Light, of the Lebanon Valley Traction Co.; executive committee, W. B. Given, Frank Silliman, jr., S. P. Light, W. H. Lanius, John A. Rigg.

The next meeting will be in Pittsburg, the third Wednesday in September, 1900.

CAR TRUCKS.

Read at the Eighth Annual Meeting of the Pennsylvania Street Railway Association, Lancaster, Pa., Oct. 11-12, 1899, by W. H. Heulings, jr., of the J. G. Brill Co.

After the electrical power equipment of a street railway has been placed in satisfactory condition, its engines and boilers, roadbed and track brought up-to-date, the keynote of its successful operation is to be found in the trucks upon which its cars are carried. I am aware that this is a broad and somewhat surprising statement. I think, however, it is capable of demonstration. While I may not be able to make a conclusive proof of it, I think it is possible to make a very strong case in favor of the truck as a controlling element in the durability of the track, the roadbed and the car bodies themselves. At the same time the truck has very much to do with increasing or discouraging pleasure riding at times when the ordinary traffic is at a minimum.

Short and comparatively light car bodies if mounted upon rough riding trucks which pitch and gallop constantly will pound to pieces the best roadbed and twist and bend the heaviest rails more or less out of shape. This result can be accomplished in a surprisingly short time. I could cite instances where such a result has been reached within two or two and a half years. It has happened also upon roads where only moderate speeds were used and where the car bodies were quite small.

W. H. HUELINGS, JR.

The first electric truck introduced upon street railways was of the four-wheel non-pivotal pattern. Its simplicity and convenience seemed to meet every requirement of the street railway men. It was quite in line with the horse car practice which preceded it, and it was accepted as the natural development of the old horse car. Of this four-wheel type of truck more are now in service than of any other. After going through an extremely rapid development which brought out numerous modifications, a standard form was reached which has proved itself fairly soft on the rails, easy on the car body and comfortable for passengers. Its features are, or should be, a solid side frame, preferably forged, making each wheel piece a single bar. The two wheel pieces connected by heavy end irons are carried upon palms forged on the ends of the wheel pieces. The ideal frame for the purpose would, of course, have both ends and side pieces in one piece without a joint. The expense of such a construction, however, has been found to preclude its use, although the cost of the frame in one piece is but little greater than that of the composite type. Either of these frames gives a positive alinement to the wheels and axles and makes the truck what it should be, a self-contained motor vehicle. It possesses ample strength and stiffness to carry the machinery and has enough vertical strength to make it well fitted to carry by means of springs the body of the carriage in which the passengers are contained. The truck of an electric car has a double function. It is both carriage and locomotive. It is self-propelled and in most cases is fitted to haul a trailer when necessary. It has also to perform the function of a carriage, that is, to support the car body easily and while carrying it prevent the passengers from feeling those irregularities of motion which are set up even on the best tracks. The arrangement of what may be called the carrying springs, to which the easy riding of the body is due, is but little understood and the violent pitching and galloping, for which four-wheel cars are notorious, is largely due to ignorance in regard to the work which different forms of springs are fitted to perform. It is perfectly easy, by a slight change in the arrangement of the springs beneath the car body to make it gallop persistently even on a good track. On the ordinary or poor tracks such an arrangement would set the car "teetering" until standing in it would become practically impossible.

The standard four-wheel truck which is known to the world as the Brill 21-E has eight journal box springs. This is double the number usually employed. The advantage gained by increasing the number is found in the great steadying power obtained by having a spring on each side of the journal box instead of a single spring on top and in softening the work of each spring. Not only is the box held steadily without friction or canting in the jaw, but the large number of springs carry the truck frame smoothly, and an advantage is gained inasmuch as two springs accomplish easier motion than a single spring of nearly the same height and the car body can with double journal springs under the frame between it and the journal boxes be rested at a lower height relatively to the rails. It therefore starts by making the locomotive itself easy riding and low in weight. Upon the solid frame of the locomotive are placed the springs which carry the body of the car. These are so disposed that the body receives practically equal support from end to end. To carry the load, the outer ends of the wheel pieces are made with a large and sufficient factor of safety. The outer springs are half elliptics, while those at each side of the jaws are helical springs. This combination has been adopted because it reduces the galloping or pitching motion to a minimum. With such a combination it is almost impossible to set up a continuous galloping motion. The riding is in fact as smooth as is possible with a four-wheel truck.

The records of the Patent Office show that there have been almost numberless endeavors among inventors to devise a truck for four-wheel cars which will possess the feature of equalization. This word, while not quite exact, has come to have a definite meaning among railway men. When applied to a truck it means that the load upon each wheel remains constant even when the wheels are standing or running over very irregular surfaces. The aim of the inventors has been to make a four-wheel car and truck in such a way that the load upon any one wheel would never vary. This has been accomplished but the result has been far from satisfactory. The four-wheel equalized cars have been found to ride extremely hard. In all cases that have come under my observation their pounding while in operation has been so severe as to prohibit their use. With the ordinary construction the fatal defect of the four-wheel car is that when an irregularity occurs in the track, such as a loose or defective joint, nearly the whole weight of the car is instantly concentrated upon two wheels whenever the wheel passes over this low point. Concentration of load takes place instantly upon diagonally opposite wheels. As the car passes forward the load changes its corners. At each change a severe blow is struck upon the rails and there is usually a distinct tendency to a side motion. This ultimately bends the rail so that the joints are thrown outward, each rail becoming slightly convex toward the centre of the track. Where rails are laid to break joints over a private right-of-way, where there are no passing teams, this pounding of the car upon the track is sometimes very forcibly illustrated. Opposite each joint will be found in the center of the rail a depression caused by the blow which the load strikes when the wheel dropping at the joint, shirks its work and throws the load upon the diagonally opposite wheels. In going down the wheel strikes the rail a severe and sharp blow out of proportion to the weight as it is forced down by the spring after the fashion of a hammer.

Any irregularity in the wear of the wheels under four-wheel cars introduces another and very serious cause of destruction to the rails, which aggravates that just mentioned. This irregular wear results in the car "hunting" when in motion. That is, it is constantly

"weaving" from side to side and strikes an outward blow at every joint. In the old fashioned horse car this motion ultimately resulted in the destruction of the track. I know it is the fashion to say that the rails are distorted and destroyed by the heavy trucking that goes over them. This is nonsense. It only requires the most superficial observation to show that with their large wheels, long springs and easy motion that the heaviest trucks as they move on the rails are never as destructive as the defective four-wheel truck. It must be remembered that a wagon having a fifth wheel is perfectly equalized, and in passing over such inequalities as a low joint its load is not concentrated upon a single pair of wheels. The two-horse street car with its four to six miles an hour could easily destroy the rails of its day, and the lightest electric cars when mounted on four wheels and running at the slowest speeds which are found profitable in electric railway work can and do ruin 90-lb. girder rails in a length of time which is altogether too surprisingly short for the profits of the company.

It may be considered heresy to make such a statement, but in spite of that, I doubt whether four-wheel cars are suitable for any service on modern street railways. I cannot conceive how a road which has a small income can afford to have its roadbed and rails destroyed by four-wheel cars. Even in the smaller towns and cities larger units than can be carried on four wheels are found to be profitable. Well substantiated figures from both steam and street railway engineers point to the fact that the cost of propulsion by steam or electricity varies with the number of units rather than with their size and is practically independent of the load carried. The larger the street car the greater number of passengers can be handled with a single crew, and the higher the speed the smaller number of cars required for a given service or for a given headway. For profitable operation speed is indispensable to the street railway. The four-wheel car, whether it be of large size or small, should not be run at a high speed, because the destructive power of the car increases in proportion to the square of the speed. I think I have said enough to make a strong case against the four-wheel car, and certainly sufficient to prove that the wrong kind of truck driven at the wrong speed can pile up an uncomfortable repair account.

In city and suburban service high speeds are indispensable, and a large tractive force is necessary. Here long cars are also required, and the maximum-traction truck appears to give the greatest satisfaction. In 1896 Mr. Darlington in an address before the Street Railway Association of Pennsylvania took the ground that the maximum-traction trucks were not wanted for service of this kind, that their friction was greater than with four-motor cars and that the maximum-traction trucks were "Practically no better than were the light wheels made the same size as those carrying the motor and the weight of the car placed centrally over the truck." Looking back now at Mr. Darlington's remarks it is easy to say that he was mistaken in his statement of facts as well as in his deductions. Careful experiments have proved that the maximum-traction car requires no more power for its operation than the four-wheel car. To fortify this assertion I will cite an instance undoubtedly of interest. In 1894 the New Orleans Traction Co. contracted with the Louisiana Electric Light Co. to furnish power for its cars at a given rate per car per day. The fact of the Traction company introducing maximum-traction truck cars was the foundation for litigation brought by the Light company, claiming more compensation to cover the increased consumption of electricity. The Traction company's engineer, B. Willard, and the Light company's engineer, J. B. Craven, selected Walter H. Knight, then of the General Electric Co., as the third of a committee to conduct a series of tests. Their report was: "We cannot find that the 22-ft. cars on maximum-traction trucks consume any more power than the ordinary 18-ft. car bodies on single four-wheeled trucks, such as used on some of the New Orleans Traction Co's. lines." Experiments by the Consolidated Traction Co., of Jersey City, showed that the repairs to motors and trucks varied directly as the number of motors and was independent of their size, that the eight-wheel car had a repair account practically twice as large as that of the four-wheel cars. Now the maximum-traction truck gives two motors to the car. It carries a long and heavier car body and without increasing the weight of the driving wheels over the weight on the wheels of a four-wheeled car, yet it allows the whole weight of the car body to be increased by one-third. At the same time it has ample traction for the most rapid running. I may allude to the Washington, Alexandria & Mount Vernon line where maximum-traction trucks are habitually run at a speed of 40 miles per hour. The advantage of this truck over those with four wheels of equal size with either one or two motors per truck, is that the car can be brought so low that a single step of the usual height gives access to the platforms. This cannot be done with the four wheels of equal size. Increasing the height of the step or increasing the number of steps increases the danger of accident and decreases the speed of the car and consequently its earning power. The maximum traction truck can be successfully used beneath open cars as well as closed. This simplifies the equipment and reduces its cost. Four wheels of equal size, unless the car body is made of great width cannot be used under open cars. Even then the height of the step becomes objectionable. Referring again to speed, I may say that they are capable of anything allowable on street railways. In fact it may be of interest to know that the road which makes the greatest daily mileage of any in the country uses maximum-traction trucks. From this and the previous reference it is evident that the maximum-traction trucks, properly arranged, are up to any possible speed requirements of the ordinary city and suburban traffic. They can run around curves of the shortest radii. They have a tractive force which makes them favorites with the motormen during the winter snows, as is evidenced by the remarks frequently heard in the car barn on the eve of a snow storm to the effect that "if we can get a maximum traction truck we can get through." In 1897, on the line of the Brooklyn Rapid Transit Co., the cars mounted on maximum-traction trucks more closely adhered to their schedule than any others, and an official of the Buffalo Railway Co., of Buffalo, N. Y., stated to me that the cars on maximum-traction trucks were the only ones out of the whole equipment that maintained their schedule time in heavy snows. They are noted for their ability to "get there" under all circumstances.

The contrast between the riding of a car carried on maximum-traction trucks and one on a four-wheel truck is very great. The steadiness of the body on maximum-tractions is at once remarked by passengers. An example of this is found in Philadelphia where the ease and steadiness with which the long cars are carried is a matter which has apparently not escaped the notice of any passenger who has tried both styles. Where cars of both kinds run over the same route it is not unusual to have passengers wait for a double truck car. For the heaviest service in the world where easy entrance and exit is absolutely essential and where a high acceleration is called for the maximum-traction truck has demonstrated its advantages. It is used on the electric lines of the Metropolitan in New York City and the Brooklyn Heights in Brooklyn. For such service it is indispensable.

The suburban and interurban services which send cars to city centers have the most exacting requirements. They have to run long distances in the country over T-rails with the ordinary construction, frequently at high speeds over private right of way; they also are obliged to enter cities and conform to the ordinary conditions of city service, where grooved rails are bordered by stone blocks. Shallow flanges and narrow treads are a necessity in the cities. In the country the speed is often as great as 50 miles an hour. For this service an entirely different type of truck has been developed. It is known as the "Perfect" passenger truck. Several years ago the Brill company designed a truck for a special and very difficult service, and it must be confessed that beyond meeting the unusual requirements they had little or no idea of the value of the invention which they had made. A truck was built and put in service with fifty or a hundred other trucks. At the time the purchasers were promised that if this one was not satisfactory it should be replaced without expense. The history was rather unusual. The easy riding of the car mounted on these trucks was so much greater than anything else on the road that the people waited for it, and its fame soon spread along the line. Without knowing it, the first radical improvement in 30 years had been made in the type of truck known on steam roads as an equalized swing beam truck. Its salient features are actual and complete equalization of the weight thrown upon each wheel. The ordinary steam passenger truck is very defective in this respect and leverage is greatly against the springs. In the new truck the equalizing bar, spring plank and swing beam are all combined in a single set moving together. The links are removed from the transoms to the wheel pieces. Three sets of springs instead of two are used, one of which is placed in the links themselves. Journal springs are placed on top of the axle boxes. The old fashioned short link is replaced by one which may be more than double the length of the old style. The result is an ease of motion in the car body, almost impossible with the old type of truck. At the same time it is found that owing to the even

distribution of the load on the wheels at all times, and the absence of any shock upon the wheel flanges when passing a curve or meeting a crook in the rails, that it is almost impossible to make the truck jump the track. In the three years during which these trucks have been in use the only case of derailment which has come to my knowledge was that of a runaway on a steep hill. The car left the rails when it encountered a sharp curve at the bottom of the hill. Even this could hardly be called a derailment, for I understand the car left the trucks, pitching over onto its side, before the trucks were thrown from the track. The No. 27 truck is the type from which we have developed the No. 27-G especially for city and suburban use. It has four motors, an inside brake and so short a wheel base that it can be used on cars which have to pass short city curves. It will be understood that the swing of the wheels is so short as to make it possible to use them under cars of ordinary width without unduly raising the car body. The equalizer is replaced by long half elliptic springs which also take the place of the elliptics on the spring plank. The four motors employed give the car the greatest possible tractive force and fit it for running at any desired speed. For certain purposes it is possible to modify this truck in such a way as to make it perform many of the functions of the maximum-traction, using only one motor per truck. In this case the motor is carried outside the axle, thus bringing a considerable increase of weight upon the driving wheel while the center bearing and center radiation is retained. The spring links, the swing motion and the perfect equalization, three sets of springs, together with journal springs of ample size are features which are retained and which together are the reason for its exceptionally easy motion. The "Perfect" truck has shown itself capable of meeting a surprisingly large variety of conditions. At all times it retains its characteristic ease of riding.

While I have no figures to present to you relative to the diminished flange wear of wheels in these trucks, yet it is notable owing to the softening of the side motion by the spring links little pressure is ever brought upon the flanges. The truck may be forced violently from side to side by the irregularities of the track, yet so perfectly is the body hung that it only follows the truck slowly or allows the truck to move without itself moving at all.

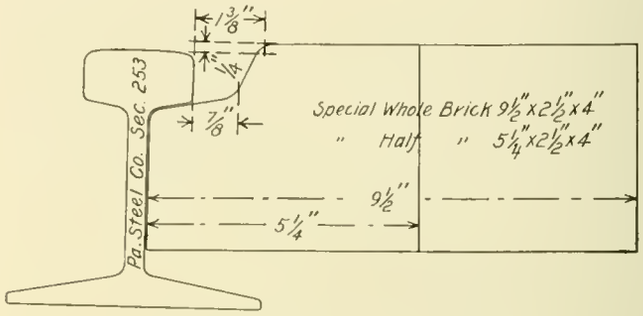
Incidentally in the construction of this type of truck great gain was made in strength. Instead of transmitting the weight of the car body through the transoms to the center of the wheel piece and then from the wheel piece out toward the spring pockets, a considerable distance, in the present case the weight where the spring links throw it upon the wheel piece is but a short distance from the jaws. The wheel pieces are constantly subjected to very little strain and the truck is much stronger in consequence. In fact getting out of square from the stresses set up in running ought to be and is practically unheard of.

TRACK CONSTRUCTION USED IN SCRANTON, PA.

Read before the Pennsylvania Street Railway Association, Oct. 11-12, 1899, by Frank Silliman, Jr., General Manager Scranton Railway Co.

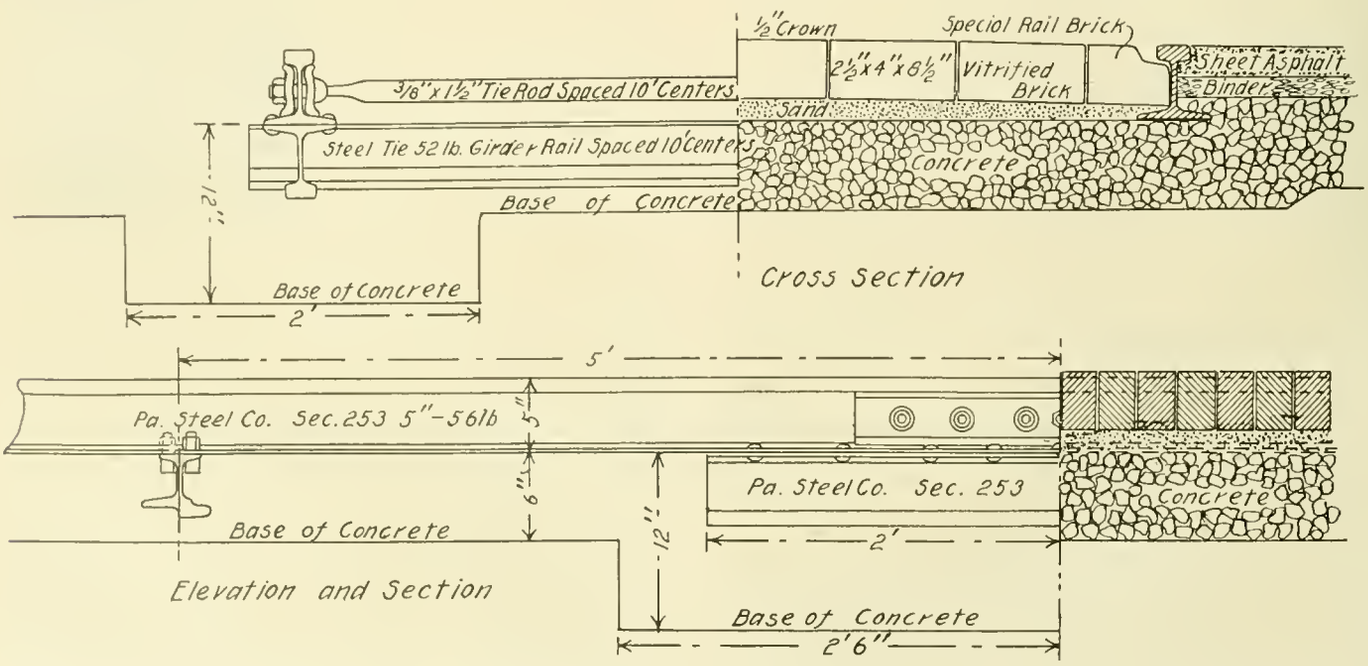
In the design of a construction of track that has been used on the lines of the Scranton Railway Co. to a considerable extent during 1899, the two main points sought, were a rigid joint without the use of an unduly heavy rail between the joints, and the employment only of such materials as are practically imperishable.

The rail used was a 5-in. T section having a base of a width equal to the height of the rail, and weighing 57 lb. per yd., with a web 3/8 in. thick, and having parallel sides. The joint consists of the ordinary six bolt joint that has been heretofore furnished with such rails, except that it has been rolled to a little heavier weight. Entirely in addition to this joint is what we claim to be a novel fea-



SPECIAL BRICK USED AT SCRANTON.

ture of the construction; it is a 4-ft. length of the same section of rail, inverted and placed under the joint, and secured to it by eighteen 3/4-in. rivets, which are driven by a pneumatic bridge riveter in the field. Four of these rivets are of copper, and constitute bonds of the joint. As long as the rivets hold tight, this makes a rail that is 10 in. in depth at the joints, securing a girder as deep as the heaviest sections of rail that are rolled. Between the joints it is, of course, not necessary that the rails should be as heavy, and the great waste in the ordinary 9-in. or 10-in. rail track construction is owing to the fact that there is so much of this great weight of rail used in between the joints, in order that the joints themselves may be of the necessary stiffness and rigidity. Through the middle of each joint is a tie-rod, and every 10 ft. of track contains a tie rod. Ten feet apart and intermediately between the tie rods, are ties which are made, in our own case, of a 52-lb. girder section that we have been taking up from old track. Almost any rail section may be



TRACK CONSTRUCTION AT SCRANTON, PA.

used for ties that has a sufficient width of base to allow the bolt holes to be drilled in it. The ties are bolted to the rails, and not riveted. The tie rods are the same as those that have been in use for many years, being flat bars, so as to interfere as little as possible with the pavement. This metal part of the construction having been

SIDE VIEW OF RIVETED JOINT.

assembled, as heretofore described and surfaced and lined on blocks on a bed prepared by grading and by rolling with a 10-ton roller, is filled underneath with a sub-structure of concrete having a uniform thickness of 6 in., except at the joints and at the ties, where the thickness of the concrete is increased to one foot. The work

BALLAST CAR.

of concreting having been completed, the whole is allowed to stand for at least five days, a week if possible, before any traffic is allowed on the rails. The top of the concrete is the bottom of the rail, of course, and this leaves a height of 5 in. from the top to the concrete to the level of the surface of the street. The pavement between the rails is made of brick which are 4 in. in width, leaving 1 in. for sand on top of the concrete. The bricks next to the rail are of special form, made so that the surface of the pavement is the same as the surface of the head of the rail, with the exception of a groove for the flange along the inside of the rail. On the outside of the rail, plain bricks are used which come up against the head of the rail, and the space between the head and the base, out to a line flush with the head of the rail, is filled with cement mortar. The whole brick pavement is grouted with cement grout, and rolled to a level surface and uniform crown, by a 5 ton roller, running on the rails of the track.

The machinery used by us in this construction is shown in the accompanying photographs and drawings, and a sample of the street is shown also, in a photograph. The work of construction is very much facilitated by the use of machinery, and the uniformity of the work is, no doubt, very much greater than in the case of hand work. Our concrete mixer is mounted on a low car, and driven by a No. 3 Westinghouse street car motor, while the pneumatic riveter is mounted on a car having on it a derrick for handling the riveter, and a motor-driven air compressor for furnishing the air.

This construction has given a great deal of satisfaction to the authorities of the city, and seems to be very popular with those who have to drive on streets where tracks are located. More can

DUMPING BALLAST.

be said of the durability of this construction in the course of a few years time, but it being entirely free from such perishable material as wood, should last a long time. The lightness of the rail is compensated by the fact that it is supported at all points. A wider base for the rail would still further improve the construction.

RIVETING JOINTS.

COMPLETED STREET.

VESTED WRONGS.

A paper upon this subject was read before the League of American Municipalities at Syracuse, N. Y., Sept. 19-23, 1899, by Hon. Robert P. Porter. Mr. Porter said in part:

So far as my own personal inquiries in relation to municipalization of street railways indicate anything, they clearly point out that the glowing accounts we have had of such experiments by returned American travelers from the other side are valueless when submitted to practical American tests. Not only are the statements of success and profits greatly exaggerated, but municipal ownership has not made anything like the headway in the United Kingdom which many would have us believe. Indeed, there is much misapprehension in the United States on this subject. Some accounts would seem to indicate that England has municipalized such undertakings as water, gas, electric lighting and street railways to a much greater extent than the facts warrant. In reality, if an absolutely accurate comparison could be made between the United Kingdom and the United States, it is doubtful which of the two countries would lead in this respect. I refer, of course, to public service, with profit-earning possibilities. For example, should we consider the four important branches of service—the supply of water, gas, electric light, and street railways—together, it would be safe to say that honors in favor of the municipalization of these undertakings would be about equally divided in the two countries.

To those without practical experience in handling such vast undertakings, and who therefore cannot possibly realize the obstacles in the way of turning over such stupendous enterprises as these, requiring, as they do, so much expert knowledge, to officials in no way specially trained, municipalization is no doubt a fascinating idea. Hence we find many writers at home taking it up with avidity, and as a result the literature on the subject during the last decade has increased far more rapidly than the experiments themselves. A few instances of municipal ownership have been made to do duty for so many books, essays, lectures, and articles that the practical man of affairs is beginning to inquire for additional particulars. Exaggerated and enthusiastically written accounts of the municipal millenium of Glasgow and Birmingham no longer arrest his attention, while the sudden change in public sentiment in 1894 in favor of a halt in the startling experiments inaugurated by the London County Council has greatly increased the doubts of those who are not sure that, even if the success in this direction had been as great as intimated in England, similar experiments might not be fraught with great danger this side of the Atlantic.

The results of my own inquiries into the working of municipalized street railroads in England are supported by almost identically the same investigation and analysis of the same facts by Benjamin Taylor, F. R. G. S., who thus sums up his facts in the August (1899) Cassier's Magazine:

"This review, then, of municipal enterprise in the working of tramways in the United Kingdom, leads to the conclusion that in no single instance has it been perfectly successful. Glasgow furnishes the nearest approach to success, but in Glasgow, with a small track for an enormous dependent population, it would take very bad management indeed to produce financial failure. And in Glasgow the system is a very long way short of perfection, while the retention of horse haulage renders the future exceedingly insecure. In no single instance can the municipal working of tramways be demonstrated to be a commercial success; and in no single instance has municipal management fulfilled the socialistic ideal, either in respect of its servants or its passengers."

The fact that these socialistic experiments rarely meet the anticipation of the labor side of the problem is receiving emphasis at this moment in London. In August last, when in London, the newspapers were giving in detail the woes of the County Council tramway employes, who were piteously calling upon their brother omnibus drivers—employed by soulless private corporations, but as well paid as any labor in Great Britain—to come to their rescue. When in London the general secretary of the union gave me a brief list of the grievances of the men thus employed by the London County Council—the body that started out six years ago to relieve all the burdens of London labor and London poor. From this it appears that the men are being asked to sign an agreement to work under the Council's rules and regulations, many of which are said to be decidedly unfair toward the workers. In one case, by Rule 33, the men are required to be always within call. During their hours of rest they are liable to be called upon at any moment to begin work, so that they dare not leave home, and cannot call a single hour of the week their own. Again, by Rule 31, any disparaging remarks made by employes concerning the conduct and management of the tramway system are to be treated as a breach of the rules, and Rule 35 provides that any such breach of rules may be punished by instant dismissal. Further, although a workman is liable to instant dismissal, he may not leave of his own accord without giving a full week's notice. The workmen also object to the exceptionally long hours which they are called upon to work, one instance being an unbroken period of twelve hours and twenty minutes on Sundays. The extra men, moreover, are obliged to loiter about the yards for hours without getting a job, and their work is paid for at the rate of 9s. a week less than that of the regular workers. The men complain that they have been left in the lurch by the Council. The London County Council has always prided itself with being a model employer of labor. Now these men openly claimed to me a few weeks ago that the union could prove that the London County Council was the worst. The tramway enterprise has been conducted contrary to all the principles of trade unionism. Surely the second condition of these men is worse than the first. A London newspaper, in an editorial, takes this view of the subject:

"What seems most likely is that, when the Council came to examine the subject of tramway administration practically, they found that the prospects of extensive improvements in the conditions of labor which the advocates of 'Collectivist' control had held out could not be realized without throwing upon the rates additional burdens, for which even a progressive majority lacked the courage, when it came to the pinch, to become responsible. . . What it means is that the pressure now applied to the men will be transferred to the masters; that under pain of losing votes the Progressives will be urged to concede what their servants insist upon. It would be an interesting struggle, for outsiders to watch, if it did not seem so very probable that the settlement will be arranged at their own expense."

This is a phase of the municipal ownership question which American taxpayers will do well to study. When the wages of men become political questions the men will likely get the increased wage, the political party the votes, and the taxpayer the bill of expenses. If it should appear that, with officials less subject to political influences than the officials of American cities, England has made no greater headway on the whole in the municipalization of such undertakings as water, gas, electric lighting and street railways, then it may be worth while for us to study more carefully that middle and safer ground which may be found in good working condition on the Continent, and which has been able to obtain the best expert service of private enterprises with such municipal control as absolutely protects the public interest; in other words, the highest efficiency of service, adequate compensation for rights and franchises conferred, reasonable public control, without making the municipality an enormous labor employing bureau, with its innumerable complications and stupendous dangers.

It is doubtful, when all the important factors of the problem are taken into consideration, if the advocates of municipal operation can point to a single instance in which such service is performed better and cheaper and on more intelligent principles abroad than in the United States. If American labor would be contented with the foreign scale of wages, we might be able to give our theoretical friends even lower car fares than they now enjoy. This statement is made, however, as the lawyers say, without prejudice to the claim which I believe can be sustained, namely, that in spite of the great difference in wages, such service is performed in the United States today as well and cheaper than similar service in any European city.

Politics, red tape, ignorance, timidity, opposing interests, and the deadly fear that private enterprise should make a dollar profit, have all helped in England, and to a lesser extent on the Continent, to retard the entension of street railways to meet the pressing demands of population. In America, however, private capital has had full swing, and with a courage almost akin to recklessness has not hesitated to discard, regardless of cost, one system of propulsion as fast as a better offered. Whatever the sins of the American street car man may be—and, like all the rest of humanity, he is far from perfection—he is up-to-date. He has planned his railway system on broad lines, including the districts that pay and the districts that must be run with a loss. He has gone ahead and taken his chances with the rest of the community, pinning his faith on the growth of the city and the increase of the suburban districts. He has not

been contented to pick up the pennies within the city walls, but has boldly branched out in all directions, building up suburban districts where none existed, and increasing real estate values along the route. The American street railway man may have driven good bargains for himself, and directly he may not pay much into the coffers of municipalities as toll for the use of the streets, as his co-laborer beyond the Atlantic. Weighed, however, in the balance of good business and common sense, he can point to achievements which far outweigh the results attained in England, where municipal pettifogging has effectually soaked the enterprise out of street railways, and on the Continent, where private enterprise has only been allowed to go ahead after being enveloped in a sack of governmental restrictions. Instead of petty railway budgets, showing so much profit to the municipality, the American city can point to largely increased real estate values, and millions added to the tax rolls, in a large measure the result of distributing the population of our cities beyond the boundaries far into the country districts. Look at the area of American cities compared with the larger cities of Europe. Without cheap and rapid transit, all the recent extensions of the boundaries of our cities would have been impossible.

The American street railway man may therefore point with righteous pride to his track mileage, exceeding by 6,000 miles that of Europe, to the 4,000,000,000 passengers which he annually conveys to and from their homes, and to the fact that he has not waited for the population to come to him, but has gone out, true American fashion, in advance of population, and built up districts at great expense, which he now works with a profit, not alone to himself, but to the city whose revenue from taxes is thereby increased. On the question of charges, the American street railway compares favorably with similar systems abroad. In the first place, we have solved the question of a uniform fare, while nearly every municipality which I have visited in Europe is struggling, apparently hopelessly, with this question. Why? because the municipality has not the courage of private enterprises. A uniform fare, it is contended, gives the longer haul an advantage over the shorter; so, to avoid this, in Glasgow the acme of absurdity has been reached by a one-cent fare for a trifle over a half a mile. It is far better for a man to walk half a mile than to ride anyhow, and quicker, it seems to me, after trying halfpenny fares on the newly inaugurated municipal horse tramways of the Scottish city, which social reformers claim has solved the true art of municipal government and municipally operated transit.

With their eyes bent on the puttering short haul, the street railways of the United Kingdom, and, to a lesser extent, of continental Europe, have failed to realize that it is the cheap long haul that relieves the congested spots of our great cities; that creates cheap homes; that carries the people into the suburban districts; and, lastly, that builds up new taxable areas, which ultimately give back to the city a hundred-fold more than it would ever make trying to do for itself that which can be far better done by private ingenuity, economy and enterprise. So Liverpool and London and Paris are all at this moment in their new street railway enterprises agitating the uniform fare question, as though it was something new and strange and wonderful. To the canny Scotch mind, however, in Glasgow, it seems a dreadful thing that one passenger should get a fifteen mile ride for the same price paid by another passenger for the privilege of going one mile. I say fifteen miles, but on this point I may be corrected because it was only the other day I was told that in New York City you can now ride for 5 cents along 25 miles of road and through territory which 10 years ago would have cost you 25 cents and three hours' time. The efficacy of the American nickel, it is true, has helped us out, though with the elaborate systems of transfers inaugurated in the larger cities, the actual American fare cannot be measured by 5 cents. In New York City the enterprising Metropolitan Railway Co. has, during the last three years, increased the transfer system from thirty-two millions in 1896 to sixty four millions in 1897, to ninety millions in 1898, and to one hundred and thirty millions in 1899, thereby reducing the average fare to about 3 1-3 cents, which, as I have shown, is less than the average fare on the Paris tramways, less by more than a quarter of a cent than the average fare on the omnibus of Paris. In London, where the "Penny Bus" is so much in evidence that one would imagine he could get all over London for 2 cents, the mean rate per mile is nearly 2 cents—that is, 92 of an English penny. The tramways of London charge over one and a half cent per mile, and the fares range, as do those of the omnibus, from 2 cents to 12, according to distance.

DELEGATES TO THE STREET RAILWAY CONVENTION AT THE SOUTH SIDE ELEVATED POWER STATION, OCT. 20, 1899.

VISIT TO THE SOUTH SIDE ELEVATED PLANT.

At the invitation of the Westinghouse Electric & Manufacturing Co., about 100 attendants at the convention visited the power station of the South Side Elevated R. R., the company furnishing a special train. When the tour of inspection was finished the party was grouped about one of the large units and a photograph taken, from which the accompanying engraving was made.

The Chicago council judiciary committee has decided to recommend the adoption of a resolution authorizing the mayor to appoint a commission of seven aldermen to gather information on which to base ordinances for renewal of the street railway franchises. The commission is given the power to gather information and make recommendations regarding the questions of terminals, transfers, switches, motive power, rates of fare, municipal ownership, compensation to be paid the city, tunnels, accommodation of passengers and other terms and conditions on which franchises should be extended.

The Third Avenue R. R., of New York, on October 21st, began operating by the conduit electric system that portion of its road extending from 65th St. to 120th St. The company has recently let a contract to the Electric Storage Battery Co., for storage batteries aggregating 10,000 h. p. These will be located at two sub-stations on the system, for regulating and sustaining the voltage on the line.

MECHANICAL DEPARTMENT

CAR BUILDING IN MINNEAPOLIS.

The Minneapolis Times recently contained the following complimentary notice of Master Mechanic Brown, of the Twin City Rapid Transit Co.:

"The cars of this company are being built at its shops, 31st St. and Nicolett Ave., and were designed by W. M. Brown, the company's master mechanic, and are being built under his direction. Mr. Brown has been with the company for nearly ten years, and for about five years has been master mechanic. All new cars and the rebuilding of all the old cars and motors has been done under his direction. Mr. Brown takes second rank to nobody as designer and car builder and the company acknowledges his ability as a street car man by the confidence it places in his ability to manage this, one of the largest departments of its system. His work speaks for itself and one has only to look through Mr. Lowry's private car to be convinced of the truth of this assertion."

M. C. B. BRAKE SHOE TESTS.

The Master Car Builders' Association, through its Standing Committee on Brake Shoe Tests, has decided to make another series of tests at an early date, which will include only brake shoes of new kinds that have not already been tested by the committee, and which may properly be considered as being on the market, or having some extended use on some railroads.

All makers of brake shoes desiring to enter their designs should communicate at once with the chairman of the committee, stating to what extent their shoes are in use. Address S. P. Bush, superintendent motive power, P. C. C. & St. L. Ry., Columbus, O.

SMALL ROADS ECONOMY.

BY G. J. A. P.

Articles referring principally to small roads may not be of very much interest to many of the readers of the "Review," but there is a large number of small roads, the management of which may be interested in a few experiences along the line of repair economy.

There is so much to be said about economy for any road that it is advisable to start at the "root"—the power house. My experience has been, that to have the best firemen and engineers, is the cheapest in the long run, for the reason that a capable man in this place will keep engines and boilers in far better condition, and consequently the oil and coal bills will be proportionately less than if the machinery is in less experienced hands. To allow boilers and engines to run down is simply increasing the expense, for what is saved at the start will be expended twice over in a short time thereafter.

In the matter of cars and car repairs, a great many managers will buy old and worn out material, expecting it to answer their needs; it does so for a short time and then it begins to need repairs and in the course of a few years (perhaps only months) the company has some worthless cars and equipments on hand, which means a considerable amount of money expended and nothing to show for it. The same is true of the track and roadbed. A tie 6 in. x 6 in. x 6 ft. 6 in. can be bought very cheap; but, as a good building requires a good foundation, so a good roadbed requires a good substantial tie and rail.

In regard to the repair shop my experience has been that few roads look to the small things with sufficient care. Taking charge of a small road some time since, I found on arrival that the total of the company's tools consisted of a few wrenches, one hammer, a saw and a few other small articles. Other tools were "borrowed" from time to time, and the owners supplied with "annuals" which really paid in a few weeks what all the tools were worth.

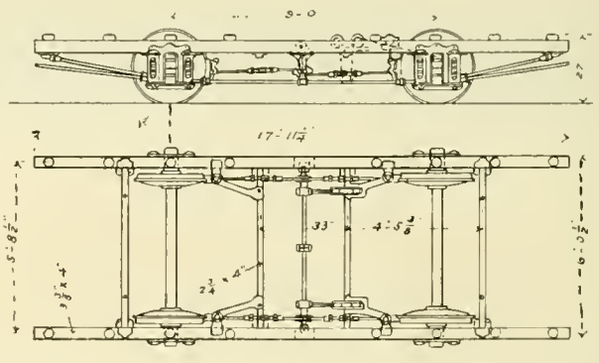
Too many roads count only on the original expense, and do not consider what they are paying at the blacksmith and machine shops for work which could easily be done "at home," if the company would buy the necessary forges, anvils, drills and tools. At an expense of $100 to $150 any road can supply itself with sufficient of these tools to do any ordinary work of this kind.

A wise plan in selecting your trainmen is to secure one of each of the various trades. Where a road has a painter, a carpenter, a blacksmith, and a machinist on its pay roll as trainmen, it is prepared to do its own work very easily and the saving in repair bills will soon become notable. If, however, a road is obliged to send everything out which it has to do in these lines, it will be paying high prices for it, not to mention the delays.

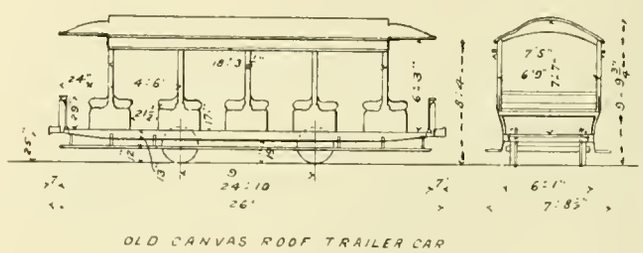
Above all, a too watchful eye cannot be kept on the wastes about a shop or car barn. Have a place for every piece of scrap, and see that it is put there. And keep your oily waste outside the buildings.

POCKET REFERENCE DRAWINGS.

Mr. G. O. Nagle, assistant general manager and superintendent of the Chicago City Railway Co., has originated a plan for bringing into convenient shape for reference, data relating to different features of the system, that may be of interest to officials, holding similar positions with street railway companies. His idea is to



MOORE WOOD TRUCK



OLD CANVAS ROOF TRAILER CAR

reduce to small uniform drawings, 6 in. x 4 in., plans, end and side elevations, etc., of different types of cars, trucks, and other apparatus, in use on the road, and diagrams of car barns, power stations and other buildings. These drawings give dimensions and sizes, and in the case of buildings show the location of tracks, division of floors into offices, etc., thus condensing into a very small space an immense amount of information that a general manager or superintendent is constantly requiring.

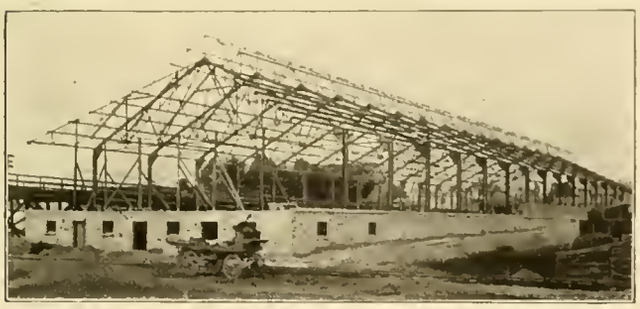
Mr. Nagle does not use the original drawings, but has blue prints made; these may be carried in the pocket, until they are worn out, when a new set of prints is made. We reproduce two of the drawing herewith, one showing side and end elevation of an old canvas roof trail car, and the other a plan and side elevation of a "Moore" wood truck.

NEW CAR HOUSE DEDICATED.

The new car house of the Cincinnati, Newport & Covington Railway Co., shown partially completed in the accompanying illustration, was formally dedicated on September 28th, and was in full operation by October 1st. The building is entirely of brick and iron, 90 ft. wide by 375 ft. long, and is located at 11th and Brighton Sts., Newport. There are eight tracks extending the whole length of the building, each one having a pit 80 ft. long. At the front end of the building a second floor has been suspended from the roof trusses and here are located the private offices of the chief inspector and the superintendent of lines, and a library



NEW CAR HOUSE, CINCINNATI, NEWPORT & COVINGTON.

and club room for the employes. On the ground floor at the front end are the division superintendent's offices on one side and a fire-proof oil room and a repair shop at the other. Beneath the stairs is the lavatory, which is fitted with bath tubs, showers, etc.

The evening of the reception, September 28th, the house was ablaze with electric lights and handsomely decorated with flowers and bunting. A very interesting program with music and addresses was provided. President Ernst was called to New York, and was therefore unable to be present, and Superintendent Ledyard did the honors for the company. Col. R. W. Nelson, the Democratic nominee for mayor, made an address. The set program was followed by dancing and supper.

When about one-half of the framing for this building was in position on May 21st last, it was blown down by a storm, as noted in the "Review" for June.

Wages of conductors and motormen employed by the Indiana Railway Co., of South Bend, Ind., were increased 20 per cent on November 1st.

A REMARKABLE RECORD.

The Consolidated Car Fender Co., of Providence, R. I., was one of the pioneers in the introduction of life saving appliances for street cars, placing its fender upon the market long before the necessity for such devices had been recognized by managers. It now has the satisfaction of knowing that Providence fenders are in use on more than 5,000 cars in nearly 70 cities and towns.

This fender is of the cradle type, and in its normal position is carried a few inches above the roadbed, but by a slight pressure of the foot or knee the motorman can drop the cradle to the ground at will. In the latest improved patterns, an automatic wheel guard is also provided as an additional protection in the very few cases where the person struck falls in such a way as to be thrown from

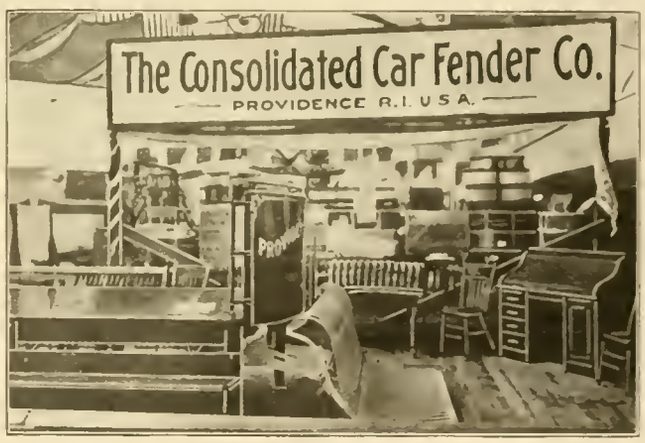


EXHIBIT OF THE PROVIDENCE FENDER.

the fender under the car. This guard is a cradle similar to the main fender cradle and is hung immediately in front of the forward wheels. By a simple connection with a swinging apron it is made to drop whenever the apron swings to the rear, which it must do when it strikes the body of a person.

The Consolidated company's exhibit at the convention attracted considerable attention, as from the samples of Providence fenders shown, their efficiency and reliability were at once apparent. Col. A. C. Woodworth was on hand to greet his many friends and distributed a neat stamp holder as a souvenir.

Electricity will take the place of the cable on the Payne Ave. and Superior St. lines of the Cleveland City Ry. within the next few months.

A New York citizen suggests that the street railway lines ought to be used for removing ashes, garbage and snow, which could be loaded in cars on sidings and the cars drawn by regular motor cars to one general dump.

CONSTRUCTION WAGONS AND CREWS.

The accompanying illustrations show the construction and emergency wagons of the New Orleans City Railway Co. together with their crews, which are well organized and have proved themselves an efficient body of men in this service. The emergency crew which has 144 miles of track in charge, consist of David Rombold, foreman, William J. Kane, J. Criss and Jacob Siebert, linemen, and Oscar Bendix the driver, who has a number of very fine horses under his care. The company places great confidence in this crew which is always in readiness to respond to calls both during the day and night.

The construction crew, which is under the same foreman, consists besides an assistant foreman, of two linemen and six groundmen. These are Alfred Weber, assistant foreman, James Craven and James Harrington, linemen, and V. Jolley, James Howley, M. Joyce, George Bendix, D. Buchman, groundmen; also Jos. Wolf, electrician, and Martin Ryder, driver, who until recently was driver of the emergency wagon of the Nassau Street Railway Co. of Brooklyn, N. Y. In addition to those shown the company has two more tower wagons and two ladder wagons, all of which are stationed at 108 Wells St., New Orleans. The crews take great pride in the appearance and equipment of their wagons and are always pleased to exhibit them to street railway men visiting the city.

ing: Directors, Francis B. Clapp, managing director, South Yarra, Wm. McCulloch, J. M. Pratt, Wm. Cain, and Andrew Rowan, of Melbourne. Auditors, W. S. Flint and I. C. Foden. Secretary, W. G. Sprigg.

EXTENSIONS TO THE BRILL PLANT.

On a recent visit to Philadelphia, it was noted that the J. G. Brill Co., which is now turning out more material than at any time in its history, has begun the erection of a new building, 100 x 200 ft. which will be temporarily used as a machine shop, but is designed for the foundry department. The building is to be equipped with new iron working tools. An extension of 100 ft. is also being made to the blacksmith shop and new machines will be installed. A 150-h. p. Cahall boiler has been installed, making the total boiler equipment of the blacksmith shop 300 h. p., and the total for the plant 950 h. p. The old stable north of the plant has been removed to make room for storing lumber, car wheels, etc., and a new stable is being erected directly along the driveway leading into the plant. Two new electric locomotives, equipped with G. E. motors, will be employed for shifting the material about the works. A new crane car for loading and unloading heavy material has been constructed in the shops; it is provided with friction clutches so that the motor not only drives the car but elevates the load.

CONSTRUCTION AND EMERGENCY WAGONS, NEW ORLEANS CITY RY.

REPORT OF MELBOURNE TRAMWAY CO.

At the recent annual meeting of the Melbourne Tramway & Omnibus Co., Ltd., of Melbourne, N. S. W., the following report for the year ending June 30, 1899, was made:

Traffic receipts	£389,428
Other receipts	10,344
Total receipts	£399,772
Operating expenses	234,145
Earnings from operation	£165,627
Interest, sinking fund, etc.	124,882
Net income	£ 40,745
Interim dividend	14,400
To surplus account	£ 26,345
Balance from previous year	28,474
Total surplus account	£ 54,819

The passengers carried were: By omnibus lines, 603,828, or 6,942 more than last year; by tramway lines, 38,271,382, or 2,026,102 more than last year; being a grand total of 38,875,210, or 2,033,044 more than in 1898. The miles run were: By omnibuses, 280,687, or 2,726 more than last year; by tramcars, 8,084,020, or 100,168 more than last year; or a total of 8,364,707, being 102,894 more than in 1898. There had been no change in the miles of track operated, which still remained at 43½ for cable lines, and 4½ for horse lines.

The following officers and directors were re-elected at the meet-

TRAMWAYS IN VERACRUZ.

There is to be reconstructed in Veracruz a well-equipped modern street railway which will be undertaken by a syndicate of Englishmen who have acquired the property of the Empresa del Ferro Carril Urbano de Veracruz. The organization has not yet been completed but it is understood that the company's capital is to be $250,000.

Vice-Consul Page, of Veracruz, states that there are also five other railways in that city operated by mule power. Three of these are private or individual enterprises run upon a small scale, but are said to be conservatively managed and all of them, including the least profitable, are said to be on a paying basis. They have no bonded debts and no financial reports are given out except to those financially interested. No present improvements are expected to be made except in the case of the road now in English hands.

Patterson, N. J., has been visited by wire thieves. Nearly a mile of trolley wire was stolen near that place a short time ago.

A consolidation of the Johnstown (Pa.) & Somerset Traction Co., and the Johnstown Passenger Railway Co., will shortly be effected.

The Court of Appeals has sustained the action of the New York Board of Railroad Commissioners in granting to the New York & North Shore Railway Co. permission to construct and operate an electric road from Flushing to College Point and Whitestone, on Long Island.

RECENT STREET RAILWAY DECISIONS.

EDITED BY J. L. ROSENBERGER, ATTORNEY AT LAW, CHICAGO.

LIABILITY FOR JERKING OF CAR ATTRIBUTABLE TO CLOSELY FOLLOWING ANOTHER.

Scott v. Bergen County Traction Co. (N. J.), 43 Atl. Rep. 1060. July 8, 1899.

The occurrence of a sudden lurch or jerk of a street railway car, of sufficient violence to throw a passenger off the platform, who was there preparing to alight, and awaiting the stopping of the car for that purpose, the supreme court of New Jersey holds, justifies an inference of a breach of duty upon the part of those operating the car, within the maxim "The matter speaks for itself." That the car was following another closely, which was stopping and starting suddenly, it holds, is a fact for the consideration of the jury in determining the cause of the sudden lurch or jerk, and as bearing upon the questions of negligence arising in the cause.

It is not negligence in itself, the court says, for a passenger to ride upon the platform of an electric street railway car, nor to get up and go there from inside the car before the car has stopped, to await an opportunity to alight.

The railway company operating such a car is bound to exercise a high degree of care to carry its passengers safely in or upon whatever part of the car they are permitted to ride.

Whether a passenger riding upon a platform, or standing there awaiting an opportunity to alight, while the car is moving, should, in the exercise of ordinary care for his own safety, take hold of the hand rail there, the court pronounces a question which, under all the circumstances, must be determined by the jury.

DUTY AS TO ALIGHTING PLACES CHOSEN BY PASSENGERS.

Flack v. Nassau Electric Railroad Co. (N. Y.), 58 N. Y. Supp. 839. June 13, 1899.

As a general proposition, the second appellate division of the supreme court of New York does not understand it to be the law that a street railway company, whose car is brought to a standstill at the instance of a passenger, not at any terminal point or at a stopping place regularly designated as such by the management of the road, is bound, in the discharge of its duties as a common carrier, to furnish to the passenger a safe place at which to alight. The passenger, under such circumstances, chooses the place for himself; and unless there is evidence that its dangerous character was known to the persons operating the car, and that they allowed him to alight without giving him any caution, the court says the railway company is ordinarily not responsible for the unsafe condition of any part of the street, except that which constitutes a part of its roadbed, or which it is legally obligated to keep in repair. But the court holds that if the company provided any part of its roadbed as a place for passengers to alight on, it was bound to exercise reasonable care to keep that particular place safe for the purpose.

Here a car was stopped, on a passenger's signal, near a certain cross street, and when she stepped from the car to the ground the soil of the roadbed gave way under her feet, and she fell to the surface of the street, sustaining a fracture of the hip. The street on which the tracks were had been lowered 18 to 20 inches, making of the roadbed an embankment. There was also evidence that other similar accidents had previously happened to passengers alighting from the cars of this company, under similar circumstances, while the street was in the same condition.

This last proof, the court holds, rendered the company chargeable with notice that its roadbed in that neighborhood was likely to give way under persons leaving its cars, and imposed upon it the duty of exercising greater caution than might otherwise have been necessary to afford passengers an opportunity to alight in safety, even if the company was in no wise responsible for lowering the adjacent surface of the street.

And if the company was unable to maintain its own roadbed in a condition safe for passengers to step upon, by reason of the action of the city authorities in lowering the grade of the street, it was, at all events, the court insists, bound to inform its passengers who were to alight upon that roadbed that they could not do so with safety.

Judgment for plaintiff affirmed.

NO COMMON LAW DUTY TO PROVIDE FENDERS AS SUCH.

Hogan v. Citizens' Railway Co. (Mo.), 51 S. W. Rep. 473. May 23, 1899.

It was argued on appeal in this case that the trial court had committed error in striking out from the petition the averment that the "defendant did negligently fail to use ordinary care in providing said gripcar with a fender to prevent its running over the children it had run down and upon." The court's ruling was that the acts averred did not constitute negligence on the part of the defendant, and hence should be eliminated from the case.

There was no contention that there was any law of the state or any ordinance of the city which made it the duty of the defendant to place fenders on its cars. The obligation to do so, says the supreme court of Missouri, division No. 1, in reviewing the assignment of error, must therefore be found in the common law, if there was any such obligation resting upon the defendant.

It was not contended that the common law expressly imposed any such obligation, but it was argued that "defective appliances, or no appliances at all, or insufficient appliances, is a question of negligence, for the jury."

This leads the supreme court to say that the obligation of the common law is that the defendant shall exercise ordinary care to prevent injury to the public. No particular kind of appliance is required to be used. It is only necessary that the defendant should have used such means to prevent injury to the public as a man of ordinary prudence would have used under the same circumstances. To predicate a charge of negligence upon a failure to use any particular kind of appliance is insufficient, especially in the absence of any averment that the appliances and means employed by the defendant were not reasonable safe.

As between master and servant, continues the supreme court, the master is not required to furnish the best and safest known appliances. It is enough that what he does furnish are reasonably safe for the purposes for which they are intended and used. So, with respect to its common law duty to the public, the court goes on to declare, it is not whether there are known appliances which the defendant did not use, but whether the appliances it does use are such as a person of ordinary prudence would have used, which determines the question of its negligence.

There was therefore, the supreme court holds, no error in the ruling of the trial court sustaining a motion to strike out this allegation in the petition.

RIGHT TO ASSUME THAT RIDER OF BICYCLE WILL TAKE CARE OF HIMSELF.

Gagne v. Minneapolis Street Railway Co. (Minn.), 79 N. W. Rep. 671. June 28, 1899.

To attempt to ride a bicycle between the tracks of an interurban electric street railway, where the street is 120 feet wide and the distance between the inside rails of the two tracks is but 7 feet and every 135 feet there is a trolley pole in the center of the space between the tracks, with a distance between a trolley pole and a passing car of only 16½ inches, the supreme court of Minnesota thinks ought, under any ordinary circumstances, to be held negligence as a matter of law. Indeed, the evidence in this case showing that a man, for no apparent reason, except that it was smoother than the remainder of the street, undertook to ride in such a space between the tracks, sometimes nearer one rail and sometimes nearer the other, down a grade, and then, apparently without the least use of any of his senses to ascertain whether a car was approaching him from behind, turned suddenly to cross the track on his right when a car coming up from behind was within 10 to 20 feet of him on that track, the court holds it was conclusive that the man

was guilty of contributory negligence so gross as to amount to extreme recklessness.

This, the court says, left only the question of whether there was any evidence to go to the jury that the motoneer, after he saw the man in a place of danger, was guilty of wanton or willful negligence in failing to exercise reasonable care to avoid injuring him. And if the fact was, as contended, that the man rode continuously near the rail of the track on which the car was, the court does not think that this would have justified a finding that the motoneer was guilty of any wanton or willful negligence, particularly as the car was in plain sight of the man, if he had looked in that direction, and he had been warned of its approach by the sounding of the gong.

The fact that the man gave no visible indication of having heard the gong, or of being aware of the approach of the car, the court holds, was of very little weight. Any one accustomed to ride on street cars, who is at all observant, it says, must know that there is a very large number of bicyclers who ride between or near street railway tracks, and who seem to think that it is not "good form" to get out of the way of an approaching car, or to give any indication of being aware of its approach until the very last moment.

Under such circumstances, and considering the ease and quickness with which a bicycler can turn aside, and that if a motoneer was required to stop or slow up in every such case until he was sure that the rider would get out of the way, it would be practically impossible to operate the cars so as to properly serve the public, the court holds that the motoneer had a right to assume that the bicycle rider in question could and would take care of himself.

RIGHTS OF AN EMERGENCY EMPLOYE.

Marks v. Rochester Railway Co. (N. Y.), 58 N. Y. Supp. 210. May 24, 1899.

Two bobtail horse cars met on a single track. After some altercation between the conductors, it was decided that one of them should be moved back to a siding to let the other pass. There was no brake on the rear end of the car, and only the one employe on it, who called upon a boy 11 years and 4 months old, who appeared upon the scene, to drive the horse while he himself handled the brake at the oposite end of the car. Some other boys also got upon the car and commenced jolting it by dancing. The conductor made a rush or feint at them, at which they took fright, and, in scrambling off, pushed the boy driver off the platform, whereby he sustained personal injuries.

By a former adjudication it was settled that the platform of the car was not an unsafe place, that the boy was sui juris (under no legal disability), and that the company was not guilty of negligence in placing him, through its conductor, upon the platform of the car, for the purpose of driving the horse. Indeed, with passengers upon the car, the fourth appellate division of the supreme court of New York says that, under the circumstances, it would seem that it would have been grossly negligent for the conductor to have driven the horse himself, and left the brake unattended.

Asuming then that the boy was an emergency employe, the court goes into the question of what are rights of such an employe and the liability of the company to him for injuries while so employed. Concededly, it says, in the employment of the boy the conductor stood in the place of the company, and any contract which he made in that regard would be enforceable against it.

If, under such circumstances, the person so representing the company employs an incompetent person, or a less number of persons than are requisite for the performance of the work, or puts the person so employed in an unsafe place, or furnishes him imperfect or unsafe tools or appliances, and injury results because of such failure, the company, the court holds, is liable.

In the employment of an emergency man, the court goes on to say, the servant of the master making such employment acts for, and stands in the place of, the master; and he is charged with all the duties and responsibilities that the master would have been chargeable with if he had made the employment direct. But, having properly discharged all those duties, when such servant employer returns to the performance of his duties as servant, the court holds, he ceases to occupy the relation of master, and becomes co-employe, as to the person employed by him, and as to every other person in the master's service, and the master is not liable, even to the emergency employe, for his negligence. It cannot be of consequence, the court adds, that the employment of an emergency man is continued but a few moments, or that the service continues for hours or days.

Thus, does the court come to the conclusion that, the conductor having fully discharged his duty to the boy, so far as the employment was concerned, when he commenced managing the car he became a co-employe with the boy, assuming that the later was an emergency employe; and, if the conductor's negligence caused the injury sustained by the boy, it was the negligence of a co-employe, for which the company was not liable.

Furthermore, assuming that the jury, upon the evidence, might have found that the boy was not an emergency employe, but a trespasser upon the car, and sustained that relation to the company when injured, the court holds that the result of the action of the conductor, which was directed towards the other boys upon the car, was so unusual that the company was not liable.

Nor does the court think that the jury would have been justified in finding that the boy was a passenger upon the car. And if it had found that he was taking a gratuitous ride on the invitation of the conductor, being sui juris, or not to be treated as a helpless child, the court holds that the company would not be liable for injuries he sustained through the negligence of such conductor or other employe.

CANNOT ABANDON OPERATION OF ROAD.

State, on relation of City of Bridgeton v. Bridgeton & Millville Traction Co. (N. Y.), 43 Atl. Rep. 715. June 21, 1899.

The supreme court of New Jersey holds that a street railway company incorporated under the laws of that state, and the route of its road, and the location of its tracks, established by an ordinance of the municipality in the streets of which the company is to operate its road, such ordinance being accepted by such company, and its tracks laid in accordance therewith, and the road constructed and in operation, cannot, at its mere will and discretion, cease and abandon the operation thereof, or any portion thereof. It holds that it becomes the duty of the railway company, in the exercise of its rights, privileges, and franchises, for the benefit of the public to maintain and operate its road according to the terms of the ordinance, and in compliance with the statutes which confer upon the company such rights, and franchises.

An implied condition, the court maintains, attaches itself to the grant of the franchise that it be held for public benefit, and the duty upon the railway company is to exercise it for such purpose, and, as a public agent, it cannot escape this duty.

The court further holds that the company, duly incorporated, which has the ownership of, and is in possession and control of, such street railway, its appliances and property, whether under a lease of or by sale from the original or other company incorporated to construct and operate such railway, or by sale under a decree of the court of chancery upon foreclosure under the statute of that state, has conferred upon it all the corporate rights, liberties, privileges, and franchises of such original or other company, and upon it rests the same burden and duty to maintain and operate such street railway under the statutes and the ordinance of the municipality as was imposed upon the original company.

The fact that the located route of the railway is laid across a bridge which is under the control of the board of freeholders which will not permit the tracks to be laid thereon except upon proper and reasonable regulations for the safety of the bridge for the traveling public, the court holds, furnishes no excuse why the road should not be operated upon its route through the streets of the municipality lying upon either side of such bridge.

Mandamus, the court pronounces the proper legal remedy to compel such street railway company to perform the duty of maintaining and operating such railway for the benefit of the public, as the public duty imposed upon the company is always active, potential, and imperative, and must be executed until lawfully surrendered, suspended, or abandoned by the legally expressed consent of the state.

The Kings County Elevated, of Brooklyn, N. Y., and the Brighton Beach road are now operated by trolley and the third-rail system from the New York end of the Brooklyn Bridge to Coney Island.

THE CHICAGO CONVENTION.

The Most Successful of Street Railway Conventions Good Papers and Interesting Discussions Extensive and Well Arranged Exhibits Over 1,300 in Attendance Epitome of Entertainments Kansas City in 1900.

The 18th annual convention of the American Street Railway Association was held at Chicago, October 17th to 20th, and the general opinion of those who were here is that never before has the Association had a meeting more satisfactory in all respects, and particularly as regards the large attendance at the business sessions and the animated discussion which followed the papers read. The credit for the success of the convention is very largely due to Mr. John M. Roach, who, as chairman of the general committee and of the committees on entertainments and banquet, was charged with the general oversight and in particular with the duty of seeing that our guests had an enjoyable visit to Chicago.

The exhibits were displayed on the main floor of Tattersalls, 16th and State Sts., and on the curb at the west side of the building; the meeting rooms for the two Associations were on the second floor at the north end of the building. The "headquarters" of the convention were at the Auditorium, which was the social center of the convention.

The exhibits were well arranged and made a most attractive and instructive display, and Mr. J. R. Chapman, chairman of the committee on exhibits, received many compliments upon his work. He had made the most careful plans, working out all details and making all the necessary arrangements in advance, so that there was no delay in installing the exhibits and everything was in place by Tuesday afternoon. The action of the Executive Committee in setting apart Friday as "Supply Men's Day" was greatly appreciated by exhibitors, and also by the delegates, as was shown by the large number of blue badges seen on the exhibit floor that day.

The other committees, and they all did their work well, were: On halls and hotels; George O. Nagle, chairman. On finance; George A. Yuille, chairman. On reception and ladies; H. M. Sloan, chairman. On transportation; F. L. Fuller, chairman. On publicity and information; H. H. Windsor, chairman. The Bureau of Information is an institution which Boston has the credit of introducing at our conventions, and its success there, and again here, insures that it will be a permanent feature.

In the meeting room of the American Association Mr. C. S. Sergeant presided with dignity and tact. The papers before the Association were four in number, as follows:

"Investments in Street Railways: How Can They Be Made Secure and Remunerative?" By Charles T. Yerkes.

"Maintenance of Car Equipment." By J. H. Vanderveer.

"Construction and Maintenance of Street Railway Track." By Edward Butts.

"Train Service and Its Practical Application." By Ira A. McCormack.

There were over 1,300 street railway men and supply men and 100 ladies in attendance.

The entertainments and social features were particularly enjoyable. An informal reception was held in the Auditorium parlors Tuesday morning by the local committee of ladies, about 40 in number, under the direction of Mrs. J. R. Chapman, and the visiting ladies registered and received their badges at this time. There were about 100 ladies from out of town at the convention.

Tuesday evening the reception, which always marks the first day, was held at the Auditorium, about 500 people being present.

On Wednesday the excursion provided was a trip to the Chicago Drainage Canal, and 504 persons, by actual count, availed themselves of the opportunity to inspect this interesting engineering work. A special train of nine cars left Dearborn Station at 1:45 p. m. over the Santa Fe, and proceeded as far as Lockport, making stops at various points of interest. After inspecting the works at Lockport the party was photographed, after which the return to Chicago was made, arriving at 7 p. m. Mr. Isham Randolph, chief engineer for the Sanitary District, and a corps of assistants, accompanied the party. Badges were distributed by the McGuire company.

For Wednesday afternoon a tally ho ride through Jackson Park and a visit to the packing house of Swift & Co., at the Union Stock Yards, were the alternative trips provided by the entertainment committee. Nearly all preferred to see the Stock Yards, a portion of the party going by the tally ho, about 500 visited Swift & Co's. plant. Wednesday evening the Chicago roads entertained delegates and visitors at the Columbia theater; the street railway party occupied the whole of the parquette, the boxes and a large portion of the balcony. The play was "His Excellency, the Governor."

On Friday morning visiting ladies were taken to the Art Institute and then for a drive along the Lake Shore boulevard, returning in time for luncheon at Marshall Field's, where they were the guests of the firm. In the afternoon the ladies were driven to Tattersalls. Friday afternoon the Westinghouse Electric & Manufacturing Co. arranged for a special excursion to the power house of the South Side Elevated R. R.

JOHN M. ROACH.
President for 1899-1900.

Friday night the annual banquet of the American Street Railway Association was held at the Auditorium. President Sergeant acted as toastmaster; among the speakers were Senator Wm. E. Mason, Mr. James W. Duncan, Mr. John H. Stedman, of Rochester, N. Y., Mr. W. J. Hynes, and President Calderwood, of the Accountants' Association. The newly elected president, Mr. Roach, was then introduced and made a very happy inaugural address, in which he took occasion to pay a graceful and well-deserved compliment to Mr. Sergeant on his administration of the affairs of the Association. After the installation of the other officers a number of short addresses were made and the convention then adjourned sine die.

All Chicago railway men feel that they, by reason of their more intimate acquaintance with Mr. Roach, can most heartily congratulate the Association on its new president. We wish him every success and trust that in 1900 he may preside over another record-breaking convention in Kansas City.

Any report of the Chicago convention would not be complete without a reference to the Daily Edition of the "Street Railway Review." Five issues of the Daily Edition, averaging over 20 pages of reading matter each, were printed, giving a complete verbatim report of the proceedings of the two conventions for the preceding day, descriptions of the exhibits, lists of registra-

tions, and other matter of interest to those in attendance, and hearty appreciation of the Daily was shown by the two Associations and by the supply men. The "Daily Street Railway Review" will be found at all future conventions of the A. S. R. A.

Tuesday, October 17th.

President Sergeant called the meeting to order soon after 11 o'clock. About him on the platform were the members of the executive committee and the past presidents of the association. Every seat in the meeting room was occupied, the attendance being larger than at any previous first meetings of the association. The president announced that the meetings would be called promptly at 10 o'clock. He then introduced Mr. H. S. Taylor, public prosecutor of the city, representing his honor, Mayor Harrison, who delivered the address of welcome as follows:

Mr. President and representatives of the American Street Railway Association: I am here at the request of his honor, the mayor, who is unable to be present at this time, but who has such an appreciation of the highly respectable character of the individual delegates and of the interests that you represent, that he wanted some one from his cabinet to be present to extend to you, not only formally, but officially and very heartily, the freedom of the city. The only direction I had from his honor—the only message, commission or authority—was to be very brief, as he conceived that you would have weighty business topics on large interests to discuss among yourselves, and that any merely conventional speech would not be appropriate. I think even without that direction I should have fully understood what was appropriate upon this occasion.

The street railroad business has grown with the rapid development of our great municipalities and the increased momentum of commercial and social life. We are all growing gradually out of a walk into a trot, and the trot merging into the gallop, and the problems of urban transportation become more and more important and complicated.

You are to discuss these things. I dare say you are to discuss all of those questions which are arising from time to time in the evolution of the future. When the first street railway was put down in this great flat city of Chicago, it was merely a soliloquy on the part of the management. It has long since become a colloquy between the officials and employes and the officials of this great metropolis, and how to adjust and arrange urban transportation in them will become more and more important, and more and more complicated. It may be possible to at least ameliorate those occasions, which almost amount to the dignity of civil war, or the indignity; and how to anticipate the rapid development of the science in the age in which that great door of the electrical science has just been pushed ajar, and compressed air and liquid air and a dozen other motors, possibly; how to satisfy the problem of taxation and dividends as between the railway companies and the people; how to make franchises fair to companies and equitable to the communities that own the street are rising problems which you are to discuss, and upon which I have no useful or pertinent information that is not already in your possession.

The mayor fully appreciates the importance and value and dignity of this convntion. He sends you his respectful salutation, and he wishes you may have a profitable and a pleasant time. Ever since the street railway companies have abandoned the jingling horses, and the epoch of cables has passed away and given place to lightning, we recognize the fact that the street railway man is fast—is becoming fast—and yet, notwithstanding that knowledge, common to us all, I assure you, as the public prosecutor, we have not taken any extraordinary police precautions on account of your presence here.

Once more, Mr. President and delegates, on behalf of the mayor, and speaking for the city of Chicago, we bid you a most hearty welcome. (Applause.)

The president responded briefly, accepting the hospitality offered, and then announced that the roll call would be dispensed with and extended an invitation to all street railways and street railway elevated roads to join the association and then delivered his annual address as follows:

PRESIDENT'S ADDRESS.

Gentlemen of the American Street Railway Association: We are today assembled for the eighteenth annual gathering of our Association, and for the second time we meet in this great and prosperous city. I feel very deeply the honor which makes it my duty and pleasure to welcome you to Chicago in behalf of the street railway men of this city, whose generous exertions have provided us with all the essential elements for a profitable and enjoyable meeting. What remains to be done lies in your own hands, and I may be permitted to urge upon you the desirability of a full attendance upon the business meetings, and a free and ample discussion of the papers which will be presented. In order that the time may be sufficient for this purpose, your Executive Committee has purposely restricted the papers to a smaller number than usual, and earnestly solicits your co-operation in giving them full audience and ample discussion.

As will be seen by the report which is to be submitted, the financial condition of your Association is good and improving from year to year, for which happy condition we should not forget we are indebted to the efficient efforts of your officers in prior years when the bank balance was not so readily visible; nor should the generous support of our exhibitions by our friends, the supply men, escape our notice. The devotion of one day of your convention to the especial purpose of visiting the exhibits, which has been arranged by your Executive Committee, will be availed of, it is hoped, by every delegate, to the mutual profit of all.

Those gentlemen who met here in Chicago in 1883, many of whom are I trust present today, could have had little conception of the changes in their business which were to occur before the end of this century. At that time there were in Chicago, street railways operating about 153 miles of single track. At the present time the mileage of the surface street railways of this city is about 736 miles, of the Chicago interurban street railways about 261 miles, and of the elevated street railroads about 100 miles, either operated or under construction, making an increase since your last meeting here of 944 miles of track. This remarkable extension of street railways, their equipment with mechanical motive power, the unique union loop system, and the successful application of electric power in the elevated railway service, are not only a wonderful testimonial to the courage, energy and capacity of their projectors, but they have made Chicago a street railway Mecca to which we all may come to observe and learn. We are, therefore, to be greatly congratulated upon the advantages afforded us by the selection of this city for our convention.

The year which has passed since we met has presented some unusual features, which are worthy of our attention. The tendency towards consolidation of small or competing roads into larger homogeneous systems has been manifested by many examples. With the introduction of electric motive power the old time horse railway company, operating a few miles of track on two or three city streets, has disappeared, and its larger successor has found necessary such changes in administration, such extensions of its system and service, that the advantages of combination with rivals have become more and more manifest. The street railway which formerly gave a short distance urban service has found itself extended far into the country; the same car which disputes the passage of a busy city street with a truculent teamster, may an hour later be flushing partridges and grouse along the rural highway, stopping to leave the tired artisan at his country home, and bringing a healthful excursion within reach of the humblest family; thus the trolley car is rapidly filling a long felt want, which was neither within the power nor the disposition of the great steam railroads to supply. All this means changed conditions with new responsibilities, and emphasizes the need of consolidation.

To successfully amalgamate such properties, and organize and operate them with due economy and a just regard for the needs of the communities to be served, requires of the operating officials a high degree of experience and skill. The new problems to be met offer better positions to which those who are ambitious may aspire, and the wonderful rapidity with which this situation has been developed, will be a lasting monument to the officials of our American street railways. The advantages of this larger growth are many, and perhaps not the least is a growing respect for the value and importance of the street railway industry, which we may all hope will ere long be recognized by just laws which shall deal fairly and equitably with the relations of the street railways to the municipalities, and give to capital invested in urban and suburban transportation, security and a fair return upon the investment.

Another of the notable events of the year has been the failure

of a striking attempt at municipal ownership, with which we are all familiar.

It is greatly to be regretted that the year has been signalized by several very serious strikes and attempted boycotts. With the consolidation of systems, the question of labor assumes a greater importance. The paralysis of all the transportation of a large city is a grave public calamity, to be prevented by all reasonable means in the power of the officers and men of the transportation companies, and by the municipal authorities. The larger the system of any corporation is the more necessary it is that its management shall firmly and wisely conduct its affairs, and the more impossible that the responsibilities imposed upon the management should be delegated to others. Does it not, therefore, devolve upon us who are charged with such responsibilities to take the greatest care that our representatives before the public, the employes, shall always receive such liberal and just treatment at the hands of all our officials that they may feel their interests and ours to be identical, and may loyally work with us for the good service of the public and our corporations?

Care in the selection and instruction of employes may, therefore, well engage our constant attention. We are all merchants in that we have transportation to sell and must present it in an attractive manner if we wish to retain our customers.

The good will of the community which it serves seems to be an essential element of success with any public transportation company, and the best means to obtain that good will should receive our careful consideration. In this direction lies, I believe, a field of work for our Association, and for each and every one of its members, which may be far more fruitful for good than our technical papers or our exhibits of apparatus. We are all aware of the wide difference of opinion which exists in the community as to the proper relation of street railways to the public, the service they should render and the burdens they should bear, and last, but not least, the returns they should expect upon capital. In the press and in educational and social reform institutions much prejudiced opinion and misinformation is promulgated calculated to injure public service corporations, and in so injuring them to deprive them of much of their ability to adequately serve the public. Is it not our duty, each and all, in our own communities and wherever else opportunity offers, to take steps to remedy this state of affairs? Let us seize every opportunity to refute these current fallacies, meet the self-styled economist on his own ground and show him that his "quasi-public octopus" is the greatest public benefactor and social reformer the world has ever seen!

Fair-minded men will generally listen to both sides of any question, and the ignorance of even those who should be well informed as to our industry, is so great that mission work to disseminate truth is imperatively demanded. I believe that work of this character has already been undertaken by one of our friends of the Chicago technical press, and that in so doing he has set a worthy example which we may beneficially follow.

One of the saddest events of the year was the sudden death in April last of our lamented friend, Mr. M. K. Bowen, president of the Chicago City Railway Co. Beloved by all who knew him, ever ready to spare his valuable time for the aid and information of others who sought to learn from his experience, he was an honor, not only to the corporation he served so well, but to the profession which will miss him so sadly. Ever faithfully interested in your Association, his untimely death brings a feeling of deep loss to us all.

I venture to remind you of the work which our friends of the Accountants' Association have undertaken and are accomplishing. The importance of accurate and uniform accounts to the success of any railroad can hardly be over-estimated. A thorough knowledge of accounts and of finance is an essential qualification for the administration of large properties. The work so far accomplished by their Association, and their further deliberations merit your earnest support, which will not only be beneficial to them, but to each and all of the members of our Association.

I wish here to express my appreciation of the cordial support and valuable work of your efficient secretary and executive committee. That our Association may always be so fortunate is my earnest wish. In conclusion may I once more express my sincere appreciation of the honor which you conferred upon me by electing me to preside over this meeting, and bespeak your patience with my shortcomings.

Then followed the reports of the executive committee and secretary and treasurer, which were adopted. In substance they were as follows:

Report of the Executive Committee.

The executive committee reported that it had received the report of the secretary and treasurer showing the statement of the finances of the association, the members in arrears and the Boston convention exhibit space remaining unpaid for. The secretary was instructed to write all eligible companies, inviting them to join the association. On motion of Mr. Woodruff it was voted that any American elevated railroad is eligible for membership. On motion of Mr. Lang it was voted that the publication by the association of legal decisions affecting street railways be dispensed with, as the street railway periodicals devote considerable space to this subject each month. The president read a letter from Mr. John T. Burnett, chairman of the special committee on the carrying of the United States Mail on Street Railways, in which he stated that the conditions during the year had not been opportune for effective work, and he believed that the committee should be continued for another year and be given further time for action; or, if preferred, a new committee should be appointed; on motion it was decided to recommend to the association that the committee be continued for another year. It was decided to enforce the usual rules concerning banquet tickets. On motion the following rules for the convention were adopted:

1. No member will be recognized by the president unless he shall announce distinctly his name and address.
2. Speeches will be limited to 10 minutes unless the time shall be extended by the convention.
3. Members who desire to offer resolutions or other matters to be considered by the convention, are requested to submit them in writing, over their signatures, to the secretary.

Report of the Secretary and Treasurer.

The statement of the finances of the association showed cash on hand Aug. 25, 1898, as $3,656.28 and the receipts to Oct. 11, 1899, as $7,650.87, of which $450 was for membership fees, $3,930.67 for dues, $3,137.70 for space at the Boston convention and $132.50 for space at the Chicago convention. The total expenses to Oct. 11, 1899, were $5,648.28, leaving a balance of $5,658.87.

Aug. 25, 1898, there were 173 members; to Oct. 11, 1899, 7 new members had joined and 8 had withdrawn, making the membership at that date 172.

The president then said some other committee reports would be presented later. Mr. Charles T. Yerkes of Chicago was then introduced and presented the following paper:

INVESTMENTS IN STREET RAILWAYS: HOW CAN THEY BE MADE SECURE AND REMUNERATIVE?

By Charles T. Yerkes, President Chicago Consolidated Traction Co. and Union Elevated Railroad Co.

The subject you have given me for consideration is one in which I take great interest, and for a very good reason; about all the investments I have are in street railway securities. You can therefore see that my faith is great, for it is from our actions that we are judged.

My experience with street railway securities dates back to a period almost 40 years ago, at which time street railways were in their infancy, in fact, you may say, in their swaddling clothes. It was in the early 60's, when the scientific operating of street railways was unknown, and, in fact, not dreamed of. In those days the men were worked from 16 to 17 hours out of the 24, and they, as well as the officers of the companies, did not seem to be aware of the fact that this condition could be bettered. The roads themselves were of a cheap character, and while intended to be permanent, they were far from it. But they were equal to the demands of the public and requirements of street railway transportation. In those days even a car register was unknown. The street railways in each city were owned by a few influential persons, generally men of large means, and the stocks and securities of the companies were but little distributed. Few people knew of their value or cared to have much to do with them. To hypothecate street railway stock as collateral with banks was unknown, and it was not until 10 years after, in the early 70's, that the banks would look at them. The dividends in the meantime were generally fair, particularly with companies doing a

Charles T. Yerkes was born June 25, 1837, in the city of Philadelphia, of Quaker parents, and his early education was received in Quaker schools. After establishing and putting upon a successful basis, a banking and brokerage house in Philadelphia, he came to Chicago in 1881, for the purpose of starting a Chicago branch of this business. While here Mr. Yerkes early realized the possibilities for investment that were offered by the transportation systems of the city, and in 1886 he succeeded in gaining control of the North Side lines and reorganized the company as the North Chicago Street Railroad Co. Two years later he purchased the West Side systems. The substitution of cable and electricity for the horse on

CHARLES T. YERKES.

all these lines, and the extension of branches out across the prairies, began at once after Mr. Yerkes secured control and has continued to a greater or less degree ever since. Mr. Yerkes next turned his attention to the elevated roads and organized the Union Elevated Railroad Co. to build the down town loop connecting all the elevated systems; he is also the controlling spirit in the Lake Street and Northwestern Elevated roads. He has within the past few months sold his interests in the North and West side surface lines, and is at present giving a large amount of his time to the Chicago Consolidated Traction Co., which he formed for the purpose of uniting under one management eight companies operating systems in the outlying districts.

---

large business in the thickly populated part of the cities in which they were located. To my mind, the chief reason of their unpopularity was that the building of street railways in those days was always opposed by the people in the vicinity of the location, and particularly on the streets where the rails were to be laid. I remember very well the first track laid in the city of Philadelphia, where I then lived. It was the Fifth and Sixth St. line. The people tore up the track at night which the company had laid during the day, and it was not until after there had been several riots, and the authorities had awakened to the fact that the law must be sustained, that the company was able to finish its road. The Chestnut and Walnut St. line in the same city was bitterly opposed by the citizens, and everything was done in the legislature and in the courts to prevent the charter from being granted and the tracks from being laid. And this has been the experience in most all large cities. Consequently, the people who were promoting the laying of street railway tracks were looked on as sort of "free booters" and their securities with much distrust. To some slight extent this feeling still exists, notwithstanding that there is scarcely a road which was laid years ago that could be taken up today without great objection being made on the part of the people.

It was not until the early 80's that street railway securities were seriously considered as popular investments, and since that time their popularity has continued to increase as time developed the great resources which lie within them. The quality of the street railway plants of those days consisted in the kind of track, the condition of the cars and the class of horses which were used. These differed most materially. On some roads it looked as though the cars were never repaired or painted and the broken down horses were very much in the majority. Added to that was the uneven rail, spiked to a string piece, which almost made the rider seasick during a passage over it. Then again, there were other companies where the track was well laid and kept in good order, the cars in a good state of repair and well painted, and the horses of the highest class for their work. These two conditions were almost invariably the result of the adversity or prosperity of the different companies, and while the latter class, that is, those that were prosperous, came to be sought as an investment sooner than the other, the anxiety of the public to so invest was never great. But about 1880, when consolidation of different roads came to be more in fashion and the economics resulting therefrom and also the studious consideration which was given as to how to operate roads, it was more a matter of reality. The attention of capitalists and the people generally was drawn to the stocks and securities of street railway companies, and this condition has been on the increase ever since that time. The fact that great improvements have been made after the horse was relegated to a past era has had much to do with this, and naturally so. The mechanical propulsion of street cars has attracted the attention of the whole civilized world, and the question naturally arose in the minds of those who witnessed these changes, and who had money to invest, "Isn't this a good place to invest our money, and isn't there profit in it?"

The change in the mode of propelling the cars and in fact the whole outfit of street railways, has created what might be safely termed a "revolution." To look into the history of all the street railways of 20 years ago and see the changes which have taken place, is certainly wonderful. I can see before me a plant that was run with one-horse cars, a driver and no conductor, a pay-box in the front of the car, where the passenger was required to advance and deposit his fare. I see that line changed to two horses and obtaining the dignity of a conductor to collect fares from passengers. That was a great improvement, and then we had straw in the bottom of the cars in winter—not overly clean, because we could not afford to put fresh straw in every day, but still this was a luxury—an oil lamp at each end of the car which supplied the double purpose of lighting the car and showing the signal on the outside. We went at the rapid rate of six miles an hour when we could make it and keep on the track. The motion of the car was most agreeable to a person who desired to ride on the billowy waves. We see this changed, so that the track was smooth, the straw in summer time was taken out, floor always clean, and a stove giving comfortable warmth placed therein in winter time. This was advanced luxury. We were pleased with all this, except when the snow would come, or the days were hot in summer, when the horses were not able to pull us to our destination.

We see another change—the great power of electricity was brought into use, the horses were gone, and instead of making our six miles an hour we could go twice that rate. The oil lamps were removed and electric lamps put in their places. As like begets like, the conditions of the cars were improved, cleanliness—always, an adjunct to electricity—was substituted for uncleanliness. The districts of the city were expanded, lines were made in the suburbs, creating new towns, improving the property of the people, increasing the amount of the assessment on real estate, until we seemed as though we were living in another world. Aladdin's lamp did not produce any more wonderful changes, and this could not have been done had it not been that the attention of investors, both great and small, had been attracted to the street railways. And what of the great benefits to the people? Instead of the slow, uncomfortable manner of travel, rapid and easy means are given. Points that could not be reached with the old system are brought within easy access. Everything is better and cheaper. While in days gone by it cost 5 cents to travel three miles, with the new improvement, four times that distance can be traveled for the same money. Then it cost a person to ride about 2 cents a mile, now it costs ½ cent per mile. Why, then, I ask, should not a continuance of this condition be encouraged?

And now I come to the second and most important part of my subject, "How can they be made Secure and Remunerative?" To my mind security is most to be considered. The remuneration must be brought about by hard work and close attention to the corporation. We cannot do much to increase our receipts, they come from

natural causes, but we can control our expenditures, and that really, together with knowing where and what to do, in the science of street railway management.

But in regard to making them secure, we must depend very much upon the justice of the people and the fact that we, as managers, are willing to do what is fair with the public. There seems to be an idea in the minds of many legislators that a street railway is a very simple affair and of very little account. This, feeling has been engendered by their knowledge of long ago, and that knowledge has not advanced with the change in street railways. In fact these changes have come and been accepted as such a matter of course that little attention is given to their worth.

The most important matter in regard to the security of street railway securities is the length of charter under which they are operating. This question is of as much importance to the people as it is to the street railways themselves. The longer time that is given to a charter to run, the greater improvements and the more expensive plant can be operated by the companies. That is to say, it can be made more permanent than if the charter was of short duration, and naturally it would be. If a company had a charter with but a few years to run, the improvements will be of a cheap character, commensurate with the length of that charter, and the better the improvements, the better it is for the people. Not only for those who own property, but for those who ride and have no property. We see this exemplified daily. Let us ask the question, how many bridges of iron or stone would the steam roads have if their charters ran for only a few years? There would certainly be none, and the speed of trains would be greatly reduced. Years ago 30 miles an hour was considered rapid traveling, with 20 as an average. Now the rate has been run up to more than 80, with 45 as an average on fast trains. This latter condition would never have existed if the steam roads had not had charters long to run. Why should not the charters of street railways be equal to those of steam railways? In fact, considering them all in all, they should be longer. The cost of a steam railroad today is not nearly equal to the cost per mile of a street railway, even counting all the appurtenances that go with each. One hundred years has been the time granted in this state for a charter to a street railway, and the municipality grants an ordinance for 20 years. That this was wise or unwise at the time that period was designated, I will not argue, but considering that it was a proper time for what we had in street railways then—rails weighing 40 lb. to the yard, laid on a wooden string piece, this string piece laid on sleepers 5 ft. apart, cars of a cheap class, a lot of horses, good ones, if you please, and a five-acre lot in the suburbs where the car barns were erected—this practically constituted their outfit. At the end of 20 years, if there was to be no removal of the ordinance and the charter was allowed to lapse, what would be the loss? The track, considering that it had been kept in good order would sell for, say 20 per cent of its cost, the cars for about 30 per cent of their cost, the horses for about 25 per cent of their cost, and the real estate which had been bought by the company 20 years ago, and where in all probability, a settlement had since gathered, would sell by the front foot, realizing without doubt 20 times as much as it had cost. There, you see, there would not be much loss if this road had to be given up. But what are the conditions today? The street car tracks are laid with heavier material than that used by the steam roads, the power houses cost hundreds of thousands of dollars, where the old structure cost but a few thousand, the electric plant on the cars and in the power houses and the wires and poles cost immense sums. So that it can truly be said that the electric plant cost more than 10 times as much as the horse car plant. If, therefore, it was right to give a horse car plant a charter for 20 years, the electric plant should receive a charter for 200 years, and city ordinances to correspond.

It has been argued that if grants were made extending over a long period of time other means of transportation might come into existence and these charters would interfere with the adoption of these improved methods.

Let us suppose 50 years ago perpetual privileges had been given to operate exclusive omnibus lines in this city, or privileges of the same character had been given to operate ferries across the Chicago River, what would they be worth today? Long ago the charters would have been forfeited, simply for the reason the improved methods had rendered them worthless.

But while I feel that the legislature should treat the street railways fairly, I also feel that the street railway companies should treat the municipalities and states in the same spirit. I believe that a fair amount of the earnings of the companies should be given to the municipalities in which they are located. There is no doubt but that the street railways are of great benefit to these municipalities and to the people generally and to the property owners, but at the same time, it is my opinion that a spirit of liberality should be engendered by the street railways towards the municipalities, for the reason that it is through the municipality that they are permitted to transact their business. It is a mutual benefit, with the burden on the corporation. There is no doubt but that the extending of the lines in a large city is a great burden on the railway company. There is little money to be made out of them for years, and while the company is waiting, the property owners and people are being benefitted. The very mention of the fact that a line is to be extended in a certain district causes advances in the value of real estate, and these advances are emphasized when the extensions are really made. There is nothing that has added so much to the health of the inhabitants of a city as the extension of street railway lines. In this city the tenement house district, which would have been a perfect pest hole, is scarcely to be found. The prairies have been covered with street car tracks, which forces the opening of streets. Cheap lots and cheap homes for the working people and the poorer classes, as well as the well-to-do, is everywhere in evidence. While there may be efforts to influence the people against street railways, they cannot but see these conditions, which are so plainly visible to them, and seeing them, fail to properly appreciate them. I believe in educating the people, of whom the legislatures are the representatives. Every state wherein there are large cities, which necessarily have important street railways, should have a commission appointed to ascertain the condition and requirements of this industry. The commission should be appointed by the governor of the state and should be composed of intelligent business men, of first class standing who are not interested in street railways. Under no condition should a person holding office, or who is ambitious to do so be named. A man of this character is never to be trusted in any affair where courageous opinions are expected. The reports of such a committee should have great weight with the legislators.

I believe that all corporations which receive their life from the commonwealth should be subservient to that commonwealth. That there is nothing in their formation or general business which should not be reported to the proper authorities and be subject to investigation. I believe that the law should provide that an intelligent commission be appointed by the governor of the state in the same manner as is now done in this state, in regard to the commissioners of the park system. The duties of this commission would be to see that the laws concerning street railways are carried out and that the companies have the protection to which they are by law entitled. The commissioners should have terms of 15 years, so as to insure their becoming experts and receive such salaries as would enable them to live well and take care of their families in a good manner. They should understand when appointed, something of the street railway business, and as years pass by their knowledge would increase, as also their worth. They should have the power to dictate to the railway companies where new roads should be laid, if at all, and also the kind of new improvements to be used, when a railroad contemplated making any change in motive power. They should have the power to regulate the devices to be used for saving life and preventing accidents. With an intelligent, honest commission of that kind, street railway managers would be made more comfortable, the people would be benefitted and the securities of the corporation would be more solid. The advice of the commissioners would be sought and the advice of such men, with the experience and knowledge they would naturally have, would be most valuable to any railway manager. Their reports would be explanatory, and much of the ignorance regarding street railways which is fostered by our enemies, particularly in this part of the country, would be done away with.

To make securities more secure, we must have these different matters fully understood. We must do our business in a straightforward manner, with due consideration to the public, who are our patrons, continuing to increase facilities as opportunities offer and adopting the most improved kinds of transportation, which experience is proper. And last, but by no means least, holding with the kindest regard our employes, who are faithful to us to the end, that there may be perfect harmony between them and the management, and seeing to it that our corporations are able to earn honestly a fair remuneration for their money, time, experience and labor that have been spent upon them.

Mr. McLean moved a vote of thanks, after the adoption of which the president said: Mr. Yerkes, I wish to thank you personally also for the very able paper that you have given us and for the points on how to get at the real meat of the whole financial question, which from your experience outlined in this paper I am sure will be a most valuable lesson to us all. The paper is now open to discussion, and I think I will call upon Mr. C. D. Wyman, of New Orleans, to open the discussion.

Mr. Wyman: Mr. President and gentlemen of the Association, I think that by the vote we have just passed, in which I most heartily joined, we have expressed our sentiments touching this paper most sincerely. When I was notified that such a topic had been assigned by the committee having that matter in charge for presentation at this time, I felt that it was a topic of the greatest importance, and one which we might congratulate ourselves upon having presented here, and especially that we were to be congratulated when it was announced that Mr. Yerkes would read a paper upon that subject. He is a gentleman who has been so thorough a student of street railway affairs, from both the financial and operating sides, it seems almost a work of supererogation on my part to attempt to add anything to what he has said upon this subject. But I venture to say a word or two upon some lines which may possibly touch us as managers in our relations to our stockholders, to our investors, that we have all duly considered, and yet which it might be proper to suggest in connection with the lines of thought that Mr. Yerkes has presented. Of the importance of sustaining and preserving the confidence and faith of the investors in the enterprises in which we are engaged there can be no question. When it is remembered that one-third of the invested wealth of civilized nations is today in railroads, and not an inconsiderable portion of that investment is in the street railways, that we should secure and hold the confidence of our investors and that we should make their investment profitable, is very manifest. The great desire which now is manifest on the part of capitalists to put their money into street railroad enterprises is one which should be met by a corresponding effort on our part to make everything plain, clear and distinct to them in regard to such enterprises.

Now in the selection of a board of directors from our stockholders it is always customary, of course, to select men not only of financial responsibility in the community, but we always regard it as necessary and proper to select men of high probity, men of reputation and of position and for officials of the company. There is made emphatic in the eyes of the public this feeling of responsibility to the public, and also the equal responsibility to their investors and the capitalists. The impression is wise, beneficial and tends moreover to the extension and expansion of our business, for I take it in this respect, at least, we are all expansionists.

I remember reading in a paper recently of a distinguished orator here in Chicago on the occasion of the great gathering which was talking about trusts, I believe that he said, "In his opinion there was no danger from aggregated capital if there was a sufficient amount of publicity given it." However much we may agree as to the causes and reasons that suggested that convention, I submit to you as my belief that we should be frank, free and open with our investors; that we should tell by means of circulars or statements, or printed publications of our operations and results, the truth, and the exact truth as near as we can ascertain it, to all that are interested in our respective companies, whether they be interested to a large or to a small degree. While it is true that a complete disclosure at all times of the policy of the company might hurt it, I still hold that the results of our work should be set forth constantly, fully and freely; I believe this can be done, and I believe that the more of it that is done in a proper manner—a complete and thorough manner—the more we shall secure and retain the confidence of our investors and likewise what is a very important thing with us, to the increasing of their holdings in our enterprises. We often have what are known as panics, a sort of neuralgia that pervades the financial market, and the reason given to us by those who are skilled in these matters, is that it springs from want of confidence; that actual values are not disturbed but that speculative values are, but it results from a want of confidence, and fear and distrust and uncertainty as to what is going on. Credits are withdrawn. We may, to some extent, ward off any such feeling, any disquietude on the part of our investors by letting them know the facts as far as we are able to do so, and giving them frankly and freely our best judgment as to present facts and future anticipations in reference to the enterprises with which we are connected.

I also believe that we should adopt, so far as possible, a plain, simple and thoroughly understandable method of bookkeeping, and I am therefore most heartily in accord with the Accountants' Association, which is now in session, and is endeavoring to do just precisely that which I am attempting feebly to speak concerning. The average stockholder often becomes very much muddled when he attempts to study out the question of what we shall charge to operating expenses and what shall be charged to permanent expenditures, and so far as it is possible, such a system of bookkeeping and record of expenses should be made clear and comprehensible to his mind. I would also suggest in this connection the question of depreciation. I am exceedingly glad to see that some of the railroads and notably, so far as I know, the Milwaukee road, has taken up the question very carefully, and very particularly that of the depreciation of the different mechanical parts entering into the physical equipment of the road, and it is setting aside, as I understand it, annually, a certain amount of money from its receipts to make good that depreciation. It is not infrequent that railroads electrify or cableize, and the first year or two their receipts naturally increase, properly so, and their expenses may remain at a very low ebb by virtue of the fact that everything that they have is new, and the era of repairs has not set in. It is, it seems to me, unsafe to base our calculations upon the result of a particular year, or some years—to predicate upon those results what the earning power of the company is to be, and to publish to stockholders that they might be always expected. While it is always to be hoped, of course, that the increase of receipts will take care of repairs and depreciation, nevertheless if we can make certain and absolute that point by studying out what this depreciation is, we are at least on the safe side if we begin to provide for it, publish it and set an amount aside to make certain of it, tell our investors what we are doing from the very first roll of the wheels upon our line. I think this is very, very important. The average net receipts of a few years as they pass should be made up, and out of these net receipts should be taken an amount of money necessary to replace the rolling stock, the power houses, etc., after their life shall be exhausted, and if a certain amount is set aside it may be very positively found what electricity or that motive power which the major portion of the railroads are using, has been in our hands, and it is, therefore, not a very difficult matter to ascertain as to the life of these various mechanical devices, and the material which we use in our different operations may be. Sometimes we may be put under pressure possibly to hasten matters, but I think a conscientious, prompt, truthful and honest management, while it may be criticised as too conservative, had better to err upon this side than upon the other. (Applause.)

Mr. J. I. Beggs, of Milwaukee: Mr. President, I feel very deeply interested in this subject that is so ably presented here by a gentleman that has spent almost a lifetime in the ownership and in the direction of the affairs of street railways, and I feel so deeply interested in it because I am in a similar condition to that stated by Mr. Yerkes. I am charged with the responsibility of managing what is becoming one of the larger street railway systems of the country, but I am more than that, Mr. President, and have, therefore, given to this matter the most close and careful thought. I can say with Mr. Yerkes, all I have in the world is in street railway property. I am, therefore, particularly interested in the security of these investments.

I think there is a side to this question that has not been touched upon in Mr. Yerkes' paper, even so thoroughly as he has discussed it, or in Mr. Wyman's analysis of it, and I desire to throw out that thought here. It is one which the Milwaukee company, as my friend, Mr. Wyman, has suggested, has taken hold of. I want to know when I have been laid to rest, and those to whom I may leave the results of a life of hard work, want to know what protection for the payment of these securities there is when these short term franchises have ceased to exist. Taking the property of which I am now speaking, a little over 20 years to run and yet we are discussing it as they are in some other sections of the country, trying in advance to make calculations as to the franchises to know how much we are justified in putting into that property; how long we have in which to get a return from it. I do not know that it is being done so methodically by other properties—it may be. We have calculated, and I be-

lieve you will recognize that it is a proper charge against earnings, that you have a right to set aside this amount before the public can demand that you shall give greater accommodation for the carrying of a passenger 12 or 15 miles, to which Mr. Yerkes has alluded, or that the fare shall be reduced. We are setting aside a certain amount for this purpose, and we want to know what is to be paid to those who may succeed us in our investment in these properties and if, after the 20 years expire, they will simply have turned over to them out of which to recoup the investment there a pile of junk on the streets that the city wants to return in order that it may make a better dicker with some one else. I feel that we have a good investment in the property if properly run. We usually do not, when the road is new, and the equipment requires very little repairs, and the roadbed is new, look forward to the time when we shall be taking out 45-lb. rails and replacing them with 80 or 90-lb. rails, nor to the time when we shall be taking off the single truck cars, the equipment of each one of which is $2,900, and replacing them with cars costing almost four times as much. I desire to throw out in connection with this paper of Mr. Yerkes, the thought that we want to make some provision for the time that these bonds of ours will mature. In the case of the Milwaukee property, our bonds do not mature until two years after the expiration of the franchise.

Now, as to the other point suggested—as to the security—because I have always believed in holding this security myself—I do not want to have anything to do with a thing that I cannot put my own means in—I want to know what provision has been made to pay them. Is there any sinking fund being set aside by your companies to take care of these various investments when they shall mature? Gentlemen, you must make proper provision for your property, by looking forward a very few years, when they will have to be thoroughly reconstructed from the ground up. I estimate that we replace 10 miles of track every year, and that is not conservative at all, because we have got about 150 miles of road in the city limits, and I estimate that it will last 15 years, which no road has done thus far; therefore, we must put down 10 miles per annum to make it good. We estimate our rolling stock in the same way. It is a wonderful thing to tell, not only to the specialist, but to any business man or to any court, and it was very influential in the argument where the city tried to make us give 4-cent fares, that with proper maintainance of our system we could not do. Although if we had taken the figures as they appeared on their face, our earnings would have seemed to be sufficient to warrant a reduction in fare, but they were fictitious, they did not represent our normal repair condition as it was, and I desire to know in connection with this what provision is to be made for the redemption of those securities, when your city gets to the point when the socialistic element exists, which seems to argue that you have no right to use the streets when you are performing the functions for which the street is made, and carry the public over it without any burden upon the city whatever. I desire, gentlemen, to impress upon you the necessity, in order to make these securities safe, of having the public take them as they do our water works and gas stocks, in nearly all of which their charters are perpetual. The longer time our franchises have to run the more you can afford to spend upon the betterment of your system, the greater the facilities you can give. We are merely merchants, as Mr. Yerkes stated, in selling transportation, and we must make it the practice of, I sometimes use the phrase, "Provoking the public to ride." It seems necessary to me in order to give security to these investments, to make some provision for the bonds when our franchises have expired and when you cannot earn the interest on them, to say nothing of the principal.

Mr. H. H. Vreeland: I had hoped that our president could have waited until a little later to have called upon me, because it is placing me in rather an embarrassing position, calling upon a boy to talk in the presence of a lot of men. I am but a child in street railroad work, and it seems that anything that I might say in the way of analysis of the very valuable paper of my friend, Mr. Yerkes, would be criticising the pioneer and the patriarch in street railroad work. I have learned since my connection with the industry that of the few men who started their life's work in connection with street railway interests, who have invested their money as they made it in the interest which they had created, who have followed up as a life work until it reached a success far beyond what was considered possible for men to attain in any line or calling years ago, that Mr. Yerkes is really the pioneer in that direction.

There is a thought in connection with Mr. Yerkes' paper that occurred to me when he suggested the question of management, the consideration not only of the average revenues, but the average of expenditures; that is one of the very strong points that appeals to the confidence of investors and the general public in properties. The great steam railroads of this country with which the greater part of my life has been spent—you have only to mention the Pennsylvania, the New York Central, the New York, New Haven & Hartford and roads of that class to bring it to mind—have created a confidence in and permanency of management. Secure the proper man to manage the property. It is really more important in the street railway interests than it is in steam railroading, from the fact that in the steam road the directors do direct. There is not very much done in street railways in that direction. The manager is elected and put to work and allowed to run the property. He does not get much help and he has to be a man who can meet the local municipal conditions, the state conditions and the general conditions as affecting the properties as far as the legislative and municipal affairs are concerned. He has to be a man who can take care of the financial part and of the operating side, and he has to do it with very little assistance.

The next thought that occurred to me was what my friend, Mr. Wyman, suggests, and it is a very important one—the question of publicity. Coming out of the school where we are taught—were taught for years—not to submit a report to your directors or president without analyzing it thoroughly, not simply showing that their train tonage increased so much, mileage increases so much, revenue decreased so much, but went to work and analyzed it, and the same with reference to passengers—coming from that school then I was surprised to find how very little of that there was connected with the street railroad system. In many cases in an early day there were good reasons for it. From the fact that two or three men ran the railroad and for years acted in the same manner that they run a country store, and divided the money in the drawer among themselves. But the effect of consolidation and merging of the railroad interest in this country, both of steam and of street railroads, where 946 properties have been consolidated within the last ten years, irrespective of what may be termed trusts or monopolies, have changed this. The consolidations have reached a point where our securities by reason of recapitalization and reissuing of bonds necessary, have come into the hands of the investing public, and the managers are the caretakers of the property, not of the few, but of the many. But it is necessary to let people know what they are buying and what values they are getting to determine whether it shall be made into a fund or be a different proposition. The number of the stockholders in the large corporations, I am glad to say, is increasing very rapidly in the different properties with which I am connected. The increase in the average number of stockholders has been very large. In the Metropolitan Street Railway Co. the increase has been over 150 per cent in the last 10 or 15 years, both in the increase of capitalization and the bringing in of new investors. At the present dividend we had 130 more stockholders than we had at the last dividend three months ago, and not one of them held over 100 shares of stock in the increase, and they are residents of New York City. That is one of the greatest elements of strength in the handling of this property where we have to meet with the municipal and state question—a common interest with citizens in our properties—are located in the properties themselves. It assists and helps out with the question, gains friends for the property and assists very materially in the management.

With the question of 20-year franchises and 25-year franchises, I am very glad to say, that many, many years ago my predecessors, with very wise views for the future helped the state legislature to grant permanent franchises, and after we had secured all the permanent franchises that we thought were necessary for the handling of the business for the territory where we operated, we arranged it so that others are limited to 25 years, so that it is not a question for me, as manager of the property, to seriously consider, but it is a very serious question for the other fellows.

There is one further point that Mr. Yerkes suggested, and that is the labor question. It is the life of the street railroad. All other matters connected with the property are insignificant. The financial side, the transportation side, except as represented by labor, are insignificant as compared with the great problem of handling labor. In the large consolidations there are, say, 15 or 20 different lines in which the employes have been handled under the theory and ideas of as many different managers, and you see how difficult

it is to bring that body together, to try to get them responsible to one man and responsive to one method of management. It is a thing that requires a great deal of energy and ability, but it is a thing if once accomplished, that gives the public to understand that the manager is managing the labor problem and not the agitator. And if you can get that confidence you must adopt the same policy of the agitator and take the platform that he does when he talks in his interests and decide that it is just as valuable to the manager to go on that platform and talk to them in his interests; that is one of the greatest elements of strength in the street railway question in my mind, and I feel that it is one of the works in connection with the large work of consolidating the property, and I feel today that the success that has come to our property is largely attributable to this. The success of the investment is in the confidence of the stockholders and the general public that there is no crisis going to confront the property this year or next, that may not only wipe out the dividend, but mean the wiping out of the entire earning capacity for that period and the disturbance of all the smooth working conditions that is necessary to have at all times.

Mr. President, I consider it an honor to have the opportunity to reply in a small way to the very valuable paper of our mutual friend, Mr. Yerkes. (Applause.)

The President: We have all heard with very great pleasure the remarks of Mr. Vreeland on this subject, but we want to hear from everybody. Mr. McLean, I think we ought to be entitled to some remarks from you.

Mr. Thos. H. McLean: I have felt, Mr. President and gentlemen, that I am amply repaid for attending this convention by listening to the discussion already had upon the very valuable paper of Mr. Yerkes, and, without taking up the time of the convention, I think it proper to say that the paper itself and the discussion had upon it stirs up a line of thought that we can carry home with us, and that will inure to the highest benefit of all the members interested.

The President: We should be glad to hear from Mr. Foster, of Lynn.

Mr. E. C. Foster: Mr. President, and gentlemen of the Association: I feel entirely unable to express to you my opinion upon this subject, although I have listened with a great deal of interest to the very able paper read to us by Mr. Yerkes, and to the very able discussion by the other gentlemen who have preceded me, and I agree with them that it is a subject of very great importance, and it appears to me to be a subject of far more importance to those operating street railways in the western country than it may be to us in Massachusetts, for in Massachusetts you understand that we have a board of Railway Commissioners who have the supervision of the accounts of the street railways. Our tenure of franchise is entirely different, as I understand, from what it is in this part of the country. There the franchise is granted to the corporation without limitation. To be sure it is subject to revocation by the local boards, approved by the Railroad Commissioners, but, gentlemen, it would seem to be absurd on the part of the board of Railroad Commissioners to revoke a location on which they had approved the issuing of security. Their approval is set upon the securities as a seal. Also the amount of securities which are issued or may be issued upon any street railway is limited. They have the power of limitation. I understand that not to be the case in the western country, and it would seem that you were justified in seeking some better and greater protection than you now enjoy. I do not say, gentlemen, that the laws of Massachusetts are superior, as regards street railways, to those of any other states, but I do feel that the investors are protected. It is frequently remarked by those holding the securities of the street railways of the home companies in Massachusetts that it is a dividend paying stock, and it is free from taxes, making it a very desirable investment. A person holding a street railroad stock in any of the home companies, I believe, has a security which would justify any one in investing in it. There we are subject, of course, to the whims and caprices of the local authorities to a certain extent, but that is limited by reason of our right of appeal to the board of Railroad Commissioners. Gentlemen, I do not think it necessary for me to weary you with further remarks, as I feel that there are others here far more competent to discuss this subject tonight. I thank you. (Applause.)

Mr. Yerkes: May I be permitted to ask the gentleman a question on one point that he made. I understand you that the franchises of street railways are liable to revocation at the instance of the local authorities, confirmed by the Commissioners.

Mr. Foster: Yes.

Mr. Yerkes: That is what I understand. Now isn't this a fact, and this I merely ask for information—isn't it a fact that the courts have decided that these revocations cannot be put into effect unless it can be shown that the roads are not needed? That is the point that I want to make. As things stand now, according to your argument, it would seem that if the municipal authorities and the commissioners would get their heads together they could compel all the tracks in any town in Massachusetts cities to be taken up.

Mr. Foster: In reply to that, Mr. President, it would have to be shown that it was for the public interests and convenience that they should be removed, otherwise it would not.

Mr. Yerkes: Then it is a pretty difficult thing to get a track up when the people want to use it.

Mr. Foster: I don't know of that ever having been done, except in one instance. I think there was at least one road where they undertook to revoke the location. And the location was revoked, but another was substituted for it, so that it was not a complete revocation.

The President: We do not want to hear from one section alone. I may recognize the faces of some gentlemen more readily than others, because they are from New England. I want to hear from all sections of the country. The South is right here. We would be glad to hear from Mr. Jones, of Memphis, or any other gentleman from the South. Mr. Jones, won't you favor us?

Mr. F. G. Jones: Mr. President, and gentlemen of the convention: We certainly have gathered very considerable information for the business in the line of making investments attractive to people looking for that line of security. I do not believe it would be possible for me to say anything that would be of interest on the subject. We have gathered some points here—ideas that are new to us, on the line of these short franchises. You heard from New York; from our friend of the Metropolitan, who gives a pretty good idea how some of the larger companies have gone in and succeeded in getting a perpetual franchise, and then gone and procured legislation as to the 25-year law. Those ideas are certainly new and will help us when we ask for extension, and it is gratifying to me to hear these things.

The President: I see in the hall another New England gentleman, Col. Heft, of Bridgeport, Conn. He has had a very large experience in street railway business and is very level headed.

Col. N. H. Heft: Mr. President and members of the American Street Railway Association: While my time has been given to building these roads, I have not been required to direct any of my energies to raising the money for them. Our board of directors has done that. I have simply directed my energies in the direction of seeing how I could best spend the money to make the investment the most desirable, and while I believe that it is necessary to look after your municipalities, your Legislature and your representatives in general, yet I believe that the greatest benefits that will come to the street railway investment will be through the mechanical and electrical engineers in improving the present equipment of the railroad. I believe that our attention never has been sufficiently called to this matter, and that in a great many cases we have suffered from this lack of attention to the question of car equipment and to the weights that we are hauling today. We haul one passenger for whom we receive 5 cents, and for whom we are compelled to stop our cars twice, to take him on and to let him off. In going over the question of weights that we are drawing today, I was simply horrified to find that for every passenger we were hauling 720 lb. of dead weight, where the steam railroads are hauling 137 lb. with their standard system of railroad equipment. Now, I think that it behooves the street railroad managers to turn their attention to the question of equipment to see if we cannot get rid of some of this weight, and we expect to produce within the next two months a car, including the entire equipment, that will not exceed 227 lb. per passenger.

Now, I have been very much gratified in listening to the paper of Mr. Yerkes. I have also been very much interested in what our friend Wyman has said. He is always good, and I have also listened with a great deal of pleasure to our friend Vreeland of New York. I do not think I can add anything more, and can only say that I am very glad to have been here, and very glad to have listened to you all.

The President: If there is no further discussion on this paper, the business which has been laid out for the day is over, and the convention may adjourn until tomorrow morning at 10 o'clock sharp.

It is the intention to have these meetings open promptly at the hour appointed. Our friends have laid out so much for us outside of the meeting to do, it is absolutely necessary that we should depart, and I think that every member should be here promptly tomorrow morning.

The Secretary: It is the desire of the local committee that every delegate here, from both railroads and supply houses, will be at the Auditorium this evening at the reception. We want to get acquainted with our friends from a distance. The reception will be held in the Auditorium parlors at 8:30 p. m.

The convention then adjourned.

Wednesday, October 18th.

The second session of the convention was called to order by President Sergeant at 10 a. m.

The secretary read an invitation from the Siemens & Halske Electric Co. to visit its works, and announced that the excursion to the Drainage Canal would leave the Dearborn station at 1:30 p. m. sharp, and that no tickets would be required. It was also suggested that the delegates bring the ladies to see the exhibits in the hall tonight.

The following paper was then read by Mr. Vanderveer:

CARE OF CAR EQUIPMENT.

By J. H. Vanderveer, Superintendent of Shops, Brooklyn Heights Railroad Co.

In giving the writer's views as to the proper care of car equipments he expects them to be thoroughly criticised, but at the same time it should be borne in mind that different conditions obtain in different cities.

When the writer was first put in charge of a street railway equipment, the road had a certain number of cars and it took all of them to operate the road, except from 8 p. m. to 6 a. m., during which time all inspections were made and all possible overhauling done. If a car broke down during the day every one possible was put to work on it, including the motorman and conductor. As the motormen in those days all carried a kit of tools with them, and inspected the motors at the end of each round trip they were very helpful when it came to overhauling. However, those days have passed away with the double reduction motor.

In the maintenance of motor equipments today, where almost continuous service is demanded and high mileage made, only those equipments fitted with both oil and grease boxes will safely run over 40 days without a thorough overhauling. To do this overhauling a large road will be obliged to do it at a number of different points. To overhaul a motor car thoroughly it is advisable to have at each overhauling shop, extra trucks with motors mounted and all in first-class order ready to run under a car body whose trucks and motors need overhauling. To properly lift the body from the trucks four duplex chain hoists, or air hoists, conveniently located together with two cross timbers and four stirrup irons form as good a combination as can be found, and will do the work with the least possible injury to the car body. When the body is lifted the truck to be overhauled is run out and the good truck substituted, the car lowered, connected up and turned over to the operating department. The whole operation taking about one hour, and for that length of time only is the use of the car body lost. For convenience in overhauling, a suitable crane, properly located, equipped with a carriage and another duplex or air hoist, will be found of great convenience. Such a crane can be readily made in any blacksmith shop and for the arm a piece of old rail can be used. When the motor is opened the armature should be lifted out and placed on a suitable rack, where the commutator can be cleaned and the armature tested for insulation. The fields should also be tested for drop, and where there is a drop those fields and armatures should be used in motors by themselves, keeping new and rewound fields and armatures in motors by themselves. This prolongs the life of the equipment and reduces the number of crippled cars taken off the road. The motor shell should be thoroughly cleaned out, either by compressed air or by washing with kerosene. The grease in the grease boxes should be taken out and put in a gear case and the grease boxes thoroughly washed out with kerosene. Brush holders should be taken out and thoroughly inspected and cleaned. At the same time is the best opportunity for truck inspection. The writer has found that all overhauling done with the car standing over the pits, the bottom half of motor dropped, does not allow the thorough overhauling necessary to keep the motor equipment in the shape it should be kept, besides tying up a complete equipment while such overhauling is being done.

In the matter of general inspection a car started out, say today, in perfect order, will safely run five days before it is necessary to inspect again. In this connection, to inspect from 20 to 25 cars per day, one man can be responsible for the proper inspection of all trolleys, including the taking out and replacing any defective poles, wheels or springs, and the straightening of all bent poles. Another man should be responsible for the proper inspection of all circuits, together with hood switches, fuse boxes and lightning arresters. Another should give his whole attention to controllers. While the brakeman and his assistant should be able to keep all brakes in good shape and replace all worn out shoes. This arrangement of inspection and overhauling should keep the truck and motor equipment in good shape, if the night men take equally as good care. The writer recommends doing as little work as possible at night. At a car house operating, say, 100 cars, three men should be able to grease motors, inspect brushes and make any small trolley repairs. Car cleaning should come directly under the operating department. The night car cleaning should be limited to sweeping out, cleaning windows and dusting cars, while all washing should be done in the day time while the car swings or is on the stand, if the car house is on one end of the line. In connection with car cleaning, if the cars are of the closed type with seat risers and drop sash, the space under the seat should be cleaned once a week, as the traveling public have a tendency to drop newspapers, apple cores, etc., down behind the seat back, not to mention the bits of lunch the motormen and conductors drop there if their runs compel them to eat on the car. The best way to avoid this and to also save the annoyance of rattling sash, is to make the sash stationary and cover over the space between the top of the seat back and sash rail. This, of course, does away with blinds and compels the use of curtains. The cost of maintenance is reduced by using curtains and, at the same time, if you happen to be an official riding in a car of this type you need not be in fear of a passenger pulling a blind with three or four broken slats, and the whole thing covered with dust so thick that you can write your name in it with your finger.

A car house from which 100 cars are operated should have a good carpenter stationed there, to make small running repairs and to take care of bell cords and register ringing devices. Any car

J. H. Vanderveer was born in Somerville, N. J., Mar. 28, 1864. He passed through the public school in that city and entered the grammar school with the idea of preparing for Stevens Institute. While in this school he passed the examination for admittance to the Naval Academy at Annapolis, but was rejected as being under age. In the meantime, through an unfortunate investment in real estate, he was obliged to give up the idea of going to Stevens, and entered the employ of the Central Railroad of New Jersey, in the terminal station at Jersey City, as office boy. On June 1, 1884, he was appointed chief clerk and also put in charge of the harbor transfer work. He remained with the Central R. R. until Dec. 24, 1888, when he accepted the position of superintendent of the People's Street Ry., of Scranton, Pa., which was then being changed over by the Sprague Co. from horse to electricity. The following year he was made manager, and remained with the company until the spring of 1892, when he resigned. During the time he was in Scranton the other two trolley roads in the city were taken into the People's company. During the summer of 1892 he was engaged in inspecting street railway properties for several Scranton gentlemen. On September 1st he entered the employ of the freight department of the Erie R. R., where he remained until 1893, when he became connected with the engineering department of the old Brooklyn City R. R. He has been in this department ever since, through the different consolidations, and at present holds the position of superintendent of shops.

that has been in a collision and damaged so badly that it cannot be repaired in one day should be sent to the general repair shop. All cars should be taken to the general repair shop once a year and the body put in thorough repair, and the car varnished or burnt off and painted anew, as the case may demand. While the car is in the carpenter's hands the wiring should be gone over carefully and put in shape. If the car goes to the shop with its regular truck and motors, the truck should be run out and gone over thoroughly. In case it is a built up truck, all rivets and bolts should at this time be carefully inspected and renewed where necessary. In case of a solid side frame truck it should be carefully squared to see that it has not sprung. The brake rigging at this time should be taken apart, and if it is a truck with brake beams working in slides, the beams should have what are termed "Dutchmen" jumped into the ends to bring the wearing parts back to their original thickness, as the beams will probably be found to have worn wedge shaped. If the brake beams are hung in links, these should be renewed where signs of wear show. At this repair shop should be concentrated all classes of repair work, not only repairs to bodies and trucks, but all electrical repairs. The writer believes it pays for all railway companies to make their own repairs to electrical apparatus, including the making of armature coils and renewing of commutators.

In connection with the latter the writer has found that hard drawn copper makes the best commutator. This is bought in lengths and the bars sawed off with an ordinary metal saw. It will be found that the same bar will often do for several types of commutators. In making commutators yourself it is well to study out the diameter and increase that over these turned out by the factories as much as you can safely get between the brush holders. Drop forged bars can also be had for any width of commutators you wish.

On repairs to controllers, hood switches, etc., most roads will find it cheaper to buy the ordinary repair parts and then assemble them, themselves.

In conclusion, the writer would say that he has found it is advisable to make car body repairs, painting, rewinding armatures, making commutators, armature coils, field spools, etc., by piece work. If good inspection is provided and the prices honestly watched, both the company and the employe are gainers by this method. The writer has in mind a case in point. A shop was operated by day work and the regular carpenters' wages were $2.25 per day of 10 hours. Cars that were being remodeled were costing $120. This was changed to piece work and each car given to four men for $110 per car. It was found that the men could do it easily for this and make about $6 over their regular wages. They soon became so expert at this line of work that the price was cut to $80 per car gradually, and the cars are being turned out at this price now, and the men are averaging $2.50 per day. Close inspection, however, is a necessity.

The President: The thanks of the Association are due to Mr. Vanderveer for his able paper. I trust that it will be very fully discussed by all the practical men that are here—and I don't think there are many impractical ones. I want to call on some one to open this discussion, and I will ask Mr. Connette, of Nashville, to speak. I know he is able to discuss this thoroughly.

Mr. E. G. Connette: Mr. President, and gentlemen of the Association. My primary education in the railway business being with steam railway systems, has probably diverted my mind in a different direction from the opinion of some street railway people in regard to the inspection and maintenance of street car equipments. You know that when a locomotive makes its trip of 100, perhaps 150 or 200 miles, it then enters the round house and is inspected and cleaned and all necessary repairs made before it makes its next trip. So with the line with which I am connected I adopted this method; when a car comes in from its trip of 100 to 150 miles, it is first cleaned, then inspected. All the parts of the motor, including the wire connections of the brush contacts and all the parts of the truck are properly inspected, loose parts tightened up, and all minor repairs made, and the car is prepared then for its journey on the following day. My experience with that method for perhaps 10 years prompts me in saying it has been entirely satisfactory. It is argued by some that daylight inspection is better because the men have a better opportunity and perhaps feel more like working in daylight than they do in night. That is true to a certain extent, but with a limited car equipment, and perhaps with the car barns located in such a manner that it would be inconvenient to have the car run in during the day from time to time to have the inspection, cleaning and repairs made, it therefore becomes necessary with some companies to do the work at night, and this to a large extent is so with the system in Nashville. But, as I have stated, the system of cleaning, inspecting and making minor repairs at night has been very satisfactory. If a car goes out in the morning and something occurs to disable the car and it is brought into the shed, and the defect is caused by the lack of inspection at night, why then, of course, proper action is taken, and that is an incentive to the night inspectors to do their work properly, because if they do not do it, results will tell. Then the general overhauling of the car is done by the regular repair force in daylight, and we make it a rule to give the motors a genuine overhauling perhaps once in six months. About two years ago we had a very large exposition in Nashville, the Centennial Exposition, in commemoration of the 100th anniversary of the state. During that period we hauled a very large number of people, trail cars behind every motor car, with a headway of from one to one and a half minutes regularly during the six months of the Exposition, and there were but six motors disabled. I think that record will justify me in stating that the adoption or the application of steam railway methods to street railway service has been entirely satisfactory to our company. (Applause.)

The President: Gentlemen, I hope this discussion will go on. It seems to me that the subject is one that comes right home to all of us. There are a great many different practices in the country, I think, as to the number of men employed, and as to the frequency of inspection, and as to the records which are kept of failures on the street or the failures of armatures, wheels, and other parts of the motor; and it seems to me that we should have a pretty free discussion here. I am unable, perhaps, to call on gentlemen by name, but I should be most happy to have them get up and announce their names and tell us what they know about it.

Mr. W. P. Harrington, Camden, N. J.: We have a road on which we operate at this time about 43 cars, and do the bulk of our inspection and general repairs at night time. We do the general repairs and painting on the piece work system, and it is very satisfactory. One of the difficulties we found in adopting the piece work system was in fixing the price for the work, not having any precedent, and we struck upon a method of covering possible mistakes in price by limiting the amount of bonus that we would give. If we set a contract price for a piece of work at say $5, and the work was actually done for $2, that would make a profit of $3, which would be entirely disproportionate; so we settled on the limitation of 20 per cent of the actual cost. If it cost $20 to do it and the price was $5, the bonus paid was 40 cents, whereas, if the cost exceeded $5 the loss would not exceed 20 per cent of the actual cost price. That seemed to satisfy all the shopmen and enabled us to settle quickly and use our best judgment in price, and it has been very satisfactory. We have followed that same practice in track construction, and in every respect it has been very satisfactory.

The matter of car cleaning and washing with us is a very serious matter, on account of the great amount of dirt and dust. We do our washing at night, and are doing that also by piece work, and washing 16 to 18-ft. bodies, single trucks, at 15 cents a car, and double truck cars at 22 cents. It formerly cost us from 40 cents to 60 cents for our cars. Those figures are exceedingly low, I think, and the work is very satisfactorily done. I personally would like to know what the expense is in reference to the number of cars that are housed for repairs, taking the percentage of cars in actual operation. On one road we average about 10 per cent of the actual cars in operation in the house of repairs. I think this point ought to be brought out pretty thoroughly, because it is a guide to know how many equipments to buy and provide for in a road, and it is a point that I never heard discussed.

The President: Perhaps Mr. Vanderveer can answer that question.

Mr. Vanderveer: In regard to the allowance of 10 per cent, we found that on some lines it would average 10 per cent, but on others it would go as low as 4 per cent, depending a great deal on the service and on the equipment we may have at that particular depot. Ten per cent of the total number of cars is the extreme limit.

Mr. Harrington: What bearing would having a single or a double motor equipment have on the percentage? We are running single

motor equipments and I know our depreciation is relatively high on our armatures. I assume a great deal of the large percentage is due to that fact. What is your experience in that matter, or your judgment?

Mr. Vanderveer: Well, with the single motor equipments, I have had nothing to do the last year or two. But my recollection is that we ran higher than 10 per cent on single motors. Of course the number of miles run per day and the style of motors have a great deal to do with that.

Mr. Elwin C. Foster, Lynn, Mass.: I would like to ask Mr. Vanderveer if he considers that there is any economy in operating a single motor. As I understand, the gentlemen have been speaking of disabled cars which are lying in the car house during part of the day, and this, I understand, is due to defects in the apparatus, and he says that 10 per cent of his cars were in the house all of the time. I might say, for the benefit of the Association, that we have not found it profitable to operate single motor cars, practically on account of the increased expenses created in the maintenance of them, as compared with the double motor cars. This past season we have been operating one 10-bench open car with one pair of G. E. 57 motors of 52 h. p. capacity each. That, as of course you all recognize, is much greater than the power required to operate a single 10-bench single truck car. But the result, so far as repairs are concerned, has been very satisfactory, there being no repairs necessary on that car the entire summer. The car has made about 120 miles a day and we have not worn out even a set of brushes. Now, I believe it has been the custom in the past to operate a motor of too small capacity, and by reason of that small capacity the expense of maintenance has been increased very materially. I would ask the previous speaker if he has any figures as to the cost for labor of painting up and varnishing the cars.

Mr. Harrington: In reference to the first matter, the depreciation in using single motor equipment, we have been using single motor equipment practically up to date, with the exception of a few double truck cars we recently purchased. About a year ago we took one of our 18-ft. trucks with double equipment, 330, and where we average a car in the house say once in 10 days with a single motor equipment, that car has only been in the house three times in the year, and that for only petty repairs. On the strength of that, our directors have concluded to double the equipment of 12 of our cars as a starter. Our armature depreciation has been, in my judgment, tremendous, and altogether out of reason. For a 50-mile road we have one armature man busy all the time, doing nothing else, and I think we can put him on other work when we get a different equipment. The exact difference in cost is difficult to say, but we are sure that we will very materially cut that down. In reference to the cost in mounting, we have the figures all listed out for the general run of the work. For a car to be taken in the house and the paint burned off and painted and varnished throughout, the inside varnished, the contract price is $20. For ordinary touching up and varnishing the outside with the paint that is already on, and one coat of varnish on the outside, the contract price is $6. The cost of the material runs approximately the same as the other. But I have the figures for all that on file.

Mr. Foster: I would like to ask the gentleman the rate of wages paid, where the work is done in the house.

Mr. Harrington: We pay painters $2.50 a day and carpenters $2 a day for that class of work.

Mr. W. P. Read, Salt Lake City: How many coats of paint do you include in your specifications? The number of coats of varnish that you are under contract to receive?

Mr. Harrington: The usual formula of putting on the first coat, that is the rough stuff, rubbing down, putting on the second coat, rubbing that down, and putting on three coats of varnish. There are really five distinct steps in the operation.

Mr. Connette: There is one element of saving in running single motors where they can be run, and that is in power. In Nashville, Tenn., there is very little level ground. It is up and down hill everywhere. But I tried the experiment of a single motor and found that by test it used about 35 per cent less power than with double equipments, but we could not use the single motor for the lack of traction. Most of our roads have no loops at the ends, and consequently the ends of the cars are reversed, and when the motor was in front there were a great many places where it was quite difficult to get up with a single motor, on account of traction. When the motor was on the rear axle, that difficulty was not so great, but there is a saving in power by the use of a single motor. It strikes me that where single motors are used it would, to a large extent, limit the capacity of the car or the size of the car in proportion to the power of the motor used. Now, in Louisville, Ky., where they operate possibly 200 or 300 cars, it has been my observation that nearly all of them are run with one motor, one S. R. G. motor, but the cars are small, most of them having been old horse cars converted into electric cars, and the city is comparatively level, and, as I understand it, they are operated very satisfactorily.

Mr. R. Douglass, Cleveland, O: It seems to me that this question of single and double truck cars depends a good deal upon the condition of your track. I represent the Big Consolidated road of Cleveland, where we recently had a little disturbance, and we have some old Johnson rails on chairs, and all that sort of thing. Our people have recently purchased 150 double truck cars, modern cars. One motive was to keep up with the times, handle our people promptly, and another reason was because we had some bad track. By putting these double truck cars on we could run our cars very smoothly over that track that was almost unbearable with our single truck cars. It seems to me it is a question of track to a great extent. I think a 10-bench open car or an 18 to 24-ft. open car on long wheel base, single truck can be operated much better than the other kind.

When I went to the Big Consolidated road, May 1st, I found that painting contracts were in force there, and they were very unsatisfactory. The company was paying 25 per cent more for painting cars, that is, painting, touching up, burning off old paint and varnishing the different equipments, than it actually costs now by day work, and we were not getting as good work. We get much more satisfactory work by day work, and I think we save 25 per cent. That would apply to painting and varnishing. We have a contract for making armature coils and doing that sort of work, which is entirely satisfactory. I have not canceled that contract; it is still in force. That is the only contract work we do. I have not seen fit to change that.

Now, about the trolley wheels. When I went to the Brooklyn Heights road about five years ago Mr. Vanderveer was still there, but I don't think I ever made his acquaintance. They were making their trolley wheels out of tempered brass and copper. I have often wondered since why we do not put in a brass foundry and make our own trolley wheels. We are buying our castings in the rough, and have a very well equipped shop and are turning them out. I wonder why we do not make those castings ourselves. We have to scrap our old copper and brass at about 15 cents a pound, and then pay a large price for new wheels. Yet I believe the Brooklyn Heights Co. has discontinued that, have they not, Mr. Vanderveer?

Mr. Vanderveer: In regard to the brass foundry, while it is very handy to a large road, our experience was that we made things out of brass that we should have made out of iron, and we shut it down for the time being, but started up a short time ago to help out on some parts for motor equipment. That was a part that could have been made out of cast iron if we could have reached the cast iron people as well as we could the brass.

Mr. Douglass: Is it not economical to make your own wheels?

Mr. Vanderveer: Yes, if the matter is followed up properly, I think it is the proper thing to do.

Mr. Douglass: And you can save 25 to 30 per cent?

Mr. Vanderveer: Easily. There is always a tendency though to drift out into other matters.

Mr. Douglass: I am surprised more of us do not make our wheels.

Mr. Beggs: Whether or not a road could profitably make trolley wheels, like many other parts in use, would depend upon what they are compelled to pay for them. I have a contract for trolley wheels at the present time, made according to our formula, such as have been used on our lines, and seem to be the most advantageous as to the proper degree of hardness to give the best results without wearing the wire; these preferably permit wear on the wheel, which is easily repaired, at 23 cents a pound, and we contract for converting the worn out trolley wheels into others of equal weight. Now, I don't believe that any road can afford to put in a brass foundry and make trolley wheels if

they can buy them for approximately that amount, because the old wheel you could get 16 cents a pound for.

Mr. Douglass: That is the rough casting?

Mr. Beggs: No, the finished wheel. We use a 5-in. diameter wheel on our line, because a large wheel travels at less speed than a small one. Our wheel weighs approximately something over three pounds, nearly three and a half pounds, finished. Take that, with the brushes, and I do not believe that there is any road that is making its own wheels that can maintain a brass foundry. In that connection I would like to suggest, the argument is so often made by municipalities that they can operate an electric lighting plant and other public utilities at less than we gentlemen who are in that business; that very many times our special foundry in connection with our roads is not charged with all that it should be charged. That is too often the case with the brass foundry and other appliances run in connection with the road. There is nothing charged to it for superintendence. You fail to charge up to it the amount that it represents, and when it covers that amount I do not believe any road that makes a proper contract for trolley wheels can begin to make them as advantageously as some shop which has other things to make of the same character. It depends very largely on how the contracts for the roads are made. For instance, I am now paying 30 per cent more for trolley wheels than a contract made about eighteen months ago called for, and in order to get what was a satisfactory figure to me, knowing the difference between the relative value of brass, copper, zinc and tin entering into the composition of a trolley wheel for our own use, I made a contract for 5,000 wheels, to be delivered to us at the convenience of the shop turning them out, made according to our formula and according to our pattern. They can turn them out between times at their shop, and I know that I could not run a brass foundry and begin to turn those wheels out for what they cost us today under a 5,000 wheel contract. I would like to throw out a suggestion here, Mr. President. It is not in line with this, but in regard to motors, and particularly in reference to what my friend Douglass says, who claims they just made a contract for a large number of double truck cars. I would like to give him the benefit of our experience at Milwaukee in reference to the increase of motors. I do not believe any road can advantageously run one motor. I never have believed so in ten years. I do not believe so now, for the reason that the 35 per cent power that is saved I think is three-fold paid out in the greater cost of repairs to the single motor, and to other parts. The cheapest thing, virtually, that we put in the electric railroad today is the power that moves the cars. It costs less than almost anything else in the service. Three and a half years ago we adopted a standard car on our lines; a double truck car. We have been steadily advancing and improving that equipment, until this year we put on 25 cars. We put on about 35 new cars annually in order to keep up our equipment. They are double truck cars, our standard. For three years we contented ourselves with two motors on these cars. We put on 25 cars this year and have a contract now for 30, to be delivered in April next, on which we shall put four motors, a motor on each axle. We have done this for the sake of economy and in order to provide facilities for giving good service. Our traction is very much better. We can speed up a car very much more quickly, and in a city where you have to stop every 300 or 400 ft. it is an important matter to gain a second or two in getting in motion. For that reason we have finally adopted, at considerable expense, the four motor car. We put on ten cars 15 or 18 months ago, with four motors, and we find it costs less for the maintenance of cars with four motors than it does those of two. The actual cost of repairing that equipment is very much reduced, and the number of cars we have in the shop do not average 2 per cent. Taking up what my friend from Camden says, we seldom have to pull one of them into the shop. We can get the cars up to speed between streets in a very few seconds, and if the car gets behind time it has the reserve power which enables it to make speed, which is a very important element in the economical running of street railways. We run pretty long lines in our city, few are less than seven or eight miles from terminal to terminal; in that run we make, say, 200 stops, and a second or two in each stop means a considerable amount in the run, and aids us in maintaining our schedules. We know that the cars with our four motor equipment, speaking off hand, require 30 per cent more power than the others to pull them over the same line, but we are making higher speed, consequently saving money in other ways, giving more satisfactory service and saving our equipment. As I said, the cheapest thing we have is power.

Mr. Douglass: What type of motor have you?

Mr. Beggs: We have the G. E. 1,000. We put one G. E. 1,000 motor on each axle. We have a number of grades, but none are very severe, and we have no trouble. When it comes to a slippery rail in winter we never have to worry about whether our four motor equipment car is going to get over the line. Our number of flat wheels is very greatly reduced. So that in every way the cost of maintenance of the four motors is 25 per cent less than on the two. One of the reasons we adopted these cars was to give better service to the public and to be able to make our time more regularly and haul larger crowds. We use pretty large cars, almost as heavy as steam railroad cars. We have them built to seat 44 passengers; 22 double seats. We frequently have over 100 passengers in those cars and on the very wide platforms. The car is 41 ft. over all. This is the car we have taken as a standard, after many years of careful experimenting. I don't remember the number of men in our armature shop, but it is half of what it was 10 years ago.

Mr. Connette: I don't mean to advocate a single motor equipment, but I do say this, that for small cars, where the streets are comparatively level and where the power of the motor is in proportion to the size of the car, that it can be operated for less expense than a double motor equipment. I know by actual meter testing that with an 18-ft. closed car body, single truck, double motor, that it requires about 150 kw. hours per day for 125 to 140 miles. The cost of power, of course, varies, but a fair average is one cent per kw. hour, therefore if you use 150 kw. hours per day and save 33 1-3 per cent, the saving of power would be 50 cents per car per day, and where, we will say, 30 cars are run it means $15 per day, and it strikes me, with the experience I have had in maintenance, that it will not cost as much to maintain one motor, even with a little extra service, as it does to maintain two motors. We have, with two motors of the ordinary kind that is used, four fields and two armatures, with all the incidental connections, and it is common sense to say if you are running only one motor with even extra service it would not cost as much in power to maintain it as it would two motors. But when the element of service enters into the question in larger cities, where you have got to have large cars and high speed and heavy travel, then perhaps our judgment would change to the double motors, because you can give more effective and more satisfactory service with two motors on a car than you can with one motor. But so far as the element of service is concerned, I believe that it is more economical to operate one motor than it is two motors where it can be done, and I believe that this practice is limited to small places, and where the streets are comparatively level.

Mr. Foster: I would like to ask Mr. Beggs what is the average rate of speed made by the four motor cars, also if he uses power brakes, and if so what kind?

Mr. Beggs: No, we don't use power brakes on our city equipments. We try to maintain a speed of about 8½ miles an hour over the whole city system. We furthermore maintain on our lines probably the longest headway of any city in the United States for a thickly populated city, and one of the means of doing it is the larger cars, the great regularity we maintain in our time table, which is adhered to as closely as that of a steam road. Even on lines where we stop every 300 or 400 ft. we make on an average 8½ miles, and sometimes 9 miles per hour. There is none of our equipments that runs less than 160 to 170 miles daily. On our interurban lines we make as high as 380 miles a day. We have a considerable number of interurban lines spreading out like the spokes of a wheel. We use only the ordinary ratchet brake on our city cars. We have one line on which we make 19 trips a day, with hourly cars, and we do that with two cars. These two cars keep up the service, making 19 trips of 20 miles each. On those cars we have air brakes and arc headlights, both of which elements are indispensable to a high rate of speed.

Mr. Foster: What is the maximum rate you are able to attain on the interurban line?

Mr. Beggs: Fifty miles an hour on certain portions of the line. The cars become part of the city service when they get within the city limits. We make a speed outside the city limits

of from 30 miles an hour up to as high as 40 and 50 miles an hour. On all of our city lines we have high speed gears.

Mr. Foster: Is that on the public highway, or on a private right of way?

Mr. Beggs: On the particular line I refer to half of it is on a private right of way. We have one interurban line which is all on the public highway. On that line we do not make quite as high speed.

Mr. Albion E. Lang, Toledo, O.: Mr. President, I want to touch upon two subjects that seem to be most prominently before the convention this morning, and the first is with reference to the maintenance of a brass foundry. We are operating a street railway and electric light plant combined, and we maintain a brass foundry, and I take it that that is an endorsement of the wisdom of maintaining a brass factory. We pay our brass foundryman daily wages of $1.75 per day, and he is a good man. He spends his entire time in the brass foundry and he takes every scrap of brass that we have and works it into every place on the cars and about the power house that brass is used, and we are satisfied beyond any doubt, the most economical way to operate a railroad is to maintain your own brass foundry. We cast our own trolley wheels, and, as I say, every fitting of the car that brass enters into is manufactured from our furnace. Now, with respect to the double car equipment. It depends, I think, very largely upon local conditions with respect to grades. We operate two motors on each car, our standard being the No. 3 Westinghouse motor. We have a few G. E. 800, but a suggestion that I desire to make that may be of value to some of you is the fact that we have just entered upon a method of splicing two 16-ft. body cars together. It has been a serious question with us what to do with four-wheel cars that have been in operation from eight to ten years, and following the same line of procedure that they adopted at Columbus about three years ago, we have just taken two 16-ft. body cars and spliced them together, and put them on double trucks, and we have placed those cars upon one of our longest lines, where we have been maintaining a nine-minute interval for some two or three years, but found a necessity for shortening the interval. To overcome that necessity we have concluded to put these double truck cars upon that line, and we have had them out now about sixty or ninety days, and they look just like new cars. An expert, of course, could tell the difference, but the riding public say "What a magnificent car this is!" They are pleased beyond measure, and we think by that means that we are going to still maintain our nine-minute headway without complaint, because they take more passengers and their speed is just as good as the 16-ft. car. It was argued that we would not be able to maintain our speed, using a 25-h. p. motor, but in our city where we have few grades we find we can maintain our speed just the same with our double truck cars as we did with our 16-ft. cars, and you can see that it can earn a good deal more money, and I think that where the situation of the road is similar to ours that you will find it of great advantage to take some of these cars that are nearly ready for retirement, and by putting in new sills and bracing them up properly you can utilize them for a long time.

Mr. Beggs: Have you any estimate as to what it has cost to reconstruct these cars?

Mr. Lang: In the neighborhood of $300, including the labor and material entering into it.

Mr. Beggs: That, of course, makes a longitudinal seat car when you are through with it?

Mr. Lang: Yes.

Mr. Dimmock: I would like to say for Mr. Lang's benefit that we took 16-ft. car bodies after they had been in service between 6 and 7 years, spliced them together, made a 42-ft. car over all, including vestibules, and have run them 5 years, and, outside of the painting, we have had practically no repairs to speak of since the day they were built. I think the splicing of those cars cost us in the neighborhood of $300 or $400. I have forgotten the exact price, as it was some time ago, but we find with the double truck cars that the service is better. It was also claimed that we could not keep up our schedule, with the same headway, after splicing these cars, and especially after putting gates on them. We equipped these cars with gates, which are operated with a lever by the motoneer, and we find that although the power consumed is greater than it was before the gates were put on, on account of the greatest number of dead stops that are required to be made, nevertheless this type of car is giving good service, and is running on the same time card as the 16-ft. cars, the speed being as high, many times, as 30 miles an hour, and the repairs are not any more than they are on the cars running up town, which are only 16-ft. cars.

Mr. Beggs: I would like to ask if the cost of splicing the two 16-ft. car bodies makes provision for the trucks?

Mr. Lang: No, it does not.

Mr. Beggs: What do the trucks cost, or do you put regular double trucks under them?

Mr. Dimmock: Double trucks.

Mr. Beggs: That is an important question, because we have canvassed that matter thoroughly for three years, and we finally determined that it was not economy to splice our old car bodies, for the reason that by the time you have added the cost of these trucks to the cost of the car, it would still be an old car and will have cost half as much as the best car that can be built. Of course, as Mr. Lang has said, local conditions have a great deal to do with it. We, in our city upon the lake, this summer have had very little warm weather that would require people to go out to take rides in the open cars. We intend to dispense entirely with open cars and get our equipment down to a standard that we can run all the year. In order to do that we have cross seats on all cars and must have greater width of body than you have, ours being 9 ft. 6 in. This gives us two cross seats with a very good center aisle. We do not want any longitudinal seats on our cars. Our patrons prefer our standard car, and with the sash down it virtually becomes an open car. We have a car, then, on which we do not have to change the equipment. There are no trucks to take out or anything of that kind. I want to bring out that the $300 does not begin to cover all the expense that is involved in reconstructing the old car bodies, and I think you will all admit that when you have taken an old car body that was built for the lighter traffic for which it was intended some years ago, it will only be a little time before the car will begin creaking again.

Mr. Dimmock: We have run our cars five years without repairs, but in order to make the car as good as we thought it ought to be, we had a steel frame put around the bottom of it, and very heavy truss rods, which have caused the car to stand up to all conditions of traffic, bad track, etc., but I will admit one point, that if we were buying new cars we would prefer them wider and prefer the cross seats; and as to your open car we also spliced our 16-ft. open cars and the difference in the two cars is that the closed car seats 44 people, while the open car seats 75. Another feature that we could not lose sight of was the track center. Our track centers will not permit of a wide car, therefore that aided us in making a decision much quicker. If the track center had been wider we might have considered a new car. Still we feel we are money in pocket by the splicing of them as we have.

Mr. Foster: What is the depth of the flange on your wheels?

Mr. Beggs: I think it is an inch and an eighth.

Mr. Foster: Do you run that over a T rail or a grooved rail?

Mr. Beggs: Our standard road bed construction is a T rail, with granite headers and stretchers. We form the groove out of granite, and I think if you come to Milwaukee you will see almost the same effect as a grooved rail. We put down a rail that will permit the city to pave in any way it wants.

Mr. Dimmock: Before we get away from the question of trolley wheels, I would like to ask if any of the gentlemen present have kept the mileage on their trolley wheels.

Mr. Beggs: We get from 8,000 to 9,000 miles out of our trolley wheels. I know there are roads that get as high as 16,000 or 17,000 miles. We use a composition consisting of 86 per cent of copper with 8 or 9 per cent of tin and 4 or 5 per cent of zinc, and we get a composition which allows the wheel to wear rather than the trolley wire. It costs us much more to wear out a trolley wire than it does to wear out trolley wheels. I know there are certain roads that make a boast of how many miles they get out of a trolley wheel. When I went to Milwaukee three years ago I found them using a steel wheel. The result was rapid wear on the trolley wire.

The President: Is there any further discussion on this subject? If not, I think we should take up the subject on which we were promised the paper from Mr. Kilgour, of Cincinnati, which is "The Modern Street Railway Shop." I would ask whether Mr. Kilgour is in the hall. The committee has not heard from Mr.

Kilgour, and I think there will be no paper on this subject, but it is a subject that I am sure every one here is ready to talk upon, and I am in hopes that it may be started by Mr. Knox, if he is in the hall.

Mr. Holmes, Cincinnati: I want to say for Mr. Kilgour, I am sorry he did not prepare this paper for us, but he expects to be married tomorrow or next day, and is quite busy making his arrangements. He is a bright young street railway man, and I think we ought to forgive him this time. It is a disappointment to me, because I think Cincinnati has about the best street railway shop I ever saw.

Mr. Knox: I was only notified a couple of days ago that I was expected to participate in this discussion, and I have not given it any special thought. It was a paper I hoped would be presented to the convention, because I consi er it one of the most important problems we have, where there are perhaps greater leaks than in the other departments, but I am not prepared to speak upon it at this time.

Mr. Penington: Mr. President, and gentlemen, I have just been informed that it is not necessary for anybody to get lunch at the hotel today. Mr. Roach says he has a baggage car on this train that is full. (Laughter.) I didn't ask him of what, but he said he had plenty of sandwiches "and so forth," so that you need not go to a hotel to get lunch unless you wish to. The train will leave at 1:30 from the Dearborn station.

The President: If you will please give your attention for a few minutes, gentlemen, we will adjourn the meeting. The chair has today to make the announcement of a committee of five, which committee shall determine upon a location for the next meeting and shall report nominations for officers. The location and the nomination will be presented to us as recommendations by this committee, and the Association will act upon it. I would nominate for this committee: Mr. H. C. Moore of Trenton, Mr. E. C. Foster of Lynn, Mr. E. G. Connette of Nashville, Mr. Robert McCullough of Chicago, and Mr. A. E. Lang of Toledo. Invitations to the Association to hold its next convention in any city should be presented to this committee and any arguments or inducements that are held out by any city should be laid before them, which does not, of course, in any way preclude the presentation of any arguments at the time of the committee's report. Mr. Moore announces that he can be seen at his room at 8 o'clock this evening—room 316, Auditorium Hotel.

The convention then adjourned.

Thursday, October 19th.

The convention was called to order by the president at 10:30 a. m.

The secretary read a letter of regret from Mr. H. M. Watson, of Buffalo, who was unable to attend the convention. He also read an invitation from the Westinghouse Electric & Manufacturing Co. to visit the power House of the South Side Elevated Railroad. The South Side Elevated will furnish a special train, which will leave from 47 Congress St. at 2:30 p. m. Friday; the train will leave the 18th St. Elevated station at 2:35.

The first paper was:

CONSTRUCTION AND MAINTENANCE OF STREET RAILWAY TRACKS.

By Edward Butts, Chief Engineer, Metropolitan Street Railway Co., Kansas City, Mo.

The construction and the maintenance of street railway tracks are inseparable, when we have to consider the capital required for the enterprise; that is a cheaply built track will be expensive to keep up, and to reduce the maintenance charge, more must be spent in the construction. One of the preliminary points is to decide upon the kind of a street railway that is to be built. Is it to be built simply to float on the market, or is it intended to last and give good service for as long as possible? In other words, is the road built to sell or to keep? The writer in preparing this paper had in mind a road of the latter kind.

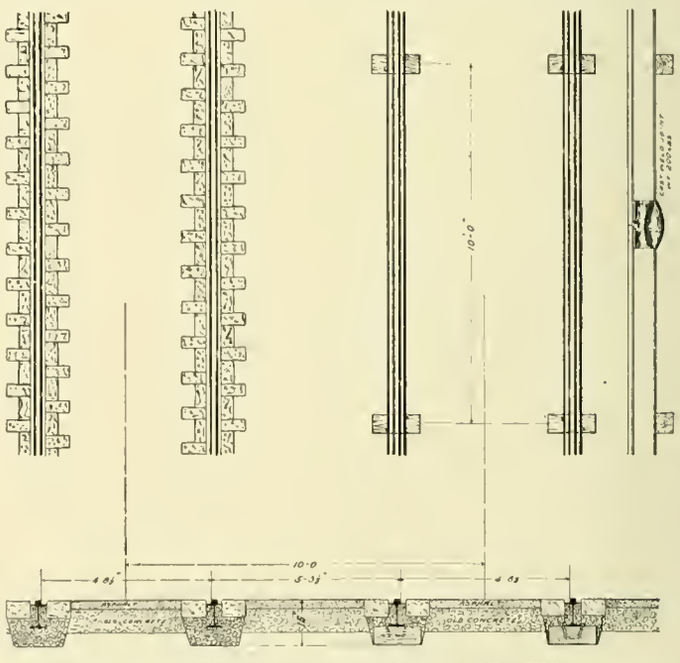
Local influences which may affect the cost of maintenance or may in the future compel changes should be carefully considered, and these local influences lead to the primary division of street railway construction into urban and interurban.

EDWARD BUTTS.

Edward Butts is a civil engineer and surveyor of wide experience. He commenced work as transitman on railroad lines between Albany and Steventown in 1869, and from that time until 1892, he served for varying periods as draftsman for the New York Central R. R., transitman in charge location L. E. & N. W. R. R., leveler Kansas City & Northeastern R. R., assistant engineer for the Atchison, Topeka & Santa Fe Ry., the Kansas City, Ft. Scott & Memphis R. R., and the Utah & Pacific R. R. He also acted as assistant engineer on the construction of the Grand Avenue Street Ry. cable system of Kansas City, Mo., and for the Kansas City Belt Ry. He was appointed assistant city engineer of Kansas City, Mo., and in 1892 was made city engineer. He resigned two years later to become chief engineer of the Metropolitan Street Railway Co., of Kansas City, which position he still holds.

It is desirable, in all cases, that the whole of the track shall wear out at the same time, and as the urban portion of the line is subjected to the more severe service it becomes the governing factor as regards durability. We shall take up such a construction as experience has shown, all things considered, to be most satisfactory for urban lines.

In making the rail foundations a trench is dug; this should be 20 in. wide at the top, 16 in. wide at the bottom and deep enough to allow 6 in. below the rail when it is at the established grade.



PLAN, ELEVATION AND SECTION OF TRACKS.

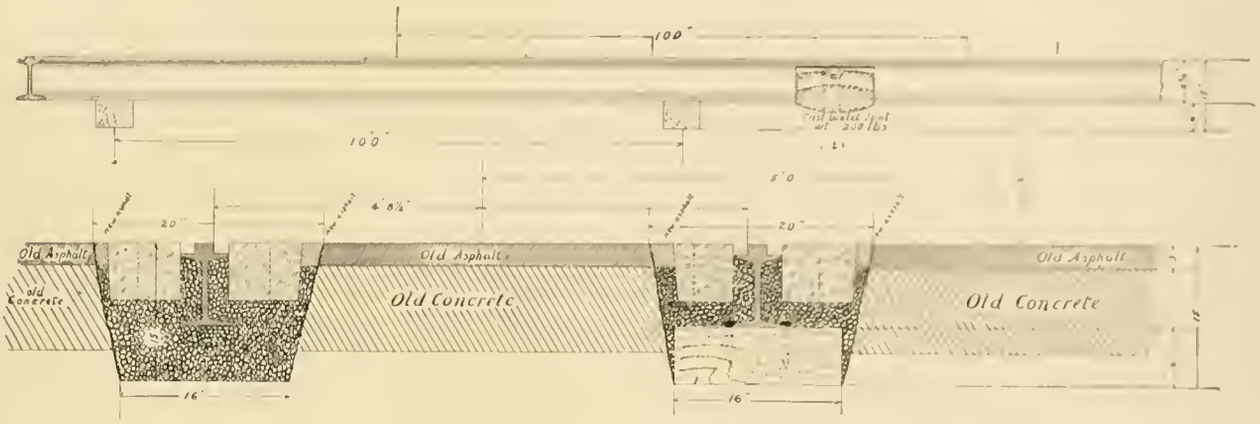
In this trench at intervals of 10 ft. are placed wooden blocks 8 x 10 x 16 in., and the rails are spiked securely to these blocks, which serve to hold the rails while they are being laid and tamped to surface, the joints being held in position by temporary splices. After nicely gaging, alining and surfacing the track the trenches are filled with concrete, covering the rails up as far as the bottom of the proposed paving. This concrete which is placed in the trenches around the rails is composed of crushed stone, measuring not more than ½ in. in its greatest dimension, mixed with portland and domestic cement and sand.

These are mixed by measure, two parts sand, one-half part port-

land cement, one-half part domestic cement and five parts crushed stone. Great care should be taken to get the mortar flushed close against the rails and to bring it full up under rail trams. The concrete in the trenches should be allowed about six days to set; however, this depends upon the condition of the atmosphere, as it sets much more rapidly in warm than in cold or chilly weather.

The concrete for the paving foundation may be composed of one part domestic cement, two parts sand and four parts broken stone by measure, the broken stone to be not larger than 2½ in. in the greatest dimension. All concrete to be thoroughly tamped till the mortar flushes to the surface.

The rails should be not less than 6 in. in depth with a base equal in width to the exposed upper surface. Where streets are paved with asphalt and a stone toothing course is placed adjacent to the rails, the rails must be at least 9 in. in depth in order that the base may be securely imbedded in the concrete below. Rails should be center bearing and rolled in 60-ft. lengths and handled so that they will be perfectly straight when placed in final position.



ELEVATION AND SECTION OF TRACK.

Tie-rods 1 in. in diameter, shall be placed 6 ft. c. to c. along the line, with hexagonal nuts which, when in place, shall clamp the rails securely on both sides. The tie-rod threads should extend far enough from the rod ends to allow the rod to be put in place without bending it. The reason for this rigid tie-rod is that the street traffic and pressure on the outside of the rails should be provided against as well as the car thrusts on the inside. The top of the tie-rod should be placed at the center between the top and bottom of the rail to better accommodate the paving, especially if brick or stone is adopted for the wearing surface.

After the concrete has set cast-weld joints shall be made at all joints, including the special work, which may be needed.

The cast weld joint on 80-lb. rails should weigh 150 lb. and on 100-lb. rails, 200 lb. of cast metal; the cast metal should be composed of two-thirds pig iron and one-third common scrap iron. The metal should be heated to a bright yellow and each joint formed with one pouring. The depressing clamps should remain in place for at least one hour after the pouring, and the surface of the rails finally dressed smooth, so that they present the surface of a continuous rail. In preparing the joint a better result as to smoothness is obtained by inserting a thin shim between the rails than by placing the rails too close to admit a shim. These cast-welded joints should be so formed as to interfere as little as possible with the wearing surface of the pavement.

As a general proposition the wearing surface of the paving should be composed of the same material as the rest of the street; if different paving is used there will be an undue amount of vehicle travel on the street railway tracks and consequently accidents will occur more frequently and the track will wear more rapidly.

For instance, if the street is paved with asphalt and the track with brick or stone, heavy loads on slight grades will be driven on the stone or brick for the reason the latter material furnishes a better footing and keeps the grease well in play in the wheel boxes. On the contrary, if the street railway tracks are paved with asphalt and the street roadway with brick or stone the drivers of light vehicles will immediately seek to occupy the street railway tracks as well as some of the other class.

At all times attention should be paid to drainage, and at street crossings where the established grade is level, the surface of the tracks on one side should be elevated several inches to prevent the retention of water pools.

At all changes of grade the rails should be bent to form vertical curves and no joints allowed in such vertical curve, as it is almost impracticable to form a uniform curve unless shop work is resorted to.

There is no economy in trying to construct a railway too hastily, as it results generally in inferior work and there will be an expense in the future.

The special work, turnouts, crossings and cross overs should be of cast steel construction, except steam railway crossings, which it is best to make of the regular built up work located on the foundation. The tongues of turnout switches should be placed on the high or superelevated rail of the curves, otherwise the guard rail of the mate should extend the full length of the casting on which the tongue is placed. All curves of a radius under 300 ft. should be provided with a guard rail, and curves of less than 50 ft. radius should be double guarded.

A very important item as a matter of economy in the construction of street railways is the contract and specifications. This document should cover, without doubt, all that is intended to complete the whole line, and in street railway construction there is so much to consider that often items are left out or neglected, which finally become very serious and costly matters.

With a track constructed as described the cost of maintenance will depend largely upon the rolling stock used; that is, whether single or double trucks are used, the wheel base, the diameter of the wheels, the arrangement of the car springs, etc. The longer the wheel base of the car the less durable the curves in the track will be. Single trucks will destroy frogs, joints and switches more rapidly than double trucks, and the diameter of the wheels and the springs between the truck and the car body have an important effect on the life of the track.

The President: The chair will ask Mr. E. C. Foster, of Lynn, to open the discussion upon this paper.

Mr. Foster: I have listened with a great deal of interest to this paper upon the construction and maintenance of street railway tracks, and it seems to me that he has well covered the specifications for building a first class girder rail track. I did not notice that he touched upon construction of a T-rail track. Now, the tracks of our road have to be constructed differently in different localities. All the city roads that I am familiar with require a construction much superior to that used on roads located in the suburban towns.

The subject of cross ties is one which we meet in the East, and I find it is met in nearly every section, as I believe over 90 per cent of the roads are using cross ties. Now the dimensions of a tie and the placing of it are points I am interested in, and I have often pondered on what are the proper dimensions of a tie. Some roads use ties 6 ft. 6 in. in length, which are 5 x 6½ in., and place them from 24 to 30 in. on centers. To my mind, on T rails, where you are going to operate at a high rate of speed, as many of the electrical roads now anticipate doing—many of them are doing it in fact at the present time—we should use a tie

of about the same dimensions as do the steam railroads. We are at the present time constructing five miles of a double track with T-rails. The ties are 6 x 7 in. to 6 x 10 in. and 8 ft. long. The rail that we are laying on this tie is a 70-lb A. S. C. E. section T-rail, and we are using one of the improved joints. We believe it necessary to construct a good track for high speed; our speed will probably be 25 miles an hour, possibly more. We believe we should adopt as near as possible the steam railroad construction. On some of the smaller and less important lines it is not necessary to have so heavy a rail, although I am thoroughly of the opinion that the money invested in a heavy rail and a very heavy cross tie is wisely invested. On the subject of girder rails we have to lay them in our part of the country on cross ties; the ties are 5 x 6 or 6½ in. x 7 ft. long. Some roads I know have a tie 7 ft. long, others 6½, and I have thought many times and could not quite understand why a tie 6½ ft. in length should be sufficient where the street is concreted, and you get but a small bearing on the outside of your rail. It seems to me the addition of 3 in., if you use a 7-ft. tie, is very important, and adds very materially to the strength of the track, keeping it in service and alinement. We all agree, I believe, that the first construction should be of the best, providing finances permit of it. The question of maintenance that is quite as important, perhaps, as the construction, and with many it is a problem as to how best to repair an old track. We all remember how in the old horse car days we used to operate over a rail weighing only 20lb. to the yard, spiked on to a stringer, and underneath that stringer was a little tie about 4 x 5 in. Then the weight increased a few pounds at a time to 60 lb. per yard. All of these, 25, 30, 35, 40, 45 lb. were made in the tram section and about as many in the T section. Then they commenced with the girders, 40, 45, 50, 70 lb.; now most roads, where it is necessary to lay a girder rail, are laying a 9-in. 90-lb. rail, and it is these lighter rails that I have referred to that make the problem. We have some 45-lb. girders laid in 1890, on to a steel chair and a small tie, which was 4 x 5 in. x 6½ ft., 3 ft. on centers, and that was thought to be the proper construction at that time. It was a road that was acquired by our road by purchase, six miles of it, and they made a pretty thorough examination prior to the building of the road, and thought they had secured the ideal construction for an electric road. Time has developed that they were in error. Now the problem with us is how to best repair that track. The lips of many of the steel chairs have become worn so that they do not hold the rail securely. We do not believe it wisdom to purchase new steel chairs, so we have been sustituting the old-fashioned stringer, knowing that we can obtain from 6 to 7 years out of the stringer and thereby get 6 or 7 years more out of the rail. I believe this to be economy under some conditions, as where you have light traffic. Of course, where you have a traffic requiring a 15 minute service, and from that down to 20 or 30 cars a minute—if as many as that can be run, which I doubt very much—you want to have the latest and most modern construction. The caring for T-rails is another subject. Take a 35-lb. T-rail; while it may answer your purpose—and there are steam railroads today operating over 35-lb. rails—I believe we cannot do it successfully on cross ties. It is very difficult to hold the joints even with any of the improved joint plates—and there are some very excellent ones.

As to cast-welding; I suppose this might be applied to some of the old tracks; I suppose it has been, but I have opposed applying it to any 26-lb. rails I have ever seen. There were many rails that were old in 1891 and 1892 that were soft and wore out quickly. That seemed to be due to defects in the formula for mixing the metals at that time. That, of course, has been very materially improved, so that today they roll a very high carbon rail. I believe on many of these small roads that this light rail construction can be repaired and perhaps used successfully and profitable until the finances of the road will permit of a more modern and a better construction. To my mind the local conditions and the ability of the company to make an outlay govern very largely that which will be best for the property which you are attempting to operate.

Mr. Thomas Hawken, Rockland, Me: In New England the question of railroad ties is a very important one. We have several woods, and I would like to ask Mr. Foster what kind of tie he has found to last the longest and give the best results?

Mr. Foster: Our experience has been that the chestnut tie gives us the best results. We have used many of the soft woods, such as cedar, hackmatak, and we have used oak, and the best results have been obtained from the chestnut tie.

Mr. E. H. Keating, Toronto, Ont: The method described by Mr. Butts seems to me to raise a very important question as to the advisability of rigid construction on lines where there is heavy traffic. I have had occasion to construct some lines on concrete foundations where the traffic has not been excessively heavy, and the result so far has been very favorable indeed, but it would be very interesting to learn from some one who has adopted this rigid construction, whether any observation has been taken to determine whether there is any yield in the rail at all. I have had observations taken on the other lines and found that the give in the rail is very considerable. Where there is heavy travel and rigid construction has been adopted, it is a question whether it does not affect the rolling stock. I should like to hear from Mr. Butts as to whether he has ever made observations to see if there has been any yield in the rail at all. Also, what is the style of joint he adopted. I take it from his description that it is what is generally known as the Falk joint. I would also ask if any provision was made for contraction and expansion of the rails. I know some companies do not make any such provision at all, but I understand that in some places a great many broken joints have been the result. On the other hand, during the cast-welding of these long lines of track what provision is made for contraction and expansion while construction is going on. The action of the sun in hot weather, naturally if the rail is exposed, would be rather disastrous.

Mr. Butts: We have operated a road for the past four years, as described in the paper I read, and there is no perceptible deflection or yielding of the rail. We have been constructing every year from that time up to the present. If any yielding did occur it would probably be on account of the quality of the material that is used, or from getting the soft material close to the rails.

In regard to the cast-welded joints, or the expansion of the rails, I would say that our method has been to put the concrete around the rails before the welded joint is put on. That holds the rail perfectly in place, and there is no displacement on street lines, though in one instance we have had to do some little extra work; but this was because we commenced welding before the concrete had set thoroughly. We put in the concrete and leave a place where a welded joint is to be placed; after it has set we cast weld it, and in that way we have not had any bad results.

Mr. Jones: I would like to hear from Mr. Butts or some gentlemen who have had experience in this rigid foundation for track as to how they can arrange to put in their construction and operate their regular service.

Mr. Holmes: We use these portable cross-overs and cut off so many feet of track. We take one track and do it in that way.

The President: Do you take your cars off that track for the seven days necessary to do this work?

Mr. Holmes: It depends a great deal upon the weather; if the weather is warm and the cement sets quickly, four or five days is enough. It has been customary in most cities to divert the traffic and put the cars on some parallel street.

Mr. Watson, Cleveland: There are one or two points in the use of cast-welded joints that we have brought out in Cleveland that I would like to call to your attention. We have had some experience with electric welding. In our experience with joints of that character we have been unable to keep perfect gage and surface. The 12-bolt fish plates have proved much more satisfactory than the cast-welded joints. We have not put in the foundations as Mr. Butts describes, but there were plenty of ties, and the work was carefully done. Now we are using cement concrete. I do not think we shall use the case-weld joint, but will depend entirely on fish plates with 12 bolts. It does not seem to me it is possible to ignore the contraction and expansion of that amount of material, no matter if seven-eighths of it is covered underground and held in place in a measure by concrete or brick pavement.

The suburban work, it seems to me, cannot be made too well. If you follow the lines laid down by the steam railroads you surely will not lose money. If you cannot afford that construction do not build the road. (Applause.)

Mr. McGregor, Houston, Tex.: Mr. Butts does not say any-

thing about cast-welded construction in streets without paving.

Then the question of bonding is not mentioned in this paper. Another question is that of the form of rail head. I have taken a fancy to what is known as the Trilby section. I have not used any, but I have always used a T-rail; but we have to use something else now to satisfy the municipal demand, and I would like to know if anyone has used the Trilby rail, and if it is satisfactory.

Then another trial we have had is that of trying to keep the pace set by the big roads. Yesterday we started out with a coach and four on cars—that is, four motors. We use one motor. I can readily understand that with a company which has business waiting for it the matter of expense of fuel does not cut much figure, but for a road that has not much business to add a fixed expense is hardly an advantage, and I think if we can get ourselves into two classes, that is, those that have all the business they can handle, and more, too, and those that have not enough, we may get a standard for each. (Applause). Speaking on the rail question, the big roads have set a standard of 9-in. rail. Now I have a 6-in. rail and I want a girder rail that will match up with it, but the supply people cannot furnish it to me. They will give me a 4-in. base, but I do not think anyone who runs an electric car wants to put a 4-in. base down now. They say everything is 9-in. We have not any ballast down our way, and we try to get up near the top. One inch of concrete we put in cost us $1,200 a mile; we have skimmed along because our pocketbook is thin, and we would like to get a standard down to the thin credit we have. We only earn $25 a day, and that is different from $150 and $200 a day. We would like to get into that class. We feel it is embarrassing for these little roads to talk with the pace makers, but at the same time, I have come up here for information, and I would like to get it.

For ties, we use spruce ties, being close to the spruce swamps.

I am putting in cast-welded joints, but I have not the experience that will enable me to express an opinion on the results yet. From those who have had the experience I would like to get information.

Mr. Heidleberg, Chicago: I have heard the cast-weld joint discussed so much that I must say that I was the second one who took hold of it. I started out about 1895. It was first tried in St. Louis; our road was the second. The alinement of the track and the surface have been mentioned here. I only ask the members of this Association to go and look at some of the track that we have made in the later years. I will call your attention to Indiana Ave., which was put down last week; on 18th St., from Wabash Ave. to Indiana Ave., and on Indiana Ave., from 18th St. to 29th St.; 10 miles on Halsted St., from Archer Ave. to 79th St., which was put down this summer; and I don't think you will find one joint that is out of alinement or out of level.

I have made experiments and I think that creosoted cedar or hemlock the only tie to use in sand, and in clay soil, white oak. We use a 7-ft. tie, 5 x 8 in., and chisel pointed spike side brace plate, which are used on a great many roads.

We have tried all kinds of rails. First we had the old flat rail. From that we came to the first girder rail that was made, and 42-lb. Johnson; then we got a 63-lb. Johnson. From this Johnson we went to the 70-lb. 6-in.; next to the 75-lb. 7-in.; and then to the 85-lb. 7 3-16-in.

We laid a great deal of 9-in. 90-lb. rails which did not give satisfaction. The reason is that we have various kinds of pavement, such as macadam, cedar block, asphalt, granite and brick, and the rail was too large; it rocks too much. Another fault we found with this section was that it was too thin for the height. The severe cold weather that we had and the extreme changes here, where we get a warm rain in the morning and a cold snow storm in the afternoon, made our rails pull and break, because the metal was not compact, the body was not close enough together. It was rolled out too thin. In the way of pavement, very often we would like to construct a road one way, but the municipal authorities will not have it so.

Our cable lines are all laid in concrete, and we find that in from 11 to 15 years concrete crumbles. Our yokes and rails go down in it and it becomes a trench. Every time a car goes over it it goes down.

Mr. Butts, in his paper, stated that for joints he poured the metal at a bright yellow. My instructions to my men are to pour no metal into a mold unless it is at a white heat; if the metal is not at a white heat they make a pig of it. The essential thing after sand blasting the joint and getting all the scale of the rail perfectly clean is to have the metal very hot in order to flux and amalgamate the rail. If you do not do that you are not sure of the bond. When you do that and have a man watching to see the metal is at the perfect heat, then your bond is sure. We have made a great many tests, and on making test after test and becoming more thoroughly acquainted with this work and getting it perfect, we found the bonds were not necessary and only a waste of money.

Now as to maintenance; no one seems to have spoken about the organization of the maintenance department. In the first place it is very essential in maintaining railroad tracks to have a thorough organization of all the men under you, so you can get them together quickly. I can get all the forces in our track department at one point inside of an hour. Track work has been my study for years. Give the men good tools. Have them thoroughly organized. Our forces are organized in this manner: We have a track master and a section foreman. Our road is cut up into six sections, 40 miles of road to each section. To these sections men are allotted according to the work to be done. If there are a great many railroad crossings in one section we take some straight lines off that section and put them on another. A railroad crossing is special work, therefore a man always has that section and knows he has to take care of it. Our system of calling men is to have one caller on a section. The telephone operator at the main office sends to the station or barn, and calls the one nearest to the barn, and that caller calls all the rest of the men, telling them where to go. These things are very essential, especially in the North, where you are liable to get a snow storm in 30 minutes, and have to have men cleaning out the slots, etc.

There is one thing I would like to have some one explain to me that I have been trying for the last eight years to cure for myself, and that is, a wavy rail. We have some, what we call wavy rail. There is a depression in the rail about every 3 in.; it looks like a wavy sea. I have taken those rails out and sent pieces of them to the best experts in America, but I never got any reply from them. (Laughter.) Now I want to see if there is any one here expert enough to tell me what is the cause of a wavy rail.

Mr. Butts: In answering some questions, I would say we have not advocated in this paper anything less than a 6-in. rail. We have not experienced any breakage in cast-welded joints, and we have welded not less than 3,000; they do not break. What depth of rail did you have on your cable construction?

Mr. Heidleberg: We have now 7 3-16 in. Previously we had a 6-in. rail without a foot, round bottom.

Mr. Butts: Generally the cable construction rail is based upon yokes placed 5 ft. apart 4½ x 5½ in., and they are not, as a general thing bedded in concrete. They are supported entirely by the yokes. That is my experience in the matter of rails, and therefore the concrete construction of cable railways does not apply to concrete trench construction, as we understand it. There is a variation between those yokes that will wear out most anything. It is not held rigid; it is not rigid construction. In regard to the bonding of the rails, we do not bond the rails where they are welded. The welded joint is of the full electrical capacity of the rail. When we do not cast-weld we bond with a No. 0 wire.

Mr. Heidelberg: Do you cast-weld outside the streets paved?

Mr. Butts: No. We have not had any experience in that line, although, as I said before, it depends entirely on the amount of material that you have embedded in the earth as compared to the amount of material exposed to the sun. I don't see why, if it could be kept embedded in the earth that it would not be just as successful as if it were embodied in other material.

The President: Gentlemen, I am sorry to cut short any discussion on this very interesting subject, but our time is getting short, and I think, therefore, that we shall have to proceed to the next paper.

Mr. Heidelberg: All the members here are interested in track work, and I would like them to make us a visit before they leave the city. They can find everything open and a hearty welcome We have a yard at 55th St. and Cottage Grove Ave., one at 30th St. and Wallace, and one at 49th St. and Oakley Ave., and we would be pleased to have any member come and see us. Tomorrow we will be welding joints at 55th St. and Western Ave in the day time, and we will be pleased to have them come.

The secretary then read resolutions passed by the supply men expressing their thanks and appreciation of the action of the executive committee of the American Street Railway Association in setting aside one day for the supply men, and also for the courtesy shown the supply men. The resolutions were signed by every exhibitor in the building.

The President: The committee appointed to nominate officers and select a place for the next convention will now report.

Mr. H. C. Moore: Mr. President, and gentlemen: The committee received invitations from three places, Cleveland, Kansas City and Charleston. We found ourselves in a very difficult position. We loved you all equally well, but had to make a decision. We also received an invitation from the city of Milwaukee for the year 1901, and from the city of Toledo for the year 1902.

The secretary then read the following report of the committee on nominations:

The nominating committee respectfully recommends Kansas City as the next place of meeting, and the following gentlemen for officers of the Association for the ensuing year:

President John M. Roach, general manager Chicago Union Traction Co., Chicago, Ill.

First vice-president—John A. Rigg, president United Traction Co., Reading, Pa.

Second vice-president—H. H. Vreeland, president Metropolitan Street Railway Co., New York City.

Third vice-president—F. G. Jones, vice-president Memphis Street Railway Co., Memphis, Tenn.

Secretary and treasurer—T. C. Penington, treasurer Chicago City Railway Co., Chicago, Ill.

Executive committee—The president, the vice-presidents and C. S. Sergeant, second-vice president Boston Elevated Railway Co.; C. K. Durbin, general superintendent Denver Consolidated Tramway Co.; Nicholas S. Hill, jr., general manager Charleston Consolidated Gas & Electric Co.; Charles W. Wason, vice-president Akron, Bedford & Cleveland Railroad Co.; John R. Graham, president Quincy & Boston Street Railway Co.

Mr. Harrington: I move the report be accepted and the secretary be instructed to cast the vote of the meeting for the gentlemen nominated and the place of meeting for the next year. The motion was seconded and carried unanimously and the chair appointed Messrs. Dimmock and Connette as tellers to prepare and cast a ballot for the officers nominated by the committee. Mr. Dimmock announced that this pleasant duty had been performed and the president declared officers, as nominated, elected.

Mr. Holmes: I desire for Kansas City, and the Metropolitan Street Railway Co., that I represent, to thank you all most sincerely, and especially the committee for this compliment. I will say that while you are with us in our city we will do everything we can think of to make your visit a pleasant and profitable one. (Applause.)

Mr. McCormack then presented the following paper:

TRAIN SERVICE AND ITS PRACTICAL APPLICATION.

By Ira A. McCormack, General Superintendent Brooklyn Heights Railroad Co.

It is an unquestioned fact that a well arranged train service is as essential to the commercial success of a street railway enterprise as is expert management of the power house and equipments, the use of economical machinery or any other vital detail, and it is perhaps one of the hardest problems that street railway managers have been called upon to solve. In presenting this paper the writer would not wish to be understood by the members as presenting a sovereign solution, but rather as submitting methods which he has found to be useful in cases that have come under his observation. The conceded fact that all discussions must have a nucleus, and that the experiences of no two persons are alike, whereby the natural law obtains, that one is certain to learn something from another, must be the apology for what follows.

In mapping out the train service of street railway systems in a large city the problem will be found very intricate. Some lines have continuous traffic at almost uniform proportions at all hours of the day; some have rush hours at morning or night, or both; some have hours of over-crowding at more frequent intervals, and with some the traffic is exceedingly irregular. There is the passenger who rides but a few blocks. There is the through passenger, and transfer passenger. The problem is further complicated by the location of parks, places of amusement, shopping or residential districts, branch lines, and the summer and winter seasons, and it is perfectly evident that no general methods can be laid down.

The problem naturally divides itself into two parts; first, the ascertaining of the conditions of traffic which are to be met, and second, the means for meeting these conditions in the best possible manner. No matter what the character of the service may be, suburban, excursion, or local, there is one ideal condition to be aimed at, and that is to have each car full of passengers. If there be less than a full car the equipment is not run to best advantage and fewer car-miles would render the same service, while if the car is crowded the traffic of those who dislike a crowded car may be lost and the management is likely to be criticised unfavorably by the public and the press. It is important, therefore, to determine with as much accuracy as possible the traffic conditions, that is to say, how many of the public want to ride, where they want to ride, where they wish to take the car and where they wish to leave it.

IRA A. McCORMACK.

For convenience in making specific illustrations and also to enable the discussion of different conditions as far as possible, the following different characters of service may be cited:

A. A line of heavy traffic in shopping districts in close competition with elevated railroads.

B. Doing a heavy traffic in residential districts without competition.

C. A cross town line serving as a transfer system to connect other lines and add to their attractiveness.

D. A cross town line connecting with centers of transportation, such as railway stations, ferries and the like.

E. An excursion line, half of which is residential, on which the excursion traffic varies with the season.

F. A suburban line of considerable length and operated at moderately high speeds.

G. A line not over remunerative and operated for such reasons as public or press opinion or hope of its future value.

The conditions that will obtain on these various lines are obviously widely different. At first it will be necessary to evolve a method of determining what these various conditions are.

At the start the manager is as helpless as an outsider. He can merely generalize and deduce a time-table which to his best knowledge of the system will fit the conditions, but having thus formed an existing time-table the knowledge of how it operates and how it can be corrected is rapidly and easily acquired by the best of all methods, that of practical experience. In collecting the necessary data a method which the writer has found of value is to provide each car conductor with a blank which contains spaces on which the number of passengers carried on the car between the termini can be conveniently listed and totalized. This slip is conveniently arranged so that on it are registered the following data:

1. Name of operating line.
2. Run number as per time-table.
3. The date.
4. The time due to leave terminal.
5. The actual time of leaving terminal.
6. Passengers carried on down trip.
7. Passengers carried on up trip.
8. Totals.

This slip, signed by the conductor, is turned into the proper office. This of course gives general information as to the traffic. It shows whether it is heavy or light, whether it is falling off or increasing, whether it is increasing on the down or the up trip, and also gives a check on the register. This information is usually collected in one way or another by almost every street railway manager.

The records are duly tabulated on a printed blank and daily compared, and if it be found that the traffic is increasing, it may be wise

to put more cars on the route, and if the traffic is diminishing, a longer headway might be good policy. The next thing to determine is how these changes had best be made and if possible to ascertain the specific reason for the increase or loss in traffic. To do this the inspectors are provided with blanks and are sent out on the line. Various points are chosen and at these points the passenger record is very carefully taken. This slip provides for the record of the following data:

1. The place of record.
2. The name of the line.
3. The date.
4. The observed headway.
5. The number of passengers on the cars at points of record.
6. The fares rung up on the register at record points.
7. The totals.
8. The general average of these quantities.

On the back of the slip the inspectors find the following instructions and queries to be answered:

MAP SHOWING LOCATION OF DIFFERENT LINES.

Note. Inspectors will be careful to show correct count. Make report plain and clear, but use as few sheets as possible. If record of but one line is being taken, show the name at top of page.

If record of several lines is being taken, indicate name of each line in blank space at head of column.

If conductors are found short, give conductor's badge number and state particulars.

Give any and all information on this report that will prove of value in permitting change of headway and condition of cars, etc., to improve the service.

Is the headway well maintained?

Is there enough or too much service at any hour?

Are cars running to proper terminals to accommodate the public?

General condition of cars.

Conductor found short?

Car No. Conductor's No. Particulars.

It is sometimes instructive to plot the results in the form of curves. Suitable section paper is selected and the number of passengers per hour are plotted as abscissae and the hour of the day as ordinates. This gives opportunity to examine a large number of figures at a glance and is sometimes useful in drawing general conclusions.

These reports give much valuable information. They show the average number of passengers on the cars at the point of record, thereby determining whether the cars are overcrowded or not. It give the total number of passengers carried up to the point of record and an approximate idea of where they left the car. If the traffic on the line is irregular it shows in a measure where it is heavy and where it is light, according to how near together the points of observation are selected and it further shows the exact time at which these traffic conditions obtain.

In order to obtain trustworthy results it will be necessary to take these records for some time, possibly for a week, for a single record might be completely misleading because of the condition of the weather or a yearly Sunday school picnic or similar flush of traffic not likely to be repeated. It remains to be said, however, that as a rule weekly records check very closely. Having obtained a fair average of the number of passengers to be carried between two points, the proper headway between these points can be computed and the next question that obtains is how to get this headway. It may be advisable to actually put on more cars, or again it may be that the increased traffic occurs between such points on the line when it would be advisable, if possible, to loop down upon this section a few more cars from some adjacent line, and more especially would this be desirable if at the corresponding section on the adjacent line the headway was found to be too short.

So far the method seems to be a simple mechanical process in which the steps for remedy are as obvious as in a station test. It is unfortunate for the sake of simplicity that this is not the case. In making a station test the diagrams and curves obtained invariably show the condition of the machinery or apparatus tested. The curve traffic above described would show the condition of traffic were it not for the fact that the public and many local conditions, which would seriously affect the traffic, must be considered. As an instance of this, when the information is being gathered to plot out the curve traffic, a fair, festival or entertainment of some nature may be in progress, which would cause traffic to go in the direction of the entertainment. Therefore, the curve traffic, without considering the local and all traffic conditions, might lead to an erroneous conclusion. The maker of a new time-table must know the lines root and branch. There are certain rules which long experience has shown are almost inviolate. There are certain traffic conditions which are temporary and others which are permanent. There are competition conditions and in many ways there is much else besides these records to consider.

For instance, those who travel on street cars, I have classified as follows:

1. The workers who travel from 5 to 7.

2. The clerkers who travel from 7 to 8.

3. The bankers, brokers and proprietors, who have sometimes been facetiously termed the "shirkers", who travel from 9 to 10:30.

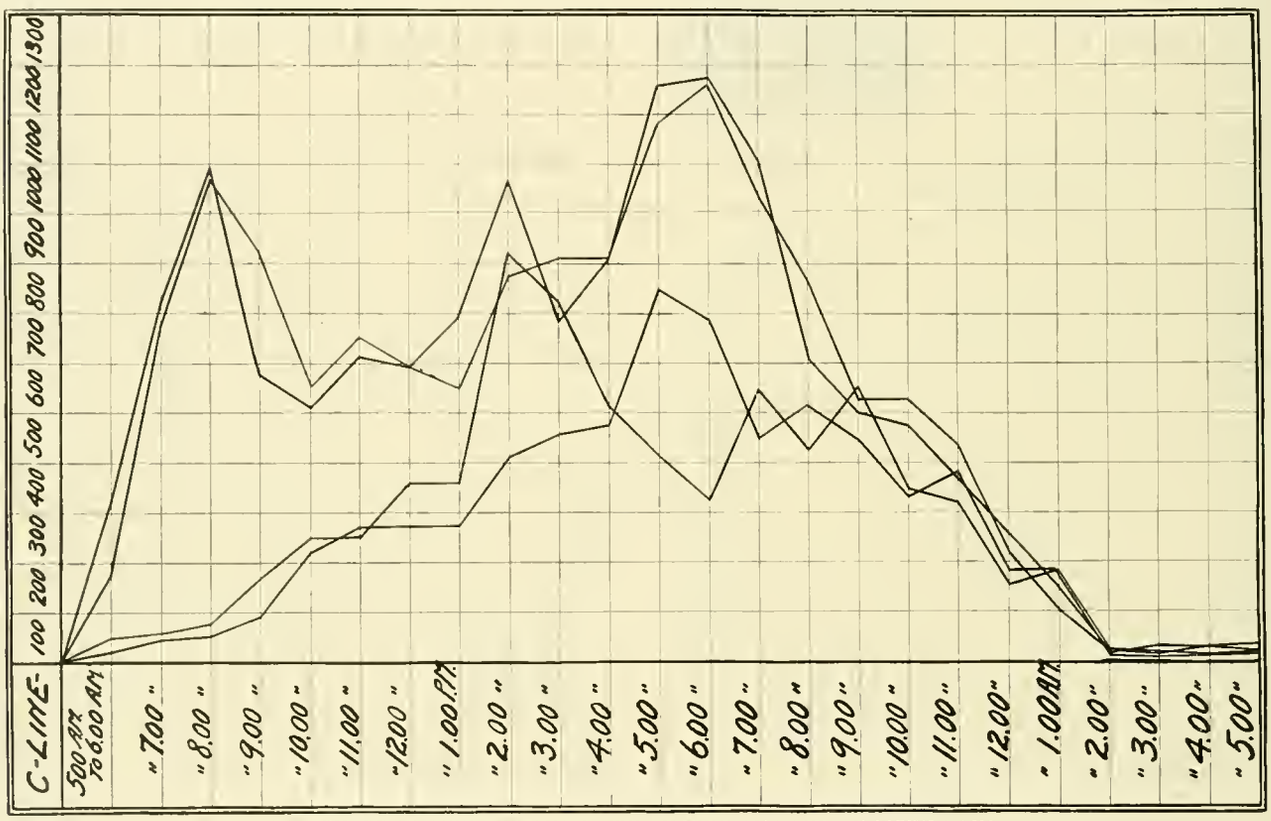
4. The shoppers who travel from 10 to 12.

The greater part of these people remain in the city, coming back in one grand rush, which begins between 4 and 5 and reaches its culmination point a little after 6, and sometimes lasts until after 7. Then the theaters and places of amusement begin to influence the traffic which swells in the direction of the metropolis till a little after 8, and outward again from 10 to 12. The regular nighthawks who take care of the traffic of the city between 12 and the early hours of the morning, it is usually wise never to disturb.

It is sometimes possible to meet the traffic conditions on a line without increasing the car mileage by simply changing the character of the cars which are running upon the line. Long cars with double trucks are advisable on through traffic, and it should be aimed to run them at such times as they will collect through passengers. Short cars should be run for the convenience of short

be the case. It is very important for the company to have a force of competent, well satisfied and not overworked men. I contend that a man earning $40 a month and who is satisfied with his surroundings and conditions, is a better employe for any company or corporation than a man who is earning $500 a month, and who is discontented and dissatisfied with the surroundings; and on the other hand it is important for the men that the company shall be prosperous, for otherwise there will be fewer regulars and more trippers.

It frequently happens that the time-table of a road can be corrected to meet the conditions of traffic by delaying the cars at certain points and increasing their speed at others, thus, for instance, it has often been found beneficial to instruct the motormen to stop their cars at junction points and wait for the car on the cross road in order to exchange transfer passengers, or perhaps to wait a stated time, say two minutes, and then to proceed. It is plainly to the advantage of the road to exhaust all such devices as this before actually running more cars to meet the increased conditions



PASSENGER TRAFFIC UP AND DOWN ON SUNDAYS AND ON WEEK DAYS.

riders and if it be found on any line that a certain hour of the day a large percentage of short riders take the cars between certain points, a little ingenuity in adjusting the long and short car service may frequently accomplish a great deal.

On Sundays and holidays the traffic conditions change radically. On some lines the traffic falls off a great deal and on others it becomes exceedingly heavy. On lines running to places of outdoor amusement, such as parks, beaches, race tracks and the like, it is well to watch the weather, for it is obvious that if the day is pleasant the traffic will be much heavier than otherwise.

The best men are picked out to run on the strange lines, and on lines of heaviest traffic in order to have the benefit of their experience in handling the public, knowing that they will be more safely handled and more convenient service given them than if a poor class of motormen and conductors are operating on the lines of heaviest traffic. A street railway manager would, were it in his power, locate amusements and entertainments upon the best built and best equipped lines; for it is on these lines that the best service to the public is given.

Of the last statement it may be well said that the duty of a superintendent may be divided into two equally important portions; first, the arrangement of the system for the good of the company and public, and second, for the good of the men. These duties are not at all incompatible, although by some this has been thought to

of traffic. If more cars are actually to be run the question should then be considered as to what kind of cars, that is to say, long cars or short cars, and if the road be a main artery receiving the traffic of several branches or cross lines, whether these cars should be main line or branch cars, and if branch cars, which branch.

From a practical knowledge of the conditions and from the data that have been outlined, a new time-table can be made up, but it is not to be expected that it will prove of lasting value. The traffic must be carefully watched, the conductors' reports carefully compared and whenever an increase or decrease of traffic is shown, the advisability of sending out inspectors with passenger record slips should be at once considered.

Traffic may be increased temporarily, particularly in manufacturing districts, when some large manufacturer will put out of work, temporarily, by the closing down of an industry—the workers of which industry were mostly patrons of the road, and the superintendent will be at once advised of these changed conditions by the conductors' slips.

Those conditions show the necessity of an intimate knowledge of the entire system. The management, however, should not deceive itself in case mere adjustment is not successful. If the cars are still crowded in spite of all manipulation of length of car and variation of headway more cars should be put on.

However instructive it may be to make general remarks on these

matters, specific cases and their solution are always interesting, and to provide this the writer has selected from his records a number of cases illustrative of different conditions which may be of interest to the members.

A practical condition that obtained recently was the case of a line H which formerly had its route down another line J to a ferry terminus. The inspector's report showed, first, that it was needed to increase the service on a certain intersecting line B and second, that a great many passengers from line H transferred to line B, in fact more than continued down line J. When these facts were known the solution was obvious. The traffic of line H was cut off altogether from line J and sent down line B, thereby giving the desired service, avoiding the transfers, and only very slightly increasing the mileage and not at all increasing the number of trips of equipments.

Another interesting case may be cited on a line I, a short line running from the terminus of a main artery upward into the country. The traffic was found to be so great that it was necessary to diminish the headway. This was done by running some of the main artery cars over line I. This had the effect of slightly increasing the car mileage, but did not require any new equipments and gave through service from the terminus of the main artery to the further terminus of line I, which was beneficial.

Another interesting case is that of a cross town line O. This line carries through passengers to its terminus and also acts as feeder to the various lines which it crosses, therefore in one portion of its length the traffic is exceedingly dense and the headway must be correspondingly short. This object is simply attained by running short lines which travel back and forth through the sections of heavy traffic, and the through service is run on a headway suited to fit the conditions of the more extended portion of the line and also helps to diminish the headway in the more heavily patronized sections. Line D—the other character of cross town line—is also very interesting. The line starts at a railroad terminal and distributes incoming passengers to their destinations. It passes through a large factory district and transfers a great many passengers to other lines crossing it at different intervals, also traverses shipping districts and gives access to the docks. It is essentially a day line and it has been found that in such a case the traffic has been met to best advantage by a practically uniform service. This is a unique exception in railway work. As a final illustration we may take a line E on which the traffic varies. The first section of this line is residential. The last is excursion. In the summer season the headway on the residential district has to be quite short to accommodate both classes of traffic. In the winter season the conditions are met by cutting the line in ⁊o and running a suitable headway through the residential district and a shuttle service of a few cars over the excursion section.

The street railway manager will easily see that these methods are typical but by no means exhaustive. There are many methods of manipulation and the opportunity for ingenuity on the part of the maker of the time-table is exceptional.

Besides ascertaining the traffic conditions on the various lines it will be found necessary to pay strict attention to the actual management of the system in order to obtain the train services that may be desirable. In the first place the power houses must be located at such points as to conduce to equal distributions of voltage. Low voltage on any line means slow time no matter how good the motorman or the equipment, and everything that may produce this trouble should be carefully avoided. Every precaution must be taken in the operation of the power house to prevent shutting down. Power house attendants often become careless and are slow in replacing a circuit breaker when it is blown out, not realizing that they may be wasting the time of as many as 1,000 persons. The writer has known cases where the circuit breakers of two different lines were thrown at one time. The man who watched only noticed one of them and replacing that, failed to close the other, resulting in a most serious delay to the line which it supplied. It has been suggested that a switchboard should be equipped with an automatic device, which, in the event of a circuit breaker being thrown, would close a circuit and cause the ringing of a large gong, which would show to the switchboard tender, or employes of the power station, whose duties it is to see that the circuit breakers are kept in, that there is some breaker or some line which is not furnished with power. In this and in scores of other ways the station attendants are responsible for the accuracy of the train service in fitting it to an approved schedule.

There are also other cases which are incident to the power house which are in no way attributable to the men in direct charge. One of these which may be mentioned is the practice of false economy in purchasing a poor quality of coal which in spite of all that can be done, allows the steam pressure to drop and does not supply the engines with sufficient energy. Similarly the use of poor oil may allow important bearings to become heated, which results in crippling the line or overloading other machinery, thereby causing a reduction in voltage, or it may be that the headway for the time will have to be lengthened, thereby departing entirely from the approved schedule. In short, everything must be done at the power house to provide at all times sufficient current at a sustained voltage at the cars. Without this, any schedule, however accurate and elaborate, will fail in carrying out its object. The details of producing such service are so voluminous and have been so ably discussed by other writers that anything further than the statement of the condition would be superfluous here.

The track and overhead construction should be secure and serviceable. It is obvious that a good track is essential to good comfortable riding which will please patrons. Special work should be maintained in first class shape and renewed promptly. It may be mentioned that it is not a wise practice to allow work of this nature to become worn to its last stages before steps are taken for its renewal. An order for special work of necessity cannot be filled promptly and it may easily be that if there is delay in placing the order, the old frogs and crossings will become very much worn, cars will be derailed, axles bent or broken, motors dropped and aside from the actual expense of repairs and maintainance, the train service, which is the prime factor, will be interrupted. The writer's experience has been that considerable trouble has been encountered in maintaining a train service by reason of the spread of the rails and consequent accidents and delays. Where the traffic is at all heavy, this accident is very liable to occur unless the rails are bound with tie rods.

Like the track, the overhead construction should be of the very best. A broken trolley wire is even worse than a disabled track, for it may tie up not only one car but a whole section, and anything which will minimize the liability of wires coming down is advisable. In order to preserve the train service, the work of repairing the overhead construction should be performed at such times as will least interfere with the service. This is usually at night.

In order that overhead maintainance can be performed to the best advantage, emergency stations should be located, each of which is assigned to certain territories. The station covering the heaviest travel should be able to reach its outer boundary in 8 minutes, while in suburban districts the further limits should be reached in from 15 to 20 minutes. The construction wagons should consist of an extension platform from which the overhead work can be reached without standing the wagon in the track way.

Track and overhead repair men should be impressed as strongly as possible with the fact, that in making their repairs, it should be done in such manner and at such times as will least interfere with the operation of the cars. The judgment of some track and overhead repair men cannot always be relied upon to carry out this injunction. Train service is often interrupted by track and linemen in making repairs to the track and overhead system, by attempting to make too permanent repairs at a time when the service is heaviest and should be least interrupted; when a temporary repair would have done just as well until such a time as the service was light and permanent repairs could be made without interruption to the service.

The writer knows of one particular case where the ear of a double pull-off on a curve had become so bent and out of its proper position, that when the trolley wheel was riding under it, the trolley would come off and one of the arms of the pull-off and the bent ear would serve as the prongs of a boot jack; the trolley harp and wheel catching in the arms of the pull-off and doing one of two things: pulling down the overhead work, or pulling the trolley pole from out of its base.

It is a common fault to pay too little attention to the application of guy wires on curves and serious delays due to failure of overhead construction on curves are very frequent. Sometimes the work is satisfactory for short cars, but on long cars the motion of the trolley being somewhat different is likely to throw the wheel off the wire. Frogs should be placed in the overhead work where the lines diverge at a point that will insure the trolley wheels following the desired route.

Another and exceedingly important feature of good train service is the selection of motormen and their instruction in running the cars. Many elaborate papers have been written on how to run a car to use minimum current and to produce minimum wear and tear on the equipment. These instructions, while ingenious and accurate from a technical point of view, and possibly of wise application in small country roads, are not at all suited to the heavy traffic conditions which obtain in large cities. In such cases the most important duty of the motorman is to make schedule time, keep a sharp lookout for passengers and avoid accidents. It is interesting to note in this connection that the best motormen are often men who can neither read nor write and are found among teamsters, drivers on horse railways and the like. These men are accustomed to do implicitly as they are told. They are accustomed to watch the street carefully and keep good track of vehicles and persons, by which means they avoid accidents and secure passengers.

The semi-technical man who is "learning the business" makes the worst motorman of all. His mind is more active, he in interested in the performance of his motors and equipment and neglectful of his primary duties as motorman. He is always on the lookout to take note of matters, which though they may be valuable to him in his personal advancement, are entirely foreign to his duties. More than that he is a dissatisfied individual, looking for better employment in the near future and for that reason he is not inclined to learn his business of motorman thoroughly, regarding it as scarcely worth his while.

Of course it is necessary that the motorman have certain instructions with regard to managing the controller. He should know that it is not advisable to give the motors too many notches at once, that he should, wherever possible, allow the motor to gain speed on one notch before passing to the next, that he should run the car on certain notches as far as possible, that he should not allow the controller handle to dwell on spaces between notches, but it is not at all necessary for him to know why the motors are more economical at full series or full parallel or just what misconnections are likely to obtain if the controller is run between notches. It is sufficient that certain things must be done and that certain other things must not be done.

It is, nevertheless, a fact that a good motorman will run a car with less energy than a poor one and still maintain schedule time. A good deal of this may be ascribed to the careful use of the brake. It is necessary in making a fast schedule with many stops to shut off the power and use the brake almost before the car has gained headway. This frequent use of the brake is a temptation to many motormen to keep the slack of the chain taken up so that a slight pressure on the brake handle will put the brakes on hard. This keeps the shoes in contact with the brakes at all times, giving excessive friction and loss of power. A good motorman will coast his car as much as possible when the schedule will permit it. It is certainly advisable to keep accurate record of the way the motorman manages his equipment, but inferences must not be drawn too hastily from such records. If a motorman in charge of an equipment wears out his brake shoes rapidly and comes in with the regulating resistances sizzling hot, the schedule on which he has been running must be considered. If he has been on fast schedule with many stops and has followed it closely, the condition of his car signifies very much less than would be the case if he had an easier run and had failed to make schedule time. In forming an estimate of the qualities of motormen, train inspectors, conductors and particularly of officials having men in charge, the writer has found first impressions to be exceedingly valuable. The well known saying that the sober second thought is seldom wrong, is not always correct. Judgment should, of course, be suspended until the second thought has been well considered, but the first thought may be right after all. It certainly has the advantage that it usually represents the only impression that the majority of people will consider and hence may be the popular impression, which in street railway work at least must be catered to.

After all has been said and done with reference to the manipulation of train service it is interesting to know what results may be expected from good work in this department and to exemplify these matters, the writer again cites from his records cases which he ventures to think will justify the statement that the matter of train service is of great importance.

It is not always easy to record the income of a line, for instance, a passenger may take line A and ride on it for 100 yards and pay in his fare simply and solely because he can obtain a transfer on line D. Line A gets the credit on the books and line D, which actually performed the transportation, carries the debit side of the account. There is nothing on the transfer to show whether the passenger rode a longer distance on line A than on line D, or vice versa. To be strictly accurate the fare and the expense should be charged to each line in proportion to the distance the passenger was carried on each, and while attempts may be made to equalize the accounts, in this respect absolute accuracy cannot be hoped for. The results are therefore submitted subject to this criticism and are the best that can be obtained under the circumstances. The following examples are taken from monthly comparison sheets, which sheets are made up from the reports of the conductors, the inspectors and the books of the company, and comprise the following data:

1. Receipts.
2. Total passengers.
3. Mileage.
4. Receipts per car-mile.
5. Number of trips.
6. Receipts per trip.
7. Average length of trip.
8. Average number of cars per day.
9. Average mileage per car per day.
10. Time-table cost.
11. Columns for the record of increase or decrease of these quantities over the same month in the previous year.

If the comparison sheet shows increased receipts, diminished mileage, diminished number of trips and diminished time-table cost, the result must be ascribed in a large degree to the management of the train service. I may cite as examples the following:

From a monthly sheet on a certain line the increase in gross receipts was $3,586, the decrease in mileage was 18,920 miles, due to the substitution of short lines for longer ones. The decrease in time-table cost was $1,612, representing an actual increase in revenue to the road of $5,198. This amount as a monthly incentive for ingenious manipulation of the train service is certainly attractive. On another line almost as large the increase in gross receipts was $13,765. It was, however, accompanied by an increase in time-table cost of $1,902, representing a net gain of $11,867, certainly a wise investment for the added expense. The large gain in gross receipts was due to changing of the terminus to a better center of distribution. This maneuver not only filled up the empty cars that were running formerly but necessitated the running of additional equipments. Another case may be cited in which the gross receipts showed a loss of $7,087 and the time-table cost a decrease of $2,814, representing in total a loss of $4,275 as compared with the same month of the previous year. This, while not so pleasant for directors' contemplation, is very important to know. The reason for this was found in the fact that a number of large factories on the line had been shut down. It might have been due to local conditions or that the train service could be improved.

In like manner a yearly comparison sheet can also be drawn and careful management can often, in a well established road, increase gross receipts or largely diminish the time-table cost. From such a sheet involving a yearly total from 37 different lines may be cited an increase of more than 10 per cent in gross receipts and a little over 1 per cent in time-table cost. The receipts per car-mile showed an increase of 5.8 per cent. The receipts per trip were increased 16.5 per cent. The average mileage per car increased 15½ per cent, whereby about 144,000 trips and the incident expenses were saved.

Such figures as these on a system in which the building of new lines has been relatively small can hardly be ascribed to growth and extension and could scarcely be obtained except by running the cars longer distances and by suiting the public taste whereby larger loads of passengers were carried, or briefly and in other words, by improved train management.

The President: We are to be congratulated on having heard so interesting a paper on a subject which I think has never been presented to us before. We are indebted to Mr. Holmes, of Kansas City, for the suggestion of this subject, and I think it is only fair to ask him to say a few words on it.

Mr. Holmes: We have adopted a plan of setting aside a portion of one day in the week, which is Monday morning, from 9 o'clock to 12, when we receive applications, and at that time generally call in some of the division superintendents, who look the men over as they pass through the office. I think it is wise to have the men who are employed under you with you at those times, and

after selecting what men we need they are required to make out an application, stating where they are working and giving such references as they are able to give. We have found that to be the best way of handling the matter and have been able to get very good men. As Mr. Vreeland very happily said, the treatment of the men or the handling of the men is a vital thing in the management of the street railroad. I think it is possible to have your men like you and respect you at the same time. I have arranged this winter to give my men, the motormen especially, a course of lectures. I have arranged with Prof. Black, one of the best lecturers in the West, to come to Kansas City and deliver a lecture on electricity to our men once every two weeks through the winter months. Our company will pursue the matter just as far as the men wish to go in their study of the subject. My position about the train service is, that we are merchants to the extent that we are selling rides, and that in the selection of our men the company is judged almost entirely by its employes. The passengers seldom come in contact with the managers of the corporation, and I think it is more important than anything else to use great care in the selection of men. We have followed the policy of promoting men from the ranks. We think that is best. We select, wherever we can, married men. In our city a great many young men, many of them married men, come in to learn the professions, to become dentists and doctors and different things, and often take up street car work for three or four years until they complete their education.

The President: There is one railroad in the United States that has the most difficult problem of train service to deal with that there is in the country, and that company is fully represented here, and I think we ought to have a few words from Mr. Vreeland, of New York, on this important subject. (Applause.) Will you give us a little information, Mr. Vreeland, as to how you run so many cars on Broadway.

Mr. H. H. Vreeland: Any information that I can give the Association with reference to this important subject presented by Mr. McCormack would hardly be valuable in connection with its work. The work that we have in New York City the greater part of the 24 hours, is to see how many cars we can run on the track we have, consistent with crossings at various points. Crossings and terminals govern our headway more than anything else.

As no doubt some of you noticed in my previous remarks, the steam railroads of the United States last year handled 560,000,000 of passengers, approximately within the borders of the United States. We moved last year 265,000,000 of cash passengers and 90,000,000 of transfers, or a movement of nearly the total of the whole of the steam railroad traffic of the United States.

I might say, following the line suggested by Mr. McCormack, that our system is handled with reference to time-tables, and the methods of making time-tables are on the same general plans as Mr. McCormack has suggested, and on lines which we very frequently talked over together. The essential point in arranging traffic, irrespective of its volume, is a study of the conditions. The division superintendent, with the amount of business that devolves upon him and the general foreman, in my opinion, are not men that can make a time-table. I made time-tables for five years for one of the largest steam railroads, and I would not attempt to make a time-table for one of our lines in New York. A man has to give his time and attention to the local conditions surrounding the problems. An expert goes to lay out a prospective railroad, and his idea of what the volume of business of that property is to be is by a complete and thorough study of the character of that section of the country and its people. The same study must be made with reference to the daily requirements of the street car lines in car mileage and the distribution. To show how essential this is, a superintendent who had operated a very large line for 20 years, was asked: "What are the heavy hours of traffic on your line, and how are you distributing your car service?" He said: "During the commission hours we run a large service, and then we reduce it, and we put it on again in the commission hours in the afternoon." I said: "Do you know the middle of the day is the heaviest hour of traffic on your line?" He said: "It is not so." I said: "It is, and I will prove it to you by figures." I had a man studying this, and I actually showed this man, who was regulating the thing, taking cars off during the day, that there were more people moved on his division per mile of track between the hours of 12 and 2 than at any other hour of the day. We don't allow a division superintendent or general foreman or a chief inspector to make time-tables for our system. The study is thorough, and the time-table is laid out by a man who is employed for that purpose. Again, east and west of Central Park there are three lines on each side of the town. The regulation of the traffic conditions or car conditions by the company are almost equal at the early hours of the day. A complete study of the people and their peculiarities, and the class of the people who live on the different sides of the town, determined that in the eastern part the large car service that went into 23d St. should be started at 6 and the large car service that went into the west end of the town should be started at 8:30; they had been running very nearly the same service on both sides of town, and the saving, of course, was large.

On the question of average speed, etc., affecting the condition, we have to study the factors very closely to keep things moving. We found it was impossible even on a short distance, to keep up the average of our lines for the heavy hours of the day, to maintain any regulation in the speed from the current direct from the generator, and we have put in two 4,000-h. p. storage battery plants to keep the voltage up so we could do our business. For a long time there was a question of what affected the time-table, and measurements were taken. Sending out men especially for this purpose, determined the fact that it was not the fault of the motorman, although he had been blamed by everybody. He had a car full of passengers and his voltage was down probably to 400 or 450, and men were being blamed for not keeping up to the schedule; by equalization through the storage battery plants we keep a uniform voltage of approximately 550, and meet the condition in that way.

The question of efficiency of employes and questions of that character are too numerous for a man to discuss in this connection. I have suggested that traffic diagrams are the most important thing for a man to have in connection with the operation of a railway. We have traffic diagrams taken at least once in two weeks on every division of our system for the 24 hours, passengers against hours, similar to the one described by Mr. McCormack, and a copy of that is furnished to the general foreman and inspector on the line, as well as the man who makes time-tables. They show the number of passengers carried per hour, in each direction, on every line of the system. We do not go by the 24-hour system, but it shows that from 9 to 10 o'clock 4,000 people went south and 3,000 people went north over the system. Now it is impossible to get any system so accurate that it will show where those people got on or off, without supplementing it by the system which Mr. McCormack indicated, special inspectors at certain points. I heartily agree with Mr. McCormack, and it would be utterly impossible for us to do the business that we do in New York City, run the number of cars, handle the number of people that we do every day without making this one of the very important studies of our transportation department. (Applause.)

Mr. McCormack: I would like to ask Mr. Vreeland whether on making the curve he shows the up and down trips on paper as I have, the upper line showing the down trip and the under line showing the up trip. You can see the traffic is almost uniform from 5 to 8. On Sunday we show the traffic up and down by different lines.

Mr. Vreeland: It is our plan to subdivide our blue sheets, using the upper half for the twenty-four hours south and the lower half for the twenty-four hours north bound. We worked on the system that Mr. McCormack has laid out there, and I do not consider it as valuable for the regular operation as it may be for this purpose here, from the fact that if you put these charts of traffic in the hands of men who are not technical men, but operating men, you must have it so that it is a graphic illustration of what you want to say, and by interlacing your lines you throw the men out. We show a clean sheet of north bound or south bound. The two peaks are coming toward each other, practically the same, only they are distinct in their location on the chart.

Mr. Heidelberg: I am interested in train service. The greatest trouble today in our train service in Chicago, something which we cannot cope with, is the trading of transfers at transfer points, and as I understand it, in New York City they have had this before the state courts and I would like to hear from Mr. Vreeland what they did with it.

Mr. Vreeland: I don't just understand what the gentleman

wants. Is it information with reference to the special cases where arrests were made?

Mr. Heidelberg: No, in general. Here you find boys standing at transfer points asking for "Transfers you don't need." The boy takes the transfer and sells it so two passengers ride for one nickle, and as I understand it, they tried to stop the practice in New York; what they did I don't know, but would like to know.

Mr. Vreeland: I fully appreciate, Mr. President, the difficulty under which you do a transfer business in Chicago, because in walking up town the other day here, I stepped into a drug store and bought a cigar, and when I was going out the fellow says, "Are you going up on the railroad? Here is a transfer." The transfer went with the cigar. But it is a long matter of detail, too long to bring before the Association at the present time; this subject was very thoroughly discussed, not only by our attorney, but by the men who directly handled it and who are the heads of our transfer business, together with the gentleman who handles the transfer system of the Brooklyn Heights road, and it was fully outlined in the report of the proceedings of the Ithaca meeting of the New York State Association, published last month in the street railway papers. While I would be very glad to give the information now, I appreciate it would be altogether too long to take up now.

The President: We will be glad to have further discussion on this train-service question.

Mr. Dimmock: I would like to ask Mr. Vreeland what laws in the state of New York, if any, govern the crowding of platforms particularly the rear platforms.

Mr. Vreeland: There are no regulations except the regulations of the board of Railroad Commissioners, that passengers shall not be allowed on the front platform of either the open or closed car with the motorman. That is the regulation. We do not follow it and a law was proposed to compel us to close the front gates and keep passengers off the cars. I made an argument against it, stating the law did not regulate the company; it regulated the public.

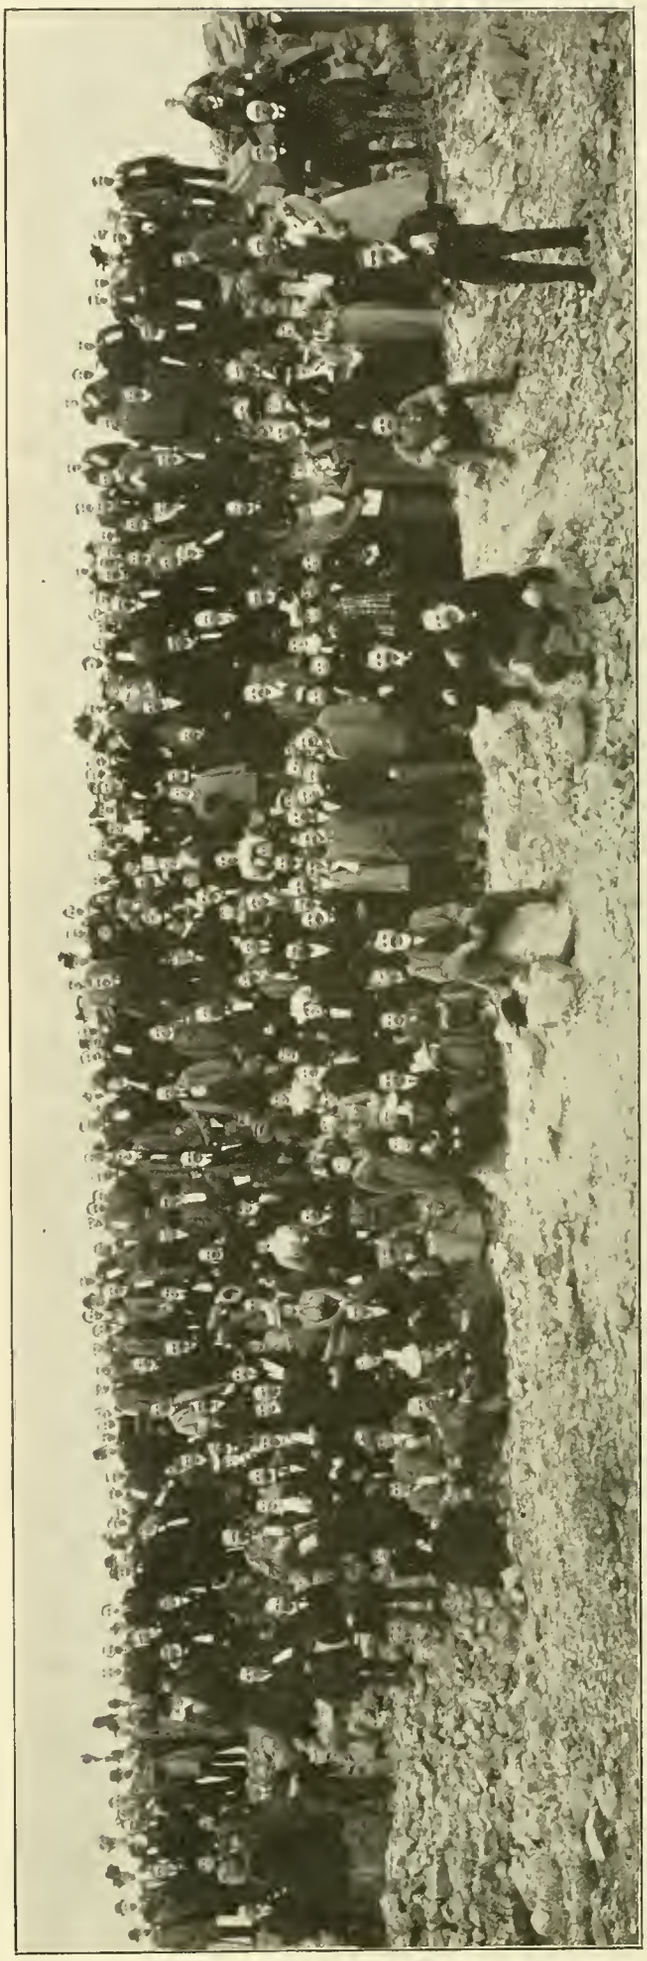
Mr. Dimmock: Have you not a law that covers the rear platform of the car when you run single cars, in regard to passengers crowding that platform so as to make it inconvenient for other passengers to get on the car?

Mr. Vreeland: There is no regulation, either municipal or state, on that question. We have, as probably you all know, the double doors in New York City, which open practically the full width of the rear platform and we insist that our conductors shall not allow a passenger to stand on the side of the door of which passengers are getting on, but that is not carried out very carefully. The Railroad Commissioners with their inspectors came down last winter and looked the situation over thoroughly with reference to our Fourth and Madison Ave. line, and they said after their inspection, "We have nothing to recommend. We do not see what you can do unless we say that the people shall not ride. You are running just as many cars as you can run. You are running them at these rush hours with frequency and dispatch, and doing everything you can to handle the traffic, and now we have to place ourselves in a position to say not what you shall do, but to say what the public shall do." And they, like good men, did not care in their own interests, to tell the public what to do. (Laughter.)

The President: Gentlemen, this is our last meeting for business, and yet it is not. The committee this year decided that it would be an interesting feature of the banquet to have the new officers installed and take charge after the speeches at the banquet. Therefore, when we now adjourn we shall not adjourn till next year, but to be called to order again after the literary exercises at the banquet.

Mr. Vreeland: I would like to say one word, Mr. President, before you adjourn. I regret very much that my engagements will compel me to return to New York this afternoon, and I wish to say that this is the first opportunity I have had since I have been connected with the street railway interests, to take any part in the convention proceedings. It has been exceedingly enjoyable and I have made a great many friends here, I think, from the expressions I have heard. I certainly have been very much benefitted by these proceedings, and I feel that even if it is a long way from New York to Kansas City, if I am in this country next fall, I shall certainly call on our new president, or our next president, Mr. Holmes, as the result of my visit here. (Applause.)

The convention then adjourned until the banquet.



A. S. R. A. AND GUESTS AT THE DRAINAGE CANAL.

THE ACCOUNTANTS' CONVENTION.

Enthusiasm and Hard Work Again Characterize the Meetings of the Accountants' Association Large Number of Delegates Present Department of Blanks and Forms Standardization Committe's Report Paper on Car Mileage.

In accordance with its by-laws, the third annual convention of the Street Railway Accountants' Association of America was held at the same time and place as the meeting of the American Street Railway Association. The sessions were held in a large room on the second floor of Tattersalls, and in a room adjoining was exhibited the complete collection of blanks and forms which now makes an important feature of the Accountants' conventions. All of the meetings were largely attended, the numbers and enthusiasm of the members testifying to the healthy and vigorous condition of the Association, while it is a noteworthy fact that the attendance at the last session was larger than at the first, a very unusual thing for conventions of this nature. This sustained interest is due largely to the happy way in which President Calderwood succeeded in getting expressions on the vital questions before the meetings, from representatives of all classes of roads, both large and small, and from delegates whose experience made their opinions of inestimable value. A large measure of the credit for the unbounded success of the convention should also, of course, go to the Association's secretary and treasurer, Mr. W. B. Brockway, whose capacity for work seems to be unlimited. As one delegate expressed it, Mr. Brockway was everywhere.

The roll of honor would not be complete without the name of Mr. C. N. Duffy, of Chicago, the new president. Mr. Duffy gave, practically, all his time for the entire week to the convention, and if there was anything to be done to add to the comfort of the delegates or the value of the meetings, he was on hand to do it. But it is impossible to mention all to whom credit is due, for that would necessitate the printing of nearly the entire list of delegates in attendance. The Chicago convention was a complete success because every member present put his shoulder to the wheel and did his part.

C. N. DUFFY,
President 1899-1900.

The exhibit of blanks and forms and Mr. Brockway's accompanying report on this department were alone worth more than the amount of the annual dues and the expenses of a trip to Chicago. This collection is the outcome of a demand by the member companies for an opportunity to exchange ideas on this important subject and as already announced is a permanent department of the association. It forms a most valuable store house for suggestions, which will be open at all times to members.

Reports were presented at the meeting, by C. N. Duffy, chairman of the committee on "A Standard Classification of Accounts"; by W. B. Brockway, on the "Department of Blanks and Forms," and a paper was read by H. C. Mackay, comptroller Milwaukee Electric Railway & Light Co., on "Car Mileage." No sessions of the Association were held in the afternoons and the delegates were thereby enabled to enjoy the many pleasant excursions provided by the Entertainment Committee of the American Street Railway Association for the visitors to the Convention.

The absence of two of the Association's best friends and hardest workers, Mr. H. J. Davies, of Cleveland, and Mr. W. F. Ham, of Brooklyn, was keenly felt by all. Both of these gentlemen were unavoidably detained and sent sincere regrets.

Tuesday, October 17th.

The convention was called to order by President Calderwood at Tattersalls, Chicago, Oct. 17, 1899, at 11:30 a. m., and the president then introduced Mr. L. E. McGann, commissioner of public works, who represented the city. Mr. McGann said:

Mr. President, and gentlemen of the Street Railway Accountants Association of America: Carter H. Harrison, mayor of Chicago, has requested me to attend your meeting and present his compliments and to extend to you a welcome in his name to the city of Chicago. He is deeply interested in this branch of street railway service, and begs to assure you, notwithstanding the impression that may have gone abroad in certain sections that there is a prejudice against the street railway men or persons engaged in that business in Chicago, that such is not the case, and that during your brief stay here, while we are not prepared to decorate you with buttons that will give you a free pass to all the good things in the city of Chicago, we can assure you that nothing but real true, gold bricks are sold in Chicago at the present time, and should you attempt to invest in one you will be sure of getting the genuine article. Seriously, and for myself, I will say that I am deeply interested in the line of work that your Association is developing, each individual having his own line of training, acquiring his views as to how accounts should be kept, how affairs should be directed, and having had myself somewhat to do with the street railway business and with the larger affairs of the municipality, I can appreciate probably more fully than many persons who have not had dealings in both matters, the importance of a classification of accounts, whether it be railway work, or whether it be the conduct of a great municipality or the conduct of states. The classification of work, putting under such uniform indexes as will simplify the work itself and convey a knowledge as to the particular class under which work is being performed, will make work much easier, and more comprehensive to the persons who are responsible for its conduct. Those of us who are not now interested in street railway business are certainly interested in the principles underlying the work that this Association is now doing; so that in addition to conveying to you the welcome extended by the mayor, I, for myself, wish to assure you of my interest in your work and to hope that you will have a most successful convention and that your work itself will be most successful.

As to your entertainment during the period of your stay in Chicago, it goes without saying that with this Association in the hands or under the guidance of committees formed in this city by Mr. McCulloch, Mr. Roach, Mr. Greene, Mr. Yuille and the other gentlemen who are in the street railway business in this city, there are none of the good things in the city that can escape the observation of you gentlemen while you are in the city. I hope every gentleman present, and every gentleman visiting the city from the American Street Railway Association, will avail himself of the opportunity while in the city of visiting the City Hall and inquiring into the methods of doing business and also into the methods of granting railway franchises. The question appears to be as great a one as that of accounts, and much prejudice exists concerning it that can be cleared up by a few careful inquiries while in the city. On the equities of the proposition as between the municipality and the companies, there can scarcely be a division of opinion throughout the world as to what they should be. Without attempting to discuss the question, I simply suggest that while here—and so that we may not suffer from the prejudice that generally attends a discussion far away from home, that the question will receive some consideration at your hands, because, after all, the accountant must in the end present to his manager and to the president of the company, the question as to whether the payments of the corporation to the municipality for the privilege of operating are sufficient or not.

In conclusion, gentlemen, I hope that you will be most successful in your deliberations, and that the work of your Association will be more far reaching than the street railway business, that it will extend to the conduct of public as well as private corporations. (Great applause.)

The President: Mr. McGann, on behalf of the city of Chicago, and gentlemen: I wish first to acknowledge to this Association

and the members present my great appreciation of the honor which they conferred upon me by making it possible for me today to acknowledge with pleasant anticipation the welcome and the good time that we shall have in Chicago enjoying the rare hospitality of this city. I speak as one, probably, who might be considered as living in the suburbs of the city of Chicago, in the state of Minnesota. In speaking of Chicago I am always reminded of that little girl, who on the eve of her family moving to Chicago said in her prayer: "Good-bye, O God, I am going to move to Chicago."

Here on Michigan's shores from age to age,
May Chicago lift her spires,
And gem with stars her history's page,
By the light of her hearthstones' fires.

PRESIDENT'S ADDRESS.

Gentlemen of the Association: "Know thyself," that simple injunction carved over the entrance to a temple of ancient Greece—so old that no one knows who wrote it—is a motto which has impressed me as ideally appropriate for this organization, the newest branch of a business which is at once the effect and the cause in what might be called the latest phase of modern civilization—Rapid Transit.

The executive head of one of the larger street railway systems of America said recently that the industry had not developed beyond 20 per cent of what might reasonably be expected as the ultimate future of street railway business in America; in other words, that there still remains four times as much to do as has been accomplished in the perfection of the art of carrying the public. If this be true, no small part of the future development must be due to the work of the men who, by analysis of accounts, establish the data for future advancement. Managers are continually balked by new problems. And while the operating department is usually able to answer satisfactorily the question: Can this or that be done? it is for the accountant to go further and ascertain what can and what cannot be done profitably; for, in the end, the wisdom of every policy must pass the ordeal of ultimate cost.

Andrew Carnegie, the captain-general of the iron and steel industry, paid this tribute to the calling here represented: "There is not a science or class of men on whom the business of the world is more dependent than the science of accounts and accounting." It is an axiom of modern business on which its success depends. I will go further and say upon which its very life depends, that of having within it a well devised system of accounting which will show at all times (with the least labor and the greatest accuracy) its true condition. In the idiom of the street, show me the management of any company, mercantile, manufacturing or transportation, that does not recognize this principle and act upon it and time will show you its "finish."

More, perhaps, than any other, does the street railway business depend upon and involve diverse and extraneous conditions, rendering it doubly necessary that a successful management, in order to secure the greatest revenue with a minimum of expense, should be prepared for prompt action and unerring judgment by careful analysis and minute comparison of the various items of revenue and expense through its accounting department. Pursuant to a general desire on the part of those who had struggled single-handed and alone through the maze of unsystematic street car bookkeeping in a desperate effort to supply these much needed data, a few accountants met in Cleveland, Mar. 24, 1897, for the purpose of promoting an organization which would bring together, for exchange of ideas, those engaged in the accounting departments of street railways.

Many of you will remember that paper, fruitful of discussion, read by Mr. C. N. Duffy, upon the Standardization of Street Railway Accounts, which, by common consent, became the chief subject of discussion at that meeting, as it has been ever since the foundation of the chief work of this Association.

For the purpose of preserving the continuity of the developments I will remind you briefly of the appointment of a committee upon this subject consisting of Mr. Duffy, chairman, Mr. W. F. Ham, of Brooklyn, and myself, which reported at the convention held at Niagara Falls in October, 1897. The report of the committee was approved, but the question arose as to the probable action of the Railroad Commissioners of the various states, since these commissioners in many states, prescribe what system of classification shall be used by the street railway companies reporting to them. As a result of the debate it was decided to continue the committee permanently, its membership being increased by the addition of Mr. H. L. Wilson, of Boston, and Mr. H. J. Davies, of Cleveland. The permanent committee endeavored during the following year to have meet with it the Railroad Commissioners of the states which exercise any control over the accounts of street railways, but arrangements could not be made previous to the convention which met in Boston. A full and complete report covering the matter of uniform accounting was presented at the Boston convention by the committee and adopted, notwithstanding their inability on account of lack of time to secure the approval of the Railroad Commissioners.

You will have presented to you, at this meeting, a full report from the committee covering its conference with representatives of the state Railroad Commissioners, and also of the American Railway Accountants' Association. At this conference Mr. Duffy and Mr. Ham acted for our committee.

I take pride in calling your attention to the recognition there accorded the action of our Association in the adoption by the conference of the entire system of classification (with a very few minor changes) as prepared and promulgated by our organization.

This tribute to our committee is admirably expressed in the language of Mr. William O. Seymour, chairman of the committee which reported to the Railroad Commissioners at their meeting at Denver, August 10th, last. Mr. Seymour, in his report, said:

"It was found that the form prepared by the street railway accountants was so much more advanced in its preparation, so complete and full in its details, and so well adapted for its purpose, owing to the familiarity of those who prepared it with street railway accounting, that we deemed it wise to abandon the work which we had commenced, and advise the endorsement and adoption of the form prepared by them."

The recommendation of their committee was adopted by the Convention of Railroad Commissioners, and we have every reason to believe that the same action will be taken by the American Railway Accountants' Association, since its representatives at the conference concurred in the action then and there taken. We have thus established, through our committee, a recognized standard classification of the various items which enter into the three chief elements of street railway accounting, namely: the revenue, the cost of operation, and the cost of construction.

This important feature is now substantially fixed, subject of course, to slight modifications from time to time as new and varying conditions make it necessary to slightly modify the present established classification, and to that end I would recommend the continuance of this permanent committee on the Standard System of Classification.

While our Association has accomplished much by the practical establishment of a permanent classification of accounts, we are far from having concluded the work necessary for a complete system of accounting, such as would be available for purposes of comparison. What we now need and must have before we shall have fulfilled our mission, is the establishment of a unit of comparison. We may have properly classified the cost of maintenance of way, transportation and general expense, and severally and collectively determined the amounts of each for a certain period as compared with another similar period; the comparison of the totals of one period with another may be in the aggregate more or less. This means nothing in itself, unless we can reduce these several sums to a unit of comparison. Now, whether this unit shall be the ratio which each item of expense shall bear to the total revenue, or whether it shall be so much per car-mile, per motor-mile, per motor-hour or ton-mile, is the next great and important question for the Association to consider and to settle. To Mr. H. C. Mackay has been assigned a paper bearing upon this subject, which will be read at this convention, and we trust he will suggest a solution of this most perplexing proposition. I would recommend the appointment of a committee on the Establishment of a Unit of Comparison. When this is done I shall feel that we are nearing our goal. With the classification and the unit established, the next important feature is a statement blank that will enable the accountants to present, in a uniform, simple and concise manner, the various results and comparisons.

We have established a Department of Blanks and Forms, and to our energetic and persevering secretary, Mr. W. B. Brockway, the Association is indebted for a remarkable exhibit of the blanks

and forms of various street railway companies. These he has arranged and will present with his report, the first important feature, as well as one of the most interesting on the program for Thursday's session.

I cannot conclude this task without yielding to a duty which I feel to be incumbent upon me at this time. I desire to remind the members of this Association that the enthusiastic accountant, charmed with the possibilities for analysis and classification which lie within apparently meaningless statistics, is frequently tempted to indulge in hobbies, which, while pretty enough from the accountant's standpoint, and frequently necessary in part, are worse than useless so far as giving practical information to the management. The ideal accountant wastes no energy upon unnecessary labor. His aim should be to prepare and present to the management only such salient facts as will enable the man in command to make instant comparison upon the three fundamental elements of street railway operation, namely: the revenue, the labor cost and the material cost; all else is subsidiary.

The revenue statement should show, by hours or otherwise, the number of passengers carried, so that the management may be enabled to secure the largest revenue with the least expenditure.

The labor statement should show, in a systematic and comparative manner, the number of men employed and the amount of wages paid in each department, that the management may compare with corresponding periods, and be able to control labor expenditure and keep within a fixed ratio.

The material statement, by showing the kinds, quantity and cost of materials bought and the consumption of the same, enables the management at all times to regulate the stock of material on hand.

I shall be pleased if what I have just said, fragmentary and brief as it must needs be in an address of this character, will create a discussion; if not at this meeting, at some subsequent meeting of our Association. I believe we get more out of the "experience-meeting" feature of our gatherings than from the set papers, valuable as they are.

In ending my term as president, I wish to express my especial appreciation of the good work of Mr. C. N. Duffy, that perfect type of an aggressive, progressive and intelligent all-around master of accounting and business man, who laid at Cleveland the corner stone of this structure, and to his worthy associate, Mr. W. F. Ham. To these two gentlemen this Association is indebted for the larger part of the great work which it has accomplished since its birth, and I hope that this Association has only begun in a field of usefulness which broadens as we advance. Purely practical and limited in scope though it be, it has afforded us a vehicle for good fellowship which I have enjoyed quite as much as the professional stimulus and suggestion. I look forward to future meetings with pleasure, and I thank you all for uniform courtesy extended to me since I have had the honor to preside over your deliberations.

Mr. Wilson then presented the annual report of the executive committee, which was adopted. It was as follows:

During the year the executive committee has held three meetings and has had five mail votes, admitting 34 companies. As was noted in the call for this meeting, the executive committee now recommends that the section of the by-laws referring to the annual dues be so changed that they provide for an annual assessment of $20 in place of the present dues of $10. We also recommend that this Association consider the advisability of holding its annual meeting at a time other than the time chosen by the American Street Railway Association. The books of the treasurer have been audited and found correct.

The report of the secretary and treasurer was then read as follows:

SECRETARY'S REPORT.

The past year has been an exceptionally busy one in the secretary's office, not alone in the regular work falling to such an office, but in the preparation of the Department of Blanks and Forms, which is explained in the report of that department, to be made Thursday.

Thirty-four companies have been admitted to membership since the last meeting, as follows:

Tiffin, Fostoria & Eastern Railway Co., Tiffin, O.
Omaha Street Railway Co., Omaha, Neb.
Stamford Street Railway Co., Stamford, Conn.
Cleveland City Railway Co., Cleveland, O.
Citizens Rapid Transit Co., Nashville, Tenn.
Ottawa Electric Ry., Ottawa, Ont.
City Electric Ry., Port Huron, Mich.
Fair Haven & Westville Railroad Co. New Haven, Conn.
Milwaukee, Racine & Kenosha Electric Railway Co., Racine, Wis.
North Hudson County R. R., Hoboken, N. J.
Metropolitan Street Railway Co., New York, N. Y.
Norfolk Street Railway Co., Norfolk, Va.
Tri City Railway Co., Davenport, Ia.
Metropolitan Street Railway Co., Kansas City, Mo.
Syracuse Rapid Transit Co., Syracuse, N. Y.
Quebec, Montmorenci & Charlevoix Ry., Quebec, Canada.
Union Traction Co., Philadelphia, Pa.
Vicksburg Railroad, Power & Manufacturing Co., Vicksburg, Miss.
North Chicago Street Railroad Co., Chicago, Ill.
Savannah, Thunderbolt & Isle of Hope Ry., Savannah, Ga.
San Diego Electric Railway Co., San Diego, Cal.
Duluth Street Railway Co., Duluth, Minn.
Glasgow Corporation Tramways, Glasgow, Scotland.
Calumet Electric Street Ry., Chicago, Ill.
Brightwood R. R., Washington, D. C.
Mobile Light & Railway Co., Mobile, Ala.
Butte Consolidated Street Ry., Butte, Mont.
Schenectady Railway Co., Schenectady, N. Y.
Central London Ry., London, England.
Third Avenue Railroad Co., New York, N. Y.
The American Railway Co., Philadelphia, Pa.
Alton Railway, Gas & Electric Co., Alton, Ill.
Kansas City & Leavenworth Railway Co., Leavenworth, Kan.
Albany Ry., Albany, N. Y.

And but two have resigned:

The Birmingham Railway & Electric Co., Birmingham, Ala.
The Manchester Street Railway Co., Manchester, N. H.

A statement of the growth of the Association is as follows:

Companies forming the Association at Cleveland, March, 1897	25
New members reported at Niagara Falls, October, 1897	12
New members reported at Boston, September, 1898	32
New members reported at Chicago, October, 1899	34
Total	103
Withdrawn	3
Total members to be reported October, 1899	109

But a new problem of consolidation is confronting us, a problem which is having a tremendous effect upon the whole street railway world, and I would commend to your earnest consideration the suggestions made in the report of your executive committee.

The statement of finances is:

Balance from Sept. 9, 1899	$ 51 84	
Received from application for membership	340 00	
Received from 1899 dues	730 00	
Received from 1898 dues	60 00	
Received from bills payable	225 00	
Received from interest and miscellaneous	4 18	
		$1,411 02
Expended for salary of the secretary	$200 00	
Expenses of the secretary's office	83 24	
Printing circulars and stationery	90 65	
Postage for reports, circulars, etc	79 03	
Executive committee meetings	46 05	
Stenographer for Boston meetings	105 00	
Printing report of the Boston meeting	224 67	
Printing 1898 report of the Standardization Committee	74 49	
Expenses of the Standardization Committee, 1898	68 50	
Secretary's traveling expenses	156 00	
Department of Blanks and Forms	157 21	
Bills payable	100 00	
Cash in Home Savings Bank, Toledo, O.	19 28	
		$1,411 02

Bills payable		$125 00
Cash in bank	$19 28	
Unpaid dues	30 00	49 28
Deficit		$ 75 72

Thus I cannot report the Association as having been a dividend payer, but I am sure the results of the work of the committee on a Standard System of Accounts and the Department of Blanks and Forms, which now has something tangible to offer, will well repay any reasonable stringency which we may encounter. The circulars sent out from the secretary's office to explain the benefits of membership have all resulted in the increase of applications. We seem to have almost accomplished most of the expensive work made necessary by the creation of the Departments of Standardization and Blanks and eventually we will sail on the smoother waters of "well-to-do."

It is again my bounden duty to express my doubly grateful thanks to all who have in so many ways assisted in the performances of the work of the Association. It has all been so cheerful that the thanks are the more heartfelt and in all sincerity I say, thank you. Respectfully,

W. B. Brockway,
Secretary and Treasurer.

Toledo, O., Oct. 14, 1899.

On motion of Mr. Hibbs the report was adopted as read.

The President: There are two very important features in the report of the executive committee, which we had probably better take up and discuss now. One is the question of revenue, which is a very important matter with this Association, in view of the fact that so many of the companies are consolidating and our list is limited; and the second is the question of holding our meetings simultaneously with those of the American Street Railway Association. There are a number of the larger street railway companies that are not members of this Association, and I think it is due in part, probably, to the fact that they have not been canvassed either personally or by letter sufficiently, and I would suggest that the secretary read a list of those companies that we would like to see members of this Association, and let each man make himself a member of a committee to see those people. I know one, the Buffalo Street Railway Co. We have never been able to get them to join, although Mr. La Pierre was seemingly very much interested in our Association when we met at Niagara Falls. Now, I understand they have a change in management and Mr. W. Caryl Ely is head of the consolidation. I understand he is here and I would be glad if some one would interview him.

I should like to hear from Mr. Duffy on the question of raising the dues.

Mr. C. N. Duffy: I do not know that I can throw very much light on the subject, but from the reading of the report and noting the condition of this Association financially, I think it is very evident that we need a larger revenue, and I do not see how we can reduce expenses. This Association is conducted on a very economical basis and the minimum limit of expenditure has been very nearly reached, taking into consideration the work that there is to be done. Now, the large items of expenditure are the publication of these books, the annual report and the classification books; for instance the books that we had published here in Chicago, which were distributed to you, embodying the report of the committee on a standard system of accounts, will cost in the neighborhood of $125. We have 500 of them, and hope that we will not have any more expenses of that character.

The president spoke about consolidation. As an illustration of that I would like to refer to St. Louis. We had seven members from St. Louis, which meant $70 a year. If we retained the united company down there it means $10 a year. There is a difference of $60 a year in one city, and every large city in the United States is rapidly reaching that same condition. Now, the dues of the American Street Railway Association are $25, and it seems to me that any company that is a member of the Street Railway Accountants' Association can well afford to pay $20 a year if it can afford to pay $10. I do not believe that the question of $10 or $20 would enter into the proposition at all. If a company wanted to be a member of this Association, I believe it would not stand on the difference between $10 and $20. Now, we have 100 or 102 members. We do not know next year whether we shall have 50 or whether we shall have 75, and according to that statement, as read by Mr. Brockway, we must look forward to at least $1,000 as revenue. With 100 members at $10 each we would only get $1,000. If we should lose any one of those members we would not have enough for our expenses next year. Another thing that is somewhat embarrassing to this Association is that under our by-laws the dues are due and payable on and after January 1st, whereas all these expenses are incurred prior to January 1st, and somebody has to carry this Association until January 1st.

It is my judgment that any company which is a member of this Association can well afford to pay $20 a year, and that it will certainly get value received for its money. I do not believe we will decrease our membership by an increase of dues, and I certainly think the executive committee has done wisely in recommending $20 a year dues instead of $10, and I hope that it will pass.

Mr. F. E. Smith: The matter was pretty full discussed in the executive committee meeting, and we decided there it was a great deal better to make the raise now than it was to get behind, and I think we had better do it. I think we can just as well get $20 as we can $15. The chances are that with all these consolidations we are going to lose some of the membership, and I do not believe that we can run on less than $20 dues. I hope that the resolution will pass.

Mr. Wilson: I hope sincerely that this motion will prevail. I think Mr. Duffy has expressed all that need be said on the subject, with perhaps the exception that he hesitated to say that the committee on standardization of accounts has been put to considerable expense, more particularly Mr. Ehrhard himself, which the members very generously paid out of their own pockets—expenses of travel and hotel bills and so forth.

Mr. Ehrhard: I cannot say much in addition to what has been said. Under the condition of things, I think it is perfectly proper to take some action on that line. If the majority thinks $20, that will be all right; if they think $15 would be enough, make it $15. Evidently we have got to raise something. I cannot enlarge on what they have said.

Mr. Durbin: If it is a question of raising the dues to $20 or even more, I think it should be done to carry on the work of the Association. I am sure our company won't withdraw if they raise to $25.

Mr. H. C. Mackay: I think the question has been pretty well discussed already. It is necessary to increase the dues to carry on the work of the Association, and a matter of $15 would be very little increase.

The Secretary: There was a question in the executive committee last night as to whether the increase of dues would affect small roads to such an extent that they could not afford it. Is there any real small company here?

Mr. Simpson, Augusta, Ga.: I represent one of the smallest companies in the United States, as far as street railways are concerned, but we are ready to pay the present dues and double it if necessary. But it looks to me, in regard to getting around and getting the larger companies interested, that we should also look to the smaller companies. It is the number as well as the size and the capital represented, I think, that make up the Association.

The question was then called for and put, and it was voted unanimously to increase the dues of the Association to $20, beginning Jan. 1, 1900.

The President: The next question, a very important one, is that of holding our meeting at the same time and place as the American Street Railway Association. I should like to hear from Mr. White, of Toledo, on that point.

Mr. Elmer M. White: It has been my opinion from the day we started that that was the only true way. Here is proof that it is the only true way. There are so many arguments for it that it is useless to try and say anything about it. I do not know where we can find one argument against it.

The President: I think there will be no question we could hold our convention at the same time as the American Railway Accountants' Association, which would be a good thing. A good many of us are working toward the steam railway business in connection with the interurban traffic. I should like to hear from Mr. Hibbs.

Mr. E. D. Hibbs: Mr. President, if I recollect right, at the original meeting of this Association, this matter was very thoroughly

discussed, and the only advantage claimed for having meetings at the same time was that we got the support of the other Association financially. On the other hand, there is a tendency for the entertainments, which are a feature of the other Association's meeting to direct our attention from the business on hand.

Mr. Burington: I have not given the subject very much thought since our meeting at Cleveland. I was then in favor of meeting separately, but since then I have changed my mind in several ways. By meeting by ourselves we would not get the reduced rates over the railroads, and that always is an item to our companies in the matter of expenses. I doubt if with the consolidations that are going on and likely to go on in the near future whether we shall be able to retain a membership of 100, which is required in order to get reduced rates. We might do better work probably by ourselves, and it is possible we might get a better attendance, from the fact that the smaller roads cannot excuse too many officers at one time. There is that much in favor of our meeting separately. It would be easier for us to get away, perhaps, but when it comes down to the privileges that we enjoy in meeting together at the same time and place as the Street Railway Association, it almost overbalances all the other considerations. Do we not get a little additional standing by meeting in connection with the Street Railway convention? It gives us a dignity that we might not have otherwise? That is one thing, I think, that should be considered very fully. I am a little at a loss to make up my mind. There are so many arguments in both directions that it is really a difficult question to settle. Possibly if it comes to a vote I may be obliged to vote for meeting at the same time and place as the other Association.

The President: I should like to hear from Mr. Lawton. Mr. Lawton is from Colorado Springs and comes a good way to be with us.

Mr. A. L. Lawton: I think that these Associations should hold their meetings at different times. Since listening to the discussion of this subject, it has occurred to me that either two days before or immediately following the Street Railway convention would be a good time to hold it, and at the same place that the American Street Railway Association meets. I traveled a long way last year to go to the convention, and I found as much interest in the American Street Railway Accountants' Association as any feature in connection with the meeting. I would like very much to have got some pointers this morning in the way of conducting street railways and managing their affairs, so as to enable a road which, perhaps, is not paying as well as some of the larger roads to buy some new equipment. I would like very much to have listened to the address of the president of the American Street Railway Association this morning. For that reason it occurs to me it would be better if the meetings were held at different dates. They are so closely associated together it seems to me it would be too bad, particularly for small roads and those who come from a great distance, to separate them entirely. I am very much interested in both associations.

Mr. C. L. Wight, Toledo: Would it be possible to join with the American Railway Accountants' Association?

The President: I don't think there would be any objection to it. They are all very much interested in it.

Mr. Wight: Could not we get the reduced rates if we went with them?

The President: They go free.

Mr. Wight: That is all right. I move that we go with them. When do they have their meeting?

The President: In May.

Mr. Wight: We would be ready by May.

The President: Well, gentlemen, this is a very important question, and I am going to defer the vote on it till tomorrow morning. In the meantime I would like everybody to give it careful consideration. Now, tomorrow morning's program is a very interesting one. The first is the report of the permanent committee on the standard classification of accounts, by Mr. C. N. Duffy, auditor of the Chicago City Railway Co.; the second is a paper by Mr. H. C. Mackay, comptroller of the Milwaukee Electric Railway & Light Co. on "Car Mileage," the question of determining what shall be the unit of comparison. Mr. Mackay has given this matter a great deal of thought and consideration. He has been in correspondence with a great many street railway companies throughout the country, something over 100, and I think he is prepared to give us some light on this subject. I know he is well prepared for arguments from different sources, and I would like to see a very full attendance tomorrow when this paper comes up, because I consider this the next very important feature in connection with our accounting, the question of determining a unit and what that unit shall be. That concludes everything for the morning, except the appointment of committees. There is the committee on nominations and the committee on resolutions. As the committee on nominations I will appoint Messrs. F. E. Smith (chairman), E. D. Hibbard, C. L. Wight, Palmer M. White; as the committee on resolutions, Messrs. Burington, Simpson and C. K. Durbin. I understand that Mr. Yerkes is now reading his paper before the American Street Railway Association, and I presume a good many gentlemen present would like to see Mr. Yerkes and hear a portion of his address, and we will adjourn now until tomorrow morning at 10 o'clock. I would like to have every one here at 10 o'clock promptly, as we have a very important day.

The convention then adjourned until 10 a. m. the following day.

Wednesday, October 18th.

The meeting was called to order by the president at 10 a. m. After the minutes of last year's meeting had been formally approved the following paper was read:

CAR MILEAGE.

By H. C. Mackay, Comptroller and Auditor, Milwaukee Electric Railway & Light Co., Milwaukee, Wis.

One of the greatest problems affecting the street railway interests is that of securing an equitable and standard unit, and the subject assigned will be treated in its general relation to accounting as such.

Car mileage has been adopted by practically every road in the country as the basis of comparison, but a study of the methods used in computing the mileage made by the different systems will convince any one that under the present conditions it is misleading and unreliable. It makes but little difference what is used as a basis, as long as its purpose is simply to show if the earnings or expenses are proportionately above or below that of a similar period; but to make a comparison with another system, on which the speed, length of day operated, size of cars, etc., are different, or where the physical conditions are dissimilar it is absolutely necessary that the units be identical.

It is not practical to make general comparisons of any given expense item as to the amount in dollars and cents for the reason that there are so many factors to be considered which have a direct bearing on the cost; hence, it is necessary to reduce the items to the same basis for all systems. When this has been accomplished, the result of the operations of the various systems will establish an average for each division or item of expense, which will be an accurate guide to the manager, an indicator showing all expense items in which reductions should be made. Here is where the greatest value in a standard unit lies; the cause of an abnormal expense is at once detected and the energies otherwise wasted in an endeavor to locate the trouble can be applied in the correction of it.

The principal objection to "car mileage" is the variation in speed. Between city and suburban lines there is a difference in speed of from eight to thirty or even more miles per hour. The increase in speed does not materially affect the cost of operation. The liability of accidents due to increased speed being more than offset by the difference in density of population of district traversed, while the principal items of expense, such as "wages of conductors, motormen, car house employes, etc.," are the same in either case; hence the suburban or interurban line would show from two to four times the number of miles run, at only a slightly increased cost as compared with a city system. The question may be asked why the interurban line should not be entitled to the credit of operating at a less cost (as the object of a standard unit is not to make expenses uniform, but to show the actual conditions). I shall answer this by saying that while the cost "per car-mile" would be less, on the basis of "passengers carried" it would be more, by reason of the longer haul, thus indicating that its expenses are not proportionately less except upon a basis favorable to itself.

Another disturbing element is the "trailer." Where trailers are

Harry C. Mackay was born in La Salle, La Salle County, Illinois, Oct. 6, 1869. In 1886 he accepted a position with the Minneapolis, Lyndale & Minnetonka Railway Co., and at the age of 18 was made paymaster, remaining in that capacity until the road was leased by the Minneapolis Street Railway Co., his services being retained by this company as bookkeeper. In 1891 the Twin City Rapid Transit Co. acquired and operated the street railway systems of Minneapolis and St. Paul and with this company he filled the positions of paymaster, head bookkeeper, chief clerk and assitant auditor, resigning in 1897 to accept his present position, that of comptroller and auditor of the Milwaukee Electric Railway & Light Co.

H. C. MACKAY.

regularly used and to any considerable extent, they are considered as separate cars, mileage being computed for both motor and trailer in nearly every case. Theoretically, a system whose equipment is exactly adapted to its needs, would assign to runs, cars of just sufficient capacity; the trailers being abandoned and in the place of say a 22-ft. motor car and an 18-ft. trailer, a 40-ft. motor car would be run, thus eliminating the expense of one conductor, as well as the extra maintenance charges.

New cars are rarely purchased for use as trailers on electric systems, those in use as such being either relics of horse car days or an indication of an extraordinary growth of the city, and consequently of the system; the trailer is an indication that the capacity of the car is not equal to its requirements while it is still in good condition and too valuable to be consigned to the scrap pile or even to be sold at forced sale, so its motors are placed under a longer car body, and it is transformed into a trailer, to be brought out and used as an attachment or extension whenever the motor car's capacity is liable to be overtaxed.

Surely no one will contend that it is cheaper to operate a motor and trailer whose combined length is 40 ft., than to operate a motor car of the same length. If so, the same rule must apply to a 24-ft. car, and we would be substituting a 12-ft. motor car and 12-ft. trailer in its stead. Yet the method of computing both motor and trailer mileage attempts to show just this result. To better illustrate, we will take two roads, one using 40-ft. motor cars, the other a motor and trailer, whose combined length is 40 ft. They are operated at same speed, headway, etc., yet the first shows a cost of say 12 cents per car-mile, the other, by reason of the double mileage, a little more than one-half of 12 cents, though with the additional expense of an extra conductor. My contention is, that a road using trailers is naturally handicapped and should not be expected to produce as good results as one whose equipment is nearer adapted to its needs, and that the trailer is but an extension of the motor car and the extra expense of running it should show as the result of unfavorable conditions.

To secure data, the writer sent to most of the railways of the United States and Canada, a circular letter, requesting answers to a number of questions, with the results as follows:

1. Is your mileage computed from conductor's trip reports? If not, how? Answers were received from 103 roads, and were as follows:

Conductors' or motormen's reports	73
Foremen, dispatcher or switchmen's reports	15
Time tables	4
Unanswered	11

From this we see that over 70 per cent of the total number and a still greater per cent of the answered reports arrive at mileage from the trainmen's reports. Some new companies have adopted a system whereby the conductor reports his route run by numbered points, each switch, crossover, etc., being given a number, permitting the accounting department to accurately trace the car. It, however, requires a careful examination of each trip sheet, which on a large system means the expenditure of considerable time. I would suggest that the trainmen be required to report only the exceptions to their regular trips; that is, either lost trips or extras made; thus, instead of going over all the trips made during the day, only the deviations from the regular schedule would be examined and computed, and this result added to or subtracted from the regular schedule. The method adopted would depend upon an answer to the following question:

2. Do you keep record of mileage made by each car?

Affirmative	51
Negative	46
Unanswered	6
Of the 51 roads that keep such records	
26 are in cities of less than	50,000
10 are in cities of 50,000 to	100,000
15 are in larger cities.	

Neither of these two questions have any bearing on "car mileage" as a unit, except so far as accuracy is concerned. A great many data are usually prepared by the accounting department, to which reference is seldom made. Mileage by cars is valuable and necessary to determine the life of wheels, gears, pinions, etc., but these tests are rather rarely made and special records can be kept in such cases at a less expenditure of time and money.

3. What method have you of verifying the figures on mileage? The answers were:

None but care in computing	45
Time tables	28
Dispatchers' reports	8
Pay rolls	4
Foremen's reports	4
Motormen's reports	3
Trip receipt returns	1
Unanswered	10

It would seem that the simplest method of verifying the results would be by a report from the foremen showing deviations from regular schedule and have this result checked by the trainmen's reports.

4. Do you include dead mileage, i. e., from the car station to the point where the car strikes the regular route?

Negative	50
Affirmative	36
Have none	11
Unanswered	6

The reason assigned why dead mileage should not be included is that the car is not earning revenue, and that it would be unjust to decrease its earnings per car-mile. Nevertheless, the mileage had to be run before it could earn revenue, the expenses were the same as when on regular service, and I consider it legitimate mileage. Thus the system whose stations are advantageously situated would receive whatever benefit there was due to that fact.

5. Do you include full trailer mileage? If not, what proportion, and give reasons why full mileage is not used?

Trailers not used	46
Affirmative (of which number only half use trailers regularly)	37
Negative	11
Unanswered	8
One-half	1

The roads using trailers regularly, as shown, are only about 20 per cent of the total. As stated before, the trailers should not be computed for general use.

6. Is any allowance made for partial trips lost?

Affirmative	57
Negative	37
Unanswered	9

This question is covered under No. 4. Allowance should be made for partial trips lost, or in other words, the mileage used should be the actual mileage made by motor cars.

7. What is your average motor mileage per day? Trailer?

8. What clerical help is required for mileage work and the approximate cost per month?

9. How long does it take to ascertain the total mileage for the day?

The object of the preceding questions was to determine the rela-

tive cost and adaptability of the method used; but owing to the different construction placed upon question No. 7 (answers covering average motor miles per day per motor and total miles per day), no conclusion can be drawn except that the speed varies so that the average motor miles per day per motor ranges from 65 to 300 miles.

10. Do you use "cars operated per day" as a basis for comparison of earnings? If so, what constitutes your car-day?

The answers were

Affirmative		44
Car-day of 20	hours	1
Car-day of 19	hours	1
Car-day of 18	hours	31
Car-day of 17½	hours	1
Car-day of 17	hours	3
Car-day of 16	hours	1
Car-day of 15	hours	4
Car-day of 115	miles	1
Car-day of 80	miles	1
Negative		48
Unanswered		11

Car-days, especially in the larger cities, are gradually lengthening and eventually will, no doubt, reach the maximum of 24 hours.

The adoption of the "passenger-mile" (being the passenger trip distances divided by the number of passengers carried) is precluded owing to the impracticability of obtaining the length of the separate passenger trips.

This applies to the "ton-mile" as well, if the element of "passenger weight" is taken into consideration. If the "ton-mileage" is based upon the dead load hauled, I do not consider it complete. In fact, the showing made on the basis of "ton-mile" would have a tendency to mislead the management. For example: One system operating "20 ton motor cars" with a corresponding large ton-mileage would show a small cost per ton-mile. Another system, operating "10 ton motor cars," would show nearly double the cost per ton-mile, when as a matter of fact the lighter car may be the more economical.

But with the mileage computed carefully, all dead miles included, and the elimination of the trailer, we have a unit which will be uniform and applicable to all electric systems as soon as the question of speed is adjusted; hence, we have but to divide the car-miles by the average rate of speed and this result, verified by the motormen's time, will be a standard unit. This is equivalent to a "motor car-hour."

To illustrate the method of ascertaining and verifying the "motor car-hours," at the same time showing the effect that speed has upon the car-mile as a unit, I submit the following exhibit:

Traffic Sheet.	City Line.	Interurban Line.
Cars operated	3	3
Speed per hour, miles	8	24
Length of trip, miles	24	24
Trips per day, regular	18	54
Extra trips	2	6
Trips lost	½	1½
Trips run	19½	58½
Miles per day	468	1404
Motor car-hours	58½	58½
PAY ROLLS—MOTORMEN'S TIME.		
Regular trips	18	54
Extra trips	1½	4½
Total trips	19½	58½
Motor car-hours	19½ x 3=58½	58½ x 1=58½

Assuming cost of operating these cars at $60 per day, the costs are:

Per car-mile	$ .1282	$ .0427
Per car-hour	1.0256	1.0256

From the foregoing we see that the time table of the city system shows 18 regular trips per day. From the conductors' and foremen's reports we find two additional trips were made and half a trip lost, a net addition of 1½ trips, or a total of 19½ trips, amounting to 468 miles. This amount divided by the speed equals 58½ motor car-hours. This figure is verified by the pay roll.

Time allowed, 18	trips at 3 hours (regular)	54 hours.
1½	trips at 3 hours (extra)	4½ hours.
Total		58½ hours.

For the purpose of comparison, the interurban line is based upon same conditions excepting speed, which is increased from 8 to 24 miles, thus increasing the mileage without changing the car-hours.

Thus it will be seen that on exactly the same cost, the city system would show 12.82 cents "per car mile," as compared with 4.27 cents, while on a basis of "motor car hours" the cost is the same.

It has been contended that the unit for earnings should be the "motor car-hour," and that operating expenses should be based upon the percentage of earnings. The car-hour certainly applies to earnings just as well as it does to expenses; but I do not think that a percentage of earnings is the correct basis for the expenses. For a standard unit it is too fluctuating. If a road's equipment were always taxed to the limit, its earnings and expenses might be held at a fairly uniform basis, but these conditions would never exist for any length of time and could not become general. Any large convention or carnival would swell the earnings abnormally, and while the expenses would increase at the same time, they should not be increased in the same ratio; hence, a comparison of the month's result under such circumstances with another system under normal conditions, would be unfair. Again, the geographical location would disturb fair comparisons, as the time of the year when expenses would be proportionately low in a northern city would undoubtedly find just the reverse in New Orleans or other similarly situated places.

It has also been suggested that the sub-divisions of "General Expenses" are not consistently covered by the "motor car-hours," and that such items as "Advertising and Attractions" and "Insurance" are not affected by the number of car-hours run. As far as such accounts as these are concerned, the same may be said of any unit. Good management will always keep the car-hours as near the point where profit and loss separate, as it is possible, whether on a large or small system, and while such accounts may not be affected by the car-hours, nevertheless, the car-hours, being the index as to the management, the amount of such expenditures are proportionately and correctly shown.

Before concluding, I wish to briefly refer to an article on the "Cost of Electric Power for Street Railways at the Switchboard," by Mr. R. W. Conant, read at the last convention of the American Street Railway Association. Quoting therefrom: "The car-mile basis is not a fixed standard. A car up hill takes a great deal of power, while a car down hill should take none, and may be made a source of power." This is undoubtedly correct, as all grades and loads affect speed, and without this adjusted mileage is not a fixed standard, but with the speed taken into consideration it would be practically the same as on a road without grades.

The President: This is a very important question to our Association, and we should like to have it fully and freely discussed this morning. We would like to have any one ask Mr. Mackay questions that suggest themselves. Mr. Vreeland, I would like to hear from you.

Mr. Vreeland: Any question connected with accounting is of very great importance to me; I went early into steam railroad work, when properties were small, mileage small, and corporations small, and as a young man, starting with due consideration of the future, went very thoroughly through all the departments of railroading. It was made possible by the conditions that existed which I have cited. The properties were very small and departmental questions were not of the magnitude they are today. I, fortunately, went into the work at a period before this evolution commenced, and went through all branches of railroad service. There was no one separate department but what I did a great deal of work in, including all branches of operating, mechanical, and accounting. I left the steam railroad service about the time that consolidations had been very largely effected, and came into the street railroad service at the time when consolidation had just been commenced. I have always looked upon the accountant or auditor or accounting officer of a railroad as the most important lieutenant and aid of the managing officer or the president of a road.

I have always insisted, in any property that I have had charge of, be it as general manager or president, that the auditor or comptroller or whatever he may be called, was my man. I looked upon

the man at the head of the accounting department as the confidential adviser of the head of the institution. You must have confidence in him. You must feel that his supervision of affairs is to your interest, and I have always said that while I liked friendship and a community of interest through heads of departments, I would rather have a superintendent and comptroller at loggerheads than too friendly, because it was an evidence he was doing his work thoroughly. There is nothing that hurts the practical hard-headed head of a department as much as interference by an accountant with his system of doing business. He looks upon it as an interference. When I went into the steam railroad business this question you have up here today was a very important one then. The old method was a computation with small properties on a percentage basis. It was not a proper guide to all because the physical conditions were different, and the characteristics of the property, hours of traffic, etc., could not be shown merely on a basis of 70 per cent, or 60 per cent, or 50 per cent, and in those days when men were not so well educated about the conditions of our country, I have heard the capabilities and capacities of different people criticised. For instance, a manager of a road in some hilly, mountainous country, the operating expenses were 80 per cent, was criticised, because in some other part of the country the percentage was only 50 per cent. The evolution was to a separation of accounts, and to the question of engine maintenance and mileage, and car maintenance and mileage, and the separation of traffic, both freight and passenger, until the basis of the train mile was reached. On the steam railroad today, the cost of maintenance and construction, buildings, transportation, general expenses and everything is computed for the train-mile unit.

When I entered the street railway service I took hold of a property that had just been the result of the consolidation of many properties, and I saw there was no systematic method of accounting. I called to my aid at that time, a man who had been for years the auditor and comptroller of steam railroads, and who was at that time acting as expert accountant in the consolidation of properties. I turned over the books to him, and told him to make a thorough study of it and start the books on what he considered good accounting practice. He worked a long time at it, and brought out a set of books. In the distribution and classification of operating expenses, we are, in New York, subject to the requirements of the law under which the Railroad Commission of New York was created. The commissioners have the supervisory powers over all that we do, and also have the say as to how we shall conduct and classify our accounts, the same as the Inter-State Commerce Commission of the United States has over the steam railroads. After we had run under that system of accounting for some time, the board of Railroad Commissioners decided, as a result of the character of the reports they were receiving from our system, to call a meeting of all the accountants in the state of New York, to arrive at some standard classification of accounts. The meeting was held in my office for a series of days, nearly a week, and the matter was thoroughly discussed, pro and con, and the system under which we were working, with a very few slight modifications, was adopted as the standard of New York. We used no trailers, and we adopted as the unit the car-mile irrespective of whether a car is to run somewhere to start a trip, and we classify our accounts so that on the 15th of each month, each month closing itself, I have a statement showing all the conditions, cost of material, etc. As you know we are, in New York City, pretty far behind the age, and it may seem strange to our western friends and cause them to smile, as it did me when I was on a trip, but we have at the present time 5,000 horses working in our system, so that we have horse, electric and cable car items. This financial exhibit is a complete abstract of the results of our auditor's work every month. This is open to the inspection of any stockholder or director, or any one who is interested in the property, There is a concise classification which covers the individual lines of the system, carried along by the month, so that I get on the 15th of the month a statement showing everything on a car-mile basis, and it is only necessary for a manager to make a comparison to determine for himself whether they are accurate or not throughout. The equipment expenses and transportation expenses and general expenses of the system are brought down to the actual cash basis per car-mile. I have had occasion in the past six years to make, in an expert capacity, many examinations of properties in this country, but I would not for an instant give any opinion on this question against the opinion of you gentlemen who are daily in the work. To me it is an incident of a large business at the present time, and my mind would not certainly be as fresh upon it as if I were working at it constantly, but the question up is a very important question. I have for a series of years been working on the line of Mr. Yerkes' paper yesterday in getting our company into a position so that we can say to the world or any man interested in our property, "There it is, you can take it or leave it, we are not afraid to give it to you or any one else; we have done the best we can with it, there is the condition."

I have taken some of the most expert accountants that we have in New York and have had them take up this accounting and go through it, and incidentally on account of my earlier association with these men on steam railroad work, my mind has naturally turned to the men that I have known in that work as expert men, but frequently in the last year or so I have taken the street railway accountant with me, and in every instance I have asked what in his opinion would be the most available unit for us to work on to get an idea by comparison of the properties in the United States or the world, and the answer has been the car-mile.

Of course there are exceptions to everything, and everybody can find good reasons why anything we do or say should be different. I remember when the system of keeping the car mileage on steam railroads was introduced. I remember that it was stated at a meeting where the question was up, that it was an absolutely impossible thing to do, and the reason why it could not be adopted was, "I can trust myself, but when the car goes anywhere else I have got to trust somebody else," but the result has turned out in such a way that every man was satisfied—I know I was always satisfied—whether the car was on my line or in St. Louis, or in California—that it was getting proper treatment, and that we were getting proper returns. I only state that as an illustration. We have to choose some course and go ahead with it, but the concensus of opinion upon this proposition as I have got it is for the car-mile as a unit. But the exceptions, such as Mr. Mackay has illustrated here, and why they cannot be handled in that way, I am not in a position to discuss at present, because I take this question up with you at the request of your president—I took it as an entirely novel position when I came into the room. It is immaterial whether you put five cars together and put a motor and cable car on ahead of them and call that a railroad, or whether you take the same number of people and put them in coaches and put an engine in front of them and call that a railroad, you arrive at the same point; you have practically the same classification of expenses, because the street railway of today stands right on the line with, and as far as its being progressive is concerned, a little ahead of the average of steam railroads, and the unit that has to be the determining factor in the end must be based upon a very careful study of all the conditions that surround it. For our part, our accounting officers are well satisfied with the car-mile as a unit in considering the expenses of the system. So far as the question of the methods of these various things are concerned, to which our friend has alluded in the paper, the question of keeping the mileage and things of that character I would say that I think that anything that can be done on Broadway in New York can be done anywhere. By reason of the congestion of our system, we do not know where a car may go when it starts out; it is likely to go two miles and be switched back, or to go four miles and be switched back, or it is just as likely to go to the terminal in another direction from the car barn, so that any statistics furnished by a starter or any car barn man are absolutely valueless, because he does not know where the car has been. The only method we have of determining this is by the report of the conductor, and we have an arrangement covering the system by which certain points are numbered, and the conductor makes his report that he left point No. 1, for instance, and if point No. 5 is his terminal, that he went from 1 to 5 and from 5 to 1; if he got switched back by orders of the inspector by a blockade at point 3 his report will show that, and the time of the men based upon the trip is governed by that as well as by the mileage. The statistics of mileage of wheels and motors and things of that character may not be accurate, but it is worked out from that system, and is as accurate as we can get it. The man whose mind has not been trained to the fact that one-tenth or one-eighth or one-quarter of 1 per cent is a valuable factor in the operation of railroad systems cannot appreciate your work, and when you go to work, and probably sit up

nights to work something out that you consider is of value to the system, it is thrown aside as of little importance from the fact that the importance of it cannot be appreciated. When you take into consideration the mileage, and the effect of the slightest fraction of a cent on the aggregate it is of great importance to determine the wheel mileage and motor mileage and everything connected with the operation of the line, and this brings up the point that the accounting department is a most valuable adjunct in determining what the system is doing.

We have the auditor and comptroller take up these matters with the division superintendents and general foremen, monthly, quarterly and yearly, and say: "Such and such has been the case. Now, boys, look out. Here is the sign; it has pointed the way." We do not think it is wise to send a man an aggregation of figures which he is incapable of analyzing, but we bring him right in to the auditor or comptroller and point out to him that he varies either more or less from others in this particular direction or that. The car-mile unit as used by us has been adopted in some of the other large systems such as New York, Philadelphia, and some others, but I am very free in saying that I would not give a snap for a departmental man under me connected with a railroad, that would not get up and express his opinion and fight for what he thinks is right, and if any of you gentlemen have anything to offer that will enlighten me, I shall be just as pleased to hear it as any man in the room.

The President: You do not run any trailers?

Mr. Vreeland: No, sir.

The President: But you attempt to have the same length of car on your system?

Mr. Vreeland: Yes, sir, but at the present time we have 18-ft. horse cars, and we have a 22-ft. and the 28-ft. car, so that there is a variation, but at the same time it does not affect the general value of the proposition when you get it sub-divided into your lines.

Mr. Mackay: I would like to ask Mr. Vreeland if the question of speed enters into the calculation?

Mr. Vreeland: We have never taken any consideration of that. Take our Lexington Ave. line for instance; from 130th St. to 105th St. it is run electrically; where there is very little congestion, from 105th St. to 25th St. it is run on a cable that runs on a speed of 12 miles an hour; from 25th St. to 5th St. and Broadway, 10 miles an hour; from 23d St. to Houston St., 8 miles an hour, and from Houston to South Ferry by a cable which runs 6 miles an hour, and that is just on one line; it is not a comparison of two lines. Take the Broadway and the Columbus Ave.; that is run at 14 miles, 10 miles and 6 miles.

Mr. Mackay: You do not run an interurban or high speed line, say at 25 miles per hour?

Mr. Vreeland: No, sir.

Mr. Wyman, New Orleans: I have been led, during the last two weeks especially, to consider the immense utility of the accounting department along the line of preparing the information to give to our investors in order that their confidence in their investments may be secured. A system of bookkeeping or accounting should be plain to the average investor. Men are studying these questions now as never before.

I have felt, as Mr. Vreeland has so well expressed it, that the auditor is the man next to the manager, and the one upon whom the manager himself must rely most implicity and most positively. The two should be most closely allied in the work, and that alliance I have always sought on whatever roads I have acted as an officer. I may say that this car mileage basis is the one which we have adopted—which was adopted in Milwaukee when I was there—and is adopted in New Orleans, and yet I very heartily sympathize with some of the points made by Mr. Mackay in his paper, that there are questions regarding it that are sometimes difficult and over which we may possibly stumble. If the motor car-hour should replace as a standard the car-mile, I am not sure but what it might be wise. In our power houses we have adopted the kilowatt hour. Now, while the motor car-hour may not be directly allied to the kilowatt hour, I can see it might be a very useful standard.

But I do hope that the effect of this Association will be so pronounced that whatever shall be decided upon will meet with the approval of all street railways. As Mr. Vreeland has stated, our business has now got to be a public business; it has reached out and become a business that is attracting the attention of everybody all over the country, and some of our neighbors. Investors are looking at it constantly. People are seeking to put their money into street railroad enterprises. They are regarded as gilt-edge investments, and properly so, and aside from it being a great factor in civilization, aside from their being, perhaps, the most important factor in municipal life today, they are a factor in the world's markets today like none other that I know of, not even steam roads, and therefore there should be standards adopted of universal application, so that the investor or one interested in these matters may read as he runs, and know precisely where we are, what we are doing, what our comparative value is as placed along side some other company; and on the other side we should be very perfect, very clear, in stating exactly what our position is financially and I think that the managers, operatives and officers and presidents of roads will join with the Accountants' Association in effecting that sort of an end. (Applause.)

The President: Mr. Duffy is a member of one of our very important committees, and as such he can explain to these gentlemen briefly what we have been doing in connection with the meetings of the steam railroad people and railroad commissioners.

Mr. C. N. Duffy: I have been very much interested in the remarks of Mr. Vreeland and Mr. Wyman this morning, in the discussion of the very able paper by Mr. Mackay, but I would have liked to have heard a little more discussion on the matter of the unit of comparison; as to whether it should be motor car-hour or car-mile. Mr. Vreeland's comparison as to the manager up in the Rocky Mountains being put on the same basis with a city line is a point very well taken. It illustrates the practicability of the motor car-hour, but I am digressing from what our president referred to. I was very much pleased to hear Mr. Vreeland say that he and his accounting officers had spent a great deal of time in the earnest study and adoption of a standard classification of accounts, which now stands as the standard of the state of New York. As chairman of the committee of this Association, and having charge of that matter, I am acquainted with the classification that Mr. Vreeland refers to, and if our president will remember, at Niagara Falls, Mr. DeFreest, secretary of the board of Railroad Commissioners of New York, was with us, and the standard classification adopted by this association is very similar to the classification adopted and used by the New York Railroad Commissioners. And I would like to say for the information of all of you, and more especially for Mr. Vreeland, as he is from New York and directly interested, that in July our committee met with a committee of Railroad Commissioners, of whom were Ashley W. Cole, president of the New York board, and Mr. Seymour, of Connecticut, and two gentlemen representing the Association of American Railway Accounting Officers. The reason for this conference was that the convention of Railroad Commissioners—that is the title, but it is really the National Association of all the railroad commissioners of the United States—wanted a standard classification of accounts for electric railways. They wanted it to operate with reference to street railways and electric railways, just as the Inter-State Commerce classification operate with the steam railroads. There were two members of our committee present, Mr. William F. Ham and myself, and there was a long discussion of this question. We went over the thing very carefully, and as a result of that conference the classification of accounts that was presented to this convention at Boston, 1898, with very few and slight modifications, was recommended for adoption. It was presented at the convention in Denver on August 10th, and unanimously adopted. And that the Street Railway Accountants' Standard Classification of Accounts has now been adopted as the standard of the Railroad Commissioners of the United States, and in every state in the United States that exercises any supervision of accounts in, and it will be the standard classification, and in 1900—Mr. Wilson here is shaking his head, we do not count Massachusetts—in 1900 they propose to put this thing in actual operation and have their reports made on blanks, modeled after this classification. The steam railroad accountants do not meet until next May, and a committee from that Association will recommend to that convention the adoption and use of the same classification. Now the effect of that will be that we will have a standard classification that will be universally adopted, and we have all four elements. We have the street railways, then we have the Railroad Commissioners, we have the steam railroad accountants, and we have the street railway accountants, then in addition the American Street Railway Association. We have a standard classification of accounts

and we ought to have a standard unit of comparison, and we ought to have a standard form of statement—an arrangement in the regular annual form of report which this Association has adopted, and I would be very glad to hear a full discussion on this subject of whether or not the car-mile unit should be the standard unit of comparison. I do not know whether you consider the different sizes of cars, whether single or double truck, whether they are 10-ton or 20-ton, and whether they run trailers—Mr. Vreeland does not run trailers—well, we run a few in Chicago. We have a train of four cars, sometimes of five, and sometimes that train on its journey is partly electric and partly cable, and like Mr. Vreeland we still have a few horses, not 5,000, but something over 200.

Now, there is one feature of this question that I do not believe has been touched upon. Even if you are figuring on a car-mile basis, how are you going to treat the trail car—in all its different phases—are you going to call the trailer the same thing as the motor; it does not take as much power to pull two trailers as it does one motor. In the summer, if you are operating a trailer, it will earn more money than your motor. These are questions that enter into the question of comparison which do not enter, I think, into the motor car-hour. This subject has a great many attractions., that is for me, and I would like to have some of these gentlemen talk upon it. (Applause.)

The President: Col. Heft of the New York, New Haven & Hartford road is with us and we should be glad to hear from him.

Mr. Heft: I was very sorry that I was not able to be present and listen to the paper, and I am in the position of a man who woke up and found himself in a place and said he had no country. But I have listened to the gentlemen in discussing the question of whether the item of cost should be made up upon the car-mile basis, or upon the motor car-hour basis. It seems to me that the question is one that is governed wholly by the conditions which exist upon the road you are operating. If you attempt to make up the cost on the motor car-hour on our system it would be very misleading, for the reason that during certain portions of the day we are hauling two trailers, other portions of the day we are hauling four trailers, and some portions of the day we are hauling only one and some other portions only using the motor car. Now any costs made up on such a basis would be wholly misleading. Our company has adopted the car-mile basis in making up the cost, and in doing so we figure the cost of power consumed when using the motor car alone, the additional power of each trailer, and make up the cost of the motor car-miles and of the trail car-miles and stating whether one, two, three, four or five trailers are used. We also follow the same rule in arriving at the cost of maintenance and in our figures on car-miles we add everything—every item except the depreciation upon equipment and upon the tracks, and the interest on the capital invested, but at the present time we are not wholly satisfied with the way our accounts are made up and are drifting around to see if some bright fellow will not substitute some other system which will be more desirable than ours. But I think in all these questions, that in arriving at the cost of any system, the manager should be governed wholly by the conditions which exist on his line and that no stereotyped rule can be laid down by which you can make up your minds on all these various systems where the conditions are so wholly different, and no one will welcome a system—a universal system that can be used by all railroad companies, more than I would, but it seems to me that it is a knotty problem and one that deserves our best consideration, and we should not decide upon any system until we feel satisfied that it will answer all the requirements of the different members of our Association.

I have attended the meeting of the Railroad Commissioners on two occasions when the accountants from the steam railroads met with the Railroad Commissioners and devised a system upon which our reports should be made to the Railroad Commissioners, and I found that there was a great diversity of opinion among all of the different commissioners, and it seemed to me that there was a work in a worthy cause for some of you bright accountants to devise such a system as we could satisfactorily adopt for all our statements.

I am very glad to have had the pleasure of speaking this morning and of meeting with you, and I wish you a full measure of success. I think your Association is a live one. There is a need of it, and you have certainly accomplished a great work, and yet I think the future is very bright and that the result of your deliberations in the end will be of great benefit to all the systems which are members of your Association. (Applause.)

The President: I understand that lunch will be served upon the train, so that while it is now 11.30 we need not hurry away from here. I would like to hear from Mr. Wilson.

Mr. Wilson: I have always supposed that I was a native up to this morning, when I have been informed that I am a foreigner coming from Massachusetts. In this respect we are in very much the same position as Mr. Vreeland. We do not run any trail cars whatever, and we run something over 300 routes every day, every one of which has a different length and a different speed. There is no basis whatever that I know of upon which this thing could be figured but car-miles. We could never take a trip and say that a car will take a certain length of time to come back, not quite in the way as suggested by Mr. Vreeland, but while we do not shift cars from point to point as he does, yet a car may go out on its route to come back on its schedule time, or it may not. The question of the basis of car-miles, I think, can only be taken up by a company of the size of the one which I have the honor to represent in comparison with a road in some large city of a similar nature. While this traffic sheet that is shown here is very interesting, when it comes down to the question of three cars being compared with 1,800 cars, which we probably run on certain days, the comparison is of but little use, and in connection with the question that Mr. Vreeland brought up, of the foreman of the men who are directly connected with the maintenance of the equipment, the system which we follow is the same in every individual car house. Each one has its maintenance crew, which keeps the motors, trucks and cars of that particular car house in condition. Each month we make up a statement giving the details of some 6 or 8 accounts, showing what the labor and material in each of these car houses has cost, and then we have a comparison.

Now when we first started this I used to have an inventory of the stock taken once in three months or once in six months, but I very soon found out that we didn't always have the stock which we should have had. Each man was so anxious to make a good showing for his car house that he would include a lot of the material that had been consumed. In order to avoid that I have for two years had the men make a return each month of the stock that they have in hand, and in that way I think that we have an accurate statement of it. On the basis of car-miles we get a very good comparison, while on the basis of car-hours I don't know of any way in which we could possibly make a comparison.

Mr. Mackay: I wish to say that the comparison here of three cars only would apply just as well to 3,000 cars. It was simply shown in small figures so that it could be readily grasped. Mr. Wilson certainly knows how many hours his motorman makes. Now that gives him right there the number of motor car-hours made. There is only one motorman to a car and he certainly knows the time made by those motormen. Now as to the speed; while it may be shown that a line will start out and run eight miles an hour and then decrease to six miles an hour, and then increase to eight again, the average speed is based upon its time cards.

Mr. Wilson: In that connection I desire to say that Mr. Mackay is entirely wrong when he says that we know the hours of our motormen. Our motormen are paid $2.25 per day for 10 hours out of 12 consecutive hours; some run 10, some 9 and some 9½, for in the congested district of Boston a car starts out, but it may not get back anywhere near on time. That man might have a schedule of possibly 9¼ hours or possibly 10½ hours, but for every 10 minutes over the 10 hours in 12 consecutive hours the man receives extra pay, so you see that by multiplying some 1,800 of these items and keeping it up by hours, would make a large item of expense.

Mr. Mackay: If the man only worked half a day would he be given a full day's work.

Mr. Wilson: He would be given half a day. He might work four hours and a half and he might work five hours and the rest of the time might be done on trips. Certain trips would have a certain price. It can be done, but it is a matter of expense, and the bigger the road the more it precludes its being done.

Mr. Hibbs: I would like to ask Mr. Mackay if that is a statement of facts actually or theoretically.

Mr. Mackay: It is theoretically.

Mr. Wilson: A comparison of a city line and an interurban line is just what I have brought out. That is hardly a fair comparison. A city line should be compared with a city line.

Mr. Mackay: We want to get a standard that will apply to both if it is possible.

Mr. Ross: I think the question of car mile and motor hour is a local one. I think the proportion of expenses to earnings is the proper method of comparison.

The President: Then you would have to get at some comparison for the earnings.

Mr. Ross: No, you cannot compare a very large road with a very small road. We also have such varying conditions. Down in New Orleans we have no snow at all, while in Montreal we spent $80,000 on snow in a year.

Mr. Wilson: It might be interesting for the gentlemen to know that in Boston we have had a snow storm that has cost us $116,000 to remove the snow alone.

Mr. Duffy: I do not see how the conditions would be any different figuring on the car-mile or car-hour. Mr. Vreeland spoke about the man who ran the steam railroad in the Rocky Mountains, whose percentage of operating expenses was 80 per cent, while the man in New York with the flat road had an average of 60 per cent. Now, in regard to this chart that has been referred to, as I understand it, it is not the purpose of Mr. Mackay to compare an interurban road with a city road, neither is it the purpose of Mr. Mackay to show that it is applicable to a three-car road, but it is his purpose to show that there is a road that runs three cars 468 miles at 12.82 cents per car mile, another road runs three cars 1,400 miles at a cost of 4.27 cents and the car-hours the same. He does not say that the interurban road could or ought to be compared with the city road, nor that this is only applicable to a three-car road. I believe what can be done in Boston can be done on a three-car road, and what is done on a three-car road can be done in Boston.

Mr. Wilson: I stated that anything could be done, but that it was the expense that precluded its being done. We make a comparison with ourselves. We have nine different divisions—eight of them are operating divisions—and we have all cars with the exception of one division come into the central portion of the city. That division is so far removed from the headquarters that we consider that a separate division and have a superintendent for it who has his headquarters in the center of the city. Cars after they pass a certain point come into his division and those are amenable to him and his assistants. They make a comparison both on the basis of car-miles and percentage, one division with another, but as to what we were discussing, we have to take the physical condition of these roads into consideration when we compare one with another.

The President: Have you formulated a classification of accounts which makes it possible to compare one road with another, or the expense of one with another?

Mr. H. C. Mackay displayed a chart exhibiting the data shown in the following table:

Month.	January.			May.			July.		
	Total.	Per cent Earnings.	Per Car Hour.	Total.	Per cent Earnings.	Per Car Hour.	Total.	Per cent Earnings.	Per Car Hour.
Motor Car-Hours...	60,000			60,000			60,000		
Earnings.	$100,000		$1.67	$120,000		$2.00	$150,000		$2.50
Operating Expenses.	60,000	60	1.00	60,000	50	1.00	60,000	40	1.00
Maintenance	15,000	15	.25	15,000	12.5	.25	15,000	10	.25
Conducting Transp'rtat'n	30,000	30	.50	30,000	25	.50	30,000	20	.50
General Expenses.	15,000	15	.25	15,000	12.5	.25	15,000	10	.25

In explanation of this chart he said: The purpose of this chart is to shew the incorrectness of a unit based upon a percentage of earnings. Here are three comparisons based upon the same service and covering the same cost, but for different months when the earnings naturally vary. For instance, January's earnings are $100,000, and the operating expenses $60,000, divided between Maintenance, Transportation and General Expenses in the ratio of 15, 30 and 15 per cent of Earnings or a total of 60 per cent. On the car-hour basis we have an earning of $1.60 per hour and an expense of $1.00, divided between Maintenance, Transportation and General Expense as shown, viz: 25 cents, 50 cents and 25 cents per hour. Now when we attempt a comparison with May, with its earnings of $120,000 and the same expense as January (and I think you will agree with me that the earnings can increase without an increase in expenses) we have the same cost per car hour, but a percentage of earnings gives but 50 per cent as compared with 60 per cent for January; an apparent decrease of 10 per cent. This shows the unreliability of the basis of percentage and likewise the correctness of the car-hour. The applies also, only in a greater degree with July's earnings of $150,000.

Now, assume that the two comparisons (January and May) represent two roads of practically the same size (as I believe Mr Wilson suggested that comparisons could only be made fairly with roads of the same size). To say that the management of the road showing 50 per cent is more conservative I do not think will hold good and the car hours bear me out by showing that the cost was the same in either case.

Mr. Ross: Comparisons can only be made from the same periods.

Mr Mackay: This would not apply in a comparison of a Southern with a Northern city.

Mr. Ross: There are different conditions covering all roads, but by taking cities of about the same size and under similar conditions, and comparing the two you may be able to determine as between the car-mile and car-hour. Mr. Duffy referred to Mr. Vreeland's statement in regard to a man running in the Rocky Mountains. I don't see how, putting it on the car-hour basis would bring the proper result.

Mr. Mackay: I think it would, Mr. Ross, for the reason that you are keeping your car-hours in accordance with the requirements of your service. In the winter when you require less you are keeping down your car-hour proportionately.

Mr. Ross: Yes, but I don't see what difference it makes figuring on the car hour in the Rocky Mountains or on a level plain, as compared with figuring on the car-mile basis.

Mr. Mackay: I don't think it does in that feature.

Mr. Hibbs: Mr. Mackay, as a matter of fact, is there any satisfactory basis for comparing roads under different conditions. We do not operate any trailers, and I cannot see how we could be compared with another road that does.

Mr. Mackay: As I mentioned in my paper, I think that a road that is operating trailers operates at a disadvantage.

Mr. Hibbs: Is there any opportunity for comparison of two roads operating under similar conditions?

Mr. Mackay: Only to adopt a uniform basis. All motor car-hours are the same as yours. Hence I advocate that as a basis.

Mr. Ross: I think it is only a question of time when trailers will be taken away—a very few years. I think in cities there will be no trailers in a very few years.

Mr. J. K. Newman, of the New Orleans & Carrolton Railway Co: I am not an accountant, I am a president, but I do not believe I could be a president without having a great deal to do with the accounting department, and there is no one branch of our road in New Orleans to which I give more attention.

Now, about the basis. You can establish any basis you want, whether it is a car-hour or a car-mile, but you cannot compare different roads operating under different conditions. It is simply impossible. But you can arrive at a unit, or two units, or three units, as we do, and you can get those subdivisions just as easily as you can the one. I believe in the car-mile basis for the reason that it is a small unit—the smaller the unit the greater the subdivision, therefore the car-mile is the basis that we adopted. But we go a little further. We have on our system the car-hour unit also. Now we go a little further and we get into percentages. We put each subdivision of the road in the statement, and we also put in our statement of percentages each of the general divisions in the operating expenses and each in detail. That will give you all the information that you could possibly ask. You cannot get a unit that will permit you to make comparisons of roads operating under different conditions, except that you can find out why the differences exist. I think it will be absolutely impossible to get any basis which will be fair for all roads alike, independent of whether they are operating in snow which cost $116,000 in one season, or otherwise.

Mr. Mackay: If this is as the gentleman says, we might as well admit that we have accomplished nothing. I am of the opinion myself that it is not an impossibility, but I believe that it is simply a matter of detail, to be worked out at different points.

Mr. Newman: I do not argue against getting comparisons, but

I mean to say that it is impossible to put in a statement a number of figures which are supposed to be comparative figures, and set them by the side of those for another road and say it is operating cheaper than you or otherwise, unless you understand all the details of the roads that you are comparing, because the conditions are so different. But I believe we have arrived at a basis so far as we can get at it, and that is the car-mile, unless you want to add on the statement the car-hours and also the percentages. I do not argue against the comparison, but against an effective comparison without knowing the conditions under which the road is operated.

Mr. Mackay: I would like to ask the gentleman how he would make a comparison on the mileage basis with the road which operates a city and an interurban line. I have shown here on this chart that a road operating a city line, on exactly the same cost, would show 12.82 cents per car-mile, and the interurban line would show 4.27 cents. If you cannot compare two separate city systems how can you compare the road which has both the city and suburban features with another system having only one.

Mr. Newman: I do not argue against getting a comparison, but take that diagram of yours and cut off the top of it. What will it show, or what would it mean? It would be ridiculous. Without this you cannot tell anything about it, and that is why I say you cannot arbitrarily take sets of figures and put them on a statement and compare them. You must take your statement and mark on it, "This is a city line, running so many miles an hour, with so many trailers, the cars are heavy."

Mr. Wilson: I do not think with Mr. Mackay that the work of the Association would be practically thrown away if some basis is not arrived at. I think that on sober second thought he will change his opinion. If we have a standard statement giving the certain distribution of our operating expenses, one may get the detail of that operating expense and compare it with others, and having the same basis can at once see in what particular operating expense account the difference is, and then by comparison of the physical conditions of the road will then arrive at the correct basis of comparison.

Mr. P. S. Mackay, Minneapolis: I may be a little dull of comprehension, but it seems to me that some of the gentlemen who were speaking here, while favoring mileage as a unit, have been furnishing arguments against it. I refer, for instance, to the case stated of "congested traffic," where cars would be sent out without any definite knowledge as to where or how far they would go or when they would come back. In such a case as this, I submit it would be easier to determine the number of motor hours involved than the number of miles run, and would not motor-hours be a better basis for comparison? The fact that mileage has been adopted all through the country is not proof of its being the best unit. We are looking for a better unit, and it is our privilege and duty to work earnestly for that which is the nearest to perfection. That mileage as a unit for comparison between different systems is not reliable I believe, particularly so when we consider the varied methods of computing mileage throughout the country, nor does it give the best information by way of comparison between different periods of time on the same system.

The Twin City Rapid Transit Co., of Minneapolis, made a computation a short time ago affecting the operation of a portion of its system for certain periods of time, with a view of determining the relative merits of the mileage and motor-hour units, and while this test was not by any means exhaustive or conclusive, it tended to show that for the time involved, the motor-hour unit was preferable.

I am inclined to think, however, that after a standard unit of this nature has been adopted by this Association, it should apply only to earnings.

I agree fully with Mr. Ross, that the ratio of operating expenses should be that of "Expense to Earnings." Our statement to the management and all others who have the right to scan the results of our labor, should show every item of expenditure from Maintenance of Track and Roadway clear down to Dividends to be a certain proportion of the earnings, thus furnishing a clear, concise, truthful and easily comprehended statement of facts, the salient points of which could easily be grasped by the examiner. I am well aware, that to the accountant who laboriously figures out the ratios of expenditures upon the basis of any unit whatever, the results of his labor seem plain. There are doubtless many here who could fill columns with algebraical hieroglyphics which would unmask all the unknown quantities in the whole proposition, and there are doubtless managements who could decipher it if they had the time and would take it for that purpose, but the management have a right to demand of us such statements as will give the fullest information in figures the easiest of comprehension.

Supposing, for instance, we have a statement showing a surplus of 25 cents on the dollar of earnings, this would be instantly understood without going any further, but, on the other hand, supposing the surplus was given as 62½ cents per motor-hour, this would not convey any information whatever until the examiner knew or his mind recalled the fact that the earnings were noted at $2.50 per motor-hour, then by a mental calculation he could reduce the figures to the 25 cents which we ought to have furnished him in the first place.

Mr. Dimmock, Council Bluffs: Mr. President, I would like to know if anything has been said as to a comparison of mileage between a long haul and a short haul, and whether with a long double truck car the mileage would be counted the same as with a single truck car if they both went only one mile.

Mr. Mackay: No. The point is that a small car would cost less than a large car, but you could get only half the efficiency, and the showing would be more particularly in the earnings. The expenses would not show in the large car as it should show.

Mr. Dimmock: If the short car runs one hour or any car runs one hour, would you regard it as each car running the same? I know of some roads where they count the short cars double what they do the long ones.

Mr. Mackay: I would base it on the actual time the car was out, without regard to the length of the car.

Mr. Ford: Mr. President, I have listened with a great deal of interest to the discussion, and without discouraging Mr. Mackay in his efforts to find a better unit, I feel that it will be almost impossible to find a rule that one could lay down against any street railway in the country as a basis of comparison. We use the car-mile, but my statement to the president and manager or directors also shows the percentage. That is good so far as it goes. Take for an illustration a statement that shows our earnings to be $100,000 with operating expenses of $60,000 for one month and almost the next month, we have shown $15,000 or $20,000 increase in earnings and the expenses are not increased $1,000. Now that has been our experience, because our schedules are governed by city franchises. We are required to run our cars on a certain headway and our expense is about the same month after month. Now, this statement also shows the earning per car per day of 18 hours and the expense per car per day of 18 hours. We also show the earnings per car-mile and the expense per car-mile. All these are figured out on percentages. We run no trailers except on our west and suburban resort line. There we run electric trains. Now I can see that on most any basis it would be hard for us to compare with another road that is not operating under exactly the same conditions, and my suggestion to this Association would be that we show, and not necessarily to our directors or stockholders, because they are seldom interested in these matters, but to our manager or to our president, who takes an active part in the management of the line, what all this includes. Let us show him the motor car-hour the car-mile, the car per day of 18 hours, the earning percentage, the expense percentage—let us give him all of this information and then if I or anybody else wants to compare with Milwaukee, I lay these things all down together. I show that perhaps his condition was different from ours; perhaps he operates trailers and that his condition is different from our own, but on a comparison of all these matters I would strike a unit by a general comparison. Now that will be my judgment in the matter, because I believe you can discuss this matter from now until the next convention and cannot be any nearer arriving at a unit that will enable you to compare your road absolutely and accurately with what we are doing down in New Orleans, or Boston, or any other place.

Mr. Wilson: I would like to ask Mr. Ford how he arrives at 18 hours a day.

Mr. Ford: Well, we just consider that the road is in operation 18 hours. We have on our road about 210 cars in daily operation. We count 18 hours for a day; it is simply arbitrary.

Mr. Mackay: Mr. Ford bears me out exactly in my diagram of percentages, and the idea of this paper is to bring about a com-

parison of each individual item of expense, the average of cost, or a minimum cost of each item of expense. Now, when we have arrived at the average cost for heating or lighting the cars, or any particular item of expense, then by comparison of these items of another road that average will show whether we are above or below the normal. A condition which will, I think, benefit any road and save lots of time and expense.

The President: We have on tomorrow's program the first thing in the morning, Mr. Brockway's report on department blanks and forms, but the first thing in the morning we will take up for further consideration Mr. Mackay's report and in the mean time you gentlemen can give it some thought and consideration for the benefit of the committee that will be appointed at this meeting probably. Now, there is a short report to be made by this committee on standard classification of accounts. Mr. Duffy has partly covered it by his report, but I understand there will be a supplemental report made here.

Adjourned to Thursday, October 19th, at 10 a. m.

Thursday, October 19th.

The president called the meeting to order at 10 a. m. and announced that the Association would take up this morning the report of Mr. Duffy, chairman of the committee on "A Standard Classification of Accounts."

Mr. Duffy: I have a letter from a gentleman who was, and whom I have always considered is still a member of this committee. I refer to Mr. H. J. Davies, of Cleveland. Mr. Davies, as you all know, was the assistant secretary and treasurer of the Cleveland Electric Railway Co., and you will recall that in Cleveland he was present at the first meeting, and afterwards, through illness, was obliged to remain at home.

He was very much interested in the Accountants' Association, and those of us who are on the committee, more especially Mr. Ham and myself fully understand and appreciate the value of Mr. Davies' services in the work of this committee, more especially the work done at Manhattan Beach in August, 1898, and in Cleveland immediately following that meeting. Mr. Davies writes me as follows:

"I have felt this year that I had no right to participate in the work and discussions of the committee on Standardization of Accounts, because I have had no connection, except as a small stockholder in a street railway company, and therefore no membership either personally or as a representative of any street railway company in the Association.

"This has been my greatest regret at leaving street railroad business. (Mr. Davies is the secretary of the National Carbon Co., of Cleveland.) I have just read again, however, very carefully your report of July 21st to the president of the Association and other papers which you have sent me from time to time, and I am sure no one will question my right to say that I approve in all respects the recommendation made by you and Mr. Ham, including the change in the classification of taxes.

"As an outsider, I can congratulate and compliment your committee, and the Association, on the progress made toward the universal adoption of the system of accounting recommended by the Association.

"If you can induce the Association to suspend its rules or over-ride its constitution so that I may have a copy of the report of the proceedings of the Chicago convention, I shall be very grateful."

I will suggest, if it is agreeable, that we should not only send Mr. Davies a report of the proceedings of this convention the same as if he were a member of this Association actively, as before, but I would recommend that Mr. Davies be made an honorary member of this Association with Mr. Windsor and Mr. Higgins, and I make that as a motion.

The motion was carried.

Mr. C. N. Duffy then presented a printed report of the conference between the representatives of his committee and committees of the Convention of Railroad Commissioners and the Association of American Railway Accounting Officials, and the report made to the former Association by Mr. Seymour's committee. The substance of this printed report was published in the "Review" for August, 1899, page 538 et seq. He then read a letter from Mr. Henry F. Billings, who is the clerk of the Railroad Commissioners of Connecticut. He says: "In reference to the classification, beg to advise you that it is the intention of this Board to recommend the same, and it will go into effect with reference to the fiscal year ending June 30, 1900. I have been at Mr. Seymour today and he promised to prepare a letter of instruction, or perhaps I should say, a letter ordering its adoption to be sent out with copies of the classification to each road in the state. I might say that if he does not get at it pretty quick I shall, for it is time that the various companies have notice of such a classification in anticipation of the report for 1900."

The report was adopted on motion.

Mr. Duffy: We have had 500 numbered copies of this copy printed, from 1 up to 500, which will be officially distributed by the secretary, and the number charged up to each company to which it is issued. In addition Mr. Duffy presented the following supplementary report taking up:

1. Construction and Equipment Account. "Investment Real Estate." The instructions classifying this account read, "Charge to this account all expenditures for land and buildings not used in operation of road." The committee wishes it understood that this refers to land and buildings purchased in connection with securing right of way, and real estate used in the operation of the road, but not a part of either, although incident to the construction and equipment of the road. This does not refer to the purchase of land and buildings bought for the purpose of investing surplus funds of the company, which should be charged to a special account; for example, "Surplus Investments." It having been suggested to your committee that the instructions concerning this account were not sufficiently clear or explicit, and that "Investment Real Estate" was not a construction and equipment account, we submit the above for your information.

2. Monthly reports, debiting and crediting the month's proportion of each item under "Income from Other Sources," "Deductions from Income," and "Deductions from Net Income," currently, each month, and charging to accounts Nos. 36 and 37, respectively, the month's proportion of the total annual charge of these accounts, estimating such debits, credits or charges, if the exact amount per month is not known.

The instructions regarding these questions appear to be complete and sufficiently clear and explicit. As far as your committee knows, they are fully understood, but they are not always properly carried out. The debits, credits or charges referred to, should be estimated and apportioned monthly, as closely as possible, from the best information obtainable, and the amounts taken up each month by journal entry, so that they would appear on the books. In many instances, these amounts are pro-rated on the monthly report, without having been put on the books at all.

3. Classification of material and supplies. A Classification of Material and Supplies is submitted, because your committee considers it of the greatest importance in connection with the use of the standard system of accounting adopted by this association. Material and supplies have been classified under 13 departments, A to M inclusive. The items properly classified under each department should be alphabetically arranged as they are under each account. In addition, the items should be indexed, showing the department or departments to which each item properly belongs. This detail would have been carried out by your committee, if sufficient time were at our disposal to do the work.

The "Classification of Materials and Supplies" submitted was as follows:

Department.

A. Material and Supplies for Maintenance of Track and Roadway.

All material and supplies as classified under Account No. 1, that properly belong only to Track and Roadway.

B. Material and Supplies for Maintenance of Electric Line.

All material and supplies as classified under Account No. 2, that properly belong only to Electric Line.

C. Material and Supplies for Maintenance of Buildings and Fixtures.

All material and supplies as classified under Account No. 3, that properly belong only to Buildings and Fixtures.

D. Material and Supplies for Maintenance of Steam Plant.

All material and supplies as classified under Account No. 4, that properly belong only to Steam Plant.

E. Material and Supplies for Maintenance of Electric Plant.

All material and supplies as classified under Account No. 5, that properly belong only to Electric Plant.

F. Material and Supplies for Maintenance of Cars.

All material and supplies as classified under Account No. 6, that properly belong only to Cars.

G. Material and Supplies for Maintenance of Electric Equipment of Cars.

All material and supplies as classified under Account No. 7, that properly belong only to Electric Equipment of Cars.

H. Material and Supplies for Maintenance of Miscellaneous Equipment.

All material and supplies as classified under Account No. 8, that properly belong to Miscellaneous Equipment.

I. Material and Supplies for Shop.

All material and supplies as classified under Account No. 9, that properly belong only to Shop.

J. Fuel (Coal, Coke, Charcoal, Kindling).

All coal, coke, charcoal and kindling, including coke for welded joints, charcoal for electric line; charcoal, coal and coke for shop; fuel for power; charcoal, coal, coke and kindling for heating cars; coal or coke for heating buildings, and fuel for drying sand.

K. Lubricants and Waste (Oil, Grease, Waste, Rags).

All oil, grease and other lubricants, and all waste or rags used with lubricants, or shop, power plant, cars, track, wagons, etc.

L. Printing and Stationery.

All printing and stationery of every description, including tickets, transfers, legal papers, signs, posters and other advertising matter.

M. Miscellaneous Material and Supplies.

All material and supplies as classified under Account Nos. 14, 21, 22, 23, 24, 28, 29 and 30, that properly belong only to those accounts, and all material and supplies not classified specifically under Departments A, B, C, D, E, F, G, H, I, J, K or L.

The following is a list of the items that it is proper to classify under Department "M."

Arc lights and fixtures.
Babbitt (metals).
Badges (employes).
Batteries (for car bells).
Bedding (stable).
Bell Cord.
Belting.
Blankets (stable).
Bolts.
Brass (metals).
Brick.
Brooms.
Brushes (car washing).
Brushes (flue).
Brushes (generators).
Brushes (horse).
Brushes (motors).
Brushes (scrubbing).
Buckets.
Carbons (arc light).
Cement.
Chamois skins.
Conductor's books.
Conductor's punches.
Copper (metals).
Cotters.
Curry combs.
Emery cloth.
Feather dusters.
Feed (stable).
Fire buckets.
Fire extinguishers.
Fuses (cars).
Garnet paper.
Globes (arc light).
Horse shoeing supplies.
Hose.
Iron.
Lamps (incandescent).
Light (lanterns, oil, wick, torches, candles, incandescent lamps).
Lumber.
Matches.
Medicine (stable).
Metals (babbitt, brass, copper, etc.).
Mops.
Nails.
Nuts (for bolts).
Oil cans.
Packing (for engines)
Painting material (linseed oil, turpentine, varnish, white lead, painter's brushes and supplies).
Paving material.
Pokers (car stoves).
Polish.
Portable registers.
Rags.
Rivets.
Sand.
Salt.
Sandpaper.
Screws.
Shakers (car stoves).
Shovels (car stoves).
Soap.
Spikes.
Sponges.
Sprinkling cans.
Steel.
Stone.
Stove blacking (car stoves).
Tape (insulating).
Tools (hand).
Towels.
Trolley rope.
Uniforms.
Washers (iron).
Washers (car washers).
Waste cans.
Water gage glasses.
Wire.

The President: What is your pleasure with reference to the vacancy on the committee? Shall we fill it here, or shall we leave it to the committee to select some one to fill the position left vacant by Mr. Davies?

On motion, it was decided to fill the vacancy.

The President: The next matter for our consideration is the report on the "Department of Blanks and Forms,'

REPORT ON THE DEPARTMENT OF BLANKS AND FORMS.

By W. B. Brockway, Secretary, Toledo, Bowling Green & Fremont Ry., Toledo, O.

When the call was issued for the meeting which organized this Association, it also included the suggestion that the companies represented at that meeting should bring samples of their blanks and forms in order that helpful and suggestive comparisons could be made. The idea was so well received that a long table was necessary to display the collection. In the exhibition the blanks of each road were placed in a pile by themselves, but the contents could only be ascertained by a detailed search of the pile. The popularity of the exhibit was attested by the constant attention it received and by the packages of exchanged blanks most of the members carried home with them.

At the first annual meeting, held in Niagara Falls, October, 1897, the plan was again tried, but for various reasons it was not so successful as the previous experience at Cleveland. However, a committee was appointed to arrange the blanks presented, and its work was as well done as the blanks and room would permit.

In view of the accepted importance of the idea, it was decided for the convention at Boston in 1898, that a special effort should be made to have the exhibit be of the size and bear the results it deserved Therefore a committee of arrangements was appointed from among the gentlemen in and near Boston, who issued a special circular and those attending that convention are familiar with the thoroughness and popularity of the work.

It was really the object lesson given by the orderly display of the blanks of the Montreal Street Railway Co. at Niagara Falls in 1897 and the classified collection exhibited by the committee at Boston in 1898, which called forth the resolutions establishing the Department of Blanks and Forms and making it a permanent part and feature of the advantages of membership in the Association.

The blanks as they are exhibited this year are mounted in 13 large books 20 x 30 in. and one 30 x 30 in. These books are bound in canvas and are made from special 120-lb. manilla paper, which will insure the wearing qualities needed for exhibition year after year. For the convenience and safety in transporting these many heavy books, there has been provided an oak box, with a shelf for each book, securely locked. And that there may be no reason for heavy handling end over end, it is mounted on heavy castors that it may be readily moved.

In the whole physical make-up of the department care has been taken to have the material as good and permanent as possible. And the assistance authorized at Boston and engaged by the secretary has been of high order, rather than cheap, as he felt confident that the result would be well worth the care and expense. The exhibition, it is hoped, will bear out the soundness of that reasoning.

As a foundation for the blanks preserved there were taken those exhibited at Boston, which, it will be remembered, amounted to several thousand; to this already fine collection there have been added the private collection of the secretary and the complete sets of very many other companies, so that at the present time there are complete or partially complete sets of upwards of 80 companies, many of which are the representative companies of the continent.

The secretary takes this opportunity to thank most sincerely the companies contributing for their cordiality and promptness in granting original and the many special requests made for additional copies of blanks that duplicate and triplicate filing might be made where the construction of the blank demanded it. This co-operation has materially lessened the burden of preparation.

Many methods of classifying were considered, but there were but three which seemed feasible for so large a collection of diversified blanks as this one, viz:

1. By companies whereby the blanks of each company would be placed together in rotation.

2. According to the standard classification in which those blanks relating to each account of that classification are filed under the different headings.

3. Logically, by which is meant the arrangement into classes all blanks of all companies intended for a similar use.

The last plan was adopted for the reasons that if the arrangement by companies had been followed it would still have been necessary to have followed some general classification of each company's blanks. But in the practical use of such a filing, a company satisfied with its entire form list, except this or that blank would be unable to obtain a comparison without searching through every book in the collection, and even then to compare any two blanks on file, possession would have to be had of two or more books, which, according to the law of average would be perpetually in use by someone else which objection would make the annual exhibition a difficult one to make of use.

And in considering the arrangement according to the Standard Classification of Accounts it was found that there were many blanks which applied to more than half the accounts, which, to make the filing complete for each account, would frequently require as many as forty copies of a blank that the face and back could be shown. This is illustrated in the blanks relating to labor, it being obvious that there are few of the 38 accounts in which labor does not form a prominent part. This difficulty seemed so insurmountable that this plan could not be followed.

In view of the difficulties and objections found in the other plans which, to make the filing system easily understood, had to be omitted in the plan adopted, it seemed to be better to make certain classes to contain blanks of all companies. This permits the closest comparisons in each class and will at the same time include in one book all blanks of all companies which in any way relate to that class. It is true this plan has broken up the continuity of the blanks in use by the individual company, but we have substituted a continuity in which all the companies join, for there is a certain channel through which the business of a company must go, and the various changes in the direction of that channel have been followed as closely as was possible. For instance, in the books containing Income it will be noticed that Book A starts with the first record of income, viz: Conductors' Reports. These are followed at once by the Report Envelopes, the Receipts of the Receivers, the Reports and Records of the Counting and Verifying Clerks, etc. Thus there has been a natural sequence kept in mind, but it is one in which all the railroads join for the benefits of a prompt and efficient comparison. It is sincerely hoped that the reasoning by which this plan of filing has been adopted is sound, for the amount of study and time involved is considerable.

The three fundamental divisions into which the collection has been divided are:

1. Income.
2. Expenses.
3. Records and reports.

These are divided further into classes, which can be best shown by the following description of the contents of each book:

Book No. 1—Income A. Consists solely of those blanks relating to the handling, reporting, verifying and depositing the actual cash income, and the daily, weekly and monthly reports of earnings only.

Book No. 2—Income B. Contains tickets and transfers, their records of the number received, used and on hand, and physical records of registers.

Book No. 3—Labor A. Includes the application, investigation, hiring, disciplining and discharging of employes.

Book No. 4—Labor B. Covers all the various steps of paying the employes, from the time reports to the comparison of pay rolls.

Book No. 5—Materials. Is for those blanks for material only from the request for, through the purchasing, receipt, and issue to inventory.

Book No. 6—Maintenance. Consists of the reporting of work done outside of and in the shops. The records of wheels and axles and other blanks not strictly labor or material, but rather the result of their combination.

Book No. 7—Power House. Contains everything relating to the power house, labor, maintenance, operation and efficiency. All blanks in this book are filed, each company by itself.

Book No. 8—Transportation A. Covers the actual operation of the cars from time tables, through the various steps of dispatching and running.

Book No. 9—Transportation B. Is the miscellaneous needs and results of the operation of cars, as instructions to trainmen, secret inspection, lost and found articles, cleaning snow and ice, care mileage, stables, benefit association, etc.

Book No. 10—Injuries and Damages. Takes the accident from the original report of, to the settlement and records and summaries.

Book No. 11—Vouchers, etc. For the vouchers, bills, journal entries and various office stationery.

Book No. 12—Contains monthly and annual reports and comparative statements of earnings and expenses.

Book No. 13—Records. Includes voucher, accounts receivable, check, cash and other general records.

Book No. 14—Electric Lighting. Consists of all blanks relating to electric lighting as a business of itself.

To make the books useful for ready reference there has been provided a system of cross indexing for each book by the use of which a company intent upon only the conductor's reports of the X. Y. & Z. Ry., can readily turn to it without searching for it until found. The index for each book is inside the cover and explains itself, and as a means of assistance to the casual looker-on each page has been labeled at the top to show what form that page contains, so that, in the rush of convention hours, "he who runs may read." Small figures in green will also be found in some corner of each blank to show the date of the original filing. This is done that an intelligent idea may be formed of the changes from year to year.

In many instances it has been important to make a duplicate and sometimes a triplicate filing. This is caused by the combining in one blank the information covered by two or more of the divisions into which the collection is separated. It was thought better to file as many times as necessary, so that the specialist intent upon but one form will still find the collection as complete as possible within the limits of the blanks filed.

In all cases where a blank contains a form upon both sides, each side has been shown and an explanatory stamp has been impressed upon it showing that is the "Front of" or the "Back of" the form to which a hand points. This will save confusion. It is expected that errors of omission and commission will be found both in the classes selected and in filing, and it will be of great assistance if a memorandum be made of each error and handed to the secretary that attention may be given to the correction.

As to the practical working of the department there is to report that the books comprising the official file and annual exhibit are intended to remain in the office of the secretary for continual additions and they will only be moved to make their annual appearances at the succeeding conventions. For the use of members there has been provided a reserve set, unmounted, which are at all times subject to the request of those entitled thereto. A letter of request is an application, and the secretary makes a selection from this reserve set and forwards it to the applicant. Accompanying them is sent a blank giving such information needed to make clear the length of time they may be kept, and the cost (which is always nominal) to the applicant.

This reserve set is treated on a library basis and selections should be returned upon the date allowed (usually 30 days) as it sometimes happens there are other roads awaiting their turn to get the set which is in use somewhere else. It will be of interest to say that this occurs oftener with those blanks relating to materials and supplies than to any other.

In a circular, No. 9, issued from the secretary's office, attention was called to the many requests for sample blanks which every company received. It may be well to repeat the suggestion made, that all such requests be referred to the secretary, who will gladly fill the request, if the company making it is a member of the association, or will courteously decline if not. By this action considerable trouble and expense would be saved the individual company and new members be gained to the association.

While I do not feel qualified to make any extended criticism of the size, shape or other characteristics of the blanks on file, there are found in working over and studying so large a mass of blanks and forms certain little kinks or tricks of practice which have become almost a habit and, while they are harmless and unnoticeable while by themselves in use on the roads where they originate, yet when included in a collection the size of this the comparison

is more or less marked and I cannot refrain from making a brief reference to some of them.

The most prominent of these is the omission of the name of the road. It is not a bad guess, I am sure, to say that of the thousands of blanks filed 30 per cent are without any mark of personality. Very many and devious were the schemes tried to locate blanks of which another copy was necessary for duplicate filing. For instance, one very important blank was recognized only by the water mark in the paper being compared with other blanks till one was found of the same kind, and from this blank we were enabled to find the issuing company. In another case an explanatory note was written on the face of a blank, of which we again needed additional copies, and in this instance no less than 12 different blanks were found with an explanation in the same handwriting, but not one had an identifying mark. The company was only found by comparing the handwriting with the correspondence on file in the secretary's office. It was absolutely necessary to the value of the collection that these two cited should be duplicated, hence the efforts made to locate them.

If there can be any second choice in the shortcomings now being referred to, it is perhaps best covered by the term "ambiguous." A number of these are of undoubted importance to the companies making use of them, yet in the hands of one unfamiliar with the ins and outs of the particular roads by which they are used they become almost meaningless and many were the inquiries sent out by the secretary where a few words printed at the head of the blank would have made the use clear.

In the next thought the other extreme is brought out and I can think of no better term with which to describe it than "Persistent Information," meaning thereby the repetition of information in two or three blanks. The persistency of some forms reminds one forcibly of the annual report required of the steam railroads by the Interstate Commerce Commission, wherein questions are asked in so many ways as to be almost bewildering at times. This class of blanks were difficult to file, requiring many times a duplicate or triplicate filing to properly care for the various information, most of which is contained in other blanks already on file.

While not the most important, perhaps, the most prominent feature of the whole department is the tremendous lack of uniformity in the shapes and sizes of blanks intended for the same service by different roads. One of the largest city companies in the United States has a report measuring 2½ x 4 in., while another road of about the same size requires a sheet 3 x 12 in. for but little more information. In another case one company uses two pages (meaning cross-pages) for a book of record, where another has precisely the same columns and headings and needs but one page, and that is smaller; the difference is in the space allowed for the columns. The larger one has a date column of 3 in. in width, and the number of the report from which the record is made has room enough to run up into the millions, with still room to spare. These are extreme cases, but the principle is unchanged.

Careless press work and ridiculous selection of type make, in some instances, a jarring effect; on the other hand there is often found beautiful and artistic work on the part of the printer, because he knows nothing but that kind of work will be accepted and is governed accordingly. In this connection there is another practice about which much pro and con can be said. I refer to the paper used. There is a vast difference in the cost of "cheap yellow" and "ledger linen," but you will find forms intended for similar uses thus dissimilarly made. There is an average where servicability and economy can and do meet, but it requires an exacting—not petty—management of this branch of the expenses of a railway property.

Further suggestions can properly be made as to the desirability and usefulness of form numbers, whether to make them continuous or to have a set for each department as applied to a small road or a large one. And, again, as to the multiplicity of blanks burdening a small road, as compared to a large one, with not enough to properly attend to its volume of business, both external and internal. These and other questions readily occur to one while examining the collection, but I will call your attention to but one other, to which I have applied the title "Confusion," or perhaps a better one would be "Lack of care in arranging," by which I mean the jumbling together of all kinds of information upon one large sheet, and further, to place on both sides of that the information intended for the busy financial or operating man depending upon your statistics for various information, and he has to literally search for what he wants. This, it seems to me, is caused by a desire to utilize every inch of space of a large sheet, rather than to cut it into smaller ones with information of a similar nature grouped together.

Opposed to these few unfavorable criticisms there will be found very much to commend and admire and use in the mass of blanks brought together. There is many an evidence of careful thought and artistic sense which shows itself in the composition of the blanks of this or that road. There is as much need of genius in the design of blanks and forms, as much a demand for brains and foresight in the logical arrangement of columns and statistics upon paper, as there is in the management of an office, for on one side are "Stationery and Printing" and "Office Expenses," and on the other "Surplus from Operation."

A special vote of thanks was given Mr. Brockway, and it was announced that the blanks would be on exhibition Friday.

Mr. Durbin: I would like to ask, in the first place, whether it is the custom that the storeroom be under the charge of the auditor.

Mr. Hibbs: There is no question but what it ought to be. It is so in your company, Mr. Wilson, is not not?

Mr. Wilson: Yes, as far as accounts go.

Mr. Durbin: I would like to ask Mr. Calderwood what the practice is of handling scrap in accounts.

The President: The scrap goes right into the storeroom account. It is considered a part of the storeroom account and is credited to whatever it is taken from; it is taken back at a certain figure and the additional cost put on at an arbitrary price.

Mr. Durbin: For instance, if you take out a pair of wheels that are to be ground and put back under a car, do you charge those at a reduced valuation?

The President: Yes, and the difference charged off.

Mr. Durbin: Suppose a case of this kind: You have taken out a new axle with a pair of wheels that are practically new for the reason that they are to be ground down, do you charge that at reduced valuation when actually it is entirely new?

The President: No, I should put it in at the full valuation, but I should make a deduction on the wheels.

Mr. Durbin: And does your monthly statement of supplies issued represent the net amount used in each account, or does that represent the total amount?

The President: The net amount.

Mr. Durbin: You credit the storeroom account with the amount received from each department?

The President: Yes.

Mr. Ford: We used to have a report monthly from the store-keeper. We carry a stock of about $25,000, and that report comes in at the end of the month. It is expected to be in the first of the month, but it is very frequently the 10th before the store-keeper gets out his figures for disposition. So we adopted a system of daily reports from the store-keeper and his report comes in, showing the material that has been issued and the accounts that should be charged. Extensions are made and checked in the accounting office, but first this blank goes to the general manager, so that he can see what has gone from the storeroom the day before. That blank then comes up to my office and is entered in another volume which shows the heading of accounts by numbers across and dates down the edge, on the left hand side for the 31 days of the month. Then we abstract under the different accounts from this store-keeper's sheet, under these different accounts, so that we get what has taken place in the storeroom each day, the next morning. At the close of the month all that we need is the last report. We total these figures together, make our journal entry and the store account is out of our way. The store stock is balanced about every six months.

We have a system of cards showing on one side—each part in the storeroom has a number and is always known by that number after it is given. Stock that goes in that particular part goes on one side of this blank, the amount and price, and on the other side the issuance. This card lasts for six months. It was a system that we got from Buffalo and used there about five years ago.

The principal thing that concerns us as accountants in the storeroom is to get the reports directly and promptly. My experience has been that we are often delayed in getting our reports from the store-keeper. On our roads the store-keeper is under the direction of the manager or the general superintendent, but he

is responsible to me for the accounting. That plan has worked very satisfactorily with us, and I am able to keep very close check on our store account. Perhaps some of you have a much larger stock than we carry, but we find that this system works very well with a stock of about $25,000.

The President: Do you carry the card system any further in connection with the storeroom?

Mr. Ford: No, sir. The motor parts have a certain series of numbers and the track parts have another series, and the repair parts have another, and so on all through the list, and these cards we keep renewing as they run out.

The President: The receipts on one side and the disbursements on the other, so that you can take out these cards and tell just what your stock is?

Mr. Ford: Yes, and it informs the store-keeper, and when he sees that his stock is running low he can make his requisition for supplies. Now, there is one question, while I am on my feet on which I desire to speak, and that is the handling of obsolete parts. You take a stock of $25,000 of thousands of parts, and have a type of car that you were using five years ago, and now you do away with that car, and consequently you do away with the particular kind of equipment required for repairs. How do you get rid of these obsolete parts? How often do you go over them to see where you stand? We show that we have an asset of $25,000 in the storeroom. If I were asked to swear to that amount I could not do it, because we could not sell all the things and realize that amount of money, and yet they cost us that amount. I would like to have some information on that point.

Mr. Newman: In answer to Mr. Ford, I would say that we lay aside an amount for depreciation in the stock account, the same as we do for the equipment. You can bring your stock to what the actual value is, or very near it. Of course, that would have to be subject to stock taking at the end of the year, when you make the final balance sheet for the year's business.

The President: Do you take up each year's account of stock?

Mr. Newman: Yes, sir.

Mr. Wilson: To what account do you charge that?

Mr. Newman: To the different accounts. If it is cars you have to put some of it to cars, but you have to arbitrarily make a depreciation of it. You cannot get at it accurately, except by taking the valuation of the stock each month.

The President: What do you do with the depreciation, for instance, on obsolete parts?

Mr. Newman: Scrap it and sell it the same as we do in accident cases. We charge off each month a certain amount of money for accidents. Of course, at the end of the year we have to adjust it, but we can tell from our past experience just about how much that amount will run.

Mr. Ford: If we have new parts that have never been used, and are using such parts in the repair of our cars, they are full value to us. That has not been depreciated, and it seems to me that instead of figuring depreciation on that store account we could, when we make up our inventory, weed out those parts that are useless and count them as scrap, or figure a depreciation on part and let the good stand at its full value.

The President: How would you treat that depreciation at the end of the year? Suppose you had $10,000 of depreciated stock in the storeroom.

Mr. Ford: I should charge it up to each account, pro rata.

The President: And would you consider that a part of the next twelve months?

Mr. Ford: Yes, I would. I don't think that it would be right to charge it up to one month.

Mr. Hibbs: We have a way of handling that which I think is very satisfactory. We add one-half of one per cent to all stock issued to the storeroom, and at the end of the year the amount of that excess is charged out. Such as has gone into scrap, obsolete material, and we think that will cover almost all the material that is used in that year.

The President: Do I understand that you increase the price of everything?

Mr. Hibbs: Yes, everything that goes to the shop.

The President: How large a store account do you carry?

Mr. Hibbs: About $120,000. We use from $20,000 to $25,000 a month in material in our repairing, and one-half of one per cent is about $2,500 a year and that takes care of the obsolete material.

Mr. Ford: At the end of the year, when you make your inventory, what do you do with the parts that have become useless?

Mr. Hibbs: They are scrapped, not taken in the inventory at all.

Mr. Ford: Then they do not affect your account at all, that is one half of one per cent takes care of that

Mr. Hibbs: Our one-half of one per cent amounts to $2,500 or $3,000, and that takes care of it We watch our storeroom very closely.

Mr. Ford: It seems to me that is a very large amount to charge to your material account, in these days, when there is a cry coming up from our purchasing agents all the time about expenses.

Mr. Hibbs: It does not add very much to the current month — about $200, and it is distributed over a number of accounts.

Mr. Wilson: I do not see but what Mr Ford does that. He scraps his material. I do not arbitrarily put on one half of one per cent, but I add something and every account gets a share.

Mr. Mackay: Then the loss appears in the month in which it occurs and not the following year?

Mr. Wilson: Yes, and you are spreading it out over the same time that your expenses are going on.

Mr. Newman: We have a card similar to the one that Mr. Ford uses. On one side the purchases and prices and quantity, and on the other side the prices and quantity issued. Now you all know that prices have gone up all the way from 25 to 100 per cent in the last year, and you may have stocked up with a stock of, say, trolley wheels at 40 cents, and today you are paying 60 cents for them. Now, you are using so many trolley wheels a month and you want to charge them up in your statement, how do you arrive at the price for those? We take and add the total cost price and total quantity on hand and charge up the average and in that way we find that after we have used all the trolley wheels on hand just what they cost.

Mr. Wilson: Are those cards kept in the store-keeper's office?

Mr. Newman: They are kept in the office. Nothing goes out of the office that is in the general office. The storekeeper has nothing to do with that, except he is sent a copy of purchases so that he will know just what is going to the shop, but the record of the shop is kept on the card in the office and the secretary, who is the man who is making up that account is the man that handles all the charges in the month from the store-keeper.

The President: Does the store-keeper keep any books?

Mr. Newman: Except the book of stock so that he can watch what is going on.

The President: He does keep a record of receipts and disbursements?

Mr. Newman: Yes, he certainly has to do that to arrive at what he has on hand, but it is not the official record of the company.

Mr. Wilson: I would like to ask if the companies represented here carry stock in all the car houses, or whether everything sent to the car houses is charged out directly?

Mr. Ross: We charge everything to each car house.

Mr. Hibbs: Our store-keeper goes around and takes inventory of them each month—paints and oils are kept in that way. We have four or five small substations. That depends very largely on whether there is any repair work being done at the barns or not. The only supplies that are carried by us in the car barn are for replacement and not for repair work.

Mr. Ross: We do repairs at our barns.

Mr. Harder, of Kansas City: Our situation is similar to that just described. At present there is not a very good system of accounts for our storeroom. We claim, however, to use all the supplies from the main storeroom. Very few repairs are made except at the main shop, and the store-keeper's report is made monthly. The store-keeper keeps a ledger of stock delivered, and he gives us a record of the stock issued.

The President: Mr. Mackay, I would like to hear from you.

Mr. Mackay: I would like to get an expression of opinion on the custom usually followed in handling material furnished and sent direct to its objective point—whether it is taken up and handled through the storehouse, or whether it is charged out direct.

The President: Mr. Mackay, we will not have an opportunity to go into that this morning, but please state how you do it

Mr. Mackay: We are charging out direct, and in a great many cases it saves labor.

The President: You mean you do not keep any storeroom account?

Mr. Mackay: Oh yes, we carry that account, but when material is purchased it is sent directly to where it is used and does not go through the storeroom. We carry a heavy stock; our stock will run up from $25,000 to $50,000.

The President: I have reference to that which you charge out directly. Do you buy what is needed for a month, or for a particular period?

Mr. Mackay: Just as occasion requires. Certain articles are always on hand, always in stock, but what I was trying to arrive at, was whether it was customary to handle all purchases through the storeroom or pass them through the purchasing department only, without putting them into the stock. As I say we charge a great many direct.

Mr. Wilson: You spoke about power stations. What do you mean by charging direct. If you buy 2,000 or 3,000 tons of coal you do not charge it to expenses for that month?

Mr. Mackay: Oh, no, but barrels of oil that will be used up that month would be charged up direct to the several houses.

The President: In that case you would have to be very careful. I should think you would be likely to disturb your comparisons.

Mr. Mackay: Yes, if there is any great quantity. That is the question whether you want to deviate at all. We are passing through a construction period now, and it is a question whether the poles that are bought for a line should pass through the storage account or the construction account.

Mr. Goodrich, of Omaha: We are little fellows out in our country, and I would like to hear something on this subject from roads that are under the million dollar point of supplies. We are not as some of the other roads here. Are there any members as small as we are?

Our supplies are brought in and charged out instanter right to the account, and at the end of the year the invoice is taken and these accounts get their credit back. Now, we have very little to credit back at the end of the year. Take our coal account, that wipes itself out practically at the end of every month, and that is the biggest account we have, and I think our last inventory only shows something like $3,000 on hand at the end of the last year. It is from the little fellows I want to hear; is there anything better.

Mr. Newman: I think as a matter of information we ought to know just what we are all doing. Suppose we ask all the members here to vote on that point—those who are absolutely keeping storehouse accounts and those who are charging their purchases directly to the proper account as the purchases are made. I think it would let us know what the general trend of the accounting is, and I would like to know.

The President: Gentlemen, those of you who charge out direct, please raise your right hands. Those who keep a storehouse account, their left hand. It seems to be about equally divided, Mr. Newman.

Mr. Newman: I have been devoting a good deal of time during the last five years to this accounting business, working it up to my satisfaction, and I have never reached that point. That is why I want to talk so much. Referring to the able paper that Mr. Brockway has presented, and which has taken a great deal of work, it seems to me a great shame to just hear it read and then set it aside. Why cannot we do with this what the Association has done with classification of accounts. I believe those blanks ought to be got together and that we should get at a standard system of accounting, taking each branch of a road. A system of blanks which would give the greatest amount of information with the smallest amount of work, and I think that every street railroad company ought to assist in getting these blanks and adopt them, and then we would not come in here and have these discussions. We would come in here and improve the system, but we would not have these discussions, which are so short that we cannot find out really what the other man is doing, and I think that is the greatest work now before the Association. I know of accounting departments in the United States where the same amount of receipts are being taken that are being handled by a certain number of men and of another handled by another set of men just twice as large. I know the reason is that we are all striving for the same object, but do not reach it in the same way. We have not yet a method of reaching the result which the accountants have set before us all. We have been working to get at a system of classification of accounts which furnishes the information to the president, the managers and the stockholders, but we are not yet to the point where we have furnished ourselves with the information by which we can get at those results with a minimum amount of labor. I think the first start has been made in getting the blanks together. Is there anything we can do to get a standard system of blanks, and a standard system of accounting—I mean of handling all the details of the accounting system.

The President: Then your idea, Mr. Newman, would be the appointment by us of a committee on standard blanks.

Mr. Newman: Yes, but I do not think we ought to do it so quickly. It is going to be the next work, as I see it, for the Association.

The President: It seems to me the question before the Association is the handling of supplies. Possibly the committee on the standardization of accounts might take that up. What do you think of that, Mr. Duffy?

Mr. Duffy: I have been very much interested in all this discussion with reference to material and supplies. I have everything to learn about it. In St. Louis we did not have a storehouse account as you gentlemen understand it here, but we appear to have been about as near to it as some of the other gentlemen. In St. Louis we had five different companies that had about seven or eight different barns, and we had four different power houses, we were a road that took about $1,500,000 in receipts, so that we are pretty close to Mr. Goodrich's condition. I made this subject of store-keeping a matter of very great deal of consideration and investigated it among some large systems in St. Louis, but in only one of them was the absolute store-keeping system carried out. I went further, and went into manufacturing plants, notably foundries, and my conclusions were that to go into an elaborate storeroom system on that sized road and under the conditions under which we were operating, would use up a good deal of my energy directed elsewhere, and as a business proposition that I might be spending $2 in one case to save $1 in the other.

Now, I was very much surprised, in answer to the question which was asked, to hear some say that they charged out direct certain things that properly belong in a storeroom. Now, in St. Louis, in taking up the question with Mr. Atkins, who was secretary of one of the companies, I found he did not charge power house fuel, car coal, salt for track, or macadam to his storeroom. Then, I said, none of the larger items that should go into the storeroom account are in at all.

I looked into the thing close enough to find out that about 12½ per cent of our total expenses were expenses that would enter into the question of material and supplies. That included everything. Of that total 40 per cent was power house fuel. So that I concluded that the way that I was doing the thing for as small a road as we had was the best that could be done under the circumstances. Now, in the Chicago City Railway Co. I find they are doing what a number of you gentlemen are doing. As to a large number of articles of value, they carry them in their storeroom account. Now, our storeroom account is very large, nearly $100,000, made up nearly or largely of rails, poles, wire and things of that kind. Now, I believe that the classification of material and supplies is just as important as the classification of the receipt and expense account. If we want to know what our expenses are, divided up into 38 accounts, should we not want to know what our $100,000 stock material consists of; how much of it is distinctly and absolutely material that belongs to any one particular department? For instance, that is absolutely track material and only track material. Now, I approach this question of material and supplies with hesitation, because I am not familiar with it. I have had no experience with it whatever, but it seems to me that the storeroom account in your ledger ought to show, if you have on hand $100,000 worth of material, just what is track material, show what is line material, show what is car material—but there you are again, the question confronts you, what is car material. Do you mean the coal that is carried to heat a car, or the broom for the purpose of sweeping it out? and that is the reason that this classification that was presented to you suggested itself to me. Now, another thing which I might say. Take a road that has 100 miles of track and concludes to reconstruct 10 miles of it. The question of cost comes up. Your engineer makes his calculation as to the cost of tearing up and laying down is so much, and then there is the track material.

How much track material have you on hand? How much line material have you on hand? You are going to put on 10, 20 or 40 new cars, or build them; how much material have you on hand to do the work with? and so on. We have on the sheet that was presented to you this morning, down at the bottom, over 100 alphabetically arranged items. Now, I want to classify the material and supplies. Shall we classify it as it has been suggested here, or shall we ignore that thing entirely. For instance, you have the question of poles, sponges, nails, screws, iron or steel, things of that kind. Now, if you undertook to carry ledger accounts of all these thing your storeroom accounting department would be a bigger institution than your general accounting department. On this question of charging up direct I was struck by what Mr. Mackay said. Rails and poles and things of that kind he charges up directly to the construction account; that is properly chargeable there, but he has a power house that he knows will require five barrels of oil every month, and the oil company receives an order for so many barrels to such a plant. It is a question on one hand of the goods being received, because the power house may at the very end of the month be found to be without any oil, so that on the first day of the next month they would not have anything to lubricate their engines with. This matter of charging out things directly is worthy of consideration in my judgment.

Mr. Ross: I was going to say for the benefit of Mr. Goodrich, that I have three or four roads under my wing, from a hundred thousand up to one million dollars, and that everything for our company, large and small, goes through stores, and I think that is the only way that you can carry out your system properly.

Mr. Henry: With us, we send everything through the store room except such items as are consumed in the month. For instance, macadam cannot be put through the storeroom unless it was stored in a material yard, but we are now taking up the matter of making a store supply account for material in the storeroom as well as the material yard. We found that necessary because we are buying a lot of rails, poles and ties, and other material which would be impossible to charge to any special construction, consequently we will open an account in which to take care of all those matters.

Now, as to the operation of the storeroom, we use the card system. We do not have any trouble in regard to the prices on account of giving all the material that goes into the storeroom, a lot number, and that number carries right through, and it is credited according to the card prices. When that material is consumed, it is called "dead," so that all our cards in use are "live" cards.

The President: How many "live" cards do you have?

Mr. Henry: I think there are fifteen or sixteen hundred in use, something like that, and I figure we will have 2,500 lot numbers. It is increasing rapidly, and those are charged off, not daily, on the cards, but I think we will find it necessary to recapitulate three times a month. Now, if the clerk who has charge of the storeroom gets an order from the office that such an article was delivered on lot so and so, and finds that there was some of the old lot left, he would call me up. That gives a chance to keep track of all the dead material that these gentlemen are concerned about. We are trying to get rid of that all the time. This classification I cannot give you any information on, because we have not adopted any system yet. The committee's classification will help me.

Mr. Ford: How long have you been operating the card system?

Mr. Henry: About seven or eight years.

The President: With reference to Mr. Mackay's paper, we will refer it to a committee of three, consisting of Mr. Mackay, Mr. Ford and Mr. Smith, to report on at the next meeting.

I see we have with us today Mr. C. B. Fairchild, who is now connected with the "Street Railway Review." Some seven or eight years ago, when I first went into the street railway business, I had some very pleasant interviews with Mr. Fairchild on the question of street railway accounting, and I am going to ask Mr. Fairchild to say a few words on this subject.

Mr. Fairchild: Mr. President and gentlemen of the Accountant's Association: I thank you for this invitation for I am glad of the opportunity to look into your faces and to make your acquaintance. I happened into your meeting yesterday nearly at the close of the discussion and was very much interested, and could not but wish that I were a member of your Association that I might engage in the discussion. I heard the expression yesterday two or three times while you were discussing the question of a standard. "You cannot do that" "It is impossible" Now it occurs to me to say that one should never say "I cannot" It is better to say "I can and I will." "It is in me and must out."

In this matter of seeking a standard for making accounts do not get discouraged for it is possible for you to discover a natural standard or unit of measurement for the distribution of your accounts. It is also possible for you to discover or invent a standard for report blanks. It is a matter of thought. All the triumphs of skill in the development of street railways and all that pertains to them and in fact in all the schemes that men put forth, and in the organizations that are formed to carry great schemes to success, thought is exhibited. It is the application of men's thought, (and that of common men just like you and me) to the thing to be done and the conditions to be observed in every detail of daily occupation. Now, I ask, why should we continue to hold to old customs and follow slavishly past methods of accounting? The grandeur of thought is as near to you and to me as to any one. So if each one would study the precise thing to be done by him in his place, to meet the requirements of this accounting matter, he would discover or create a system that will be well fitted to every possible condition. "Insist on yourself" and you can never be discouraged, for what ought to be, ought to be. Nature always works by the shortest possible methods. So if you feel that the system of accounting that you are following is too cumbersome and too laborious then you may be sure a better and simpler method exists, and some one some where will yet find it.

All the things that men have done and are doing are evidences that they have in the past had, and that they still have, undeveloped possibilities beyond what they have ever imagined, and that the secret of developing these latent possibilities is the science and art of thinking. Thought is mind in action, and it is a power which is subtle and potent beyond any other known agency. Since ability is within each one as a truth, by concentrating his thought upon the truth, he will bring it into expression, will solve his problem.

In the science of arithmetic we have a certain relation of numbers; seven plus seven makes fourteen always, and so whenever you have a problem in this science to solve, this combination is always available. In geometry we have a certain relation of lines and angles, and by following the principles involved in these relations we solve problems in the science of geometry. These mathematical facts are merely the right relation of things in this particular science. Now it is natural for us to assume that there is a right relation of things in other lines, in all branches of business, we have facts or truths just as certain, and according to the working of things the taking of these truths into one's thought will bring them into expression. We have but to get the true idea in mind, and it will find expression. And this matter of science of accounts is no exception. So I wanted to say yesterday do not say you cannot do this or that, but be willing to work on and believe that you will yet discover the natural relation that exists in this particular line of business. Let me refer you to Kepler's experience in discovering the true relation between the orbits and the times of revolution of the planets. Believing that a relation did exist he worked for seventeen years on this problem before he found it. He tried all sorts of standards but he finally found the relations between the squares of the times of the revolutions and the cubes of the mean distances from the sun. This relation always existed, but it cost him seventeen years of hard and careful study to demonstrate it. It is not likely, however, that any of you will have to work as long as that to solve this problem on which you are now engaged.

You will pardon me if I speak of my early connections with this subject of classification of accounts, and this subject of blanks. At one of the conventions (at Cleveland, I think) long before this association was formed, I prepared and had on exhibition a large blank book with a very large collection of street railway blanks, but if I remember rightly there were no two sets that were at all alike, so I feel I am almost a pioneer in suggesting the desirability of a uniform system of blanks. Those of you who have read the book published in 1892, entitled "Street Railways or Trams" know that we published at that time a classification of street railroad accounts. When I undertook that work for this publication I found no precedent anywhere, and no forms that I could use; I simply had to invent a classification upon which your association has improved, so I claim to be one with you in this work, and I take a great interest in the accounting department as well as in the me-

chanical or electrical departments, although my attention in late years has been directed more especially to the mechanical and electrical features of street railways; but having had considerable experience in theory and practice of double entry bookkeeping in my early days, I am more or less familiar with the terms that are used in accounting, and have a keen appreciation of the difficulties that you encounter in your particular vocation.

I beg pardon for having occupied more than the minute allotted me, but thank you for your attention.

The President: I should like to ask Mr. Wilson if he will prepare a paper for the next convention on the "card" system. We want to get him on record before this association, and I think that is a very important question.

Mr. Wilson: I will not promise now, but I will consider it.

The President: The next order of business is the report of the committee on resolutions. Is the chairman of the committee prepared to report?

Mr. Burington: Mr. President and gentlemen, your committee on resolutions beg to submit the following:

WHEREAS, At this Third Annual Convention, now assembled in the City of Chicago, the Street Railroad Accountants' Association of America, desires to express its hearty appreciation of the reception given and unstinted hospitality shown its delegates by this great city, and in the same spirit it feels it is indebted to the steam railways and the street railways, which have contributed so much genuine enjoyment through their officials and the local committees having the entertainment in Chicago in charge.

To the American Street Railway Association for its unfeigned friendship and its participation in the discussions and councils of this body.

To the press of the city for the many kind expressions.

To the mayor of the city for a most cordial welcome to this Association.

To the editors and publishers of the "Street Railway Review" and the Street Railway Journal, for their personal attendance and co-operation, and to the "Street Railway Review" for its "Daily Edition" of convention proceedings, therefore

BE IT RESOLVED, That the Street Railway Accountants' Association of America, desires by this resolution to express its sincere acknowledgment of the generous offices and good will shown this body;

And further be it resolved, that these resolutions be spread upon the minutes of this Association and copies of the same given to the press.

On motion, the resolutions were unanimously adopted.

Mr. Smith presented the following report of the committee on nominations:

The nominating committee submits herewith the names of the gentlemen selected to represent the Association for the ensuing year, subject to the approval of the convention:

President—C. N. Duffy, auditor Chicago City Railway Co.

First Vice-President—W. F. Ham, auditor Brooklyn Rapid Transit Co.

Second Vice-President—W. G. Ross, comptroller Montreal Street Ry., Montreal, P. Q.

Third Vice-President—Elmer M. White, cashier, Hartford Street Railway Co., Hartford, Conn.

Secretary and Treasurer—W. B. Brockway, secretary and treasurer, Toledo, Bowling Green & Fremont Railway, Toledo, O.

Executive Committee—J. F. Calderwood, chairman, C. L. Wight and C. K. Durbin.

The secretary was instructed to cast one ballot for these names, which was done.

Mr. Duffy: Mr. President and gentlemen: I was cut in the other room trying to find out where our next session would be held, and my friends, Mr. Smith and Mr. Wilson, held me up and said it would be my pleasure and honor to preside at the next convention. I want to say to you that I deeply appreciate the honor. I want to thank you all for having elected me to the presidency of this Association, and I hope that you will all give me all the assistance necessary, and I shall need it, considering the record of my predecessors, Mr. Wilson and Mr. Calderwood. I suggested to the gentlemen when they notified me of my election, that it seemed to me that we should draw from some of the new material. We started out with 25 members; now we have got over 100, but a good many of those 25 seem to have a good deal to do with this Association, and while I appreciate the honor and thank you for it most heartily, I rather thought you should have selected some of the new material, from some of these new companies that are coming in. But be that as it may, I will do my best and use all the energy I have in the work of the Association.

Ex-President Calderwood: Gentlemen of the convention: I want to thank the gentlemen present for their uniform courtesy, and their co-operation. My trip down the presidential track has been a very pleasant one, and I now take a transfer and will let Mr. Duffy have my seat.

President Duffy, assuming the chair:

As I stated, I have just come from a meeting of the other Association, and I beg to say that the next session will be in Kansas City.

Mr. Smith: Shall we take up the matter of the shortage?

The President: As I understand from the report of the secretary and treasurer, counting $30 dues, that are due, but unpaid, as an asset, we have a net deficit of $79 and some cents. Now, one of the unfortunate conditions of this Association is that we do not get any revenue until the 1st of January, and our expenses are always created prior to this convention. This association has been very economically managed. We cannot expect to reduce our expenses, but we can increase our earnings. The American Street Railway Association at Montreal four or five years ago found itself in exactly this condition, and it very promptly and cheerfully raised enough money at that Montreal convention to more than wipe out the deficit. Now it may suggest itself to you that the raising of the dues from $10 to $20, coming right in with the statement that there was a deficit of $79 might strike you as a very peculiar condition of affairs and that we cannot be very good managers financially. We have had an income of about $1,000 a year, but we are too close to shore; we had better have a surplus than a deficit, and we had better not be confronted in this Association with the question of from where our fixed charges are to come. Now, if it is agreeable to you to make subscriptions towards this end, I will be very glad, on behalf of the Chicago City Railway Co., to subscribe $25 on condition that a sufficient sum is raised to wipe out this deficit, and any others who represent other companies, who wishes to subscribe on the same conditions, can now have an opportunity for any amount he may be willing to give.

Mr. Newman: Inasmuch as I have done so much talking I think I ought to pay for it. You may put me down for the same amount as the president.

Mr. Smith: Will it not be better to send out bills for next year's dues right away at the $20 rate, and then see if we do not have enough. If we do not, then issue a call for subscriptions.

The Secretary: Let me suggest that these subscriptions be made with the understanding if they are needed they are to be called for.

Mr. Ross: I think the subscription should be limited. I think $10 is quite sufficient for any road to subscribe.

The President: I think the idea is a good one, and I think that I will reduce the voluntary subscriptions from $25 to $10 if it is agreeable to Mr. Newman and Mr. Smith.

The convention then adjourned sine die.

CINCINNATI, NEWPORT & COVINGTON.

For the months of September, 1899, and September, 1898, the receipts, expenses, etc., of the Cincinnati, Newport & Covington Street Ry. were as follows:

	1899	1898
Gross receipts	$62,782.30	$80,394.65
Operating expenses	24,078.34	30,591.83
Net earnings	38,703.96	49,802.82
Tolls, damages, taxes, etc.	11,897.93	10,555.74
Net profit	26,806.03	39,247.08
Ratio of expenses to earnings, with tolls	49.78	45.93
Ratio of expenses to earnings, without tolls	38.35	38.05

For the first nine months of 1899 the gross receipts were $527,192.79, an increase of $13,000.63 over the corresponding period for 1898; and the operating expenses $214,269.14, a decrease of $51,649.71. For this period the operating ratios are 52.96 and 40.64 per cent as against 62.39 and 51.78. The net profit to October 1st, is a trifle more than the entire net profit for the year 1898.

AN OPEN LETTER TO MR. YERKES.

Mr. Chas. T. Yerkes, President,
Chicago Consolidated Traction Co.

Dear Sir: When I tell you I represent the smallest street railway in the United States, and possibly in the world, I am very sure you will pardon this encroachment upon your time. I read with much interest in the daily edition of the "Street Railway Review" of October 18th, your ideas touching street railway investments, and mean to treasure up the suggestions made by you and by Messrs. Wyman, Beggs and others on the same line, and hope in the near future to profit by them, not so much by investing myself, but by clear and full statements to induce others to help me.

Your description of the little horse lines, first with one, then two horses, with the fare box in one end of the car, was very good, and seemed natural to me, although it made me feel all fired poor, but remembering that you, too, had seen street railways "in their infancy and swaddling clothes," it gave me great satisfaction to be able to say that here in Hendersonville, 2,252 ft. above sea level, amidst the finest scenery and with the finest water, and best all year round climate under the canopy of heaven, is a horse street railway which has been operated eight years and does not owe a dollar.

At the date of the World's Fair, Chicago, with a million of people, stood by us like a sister, with a great number of horse cars; but she has since deserted us and only Washington, the capital of the United States, New York, and a few other small towns remain true to their first love and linger with us at the tail end of the procession. But we are coming, though we may have no cow to kick a lamp for us. Hendersonville stands upon the western border of a 10-mile square plateau, nearly as level as the lands upon which the great city of Chicago stands. The number of business houses in the place has doubled within the past year. The Flat Rock, which has been the home of wealthy southerners for more than a half century is three miles south, and the entire space between is rapidly filling up with good residences, thus increasing a demand for street car service of modern type.

I have 1½ miles of track well located in town and a 90-year city charter, with exclusive rights on all streets and avenues within the town limits, now extending one mile from a common center. We must have an electric street railway and electric lights. I will transfer my little line and franchises on liberal terms, or will aid in the enterprise to the fullest extent of my ability. Can you do anything for our good? Yours truly,

S. V. PICKENS,
Owner Hendersonville Street Ry.

Hendersonville, N. C., Oct. 22, 1899.

WARSAW TRAMWAYS.

In endeavoring to obtain information at first hand regarding the street railroad operations in Russia we have received the following from a correspondent at Warsaw:

Electric street cars are operated in Poland and in the neighboring provinces of the empire at Lodz, Minsk and Witebsk. New lines are in course of construction at Lublin and from Pabianice, via Lodz, to Zgiers. Another line is proposed between Dombrowa, Sosnowice and Bendzin. The systems used are overhead wires and trolleys. The machinery is obtained from Germany, where also the cars are constructed. No statistics whatever are to be had in reference to the mileage, number of passengers carried, rate of fare the cost per mile of transportation, the wages of employes, the regulations as to speed, etc., of the various roads in the different towns, as the builders have no reason to publish them; besides this the lines have only been in operation for a few months. The line from Pabianice to Zgiers is 18 miles in length. Americans do not have any share in extending and operating these roads. In electrical undertakings the capital stock is mostly held in Germany; in street cars it comes from Belgium.

A line of horse cars is in operation at Wilna, length 9 versts, (6 miles). The fare is 5 copecks (2½ cents). This was built in 1883 There is also one at Warsaw. The distance traversed is fully 5,3 miles. The number of cars running is 130. They carry 22 passengers in winter and 30 in summer (closed and open cars). Last year the number of passengers was 20,465,000. The fare is 7 copecks (3½ cents) in the first class and 5 copecks (2½ cents) in the second, for a run of about 3½ versts (2,321 miles). The average speed by contract is about 8 km (4,968) per hour and each passenger is supposed to travel about 2½ versts. The drivers receive 33 ruble (ruble, 51 5 cents) the guards from 36 to 42 rubles a month. The cost per mile of transport is not published, in fact it is kept a secret.

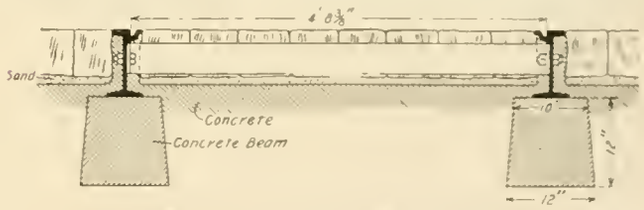
The capitalization of the principal tramway companies in Russia is, Warsaw, 6,000,000 francs; Kazan 2,100,000, Moscow, 5,000,000, Odessa, 6,300,000; Rostoff, 3,000,000, Tiflis 1,300,000; and in Charkoff, 1,500,000 francs. The net earnings are not known The Warsaw trams have paid steadily increasing dividends from 6 to 10 per cent The electric trams at Witebsk were only started a few months ago by a Belgian company They run 20 cars for 30 passengers each It is said that the gross income is 20 rubles per car, against 6 rubles working expenses. The fares are 5 copecks (2½ cents) and 3 copecks (1½ cents) The Lublin electric trams are to be built and worked by Messrs. Lameyer, of Aix la Chapelle

There is a good opening for American capital in this district German, French and Belgian capitalists are continually starting manufactories of all sorts in this country; they also put large sums of money in coal and other mines in Poland and which make this country essentially fit for industrial enterprises of all sorts.

The Belgian company which built and worked the tramway system of Warsaw is now expiring and a new company has taken its place. This is nominally a Warsaw syndicate, but is so only by name as it is really the firm of Siemens & Halske. The contract is for four years only, for it is reckoned that before the expiration of this period the electric light question for the city will then be definitely settled. Siemens & Halske would, of course, like to take the matter in hand and for this reason they have taken the four years contract at the nominal price of 20,000 rubles a year. They give the magistracy an insight into all their earnings and expenses and hand over the whole of the profits, bar the above sum.

TRENCH ROADBED CONSTRUCTION IN BROOKLYN.

The engineering department of the Brooklyn Rapid Transit Co has recently completed a section of track 1,000 ft in length or Court St., extending from Joralemon St to Atlantic Ave., with the construction illustrated in the accompanying engraving; only one track has been built in this manner. From the illustration it will be noticed that the rails rest on concrete beams without wooden ties, and are held to gage by means of tie bars as shown. The standard grooved 98½-lb. girder rail is employed and the paving is laid flush with the top of the rail on both sides. The two concrete beams con-



BROOKLYN TRENCH CONSTRUCTION.

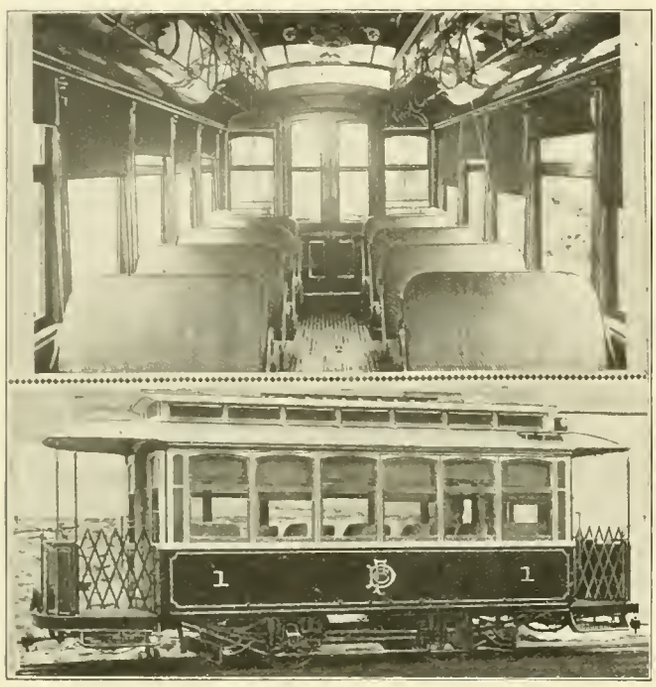
tain 1 5-6 cu. ft. of concrete per lineal foot, being 12 in. on the base and 12 in. in height, tapering to 10 in. across the top. The construction has been installed partly at the suggestion of the city engineer with the view of securing a uniform foundation for the paving blocks between the rails, for the reason that on such lines as have been constructed with concrete between the ties the paving has settled so that the location of the ties can be noted by examining the surface of the paving. Some experience has already been had by this company with rails laid directly on concrete foundation, for concrete construction was employed on the approaches to the Brooklyn Bridge. The service, however, has not yet been sufficiently extended for any report as to durability and cost of maintenance.

The Uniontown (Pa.) Electric Ry. has passed into the hands of the combine which will control the electric roads of Connellsville, Scottdale, Mt. Pleasant and Greensburg. The Uniontown road sold for $60,000, the option being just about to expire when the purchase was made.

NOVEL TYPE OF STREET CAR.

The car shown in the accompanying illustration is one of a large number recently constructed for the Ferro Carril del Districto, of the City of Mexico, by the J. G. Brill Co., of Philadelphia. These were all built on the Brill special system of construction, by which, after being entirely finished "in the white," they are taken apart and shipped, one only of the whole number being completely painted in this country. They have an unusually handsome appearance when finished, the straight side panels setting off to good advantage the gold of the monogram and lettering.

The cars, which are mounted on Brill No. 21 E trucks, equipped with two G. E. 1,000 motors, are 18 ft. in length over the end panels, and have two 4 ft. platforms, making the total length over dashers 26 ft. The total width is 8 ft. 2 in. and the trucks have a 7 ft. wheel base. By a proper designing and putting together of the side frames of the car bodies, an exceedingly strong belt was obtained the entire length below the windows; in addition, braces were also cut in the belt and posts and secured with screws, the sheathing being then put on in the usual way and glue blocked.



BRILL ELECTRIC CAR FOR MEXICO.

From the engravings, it will be seen that the cars are elegantly finished inside, with solid bronze trimmings, and possess the additional good feature of having plenty of light, there being twelve large windows, which are made to drop down into the sides, giving practically a convertible car. The height in the interior from the floor to the belt rail is 2 ft. 3 in. and from the bottom of the sill over the trolley board is 9 ft. There are eight reversible-back seats covered with woven cane and four stationary-back seats in the corners.

As these cars have to be run in trains, there is a 15-in. opening in the center of each dasher to permit of passengers going from one car to another, the openings being fitted with sliding iron doors, which go in from the top and when not in use are placed in grooves at one side of the dasher.

The signal lamps are in a rather unusual position, being placed diagonally opposite each other on the roof landings, on the right hand corner of the car when going forward. Each lamp has four spectacle glasses, presenting four different colors, red, blue, green and yellow. Brill angle iron bumpers, gates, sand boxes and two Dedenda gongs, together with electric headlights, are placed on each car.

The Hartford (Conn.) Street Railway Co. has completed a spur track into a large brickyard on the Windsor road and will put on cars for carrying brick.

MR. O. S. LYFORD.

Mr. O. S. Lyford, the newly appointed vice-president and general manager of the Siemens & Halske Electric Co. of America, was born at Cleveland, O., in 1870. He has had an unusually complete technical education, having graduated from Yale in 1890, after which he took a course in the electrical department of the Sheffield Scientific School and a post-graduate course in electrical engineering at Cornell.

He commenced his practical training in the engineering department of the Chicago Edison Co. In 1893 he entered the employ of the Siemens & Halske Co., rising rapidly to the position of superintendent and chief engineer, which office he resigned in 1897 to become chief engineer for the Westinghouse Electric & Manufacturing Co. He now leaves the Westinghouse Co., to join the executive force of the Siemens & Halske Electric Co.

A NEW ELECTRIC BRAKE.

Of the many powers that have been suggested for applying the brakes on electric railway cars, none seems to offer greater advantages than electricity itself, the greatest point in favor of electrically operated brakes, being of course the absence of auxiliary storage or generating apparatus, as on every motor car current can be taken either from the line circuit or from the motors themselves acting as dynamos. A number of methods have been patented for utilizing electrical energy for setting brakes, the latest being the Hubbard brake, brought out by the Hubbard Brake Co., of Chester, Pa.

This is an electro-magnetic device arranged to operate the ordinary wheel brake shoes by means of a large solenoid which takes the place of the cylinder in the usual air-brake equipment. The brake is operated from independent controllers, about one-third the size of the car controller, placed on each platform and so connected as to change the motor terminals when desired, converting the motors into generators. This is done independently of the position of the car controllers, whether on or off as the instant the brake controller is set the car controller is dead. The device works whether the trolley wheel is in contact with the wire or not, and will, it is claimed, entirely prevent flat wheels.

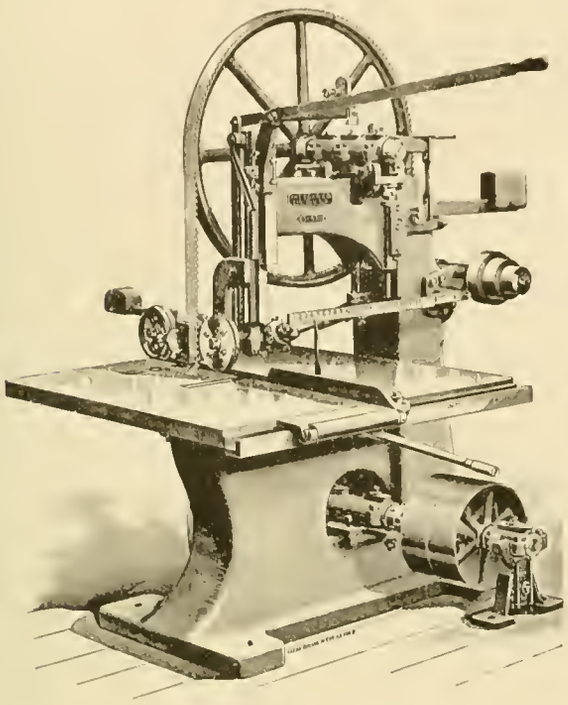
PROJECTED STREET RAILWAY IN HONGKONG.

A number of Canadians, headed by Sir Charles Ross, of Montreal, are said to be interested in the development of street railways in Shanghai and Hongkong. Recently Sir Charles Ross made an offer to purchase the electric light plants of the municipality of Shanghai, provided the municipality would allow the purchaser the right to establish street railways operated by electricity. It appears that this deal failed, for a recent issue of the China Mail says that after his failure to purchase the electric light plant at Shanghai, Sir Charles Ross went to Hongkong, where he remained about a fortnight. The article continues:

"During that time we understand the subject of a low-level tramway for Hongkong was discussed by Sir Charles with a number of influential citizens, and it is believed that a successful issue was reached. It is therefore probable that at last Hongkong will be placed on a footing of equality with the majority of modern cities by having an electric tramway service from end to end of Victoria with possibilities of extension as the colony continues to prosper and to spread. We are given to understand that it is in connection with this scheme, and the proposed addition to the capital, that the present boom is taking place in electric shares which have jumped from $12½ ex dividend, a month ago, to $15, with few shares obtainable at that figure. It goes almost without saying that a low-level tramway of any description will pay in Hongkong. An electric tramway, moreover, is better suited for the narrow Hongkong streets than any other; and given facilities for reaching the outlying districts the people would leave the city more and thus obviate the surface overcrowding which is one of the greatest evils of Hongkong. The scheme should receive the cordial support of the Government, for the reasons we have given that it will help to relieve the congestion of the city."

IMPROVED BAND RIP SAW.

The Egan Co., No. 322 to 342 W. Front St., Cincinnati, is now introducing an improved band rip saw, shown in the accompanying illustration, for which the following advantages are claimed: It is safer to operate, a less kerf is removed, wider and thicker material ripped, less power is required, work is accomplished far more rapidly, table always level and at standard height, rolls close together enabling short pieces to be fed, adjustments of fences and rolls far more quickly accomplished; there is a great saving in time each day in every adjustment made, over circular rip saws. Like all the machinery built by this company, this saw has been very carefully designed for the work it is called upon to perform, and it represents the latest achievement of the large corps of experts which the



IMPROVED BAND RIP SAW.

company has for several years employed in designing new machines and improvements for its existing ones.

There are three speeds of feed, 60, 90, and 135 ft. per minute, and faster feeds will be furnished where desired. The feed is very powerful; the driven feeding-in and feeding-out rolls are placed close together, enabling short stock to be worked to advantage. They are adjustable up and down instantly by means of the long lever above, and convenient to the operator, or they may be raised from the board, instantly stopping the feed, or lifted instantly out of the way for use as a hand-feed rip saw, all of which may be accomplished by a single movement of the long lever.

The Egan Co., as is well known, is the largest maker of wood working machinery in the world.

NEW LONG ISLAND ROAD.

The Nassau Belt Line Traction Co., known as the "Nassau Belt Line," is to build 30 miles of road connecting 12 of the largest villages and towns on Long Island, with a terminus at the famous resort, Long Beach, and the other beaches, and an outlet to New York City by two proposed connecting trolley lines and the Long Island steam railroad system which it touches at five different points and with which the new road has been fortunate enough to make agreements for interchange of traffic, both freight and passenger, by which passengers can be taken to and from their doors to New York or to their homes for a single fare. In fact, nine miles of its tracks consist of branches of the Long Island R. R. which have been leased by the Nassau Belt Line to be equipped and operated by electricity in connection with its system.

The capital stock is $300,000, shares, par value of $100.

The officers are Paul K. Ames, president; William G. Miller, vice-president; Henry L. Nichols, secretary, Fred Ingraham, treasurer. The directors and incorporators consist of fifteen of the leading merchants, bankers and railroad men of the territory covered. The offices are at Rockville Center, N. Y.

Building will begin as soon as the markets show favorable prices and material can be gotten within reasonable time.

DIMENSIONS OF PIPE FITTINGS AND VALVES.

The Walworth Manufacturing Co. has published tables giving the principal dimensions of many of the valves and fittings made by it, and thus placed in a convenient form for reference a great mass of information which is very valuable to engineers and draftsmen when laying out the details of a system of piping. Just how necessary such a set of tables is can only be appreciated by those who have had experience in the class of work mentioned.

The Walworth tables comprise 32 sheets 9½ x 13½ in., arranged in a cloth covered portfolio. They give the dimensions and weights of cast iron tees, elbows, 45° elbows, crosses, long turn tees and elbows, Y branches, flanged unions, companion flanges, riveted flanges, etc., both for 100 lb. and for 250 lb. working pressure; dimensions and weights for wrought iron and steel pipe bends, Van Stone joints, light weight babbitt seat gate valves, bronze seat gate valves, standard and extra heavy globe, angle and gate valves, check valves, Adams angle valves, and suction pipe boxes; dimensions and weights of composition fittings of all kinds; data for floor stands; and four pages of tables giving data for wrought iron, extra strong wrought iron, double extra strong wrought iron, seamless drawn brass and copper, and cast iron piping.

One of its specialties to which the Walworth company directs particular attention is the Van Stone joint for piping under 250 lb. pressure. In this joint only the best quality of soft steel piping can be used as the pipe ends are flanged out over the flanges of the joint which are made of cast iron, gun iron, cast steel or weldless rolled steel.

The company has prepared these data for publication expressly for the use of engineers and will be glad to send a set of the tables to anyone having use for it upon application. The general offices of the company are at Boston, with a branch office at 141 Center St., New York. At the convention the Walworth company was represented by Mr. Herbert L. Rideout.

A MASSIVE VERTICAL ENGINE.

The 1,000-h. p. Allis compressing engine, which is doing such excellent work at the 24th St. air compressing station of the Metropolitan Street Railway Co., of New York, is unique, both as regards its abnormal size and power and the high working pressure which is obtained.

The engine is of the vertical cross-compound type, built at the Milwaukee plant of the Allis Co., and is 60 ft. in height, including the brick foundations. It has cylinders 32 in. x 68 in. x 60 in. stroke. Working with the most economical point of cut-off, with steam at 150 lb., the horse power developed is 1,000. The bearings are 20 in. in diameter by 36 in. in length, while the flywheel, which is placed centrally on the shaft between the cranks is 22 ft. in diameter and weighs 60 tons. The crank shaft is 22 in. in diameter. The air compressor is of the four-cylinder type and placed directly under the engine, four distance rods connecting each engine crosshead with the pump crossheads. The compressor works in four stages, the final pressure of the air after cooling being 2,400 lb. The air cylinders have diameters of 46, 24, 14 and 6 in.; the stroke is 60 in.

SALE OF THE SUTRO ROAD.

A controlling interest in the Sutro Railroad Co., of San Francisco, Cal., consisting of 21,310 shares of stock owned by the estate of Adolph Sutro, deceased, was sold, October 17th, to Robert F. Morrow, president of the Sutter Street Railroad Co., after lively bidding for possession of the property by Mr. Morrow and Jas. B. Stetson, president of the California Street Railroad Co. The price was raised in a few minutes from $160,000 to $215,000, the figure at which the stock was sold.

CLING-SURFACE AT THE CONVENTION.

Messrs. F. C. Willis and A. B. Young, of the Cling Surface Manufacturing Co., of Buffalo, with Chicago office at Temple Court Building, were in constant attendance at the exhibition hall, where they made a display of samples of "Cling-Surface" and told of the good results that are being obtained with this material. As is well known this is a dressing, which when applied to a power transmitting belt, whether leather, rubber or cotton, will permit it to be run so slack that the two sides will nearly touch, without slipping or loss of power. It also renders belting soft and pliable and waterproof.

EXHIBIT OF THE CLING-SURFACE MANUFACTURING CO.

The laboratory force of Sibley College, Cornell University, early in April of this year made an exhaustive test of this material under the direction of R. C. Carpenter, professor of experimental engineering. Prof. Carpenter in summing up the results of the test says:

"The general results of the test with 'Cling-Surface' show an increased transmitting power as compared with the same belt in an untreated condition; it also shows an increased arc of contact, and very much less slip. It shows a very high transmitting power when the belt is run extremely loose or with very little tension on the pulleys, the reverse of which is true with the untreated belt."

IMPORTANT EXTENSION AT UTICA.

The Utica (N. Y.) Suburban Railway Co., of which Mr. J. W. Boyle is general manager, is about to build 10 miles of new track. This extension is from the village of Oriskany, about midway between Utica and Rome, direct to the city of Rome. Near Oriskany, where the battle of Oriskany was fought, is located Summit Park, one of the principal summer resorts of central New York, and which receives an extensive patronage from Rome, with its 18,000 population, Utica with its 65,000, and other nearby villages. The proposed extension will afford Romans the same conveniences and opportunity of reaching the park which Utica has. The line will connect Utica and Rome, making, when completed, a 15-mile ride between these two cities.

Oneida County is a double shired county, courts being held alternately at Rome, one of the shire towns, and Utica, the other. The business relations between the two cities are close and quite extensive. The only communication now is by way of the New York Central, and it is believed that this new line will prove not only a great convenience to the locality, but a decided financial success.

The three-phase transmission system will doubtless be used, the power being generated at the plant of the Utica Belt Line Co., the lessee of the Suburban road, and transmitted to a point near Summit Park, where a converting station will be placed, and also to Rome, where another converting station will be located. It is planned to construct the road in the best possible way, and to provide powerful equipment so as to permit of fast time being made between Rome, Oriskany, Summit Park and Utica.

The property owners along the route have held meetings to promote the scheme, and prominent citizens of Rome have been active in aiding the enterprise so that, although a franchise had at one time been refused the company, the sentiment has so changed that at the last meeting of the common council a very favorable franchise was obtained.

CONSTRUCTING A DOUBLE CONDUIT IN NEW YORK.

The work of installing a double conduit on that portion of the Amsterdam Ave. line in New York, which will be used jointly by the Metropolitan Street Railway Co. and the Third Avenue Railroad Co., has been attended with great difficulties, as cars were constantly passing on a two minute headway and the conductor rail had to be kept alive the entire 24 hours of the day. The Metropolitan company has been using this track for over a year and a half, and had its standard center slot conduit construction in place, but when the Third Ave. company was granted rights of way over the same street, it became necessary to push the existing conduit over to one side of the center, in order to make room for the conduit and conductors of the new comer.

To do this the pavement was first removed, and the heavy concrete foundation and conduit wall broken up. This was removed piece by piece from around the yokes and live conductor rails, the track being shored up to carry the heavy cars and street traffic. Temporary wooden yokes were then inserted to maintain the gage of the track rails, and the old yokes were loosened and pushed to one side, carrying with them the old slot rails, insulators and conductor rails. The conductor rails were then removed in single lengths and the free ends fitted with slippers to prevent the shoes on the plows from being carried away. The old yokes were next taken out, and the new ones inserted. These were fitted for the two conduits which are symmetrically placed between the track rails. Both companies will use the same track rails but will have separate sources of power.

ANNUAL MEETING, TOLEDO TRACTION CO.

The annual meeting of the stockholders of the Toledo Traction Co. was held on October 10th, at which the old board of directors was re-elected for the following year, with the exception of George W. Hale, who succeeds his brother, William E. Hale, deceased. No change was made in the officers of the company, who are: Albion E. Lang, of Toledo, president; Thomas H. McLean, of Toledo, vice-president; John B. Dennis, of New York, treasurer; Barton Smith, of Toledo, secretary. At the meeting a number of plans for improvement were discussed, and these will be made from time to time to keep pace with the growth of the city. No radical changes are contemplated at present. At the close of the business meeting the Traction company's Centennial Band gave the officers and directors a complimentary concert.

MILLIONAIRE GOES TO JAIL.

After more than two years of appeals and writs and other technicalities known to the law, W. B. Bradbury, the San Francisco millionaire, who on May 13, 1897, was sentenced to 24 hours in jail for violating an ordinance against expectorating, has at last served his time in the county lockup. When the expectoration ordinance applying to street cars was passed in San Francisco, early in 1897, Mr. Bradbury became its first victim. He was convicted, but at once commenced a legal fight for stay of sentence, that is almost unparalleled in the history of the state. The case was taken to the upper courts and after it had been passed upon by nearly every judge in the locality, it was brought to a close a short time ago by the refusal of the Supreme Court to grant a writ of review. Mr. Bradbury was accordingly rearrested and compelled to spend a day in jail.

An ordinance has been passed by the Chicago City Council instructing the Chicago Union Traction Co. to run its cars in North State St. from the hours of 7 to 9 a. m. and 5 to 7 p. m. at intervals of not more than 90 seconds. The right of the city to regulate the running schedule will be contested in the courts.

PERSONAL.

MR. TOM L. JOHNSON, it is said, will hereafter make his residence at Louisville, Ky.

MR. FRANK FRYE, of Peekskill, N. Y., has been made permanent receiver of the Peekskill Traction Co.

MR. FRANKLIN WOODMAN has been chosen general manager of the Nashua (N. H.) Street Railway Co.

MR. FRANK J. SPRAGUE was married on October 11th to Miss H. C. Jones at Hillview, New Hartford, Conn.

MR. CHARLES J. BOCKHOLDT has recently been appointed general superintendent of the Freeport (Ill.) General Electric Co.

MR. F. M. ZIMMERMAN, of Atlanta, Ga., will succeed Mr. Frank M. Haines, as superintendent of the Lorain (O.) Street Ry

MR. STEPHEN A. NYE has been chosen treasurer of the Lewiston (Me), Brunswick & Bath Street Ry, to succeed the late Hon. I. C. Libby.

MR. ANDREW THOMSON has been elected president of the Quebec, Montgomery & Charlevoix Ry., in place of Mr. H. J. Beemer, resigned.

MR. H. R. FEHR has resigned his position as city engineer at Easton, Pa., to become superintendent of the Easton, Palmer & Bethlehem Electric Ry.

MR. FRANK M. WEBSTER, claim agent of the Consolidated Street Railway Co., Grand Rapids, Mich., was a caller at the "Review" office when in Chicago last month.

MR. GEORGE MOFFAT, the well known electrical engineer of Philadelphia, has sailed for Europe and will take active part in the construction of the London United Tramways.

MR. CLARENCE E. STUMP, of New York, who is widely known through his connection with the electrical technical press, has been appointed business manager of the Christian Herald.

MR. HENRY NOTT RANSOM, purchasing agent of the International Traction Co., Buffalo, on November 21st will wed Miss Alice Gillet, daughter of Mr. and Mrs. Elmslie Morven Gillet, of New York.

MR. FRANK M. HAINES, superintendent of the Lorain (O.) Street Ry., has tendered his resignation, it is said, to accept a similar position in London, Eng., on lines recently purchased by Tom L. Johnson.

MR. FRANK E. ROWELL, of Kittery, Me., who has been the clerk and a director of the Portsmouth, Kittery & York Street Railway Co. since its organization, has been chosen as treasurer of the company to succeed the late Hon. I. C. Libby.

MR. C. E. WILSON, since 1893 in charge of the electric power stations of the National Railway Co., St. Louis, was on November 1st appointed superintendent of motive power and chief engineer of the Chicago City Ry., succeeding Mr. C. J. Reilly, resigned.

MR. W. J. CLARK, manager of the foreign department of the General Electric Co., has left Europe and gone to Argentine Republic in the interest of his company. A large demand for electrical apparatus is expected from South America in the next few months.

MR. W. W. WHEATLY was on October 21st appointed acting general superintendent of the surface lines of the Brooklyn Heights Railroad Co. in place of Mr. Ira A. McCormack, who resigned to accept the office of vice-president of the Syracuse (N. Y.) Rapid Transit Co.

MR. GEORGE M. KUEMMERLEIN is about to retire from his position as superintendent of transportation of the Milwaukee Electric Railway & Light Co., in order to take a much needed vacation. He has been with the company over 25 years, having begun as a horse car driver.

MR. CHARLES S. BUTTS, until lately with the Duluth, South Shore & Atlantic Ry., a steam road, has been appointed engineer for the St. Louis & Suburban Railway Co. We welcome Mr. Butts back to the street railway field where he had a wide experience before taking up steam road work.

MR. W. F. HAM, secretary of the Nassau Electric Ry., Brooklyn was married on Tuesday, October 10th, to Miss Suzanne Mulford; they will be at home after December 1st at the Hotel St. George Congratulations are most heartily extended, particularly from Mr Ham's many friends in the Accountants' Association

LORD KELVIN'S chair at the Glasgow University has been given to Professor Andrew Gray, a well known writer on electrical scientific subjects and at one time assistant to Sir William Thomson in the University. His appointment to the place left vacant by the resignation of Lord Kelvin, will undoubtedly meet with the approval of all concerned.

MR. CALVIN W. RICE, electrician for the New York Consolidated Telegraph & Electrical Subway Co. and the New York Gas & Electric Light, Heat & Power Co., will visit Purdee University and lecture on November 15th, before the students of electrical engineering on the "Development of High Tension Service." While in Lafayette Mr. Rice will be entertained by Prof. W. P. Goldsborough.

MR. ROBERT M'A. LLOYD, whose name has been closely associated with the development of the storage battery in America, and who was recently elected president of the Electric Vehicle Co., has been made president of the Siemens & Halske Electric Co., succeeding Mr. Isaac L. Rice. Mr. O. S. Lyford, formerly with the Westinghouse Co., has been made vice-president and general manager of the Siemens & Halske Co., with headquarters at Chicago, taking the position formerly held by Mr. C. S. Knight.

MR. J. CHARLES MOORE, who has for several years held the office of secretary of the Yerkes roads in this city, and who filled the same position under the new organization of the Union Traction Co., has resigned to go into business for himself. He has become associated with the well known firm of A. L. Dewar & Co. bankers and brokers, and will carry with him the esteem and confidence of a large clientage. His numerous friends wish and predict for him a large degree of success in his new work.

MAJ. RUSSELL B. HARRISON, inspector-general of volunteers, in Cuba, who has been dangerously ill with yellow fever, has nearly recovered his usual good health. Major Harrison was much annoyed, while convalescent, to hear a report that had been quite generally circulated to the effect that he caught the fever while carelessly, and through curiosity, handling an old coffin and clothing used by Spanish soldiers in burying their dead. This the major wishes to state is false, as he was simply obeying orders when he absorbed the fever germs.

CAPT. ROBERT M'CULLOCH, formerly general manager of the National Railway Co., of St. Louis, and now general manager of the Chicago City Railway Co., was the recipient recently of a handsome memorial from Mr. Corwin H. S. Spencer, as president of the National Railway Co., attesting his sterling qualities and capabilities as a street railway man. The memorial was bound in red morocco, with Capt. McCulloch's name in gold letters on the outer cover. On the title page appeared his name in water colors and in the scroll were representations of a bob-tailed car and a modern electric vestibule car.

MR. SIEZO MISAKI, chief engineer and superintendent of the Hanskin Electric Railway Co., of Kobe, Japan, was in attendance at the street railway convention at Chicago. Mr. Misaki informed

us his road, which will be built early next year, is an interurban connecting the city of Osaka, having 600,000 inhabitants, with Kobe, a place of about 180,000. The line follows the highway outside of the two cities named and the several large towns through which it passes. Between these towns is the richest wine district in Japan. The work involves some difficult engineering problems, one of which is the construction of 3,500 ft. of bridging and trestles in crossing a river. The road will be double track, and it is intended to install according to the very latest and best practice.

MR. IRA A. M'CORMACK, superintendent of the Brooklyn Rapid Transit Co., has resigned his position as such to accept the vice-presidency of the Syracuse Rapid Transit Co., to which office he has been elected. Mr. McCormack stands among the most practical railroad men in the country. He had 20 years' experience in steam railroad work before going to Brooklyn, and was gradually promoted from a minor position to one of large responsibility. In his new position he will have complete control of the management of the Syracuse company's lines. Mr. McCormack will reside in Syracuse, where he lived before going to Brooklyn. In the latter city he has made many close acquaintances. He is a member and trustee of the Lincoln Club, and is also the second vice-president and trustee of the Eagle Saving & Loan Co., of that city. Mr. McCormack is also an active member of the American Street Railway Association and is a member of the executive committee.

OBITUARY.

CAPT. C. E. HALL, who for many years was connected with the Chicago City Ry., died at his residence in this city October 26th. He constructed most of the steam roads in Cuba which were built prior to 1863; he served through the Civil War, and was 70 years of age.

WINFIELD SMITH, of Milwaukee, died suddenly of heart disease in London, November 8th. He was one of the early day capitalists of Milwaukee, and for many years largely and actively interested in the street railway there. He will be remembered by convention goers during the first 10 years for his excellent judgment and genial manner.

ELECTIONS.

THE PEOPLE'S RAILWAY CO. has been reorganized with officers as follows: President, John A. McMahon; first vice-president, H. J. Crowley, of Philadelphia; second vice-president and general manager, George B. Kerper; secretary and treasurer, C. L. S. Tingley, of Philadelphia; assistant secretary, Eugene Wuichet.

THE HAVANA TRACTION CO. has chosen officers as follows: President, Sir William C. Van Horne; vice-presidents, P. A. B. Widener and R. A. C. Smith; secretary, J. M. Ceballos; treasurer, Frederic Nicholls.

THE YOUNGSTOWN (O.) & SHARON ELECTRIC RY. have chosen the following officers: President, W. H. Clark; vice-president J. C Whitla; secretary, B. F. Wirt; treasurer, Thomas Patterson. Messrs. Whitla and Patterson are of Pittsburg, Pa., and represent Brown Bros. of that city.

THE DUBUQUE (IA.) STREET RY. has been purchased by Linehan & Molo, of that city and the following officers have been elected: President, Bart. E. Linehan; vice-president, C. H. Eighmeg; treasurer, William S. Molo; secretary, D. E. Lyon.

THE TERRE HAUTE ELECTRIC CO. has elected the following officers: President, W. R. McKeen; vice-president, J. G. McNutt; manager, C. B. Kidder, all of Terra Haute. The consulting engineers are Stone & Webster, of Boston.

THE WILLIMANTIC (CONN.) STREET RAILWAY CO. has been organized with the following directors and officers: Directors, W. H. Abbott, J. M. Pettis and W. Ward Tuttle of Boston, Alderman W. D. Grant and George K. Nason of Willimantic, and the law firm of Clark & Arnold, of Hartford. The officers are: President, J. M. Pettis; vice-president, George K. Nason; secretary, W. Ward Tuttle; and treasurer, W. H. Abbott. President Pettis says that the company expects to have its cars running by June, 1900.

THE JOLIET RAILWAY CO. at its annual meeting chose W. B. McKinley secretary and general manager, and C. S. McManus general superintendent. The directors are G. F. Duncan, J. E. Burnham, H. P. Cox, Walter Davis, E. Winslow, E. Woodman, A. A. McLeod, S. W. Pettit and H. J. Crowley. The line from Lemont into Chicago will be laid early in the spring over the route controlled by the Cook County syndicate, a settlement to that effect having been made with the latter.

THE METROPOLITAN RY. CO., Toronto, Ont., has elected the following officers and directors: President, C. D. Warren; vice-president, S. M. McElroy; secretary and treasurer, R. Jenkins; directors, C. D. Warren, S. M. McElroy, W. A. Warren and F. B. Warren.

THE NORTHAMPTON & AMHERST STREET RAILROAD CO. has elected the following directors: B. E. Cook, jr., H. L. Williams and C. K. Graves of Springfield; M. A. Coolidge and F. S. Coolidge of Fitchburg; E. C. Crosby and C. W. Wyman of Brattleboro, Vt. The directors organized as follows: F. S. Coolidge, president; B. E. Cook, jr., vice-president; C. W. Wyman, clerk and treasurer; F. S. Coolidge, B. E. Cook, jr., and E. C. Crosby, executive committee.

THE OFFICERS of the newly consolidated New York & North Shore and Long Island Electric R. R., to be known as the New York & North Shore Railroad Co., are as follows: President, R. T. McCabe, 29 Broadway; vice-president, Jacob R. Beetem, Flushing; treasurer and secretary, G. S. Terry, Whitestone. The other directors are Edward J. Matthews, William H. Shelmerdine and Charles A. Porter, all of Philadelphia; Clarence D. Simpson, Scranton, Pa.; William F. Hogan, 643 10th St., Brooklyn; and William E. Stewart, 19 Liberty St., Manhattan.

THE PALMER (MASS.) & MONSON STREET RAILWAY CO. on October 25th, chose the following directors: E. G. Childs, H. E. W. Clark, Andrew Pinney, E. G. Hastings and H. P. Holden of Palmer, George C. Flynt of Monson, Fred T. Ley of Springfield, and Allen Page of Bridgeport, Conn.

THE AUBURN (N. Y.) INTERURBAN RY. has elected the following directors for the ensuing year: L. S. Ebright, E. I. Edgcomb, G. B. Leonard, C. D. Beebe, George B. Longstreet, William F. Rafferty, George B. Turner, Frederick T. Pierson and A. P. Rich.

THE JERSEY CITY, HOBOKEN & PATERSON STREET RAILWAY CO. has elected the following officers: President, David Young, of Newark; vice-president, John F. Shanley, of Newark; treasurer, George W. Roe, of Newark; secretary, William C. Doubleday, of Jersey City; directors, William C. Shanley, of Newark; William J. Davis, of Harrison; Bird W. Spencer, of Passaic; Peter Hauck, jr., of Newark; Edward L. Young, of Jersey City; Philip Hexamer, of Hoboken; James J. Corbiere, of Caldwell; Halsey M. Barrett, of Bloomfield; David Young, John W. Ombersen, of Newark; Frank M. Stillman, of Rahway; George R. Waite, of Jersey City; John F. Shanley and Warren S. Hall, of Hoboken. This company is a consolidation of several street railway companies operating in Paterson, Hoboken, Passaic, Jersey City and Rutherford. Its capital stock is $20,000,000.

THE BRISTOL & PLAINVILLE TRAMWAY CO., of Bristol (Col.), has elected Mr. Albert L. Sessions a director to take the place of Mr. John H. Sessions, deceased. The others of the old board have been re-elected for another year.

NEW PUBLICATIONS.

"THE PICTURESQUE VALLEY" is the title of a handsome brochure, published by the Waverly (N. Y.), Sayre & Athens Traction Co., describing the points of interest in the country through which its lines pass. We are indebted to W. E. Case, superintendent of the company, for a copy of this pamphlet.

"AUTOMATIC LUBRICATION" is the title of a new illustrated catalog published by the Siegrist Lubricator Co. This work is carefully compiled and handsomely gotten up, setting forth the merits and advantages of automatic lubrication and showing illustrations of a number of plants where the Siegrist sysem of oiling is installed. The catalog includes testimonials from some prominent engineers, and the company will be pleased to send it on application addressed to its office, 117-119 Locust St., St. Louis, Mo.

WE ARE IN RECEIPT of the Commercial & Industrial Directory of Osaka, Japan, for 1899, which also includes the prospectus and rules of the Osaka Commercial Museum. This museum, which was established in 1890, contains a number of different departments, one of the principal ones being devoted to foreign articles. This contains exhibits of various kinds collected from foreign countries, including models of machinery, etc. Large additions are made annually and a special fund is provided to facilitate the collection of samples. Foreign merchants and manufacturers are invited to send specimens of their wares and these are readily received and exhibited in their proper department.

DURING THE LAST TWO YEARS there have been issued from the press of the Open Court Publishing Co., 324 Dearborn St., Chicago, a series of books on mathematical subjects, edited by Mr. Thomas J. McCormack, which should prove interesting to a large class of readers. Not only those engaged in studying or teaching mathematics, but also those who, having to do more with the practical applications of mathematics, can read the works with profit and pleasure. Mr. McCormack is well known to engineers and physicists through his admirable translation of Professor Mach's "Science of Mechanics."

The first of the present series is a reprint of De Morgan's essay, "On the Study and Difficulties of Mathematics"; the original was published in 1831, and is now very scarce. This work is a great assistance to students and instructors, as it points out and explains many of the difficulties which will be encountered in arithmetic, algebra and geometry, and gives practical hints on methods of study. The editor has added annotations and bibliographies of modern works on algebra, the philosophy of mathematics, pan-geometry, etc.

"Lectures on Elementary Mathematics," by Lagrange, translated from the French by Mr. McCormack, form the second of this series. The "Lectures" were delivered by Lagrange in 1795, and are five in number, treating of arithmetic, the operations of arithmetic, algebra, the resolution of numerical equations, and the employment of curves in the solution of problems; they have furnished the source for many discussions on the subjects of which they treat, but contain much that has not been incorporated in the more common text books.

"Mathematical Essays and Recreations," by Hermann Schubert, translated from the German by Mr. McCormack, contains six essays which can scarcely fail to interest everyone, mathematician or not; no extended mathematical training is necessary for a keen appreciation of this work. The first of the articles—"The Definition and Notion of Number," "Monism in Arithmetic," "On the Nature of Mathematical Knowledge"—after defining number as the result of counting, show how fractions, negative numbers, irrational numbers, imaginary numbers, and complex numbers all follow as extensions of the first results, according to what the author calls the "principle of no exception." This principle is that all operations and results are to be so interpreted that they shall form no exception to those springing from the original real results. In "Magic Squares" is a very interesting account of a mathematical diversion that is now less popular than it formerly was. The fifth chapter is entitled "The Fourth Dimension," and shows what is meant by a "dimension," what the legitimate functions of a fourth or higher dimension are, and that the claims of spiritualism to the fourth dimension are unfounded. "The History of the Squaring of the Circle" concludes the volume, and is a very complete account of an interesting problem which, though it cannot be solved, has been a most important stimulus in developing the science of mathematics.

"Elementary Illustrations of the Differential and Integral Calculus," by De Morgan, is a reprint of the book originally published in 1832, and later as a part of De Morgan's "Treatise on the Differential and Integral Calculus." Mr McCormack has re-paragraphed the text and introduced descriptive sub headings. This book discusses the difficulties met in the early study of the calculus and resolves them in a manner leaving little to be desired.

To the four books mentioned a fifth is soon to be added—"History of Elementary Mathematics," by Dr Karl Fink, translated from the German by Professors Beman and Smith.

The sizes and prices of the four books mentioned are as follows:

"On the Study and Difficulties of Mathematics," 229 pages; cloth, $1.25 net.

"Lectures on Elementary Mathematics," 172 pages; cloth, $1 net.

"Elementary Illustrations of the Differential and Integral Calculus," 144 pages; cloth, $1 net.

"Mathematical Essays and Recreations," 149 pages; cloth, 75 cents net.

ROBBED OF $81,000 ON STREET CAR.

Robert P. Jennings, secretary-treasurer and general superintendent of the Broadway Cable Co., of St. Louis, Mo., was robbed on one of the cars of that company of $81,043 on October 30th. The money, which was in an envelope in his pocket, consisted of $1,043 in cash, which had just been drawn from the bank to be used in paying company's employes, and two checks for $40,000 each. As Mr. Jennings left the bank and was waiting for a car, he noticed two rather well-dressed men standing on the curb near him. When the car came along they got on the car platform ahead of him and stood in the doorway, blocking the way while they asked the conductor, Charles Roster, if the car went to the union station. The conductor told them it did not, and they asked directions how to reach the station, continuing to block the way of Mr. Jennings. As the car was between Lucas Ave. and Morgan St., directly in front of the Union Market, the two men jumped off and were lost in the crowd.

R. B. JENNINGS.

Jennings walked into the car and sat down. As he did so he felt for the envelope. It was gone. He called to the conductor that he had been robbed. The car was stopped and Mr. Jennings got off the car and ran back to where the men alighted, but they had disappeared. He then got back on the car and went to the offices of the company, at 3710 North Broadway, and reported the robbery. The police were notified and a dozen detectives at once were put to work on the case. The company asked the bank to stop payment on the checks.

The scene of the robbery is the busiest down town corner in St. Louis, right in the heart of the shopping district. The streets were crowded at the time, the cable car was well filled and policemen stood at the corner. For boldness the hold-up is unequaled by any previous occurrence of the kind in St. Louis.

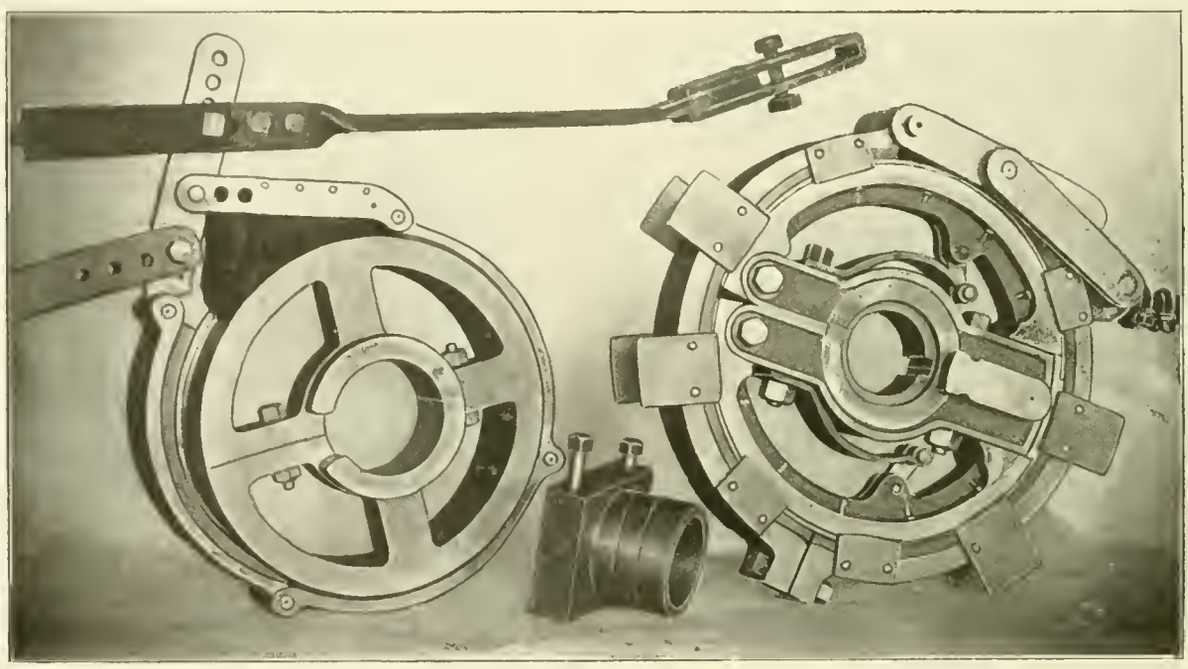
Rumor says that the Lehigh Valley Traction Co., of Allentown, Pa., is to absorb a number of outlying trolley systems connecting with its tracks.

Plans are being perfected for greatly improving and extending the street railway mail delivery service in Brooklyn. Spur tracks will be laid from the nearest lines of the Brooklyn Rapid Transit Co., directly to the dispatching platforms at the post office, so that the mail pouches can be delivered directly to the mail cars without extra handling. This will enable residents of the suburbs to receive mail regularly five times a day, and from an hour to an hour and a half sooner than they have received it heretofore. The Brooklyn Rapid Transit Co. is paid about 10½ cents per mail car-mile.

A COMPOUMD FRICTION BRAKE.

For over a year tests and experiments with a new mechanical friction brake made by the McCollum Compound Friction Car Brake Co., of Toronto, Ont., have been conducted on one of the large double truck cars of the Toronto Ry., with such success that the later company has acquired the right from the owners to equip its entire system with the new invention. Officers of the Buffalo Railway Co., and the Rochester Railway Co., have also decided to further test the device on their respective systems, and one of the large cars running between Buffalo and Niagara Falls is now being fitted for this purpose.

The invention consists of a simple adaptation of the principle of the band brake quite generally used on hoists. There are two wheels 18 in. in diameter, which when fitted closely side by side on the car axle, occupy only 6 in. The rim of one of the wheels is made in two equal sections which are hinged as shown in the accompanying cut. This wheel is keyed firmly to the axle. The other is in one piece and runs loosely on a sleeve keyed to the axle. Between the loose ends of the sections of the first wheel is interposed a rocker clutch which is simply a movable piece of metal, so placed as to spread the sections apart when given a turning or twisting motion. This piece projects far enough from the side of the first wheel to engage, at its end nearest the axle, a recess in the second wheel as shown in the cut. Both wheels turn together at the same speed, being connected by the clutch.



THE McCOLLUM COMPOUND FRICTION BRAKE.

A steel band lined with ½ in. of compressed paper encircles the periphery of each wheel, the band on the loose wheel being compressible, and the band on the expanding keyed wheel being rigid. To this second band is attached the ordinary brake chain that operates the shoes through levers.

To operate the brake the motorman, with suitable connecting rods and a draw lever on the cab, by gently pulling the lever a few inches, compresses the band on the loose running wheel, retarding its motion, and thereby twisting or rocking the loose clutch, which, in its turn, expands the other wheel within the rigid circular band, causing this band to revolve and wind up the brake chain. The wind of the chain being on a circumference 9 in. away from the center of the axle, a compression of only 1-16 in. on the loose wheel friction gives a very powerful leverage on the main keyed wheel friction.

It is claimed with the new device there is no back roll of the car when stopping on grades, in consequence of the wind being so far from the axle. It is further stated that owing to the close adjustment of the device the motorman can, by the sense of touch, tell just what the brake is doing and is able to run his car month in and month out, on any rail, in any weather, without skidding wheels.

The durability of the machine is shown by the fact, that when examined after four months' steady running, having made approximately 13,000 miles, and 106,000 stops, the band linings, upon which the frictional pressure is most severe had not worn down one hundredth part of an inch. This fact and the simplicity of replacing the wearing parts are important features. The brake complete weighs about 175 lbs.

Mr. J. B. Perry, director of the McCollum Co., Bedford Road, Toronto, is about to form a company in the United States to handle this brake.

WESTINGHOUSE ELECTRO-PNEUMATIC CONTROL OF MOTORS.

One of the latest publications of the Westinghouse Air Brake Co. is a pamphlet of 40 pages descriptive of the electro-pneumatic system for controlling railway and other motors which has been developed by that company. This system involves the use of compressed air for moving the controlling apparatus, the admission of the air to the several parts being effected by means of electro-magnets attached to air valves. The air-transmitting and applying apparatus, and the electro-magnetic devices in this system have all been tried in service, being standard parts made by the Westinghouse Air Brake Co. and the Union Switch & Signal Co.,

In this system the number of motor cars per train may be varied at will. Each motor car has the usual current-collecting and controlling devices, and, in addition, on one car at least, is a complete air compressing and storage plant, auxiliary storage apparatus being placed on all the other motor cars. The controller proper may be of any suitable type, the ordinary hand-lever being replaced by a pneumatic operating mechanism. The automatic circuit breaker in connection with each controller may be of any standard type and is also fitted with an operating device similar to that of the controller.

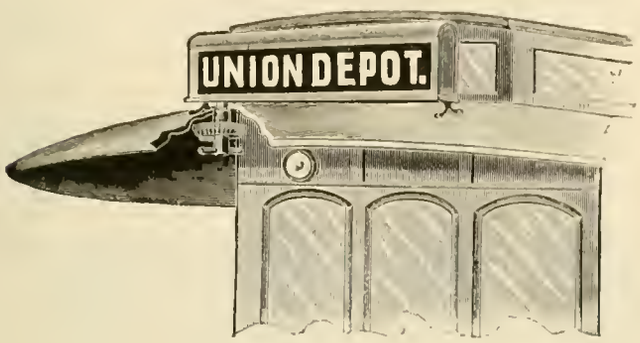
Air is taken from the reservoir which supplies the brakes, and current for the magnets is obtained from a primary or secondary battery. This makes the control independent of the power except that the air compressor is driven by the power circuit.

The operating devices move the controller shaft from notch to notch at the will of the operator just as it would be done by hand, and a complete cycle may be made as slowly or as quickly as the conditions may require. A more complete description of this invention will be given in a succeeding issue.

HUNTER CAR SIGN.

The annoyance and expense incident to the changing of designating car signs, when it is necessary to transfer cars from one route or division to another, are often considerable, especially in the case of a complicated city system, having a number of routes meeting at one central point, as under such conditions it is often desirable to send a car out over any one of a dozen different divisions at a moment's notice. To facilitate this interchange of cars and also to enable the route the car is to take to be as easily distinguished at night as at day, the Hunter Illuminated Car Sign Co., of Cincinnati, O., some time ago placed on the market its illuminated sign, which is illustrated herewith.

The device is 44 in. long and weighs approximately 20 lb. The names of the routes are printed on a strip of Holland curtain material which is carried within the sign on two rollers, the strips holding over 50 different names if desired. The Hunter signs on



HUNTER CAR SIGN.

the cars of the United Railways Co., of St. Louis, for instance, each contain 51 names, and those in Baltimore 44. At night a single incandescent light in front of a powerful reflector, makes the lettering plainly visible a block away.

Among recent orders for this sign is one from the United Railways Co., of St. Louis, for 1,700, making a total of 2,000 now in use in that city; also one from the Chicago City Railway Co. for 520. A few of the many companies which have had the device in use for some time are the United Traction Co., Pittsburg; Consolidated Traction Co., Pittsburg.; Toledo Traction Co., Toledo, O.; Birmingham Railway & Electric Co., Consolidated Street Railway Co., Grand Rapids, Mich., and the Covington & Cincinnati Street Railway Co. It is worthy of note that T. M. Jenkins, formerly general manager of the last named company, was so well pleased with the working of the sign on that system, that he has just ordered 200 for the St. Louis & Suburban Ry., of which he is now general manager.

The Hunter company will send one of its signs, free on trial, to any street railway company in the United States.

CLEANING CARS.

To keep cars bright and attractive, inside and out, requires more than an occasional cleaning down with ordinary soap and water, and this question should receive as much attention as the problem of the best way to paint and varnish a car in the first place, for it is often the case that the result of much time and expense in the paint shop, will be set at naught and made absolutely valueless within a few weeks, in the car barn, by careless and unscientific cleaning.

The Modoc Soap Co., of Cincinnati, O., has given this subject special study for several years, and has had on the market for some time a preparation for cleaning cars known as the Modoc liquid car cleaner, and which has been found by many of the leading roads in the country to be entirely satisfactory for this work. If the liquid cleaner is systematically and properly used, and applied before the car becomes too dirty, it is guaranteed to keep the rolling stock clean and bright and to add at least eight months to its time of service. The company also makes a soap for occasional use, when the car has been permitted to get unusually dirty.

PRACTICAL TESTS OF RAIL BONDS.

Harold P. Brown, of New York, took the opportunity presented by the recent street railway convention at Chicago, to make a practical demonstration of the conductivity of the Brown copper rail bonds. At his booth at Tattersalls he had available a 3,000-ampere current at 10 volts, which he passed in series through a joint of 80 lb. T rail with no bond and a joint of 70 lb. T rail with one of his solid copper bonds on each side, angle plates loosely set up. The unbonded 80 lb. joint with 2,000 amperes showed a drop of .423 volt. As the joint could not be bonded in the proper place quickly enough to demonstrate it value to each caller, Mr. Brown amalgamated the top of the rails at the inner ends and then laid upon the amalgamated spots one of his No. 0000 bonds. The drop with 2,000 amperes was then .018 volt; the drop of 1 in. of solid rail with the same current was .00223 volt. The bond was therefore equal to about 8¼ in. of rail in resistance.

The drop on the 70-lb. rail joint with 2,000 amperes was .01946 volt, and with an extra bond laid on top of the rail the drop with the same current was .00762 volt. The drop of 1 in. of this rail with the same current was .00286 and the bond was therefore equal in resistance to about 7 in. of rail. To insure accurate results the tests were made with a voltmeter reading to the fifth decimal place.

A number of readings was also taken October 24th, on bonds in place on the Metropolitan West Side Elevated Ry., with the following results:

Test No. 1. Measurements taken Oct. 24, 1899, of electrical drop between adjoining longitudinal girder on Metropolitan Elevated at expansion joint opposite stairway to electrical shop, through pair of plastic plug bonds from longitudinal girders into transverse girder. Average of eight readings .00111 volt.

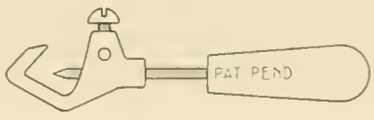
Test No 2. Measurements of same joint when plastic bonds were installed Oct. 28, 1896. Average of four readings .00112 volt.

Test No. 3. Measurements taken Oct. 24, 1899, on next expansion joint east of No. 1; joint bonded with heavy flexible copper strips, held in place by 13-16 in. copper rivet. Average of eight readings .00552 volt.

Test No. 4. Measurements taken Oct. 24, 1899, on solid riveted joint between longitudinal girders next west of No. 1. Average of eight readings .00695 volt.

NEW WIRE CLIPS FOR TESTING.

We illustrate herewith an ingenious little device made by the Star Brass Works, of Kalamazoo, Mich., for use in attaching testing instruments to insulated wires without removing any of the insulation. The device is only about 3 in. long and the method of its attachment will be readily understood from the illustration. The wire to be tested lies in the angle of the hook at one end and the screw



carrying a wooden handle is screwed forward until its point, which is in line with the axis of the wire, pierces the insulation and forms a contact with the conductor. The hook, which is nickle plated, is provided with a hole and set screw for attaching the testing wire. By the use of this device a connection to any conductor can be made in a moment and the insulation is only damaged to the extent of a small hole made by the point of the screw.

WESTINGHOUSE RAILWAY MOTORS.

In a pamphlet with this title the Westinghouse Electric & Manufacturing Co. illustrates its standard railway motors. These include: No. 46, 20 to 25 h. p. for narrow gage roads; No. 49, 35 h. p.; No. 40-B, 25 to 30 h. p.; No. 38-B, 45 h. p.; No. 69, 30 h. p.; No. 68, 40 h. p.; No. 56, 50 h. p.; No. 70, 115 h. p. at 500 volts and 150 h. p. at 750 volts; No. 50-C, 150 h. p.; 12-A, 25 to 30 h. p.

There are also included engravings of interior views of a number of Westinghouse electric railway power stations.

ECHOES FROM THE TRADE

THE GOLD STREET CAR HEATING CO., of New York, has secured a large contract for electric heaters from the Glasgow tramways.

M'GILL, POMEROY & CO., of Chicago, have closed the contract for all the overhead material for the Omaha, Council Bluffs & Suburban Ry.

THE AMERICAN STEEL & WIRE CO., recently suffered the loss by fire of one of its plants at Waukegan, Ill., but this will not seriously delay the filling of orders.

THE PITTSBURG REDUCTION CO., of Pittsburg, showed at the street railway convention samples of wire and cable for street railway purposes. The exhibit was in charge of J. A. Rutherford.

THE KANSAS CITY CAR & FOUNDRY CO., of Kansas City, Mo., exhibited at the Chicago convention various types of street car wheels, whose merits were fully described by F. W. Fisher and A. J. Fisher.

WALWORTH MANUFACTURING CO., the largest house in the East making piping, fittings, valves, etc., will on or before December 1st remove its general offices from 16 Oliver St. to 128-136 Federal St., Boston.

WILSON & CO., of Brooklyn, N. Y., report that their trolley catching device continues to meet with great favor from street railway managers and letters testifying to the satisfaction given are constantly coming to hand.

L. A. SAYRE, the punch man of Trenton, N. J., distributed souvenirs at convention which were greatly in demand. A box containing a handsome pack of cards, and a miniature punch, silver plated, made a popular combination.

THE MILWAUKEE RAIL JOINT & WELDING CO., of Milwaukee, through its agent, Henry L. Prather, of Cleveland, has closed a contract with the Rochester (N. Y.) Ry., for cast welding several thousand joints on 4½-in., 6-in. and 9-in. rails.

THE JEWETT CAR CO., of Jewett, O., has sold the Omaha, Council Bluffs & Suburban Ry. 15 large interurban cars. These cars are mounted on Peckham double trucks which were sold by Hanna & Gray, western agents for the Peckham company.

THE HAZARD MANUFACTURING CO., of Wilkes-Barre, Pa., has completed its wire covering mill and is now filling orders for covered wire as well as for bare wire and cables. It has opened a Chicago office at 1201 Marquette Building, in charge of J. B. Wallace.

THE CREFELD ELECTRICAL WORKS, of Saylesville, R. I., has been purchased by the American Electrical Works, and its plant has been removed to a substantial new three-story brick building, 130 x 60 ft., adjoining the American Electrical Works' factory, at Phillipsdale, R. I.

EXHIBIT HALL AT A. S. R. A. CONVENTION FROM THE SOUTH END.

FRANK R. COATS, until recently connected with the New York, New Haven & Hartford R. R., is now in charge of the Chicago office of the Weber Railway Joint Manufacturing Co. He will be assisted by E. W. Penfield as engineer. Mr. Penfield has been with the Weber company for some time.

THE JACKSON & SHARP CO., Wilmington, Del., was represented at the street railway convention by Mr. J. Monteith Jackson, who, though one of the younger members of the concern, found many acquaintances among both western and eastern men. He distributed a very acceptable little souvenir containing a calendar for next year, and wax coated compartments for carrying postage stamps.

THE VULCANAS FORGING CO., of Cleveland, suffered the entire destruction of its plant on October 25th. The loss is nearly $30,000. The company made street and steam railroad forgings of various kinds, and also handled the Hathaway transfer table. A. G. Hathaway is secretary of the company.

ENGINEERS WHO MAKE a trial of genuine Albany grease cheerfully acknowledge its superiority for all lubricating purposes. L. T. Snell, of Natick, Mass., writes under date of October 23d to Adam Cook's Sons, New York, sole makers as follows: "Your grease is all right. I have some of another make on hand. When used will give you a call."

THE WESTERN ELECTRIC CO., of Chicago, describes its new type "Sunbeam" incandescent lamp in bulletin No. 14001, for October. This is a 16-c. p. street railway lamp for use in series on 500, 550 or 600 volt currents and is made in three standard efficiencies, viz., 3.1 watts, 3.5 watts and 4 watts per c. p. Every lamp sent out is individually exhausted both mechanically and chemically, and the vacuum obtained is claimed to be as nearly perfect as known methods can produce.

THE BULLOCK ELECTRIC MANUFACTURING CO., of Cincinnati, O., devotes its October bulletin No. 2435 to its new type "N" direct current multipolar motors which are designed to meet the conditions obtaining in direct driven machinery in mills, factories, and workshops generally. The motors are compact, and made with either open or closed ends, the latter rendering the motor moisture and dust proof, and adapting it to service where an open motor would be impracticable.

GATES & RANDOLPH are doing an immense electrical business, having sold 30 odd complete electric plants during the past month. Realizing the extensive application of the electric motor carriage, they have also taken the agency of the Indiana Bicycle Co., of Indianapolis, which makes the "Waverly" automobiles in all styles. A number of these carriages were on exhibition at the Street Railway Convention. This firm's electrical knowledge will come into good play in the sale of these vehicles.

THE UNION BOILER TUBE CLEANER CO., of 262 Penn Ave., Pittsburg, has just completed a contract for cleaning two Hazelton or porcupine boilers with over 2,000 tubes having one end welded tight. These tubes were badly scaled and the closed end required a special tool of unique design as well as the use of the company's own design of flexible shaft. This concern is the only one on the face of the globe fully equipped with machinery, tools, and expert operators to do this kind of work quickly, effectively, and cheaply.

THE CHRISTENSEN ENGINEERING CO., of Milwaukee, Wis., has sold during the past two years nearly 1,000 air brake equipments, and during this same period, the cost of maintenance for these equipments, computed on the sale of repair parts has not equaled 1 per cent of the total cost, a record that compares favorably with any other apparatus used by street railways. The company has recently brought out a revised edition of its general catalog, which contains a discussion on the advantages of straight air over automatic or stored air for braking purposes.

THE SPEER CARBON CO., of St. Marys, Pa., is meeting with a most gratifying success in the manufacture and sale of carbon brushes. J. S. Speer, the general manager of the company, has long been connected with the manufactured carbon industry and knows the business thoroughly: his experience insures a product equal to any on the market, while the fact that the Speer company has a new plant well equipped with the latest types of machinery, and also owns its own gas wells and coal mines, enables it to put its products on the market at prices which are satisfactory to all users.

THE J. G. BRILL CO., of Philadelphia, has published a very complete catalog showing the leading types of standard American cars built by it, and indicating the lines of service to which they are adapted. The pamphlet contains styles to meet all the requirements of city and suburban and interurban service of every description from the lightest to the heaviest. This company makes a special feature of the fact that by its method of shipping cars "knocked down" and "in the white" a large saving in transportation charges to foreign countries can be made, and at the same time the danger of injury while in transit, and the labor of erection upon arrival at destination is greatly reduced.

THE CLONBROCK STEAM BOILER CO., Brooklyn, N. Y., maker of the Morrin "Climax" boilers advises us that the "Climax" boilers it had at the Trans Mississippi and International Exposition at Omaha, in 1898, and at the Greater America Exposition, this year have all been sold. The purchasers were: Omaha, Council Bluffs & Suburban Railway Co., one 500-h. p. and one 250-h. p.; Ft. Madison (Ia.) Street Railway Co., one 250-h. p.; International Packing Co., Omaha, for its Sioux City plant, three 500-h. p. and one 200-h. p. The western manager of this company is H. B. Ham, with offices at 1457 Monadnock Building, Chicago.

THE TAYLOR ELECTRIC TRUCK CO., of Troy, N. Y., exhibited one of its extra heavy 8-ft. wheel base single trucks, designed for heavy vestibule single truck cars; one of its "Empire State" radial trucks, one of its regular swing motion double trucks for double truck passenger car service, and one of its recently designed extra heavy swing motion double trucks, for long, heavy suburban cars for high speed service. The Taylor trucks are in service from Maine to California, and are spoken of in the highest terms. The exhibit was in charge of Mr. John Taylor, manager of the company, and the trucks were thoroughly examined in detail, and highly spoken of by many delegates.

THE POTOMAC TERRA COTTA CO., of Washington, D. C., which company makes the Mason vitrified salt glazed terra cotta conduits for underground electric wires, has on file and is constantly receiving letters from every part of the country testifying to the satisfaction its products are giving. The following is an example of the nature of these letters. It is from J. H. Vail, engineer-in-chief of the Pennsylvania Manufacturing, Light & Power Co., of Philadelphia, and reads as follows: "In reply to your communication I beg to say that we have laid under the streets of Philadelphia about 175,000 duct ft. of your terra cotta conduit. Up to date it is entirely free from faults."

THE TURNER OIL FILTER CO., 2777 North Lincoln St., Chicago, is receiving substantial testimonials from users in the shape of second and third orders for filters. Among such may be mentioned the Milwaukee Electric Ry., two 150-gallon filters; and the South Side Elevated, Chicago, two 150-gallon filters in addition to two of the same size in use one year. The Newark Light & Power Co. orders a 250-gallon filter, making five in use in that plant. The Elizabeth (N. J.) Light & Power Co. puts in one 100-gallon outfit, and the Yuba (Cal.) Light & Power plant orders a 100-gallon. The new Singer Building, Broadway and Liberty Sts., New York, is installing a 100-gallon filter.

THE PARIS EXPOSITION is attracting greater attention the nearer it comes to the time of holding the fair. The J. A. Fay & Egan Co., of Cincinnati, has been awarded, in the Champs de Mars, the largest space of any concern in the United States, and it expects to make one of the most elegent displays of wood working machinery that has ever been made by an American company. At the World's Fair in 1889 this company was awarded "The Grand Prix," together with the medal of the Legion of Honor. This year it expects to at least hold its own, and, perhaps, surpass the showing made in 1889 when it had 5,000 sq. ft., and received the thanks of the French Government for the great display made.

THE CENTRAL ELECTRIC CO., Chicago, has made careful preparation to supply the fall and winter needs of electric railways in track brooms, sleet cutting trolley wheels, etc. Among this company's standard lines of overhead material are Wood's trolley wire splicers, which have all the features for emergency work and at same time give lasting couplings. The "Type W" clincher ears, from the fact of the lips being cast without core, are said to per-

mit most rapid and reliable installation owing to the lip flexibility and freedom from bucking. This company expresses its pleasure with the particularly gratifying business in the Western States on its general lines of overhead and station equipment.

J. J. RYAN & CO., brass founders and finishers, 68-74 W. Monroe St., Chicago, report that the month of October has held its own in the way of trade, and in some departments made a gain over the previous two months. They have secured a number of orders for brass castings that will run from three to four months. One order was for a special lot of brass fittings for public building in Havana, Cuba, and a number of phosphor bronze castings, weighing 1,000 lb. each to be shipped South; but the most important gain was made in the babbitt metal department. Their sales on nickel "Genuine Babbitt" and "I X L Babbitt" have increased enormously. In the metal polishing and nickel plating department, they have been obliged to provide extra space in order to take care of the trade more expeditiously.

THE W. T. VAN DORN CO., of Chicago, has received during the last few weeks an unusually large number of orders for couplers, and its works are kept busy turning out contracts on hand. One of the largest orders is for 137 sets of couplings for the Northwestern Elevated, of Chicago; the trail cars for the road will have the Van Dorn, T-rail attachment and the motor cars, the standard motor draw bar. The Van Dorn Co., has also recently finished or is working on orders from the Metropolitan West Side Elevated of Chicago, for couplers for 18 motor cars and 18 trail cars; from the Boston Elevated Ry., and Brooklyn Elevated Ry., for automatic couplings; from the New York, New Haven & Hartford R. R., for couplers for the cars on its new P. W. & B. branch; and from London for 400 No. 5 type of couplers, 160 of which will be used at Bristol, Eng.

MR. FRANK ENGELHARDT, who formerly represented the American Wheelock Engine Co., in Chicago, has made new arrangements whereby he will look after the interests of the Filer & Stowell Co., of Milwaukee, makers of high grade engines for street railway and other service. He will establish his headquarters at 1232 Monadnock Building, Chicago. The Filer & Stowell Co., reports business in excellent condition. It is now erecting a large heavy duty cross compound, direct connected engine, 28 and 56 x 48 in. cylinders for the Union Railroad Co., Providence, and a similar engine for the Milford, Attleboro & Woonsocket Street Ry., of Unionville, Mass., with cylinders 16 and 30 x 48 in. It has also sold Armour & Co., two heavy duty cross compound direct connected engines, with cylinders, 23 and 46 x 48 in., and Swift & Co., one of the same type with 13 and 26 x 42 in. cylinders and one with 19 and 38 x 42 in. cylinders. These latter are repeat orders.

THE CLING SURFACE MANUFACTURING CO., of Buffalo, has received under date of October 7th, a letter from Prof. R. C. Carpenter, of Cornell University, supplementing his report on "Cling Surface" made in April last. Professor Carpenter says: "Later tests on 'Cling Surface' indicate higher efficiency of transmission and less loss of power in the case of belts treated with this material, than in the case of belts not so tested. This is due to the fact that the slipping of a belt causes considerable loss of power, the power so lost passing off in heat. The use of 'Cling Surface' reduces the slipping and consequently reduces the loss of power occasioned by the use of belts that slip. During the past six months I have had occasion to observe the practical use of 'Cling Surface' in a number of instances. In all such cases 'Cling Surface' has improved the belts by softening them, and as far as I can determine in the limited time (seven months) tends to preserve the leather of which they are constructed."

THE FALK CO., of Milwaukee advises us that it has just been awarded two additional contracts at Kansas City for the rebuilding of the 33d St. line and the Summit St. line. It has also just started welding on an 8,000 joint contract for the Anacostia & Potomac River Ry., Washington, D. C., and hopes to begin welding next week on the 42d St., Manhattanville and St. Nicholas Ave. lines of the Third Avenue R. R., New York. It is still doing other work for the Third Avenue R. R. and is about completing the interurban railway between Oshkosh and Neenah, Wis., and a further contract from the Russell House at Neenah to the lake shore. The gear and pinion department is working day and night, and the company recently shipped a carload of pinions to the North Jersey Street Railway Co., Newark, N. J. Contracts for the annual supply of gears and pinions have also been closed with some of the largest street railways in the East, and the sales of this department have increased over 100 per cent during the last year.

JOHN A. BRILL, of the J. G. Brill Co., in the course of a recent conversation with a representative of the "Review" stated that the day before he sailed from Liverpool on his return trip, October 21st, he had in connection with the foreign representatives of the company, closed an order with the Preston Car Co., of Preston, Eng., for 700 Brill trucks. This, it is claimed, is the largest single foreign order for trucks ever secured by an American firm. The order includes 100 pairs of the No. 27 G. type, which is a swing bolster center pivoted truck, having a 4-ft. wheel base, 300 No. 22 "Eureka" maximum traction trucks, and 300 of Brill No. 27 E., which is a single truck. Mr. Brill speaks favorably for the continued demand for street railway supplies from foreign roads; although he says there are several new car building firms that have started up in England and on the Continent, and that some of the old car building companies have been revived. He thinks that the demand for trucks especially will continue as foreign engineers and street railway men favor wrought iron construction for trucks, as there has been but little experience with cast steel or malleable iron construction, of any description.

THE IRONSIDES CO., of Columbus, which had a very attractively arranged exhibit at the convention of the American Street Railway Association last month, reports its doubled up business in excess of their capacity, and that much needed improvements and extensions now in progress will further double the factory capacity. Materials for preservation and protection of all classes of wire and fibre ropes through internal treatment in manufacture, and external application in subsequent use of such ropes, and also for the lubrication of all classes of gearing, among which street car motor gears seem to have received considerable attention, have heretofore been the principal specialties of this company. A metallic paint of reported great durability, capable of resisting acids and acid fumes, and to be unaffected through a wide range of temperatures is given among the more recently acquired articles of manufacture. An encouraging foreign trade is looming up, which promises to be greatly furthered through the manifested interest of many foreign visitors to the company's exhibit at the National Export Exposition now open in Philadelphia. A large and important shipment to the Hawaiian Islands was among those recently made abroad.

"NICKEL STEEL" was the subject of a report before the Railway Master Mechanics' Association at its convention in June last. The president of the Association called upon Mr. H. F. J. Porter, of the Bethlehem Steel Co., to discuss the report which he did at some length, explaning the necessity of a special equipment to make nickel steel forging and the excellence of such forgings when made by a suitable equipped plant. In conclusion Mr. Porter announced that his company would for a limited time furnish any railroad with nickel-steel forgings at a reduced price upon the condition that the road would keep a careful record of their preformance and return with a full report when they were finally broken. The following paragraph is from a circular letter issued by Mr. McIlvain, vice-president of the Bethlehem Steel Co.: "Pending the publication of the transactions of the meeting we could not take definite action with regard to this offer, but, having now received and caused to be reprinted that portion of the record which relates to it, we are distributing it and repeating and confirming the offer then made. We must limit its exceptance, however to a single month, and trust that your road, among others, will take advantage of the opportunity thus offered to obtain high grade nickel steel forgings of this character in quantities sufficient to satisfactorily determine their merits for yourselves. On receipt of drawing, blue-prints, or sketches, we will be pleased to quote prices."

FOREIGN FACTS.

A portion of the Bolton (Eng.) & District Electric Tramways will soon be opened.

The Huddersfield (Eng.) Corporation has placed the contracts for its electric power station building.

It was expected that the first electric train on the London Metropolitan Ry. would be run early this month.

The opposition of residents has prevented the grant of an order for an electric railway between Ryde and Seaview, Isle of Wight.

The Warrington (Eng.) Town Council will apply to the Board of Trade for a provisional order for building electric tramways in the borough.

Contracts for the construction of the Devonport (Eng.) & District Tramways Co., have been placed. The road will consist of 4½ miles of double line and 1 furlong of single line, and must be completed by May 30, 1900.

The Association of Municipal Corporations (Eng.) has by a formal resolution pledged itself to use every effort to defeat all electric power schemes, which offer any promise of competing with municipal electrical undertaking.

Among the English municipalities which have applied or probably soon will apply for powers to build electric lines are: Bradford, Brighton, East Ham, Rotterdam and Surrey. The Surrey scheme contemplates over 29 miles of lines.

A trolley line is being constructed to connect the scene of the decennial production of the Passion Play at Oberammergau with a railway some 14 miles distant, thus making unnecessary the former mountain ride to the picturesque locality.

In Liverpool 28 miles of tramway out of a total of 78 have been equipped for electric traction, and it is expected that next year all of the main lines will be electrified.

October 17th the London County Council resolved by a large majority to build five lines of light electric railways, and the Highways Committee was authorized to take the necessary steps in connection with the application to the Light Railway Commissioners. It is proposed to run a 5-minute service on each of these lines and the receipts are estimated at 11d. per car-mile and the working expenses at 5d.

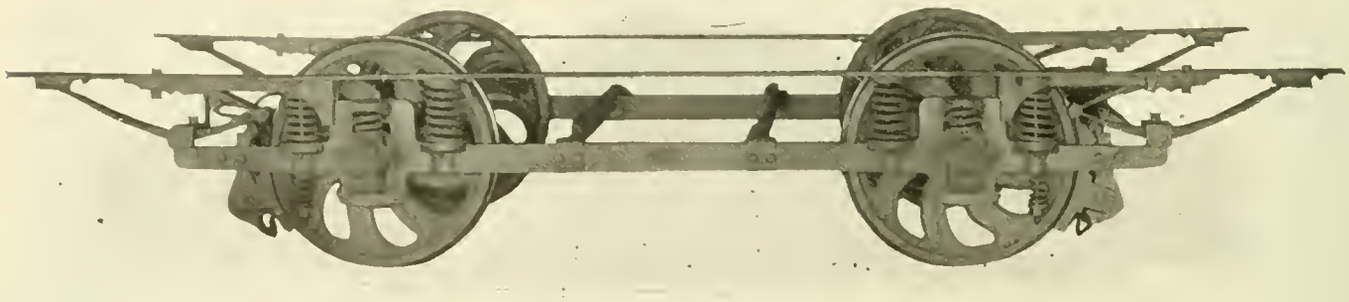
The Federal Council in Switzerland has granted a concession to Messrs. Zen. Ruffinen and Willa, of Loeche, and others, for an electric railway from Loeche, on the Jura-Simpton Ry., to Loeche-les-Bains. The first section of the road will be built on a 53 per cent grade and will be 1½ miles long. The second section has an average grade of 20 in 100 and is 5½ miles long. A water-power plant on the River Dala will be erected to give the necessary power.

Councillor Smith, of Bolton Corporation (Eng.), has compiled a pamphlet entitled, "Notes for Guidance in Organizing the Bolton Corporation Tramway System." He states that no uniform method of management for corporation tramways has been generally adopted in England, the three following arrangements having been used in various places: (1) An engineer and traffic superintendent independent of one another, which is characterized as a bad management, because responsibility can never be fixed on one man. (2) The engineer subordinate to a general manager, who is not an engineer, as on the Blackpool & Fleetwood line. This is thought to be better than the first mentioned arrangement, but causes engineering matters which are of primary importance to be neglected, through want of proper appreciation. (3) The appointment of an engineer as general manager, and the appointment of a traffic superintendent. This system has been adopted on many tramways, Blackburn, Coventry, etc., and is thought to be the best plan.

McGUIRE TRUCKS AT THE CONVENTION.

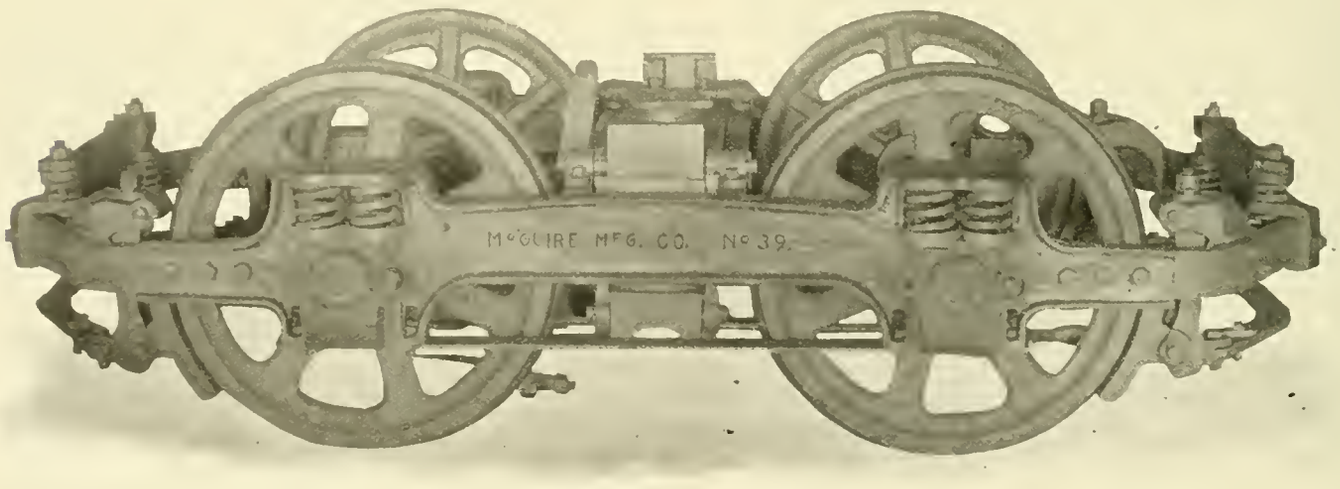
The McGuire Manufacturing Co., of Chicago, made one of the largest exhibits at the convention, its display consisting of trucks, stoves, brake handles, a sweeper, etc. Among the trucks exhibited were the McGuire No. 35 and No. 39 double truck which are shown in the accompanying engravings.

The principal departure in the construction of these is the arrangement of the springs. The frame sits upon four spiral springs over each journal box, the seats for the springs being cast on the journal box and the caps in the frame. These springs are of short movement and merely act as a cushion between the axle and the frame. The car body is carried upon a combination of spiral and elliptic springs which are arranged in a rather unique manner under the main bolster, resting upon a steel plate which is hung from the transoms by very heavy links. The bolster is so constructed as to completely house the springs. The side frames are made from cast steel, which possesses unusual tenacious qualities, samples of these side frames being shown in the McGuire exhibit, twisted and bent into the most trying and peculiar shapes.



McGUIRE NO. 35 TRUCK.

These trucks are claimed to be capable of carrying car-bodies up to a weight of 40,000 lb. at a speed of 60 miles an hour, with perfect safety. A test of one side frame of the No. 35 truck showed a deflection of ½ in. with a permanent set of 5-16 in. under a pressure of 55 tons, without sign of fracture, and the cast steel bolster under a pressure of 140,000 lb. showed a deflection of 3½ in. and a permanent set of 3 in. without sign of fracture, and it took a pressure of 160,000 lb. to break the bolster. All the bolsters used are tested up to 70,000 lb. and all side frames are tested up to 40,000 lb., and in a test of 700 bolsters and 1,400 side frames, not a single frame or bolster had to be rejected. The McGuire company claims that there is no other form of construction where so large a factor of safety is obtainable.



McGUIRE NO. 39 TRUCK.

The Union Traction Co., of Anderson, Ind., has let contracts amounting to $50,000 for the construction of four bridges.

THE ELECTRIC-CABLE OF MONT-DORE.

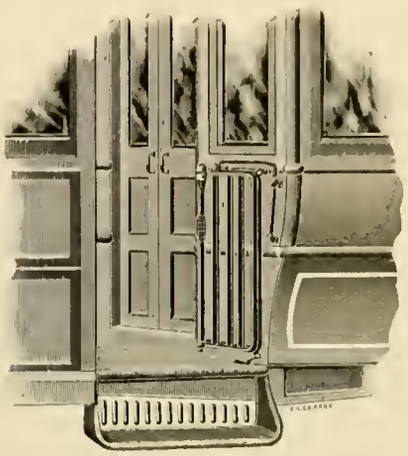
An interesting cable road was installed not long ago in the city of Mont-Dore, France, by Messrs. Guitton & Co., French representatives of the Oerlikon Co., at Zurich. The motive power for the tramway is derived from the River Dordogne and is transmitted to the point of utilization by three-phase currents by means of which an electric motor is driven.

The object of this tramway, which is described in La Nature, is to permit the invalids of an air cure establishment to follow a regime of baths and inhalations of air in a neighboring forest of pines. The River Dordogne crosses the city of Mont-Dore, and furnishes a supply of about 600 litres per second. A dam is built across the river and canal of 740 meters in length opened to the power house. The latter contains a turbine of 180 h. p. making 500 r. p. m. which is directly coupled to a three-phase generator of 138 kw. capacity, at 3,600 volts and of a frequency of 50 p. p. s. The fields are excited by a small dynamo of 600 watts at 50 volts, mounted upon the shaft of the alternator. The transmission line is composed of three bare silicon-bronze wires of 4 mm. diameter, carried on double petticoat porcelain insulators. The electrical energy is transmitted to the summit of the mountain, up which the road runs, where there is a sub-station, in which is located an electric motor which operates the cable drums. This is a three-phase synchronous motor with a revolving field of 12 poles, making 490 r. p. m. The motion is transmitted to the drum by means of two shafts and the necessary gears and pinions. The direction of rotation of the drum is changed by changing the direction of two of the three windings. The cable road is built upon the side of the mountain and the cable which carries the cars and which runs over pulleys driven by the drum motor, has a diameter of 33 mm. and weighs 3.9 kg. per running meter. There are two cars weighing 5,035 kg. attached to the two extremities of the cable.

This installation is the only one of its kind in France and is useful in permitting travelers to profit by the baths and air cures of Mont-Dore.

FOLDING PLATFORM-GATE.

In the accompanying engraving is shown a folding platform-gate, recently placed on the market by the R. Bliss Manufacturing Co., of Pawtucket, R. I., which company has been making platform gates that are sold under the trade name of Wood's patent safety gates, for a number of years, and has many thousand in use. The gate illustrated herewith embodies a number of new features developed by long experience. It consists of a light, strong frame work, made in two halves which are hinged together and which fold back,



FOLDING PLATFORM-GATE.

one upon the other, against the end of the car body when not in use. By means of a rod attachment this action is automatic, it being necessary simply to release a latch and give the gate a slight push, when the sections fold up, out of the way as shown.

The chief advantage of the device lies in the small amount of space it takes when folded up, and also in its small sweep, when being opened or closed, enabling it to be used on crowded platforms without inconvenience to passengers. It has been found where the gate has been applied to the cars of a system that the number of platform accidents has been greatly decreased.

HALF FARES.

The Cleveland (O.), Medina & Southern Electric Ry., has secured an extension of its franchise which was about to expire.

It is said contracts will shortly be awarded by the Kohaha & Hilo Railway Co., of Hilo, Hawaii, for the construction of 130 miles of electric railway.

There are reported to be seven young lady conductors on the electric cars of Chillicothe, O., and five at Vincennes, Ind. They work nine hours a day and receive $4 a week.

An ordinance has been passed requiring the Brooklyn (N. Y.) Rapid Transit Co. within six months to place board walks and a guard rail fence on each side of the tracks of the elevated road structure.

The Union Traction Co., of Anderson, Ind., is perfecting arrangements for an interurban mail service along its route as soon as the lines are completed. Each city on the route will have three mails every day.

The International Traction Co.'s line from Tonawanda to Lockport and Buffalo was opened for traffic October 25th. Manager Van Horn and a party made the first trip over the road, covering the distance in 57 minutes.

A franchise was granted last month by the city of De Kalb, Ill., to the Sycamore & DeKalb electric railroad. It contained so many restrictions, however, that the company declined to put in the road under its provisions.

It is announced that a consolidation of the United Railway & Electric Co. and the United Electric Light and Power Co. of Baltimore has been effected, and that an effort will be made to secure control of the Consolidated Gas Co., which has an exclusive franchise in the city.

The new street railway at Chattanooga, Tenn., is expected to be completed and in operation by November 10th. This line has been built at a cost of $15,000, and as soon as it is opened work will be commenced on a number of extensions, which will cost about $100,000 more.

After six weeks of mule car service the electric cars in Austin, Tex., started running on October 25th. The service was stopped by lack of water power, which has since been increased by a rise in the water of Lake McDonald sufficiently to light the business portion of the city and to run a few cars.

It is stated that in order to avoid, if possible, the trouble experienced last winter with the closing of the cable slot in cold weather, the Metropolitan Street Ry., of Kansas City, Mo., will remove the paving blocks which are adjacent to the slots and substitute therefor ashes, slack or some other yielding material.

The Brooklyn Rapid Transit Co. sometime ago offered a prize of $5 for the best paper on the duties of a motorman and on damage to electrical equipment caused by careless handling of controllers. The contest was open only to motormen attached to the Flatbush depot. Motorman Hugh Ruane was awarded the prize.

Judge Dale of the District Court at Wichita, Kan., granted a permanent injunction restraining the Wichita Street Railway Co. from operating its plant and ordering all the cars and tracks from the streets. A new company was given a franchise by the city council, but the old company refused to surrender the streets.

The Quakertown (Pa.) council sometime ago served an injunction on the Quakertown Traction Co., restraining the latter from laying new rails, on the ground that they were not girder rails. The Traction company had to obtain a letter from William Wharton, jr., & Co., testifying to the fact that the rails that were being put down were girder rails.

The Calumet Electric Railway Co., which is building an extension through Pullman, Ill., was stopped temporarily last month pending an inquiry into the validity of its franchise, which was originally granted to George M. Pullman by the town of Hyde Park, and since transferred to the Calumet Co. The franchise was decided to be valid.

A short strike of all the employes of the San Antonio (Tex.) Street Railway Co. took place in October. The trouble was finally settled by the company agreeing to recognize the union, to pay motormen and conductors $1.50 per day of nine hours, 16 2-3 cents per hour for overtime before midnight, and allow pay for time and a half for overtime after midnight.

Mr. W. J. Watson is now the New York representative for American Electrical Works, of Providence.

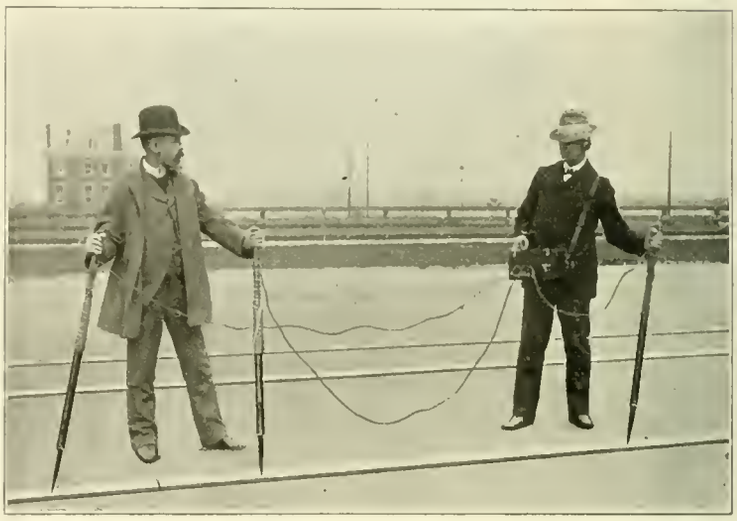
Mr. Francis E. Donohoe, agent for the American Electrical Works, of Providence, has extended his territory and will hereafter handle all the business west of Pittsburg.

We have received a copy of the new pamphlet of the Famous Filter Co., of St. Louis, entitled "Modern Engineering Practice." This should be in the hands of every one interested in the use of oil.

Mr. O. M. Hubbard, formerly manager of the electrical department of the Bradford Belting Co., has formed a new company to be known as O. M. Hubbard & Co., with headquarters at 105 East Pearl St., Cincinnati, to deal in insulating and hot surface paint, belting and general street railway supplies. The new concern desires to make agency connections with reliable manufacturers.

NEW METHOD OF TESTING RAIL JOINTS.

A simple and efficient device for determining the resistance of rail joints is being introduced by the Chase-Shawmut Co., 161-163 Fort Hill Square, Boston, Mass. The method of using the instrument is clearly shown in the accompanying illustration. The operator carries, suspended from his shoulder, the case containing a continuous interrupter in circuit, and a telephone attachment. His assistant strikes the two connecting poles into the rails, spanning the joint to be tested, with about 3 ft. between the poles. The operator then strikes his indicating pole into the rail about 4 ft. from the center pole, and by means of a switch alternately throws the telephone and interrupter into the circuit from the joint, and then from the 4 ft. of rail, comparing by means of the telephone receiver, the two sounds from the joint and rail. If he finds the sound from the joint is the louder, he shifts his pole so as to span a greater length of rail. When the sounds are found to be approximately equal, a final test of balance is made by leaving the switch



TESTING RAIL JOINTS.

on the box in the middle position, when no sound should be heard. In case a slight sound is noticeable he shifts his pole until this entirely disappears. In this way the length of rail equivalent to the joint is found, and from this, if it is desired, knowing the weight of the rail, the resistance can be calculated.

The instrument utilizes the ordinary working track current, and no matter how variable this current may be, since the variation through the joint and adjacent rail is precisely the same, it introduces no error. An intensifying attachment on the instrument permits its use with very weak currents. The invention has stood the test of continued operation in practical service, being now in use by several of the largest railways in New England, on one of which over 4,000 joints have been tested with it, and results recorded to great economic advantage.

$12.40 TO CHATTANOOGA AND RETURN.

For the unveiling of the Illinois monument on the Chickamauga battlefield, the Monon Route and C. H. & D. Ry. will sell tickets to Chattanooga and return for $12.40, November 19, 20 and 21, good to return to November 26, inclusive. City ticket office, 232 Clark St.

A MESSAGE TO GARCIA.

The New York Central & Hudson River R. R. has reprinted, as No. 25 of its "Four-Track Series," the small "preachment" by Elbert Hubbard entitled "A Message to Garcia," which has recently been attracting so much attention. Street railway managers wishing to distribute this exceedingly valuable pamphlet among their employes may obtain copies by sending 50 cents for each 100 desired to George H. Daniels, general passenger agent, Grand Central Station, New York.

EASTERN OFFICE, 100 WILLIAM STREET, NEW YORK.
C. B. FAIRCHILD, EASTERN REPRESENTATIVE.

CORRESPONDENCE.

We cordially invite correspondence on all subjects of interest to those engaged in any branch of street railway work, and will gratefully appreciate any marked copies of papers or news items our street railway friends may send us, pertaining either to companies or officers.

DOES THE MANAGER WANT ANYTHING?

If you contemplate the purchase of any supplies or material, we can save you much time and trouble. Drop a line to THE REVIEW, stating what you are in the market for, and you will promptly receive bids and estimates from all the best dealers in that line. We make no charge for publishing such notices in our Bulletin of Advance News which is sent to all manufacturers.

This paper is a member of the Chicago Trade Press Association.

Entered at the Post Office at Chicago as Second Class Matter.

VOL. IX. DECEMBER 15, 1899. NO. 12

Two Chicago men have conceived the idea of providing a dining car service on electric railways with especial reference to the accommodation of persons living in outlying towns and having to go to the neighboring city when they would attend the theater. Such a buffet service would enable the suburbanites to dine after the play, and with minds free from the care which the necessity of "making their train" now imposes. And if operating agreements could be made with the city street railway companies, so that the patrons might take the car at the theater door, this service would also do away with an often disagreeable walk to the station.

Street railway men are not much interested in steam locomotives or car interchange rules, nor are steam railroad men at the present time to any great extent concerned with electricity as a railroad motive power, yet there are a number of points, such as shop design, equipment and management, track construction, discipline of employes, signalling, etc., which the two classes could discuss together with mutual advantage. For this reason membership in one of the railroad clubs should prove attractive to superintendents, master mechanics and track masters of the electric railways located in and near the cities where the railroad clubs hold their meetings. The New York Railroad Club meeting in New York City and the Western Railway Club meeting monthly in Chicago, both have a number of street railway men on their rolls, and it seems to us that an effort to secure more members from the electric railways would meet with success.

Companies using transfer tickets will do well to instruct conductors to give the passenger the benefit of a doubt as to the validity of the transfer ticket presented when there is good reason to believe the error was caused by carelessness of the conductor issuing the same. The Citizens' road, of Memphis, had a provision printed on its transfers, which required the passenger accepting the transfer to read and examine same and failing to do so thereby forfeited his rights in case the ticket was improperly punched. This the Tennessee courts hold to be unjust and placing an unreasonable burden upon the passenger, upon whom all the burden of the "controversy" is thereby placed.

At various times since the city of Milwaukee failed in its attempt to enforce a 4-cent fare ordinance, proposals have been made with the object of effecting settlement of the differences between the company and the city. In November, 1898, Mayor Rose and the company had agreed upon what they considered an equitable basis, but as a provision for 4-cent fares was not included the popular clamor against the plan was great, and the company withdrew its offer. On another page of this issue we give the essential features of a new ordinance presented to the council last month; this represents the latest effort to compromise, but there is no certainty that this ordinance will be passed.

The past year has been a very satisfactory one for most of the street railways of this country, as the continued and increasing prosperity of the people has made itself felt in the street railway field as well as in other lines of business. One of the effects of this has been the renewal of equipment and rebuilding roadbed on the existing lines and a great stimulus given to the promotion of new roads. It is a great pity that the orders which now overcrowd the factories making street railway supplies, to the embarrassment of old enterprises as well as new, could not have been distributed over the last three years. Of course the promoter of a new company who could not then float his securities must be excused for not building his road three years ago, but there have been many orders placed comparatively recently for supplies that were badly needed, just when the makers needed the work worst and would have done it cheapest.

We have no accurate data compiled as to the number of new companies that have actually started to build electric roads since January, 1899, but it is very large. In April last we published a list of about 400 companies, both old and new, that had been recently incorporated or were engaged in making extensions or securing franchises; since that time there has been an activity quite as marked.

The greatest activity has been in the interurban field, which is largely due to the fact that practically all the towns that could support a street railway, and also many that could not, were already supplied. The interurban electric railroad has great possibilities in the way of freight and express transportation which are rapidly being developed. Pleasure riding is an important source of income on such roads and in some parts of the country a special excursion business has been catered to with success.

Next to the building of new roads, no feature of the year has been more marked than the number of consolidations of street railway properties that have been effected. Among

the most notable of the consolidations are those at St. Louis, Washington, Baltimore, Brooklyn, Chicago, Buffalo, Akron, Pittsburg, Nashville, the 33 companies in Eastern Massachusetts and Rhode Island, and combination of roads in New Jersey, in Connecticut, in Indiana, and in Eastern Pennsylvania. There is every indication that the coming year will see further development along the same lines.

From this time on the tendency in track construction will be in the direction of a much more durable roadbed than has been the general rule with such work in this country. In England and on the continent of Europe, railways have long ago decided on a type of track which was expected to be permanent, and we predict that in this country it will be found expedient and economical to construct in the same manner. The rapidly decreasing supply of wood ties, and the expense of replacing old with new, combine to form a maintenance account which reaches into large figures. A few years ago it seemed that the metal tie was destined to solve the tie problem, but we confess to a disappointment in the results obtained in this direction, and the very limited amount of it which has been used. It would now seem that cement will be the coming factor in rail support for city work. Its adaptability, the ease with which it can be placed in position, and the certain decrease in cost of this material will bring its claims strongly to the attention of managers.

While no very great amount of this work has been completed to date in this country, the total is by no means inconsiderable, and in the several cities which have used the cement construction, the results thus far are decidedly promising. Its very greatly increased use by cities for foundations in their street paving, is strong evidence of its practicability.

In many parts of the country cement plants are being pushed to completion by men working night and day; nor are these new plants small and insignificant affairs. On the contrary, they are many of them of large capacity, having an output of 1,000 barrels per day. In addition, numerous smaller plants from 200 to 500 barrels per day are building. Both the demand and the supply will be greatly increased during the next few years.

During the past few years great care and study have been given to the question of the economical production of power, and on nearly all the large roads a system of comparative records of costs is used which enables even the smallest wastes to be detected and stopped. All the many station supplies are carefully watched and the result has well paid for the expense and trouble of keeping the records.

But we are inclined to believe that in not a few cases the idea has prevailed that the power station is the only place where this degree of care need be taken in watching expenditures, and other equally important departments have been neglected.

In the matter of car repairs, for instance, very few managers have deemed it necessary or perhaps possible to work out any such reform as has been done at the station. And yet here is a department which in the course of a year consumes a great deal of money.

It is our observation that as to car repairs, the place to save is most largely in the selection and purchase of the rolling stock. It is by no means an infrequent occurrence for a road to spend in repairs the first two years alone an amount of money, which, if it had been added to the first cost of the car, would have secured material and construction which would have saved itself many times over in 10 years, to say nothing of the indirect loss of earnings during the time the car is out of service while being shopped.

In this issue is an extremely thoughtful and suggestive article on "Quality in Car Building," which is well worth reading more than once. The rage for low-priced cars is already beginning to subside, and we call to mind several roads which are not placing orders with the lowest bidders. They have learned the lesson of saving one dollar to lose ten, and it will be a good day for users and builders alike when the managers of the country come to realize the folly of trying to get something for nothing.

Within the past few years there has been a noticeable tendency to broaden the scope of street railways by the haulage of freight, express packages, mails, etc., in addition to their regular passenger traffic. This tendency has of late been very greatly augmented with the advent of the long interurban lines which are springing into existence all over the country, and which are admirably adapted to carry on a local freight and express business, especially in the line of light freight and small packages, which can easily be handled without any interference with the regular passenger schedules.

On a number of railways where a freight service has been introduced, considerable opposition has been manifested to it and the right of street railway companies using the public highways for other than passenger service has been questioned. A decision upon this point, which seems eminently sensible, was recently handed down in the appellate division of the New York Supreme Court. Some of the Brooklyn railways occupying public streets contracted to carry the freight of the National Express Co., and suit was brought to prevent them from carrying out the contract. The court held as follows:

"The right to use the track is subordinate to the right of the public to the street, and the courts will protect the rights of the public. The street railroad company has the paramount right of the use of its tracks, but not the exclusive use. It is not clear that the transportation of goods in single cars over the Brooklyn tracks will increase the burden of use of the street; certainly there is no evidence that this method will be more burdensome than would be the carriage of the same freight on wagons."

The decision recognizes that the freight must be carried through the streets in some way, and so far as the public is concerned it makes no difference whether it is carried in wagons or in electric cars. As long as a street railway can carry freight without interfering with the public's use of the street, it should have the right to do so. This right, of course, would not include the use of long and frequent trains loaded with heavy freight that would not ordinarily be transported on wagons, as such a service would incommode both the public and the railway company even to a greater extent by interfering with its passenger traffic which on most roads comprises the principal business.

This decision in regard to light freight, however, would seem to be extremely equitable, and should prove a valuable precedent in other communities where this question may arise, as there is but little doubt that at no distant date freight and express service will form an innovation in the railway business which will eventually prove as acceptable to the public as it is profitable to the railways.

System of the International Traction Co., of Buffalo, N. Y.

Interurban Lines Niagara Falls Power Arch and Suspension Bridges Transformer Stations Spliced Cars Electric Welding of Rail Joints.

By the consolidation of 14 different street railway companies in Buffalo, as many different lines have been brought under one management, with a trackage aggregating 340 miles, and the new company is known as the International Traction Co., with headquarters at 102 Main St. The lines, however, are not confined to the city of Buffalo, but include, with all the lines in Buffalo, interurban lines connecting Buffalo with both the cities of Niagara Falls, one in New York and the other in Ontario, Lockport, the two Tonawandas, Lewiston, Lancaster and Depew, with the local lines in each city, except the Gorge road at Niagara Falls, with which the company has a traffic agreement. The relation and comparative distances of the several cities included in the system are shown in the accompanying diagram, Fig. 1, which is reproduced from a beautiful relief map in colors, which is issued by the company and contains a description of the natural attractions in and about Niagara Falls, and the neighboring historical regions.

FIG. 1. BIRD'S EYE VIEW OF INTERNATIONAL TRACTION SYSTEM.

A stranger visiting Buffalo, should he have an opportunity of meeting with many of its citizens, either in a business or a social way, will be surprised at the marked good will that he will hear expressed for the new company and its management. The liberal manner in which the company has set about improving the tracks, the extension of new lines, the long cars and increased speed, are the principal subjects of remark, and everyone will claim that Buffalo has the best street railway system in the world.

The system is operated in divisions. The lines in Buffalo proper form three divisions; there are four suburban lines, and three systems in other cities. Other divisions are: The line between Buffalo and Niagara Falls, N. Y., and the local lines in Niagara Falls except the Gorge road; the Buffalo and Lockport line, with local cars in Lockport; the Buffalo, Kenmore and Tonawanda line; the Buffalo and Lancaster and the Buffalo and Tonawanda lines; the Niagara Falls Park & River road in Ontario.

The divisions most interesting to a stranger or visitor are those at Niagara Falls and those that center about the Falls. Twelve long cars are regularly run between Buffalo and Niagara Falls on a 15-minute schedule, but, in summer, as the traffic demands, extras are run and frequently the headway is as short as five or ten minutes. The distance is about 28 miles, the fare being 35 cents one way and 50 cents for the round trip. The passengers are landed in Niagara Falls at Prospect Park near the end of the company's new steel arch bridge, which spans the river gorge just below the American Falls, Fig. 2. Here the visitor has the choice of visiting points of interest near the Cataract or transferring to the bridge cars which connect with the lines on the Canada side. From the bridge a very excellent view is had of the entire falls. This bridge was completed during the past year and replaced the suspension foot bridge which occupied the same site, but by means of which the steel arch bridge was constructed. The steel arch has a clear span of 840 ft. and the highest point of the arch is 195 ft. above the water. After crossing the river the cars continue up the river along the bank to what is known as the Queen Victoria Niagara Falls Park 2½ miles to the village of Chippawa, just above the mouth of Chippawa Creek, and which was formerly the terminal of lake navigation. This route is an attractive one for tourists, for, from the various points very fine views are had of the two falls, and the Canadian Rapids, where the river descends over its rocky and wide bed 50 ft. in a mile.

For those who wish to refresh their memory regarding the falls, the following dimensions are given: The great curve of the Horseshoe Falls is 3,010 ft., with a height of 158 ft., and it is estimated that more than 280,000 cu. ft. of water pass over the precipice each second. The American Falls are 1,000 ft. long and 167 ft. high, but the sheet of water is very thin and the direction is about at right angles to that of the Horseshoe Falls, or, rather, the water falls over the side of the gorge that has been cut by the Great Falls.

From Chippawa the cars return down the river to the bridge and continue along the brink of the cliff, forming the west side of the gorge to Queenstown Heights and the village of Queenstown, about seven miles below the steel arch bridge. This is known as the Canadian Scenic Route, and gives the tourist a panoramic view of the gorge and rapids and Whirlpool Rapids. Opposite the Whirlpool Rapids the line crosses a high viaduct over what was once one of the branches of the river flowing from this point to the lake. The width of the gorge varies from 800 to 1,500

ft., but at the base contracts to 250 ft., and is from 250 to 350 ft. deep. On this route one has a good view of the steel cantilever bridge of the Michigan Central R. R., and the steel arch bridge of the Grand Trunk Ry., which was built in 1897, on the site of the old Suspension Bridge which it replaced, the work having been done without suspending the traffic over the old bridge. This bridge has a total length of 1,100 ft., is 226 ft. above the water, and the width of the center arch is 550 ft. At Queenstown Heights the

FIG. 2—NEW STEEL ARCH BRIDGE.

cars pass near the Brock Monument, which marks the battle ground of 1812, where the Americans were defeated, and where the British commander, Gen. Isaac Brock, was killed. The column of the monument is surmounted by a heroic statue of the general in full uniform; the height above the ground is 185 ft.

From the heights the line of the track zigzags down the side of the hill and on to the terminal of the new suspension bridge, which was built by the railway company during the past year. This bridge is on the site of one that was destroyed in 1864 and spans the mouth of the gorge and connects Lewiston with Queenstown. The cable span of this bridge is 1,040 ft. and the suspended span 800 ft.; the roadway is at a height of 65 ft. above the river. The cars cross the bridge and run along the cliff above the tracks of the gorge road towards Lewiston, where connection is made with the cars of the Niagara Gorge R. R., on which the return is made to Niagara Falls. The route takes the passenger along the bottom of the cliff on the east side, near the edge of the river, so that a very close view is given of the rapids and whirlpool. In connection with this route the company has established a belt line service by which the trip can be made around the gorge without change of cars and for which the fare from Buffalo and return is $1.25. It is the intention in the near future to run the belt line cars in both directions.

The Lockport division, as above noted, embraces a line from Buffalo to Lockport, a distance of 15 miles, on which six cars are run, on a half-hour schedule, the fare being 60 cents for the round trip. The local cars in Lockport are run on a 10 and 15 minute headway, and six cars are operated. The cars lie over at Lockport 20 minutes for inspection and to give the motors time to cool off. The Lockport line leads out from Buffalo along Main St. and runs to Tonawanda, from which place it occupies the former roadbed of a line until recently controlled by the Erie R. R., and on which steam cars were operated. This is one of the few steam lines in the country on which electricity has superseded steam for both passenger and freight service. For the freight service the company has installed two electric locomotives of the General Electric type, each of which hauls 18 loaded freight cars or from 18 to 30 empty cars at a time. These trains are run on the same dispatcher system that was employed with the steam service.

The lines of the Depew Division pass through four villages, namely, Sloan, Belleview, Depew and Lancaster. This line leaves Buffalo by Broadway, and is 14 miles in length. The fare for the round trip is 25 cents. The line serves a population of over 10,000. Depew is a comparatively new manufacturing village, where about 3,000 hands are employed, many of whom live in Buffalo and ride back and forth every day.

The other divisions have no special features and will not be described in detail. Some of the suburban lines are built on the public highways and others occupy private or leased rights of way.

POWER.

One of the most interesting features connected with the International Traction System is the power equipment. Although the company owns a steam generating plant in Buffalo of 7,500 h. p. capacity, and which is known as the Niagara St. plant, a large part of the power is bought from the Niagara Falls Power Co., or, rather, from the Cataract Power & Conduit Co., which is the name of the local company in Buffalo, which receives and distributes the cur-

FIG. 3—LEWISTON BRIDGE OPENING DAY.

rent, both for light and power, that is generated by the water power at the falls, over 20 miles away. The railroad company, however, now receives a part of its power direct from the transmission line and transforms it in its own station. In this connection it is interesting to note the development in the employment of this power by the railway company. In June, 1896, the Buffalo Railway Co. purchased from the Cataract Power & Conduit Co. 1,000 electrical horse power, which was delivered from the distributing

station at a pressure of from 350 to 375 volts, 25 cycles, to rotary converters which were located at the Niagara St power station, and which converted the alternating current to a continuous 500-volt current by which the cars are operated. After one year a second block of 1,000 e. h. p. was taken and a 2,000-h. p., one hour rating, storage battery of the Electric Storage Battery Co's. type was installed at the power station to assist in taking care of the peak of the load, and render the consumption of power economical throughout the 24 hours.

After another year's use the new company made arrangements to purchase direct from the producing company sufficient power to operate all the regular cars in the city of Buffalo, which under ordinary conditions require about 5,000 e. h. p., equivalent to the entire output of one of the big generators at the Niagara Falls station. The peak of the load frequently runs up to 8,000 or 10,000, and on rare occasions to 12,000 h. p. Instead, however, of receiving the current after it had undergone one transformation as formerly, the railway company has put in five new transformer stations in different parts of the city and which were put in operation the first of the present month, and to each of which the Niagara current is delivered direct from the transmission line by means of insulated underground cables at the same pressure, namely, 11,000 volts, at which it is brought from Niagara Falls to Buffalo. Each of these stations is similarly equipped, except that some have two and others three 400-kw. rotary transformers; there are three static transformers for each rotary. The general plan of these stations is shown in Fig. 4, which is an inside view of what is known as the Cold Spring Station, located in a brick compartment 50 x 30 ft., which occupies part of the repair shop building which stands at Michigan and Main Sts. This is intended to be the model station of the lot when completed. The switchboard, which does not appear in the engraving, is a very elaborate affair, and stands at the back of the room and has the very latest improvements known to the art. The station equipment consists of six static transformers, shown on the right of the illustration, two rotary converters, each of 400 kw. capacity, and which, with the static converters and the switchboard, are all of the General Electric manufacture. The current is received through a single three-conductor cable at 11,000 volts, and 25 cycles, as above noted, and is led first through an emergency oil switch by means of which the entire station can be cut off. From this the current leads direct to the station panel of the switchboard, and through a new type of shunt fuse circuit breaker, there being one for each wire, and which are operated by a time limit relay so that an overload must be on the station three and one half seconds before the switch opens. With this arrangement there is a clock work and battery, and when the main line opens it is short circuited through an explosive fuse provided with tubes which lead the gases away and blow out the arc. From this panel the current is led to oil switches enclosed in fireproof brick compartments which are located above the switchboard and supported on steel frame work. From the oil switches the current is led direct to the static transformers from which it is stepped down to 375 volts and then goes direct through reactive coils to the rotaries which deliver it at 600 volts, direct current, to a standard direct current panel on the switchboard and then to the line feeder through wattmeters. Among the auxiliary equipment of the station may be noted a resistance box that is encased and located behind the switchboard and which is employed in starting up the converters on the direct current. A third rotary is now being installed.

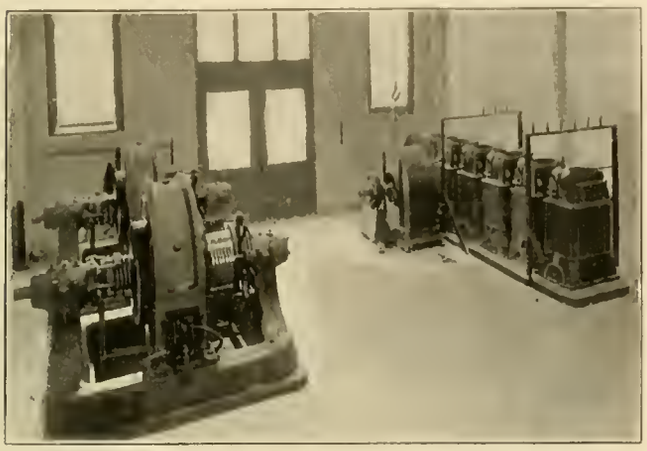

FIG. 4 INTERIOR OF TRANSFORMER STATION.

There are also two steel cased fan blowers made by the Buffalo Forge Co., and which are operated from a direct connected G. E. 3-h. p. motor. These blowers are placed one at each end of the line of static transformers and provide a blast of air which is conducted into a chamber leading under the transformers and from which it is led up about the cores and comes out through perforations in the cases. This blower with its motor is shown more fully in Fig. 5, and the 10 required for the five stations are all manufactured and installed by the Buffalo Forge Co., of Buffalo. This type of blower is the one at present employed by nearly all the General Electric transformer stations throughout the country.

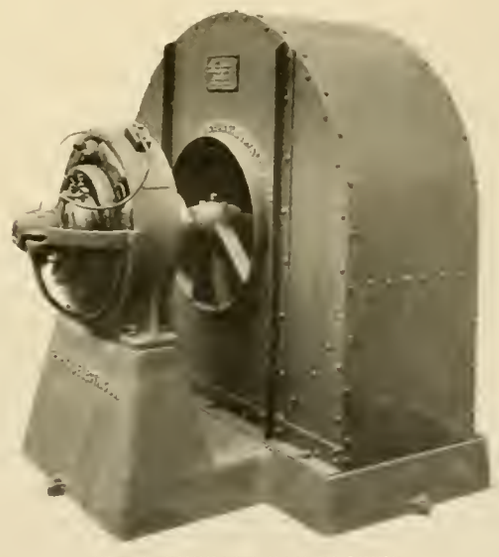

FIG. 5—BUFFALO FAN BLOWER.

In three of the transformer stations the converters are started by a direct current from the company's power station: in the other two the starting set consists of a 30-kw. induction motor with an independent set of special transformers. This motor is direct connected to a 25-kw. direct current generator which furnishes current to start the rotaries.

A special feature of the rotary is that each is provided

with an electro magnet placed in the bed frame at the end of the armature shaft and actuated by an intermittent current which gives a shuttle movement to the armature, so that the commutator moves back and forth under the brushes, thus producing uniform wear on the commutator collector, bearings and brushes.

ELECTRIC WELDING OF RAIL JOINTS.

Another interesting feature connected with the International railway system is the electric welding of rail joints. The railway company, recognizing the value of continuous rails, contracted with the Johnson Co., or, rather, the Lorain Steel Co., for the welding of 11,000 joints during the present season, by the electric welding process that has been perfected by the Steel company. The joints of all the new tracks that have been laid during the present season and a

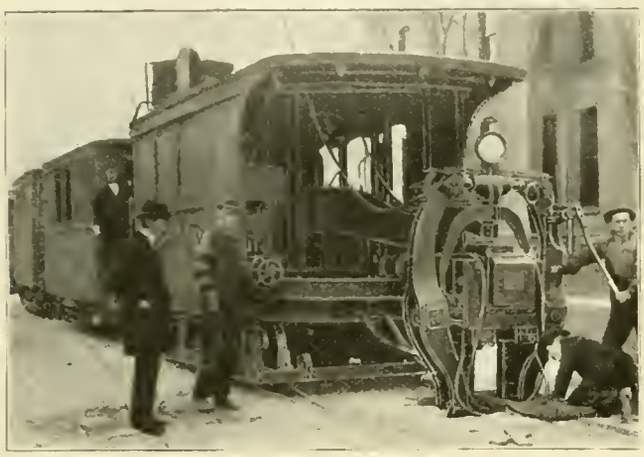

FIG. 6 WELDING TRAIN.

good many in the old track have been welded by this process, and what is still more interesting, copper conductor cables of 500,000 c. m. cross section have been provided to lead the current around all special work, and the terminals of these cables have been electrically welded to the

FIG. 7 SAND BLAST CAR.

rails each side of the special work, and the cables have been interlaced and welded together. By this means the special work is left so it can be removed or repaired without interfering with the return circuit. Although the process of electric welding has been described before in these columns, it has now become so thoroughly perfected as to details that it is regarded by its promoters as one of the cheapest and most desirable methods for uniting rail joints, both from the standpoint of durability and electric conductivity. For accomplishing the work the welding company employs two welding trains, consisting of five short cars each. The welding train proper consists of three cars, Fig. 6, while one of the other cars is known as the sand blast car, Fig. 7, and one as the emery grinder car, Fig. 8. On the last car of the welding train is mounted a 75-kw. rotary booster of the Crocker-Wheeler make. In the second car is also a rotary converter. The trolley current is led first to the booster, which holds it up to a uniform voltage of 500, when it is led to the second transformer which delivers it at 300 volts alternating to a static transformer which forms a part of the welding head shown in the figure. The secondary coil of this transformer consists of a single copper bar bent in the form of a horseshoe which terminates at the bottom of each side of the rail in a water-jacketed block, the face of which is about 3 x 4 in. In this transformer the current is stepped down to about 5 volts, but with about 30,000 amperes flowing. In the process of welding, if the rail is an old one containing punched bolt holes, the holes likely to be affected by the heat are reamed out by hand to about 1⅞ in. in diameter. The object of this is to remove the incipient checks that were formed in the metal in the process of punching and which open from the effects of the heat and form an initial rupture which has been found to give way under the stress of contraction. It is found that the rail is really stronger after the holes are reamed to the above size than before. In a test it was found that a 6-in. rail with a 2½-in. hole drilled through the web was stronger than the same rail with a punched hole of only 1⅛ in. in diameter. The breaking strength of the former was 400,000 lb., while the rails with the punched holes broke at 330,000 lb. Following the reaming, the rail ends at the welding points are cleaned with the sand blast and also the plates that are to be welded on to form the joint. The sand blast car is equipped with a 5-h. p. motor, which, in one train drives a single acting air compressor, and in the other a double acting, by which an air pressure

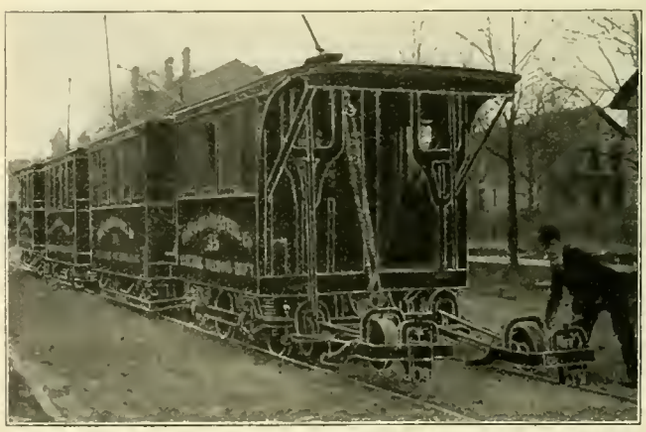

FIG. 8 EMERY GRINDER.

of 12 lb. per sq. in. is generated. This is led into a vertical tank containing sand, or an arrangement known as the Tilghman sand blast device, containing a double set of valves from which the blast is led through a 2-in. rubber

hose terminating in a ¾-in. nozzle. Sharp sand is used and it requires usually about 20 lb. to clean a joint; it is efficient and leaves the surface very fresh, insuring good electrical contact for the initial current. In the operation the attendant wears a shield over his head, as shown in the illustration. The car is also provided with an electric heater for drying the sand when it becomes necessary. The welder is next brought into position and the terminals of the movable jaws brought in position on each side of the rail. The welder proper consists of the transformer above described, and two curved pivoted jaws, which are actuated by an horizontal hydraulic cylinder which connects the upper terminals of the jaws and to which power is communicated by a small pump operated by hand power, as shown. The welding head is suspended to an adjustable jib and by means of power may be raised, lowered and turned from one side to the other, so as to operate on either rail. The splice bars that are employed are about 1 x 3 in. and from 17 to 23 in. in length. These are first prepared by having a pear shaped projection of ⅛ in. punched up at each end and a similar shaped piece fitted into the cavity on the other side of the bar. The projections form the in-

FIG. 9—OLD CAR.

itial points of contact when placed in position against the web of the rail. For the middle contact a thin strip of metal is placed between the bar and rail and the middle weld is made first. The bars being in place the terminals of the transformers are held against the base with a pressure of about 2,000 lb., and as soon as the current is well started and heat generated the pressure is slacked off until a welding heat is obtained, when pressure is increased to about 35 tons and held until the metal has cooled or become dark. The secret of success in electric welding has been found by experiment to consist in working the hot metal by pressure as is accomplished in ordinary welding by the blacksmith's hammer. The welds are made at three points on the bar, first at the middle and through the web, then at the ends of the bar. In case there is a gap between the ends of the rails it is filled by means of shims consisting of thin rail sections, which are provided in different thicknesses. An auxiliary equipment of the welding car consists of a motor to run the jib, which carries the welding head, and a motor to operate a small rotary pump, which causes the water to circulate through the welding blocks. There is also a blower driven by this motor which delivers a blast to a water cooling tank located on the roof of the car as shown, and which is provided with perforated shelves to facilitate the cooling process. Following the welding process, in case the joint is too high or uneven, the emery grinding car is brought into position and the surface is ground down to a uniform line. Two emery wheels are provided, one for each rail, which are mounted as shown, in a swinging frame, and are driven from an electric motor by means of V-shaped belts and grooved wheels. The frame is so mounted that it can be moved back and forth like a jack plane, and so bring the surface to a perfect level. With the above described equipment, from four to six rail joints can be welded in an hour. In 1897 the company welded 364 joints in a 6-in. rail at Johnstown, Pa., and up to date only one of these joints has broken, although the track has been in continuous service.

Special work with hardened steel centers is employed and is purchased of the Lorain Steel Co., Wm. Wharton, jr., & Co. and the Pennsylvania Steel Co. The Buffalo Ry. has laid about 17 miles of track with rails made by the Pennsylvania Steel Co.

SPLICED CARS.

The rolling stock includes 96 cars from 29 to 31 ft. in length, which have been rebuilt from 16 and 18-ft. cars that have seen from six to eight years' service. These long cars are not in all cases made by splicing two short cars, but in many cases the old car is expanded to the new dimension, as shown in Figs. 9, 10 and 11. The body is first cut in the middle and the parts separated. The old sills are then united by a ship's splice, when a new sill 4½ x 5 in. with entire new floor framing and end sills is placed under the whole, and the new and old sill bolted together at intervals. This plan is followed in order to give more headroom in the car and to provide strength. An 8-in. steel plate ⅝ in. thick covers both sills and is bolted to the outside, while there is a steel angle plate upon the inside at each corner extending 18 in. each way. The truss rods consist of a flat plate 2½ x ⅜ in. placed just under the window frames but bent down at each end at the second window from the end of the car, and linked into an eye bolt anchored to an angle iron on the bottom of the sill. A second straight flat bar 2½ x ¼ in. is placed just above the former and extends the whole length of the car through the end post, where it is held in position by heavy nuts. The sides of the car are filled out with new posts and panels, and the letter board in case it is wide in the old construction, is arched out above the windows. The hoods are then spliced out 12 in. The deck lights are of chipped glass and are stationary except two at each end on the opposite sides. The bumper is formed by a curved channel bar 8 x 2 in. and weighs 11 lb. to the foot. It is estimated that the cost of the spliced cars is about $700.

All the cars of the system are equipped with fenders of the type shown in Figs. 11 and 12 and which were designed by the master mechanic of the company and made in the repair shop. Quite a number of the cars on this system have an additional stationary fender consisting of steel frames placed on a line with the edge of the bumper and left to slant back to the dash.

The rolling stock of the entire system comprises 642 motor passenger cars, 98 trail cars, 72 service cars, consisting of snow sweeper, plows and levelers. All the cars are provided with vestibules of the Brill patent detachable type. Fifty of these spliced cars are mounted on Brill 27-F

trucks and equipped with G. E. 57 motors, and controlled by electric brakes of the G. E. type with a special controller and handle for operating the brake. Other spliced cars are mounted on double trucks which were rebuilt from some single trucks of the company's own make, known as the Buffalo truck, and used under 16-ft. cars. The motor and brake equipment of these is the same as for the 50 cars described above. There are 67 24-ft. cars which were built

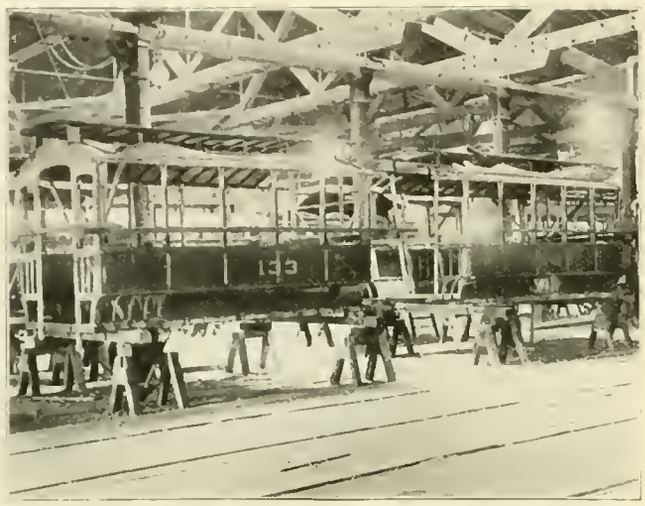

FIG. 10—PROCESS OF REBUILDING.

by the Brill company and which are mounted on Brill maximum traction trucks and equipped with G. E. 1,000 motors, and controlled by Sterling safety brakes, which are said to be giving excellent satisfaction. There are 30 27-ft. cars which were built by the Gilbert Car Co., of Troy, and which are mounted on Bemis trucks, equipped with G. E. 57 motors and electric brakes. There are five 27-ft. Brill cars on maximum traction trucks with G. E. 1,000 motors and equipped with air brakes of the Christensen type, with

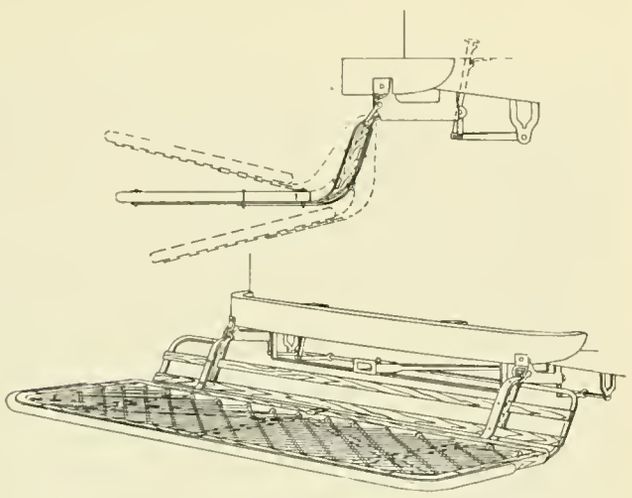

FIG. 12 FENDER.

axle driven compressors, the compressor being attached to the pony axle of the truck.

Thirty equipments of the Standard Air Brake Co's. make of axle compressors, which have been in successful operation since 1892, have recently been removed from closed cars and remounted on summer cars and the closed cars equipped with No. 57 motors and electric brakes. Thirty of Brill cars, 28 ft. in length, with Hale & Kilburn cross seats, are mounted on Brill No. 27 trucks and equipped with four G. E. 1,000 motors and hand brakes and are operated on the Buffalo & Niagara Falls line. These with some of the suburban cars frequently attain a speed of from 50 to 60 miles an hour. This speed is easily made wherever the current holds up to the full 550 volts. Ten 31-ft. cars with cross seats and mounted on Brill No. 27 trucks with four

FIG. 11 REBUILT CAR.

G. E. 57 motors, and electric brakes are operated on the Buffalo and Lockport line. On some of the other divisions single truck cars are run, some of which are 21 ft. in length, others 16-ft. and 18-ft. cars, but these are all of a style that are not suitable for splicing. It is the intention of the company, however, later on, to employ only double truck cars, and all new cars are to be mounted on Brill No. 27 trucks with four motors. Next year the rolling stock will be increased by the addition of 100 open cars, 50 of which will be 14-bench cars, the others 13-bench. There will be no seats on the platforms and the bodies will be

FIG. 13 SNOW FENCES.

mounted on 27 F Brill trucks, as stated, with four G. E. 1,000 motors. Before the Pan-American Exposition which is to be opened in Buffalo on May 1, 1901, an addition of 200 long cars will be made.

The standard color for cars operated in the city is wine color, with the exception of the 50 long cars that are run in the city limits and which are painted green. The color for the interurban cars is yellow or orange. The wheels

employed by the company are made by the New York Car Wheel Works, of Buffalo.

The snow plow equipment includes nine Ruggles rotary machines, equipped with G. E. 1,000 motors, and which were made in the company's shops. There is one McGuire plow and two old type T. H. sweepers. There are also seven double-shear plows designed by the master mechanic and made in the shops. The first of these was built last year and proved so efficient that six others have recently been constructed, with this difference that the shear of the new ones is double, so that the lower half may be lifted without raising the entire weight. These plows are equipped with two G. E. 57 motors, and weigh, fully equipped, about 13 tons. The shear is quite long and is set at an angle of about 45°. The framing is very heavy, of oak timber, with sills 12 x 6 in., set edgewise, and on the opposite sides that sill extends forward to the end of the shear near the top. The side frames of the truck are made with two channel irons which form a box and enclose an oak timber. These side bars also extend to the ends of the shear near its lowest point. The plows are provided with a fluke or leveler, which is operated from within the cab by means of worm gear and a shaft outside, around which a chain is wound, as shown in the illustration. The bracing for the shear is made from old flat and T-rails and the back of the shear is supported by vertical sections of T-rails which slide up and down in guides made to receive the head of the rail. The cab is closed with a door on each side, or an opening which on its lower half is provided with a door, with heavy curtains above, which can be pulled down to meet the door, and on the opposite side from the attendant who operates the fluke can be closed entirely, making the cab very comfortable for the workmen. The plow is operated by three men, one for the controller, one to operate and adjust the shear and fluke and one to watch the trolley pole. In addition to this equipment for snow protection, the company has erected in the city limits about 16 miles of portable snow fence, Fig. 13, which is put up in the fall and removed in summer. This fence consists of 16-ft. panels from 5½ to 6 ft. in height, and which is usually set staggered, as shown in the illustration. It is held in place by short posts driven into the ground, to which the bottoms of the panels are nailed.

The car house section adjoining the repair shop has been added to from time to time, in sections, and now is 600 ft. in length, with brick walls and steel structural roof. In constructing a new power house at Jefferson and Eagle Sts., during the present season, because of a difficulty in getting steel structural work from the mills, the company has employed old track rails, and finished up a 600 ft. structure which is 200 ft. in width, and has a capacity for 100 cars and housing for one of the emergency wagons and the horses to operate it.

The International Traction Co. is already making preparations to meet the anticipated increase of traffic incident to the opening of the Pan American Exposition, which is to be held from May 1 to Nov. 1, 1901. Both North and South America will take part, and it is claimed that this will be the first great fair exclusively American—that embraces a hemisphere. The exposition will be held on grounds embracing several hundred acres, located to the north of Buffalo, adjoining and including part of Delaware Park. The location is reached by six lines of electric cars, and it is the intention of the company to spare no expense to provide ample transit facilities.

FIG. 14 INTERIOR OF NIAGARA FALLS STATION.

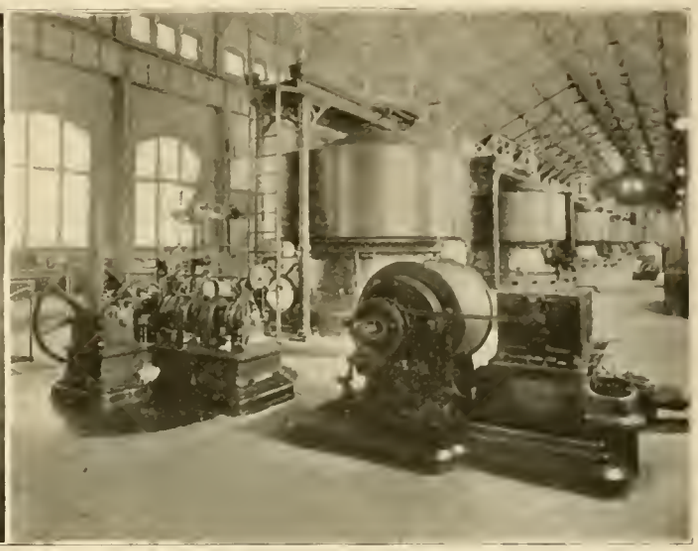

FIG. 15 GOVERNING APPARATUS

In connection with the Niagara power development, it may be stated that the companies engaged in furnishing electric power comprise the Niagara Falls Power Co., whose plant is located about a mile and a quarter above the falls. The buildings are of gray stone, the larger of which covers the wheel pit, which is about 150 ft. deep, in the bottom of which the turbines are placed, and to which the water is led by large steel penstocks. Vertical shafts support horizontal generators, as shown in Figs. 14 and 15; the latter shows the governing mechanism. The water on passing the turbines is directed into a tunnel 29 x 18 ft., located 200 ft. below the surface of the city, and discharges into the gorge just below the American end of the company's steel arch bridge, and 7,000 ft. from the wheel pit. The present capacity of the plant is 50,000 h. p., but work has already begun adjoining the former plant for a second equipment having the same capacity as the original station. A new

transmission line will also be built to Buffalo in the near future, and it is the intention of the International Traction Co. to put up a transmission line of its own.

A second company, known as the Niagara Falls Hydraulic Power & Manufacturing Co., controlled by Schoellkopf & Son, furnishes a large output of power for local manufacturers and chemical reduction works. This plant is located just below the American Falls and the water is led down the bluff in penstocks to turbines at the foot of the gorge. There is also a plant for generating power for local lighting.

On the Canadian side is the plant of Niagara Park Power Co., which was recently burned and is being rebuilt. This plant had a capacity of 2,500 h. p. The water is taken from the river just above the falls and is discharged through a tunnel leading into the gorge just below the edge of the Horseshoe Falls. This plant formerly supplied the power for operating the street railway lines on the Canadian side of the river. The turbines which were injured by the fire have been sent away to be repaired and the plant will be restored to its former capacity.

MANAGEMENT.

The affairs of the International Traction Co. are conducted by W. Caryl Ely, president; Daniel S. Lamont, of

W. CARYL ELY.

BURT VAN HORN.

Washington, vice-president; Burt Van Horn, general manager; R. S. Danforth, general superintendent, with five assistant superintendents; Richard F. Rankine, treasurer; J. E. Stevenson, passenger agent; and Robert Dunning, master mechanic.

Mr. H. H. Littell and Mr. H. M. Watson, former officers of the Buffalo Railway Co., are still residents of Buffalo, the latter being president of the local Bell Telephone Co.

By next spring the electric railway between Grand Rapids and Kalamazoo, Mich., will be in operation for the distance of 50 miles. It is said that the fare will be at the rate of one cent a mile and the line will compete directly with the steam road between the two points.

W. W. Hatch, who has been engaged in constructing and operating electric lines for the past 10 years, has organized the Goshen & Indiana Traction Co., to construct 56 miles of interurban connecting Goshen with Angola. The private right of way has all been secured and the new line will enter a large territory at present without transportation, passing through the towns of LaGrange, Lima, Orland and along the north shore of Lake James. The officers are Judge F. S. Roby, president; W. W. Hatch, vice-president and general manager; John F. Shuman, secretary; Sol. A. Wood, auditor; and T. M. Hatch, electrician. General office, Goshen, Ind.

TIE REPAIRS WITH DIFFERENT RAILS.

The following extract from a report made to one of his clients by John A. Beeler, consulting engineer, is very interesting.

The record of tie repairs extending over a period of several years, upon the lines examined, discloses the following facts, which are tabulated below. The rails have been divided into three classes, the 30-lb. and 35-lb. rail (26.83 and 2.67 miles respectively) being designated as class A. It was impossible to separate the repairs between these rails, and as the 35-lb. rail helps out the 30-lb. rail to a certain extent by it being a stiffer and better rail, it is not unfair to the 30-lb. rail at least."

The second class, B, represents but a small amount of 40-lb. rail, 3.40 miles, that has been repaired.

The third class, C, represents 11 miles of 45-lb. and 27 miles of 48-lb. rail, which are almost identical sections, the latter having the advantage of 3 lb. per yd. additional weight.

Car-house tracks, dead tracks, and other tracks, not in frequent use, have not been included in these figures, neither has the heavy T-rail track of recent construction, it having required no repairs during the period covered by the report.

	A	B	C
Total number of miles repaired	29.50	3.40	38.00
Total number of ties placed	26,867	1,249	8,637
Total cost of ties, including labor of placing	$27,355.11	$1,613.58	$9,700.43
Number ties per mile	911	367	227
Cost per mile	$927.30	$474.70	$255.27
Average cost per tie for labor placing	.52	.79⅓	.62½
Percentage of the mileage of the system covered by these repairs	29.8 per cent	3.5 per cent	34.8 per cent
Percentage of cost of the repairs	71 "	4 "	25 "
Ratio of cost per mile of track	2.30	1.14	0.68
Per each dollar expended on class "A"	$1.00	$0.48	$0.29

As is seen from the foregoing, the tie repairs have been distributed as follows:

29.8 per cent of the system has received 71 per cent of the repairs.
3.5 per cent of the system has received 4 per cent of the repairs.
38.4 per cent of the system has received 25 per cent of the repairs.

Or, for every 68 cents expended upon 45-lb. and 48-lb. rail track per mile there has been $1.14 expended upon the 40-lb. track and $2.38 upon the 30-lb. and 35-lb. track. Or, to state it another way, for every $1 expended upon class A, 48 cents has been expended upon class B and 29 cents upon class C.

This ratio will not suffice to represent the difference in joint and special work repairs, including mates, frogs, switches, crossings, etc., and as for bonds, it is almost impossible to maintain them upon the 30-lb. track. The loss in electrical return on the light rail is therefore tremendous.

Another important question arises, as to what is the condition of these various classes of rail at present. The 30-lb. rail, with nearly four times the repairs of the 48-lb. rail, it would seem, ought to be in very fair shape, but on the contrary, it is not.

The foregoing figures, based upon actual expenditures on the various classes of rail, demonstrate the necessity of employing good heavy steel rails, better than a long treatise upon this subject. Suffice it to say, that the best practice demands 75-lb. T-rail upon suburban lines, where 50-lb. T-rail was formerly used, and 100-lb. and 117-lb. girders instead of 56-lb. and 60-lb. girders. High speed and heavier cars demand this.

With a 60-lb. to 75-lb. T-rail upon lines (not requiring paving) the repairs would be much less than what a 48-lb. rail requires. The general surface and line would hold (except where interfered with by some outside agency, such as sewer, water, gas, or other excavation until the ties disintegrated.

The bonds placed under the angle bars would be amply protected, cost less, have less resistance, and give a much better return.

The weight of the rail is not only felt in the tie and track repairs, but at the power house, in decreased coal consumption; at the shops in the repairs to rolling stock; at the superintendent's office, in better time made and less interruption to the regular service; by the public in smoother track and more pleasant riding; by the stockholders in decreased expenses and increased receipts.

The electric line between Greenwood and Indianapolis was scheduled to be opened by December 15th.

CAST WELDING ON THE CALUMET, CHICAGO.

The Calumet Electric Street Railway Co., which has a total of 80 miles of track, has decided to cast weld all the joints on its system using the system of the Milwaukee Railjoint & Welding Co. under license from that company. The work to be done at once will be the welding of four miles of track laid with 7 in. 85-lb. girder rails; this is located in Pullman. The Calumet company will have the advantage of being able to prosecute the work during the daytime on all the double track sections, the traffic being such that one track will suffice for it while the other is being welded.

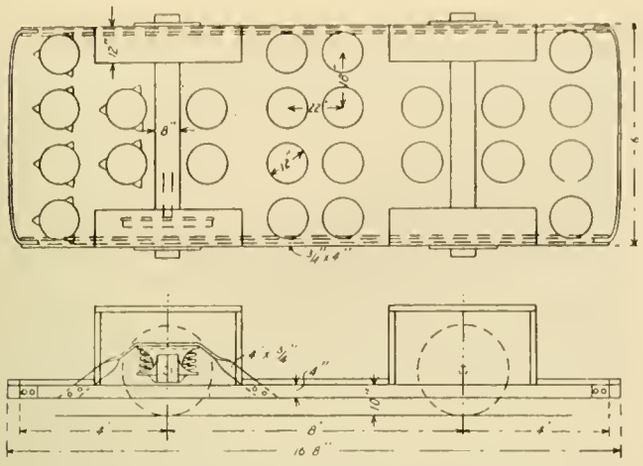

FIG. 1 HEATER CAR.

On some of the single track lines, also, there will be no necessity for night work.

Ordinarily the welding outfit is carried on a number of wagons requiring horses and teamsters, which means a considerable increase in the cost unless the road is one which has a number of horses of its own which can be put in this service. Being free to make greater use of his tracks for hauling the apparatus and supplies than could be done on most roads, Mr. H. M. Sloan, general manager of the company, designed the "welding train" which we illustrate; it was for the most part built in the company's shops, the details being designed by Mr. W. A. Harding, master mechanic and electrical engineer.

The outfit consists of four cars: a cupola car, a sand blast car, a heater car, and a supply car.

The supply car is a flat car, with a platform 6 x 9 ft. and 26 in. high above the rails; it has coupling bars so that it can be hauled or pushed by a motor car. This car is to carry the jackets, molds, clamps, etc., when they are distributed along the track; it follows the men who remove the dirt around the joints.

The heater car is a car especially designed to transport the lamps or torches used for heating the rail ends before pouring the joints. The company has 25 of the White rail joint heaters made by the White Manufacturing Co., of Chicago; the heaters were illustrated and described in the "Review" for October last, page 728. A special car body was built to carry these so that half of the torches may be burning and not interfere with each other. This car is shown in outline in Fig. 1. The frame consists of two side pieces 16 ft. long connected at the ends by iron straps ¼ x 4 in. in section. Each side piece is made up of two bars ¾ x 4 in. spaced 1½ in. apart. To the side frames are riveted the four straps, ¾ x 4 in., which pass over the pedestals. The wheels, pedestals and axles above the floor level are boxed in as shown. The heaters are 12 in. in diameter, but the pump, torch arms, etc., prevent close packing and a floor space 18 x 22 in. is provided for each heater the whole car carrying 24 of them. Each heater is held in position by blocks fastened to the floor.

CUPOLA CAR

The cupola car is about 30 ft. long and 6 ft. 10 in. wide over the side sills. It is mounted on two Cloud steel trucks which are placed 18 ft. 6 in. c. to c. The wheel base of each truck is 62 in., making the wheel base of the car 23 ft. 8 in. These trucks are fitted with the M. C. B. standard journal boxes, and differ from those made for steam railroad service only in having the transoms spaced 2 in. apart instead of 12 in. The wheels are 33 in. in diameter. The axles are 3¾ in. at the motors, 3⅞ in. in the wheelfit and 3¾ in. at the journals. The brasses are M. C. B. standard filled with babbitt. Axles of these dimensions were used because the company had them in stock, and in event of their proving too small they can be easily replaced. The brake rigging is the McGuire standard inside hung type redesigned to avoid the motors. Pressure on the brake is applied by means of a lever moving in a vertical plane; this lever connects with and gives motion to transverse shafts placed between the axles of each truck and moving the brake shoes by means of cranks and links.

The car has a metal frame, the longitudinal sills being four 7-in. "Providence girder" rails taken out of some old track in Pullman. Figs. 2 and 3 show the car before the motor and blower were housed in. The four sills are spaced 21, 38, and 21 in. between centers, and held transversely by 11 tie rods made of ⅞-in. rods, placed inside of 1-in. wrought pipes; sections of 1½-in. pipe of the proper lengths are slipped over the 1-in. pipes and act as distance pieces between the sills. The nuts on the tie rods show plainly in Fig. 2. The bolsters are trusses built up 1 x 5½-in. bars, and are arranged to get the car body as low as possible. Six diagonal braces of ⅞ x 3-in. iron are placed between the sills at the center of the car. At 9 ft. 3 in. from each end are wooden distance pieces placed between the sills and cover plates 1 x 6 in. placed top and bottom with bolts each side of each sill. The flooring of the car is of 2-in. oak planks 12 in. wide. Strap iron strips are placed along the side edges so as to protect the planking.

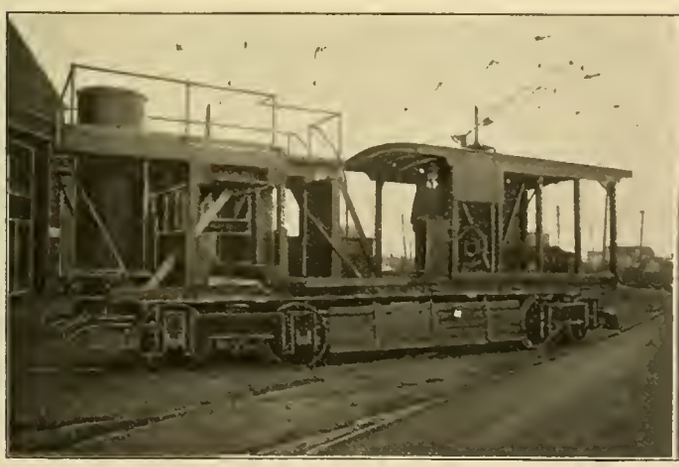

FIG. 2 CUPOLA CAR.

FIG. 3.

The cupola furnace is made of ⅜-in. boiler steel, 34 in. in diameter and 10 ft. high. The weight without the brick lining is 1,800

lb. The cupola is supended on four 4 in. x 7 in. x 7/8 in. springs by brackets riveted to the barrel aboout 2 ft. from the top. The center line of the cupola is 5 ft. 4 in. from the center of the truck. The frame supporting the cupola is built of 12 x 12 in. timbers, four sections of 7-in. Providence girder rails and bar iron. The center line of the tuyere pipe is 17 in. from the bottom of the cupola. The bottom of the cupola being only 18 in. above the rail, the doors for dumping are made double. Two spouts for the hot metal, each 20 in. long, are provided; they project at angles of 45° with the center line of the car. The charging platform is 5 ft. above the under side of the car sills, and is guarded by a railing made of pipe. The capacity of the cupola after the first charge

FIG. 4 CUPOLA CAR AT WORK.

is melted, is estimated at three tons per hour. The open space at the right of the cupola in Fig. 2 is utilized for storing the ladles and tools. The space farther to the right, under the stairway, is for the coke; a hinged platform (which is shown lowered in the cut) is provided for the man who shovels the coke up to the charging platform.

The blower for the cupola is a No. 4 Sturtevant fan belted to a 10 h. p. compound wound Crocker-Wheeler motor; these are located as shown in Figs. 2 and 3. The motor and blower are covered in the top of the box, being on hinges and sloped so that supplies and tools cannot be piled on it by careless workmen. The blast pipe is 10 in. in diameter, and at the cupola is provided with a flexible connection. The compound winding of this motor is utilized to secure a uniform speed at various voltages, to compensate for the drop of potential at the ends of the longer lines.

A special controller made in the company's shops is arranged for the blower motor giving uniform speed at three different voltages, 450, 500, 575. This is done by cutting out the series field when the voltage drops from 575 to 500, and by reversing the series winding for a voltage of 450. In series with this special "three voltage controller" is an automatic controller (Schuman & Haydon). Both of these controllers are mounted on the boards shown at the right of the car controller in Fig. 2.

The K2 controller for the car motor is at one side of the car in a position equally convenient for the motorman when running ahead or aback. The car motors are two WP. 50's, both mounted on the truck at the far end from the cupola. To mount them on the other truck would have made a greater weight available for traction,

FIG. 7 CLEANING JOINTS.

but it was deemed of more importance to have the motors where they would be readily accessible. As mounted, the end of the car may be lifted and the motor truck easily run out.

Fig. 4 shows this car as completed.

SAND BLAST CAR.

One of the things essential to cast welding is the thorough cleaning of the rail end, and nothing has been found so efficacious for this as a sand blast. The sand blast car of the Calumet is 18 ft. long by 6 ft. wide, mounted on a four-wheel truck. The truck used is a Three Rivers truck rebuilt; the length of the truck support is 17 ft. 6 in., and of the wheel base 8 ft. Extra heavy springs have been added to support the car body, which when loaded will weigh probably 10 tons. One W. P. 50 motor is mounted on each axle. The side sills of the car are of Georgia pine, 4 x 10 in. and the end sills, 8 x 10 in.

The equipment of this car consists of one 15-h. p. motor, belted

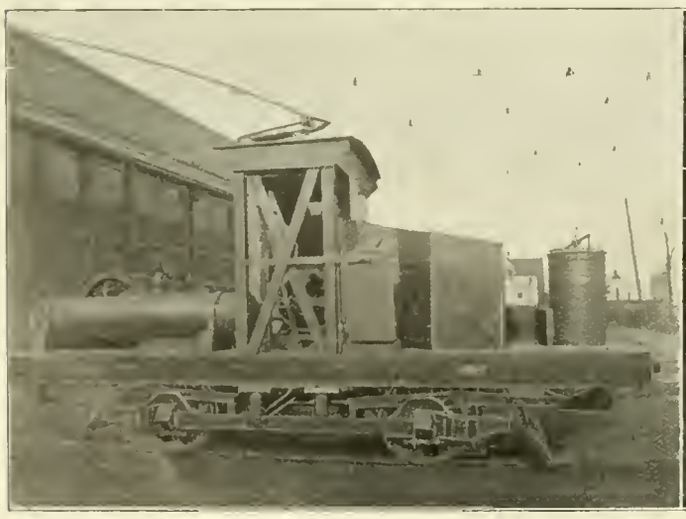

FIG. 5.

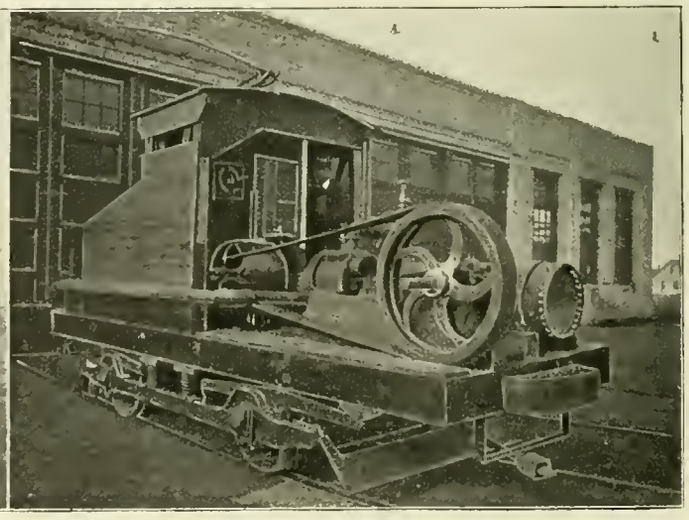

FIG. 6.

SAND BLAST CAR.

to an 11 x 10-in. air compressor, and a sand blast. The motor is located midway of the length of the car, and at one side. It is belted to the air compressor, which was made by the Geo. F. Blake Manufacturing Co., and has a capacity of 120 cu. ft. of free air per minute at 200 r. p. m. On the same end of the car is a 20-in. air tank 8 ft. long made out of an extra heavy steam header formerly used in the power house.

From this tank a 3-in. pipe leads along the outside of the car to a double feed sand blast, built to order for the Calumet company by B. C. & R. A. Tilghman. This apparatus is 20 in. in

FIG. 8 SAND DRYING HOUSE.

diameter by 5 ft. high, and is supported with the lower end 21 in. below the car floor, making it more convenient for the operator to place sand in the hopper.

Two lengths of 2-in. rubber hose are attached to nozzles below the car floor so that two joints can be cleaned at once. A water tight sand box is provided. From this box the sand runs into a tray and is then shoveled into the blast apparatus.

The position of the motorman and the location of the controllers, switch, fuse box and brake lever are shown in Figs. 5 and 6, which

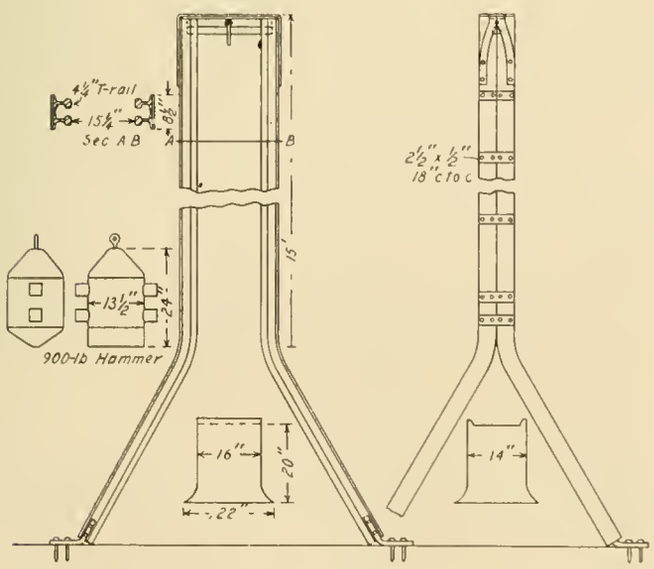

FIG. 9—DROP HAMMER.

are from photographs taken before the compressor was covered in. Fig. 7 shows the car as completed.

The men using the sand blast wear canvas helmets, as shown in one of the engravings; to further protect them small pipes are carried from the air tank to the helmets so that the sand attempting to enter under the cape will be blown away by the current of air.

As considerable quantities of sand will be required in connection with the rail welding, the chief engineer of the company, Mr. D. F. Schroeckenstein, has designed a sand drying house shown partially completed in Fig. 8. The house is 9 x 12 ft. and 6 ft. high, located near the pond and tables, for cooling the condensing water used in the power station. The hopper extends along one side of the sand house and holds 5 cu. yd. of sand. On the floor of the sand house are 53 sections of 1 in. pipe, 16 ft. long, spaced 2 in. between centers. These pipes are screwed into an 8 in. header 10 ft. long which is connected to the discharge pipe from the condensers to the cooling table. The fall from the discharge pipe to the sand house piping is 4 ft. 6 in. The water after flowing through the drying pipes is discharged into the cooling pond. This arrangement dries the sand by means of heat that would otherwise be wasted.

As one of the pieces of auxiliary apparatus a hammer for breaking scrap and pig for the cupola was desirable, and accordingly Mr. Harding designed and built that shown in Fig. 9. The standards are old 4½-in. T rails bent out at the lower end, wrought iron feet are bolted to the bottoms of the four legs for fastening to a foundation built up of cross-ties. Cement concrete cast around the legs will increase the stability. For the present the hammer will be lifted by a windlass, but it is expected later to fit it with a pneumatic cylinder.

We are indebted to Mr. J. P. Love, of the Calumet, for the photographs from which our engravings were made.

EFFECT OF BOYCOTT PASSING.

The Cleveland Electric Ry. has survived the boycott against it and has recently had to order 40 new cars. An official of the company recently said: "Our trade is coming back to us in nice shape. Saturday and Sunday, November 25th and 26th, our receipts were $2,000 more than on the same days last year. The company has not been able to take care of its patrons as it would like. Inability to secure cars has been the cause, in addition to the fact that the company is disposing of all its 16-ft. box cars. The new cars are 28 ft. long in the clear, and when they arrive we will have sufficient cars to take care of our patrons in the proper manner."

ROAD FOR WESTERN PENNSYLVANIA.

E. A. Ferrin, of Reynoldsville, Pa., advises us that the Reynoldsville Traction Co. has been organized for the purpose of building an electric railway from that place to Rathmel, Big Soldier, Sykesville and Elnora, a distance of 14 miles. The company has engaged an engineer who will complete the surveys, maps, etc., as rapidly as possible, and it is hoped sufficient progress can be made so that bids for construction can be received early in January, 1900. Mr. Ferrin is to be president of the company and the active manager.

RIGHT TO CARRY FREIGHT.

A decision by Judge Dissette, of Cleveland, recently handed down, is quite interesting, and the principle will prove an important one if it is sustained by the higher courts. The suit was brought by H. C. Herron to enjoin the Cleveland & Chagrin Falls interurban road from hauling stone over a section of its road, that class of freight being forbidden in the franchise. The court ruled that the granting of the right to use the street carried with it the right to haul whatever the company saw fit as long as it was for the accommodation of the public.

THE RAILWAYS COMPANY GENERAL.

Among the properties recently acquired by this company are the Lewisburg, Milton & Watsonville Passenger Railway Co., Milton (Pa.) Electric Light Co., Montoursville (Pa.) Passenger Railway Co., and the Philadelphia & Bristol Passenger Railway Co., Croydon, Pa. The officers of the Railways Company General are President, L. N. Downs; vice-president and general manager, John Blair MacAfee; secretary and treasurer, Taylor Faunce; general superintendent, D. A. Hegarty. The general offices are at 1002 to 1008 Hamson Building, Philadelphia, Pa.

HALF FARES.

The Rapid Transit Co., of Dayton, O., has obtained an extension of time until Jan. 1, 1900, to build its line.

Contracts have been let for a three mile extension to the Toledo (O.), Bowling Green & Fremont Electric Ry., from Mermill to Mungen.

The United States has furnished Mexico with about $340,000 worth of electrical material so far this year, according to a recent statement.

The work of relaying the street railway tracks in East Rome, N. Y., is progressing rapidly; when completed Hardie air motors will be put in service.

The Cleveland, Berea, Elyria & Oberlin Railway Co. states that it will build in 1900, an extension of its present track nine miles south of Wellington, O.

Unless unforseen obstacles arise the Greenwich (N. Y.) & Schuylerville Electric Ry., now in course of construction, will be in operation by Jan. 1, 1900.

Work on the power house of the Northampton (Mass.) & Amherst Street Ry. is progressing rapidly and it is expected that cars will be running by Christmas.

The Terre Haute Electric Co. has announced that it will sell 25 street car tickets for $1, the six for 25 cents rate, and the books of 100 tickets for $4 being withdrawn.

As a sanitary precaution the Brooklyn Rapid Transit Co. has removed the floor mattings from the smoking cars on its elevated lines.

Strong inducements are being offered by the merchants of Mound City in the shape of bonuses to the Cairo Electric Street Railway Co. to extend its service to Mound City.

A surgical department has been added to the Union Traction Co., of Muncie, Ind. This service means immediate treatment for any of the employes of the company in case of injury.

The report of the Schenectady Street Railway Co., for the quarter ending September 30th, shows gross earnings $16,505; operating expenses, $32,221; fixed charges, $3,267; deficit, $18,982.

George T. Bishop, of Cleveland, O., in connection with other capitalists, is attempting to secure permission to construct an electric road from Oak Cliff to Dallas and Fort Worth, Tex.

Abbott P. Smith, of 37 Purchase St., New Bedford, Mass., is securing franchises for an electric railway from Fall River to Cape Cod, a distance of 35 miles. The road will be constructed at an early date.

Attorney-General White, of Delaware, has commenced an action against the Delaware Electric Co. for revocation of its charter. It is alleged the company has not complied with the requirements of its charter.

The Mount Pleasant, Scottdale & Connellsville Electric Railway Co. will erect three new brick buildings at Scottdale. The car barn will be 100 x 150 ft., the power house 50 x 100 ft., and an office 30 x 32 ft.

Soda ash as a preventative of troubles from bad boiler waters received strong praise before the Traveling Engineers' Association from an officer of the mechanical department of the Chicago & Northwestern Ry.

The earnings of the Brooklyn Rapid Transit system for the month of November, 1899, were $937,849 as against $850,760 for November, 1898, and $796,614 for November, 1897.

A number of citizens of Tropico, Glendale and Burbank, Cal., are holding mass meetings relative to the construction of an electric railway through these places to Los Angeles. The need of such a line is very much felt.

The work of surveying for a new electric line between Saginaw, Mich., and Frankenmuth, has just been completed. The work of constructing the road will not be commenced this year, but will be pushed in the spring.

The street railways comprising the system of the Massachusetts Electric Companies report their gross earnings for the fiscal year ending September 30th at $4,479,122, against $4,111,132 for the previous year—a gain of $367,990.

The Syracuse (N. Y.) Rapid Transit Co. is being sued by John E. Ladd for $10,000 damages. One of the cars ran into his wagon, throwing him out. Part of the damages asked is for the bad habit which the team learned in running away.

The Toledo Traction Co. is now splicing 26 of its 16-ft. body closed cars and making 13 cars measuring 28 ft. 4 in. inside; the sills are spliced and new trusses put in. The new cars will each be equipped with two Westinghouse No. 3 motors.

Construction work on a new railway in the island of Hawaii, to be built by American capital, will soon be commenced. The road will be 130 miles long, and will be operated by electricity, which will be generated by three water power plants.

The supervisers of Middletown township have granted the Philadelphia & Delaware Electric Railway Co. the right to the highways of Middletown to extend its lines from Media along the Baltimore turnpike to Lenni. It will comprise a 5-mile extension.

Three miles of copper ground wire was stolen last month from the tracks of the Inland Traction Trolley Co., near Lansdale, Pa. The road is in the course of construction and the theft was not discovered until some time after it occurred. The wire is valued at about $300.

A trolley car belonging to the Ossinning Electric Railway Co., of Sing Sing, N. Y., ran into a wagon loaded with dynamite, recently. The dynamite did not explode, and aside from nearly scaring to death the driver of the wagon and the motorman, no serious damage was done.

A new method for calibrating the current of an alternating current instrument has been worked out by Carroll D. Jones of the physics department of the University of Michigan. A transformer is used. Less than one-twentieth as much energy is required in this method as in the ordinary industrial methods.

The American Railways Co. is negotiating for a controlling interest in the Cincinnati, Newport & Covington Street Ry. The same company has recently bought the bonds of the Dayton, Ohio, company, has bought outright the Springfield, Ohio, road, and has secured a $500,000 interest in the Chicago Union Traction Co.

The street railway company of Berlin, which is a no-license suburb of Hartford, Conn., has found it necessary to put a special car, known as the "Jag Car," on Saturday and Sunday nights to convey some of the residents home from the neighboring towns. It is manned by some of the strongest men in the company's employ.

The Aurora (Ill.), Yorkville & Morris Electric Ry., commenced operating one section of its road on November 7th. Power is purchased from the Aurora Street Railway Co., but a new power station will be erected as soon as the entire line is constructed. The completed system will comprise 36½ miles, laid with 83 lb. rails.

Oxide of iron, graphite and carbon pigment has been decided to be the best protective coatings for iron and steel by the Master Car & Locomotive Painters' Association. Pure graphite is considered excellent, but this paint is liable to be adulterated with silica, which, while being a good filler, does not give good wearing qualities.

The Nazareth & Bath Electric Railway Co. has been incorporated at Harrisburg, Pa., with a capital stock of $24,000. The directors are: Joseph J. McKee, F. W. Lembartz, Alvin Hill, C. A. Waller, Truman M. Doddson, of Bethlehem, A. S. Kick, of Allentown, G. A. Schneibelli, of Nazareth, and C. R. Horn, of Catasauqua.

A representative of the New York World, in attempting to demonstrate the possibilities of the transfer system in that city, rode for a single 5-cent fare for 24 consecutive hours, traveling 107½ miles and receiving 87 transfers. He could have probably continued indefinitely, as he had ridden over but a portion of the company's lines.

The Detroit & Northwestern Electric R. R. is fast nearing completion. There is but a small amount of track remaining to be laid, and the power house and car barns are located at Farmington. The road will be equipped with 12 50-ft. cars with center aisles, smoking rooms and toilet rooms. Some of these will also have baggage rooms.

T. Julian McGill, the Minneapolis representative of the Westinghouse Co., has been working up a project to harness the water power of Taylor's Falls and bring it into Minneapolis and St. Paul for light and power in the possible amount of 6,000 h. p. There is some doubt whether an electrical plant could be established in the center of the new interstate park.

The death of Dr. M. P. Turner, in Des Moines, Ia., recalls the beginning of the street railway system in that city. When the town was small Dr. Turner secured an exclusive franchise and constructed just sufficient roadway to maintain the franchise. Every effort was made to annul this, but unsuccessfully, and after many years of dire poverty he sold the system for $340,000 cash.

It is expected that the Lehigh Valley Traction Co. will shortly absorb a number of trolley lines that connect with its system. It is stated that the company practically controls the Bethlehem & Nazareth Railway Co. and is negotiating for the Easton, Bethlehem & Palmer and the Easton Consolidated lines. The South Bethlehem & Saucon Street Railway Co. is now practically secured by the syndicate.

A contemporary finds that the word "juice," as applied to electric currents, originated in Ireland with the employes of the electric railway running to the Giant's Causeway, one of the first street railways built in the world. Hearing the current called fluid, and thinking juice synonymous to this, they so named the electricity. It is suggested in Boston that the word ought to be changed to gravy.

A transfer arrangement has been made in Brooklyn whereby passengers on the surface cars living in the outlying districts will be transferred to the elevated lines at several points free of charge, thus enabling them to make better time to the heart of the city, and at the same time relieving the surface lines of a great deal of extra traffic, and giving more room in the cars for the shorter distance riders.

Compressed air cars have been withdrawn from service on the 28th and 29th St. cross-town lines of the Metropolitan Street Railway Co., of New York. The cars have never been popular with the residents of the neighborhood owing to the noise and greasy drippings left in the streets.

There has been considerable agitation in Cleveland, O., recently upon the subject of abolishing grade crossings between the steam and electric lines in the city. There are 133 such crossings at present and the city engineer estimates that it will cost about $10,000,000 to change them all over. The railroads are expected to bear a large part of this expense.

At the annual meeting of the Southwest Missouri Electric Railway Co. an increase in the capital stock from $650,000 to $800,000 was voted. Work on the new power house and the big barn at Webb City is progressing rapidly. The proposed extensions will be to Riceville, a double track between Carterville and Lakeside Park, lines from Joplin to Central City and Belleville, and from Prosperity to Duenweg.

The interurban electric lines entering New Brunswick, N. J., are being used by the merchants of that place as a means to increasing business by furnishing free excursions on all of them to the city on certain days. Every one wishing a free trip pays his fare on the cars and receives a ticket which is good for five cents in cash at any of the stores in the arrangement. It is not necessary to purchase anything in order to get the rebate.

W. J. Newton, president of the Mineola, Hempstead & Freeport Traction Co., advises us that his company proposes to build an electric railway from Mineola, Long Island, nine miles south to the water front at Freeport, passing through several villages. From Freeport the company contemplates running a line of small passenger steamers across the bay. Others connected with the enterprise are Benjamin F. Hamilton and Charles Hills.

According to figures given out by the Inter-State Commerce Commission, one passenger is killed for every 2,267,270 carried on steam roads, through accidents, and one is injured for every 170,141 carried, or upon a mileage basis, 60,542,670 passenger-miles are accomplished for each passenger killed, and 4,543,270 passenger-miles accomplished for each passenger injured. Of the trainmen employed on steam roads, one out of every 150 was killed and one out of every 11 injured.

Los Angeles, Cal., is about to create a department of electricity, which shall have charge of all electrical systems in the city. The board of fire commissioners will be empowered to appoint a chief officer of the department, to be known as the city electrician, whose salary is fixed at $2,000 a year, and who will be required to give a bond in the sum of $1,000. The electrician will be allowed a deputy, to be known as inspector of wiring and appliances, and who is allowed to retain out of fees collected for his services not to exceed $1,080 a year.

Another cable road has had to disappear to make room for electricity. The Third Avenue R. R., of New York, is now operated throughout its entire length by the electric conduit system, the last section of the cable road having been changed over on November 22d. Mr. John H. Robertson, superintendent, and Dr. Louis Duncan, chief engineer, deserve the highest praise for the way in which they have met and solved the various operating and mechanical problms that have arisen in the work of practically rebuilding the old roadbed and substituting electric for cable cars. This has been accomplished without interrupting the service to the public and with but little loss of traffic.

Crosby & Coolidge, who are building the Northampton & Amherst Street Ry., a line eight miles long, between the city of Northampton, Mass., and the college town of Amherst and through the town of Hadley, have the line nearly completed. The power house will be located in Hadley, near the tracks of the Boston & Maine R. R. The power house and car electrical equipment will be of

Westinghouse make. The Wason Manufacturing Co. furnishes the cars of the latest pattern cross seats. Cars will probably not be in operation before January 1st, owing to delays at the power house.

Franchises and rights of way have been secured for what promises to be one of the most valuable street railway systems in the South. The line runs without serious grades or curves from Lynchburg, Tenn., to Wartrace, Tenn., a distance of about 20 miles. A 30-ft. dam will be built at Duck Creek, and a 5,000-h. p. water plant constructed for furnishing electricity for light, heat and power to the adjacent country. Heavy freight, such as grain, live stock, etc., will be handled in addition to the passenger service. The company is known as the Wartrace & Lynchburg R. R., and the officers are: President, H. H. Evans, of Aurora, Ill.; vice-president, S. H. Case, 312 Roanoke Building, Chicago; secretary and treasurer, Frank B. Smith, of Aurora, Ill. J. Y. Garlington, of Lynchburg, Tenn., is a director and one of the prime movers in the enterprise.

JAPAN NOTES.

At the last semi annual meeting of the Tokyo Tramway Co., the report for the first six months of 1899 was submitted, showing receipts of 469,813 yen; disbursements, 253,490 yen; balance, 216,323 yen, of which 155,400 yen was paid in dividends, 32,420 yen to reserve and bonus accounts, and 28,503 yen to surplus account. The stockholders voted to consolidate with the Shinagawa Tramway Co., and to increase the stock for the purpose of purchasing the stock of the latter company. The Tokyo Tramway Co's. stock, par value 50 yen, is quoted at 245 yen.

Japan has her own way of doing things. The Sanyo Railway Co., a steam road, employs a train boy to carry an album through all its express trains for the purpose of securing the signatures of all the first-class passengers, believing "the album will soon become an interesting collection of signatures and autographs," and will form a means of whiling away the time for the passengers.

Under the auspices of Viscount Katsu Inouye and other promoters, a factory to be named the Kisha Seizo Goshi Kwaisha (Railway Rolling Stock Factory) has lately been established at Nishi-ku, Osaka, for the purpose of making cars and other railway supplies. The capital is 900,000 yen, and the officers are: President, Viscount Katsu Inouye; vice-president, Ki Hiraoka; auditors, Eiichi Shibusawa and Sadakichi Tanabe.

The Tokyo Chamber of Commerce has sent a memorandum to the home minister on the subject of street railways. The chamber's idea is that the traffic should be conducted as a private enterprise, the street railway company paying for the privilege of using the streets, besides ordinary taxes, a royalty amounting either to from 4 to 10 per cent of gross receipts, or 8 to 20 per cent of the net profit. The term of the charter should be limited to 30 years, capable of being renewed only for one term, and on the expiration of the term of the charter the city should have the right to purchase the track, rolling stock, etc., at a properly appraised price.

Several companies within the past few years have applied for permission to build electric railways in Yokoyama, but such applications have always been disapproved by the city authorities on the ground that the streets were too narrow for the enterprise. The city officials have recently announced, however, that if the rival projectors will unite into one company, the desired franchises may be granted.

A consolidation of all the tramway companies in Tokyo, including the Tokyo Denki, the Tokyo Densha, and the Compressed Air Co., is being formed, the new company to have a capital stock of 15,000,000 yen.

The city solicitor of Dayton, O., has advised the council that in the absence of state legislation on the subject the city councils have no power to compel street railways to place conductors on their cars.

A CURVED GLASS BLUE-PRINT MACHINE.

A paper read before the American Society of Mechanical Engineers by Paul Mellen Chamberlain, Assistant Professor of Machine Design, Lewis Institute, Chicago.

The desirable features of a blue-point machine are ease and rapidity of operation, such adjustment as to secure the direct rays of the sun, and means whereby close contact between the tracing and the sensitized paper may be secured. The machine here described and illustrated was designed to meet the above requirements, and was first built for, and in the shops of, the Lewis Institute.

The operation of the car and the universal adjustment is so clearly shown in Figs. 1 and 2, that explanation seems unnecessary. The iron work is all galvanized to avoid rusting after exposure to

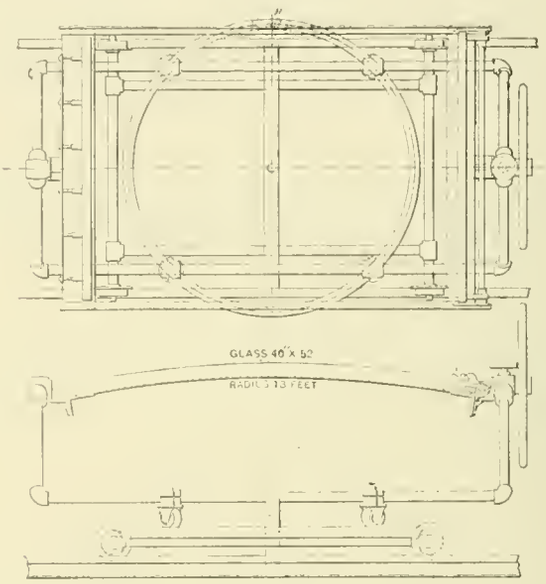

Fig. 1

rain or snow. The glass is curved to a radius of 13 ft. Attached to one end of the frame is a sheet of canvas rubber packing about 1-32 in. thick. The other end of the rubber cloth is fastened to a steel tube which serves as a roller to roll the cloth on and also as a stretcher. Square projections at each end of the roller are engaged by hook cams, which are operated by eccentrics on each end of a steel rod, rotated by a handle at one end, through an angle of 180°.

The operation is this: The rubber cloth is rolled back on the steel tube, and the paper and tracing are placed on the convex side of the glass; the cloth is unrolled with one hand, leaving the other

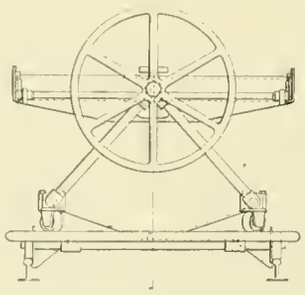

Fig. 2.

free to adjust or turn down crumpled edges of the tracing, the ends of the steel roller are engaged by the cams, and a turn of the handle stretches the cloth, giving a pressure component normal to the glass; the frame is turned over, the car pushed out of the window, and the frame adjusted to the proper angle with the sun's rays. The operation is rapid; the placing of tracings very easy, and the contact obtained between tracing and paper all that could be desired. Three years of use have demonstrated its convenience and durability.

The Easton, Palmer & Bethlehem Street Railway.

There was organized at Easton, Pa., on June 11, 1897, the Easton, Palmer & Bethlehem Street Railway Co., chiefly through the efforts of Mr. T. A. H. Hay, of Easton, who promoted the idea of building an electric railway from Easton, the county seat of Northampton, on the Delaware River, to Bethlehem, the chief manufacturing center of this section. Mr. Hay interested the Worcester Construction Co., of Worcester, Mass., in this project and when the organization was effected the Worcester company became the controlling stockholder in the new railway company.

The general direction of the route chosen was due west from Easton to Bethlehem, running through the heart of the rich and fertile valley, 18 miles in width, alongside of the Lehigh River. In locating the line of the new road, which is 12 miles in length, the route was chosen so as to offer rapid transit facilities to the 100,000 people which form the population of this section. Directly upon the main line is the township of Palmer with its dozen hamlets and villages, besides which are the towns of Farmersville and Butztown. To the south of the line are Fremansburg, Hellertown and Lower Saucon, while to the north are Nazareth, Bath, Chapmans, Wind Gap, Pen Argyl and Bangor.

At the western terminus of the road are the Ordnance Works of the Bethlehem Steel Co., where 4,600 mechanics are employed in the manufacture of armor plates and guns for the United States Navy. Many of these men reside in homes scattered along the route of this trolley road, which has proved a great convenience to them.

Work on the road was started June 15, 1898, and it was finished on November 6th of the same year. The construction was carried out in a substantial manner. Part of the rails are 64½-lb. T-rails, while in the rural districts the Siberia section of rail manufactured by the Maryland Steel Co. is used, and in the cities is a 7-in. T-rail, 72 lb. per yard, made by the Cambria Iron Co. The fine chestnut groves in the neighborhood afforded the company ample material for ties, which were hewn 7 ft. long, 6 in. face and 5 in. deep, and laid 2 ft. between centers. A foundation of broken stone was used and ordinances in the cities required that within the city limits the company place Macadam pavement between the tracks as well as one row of Belgian block outside the rails.

The overhead construction includes chestnut poles 30 ft. in length and 7 in. thick at the top, which are set 100 ft. apart with 5 ft. in the ground. The trolley wire is No. 00 made by Washburn & Moen, and is carried on span wires within the city limits and upon brackets in the rural districts. The brackets were made by the Walworth Manufacturing Co. Twelve miles of overhead feeders are carried on these poles, the feeders being No. 0000.

The company operates nine open and five closed cars, manufactured respectively by the Newburyport Car Manufacturing Co. and the Massachusetts Car Co. The open cars are 10-bench cars, 31 ft. over all, seating 50 people, having curtains between the side posts, and single trucks of the Peckham extra long style, with a 7-ft. 6-in. wheel base. These are equipped with two G. E. 1,000 motors and K 10 controllers. The closed cars have vestibules, are 30 ft. long over all and 20 ft. long between the doors, having a seating capacity for 28 people. These have Peckham "Excelsior" trucks with a 7-ft. wheel base, and are equipped with two G. E. 52 motors and K 10 controllers. Each car is lighted with a 5-light cluster, and the closed cars contains six heaters, each of the electrotherm type, made by the H. W. Johns Manufacturing Co. They also contain New Haven single fare registers and are equipped with fenders made by Louis Pfingst, of Boston; Van Dorn Dutton track scrapers are used and the company owns one Taunton snow plow.

The power plant and car barn of this road are situated at the little village of Butztown, which is located about midway between the termini of the line. The advent of this new industry in addition to the railway traffic on the new line through this village has changed its rural aspect into one of business activity and has opened up much needed communication with the neighboring towns. The power house is a brick building, 86 x 45 ft., having a boiler room 50 x 60 ft. and 26 ft. high. This room is equipped with three return tubular boilers, built by Stewart & Son, Worcester, Mass., having a maximum capacity of 250 h. p. each and containing 292 tubes. They are run at 120 lb. steam pressure. To these are connected two Deane feed water heaters and two Deane steam pumps. The main steam pipe is 10 in. in diameter, supplied by the Walworth Manufacturing Co., and is fitted with valves of the Shipman and Jenkins' makes. The boilers are connected to a 75-ft. steel stack set upon a stone foundation 8 ft. square and 8 ft. deep. The lower section of 25 ft. is 4 ft. in diameter and made of ⅝-in. steel; the second section of 25 ft. is of ½-in. steel, and the remaining section is of ⅜-in steel. The smoke flue is 4½ ft. x 2 ft. in section. No. 2 Buckwheat coal is used for firing the boilers.

The engine room is 52 ft. x 45 ft. and contains two Greene engines manufactured by the Providence Steam Engine Co., of Providence, R. I. These have cylinder dimensions of 18 in. x 42 in. and run at a speed of 104 r. p. m. The shafts are 9 in. in diameter and the fly-wheels weigh 18 tons each and are 18 ft. in diameter. These engines have been running constantly since they were started nine months ago without any delays or stops whatever. The engine room also contains one jet condenser of 600 h. p. capacity, built by the Deane Steam Pump Co., and two steam pumps of the same make, 6 x 6 x 4 in. The steam piping of the engine room is run overhead. There are two G. E. generators of 240 kw. each, which are belted direct to the engines with 26-in. 4-ply belts. The switchboard which is located between the generators is of the Standard General Electric railway type, having panels 8 x 2½ ft. on which are mounted the usual switches and instruments.

The water used in the plant is drawn from a well and pumped into a reservoir located 300 ft. from the boiler room. The water is hard, containing considerable lime, and it has been found necessary to treat it with an "emerald" compound before taking it into the boilers. This compound has proved very satisfactory in softening the old scale and preventing the formation of new scale in the boilers.

The company has established a pleasure resort just beyond Butztown known as Oakland Park, which has proved a very attractive feature of the road and is visited by thousands of people daily. It is located on the crest of a hill in an immense grove of oak trees, and scattered about the grounds are numerous attractions for visitors. At night hundreds of electric lights illuminate the grove, and wide cinder paths are laid out leading to all parts of the park.

A splendid and abundant water supply has been provided by means of an artesian well, which was bored 150 ft. deep through solid rock, and everything possible has been provided for the comfort and pleasure of visitors. Centrally located is a large combination stage and band stand, where entertainments are given and bands are heard in daily concerts. Surrounding the stage is a natural amphitheater easily accommodating 3,000 people. There is a baseball diamond, lacrosse and football field, as well as a tennis court and a large dancing pavilion with a promenade walk hidden in natural shrubbery. The park is less than half an hour's ride from the heart of Easton and Bethlehem with their 60,000 population.

The park was laid out in just five weeks by landscape gardeners from Boston under the direction of Supt. Charles H. Cox and according to his own ideas, and he also rushed the construction of the road through quickly, having started the work in July, and opened it for traffic on November 6th.

Among other innovations that have been introduced by Superintendent Cox, which have made the road popular with both the public and the employes, was the opening of a motorman's school at the car house. Here the motormen in the company's employ as well as advanced students from both Lafayette College and Lehigh University take a prescribed course of lectures on electricity, with Mr. Cox as the instructor. Matters pertaining to car motors are discussed in the pits of the car house where the motors are assembled and repaired. The class at times numbers 50 students. Through Mr. Cox's efforts the fare between the terminals of the road was reduced to 15 cents; he also established a telephone system along the line, introduced electric lighting at every street crossing on the road, and converted the original 4-car schedule into the present one in which 12 cars are operated.

The officers of the Easton, Palmer & Bethlehem Street Railway Co. are: J. S. Rodenbough, president; A. D. Chidsey, treasurer; J. B. Bull, S. H. Hackett, W. A. Stern, E. B. Smith, W. Hinkle Smith, and Geo. W. Norris, directors; Charles H. Cox, superintendent.

The company was organized with a capital stock of $200,000, one-half being common stock, and one-half preferred stock, all of which was subscribed before the building of the road. There were $200,000 of bonds issued. From the date of opening until January 1st, 113,652 passengers were carried, the receipts being $4,925.90 and the operating expenses 59 per cent of the earnings. The operating force consists of 35 employes.

The Bradford (Pa.) Electric Street Railway Co. is about to run its cars by the block system, which though simple, is very effective. It is self operating, being connected with the electric power which operates the cars, and mistakes will be impossible. Only one car can be in the same block at the same time.

Children Passengers on Street Railways.

The carrying of children passengers upon street cars, whether free, at half fare, or full fare, is a subject which calls for special regulations by street car companies upon which no special unanimity exists. With a view to inquiring into the general practice upon this subject, the "Review" has secured data from a large number of roads in regard to their regulations for children passengers, and from the 61 typical roads selected for comparison, one is led to the conclusion that practically no general practice exists in this regard.

On all of the roads reporting, children are carried free up to certain ages and under certain conditions. The free list is confined in some cases to infants in arms and extends on one road to children eight years old accompanied by parent or guardian. Forty-one of these roads have no half fares whatever and 25 roads give 3-cent fares for children between certain ages, while five roads limit their ½ fares to school children and during school hours only. Out of the roads having no ½ fares 11 demand fares for children of whatever age if they occupy seats to the exclusion of passengers paying fares, while on a few roads the regulations seem to imply that children under a certain age are carried absolutely free whether they are accompanied by a passenger paying fare or not. As to the number of children carried free in charge of one passenger, no limitations are generally given. One manager writes: "A parent rarely has more than three children under the age of five, but we have found cases where teachers of a Sunday-school or kindergarten expected that their classes, being under paying age, should be given free transportation, but such cases are not frequent. Under such circumstances not more than three children are allowed to ride free."

There is a wide difference of opinion between managers of street railways in regard to the advisability of 3-cent fares for children, and in most cases the adoption of ½ fares for children of certain ages, where not prescribed by city ordinances, varies with the individual opinions of the railway managers. Some of these consider children a very undesirable class of passengers on account of their tendency to play in the cars, standing upon the seats, annoying other passengers and in general enjoining much more care and trouble on the part of the conductor than do adult passengers. Another argument which is brought forward against 3-cent fares is the complication which they introduce in the accounting department and the difficulty which they involve in checking up the conductors returns. These troubles seem to warrant upon the majority of roads the establishment of a single 5-cent fare, and children under a certain age are regarded in the light of necessary evils and carried free.

Among those roads on which ½ fares are charged are a few in which this question is determined by city ordinances to that effect, but aside from this the question of ½ fares does not appear to bear any relation to the size of the roads or the amount of the population from which their traffic is derived. Out of the 25 roads selected for comparison upon which ½ fares are charged, 10 roads fix the age for 3-cent fares between 5 and 12 years. These roads vary in mileage from 8 to 475 miles, in number of cars operated from 16 to 3,276, and draw their traffic from populations varying from 5,000 to 2,000,000 people. Of the other roads charging 3 cent fares, two fix the age limit at from 5 to 10 years, three from 6 to 12 years; two at from 4 to 12 years; two from 2 to 10 years; one at from 4 to 10 years; one at from 4 to 8 years; one at from 7 to 10 years; one at from 3 to 12 years, and one at from 6 to 13 years. These examples are taken from roads in every section of the country, and as we have said before, seem to follow no special rule.

On a few roads on which ½ fares are not generally charged, special rates are given to school children going and returning from school. Figure 1 illustrates the school childrens' tickets issued by the Newton & Boston Street

FIG. 1. FIG. 3.

Railway Co., which are furnished in quantities of 1,000 for $25 to the superintendents of schools. These tickets are good for school children only, under the age of 10 years, and are paid for by the city of Newton, Mass. The tickets are 1⅞ in. long, by ⅞ in. wide, and are printed in black, as shown, upon white cardboard. No tickets are issued direct to school children, who must either obtain them from their school superintendent or pay full fare.

Figure 3 shows a sample of the school ticket used on the Austin Rapid Transit Ry., of Austin, Tex. These are supplied to school children under 12 years of age, and are made up in books of 40 tickets, which sell for one dollar. The tickets are 2 in. by 1 in. in size and are printed partly in black and partly in red ink, on cream colored cardboard. The words "school ticket" and the serial number are printed in red.

The Ashland & Catlettsburg Street Railway Co., of Ashland, Ky., uses the school ticket illustrated in Figure 4. This company has been selling these tickets at ½ price for several years, and finds that it pays, as there are a great many poor children who could not afford to pay full fare who use the ½ fares liberally. The tickets are 2⅛ in. long

FIG. 4.

by ⅞ in. wide, and are printed in red on white cardboard. Under the company's rules the ½ fares are confined to travel to and from school, and are not good on Saturday or Sunday, nor to and from the company's park at any time.

The school ticket of the Ogden Electric Railway Co., of Ogden, Utah, is illustrated in Figure 5, together with the book in which 40 tickets are bound. These books are sold for the use of children attending the public schools at $1 each. The book measures 1⅜ in. by 2⅛ in., and the tickets are 1 in. by 2⅛ in. The tickets are printed in black on

green paper, the serial number being in red. These tickets have been found to be a source of considerable income to the company, and a great many of them are used where otherwise the children would walk. The company has issued these tickets for several years and is thoroughly satisfied with the results. Inside the cover is printed the following instructions: "Good only to and from day school.

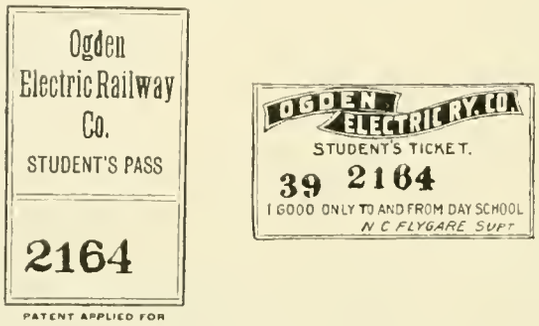

FIG. 5.

If presented at any other time the conductor will take two fares." The tickets are not good if detached from the book.

Figure 6 illustrates the school tickets furnished by the Union Traction Co., of Anderson, Ind., and the book in which they are bound. The book measures 5 in. by 2 in., and contatins 10 pages of four tickets each, the book selling for $1. At the close of the school term any tickets which may not have been used are redeemed by the company. The covers and tickets are red, and printed in black. The following rules for conductors are printed inside the cover: "Do not accept detached tickets for fares. Do not accept tickets from this book for fares only between hours named on front hereof, and for person to whom this book is issued. When last ticket is used from this book return the back to the office."

A special method of handling ½ fare passengers is in use on the Southwest Missouri Electric Railway Co., of Webb City, Mo., which is as follows: The conductors buy from the office a pad of ½ fare tickets—20 in a pad—for which they pay $1. These tickets are sold on the cars to ½ fare passengers at 5 cents each, and the conductor punches the ticket and hands it to the passenger but does not ring up the 5 cents received. The punched ½-fare ticket is then good for another ride when presented by a passenger, from 5 to 12 years of age, and it is then rung up and turned in by the conductor receiving it. These tickets are illustrated in Figure 2. They measure 3⅛ in. by 1¼ in., and are printed in black on yellow paper.

The most troublesome feature of carrying children, either free or at half fare, arises out of the difficulty of determining the age of the child, and on this point numerous disputes arise between conductors and passengers on almost all railways. One manager, on whose road children are carried free under five, writes that his experience is that most children from the time of their birth up to seven years, remain at the stationary age of four years. Another one states that children riding on his road seldom attain to the age of three years, or if having unfortunately become three years old, they never get to be 12.

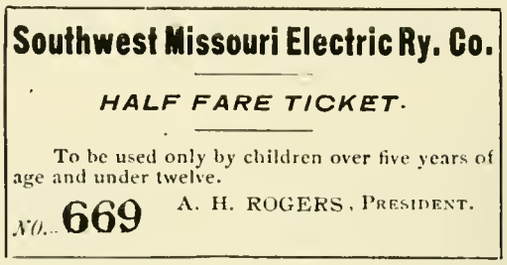

FIG. 2.

The instruction to conductors on the majority of roads on this point is to use their own judgment; collect the fare if possible, and avoid arguments with the parent or guardian; but never to eject a passenger for this cause. On a number of roads, however, where this trouble is more frequent, the orders to conductors are somewhat more stringent. One road writes: "Our experience is that the parent or guardian will never admit that a child is over six years of age and voluntarily pay a fare for it, but wait for the conductor to demand the fare. We expect our conductors, when in their judgment they consider a child six years of age, or over, to collect a fare, and the judgment of our conductors must be absolute, otherwise we would find it impossible to enforce the rule."

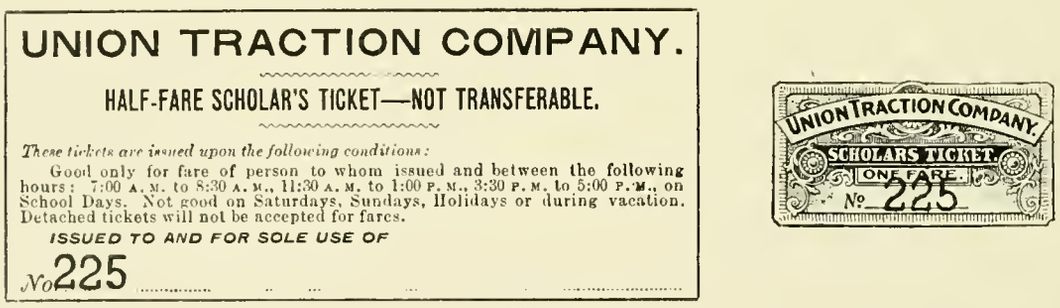

FIG. 6.

On another road the following orders are issued to conductors:

"Children under five years of age, not occupying seats to the exclusion of paying passengers, may be carried free, providing each such child is accompanied by and in charge of a paying passenger. Children will not come under this rule when placed on the car in charge of a passenger who has boarded the car at another point, nor when taken on the car by a passenger and put off at a point other than that where such passenger leaves the car. Conductors will not ask the age of children nor have any discussion whatever with parents or those in charge of children. They will be guided entirely by the size and general appearance of children, demanding fare for all those who are clearly over five years of age and giving the benefit of the doubt to any about whom they may be at all uncertain."

In addition to these instructions the cars of this company contain a printed notice to the following effect:

FARE, FIVE CENTS.

"Children free only when under five years of age, not occupying seats and when accompanied by grown persons. But one such child will be carried free with each grown person. Full fare will be charged for all others. Parents and guardians will be required to pay fare for all children who are of the size and general appearance of five-year-old children, regardless of actual ages, as conductors are forbidden to discuss the ages of children with parents and instructed to be guided entirely by size and general appearance."

CHICAGO CITY RAILWAY TRIP SHEET.

The method of accounting for ½ fares by the conductors varies on different roads, that of Chicago City Railway Co. being given as an example.

On this road when two ½ fares are collected at once from one person the conductor rings up one 5-cent fare, but where a single ½ fare is taken it is punched on the trip slip by the conductor and not rung up on the register. A row of numbers beginning with X, 3, 6, 9, etc., is printed across the top of the slip, which is illustrated below. The first ½ fare is punched at X, the second at 3, the third at 6, and so on, so that the number following the last punch mark shows the amount in ½ fares to be turned in for the trip. The slip is 7¼ in. wide and 13 in. long with spaces to report 17 full trips. On the back of the slip is a column for registering the number of passengers carried for each ½ trip on passes and badges.

In the case of a few roads conductors are obliged to take the name and address of a passenger refusing to pay a fare for a child, and a letter is forwarded to the party from the office of the company stating what the rules are in this respect. On almost every road orders are positive to conductors to avoid disputes on this head. What we believe would prove a sure method of avoiding all disputes on the question of age was recently described in one of our contemporaries as follows:

"On one of the Bavarian lakes there is a steamer which formerly carried children under five, free, and those under 12 at half price. American railroad conductors will be astonished to learn that 5 and 12-year-old children traveling on this steamboat very often were found to be astonishingly large for their ages. Suspecting some error and unwilling to call in question the accuracy of the memories of the mothers who bore these children, and who answered the question, 'How old is this child?' the steamboat authorities gave up any attempt to discriminate in fares according to ages, but with the malignity worthy of an American soulless corporation, substituted a discrimination according to size! Children under 24 in. high travel free, and those between 24 in. and 4 ft. 3 in. pay half price, and the ticket collector goes around with a 5 ft. rule. This is said also to be the practice in India, where, for Europeans at least, it is exceedingly difficult to judge of the ages of children by their appearance, and the native parents do not know how to speak the truth."

QUALITY IN CAR BUILDING.

BY A CAR-BUILDER.

There are two generally prevailing and firmly fixed ideas among railway men in regard to cars and car building, and unfortunately neither of the ideas is correct. The first one is, that one car builder is as good as another, providing the price is right. The other one is, that if a road undertakes it it can build better cars than can be obtained from any contract shop.

The first idea results in the placing of every contract with the lowest bidder and allowing the price to be the controlling element in the selection of the builder. Most large roads, and some of the small ones, possess most elaborate sets of specifications. They reason that if their cars are built in accordance with these specifications they cannot fail to be satisfactory. They believe that with careful inspection it is possible to make the work correspond with the specifications. This is a great mistake. No matter who the inspector may be nor how carefully he goes over the work, cars must be built after the general practice of the shop. A man on piece work cannot change his method of work to suit the whim or the orders of an inspector. He is controlled entirely by the price he is getting. Men who are working by the week know that they must turn out the usual quantity of work regardless of the special demands of the inspector. One man cannot look after the workmanship of a large establishment. There are innumerable details in filling an order for cars which cannot be seen until they are so far completed that the quality cannot be ascertained without taking the work down. The inspector may exercise a general supervision over the quality of lumber and the iron and the soundness of the castings. He can throw out the radically bad, but the inspector finds himself handicapped and at the best can only get the average work of the shop.

If an inspector undertakes to materially improve the workmanship of a shop he is called too particular and a complaint will be lodged against him by the car builders. Final argument between the inspector and the builder is reached when the builders say that if his style of complaining and inspecting is kept up they will throw up the contract. As the price is probably much below that of any competing contractor this threat settles it, because with a new contractor the price will be considerably higher. The inspector, therefore, is told to be a little easy "while the work or the material is not quite up to our standard, we think it will answer, and you can allow it to pass." After this it will invariably be passed. The inspector's influence, unless he is a man of unusual strength of character, is at an end. He may be able to have a cracked casting thrown out or a manifestly unsound piece of timber rejected. Under these conditions the value of the inspector to the railway company is very small. Of course the car builder does not have an altogether easy job; if the inspector is retained the cars cost him somewhat more than he expected, but when the

contractor has reached this stage he is over the hard places and builds the car practically to suit himself.

After a car builder has appealed to a railway against an inspector, and the company turns the inspector down, he is careful never to repeat the experience. His inspections never go so far that there is likely to be an appeal to headquarters. Occasionally some old hand gives the new inspector a hint in regard to these matters and he takes it in the beginning and so never has the unpleasant experience. After this point has been reached inspection takes a new phase, only such materials as are manifestly rotten, unsound or beyond all reason bad, are thrown out. Palpable departure from construction shown in drawing are made the subject for reports to the railway superintendent. In such cases the decision is reserved until the home office can be heard from. Usually the answer is that the change does not seem to be material and can be passed, so the car builders vote the inspector "very sharp," but a pretty good fellow. The company says: "He is looking after those fellows very closely—we shall have very fine cars." Every one concerned is pleased except the poor inspector, and he knows more than he is willing to tell the newspapers.

For many reasons the detailed car specification by the railway company is a mistake. In itself it is usually the result of some official's desire to show off what he knows about car building. In many cases what he does not know comprises the whole of human knowledge on the subject. His method of procedure is to correspond with various car companies and street railway superintendents and get as many specifications as possible, then he sets a clerk at work to pick out all the good things from each one. The detailed drawing is made up from the blue prints which accompany his collection of specification. The result is something to make angels weep, if they know anything about car construction. The specification itself, being a heterogeneous collection of things which look well on paper, is mechanically bad as a whole.

Every car builder of any repute has a series of specifications suited to his own methods of manufacture and construction. He can build to these to better advantage probably than to any other. They suit his shop system and the organization of his force. By using them he can secure the greatest economy in production. Usually his designs embrace good features of construction. They are the result of a wide experience and more study than is within the reach of any single railway company, because no railway system, no matter how large, has such facilities for gaining experience as the ordinary car building establishment. These shop specifications can be easily modified to suit the special ends of each road and to conform to such parts as it may be necessary to standardize. If the railroad company wishes for the best car possible, it will select the shop where the workmanship and the material used are of the best character and then leave the detailed specifications to the builder, merely exacting the best quality of work which the shop turns out. In such a case the superintendent will not have an opportunity to display his great apparent knowledge of car building, but the road will get a car of as good a quality as the establishment where it is ordered can produce.

For many reasons the car produced from a company's own detailed specifications is a great mistake. It may be called a failure both mechanically and commercially.

A street railway will also get a contract car at a much lower figure than one built upon its own specifications. This will result from the entire harmony of the design and the organization of the shop. A case might be cited of two street railway companies in a large city which ordered a large number of open cars during the past season. They were of the same size and general character. The cars in one lot were built to the detailed specifications of the road. They conformed in fact to the smallest particulars. The other lot were constructed according to the builder's regular specifications, and they cost at least 12 per cent less than the others. In quality and durability the builder's cars were certainly somewhat ahead of the others.

When it is decided to accept a builder's specifications all that is necessary in the way of inspection of the establishment is one visit, in which the general methods, quality of workmanship and quality of timber habitually used are carefully gone over. The resident inspector then becomes unnecessary. The work is accepted on the general character of the establishment.

The idea that the railroad company can build a better car than a contract shop is one which has in the past taken a deep hold upon railroad men. It probably grew out of the fact that years ago, when roads were more frequently building their own cars than they are at present, the railroad workmanship in its details was always of the highest character, while the contract work was frequently doubtful in this respect. It is true that railroads have occasionally produced better cars than some of the contract shops, but it is also true that the cars built by the railroads have in every instance cost much more than those of the same class in any contract shop.

The great difficulty in railroad car building is a lack of business competition. The master car builder is only controlled by his judgment, and being human, he is prone to indulge in costly mechanical fads. Mechanical human nature is the same the world over. When a superintendent is building for his own road he has nothing but the quality to think of, and he measures the increased cost against what he imagines is to be an increased durability or an increased advantage. He also has the repair shop to carry part of the expense and will almost invariably do things which would never be dreamed of if he had the car to build for so much money and was forced by his employers to get a profit out of the sum.

The railroad shop is always hampered and handicapped by a lack of experience. Of course no railroad man is willing to admit this, but no matter how large a road may be the experienced gained upon it is limited and but a small fraction of what can be gained in the smallest contract shops in the country. The cars suffer accordingly in design. The strong point of the railroad shop is always the workmanship and usually an unnecessary amount of labor is expended upon details. The cost of this is out of all proportion to the results obtained. Fine joints, fine varnishing, unlimited rubbing down and other things of the same kind eat up money. In the end, however, the car is usually much less durable than a very common quality of contract work

Some years ago the writer had an opportunity to inspect several hundred cars built "upon honor" by a railroad company for itself. They had been in service some five or six years. The workmanship had been all that could be desired, but as is usual with railroad cars, the design was faulty, and after the six years of use those cars were of no value except for old glass and scrap iron. They were not worth carting away for chicken coops. If these cars had been built from a design furnished by any first or

even second class contract shop, they would have been good in such a service for 25 years of wear.

When it comes to a matter of first cost the argument is all on the side of the contract shop. There are a dozen large railroad systems in this country which have sufficient facilities for building a large proportion of their own cars. A little alteration or remodeling of machinery would make them ready to begin such work. All of these companies have in past times done a greater or less amount of new work. One extensive system in the West some years ago built all the new cars which it required. Its repair account, however, showed $300 per year expended on every car operated. This, of course, was in one sense a fraudulent record. Probably the repairs were normal in amount. The method employed was undoubtedly to charge the new cars at what they would have cost if purchased outside. The excess went into the repair account and made the showing of $300 per car per year. It was the usual plan of roads to charge the cars they built at a current market rate for the given kind of car, and then smuggle the difference into the repair account. This was general practice a few years since, when many roads were engaged in building new work.

With the old horse car construction the life of a car, where the roof and exterior paint were properly attended to, seems to have been indefinite. Twenty-five and 30 years was no uncommon matter. Three years ago on the old Steinway road on Long Island the writer inspected a number of old and disused motor cars. They had been made by utilizing horse car bodies for the electric service. They had had two, three or four years, as the case might be, of electric service of an exceptionally severe kind, and of course were wrecked. They were from the shops of Jones, Stephenson and Brill, and many of them were of the lightest possible construction. One of the Brill cars was of the old open type, with a canvas roof, and yet this light roof had successfully carried a trolley pole for some years. It was said that the Stephenson cars in this lot were built in 1866, which would give them a total service of 30 years. None of the cars had seen less than 20 years' service, and all of them had finally given out from the results of abuse. Paint and canvas had been neglected, and water finding an entrance had so rotted the structure as to produce the final disaster. This may be taken as a fair illustration of what old contract work would do. It is not quite fair to compare horse car construction with the electric work of today, which more nearly approximates steam car practice. The electric cars have not been running a sufficient length of time for us to know how long they will wear. To get some idea of what may be expected of them we can go to steam practice. On the Erie Railroad there are many light cars still in operation on local trains, which were built in 1872 or previously. These cars are from 27 to 30 years old. They were built with extreme care by the railroad company itself. On the branches and local trains of the Central Railroad of New Jersey there are a large number of cars which were built by the Wason Manufacturing Co., of Springfield, anywhere from 1865 to 1872 or 1873. They are somewhat out of date, but the external paint and varnish having been well cared for, so as to exclude water, these cars are practically as sound as they were when they were turned out of the shop. The conclusion, therefore, is that the contract electric car of today is good for a life of from 25 to 30 years. In the large cities the cars will probably last until fashion or interior dinginess calls for a change in the rolling stock.

In the matter of durability reference has been made only to the Erie and the Jersey Central. Several other steam roads could be cited in which the cars built at home would not show as good a record as those obtained from contract shops. Careful bookkeeping has demonstrated the fact that the home made cars are not only more costly to build, but more costly to operate than those purchased outside. The question has been definitely settled by the accountant, and it would be well for railroad men who are turning over in their minds the scheme of utilizing their own shops for construction to give these matters most careful attention.

RAPID TRANSIT IN NEW YORK.

One of the greatest obstacles standing in the way of a rapid transit railway for New York City, was removed on November 11th, when the Appellate Division of the Supreme Court, on the application of the Rapid Transit Commissioners, reduced the amount of the bond required for the construction of the underground road from $15,000,000 to $5,000,000. The application was accompanied by affidavits by the City Comptroller, the President of the Rapid Transit Commission and the Corporation Counsel, setting forth the necessity of reducing the bond, and it would therefore appear that for once the various officials having authority in the matter had reached an harmonious agreement upon one point at least.

Acting on the decision, the Commission on November 13th published an invitation for proposals to construct and equip a rapid transit railroad in the City of New York, and to use and operate the same under a lease from the city for the term of 50 years, with a right to a renewal of the lease for a further term of 25 years. The invitation describes at length the proposed route and the conditions under which bids for construction will be received.

The main route is to run from the corner of Broadway and Park Row, northward underground on the west side of the city, to 124th St.; thence by viaduct to 134th St.; thence underground to Ellwood St., and over Ellwood St., Kingsbridge Road and Riverdale Ave., to Kingsbridge Station of the New York & Putnam R. R. A branch is to leave the main line at 103d St., and run east, crossing Central Park to Lenox Ave., thence northward under the Harlem River to Boston Road and Bronx Park. A loop under City Hall Park is also to be included.

All bidders must submit their proposals in sealed envelopes, accompanied by a certified check for $150,000, which will be returned in the cases of contractors whose bids are not accepted. The proposals will be opened Jan. 15, 1900, at 12 o'clock, noon. The successful bidder must pay upon completion of his contract, an annual rental equivalent to the interest on the bonds issued by the city to cover the cost of construction of the road, and in addition 1 per cent on such cost of construction as a sinking fund; also a percentage of gross receipts when receipts exceed $5,000,000 per annum, such percentage to be part of the proposal. He must deposit when his bid is accepted, $1,000,000 in cash as security for construction, a continuing bond of $1,000,000 to secure all other obligations of the contractor, and an additional bond of $5,000,000 to insure the satisfactory construction and operation of the road. He must also leave his certified check for $150,000 as a guarantee of good faith.

RECENT STREET RAILWAY DECISIONS.

EDITED BY J. L. ROSENBERGER, ATTORNEY AT LAW, CHICAGO.

LESSEE NEED NOT MAKE TRANSFERS REQUIRED OF ONE CONTRACTING FOR USE OF ROAD.

Roosa v. Brooklyn Heights Railroad Co. (N. Y.), 59 Supp. 664. July, 1899.

Judge Maddox, at a trial term of the supreme court of New York, Kings county, makes a distinction between a contract for the use of a railroad, or part thereof, and a lease. In the former, he says, the parties use in common the road, or part thereof, while a lessee, subject to the restrictions of the lease, gets an absolute and exclusive possession of the leased property. Consequently, he holds that section 104 of the New York railroad law—which provides that one party to a contract for the use of a railroad or part thereof shall carry, and that the other party shall permit any other party thereto to carry, a passenger so desiring to ride for one single fare not higher than the fare lawfully chargeable by either of such corporations for an adult passenger between any two points on the railroads, or portions thereof, embraced in such contract—does not apply to a company in operating as lessee the roads or routes leased from another company.

NOT TAXABLE ON ACCOUNT OF STOCK-TRUST CERTIFICATES.

Commonwealth v. Union Traction Co. of Philadelphia (Pa.), 43 Atl. Rep. 1010. July 19, 1899.

The supreme court of Pennsylvania affirms, in this case, the decision of the court of common pleas that the commonwealth is not entitled to recover any tax from the defendant in respect of Electric and People's Traction stock-trust certificates, under the state law imposing what is commonly known as the "tax on loans." Such certificates the court does not consider constitutes or represents any indebtedness on the part of the defendant, within the meaning of the statute in question, the 4 per cent paid by it not being regarded as interest, but as rentals; or, rather, the court makes the point the money with which the so-called interest was finally paid was derived from the rentals paid by the defendant. It also holds that the commonwealth was not entitled to recover from the defendant any tax in respect of mortgages issued by private parties and secured upon property subsequently purchased by the defendant.

ADMISSIBLE EVIDENCE OF EXCESSIVE SPEED.

City Railway Co. v. Wiggins (Tex.), 52 S. W. Rep. 577. July 1, 1899.

That cities, in providing for the safety of their inhabitants and visitors, have the right to pass reasonable enactments regulating the speed of street cars, the court of civil appeals of Texas says, is not longer to be questioned. The structural capacity of a car, and the voltage of electricity at the time applied, being peculiarly within the knowledge and power of the company to produce, the court considers that the best evidence attainable by a person suing the company for damages for personal injuries sustained in a collision alleged to have been caused by its negligence in running the car at an excessive rate of speed would be the estimate of those riding on the car at the time, and others having reasonable opportunities for observing and of judging. And the court declares that it cannot say that, in an effort to convey the idea of the existing velocity of a car, it was error to permit a witness to illustrate by reference to the speed of a trotting team and buggy, which, it adds, among a people of "our" history and habits ought to be within the common observation and judgment of all.

WHEN NO PUNITIVE DAMAGES FOR EJECTION OF PASSENGER.

Forhman v. Consolidated Traction Co. (N. J.), 43 Atl. Rep. 892. June 12, 1899.

The plaintiff's case was that he was ejected from a car of the defendant without cause and with unnecessary violence. The case went to the jury upon conflicting testimony, with special instructions upon the question of punitive damages.

Punitive damages, says the supreme court of New Jersey, are in the nature of a penalty, especially designed as a punishment for the wanton conduct or malicious motives of a wrongdoer, and can lawfully be imposed only when the reprehensible act is brought home to the defendant.

A principal, whether an individual or a corporation, cannot be charged with punitive damages for the illegal, wanton or oppressive conduct of a servant, unless the principal participated in the wrongful act of the servant, either expressly or impliedly, by his conduct authorizing or approving it either before or after it was committed.

This doctrine, the court holds that the defendant was entitled to the benefit of, in this case, and, because it thinks that the defendant was presumably injured by the submission of the question to the jury, as the verdict was for $5,000, it makes absolute a rule to show cause why a new trial should not be granted.

AFFIRMS JUDGMENT FOR $20,000 FOR LOSS OF USE OF BOTH LEGS.

Fonda v. St. Paul City Railway Co. (Minn.), 79, N. W. Rep. 1043. Aug. 1, 1899.

This action was brought to recover damages for personal injuries alleged to have been sustained by reason of the negligence of the defendant in operating its cars when the plaintiff was about to take passage on one of them. The injuries were serious, resulting in the loss of a portion of both legs. The jury, upon a retrial ordered by the supreme court of Minnesota, rendered a verdict in favor of the plaintiff for the sum of $20,000. The trial judge said with regard to this: "Defendant contends that the damages are so excessive as to show that the jury was influenced by passion and prejudice. I do not think so. While the verdict is a large one, it must not be forgotten that the plaintiff's injuries were very serious; that he lost the use of both legs, and is a cripple for life; that he never will be able to work or enjoy life as others do; that he was nearly a year in the hospital and suffered much pain; that his mental suffering, by reason of his condition, must have been, and must always be, great. In view of these and other facts, I am unable to say that the verdict is so excessive as to warrant the assumption that the jury was influenced by passion or prejudice." This language is adopted by the supreme court, which holds the damages not to be excessive, and affirms an order of the court below refusing a new trial.

A VOTE IS NECESSARY TO RENDER STOCKHOLDERS LIABLE ON BONDS.

Boyd v. Heron (Cal.), 58 Pac. Rep. 64. July 24, 1899.

This was an action brought against stockholders of the Consolidated Piedmont Cable Co., a street railroad corporation, for the purpose of enforcing their liability as stockholders for an indebtedness arising upon 10 bonds for $1,000 each, issued in part payment for the construction of the company's road. The plaintiffs suffered nonsuit, and the supreme court of California affirms the judgment of the court below. It holds that, construing sections 456 and 359 of the Civil Code together, under section 456 the directors may prescribe reasonable regulations which shall govern a proposed bond issue, but before the issue can be legally made the assent of the required number of stockholders thereto must be had in compliance with the mode laid down in section 359. Section 359 is a general section, applicable to all corporations, and was not complied with before the bonds in question were issued. Hence the supreme court holds that, without considering whether or not the bonds are void, so as to cast no liability upon the corporation, it is quite plain that those who were stockholders at the time of the bond issue may be heard to say that, because of the irregularity of the issue, and of their deprivation of an important right to vote upon the bond issue, no liability against them has been created.

BOUND TO KEEP EYES AND EARS OPEN FOR NEW DANGERS.

McGovern v. Union Traction Co. (Pa.), 43 Atl. Rep. 949. July 19, 1899.

A foot passenger crossing a street, especially a wide one with double tracks, the supreme court of Pennsylvania holds, does not do his whole duty by a single look before starting. In the space where cars and other vehicles have concurrent rights with his own, he is bound to keep eyes and ears open for new dangers, and to use reasonable care in avoiding them. Moreover, the court holds that how far a person's standing "some time" on the curb after looking before stepping into the street may have modified the act of looking, is clearly for the jury. And where the distance of the car and the rate of speed were the subject of testimony not entirely uniform, and there was no evidence as to the action at this point of the person struck in regard to the approaching car, the court holds that it was not one of those clear cases that should be taken from the jury. There are two classes of cases, considered with regard to the kind of accident, it says, in which nonsuits are properly entered: First, where a person, not looking, or claiming to have looked and not to have seen what was manifestly and unavoidably visible, steps directly in front of a moving car; and, secondly, where a person, seeing a clearly impending danger, accepts the risk, relying on his own judgment that he can escape it. In either class the negligence of the injured must be the clear and unavoidable inference from the undisputed facts, before the court can pronounce it as matter of law.

NO "MIGHT" ABOUT IT IF PASSENGER TRIED TO GET OFF MOVING CAR.

Neff v. Harrisburg Traction Co. (Pa.), 43 Atl. Rep. 1020. July 19, 1899.

Two disinterested witnesses testified positively that the plaintiff and her sister left the car while it was in motion, and before it stopped. She and her sister testified that they did not leave the car until it stopped, and that it started with a sudden jerk while they were getting off, and that this was the cause of the plaintiff's fall. If the testimony of the witnesses first mentioned was believed, the supreme court of Pennsylvania declares that the plaintiff certainly could not recover damages, all of its decisions being to that effect. And so it holds that it was error for the trial judge to instruct the jury that "if you take the version given by the defendant, that the car had not yet come to a stop when the plaintiff undertook to get out, then you might find her guilty of contributory negligence, and in that case she would not be entitled to recover." This it considers fatally defective, because, while it was altogether probable from the context that the judge did not intend, by the use of the word "might" in this connection, to put or to intimate a qualification upon the defendant's right to a verdict in case the jury found that the plaintiff left the car while it was in motion, yet the jury would be at liberty to understand from the words of the charge on this subject that the plaintiff's act of leaving the car while it was in motion would be no bar to her recovery of damages. As there was no evidence to show that the car was going so slowly as to be subsequently stopped when the accident occurred, the court further holds that it was a mistake to introduce that element into the answer to an instruction asked by the defendant.

ADMISSIBILITY OF PHOTOGRAPHIC AND OTHER EVIDENCE OF PROJECTION OF RAILS.

Cunningham v. Fair Haven & Westville Railroad Co. (Conn.), 43 Atl. Rep. 1047. Aug. 1, 1899.

Where an accident occurred at a point about midway between two cross streets through an alleged defect in the track consisting in the rails projecting several inches above the surface of the roadway immediately adjoining the same, the supreme court of errors of Connecticut holds that testimony as to the condition of the road at places other than the place of accident, such as testimony as to the condition of the road from the one cross street to the other, was inadmissible. On the other hand, it does not consider that there was any error in allowing a witness to testify as to the condition of the road at the place of the accident for some time prior to the accident, as the existence of a defect there for some time prior to the accident would tend to establish negligence in the failure to repair it.

As to photographs. The court does not believe that any case can be found which would warrant the admission of them to prove the height of the rails, without evidence of their accuracy. It says that a photograph offered for the purpose of proving the appearance of a physical object which cannot be produced in court nor inspected by the jury is secondary evidence. Its correctness or accuracy, like that of a map or diagram, must be proved, before it can be received. The accuracy sufficient for the admission of a photograph as evidence," it goes on to state, is a preliminary question of fact to be determined by the trial judge. The testimony of the photographer is not essential if other evidence is produced which in fact convinces the court. The proof of accuracy varies with the nature of the evidence the photograph is offered to supply. Thus, when it is offered as a general representation of physical objects as to which testimony is adduced for the mere convenience of witnesses in explaining their statements, very slight proof of accuracy may be sufficient. But the mere fact that the identity of the place photographed has been proved, is not enough.

PRESUMPTION OF NEGLIGENCE FROM COLLISION BETWEEN CARS.

Madara v. Shamokin & Mt. Carmel Electric Railway Co. (Pa.), 43 Atl. Rep. 995. July 19, 1899.

A car stopped on an up grade, from some defect in machinery or power, and could not be moved. A man who was there at the time assisted in trying to get the car started, giving directions as one in authority. Not succeeding, he said to the motorman that he would go to the car barn, a short distance off, and get another car, into which the passengers could be transferred and carried to their destination. He soon returned with another car, approaching the disabled and standing one on a steep down grade. From some cause the car he was on became unmanageable, ran into the disabled one standing on the track, and seriously injured the plaintiff. To the charge of negligence made against the company it set up the defense that the man who brought the second car was a mere intermeddler, who acted without any authority from the company. It offered no evidence to establish that fact, but relied on that of the plaintiff to make it out. It was conceded that the man was an employe of the company, though not a conductor or motorman, but in just what capacity was not clear.

The supreme court of Pennsylvania affirms a judgment against the company. It says that the plaintiff was a passenger to whom the company owed the utmost degree of care. Being injured by one of its cars while occupying that relation the presumption would be that it was through the negligence of the carrier. The burden was on it to rebut the presumption by showing that the man in question was a mere intruder upon the relieving car, acting wholly without authority. The burden was not upon the passenger to prove that one apparently in authority, having access to the car barn, and the power to assume control of a car, and run it on the road to the relief of the stalled car, was a servant of the company. If the accident had been apparently caused by the act of a stranger, while the plaintiff was a passenger, as in the case of a collision with a wagon, the burden would have been on her to show negligence on the part of the company. But when it arose from a collision between the defendant company's cars on its own rails, the court repeats, the presumption of negligence arose, and the burden was on the company to rebut it.

AGAINST KISSING AND HUGGING ON STREET CARS.

Sailors v. State (Ga.), 33 S. E. Rep. 813. July 18, 1899.

Where, in the trial of a criminal case, the proof shows that a man and a woman, in an intoxicated condition, were riding upon a street car, using profane language and kissing and hugging each other to such an extent as to attract the attention of other passengers upon the car, upon which were also other females, the supreme court of Georgia holds that this is sufficient to sustain a verdit of guilty, under section 396 of the Penal Code of that state, notwithstanding the female passengers may not have heard or witnessed such conduct. The latter part of the section mentioned is as follows: "By indecent or disorderly conduct in the presence of females on passenger cars, street cars, or other places of like character, shall be guilty of a misdemeanor."

This salutary statute, the supreme court says, was enacted for the purpose of preserving peace and good order in the public conveyances of the state. The members of the legislature, besides many others who were in the habit of riding in public conveyances, it somewhat startlingly continues, had doubtless witnessed many scenes of disorderly conduct upon passenger cars or street cars in which females were also passengers. They had doubtless seen vulgar and drunken creatures acting in such disorderly and indecent manner as to attract the attention of the other passengers, and using oaths in the presence of ladies who were also passengers on the cars. This law, it therefore reiterates, was enacted for the purpose of punishing for such disorderly and indecent conduct, and preventing its repetition.

But it was argued in this case that, inasmuch as the females, who were sitting in the front portion of the car, had their backs turned to the accused persons, who were in the rear, the offense was not complete, because not "in the presence of females." With this the supreme court does not agree. It holds that, under this statute, if the females were in the car upon which the disorderly conduct took place, it was not necessary, to make the offense complete, that they should be eyewitnesses of the disorderly or indecent conduct. Certainly they could hear oaths as well with their backs turned as though they were looking at the persons using them.

So the court holds that the true construction of the statute is that, if the disorderly or indecent conduct takes place on a street car on which females are riding, it is in their presence, although their backs may be turned to the offenders. And it insists that it is too clear to require any discussion that being drunk, cursing and hugging and kissing, in an offensive manner, as was here shown to be the case, by a man and a woman on a street car, is disorderly conduct.

ACCOUNTED PROPERTY BENEFITED BY STREET IMPROVEMENTS.

City of Shreveport v. Prescott (La.), 26 So. Rep. 664. April 17, 1899. May 15, 1899. Rehearing denied June 29, 1899.

To begin with, the supreme court of Louisiana holds that the matter at issue in this case, being a question of local assessment or charge upon property of abutting proprietors in a municipality, levied upon compulsion of law alone, to pay the cost of street improvement, and without their knowledge or consent, was a tax, in the sense of the constitutional provision conferring appellate jurisdiction on the supreme court.

The uniform current of judicial opinion, the supreme court goes on to say affirms the principle that the right of occupancy of a portion of the streets of a municipality by a street railway corporation is property which is benefited by a street improvement to the extent of the space occupied by its roadbed and tracks, which renders same liable for its proportionate share of its cost, just as the property of abutting owners is liable; that the railway company using the streets for the operation of its cars is in duty bound to pay for the work on the streets which its track alone makes necessary—that is to say, all expense for that portion of the work lying between the exterior rails of the tracks of the road, and for a distance of 2 ft. from and exterior to the track on each side thereof.

That in no case can any portion of the cost of such improvement be attributed to, or assessed against, the abutting property owners.

That, when a statute or municipal ordinance makes provision for the assessment of a street railway corporation for the pavement of such space as its tracks and roadbed occupy, such provision is mandatory, and any portion thereof which is put upon the abutting property owners is illegal and void.

Here was involved an interpretation of an ordinance of the city of Shreveport which required that abutting property holders throughout the length of a street that had been paved should pay two-thirds of the cost of same, each one paying in proportion to frontage; that the street railroads should pay in proportion to the space occupied by their roadbed, compared to the width of the street; and that the city should pay the remainder. The ordinance was founded upon the supposed authority that is conferred by the second section of Act No. 10 of 1896, which provides that abutting owners shall pay two-thirds of the entire cost, and the corporation shall pay one-third from its general resources, and provided that, where a railway bed or track occupies a part of the street, it shall pay in proportion to the space occupied by its roadbed, compared with the width of the street. The supreme court holds the ordinance and statute irreconcilable in that the ordinance transposed the terms of the statute by stating (1) the share of the abutter to be two-thirds, (2) that of railroad companies in proportion to the space occupied by them, (3) the city should pay the remainder, whereas the statute states (1) the share of the abutter shall be two-thirds, (2) the city one-third, and, (3) provided that a street railway occupies a portion of the street, it shall pay in proportion to said space.

Entertaining this view, that the ordinance was not in keeping with the terms of the statute, the true import of which is to require the portion of the cost due for street improvements by railroad companies to be first deducted from the total amount, and the remainder distributed between the abutters and the municipality, two-thirds to the former and one-third to the latter, the court declares the ordinance null and void.

The space occupied by a street railroad company, the court further holds, is matter of proof, to be administered and determined in some proceeding contradictorily between all parties in interest—the municipality, the abutting owners and the street railway companies; and, it adds, the ordinance which arbitrarily fixes said space, without a contradictory hearing, cannot be sustained as valid.

LIABILITY FOR INJURY TO EMPLOYE OF INTERSECTING LINE.

Bailey v. Citizens' Railway Co. (Mo.), 52 S. W. Rep. 406. July 14, 1899.

This was an action for damages growing out of personal injuries sustained by a conductor on a cable car on a line that intersected the defendant's line of cable railway. The defendant was repairing the crossing. Somehow the slot rail got displaced, so that the grip of the plaintiff's train ran against the obstruction thereby caused, throwing the plaintiff against a seat, quite severely injuring him. He obtained a judgment. But this the supreme court of Missouri has reversed, remanding the case for a new trial.

First of all, the supreme court condemns an instruction given the jury that even if it should appear in evidence to its satisfaction that there was negligence on the part of the gripman of the plaintiff's train in attempting to move his train over said crossing at an improper or reckless rate of speed, and that such rate of speed caused or contributed to the displacement of said slot, yet the finding of such facts would not, and could not, under the law, prevent the plaintiff from recovering in this case, unless the jury further found from the evidence that said gripman was at the time under, or subject to the direction and control of the plaintiff, as to such rate of speed.

The error in this, the supreme court points out, was in making the defendant liable for the independent negligence of the gripman, over whom it had no control, and to whom it did not bear the relation of master, in any degree, without proof of negligence by the defendant or any of its employes. And it declares that to hold a defendant liable for a pure tort, or wrongful act, of one over whom it had no control, to make it liable for the negligent or mischievous act of a stranger, as the gripman of the plaintiff's car was to the defendant,—would be to violate every principle of natural justice, and finds no support in "our" laws. The law makes each man liable for the consequences of his own negligent or wrongful act, but does not attempt to hold him for the misconduct of another, over whose acts he has no control, or unless his negligence concurs with that other in causing damage.

So the court holds that if the defendant could establish that the gripman was under the control of the plaintiff, and that the plaintiff directed the rapid running, and that caused the displacement of the slot rail, it was clear that the plaintiff could not recover, because his own negligence had directly contributed to the act which produced his injury; or, if the defendant was not able to establish that the gripman was under the control of the plaintiff, still, the defendant was not liable, if the jury found that the rapid running of the plaintiff's train was the sole cause of the displacement of the slot rail.

Then, it was urged that because the work was entirely under the care of the defendant, and because an accident happened, the presumption arose of its negligence. But the supreme court does not think that doctrine ought to be applied here, because, while it was true that the defendant had charge of the work, it was well known

to the operatives of the intersecting line that it was repairing, and that, in order not to stop traffic altogether, the conductors and gripmen of that road must go over the junction very carefully. The burden of the case, it says, was on the plaintiff to establish negligence, and not one entirely of presumptions. Certain risks are inevitable in making repairs of this nature, and if those charged with notice of the conditions will disregard the common dictates of prudence, and are hurt, they must bear the consequences. In this case the defendant was only required to exercise ordinary care; that is, such care as a reasonably prudent person would have exercised under the same circumstances.

The court also holds that another instruction was erroneous, in leaving to the jury to find that the unsafe condition of the crossing was exclusively with the knowledge of the defendant's workmen, when there were facts showing it was not.

Again, it says that it was at least a controverted fact that the misplacement was caused by the defendant's servants, and, combining the character of the work with the proof that rapid running of cars over it would produce a displacement of the slot bar, it was error for the judge to declare that it was a presumption of law that it was the defendant's negligence that caused the displacement.

When, it says, an independent factor or agency is introduced into the otherwise exclusive management of a work like this, and its action is uncontrolled by the defendant, and its negligence is also liable to cause a disarrangement of the defendant's plans, or interfere with the safety of the work, then the presumption growing out of the exclusive management of the work no longer obtains, but it is a question of fact, to be resolved in the light of all the circumstances.

DUTY TO FURNISH SUITABLE MACHINERY AND KEEP IT IN REPAIR.

Meehan v. Judson (N. Y.), 59 N. Y. Supp. 578. July, 18, 1899.

This was an action brought to recover damages for personal injuries sustained by the plaintiff in being struck by a motor that slipped off a block of wood placed on a plate on the top of the piston rod of a jack which he had operated for about two days in removing and replacing street car motors taken off to be cleaned. The trial judge granted a nonsuit on the ground that the testimony, as he viewed it, failed to show any specific cause for the falling of the motor, and no connection between it and the defect shown to have existed in the jack. But in nonsuiting the plaintiff on the ground that the evidence failed to show that the motor sagged at this particular juncture, the fourth appellate division of the supreme court of New York holds was reversible error. With the proof establishing that was its condition almost daily, and no other efficient reason being suggested for the accident, the court holds that it was for the jury to pass upon the question. It adds that this would not be permitting the jury to speculate upon what caused the accident, for there were facts which fairly justified the deduction that the accident was due to the sloping of the piston rod of the jack and the motor.

The burden is incumbent upon the plaintiff always to establish that his injuries are due to some specific negligence of the defendant. That negligence, however, the court goes on to say, may not in every instance be susceptible of direct proof by an eyewitness; but, if the facts proved warrant the inference that the injuries are attributable to the failure of the defendant to perform his precise duty, then it is the province of the jury to decide whether or not the defendant is chargeable with negligence.

Commenting further on the case, the court says that it was not contended that it fell within the class where the risk is an obvious one to the employe. The business was not of itself hazardous. If the piston rod remained erect, there was very little danger of the motor falling off. If the machinery was in proper condition, then the risk was the plaintiff's. It is elementary, however, that the fact that he assumed the risk incidental to the business is upon the hypothesis that the master performed his duty by providing an adequate appliance and reasonably safe machinery. The doctrine of obvious risks has never included the danger resulting from inadequate machinery and appliances, where the defects were known to the master, and he failed to remedy them. The duty of the master to exercise reasonable care, both by furnishing suitable machinery and keeping it in repair, is one always in force. Of course the superintendent, in the performance of this obligation, was the alter ego (another self) of the defendant.

In conclusion, the court declares that it cannot say, as matter of law, that the plaintiff should have discovered that the motor tipped forward. He was inexperienced in the use of the jack. His work took him to the bottom of the pit containing the jack which was under the main track in the car barn, and he was bending over, working the lever, as directed by the employer. He had a right primarily to assume that the appliance was in proper repair and in a reasonably safe condition. While an inspection might have apprised him of its condition, yet the short time of his employment upon it, the fact that it had been long in use, as he knew by casual observation, and his position in the prosecution of his work, were circumstances which made it proper for the jury to decide whether he exercised care commensurate with the situation in which he was placed.

OVERHEAD BRIDGE CROSSING CALLED FOR.

Williams Valley Railroad Co. v. Lykens & Williams Valley Street Railway Co. (Pa.), 44 Atl. Rep. 46. July 19, 1899.

In reversing a decree denying a steam railroad an injunction against a grade crossing, the supreme court of Pennsylvania remarks that its utterances on the question of grade crossings have been so frequent and emphatic that it ought not to be necessary to repeat them. Nevertheless, it does take the pains to state that it has held in substance, that the manifest purpose of the act of 1871 was to discourage grade crossings, and to absolutely prohibit them where it is reasonably practicable to avoid them; that what is reasonably practicable, under such circumstances, is determined largely by what is physically practicable, and not by what is practicable to the treasury of the road seeking to cross; that the cost of avoiding a grade crossing is a matter to be considered in projecting the new road, and that then sufficient capital should be provided to avoid that which the law in effect condemns. It further recalls that it has held that neither the street railway act of 1889 nor any subsequent legislation repealed the crossing provision in the act of 1871.

But before taking up the question of practicability, the supreme court states that the lower court was clearly right in holding that the ownership of the land in fee by the steam railroad company, whereon rested its superstructure, gave it no right to exclude subsequent grantees of the commonwealth from the use of the highway or public road which crossed it. Further than that, however, it does not agree with that court, which held that prima facie, under the act of 1889, the street railway company had the right to cross at grade; that the burden was upon the objecting steam railroad to establish that other than a grade crossing was reasonably practicable, and that not having established that fact, the court must allow the crossing. The supreme court says that it does not think that the case should turn on a rule of evidence applicable to a common law action.

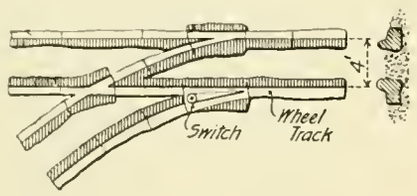
The first and second sections of the act of 1871 make it the duty of the court to inquire and ascertain the facts with reference to the authority of the corporation, and especially, as a basis of information for a proper decree for a crossing, to ascertain whether one at grade can be avoided. The commonwealth intended by the act to protect the lives and limbs of citizens as well as the property rights of litigating corporations. Therefore, the supreme court goes on to say, there is a duty upon the court to inquire in the interest of the public, which is not directly a party to the issue, whether it is reasonably practicable to avoid a grade crossing. And so it holds that the court cannot lightly assume, as here, because the steam railroad, in the main, rested its case on the ownership of the fee of its right of way, that there was no duty of further inquiry. To this it adds that the learned judge was wholly mistaken in assuming that judicial opinion as to the danger of grade crossings is largely prompted by that incident to the ordinary public road crossing of a railroad; and it declares that no local sentiment favorable to increased facilities for local travel and communication should swerve a court from its duty to carry out strictly the intent of the statute.

Furthermore, the supreme court holds that the evidence before it showed that it was reasonably practicable to avoid a grade crossing at the point in question. An inspection of photographs showed that the public road, for between 300 and 400 feet on each side of the railroad, was almost level, and that an overhead bridge presented no engineering difficulties in construction or use. Consequently, when it is known by everyday observation that such bridges are built to avoid just such grade crossings, the supreme court asked why was not the avoidance of this one reasonably

practicable? Referring to the fact that, while the engineers of the steam railroad company testified that it was, those of the street railway company testified that it was not founded in the main on a possible obstruction of the highway by a bridge and the want of authority to deflect it, the supreme court cites the Fairmont Park trolley railway, which is absolutely prohibited from crossing the park roads at grade, as demonstrating the practicability of avoiding this grade crossing. Besides, it holds that the cost of an overhead crossing,—seven to ten thousand dollars,—when compared to the peril to the public thereby avoided, is trivial.

THE HEYTOR GRANITE TRAMWAYS.

An interesting account of an ancient tramway is given by W. B. Paley in the Railroad Gazette, and a considerable portion of this unique road is still to be found in an out-of-the-way corner of the West of England. What there is left of it extends from a point on the Moreton Hampstead branch of the Great Western, about one mile south of Bovey Tracy, in Devonshire, up to the quarries at Heytor, on Dartmoor. These quarries produce a splendid quality of granite, and in 1820 their owner, Mr. George Templer, laid from them a railroad composed of granite blocks, and of nothing else. These blocks formed both the rails and the sleepers in themselves, the outer half of the top surface being cut away longitudinally to form a wheel track. This track averages about 4 in. in width, but is often 5 or 6 in., whilst the depth of the cut is somewhat less.



HEYTOR GRANITE TRAMWAY.

The inner raised portion, of course, formed a flange to keep the wheels on the line. No means of preserving the gage are anywhere adopted, and owing to a tendency of the blocks to tilt, from the weights coming nearest their outer edge, the gage varies about 3 in. On the best preserved portions of the line, however, it is 4 ft. and from many measurements the writer believes this may be taken as the actual gage. The granite blocks are quite roughly hewn all over, the ends being only sufficiently dressed to enable a fairly close fit to be made between one block and the next. They are not in any way joined. In length the stones differ considerably, from 4 ft. or so to nearly 8, but perhaps 5½ ft. is the most usual size, by about 1 ft. square.

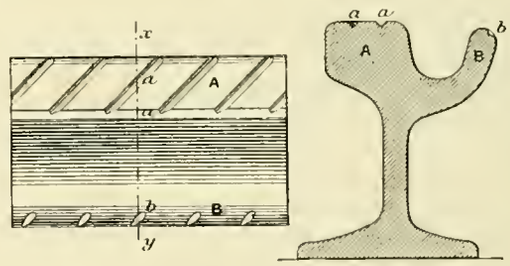
Commencing on the north side of Heytor Rocks, in five or six working faces, the branches unite with the main line, as the longest branch may be called, on Heytor Down, at about 1,200 ft. above sea level. At each of the junctions the hole which contained the heel of a switch may still be seen, but the switches have long since disappeared. No other ironwork seems to have been used. On these breezy downs nothing grows except grass and furze bushes and the bare white stones of the old tramway are as clean as if scrubbed every day. The line runs along the road from Bovey to Widecombe. Here some portions have been dismantled, the blocks lying about in disorder. At Lower Down the line is about 500 ft. above sea, having fallen 700 ft. in 3½ miles. Through the woods and on the down the line is greatly grown over with moss and furze, and, in fact, it is difficult to find it here and there. Near Bovey Grammar School the line crosses a small stream by what is surely the most primitive railroad bridge in the world, simply four large stone slabs thrown across. Two of these have a groove cut in for the wheels to follow. The stream is about 10 ft. across, the bridge itself being 14½ ft. At the Newton Abbot high-road the line crosses another stream by a broken-down wooden bridge and then ends at the Great Western Ry. at Bovey Gas Works. Originally it went on two miles further to the head of a short canal near Teigngrace, but this portion was used in making the Moreton Hampstead line, in 1862-6. On the parapets of the bridges over the latter may be found portions of the old granite blocks of the Heytor tramway, used as coping stones. The canal in question was made in 1792-4, branching from the River Teign for the convenience of the pottery works.

The stone was taken by the canal in barges to Teignmouth for shipment. Most of the granite in the western face of London Bridge (built 1825-31) came down over the Heytor tram, as did the columns of the General Post Office (1829) and the Waithman obelisk at Ludgate Circus, 1833. Rough and ready as it is, the tram was capable of real work and was in use more or less for nearly 40 years. Since then it has been disused for another 40. The quarries are now only worked when some specially large and long piece of granite is wanted, which is brought down by road. The line probably falls another 400 ft. from the center of Lower Down to the present termination, or about 1 in 30, so that considerable brake power must have been needed in coming down. The remains of an old wagon or truck are to be seen in one place; it is quite flat and without sides, consisting of three longitudinal timbers with close cross-pieces on the top. It runs upon four cast iron wheels of 2 ft. diameter, 3 in. wide on the tread, with six spokes curving outwards to a journal 10 in. long. The wheels, of course, run loose on the axles, with a liberal amount of side play. The truck is lightly constructed, is 13 ft. long, 4 ft. wide, with a wheel base of 10 ft. A smaller truck or cart having shafts for a horse was used as the leading vehicle of a train.

There is not a single passing place or siding throughout the line, which may now be considered as 7 miles long, including 1¼ miles of branches at the quarries. Altogether it is an exceedingly curious and interesting piece of work, but having been made by a private individual for his own purposes, without an act of Parliament, it has never attracted the slightest attention or notice. It was opened for traffic Sept. 16, 1820. Mr. Templer was his own engineer. In 1829 the line and quarries were sold to the Duke of Somerset, in whose family they still remain.

A SAND RAIL.

The accompanying illustration shows a plan and section of a Vignole rail especially designed for use on heavy grades, or in damp subways where the use of sand is habitual. The improvement,



SAND RAIL.

which is the invention of M. Vez-Mairet, of Geneva, Switzerland, consists in providing diagonally placed grooves, aa, and the smaller indentations such as b to receive the sand.

We are informed by Isaac S. Cook, of Chillicothe, O., that the Chillicothe, Mt. Sterling & Columbus Electric R. R., of which he is president will be built between the cities named, a distance of 50 miles. The company is fully organized and the survey has been made through Ross County. Rights of way are now being secured after which the survey will be continued. The officers of the company are Isaac S. Cook, president; S. F. Secrist, secretary; and Jacob Houk, treasurer, all of Chillicothe, O.

The ordinance at Atlanta, Ga., for preventing electrolysis contains the following salient features: (1) All producers and owners of electricity must use appliances to retain it within its proper channels and not allow any to escape and injure any pipes or other structure or property of the city; also keep all such electric appliances in good order and use improvements thereon. (2) Penalty for each violation $100. It is not necessary to show that the whole of any injurious electric current comes from any one source! Each contributor to the injury shall be fined. (3) The city may collect damages in addition to each and every fine imposed.

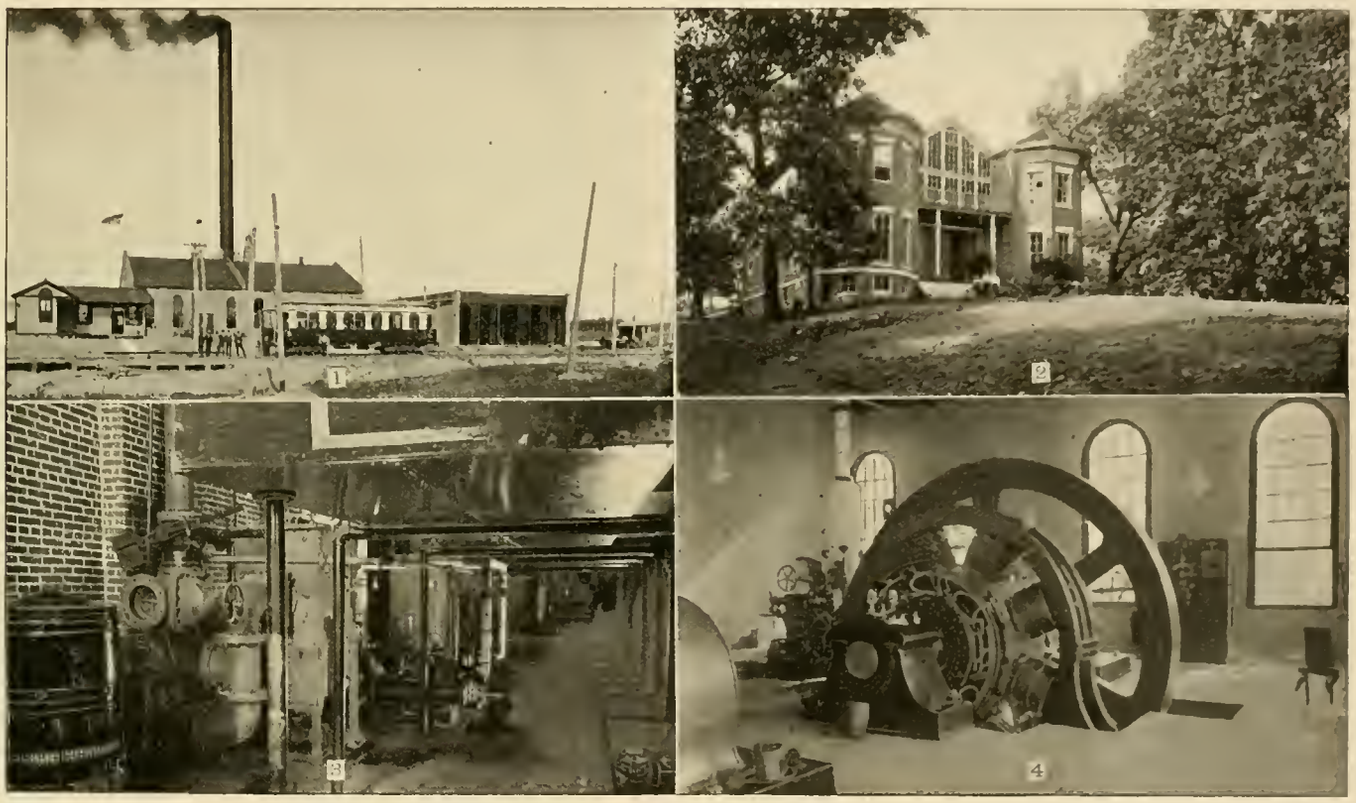
THE ST. LOUIS & BELLEVILLE ELECTRIC RY.

Of all the interesting interurbans from east to west none gives a stronger first impression of having been exceptionally well built than the St. Louis & Belleville, and as one more closely inspects the line and plant the impression is still further strengthened and confirmed. What cannot fail to be noticeable is the extreme simplicity of it all; there seems to have been a carefully studied effort to avoid all unnecessary complications of construction and the result is pleasing to the eye.

The road was under consideration for some two or three years by prominent Belleville men, but little headway was made until Maj. L. N. Downs, of Kalamazoo, was induced to take an active interest in the enterprise. From that day dates the beginning of activities, and a vigorous pushing of the preliminary arrangements and later construction.

The line is double track and all upon a private right of way outside of the two towns. The local road in Belleville has been absorbed by the new interurban, and the local service there continued with the former car equipment; the cars of the interurban run to the public square, which is in the center of town.

In the construction of the track several engineering problems were encountered—none of extreme difficulty, but expensive. Long, deep cuts were made to reduce a grade, which most builders would have climbed or cut but little. In one of these cuts, some 600 ft. in length, at a depth of about 20 ft. a strata of what appears to be a mixture of quicksand and greasy clay, was struck, and this exhibited a tendency to flow in times of rain, with the result that the track would "hump up" in a single night, or move out of line to an extent which would make things interesting to everybody. Surfacing and lining failed to produce any last-



1—POWER HOUSE.
2—CLUB HOUSE.
3—BOILER ROOM.
4—ENGINE ROOM.

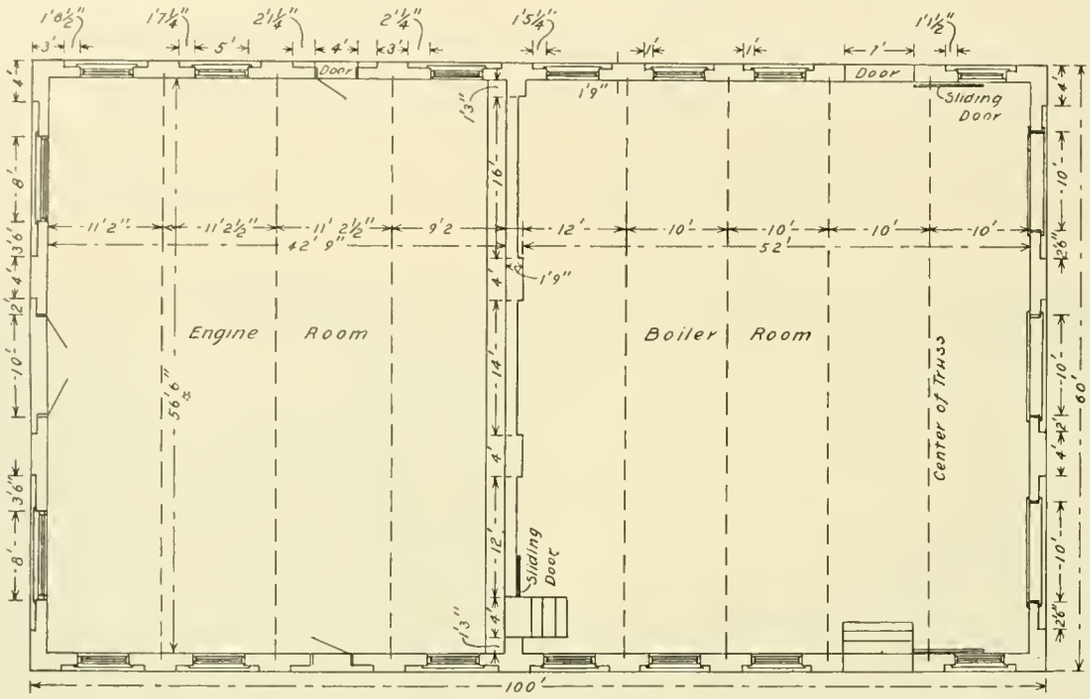
East St. Louis has had a rapid growth during the past decade and from a transfer yard for switching freight trains has grown to be a thriving city of nearly 40,000, with its street railway, paved streets and other evidences of metropolitan life. The whole town practically is built on raised land, which has been brought up from 10 to 15 ft. above original grade.

Belleville, the other terminus of the line, is 14 miles distant and has a population of some 25,000. It is one of the oldest settlements in the state of Illinois, and on its business streets today quaint landmarks of 60 years ago are side by side with modern, up-to-date business houses. There is much business intercourse between the residents of Belleville and the cities at either end of the big Ead's bridge, and the new and improved facilities for inter-communication are already seen to be appreciated, and travel is increasing daily.

ing results, and it was not until tiling was resorted to, that any permanent relief was found. The remedy, however, proved highly satisfactory. A line of 8-in. drain tile was laid at a depth of 2 to 3 ft. in the two traci ditches on either side, and one line between the tracks, all for a distance of 600 ft. Several laterals were also introduced, and a retaining wall of rejected wooden trolley poles and 2-in plank, run for a distance of 300 ft., since which time the hill has shown no disposition to play tricks with the track. Rail of 60 lb. weight and 60-ft. lengths was used and a considerable portion of it laid during the past winter. Although what was thought to be more than ample space was left between the rail ends, the early hot weather produced an expansion, which in a few days made many snaky spots where it was necessary to cut out a section. The steel laid during extremely cold weather was, of course, the worst, and here

the shortening process was resorted to as many as five times before the cure was complete. Major Downs says if he were to lay 60-ft. exposed T-rails again in very cold weather he should leave from 5/8 to 3/4-in. space between rail ends. The work of ballasting the entire 14 miles of double track with cinders is progressing rapidly, and when completed will protect the rail from further excessive expansion. To sight the track at present one would never imagine it was train of steam cars in the country. At one point, where a highway passes below, a platform has been built and steps lead down to the road.

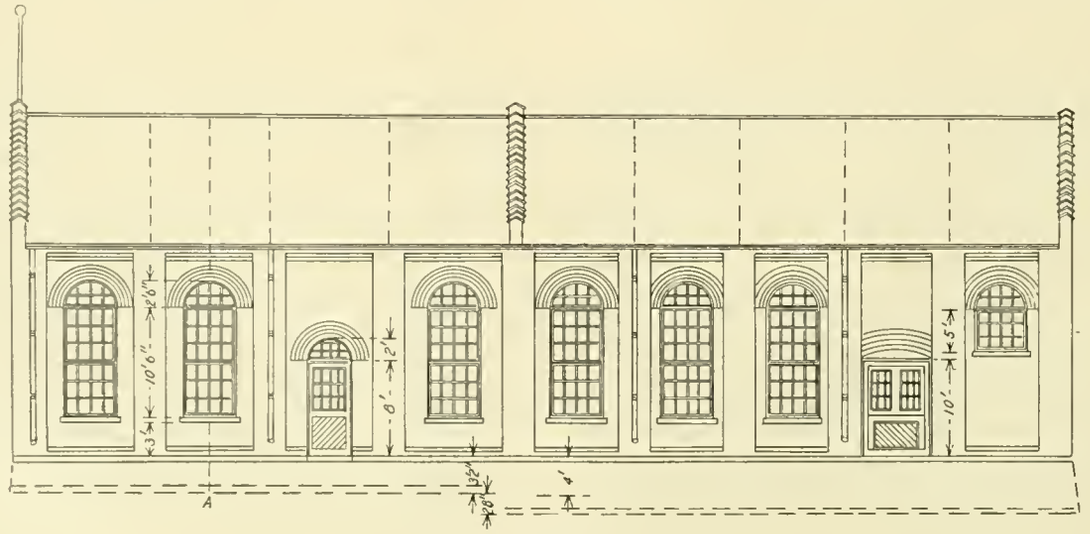
The long trestle is shown in two of the reproductions from photographs, and a sketch of one bent is shown in the line drawing. There are 95 bents of six piles each spaced 15 ft. 9 in. c. to c., making a total length of 1,485¼ ft. The piles are from 22 to 30 ft. long, except at Creek Crossing, where



PLAN OF POWER HOUSE.

once a series of connected S's. The ballast is of excellent quality and to be had in abundance from a burnt out culm bank from a mine about midway on the road. With selected oak ties 6 x 8 x 8 spaced to 2 ft. centers, the track is as smooth and true as most roads at the end of their second year, and the high speed attained makes delightful riding. The curves are nearly all of large radius and are passed at full speed.

At another point a trestle, starting at 6 ft. high and rising to 22 ft. extends for a distance of nearly 1,500 ft. It is built in a most substantial manner and would easily carry any there are some piles 40 to 45 ft. long; they are all of white oak, driven plumb, about half the length being in the ground. The caps are long leaf pine, 12 x 12 in. x 24 ft.; the stringers pine, 7 x 16 in. x 15 ft. 9 in.; chuck blocks, pine, 3 x 14 in.; guard rails, pine, 6 x 8 in; ties white oak, 6 x 8 in. x 8 ft. The caps are drifted to the piles with 1 x 24 in. iron bolts; the stringers are bolted with 5/8 x 26 in. bolts and have 3/4 in. cast iron thimbles between the wood. The packing block between the stringers are pine, 3 x 18 in. x 6 ft., and are mortised 2 in. deep in the stringers. The ties are spaced 18 in. c. to c. and every fourth one is mortised 2



SIDE ELEVATION.

in. on the stringers; the guard rails are mortised 1 in. on all ties and bolted to every key-tie with ⅝-in. bolts.

The trestle and bridge work was all done by the Myers Construction Co., of St. Louis, and we are indebted to Mr. W. S. Henry, vice-president, for the data and photographs of the trestles. Mr. James A. Tiernan, of St. Louis, was chief engineer and drew the plans and specifications.

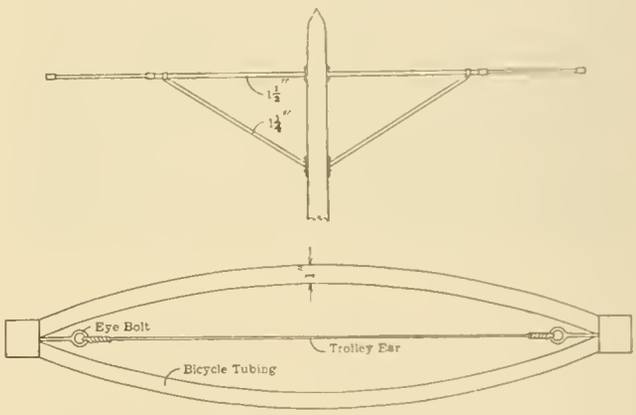
Another trestle is 180 ft. long, with 24 ft. in the clear

TRESTLE 1,500 FEET LONG.

where the Air Line tracks cross below. The proposition was completed by the middle of the trestle coming at the highest point of a 2-mile grade and by a curve which takes in more than half the bridge work. From a distance a car appears to be climbing a roof, but in reality the grade is less than 7 per cent.

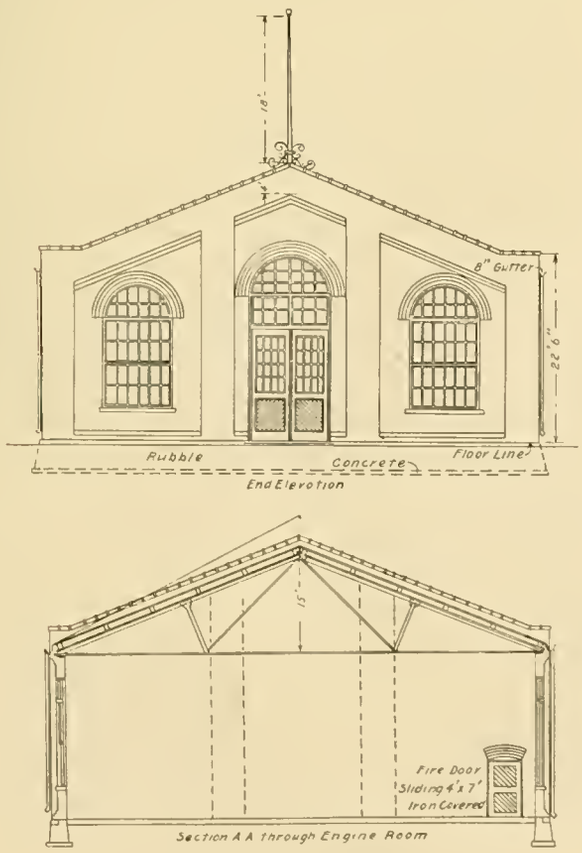
The tracks are 11½ ft. c. to c., which gives ample clearance for the cars, the windows of which, however, are guarded with a wire screen. The line construction includes cedar poles 32 ft. long, with the trolley wire 20 ft. from the rails. Our illustration shows the form of bracket, the arms of which are each 6 ft. long of 1½-in. piping, and the supporting brace of 1¼-in. stuff. The hanger is flexible, made of two pieces of bicycle tubing 1 in. diam. pressed into caps at each end and a wire cord 2 ft. 10 in. long run through, being held at one end and drawn taut with a turnbuckle at the other. The insulation suspending the trolley wire has an adjustment of over 2 ft. Arms and hangers were furnished by the Ohio Brass Co.

The trolley wire, furnished by Ansonia Brass Co., is No. 0000 of the Figure 8 type, and serves the double purpose of feeder also. A voltage of 550 is used, and with the power house situated midway on the line, abundance of current is delivered to both terminals.

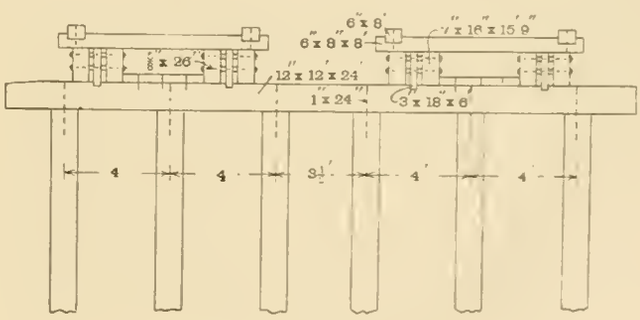


BRACKET AND DETAIL OF HANGER.

The power station, 60 x 100 ft., and car house, 66 x 200 ft., are of a handsome red brick; the general office adjoins, and is a frame building. In the station are two "St. Louis corliss" engines of 625-h. p. each, built by the St. Louis Engine & Machine Co.; they are direct connected to General Electric generators of 425 k. w. each. The four boilers are Babcock & Wilcox, in two batteries, with a nominal



END ELEVATION AND SECTION.



SECTION OF TRESTLE.

capacity of 1,000-h. p. The water supply is abundant, obtained from two deep wells 12-in. drain, and 550 ft. deep. It is soft and clear and remarkably free from impurities. The pumping is done with an air lift of 30-h. p. furnished by Allison & Bremer, Port Carbon, Pa., which delivers water into a 35,000 gallon wooden tank set on iron framework 50 ft. high. Two Warren-Webster 500-h. p. feed water heaters are installed and two Worthington hot water pumps. The oil fillers are the "Famous," made by the Famous Oil Filler Co., of St. Louis.

The switch board is General Electric, with Western Electric Instrument Co.'s instruments. The line station and cars are equipped with Garton lightning arrester.

The fuel supply is close at hand in a mine directly on the line of the road less than a mile from the power house. It is owned by parties who are interested in the road, and the railway is furnishing current for lighting, mining and hoisting, the revenue from which more than pays for the coal used. Other mines have applied for power and a very considerable revenue will be received from this source.

CROSSING OVER AIR LINE TRACKS.

The car equipment comprises 14 cars, of which 6 are open, 6 are closed and 2 closed combination. Each car is equipped with Christensen air brakes, New Haven registers, and the Wilson-Thompson automatic trolley catcher. The cars are certainly models of beauty within and without. The cross seats have leather cushions and are large and comfortable. Seats are provided for 56 persons, with standing room for easily 100 more. The cars are all equipped with improved hand brakes, which are used twice each trip to insure their being in working order, but aside from these applications all the braking is done by air. Circuit breakers instead of fuses are used on the cars. The cars and trucks were built by the St. Louis Car Co.; the trucks have solid 33-in. wheels. Arc headlights of 2,000 c. p. are used. This road carries the mail between Belleville and East St. Louis.

The construction of this road will furnish a delightful pleasure resort to the people of both Belleville and East St. Louis, and will also draw largely from St. Louis. For the two first named cities it is practically the only accessible place. The company has secured a most delightful park directly opposite the power station, and a spur track is being laid which will connect the grounds to main line. The park was laid out some 20 years ago by a very wealthy St. Louis gentleman, who also erected a mansion costing $40,000. This building will be turned into a grand cafe and used as a club house. Artificial lakes, a theater, building and other usual means of outdoor entertainment have been provided, and the whole place made one of the most attractive in the country.

The active work of construction was commenced in October, 1898, and the line opened to travel on May 20th, which was the day originally set. The mainspring of the enterprise was Major Downs, who has carried it through to completion in the face of obstacles which would have long ago discouraged most men. In charge of electrical and mechanical work has been Mr. A. C. Thompson, who was for eight years with the Missouri Railroad Co., of St. Louis. A. D. Marhoff was engineer for the construction company.

Since the completion of this road a consolidation has been effected which, under the name of the St. Louis & Belleville Traction Co., includes the St. Louis & Belleville Electric Railway Co., with 22 miles of track; the St. Louis & Belleville Suburban Electric Railway Co., a competing line, with 22 miles of track, and the Belleville Electric Railway Co., with 6 miles. The company will build a line from Edgemont to Collinsville, about 7 miles, making its total trackage 57 miles.

The officers are: President, John Day; vice-president, George J. Kobush; secretary and treasurer, Z. W. Tinker.

SOME PARK ADVERTISEMENTS.

The Northern Ohio Traction Co. and the Cleveland, Painsville & Eastern R. R. have some rather novel advertisements to call the attention of patrons to the parks on their respective lines. The cards are 11 x 12 in. and bear two lines printed in type ½ in. high.

The Northern Ohio, the old A., B. & C. road, has some cards with the legend:

"With heavy baskets and light hearts
The Gorge-bound Akron car departs."

Others read:

"When the Gorge is green with Nature's bounty
Other Parks are green with envy."

The C., P. & E. cards say:

"Where are you going to, my little man?
To Willoughbeach, sir, as fast as I can."

NEW TRANSFER TICKETS IN WASHINGTON, D. C.

The new transfers recently put in use by the Washington Traction & Electric Co. have been specially designed to allow the conductors to issue them rapidly and with but little loss of time on account of numerous punches. In the old transfers used six different punch holes were necessary: for the month, day, hour, fraction of the hour, junction and direction in which transfer was good. To do away with so many punches the new transfers are issued daily, bearing in print the day and month with the addition of the letters a. m. and p. m. for morning and afternoon tickets. The direction in which the transfer is good is denoted by its color, the tickets being issued in four different shades.

Only two punch holes are required for these tickets, one for the time and the other for the junction. An ingenious device has been planned which makes only one punch necessary for the hours and fractions. Three circles, divided into 12 sections and numbered to represent the 60 minute periods of the day, enclose in separate cases the figures 15, 30 and 45. If the figure 6 be punched in the first circle it will indicate that the transfer is good up to 6:15 o'clock; if punched in the second circle, it will be good up to 6:30 o'clock, etc. The other punch for the transfer junction is all that is required for the conductor to do. The transfers are issued only at the time of the collection of a fare, or of a transfer ticket in such cases where a second transfer is permitted.

AN ESSAY ON PUBLIC OWNERSHIP.

Mr. Edward Wisner, of Toledo, O., in an extremely interesting little pamphlet discusses the question of municipal ownership as applied to his own city, and in doing so gives utterance to many facts of general application. We have extracted portions of an essay which really deserves to be printed in full. He writes:

Toledo is a city of nearly 150,000 people, the equal in intelligence and enterprise of any similar community in the world. It is a city of beautiful homes and thriving industry; the second railway center in the world, and situated to command a large share of the commerce of the unsalted seas. In no city in this country are the masses better clothed, better fed and better housed.

Toledo has had some experiences in owning public utilities, and the balance sheet is interesting reading at the time.

Toledo built what is known as the Woodville R. R. It cost $448,000. The city sold it to the Pennsylvania Railroad Co. for $225,000, or $223,000 less than it cost. The city borrowed $432,000 of the original cost and gave her bonds bearing 7 3-10 per cent. payable in 30 years. The bonds will become due next year, when due the city will have paid $946,080 in interest and the principal will have to be carried along until the present generation shall have bequeathed to posterity both the debt and municipal problems.

Toledo owns a natural gas outfit consisting of pipe line, gas leases, etc. The city borrowed $1,500,000 to go into the gas business. This enterprise has paid $100,000 gross to the city, but not one cent of interest, which is running at the rate of $67,500 per annum. By the time the natural gas bonds are due the city will have paid over a half million dollars in interest in excess of the $100,000 received, and will leave its taxpayers burdened with the original debt of $1,500,000.

The value of the natural gas plant is the subject of much discussion at the present time. The city has recently refused a cash offer of $256,000 for it and has entered into a contract with a New York syndicate for the manufacture of fuel gas to supplement the natural gas supply, agreeing to pay 20 cents per thousand up to 2,000,000 cu. ft. per day; when the gas taken exceeds that amount the price is to be 18 cents. The city reserves the right to buy the supplementary gas plant to be erected by the syndicate at any time after two years capitalized on a 5-per cent net earning basis, but not to exceed $250,000 for a plant capable of making 3,000,000 cu. ft. of gas per day. In any event the natural gas experiment has been a costly one.

It is only fair to state that the advocates of municipal ownership excuse this failure on the ground that the natural gas supply became exhausted or nearly so—a disaster which no foresight could provide against. It should also be stated that a competitor under private ownership, occupying the same field has made the business profitable and is still paying dividends, thus demonstrating the superiority of private business management over public management.

Toledo owns its own water works.' Financially this has been a fair success and affords a great contrast to Toledo's other business investments. Its service, however, is not such as would be tolerated were it conducted by a private corporation.

Toledo has the usual complement of overpaid and under worked officials. Public office in Toledo is both a public trust and a private snap. Some of the officials earn their money. Some of them get from two to five times as much as they could earn in private life. Some offices pay what would be only a fair salary if the official were kept busy, but which is extravagant when compared with the service rendered.

In this respect, however, Toledo is no worse than other cities, all of which proves that the people do not want more politicians, but that they have their hands full in watching those they already have.

Public ownership is a question of degree only. That the government should own the public highways, bridges and navigable streams; that it should own and conduct the postal system are matters already beyond the range of controversy.

It may also be said that a very considerable portion of the people—perhaps a majority—believe that government ownership should be extended in certain lines so as to include the postal savings bank, the parcel post and the telegraph, but it does not follow that because the government does some things well that it can do everything well. It is a well-known fact, and one which will hardly be disputed, that what is done by the government now is done wastefully, and it is possible for the government to conduct its business as it does only because through its taxing form it commands the profits of all of the productive industry of the country. The postoffice department, which is so often held up to us as a fine example of government business ability, is able to run only because it has the United States treasury back of it; as a business proposition it loses directly about $40,000 per day every day in the year—indirectly it undoubtedly loses as much more. From a business standpoint there should be considered interest on its plant, which would swell the deficit enormously. There should be charged a large sum annually for depreciation, repairs and renewals of public buildings; at present no charge is made to the postoffice department for janitor service, heat and light in the government buildings, these expenses being charged to the treasury department. If everything were charged to the postoffice department which is a legitimate business expense, it would undoubtedly double the direct deficit, making a net business loss of approximately $80,000 per day—a sum which for the year equals the total average wealth of nearly 30,000 American citizens; in other words, the accumulated savings of nearly 30,000 average Americans are required every year to make good the losses sustained in the admittedly best conducted business enterprise in which the government is engaged, and this amount has to be supplied by forced contributions from the people of the United States who know enough to conduct their business on business principles. It must, of course, be admitted that the benefits of the postal system are ample compensation for all it costs the people in the way of government taxation to make up deficits. But while the people are able to pay the losses sustained in the conduct of the most economically run department of its government, it need hardly be stated that were all productive industry run as socialism would have it, by the government, and all of it run as the best of it now is, it would be only a short run to bankruptcy of both government and people. It is a fact notorious and beyond dispute that in pretty much all of the ordinary business transactions the government gets woefully swindled. It pays more for any piece of land it may happen to want than individuals or corporations pay under similar circumstances. It pays $125 a head for mules and sells them a few months afterward for $40 or $50 per head. Any wholesale grocer who would do business on the same plan that the commissary department does, would be bankrupt in less than a month. The possession of a government contract is looked upon as a bonanza, because from a business standpoint the pay for property or service furnished is both sure and liberal. Indeed, so universal is the rule that it will be generally admitted without either argument or citation of example. Nobody will contend that municipal government fares any better from a business standpoint than does the general government. The experience of every large city between the two oceans is but an illustration of how municipalities conduct business.

Government of all kinds comes high, but we must, nevertheless, have a certain amount of it. We can stand some waste and extravagance, but good sense indicates that we should keep such losses down by keeping the government out of all kinds of business which private enterprise can do more economically.

Government business methods will improve with the improving civil service, but unfortunately the sense of duty to the public is not as strong as self interest, and the time will never come when any kind of government can conduct business as economically as private business is done.

If you had an agent conducting a part of your business and that agent had uniformly been expensive, profligate and corrupt, what would you think of a proposition to turn over to him conduct of all of your business affairs, and to place your fortunes in his keeping. Your answer must be that such a thing would be preposterous. But that is exactly the proposition of the socialist. The state and municipality necessarily have to conduct some business, but such business has always been done with an expense and extravagance which would mean hopeless bankruptcy were all business so conducted. Common sense and common prudence require a positive "no" to the demands of the socialist.

Business conduct of great enterprise by the state is nothing new, and we have abundant example in this country.

The state of Michigan built the Michigan Central R. R. from Detroit to Kalamazoo at a cost of $2,500,000, and sold it for $2,000,000, and that is one of the brightest examples of railroad building

by the state in this country. Illinois built 58 miles of railroad from Mendosia to Springfield at a cost of $1,000,000 and sold it for $21,000. Illinois' experience in the railroad business cost her $6,000,000. Massachusetts sunk $14,000,000 in the same line. The state of Pennsylvania built and operated what was known as the Allegheny Portage R. R. While operating it the running expenses amounted to $3,161,000 and its gross receipts to only $2,985,000. In "Railways and Republic," by J. F. Hudson, may be found the following:

"The canals and railways built by that state (Pennsylvania) and operated by it for nearly 20 years, are well known as an illustration of the evils of political management in business enterprises. They are salient examples of the demoralizing effect which politics and public works can exert on each other; and the constant strife for their patronage, its use for political rewards, and the expensive administration and unsatisfactory revenues of the roads finally led the state to part with them."

It is not necessary to inquire why men will not do business for the public as economically as they will for themselves. The fact that they do not is sufficient.

In these days of the political demagogue it may sound strange to the working man to be told that he has no more rights than other people; than bankers, merchants, railroad presidents and mayors, all of whom are in the true sense workingmen. Of course he has exactly the same rights and the working classes will have taken a long step in the direction of their own emancipation when they quit demanding special privileges for themselves, and use their energy and ability in seeing that nobody else gets special privilege.

The full grown workingman is no baby—no ward of the state. What he wants is just laws and a fair show. That granted, he can take care of himself, and only in case of such disaster as no economic system can provide against, will he have occasion to ask alms of anybody. He needs not more government, but less. Government has no Aladdin's lamp; no magic wand; no way to get wealth except to take it from its subject. The honest workingman whose mind and muscle directs the machinery of modern civilization cannot afford to ignore the teachings of all past experience and join with ne'er-do-wells in a scramble for the accumulated wealth of the world.

"Nothing should be done by the general government which the state can do as well; nothing should be done by the state which the county, township, or city can do as well; and nothing should be done by any government which private enterprise can do as well."

These are the words of an honored American statesman of the last generation and they are good enough for a whole political platform.

If the city owned the street railway for whom would the street car employes vote?

For the party in power.

How could a corrupt administration intrenched behind thousands of votes of employes be dislodged?

By revolution.

Who would pay the losses caused by extravagant municipal conduct of business?

The same man who pays it now—the taxpayer.

Who is the taxpayer?

Every man who owns or rents a home.

When will it be possible for an honest man to say that he wants a high office because it is a good thing to have, and that he is willing to render honest service in return for the suffrages of his people, instead of lying about it and pretending to not want it; appearing to accept it with reluctance and at great personal sacrifice?

When molasses fails to catch flies.

When will the masses of the people learn that what they want is not special privileges for themselves, but to see that nobody gets any privileges?

Nobody knows.

When will the municipality or state be able to get property or service as cheaply as an individual?

In the Millenium.

When will socialism be practicable?

When the small boy of his own accord gives to his playmate the biggest and reddest apple he has; when the ardent lover yields to his rival the girl he loves and at the same time honestly loves that rival; and when the young miss does not want the prettiest spring bonnet in the neighborhood. And then

"Life will be ravished of its zest,
And shorn of its ambition
And sink into the dreamless rest
Of inanition."—Holland.

SUCCESS OF "THE FOUR CORNERS."

The following communication is from a gentleman in Rochester, incidentally connected with the street railway there, and who has followed the company's weekly publication with much interest.

Rochester, N. Y., Dec. 11, 1899.

Early last spring Mr. H. H. Windsor, editor of the "Street Railway Review," Chicago, suggested to his friend, Mr. T. J. Nicholl, general manager of the Rochester Railway Co., the publication of a weekly paper to be distributed gratis on the cars, at summer resorts and on suburban railways. He thought it would be mutually advantageous to the company and its patrons, that the interests of both were identical; that a well conducted street railway is a city maker, and to be financially successful must have the confidence and patronage of the public. Mr. Nicholl readily fell in with the suggestion, and in April ordered the issue of the first paper in quarto form, 7 x 9 in., and dubbed it "The Four Corners," the point in Rochester from which all the car lines radiate. A photo-engraving of Hose & Engine Co. No. 10, at Driving Park Ave., adorned the first page. The issue was such a decided success it was continued. It struck the public fancy and brought many commentary letters to the officials.

The "Kickers' Column," in which the chronic street car grumblers were ridiculed and made to occupy the amusement seat in the public mind, seemed to be enjoyed by all, even the lampooned kickers. Mr. Nicholl continued the paper until November 1st, when publication was suspended temporarily. The "Four Corners" gave the time tables of all the street and suburban railways and it became indispensable to the cottagers at the White City Windsor Beach, Summerville, Charlotte, Manitou Beach and intermediate stations on those lines and on the Glen Haven road. It advertised in an attractive manner, special excursions on all the Rochester railway lines. It proved a medium for extensive publicity, that could not have been attained otherwise without incurring ten times the cost. It was also a great advertising medium for the city merchants. Elegant illustrations of local scenes were given each week.

The "Four Corners" put an absolute stop to the kicking business. This, of course, pleased the employes of the road. The editor of the little sheet was aided in his work by the suggestions of Mr. Windsor. The press of the whole country made free extracts from the paper and brought it into enviable notoriety. With the close of the summer season and the advent of cold weather, publication was suspended. It will probably be resumed in March, when the "Four Corners" will sing the praises of the Rochester & Sodus Bay Electric line, now being constructed, and which will open to the people of Rochester an ideal summer resort on Lake Ontario, 30 miles from the city, and the numerous intermediate stations, besides furnishing the farmer and market gardener on the line of the road a ready market in Rochester.

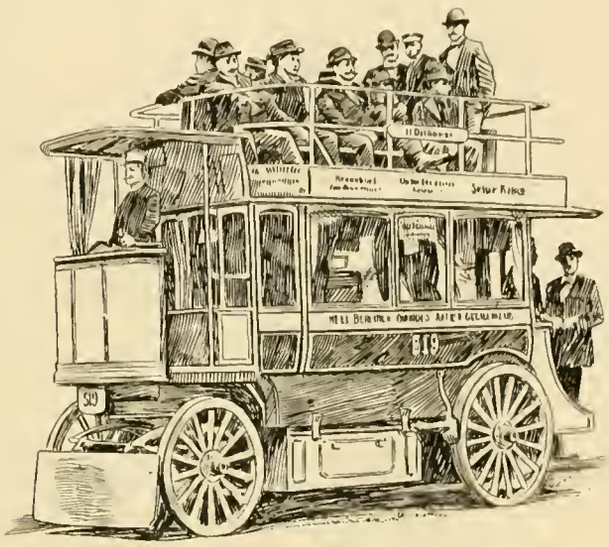
A. E.

NARROWING GAGE WITHOUT PERMISSION OF COUNCIL.

Early in November the Carbondale (Pa.) Traction Co. started the work of changing the gage of its tracks through the boroughs of Archbald, from 5 ft. 2 in. to standard. The object of the change was to enable the Scranton Railway Co., which now controls the Carbondale lines to run through cars. In changing the gage the company did not ask permission of the borough council, as it was thought unnecessary, because the ordinance under which the line was built said: "The gage shall not be more than 5 ft. 2 in." The council of the borough interfered and prevented the change of gage being made, whereupon the company petitioned for an injunction. November 24th the borough was restrained from further interfering in the work, and the change will be made at once.

NEW TYPES OF ELECTRICAL OMNIBUSES.

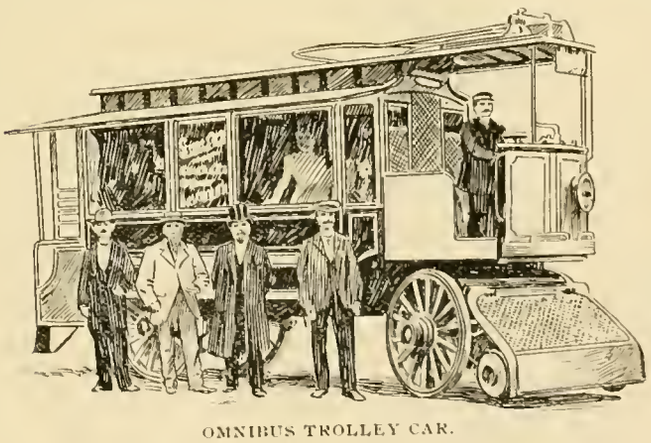
Among the numerous types of automobiles which were exhibited at the International Motor Carriage Exposition held at Berlin recently was the one shown in the accompanying illustration. Electrical omnibuses of this character are now being used in Berlin to supplement the street railway service, and are made by the Union Electrical Co., of Marienfelde. The first of these vehicles was put into service on the 1st of September in the city and has been from the start so popular that its seating capacity of 28 persons is constantly filled. A large number of them are to be put in service on Friedrichstrasse and other principal streets in the city, and the



ELECTRICAL OMNIBUS, BERLIN.

hope is generally expressed that they will eventually entirely replace the two-horse omnibusses which on account of their low rate of fare still carry more than a million passengers a year. The new omnibusses run swiftly and silently over the asphalted streets and seem to fulfill every expectation.

Another type of electric omnibus to be found in Berlin is shown in the following illustration, taken from the Electrotechnische Zeitschrift, and is made by Messrs. Siemens & Halske. The designers



OMNIBUS TROLLEY CAR.

of these vehicles have adopted a system by means of which the accumulators at certain periods of the run will receive a charge from the overhead wires of the tramway company. For this purpose a collecting bow is placed at the top of the car for making connection with the trolley wire, while on the front of the bus two wheels are provided to make connection with the tramway rails.

An omnibus of this type is designed to seat 15 passengers inside and to carry 6 more on the rear platform. The front platform is reserved for the driver only. The weight of the buses complete with batteries and passengers is 6½ tons. The accumulators weigh only 1½ tons. It will be seen that the proportion of the weight of the accumulators to the total weight carried is much smaller than is usually the case. Two motors are used on each axle, making four in all. These are so arranged that the wheels are driven independently. The motors drive by means of single reduction gearing with a ratio of 1 to 7.5 on the front wheels and 1 to 8 on the back. The regulation is effected by means of series parallel controllers in the usual way. The whole object of the design is to keep down the weight of the accumulators and at the same time to have a bus which will run over routes which are not equipped with overhead wires.

The guide wheels are attached to a light axle which is held in position by powerful springs. In a forced run of 30 km an hour during the trial of the first vehicle built these springs and the entire apparatus proved admirably adapted to their uses. Sharp curves were turned without difficulty or danger.

TRACK WITHOUT WOODEN CROSS TIES.

During the last five years a number of the larger street railways have experimented with what has come to be known as the concrete trench construction for roadbeds, where the rails are supported on (and usually partially imbedded in) concrete beams. This construction is only adopted where the paving is laid on a concrete substructure, the rails being held to gage by this sub structure and by tie rods placed at intervals of from 6 ft. to 10 or 12 ft. The "steel tie" construction used by a few other roads is a modification of the trench construction, the metal ties being placed only at intervals of 6 ft. to 10 ft., where if wooden ties were used they would be spaced 2 ft. or 2½ ft. between centers; the metal ties serve principally as additional tie-rods.

The cities where the trench or metal tie construction has been used to considerable extent include Toronto, Detroit, Minneapolis, St. Paul, Kansas City, Scranton, Pa., and Rochester, N. Y. We believe that the Montreal Street Railway Co. also has some of this work.

In the paper on "Pavements between Street Railway Tracks" published elsewhere in this issue Mr. C. H. Rust, city engineer of Toronto, states that the concrete trench construction which has been used with "permanent" pavements in that city since 1895 is much superior to the wooden cross tie construction.

Mr. F. A. Little described the metal tie and the trench work at Detroit in the "Review" for January, 1897, page 44, and in the issue for the following May, page 328, added further data concerning the use of plates under the joints. He then stated that after two years of service, cars being run at intervals of from two to four minutes for 18 hours per day, the track laid on concrete beams with tie-rods every 10 ft., was in a condition at least 25 per cent better than the tracks laid with oak ties on a 6-in. concrete foundation but using no tie-rods and extra support for the joints.

The Twin City Rapid Transit Co., of Minneapolis and St. Paul, in 1896 laid 5-in., 80-lb. T-rails on concrete beams as an experiment (St. Ry. Rev., Feb., 1897, p. 73) and now has some 20 miles (single track) of this construction in the two cities, it being put down wherever paving and other permanent improvements are ordered. In answer to a recent inquiry Gen. Mgr. W. J. Hield stated that the cost of this work was approximately $1,000 more per mile (single track) than would be the wooden cross tie construction. As to the relative cost of maintenance there are yet no data. The city engineers of both cities are very much pleased with the results.

In March, 1897, page 140, we described the concrete construction used in Kansas City, Mo., and additional data were given by Mr. Edward Butts in his paper before the A. S. R. A. at Chicago in October last (St. Ry. Rev., Nov., 1899, p. 766). The Metropolitan company regards this construction as satisfactory in every way as is shown by the fact that it is putting in more of it every year.

The Rochester (N. Y.) Railway Co. put down some of this work in the summer of 1898 which was described in detail in the "Review" for November, 1898, page 792. In a recent letter Gen. Mgr. T. J. Nicholl says:

"The rails were laid on the concrete beams. We have had two miles of single track laid in this way, but we do not contemplate laying any more until such time as we are certain of the success of this style of construction in this climate. The cost of construction is about the same as wooden tie construction, where 6 in. of concrete is laid under the ties, and first class ties used. The track has been laid too short a time to form any idea as to cost of maintenance.

and also to be able to tell of its advantages or disadvantages. We have used metal ties, pieces of old 4½-in. rail fastened to the rail by little cast iron clips and bolts. Most of the track laid in this way was laid in 1898, and, as I said before, we shall lay no more until we have further experience. Our city engineer is very much in favor of concrete work under the track of any kind."

The Brooklyn Rapid Transit Co. recently laid a short section, 1,000 ft., of track to determine whether the trench work was adapted to its conditions. This was described in our last issue and in the same number was a paper by Mr. Frank Silliman, jr., general manager of the Scranton (Pa.) Railway Co., describing the track built at Scranton last summer. The Scranton construction is with 5-in. T-rails held to gage by tie rods and metal ties (made of old rails). It differs from the other types of roadbed mentioned in that the concrete is but little if any thicker under the rails than elsewhere in the street.

TROLLEY WIRE THIEF.

We publish herewith the features of an expert trolley wire thief, who though now suffering the penalty of his misdeeds will be out again before long; he is believed to have been responsible for a large number of losses electric roads have suffered in having their trolley wire stolen.

FRED SCHMIDT ALIAS FRED NEWMAN.

His most recent experience was on the line of the Delta Electric Ry., Cairo, Ill., where he was discovered at work by the conductor of an owl car on the line of the Cario Electric Ry. shortly after midnight. The Delta people were disposed to take no trouble over the case, but not so E. W. Halliday, general manager of the Cario Electric. He too had been greatly troubled with the trolley wire thieves and determined to make an example of the guilty party. He therefore had him followed up and the arrest was not made until he had reached Memphis, where he was found to be an escaped convict from the Tennessee penitentiary, to which he was returned.

His name is Fred Schmidt alias Fred Newman; age 34; height 5 ft. 3 in.; weight 115 lbs.; hair, chestnut; complexion medium fair with hazel eyes.

MECHANICAL TRAINING FOR ELECTRICAL ENGINEERS.

Apropos of what work should be included in a college course of electrical engineering, an eminently successful electrical engineer, who is the electrician of a large electric light company, recently said to Prof. R. A. Smart, of Purdue University:

"I believe the popular judgment in regard to the necessity for mechanical work in the electrical course is wrong. I was graduated from the Massachusetts Institute in the electrical course, and my professional work has been of a purely electrical nature. I have had but little to do with the mechanical side of electrical engineering, and would be, therefore, more likely to favor the electrical side of such a course. In my opinion, however, the electrical students cannot get too much mechanical work; they need all they can get and more than they get, and if any addition is to be made to the electrical course, in which the choice is between electrical and mechanical work, the mechanical work should be added even at the expense of the electrical work. The mechanical end is where the electrical graduates fail."

A new electric locomotive has been built in Tacoma, Wash., under the direction of Supt. Frank L. Dame, of the street railway. The locomotive was built for the purpose of hauling wood trains on the Puyallup and Steilacoom lines and will haul a good sized train with ease. The wood hauling is done mostly in the early morning before passenger traffic begins.

PAVEMENTS BETWEEN STREET RAILWAY TRACKS.

Read before the American Society of Municipal Improvements by C. H. Rust, M. Am. Soc. C. E., City Engineer, Toronto.

In 1891 the exclusive privilege of operating the street railways in the city of Toronto, for a period of 30 years, was disposed of to a company now known as the Toronto Railway Co. The clauses of the agreement, made between the city and the company, that refer more particularly to this paper, read as follows:

"The purchaser shall maintain the ties, stringers, rails, turn-outs, curves, etc., in a state of thorough efficiency and to the satisfaction of the city engineer, and shall remove, renew or replace the same as circumstances may require, and as the city engineer may direct. When a street upon which tracks are now laid is to be paved in a permanent manner, on concrete or other like foundation, then the purchaser shall remove present tracks and sub-structures and replace the same, according to the best modern practice, by improved rails, points and sub-structures of such description as may be determined upon by the city engineer as most suitable for the purpose, and for the comfortable and safe use of the highway by those using vehicles thereon, and all changes in the present rails, tracks and roadbed, construction of new lines or additions to present ones, shall be done under the supervision of the city engineer and to his satisfaction

"In the event of the purchaser desiring to make any repairs or alterations to the ties, stringers, rails, turn-outs, curves, etc., on paved streets, the purchaser shall repave the portion of the roadbed so torn up at his own expense.

"When the purchaser desires or is required to change any existing tracks or sub-structures for the purpose of operating by electric or other motive power, approved by the city engineer and confirmed by the council, the city will lay down a permanent pavement in conjunction therewith upon the track allowance (as herein defined) to be occupied by such new tracks and sub-structures. This shall first apply only to existing main lines and thereafter to branch lines or extensions of main lines and branches, as and when the city engineer may from time to time recommend and the city council may direct and require; but such tracks as are now laid on a permanently formed roadway must, when so required as aforesaid, be changed by the purchaser as hereinbefore provided, without any change of roadbed being made or any expense occasioned to the city thereby."

Under the terms of the agreement the company pays the city treasurer $1,600 per annum per mile of double track and 8 per cent of the gross receipts. When the receipts exceed $1,000,000, 10 per cent is to be paid.

To raise the money for constructing these permanent pavements debentures were issued, payable in 10 years, and the revenue derived from the mileage and percentage of gross receipts is used to pay its interest and sinking fund upon these. The total amount of bonds issued up to the present time is $1,210,776, and the annual payment to provide interest and sinking fund is $149,136. This is at present very nearly the amount received from the street railway company, but as these pavements between the tracks will last for a much longer period than 10 years, in a few years there should be a considerable revenue derived from this source.

A great diversity of opinion has arisen as to the meaning of the word "permanent," used in connection with pavements. In 1888 this question was in the High Court of Justice before Judge Rose, in a case brought by the corporation of Toronto against the old Toronto street railway company, and after considerable litigation it was finally settled, without, however, the judge giving his opinion as to the meaning of the word "permanent." When the present company obtained its franchise the interpretation of the word was again subjected to a great deal of discussion, and in 1893 the work of changing the rails by the company and the construction of the pavements was postponed from April until August, pending a settlement as to the meaning of this word. The writer has always taken the ground that in this case the word "permanent" refers to pavements with a concrete foundation, and this has since been taken as the meaning of the word as mentioned in these clauses. It is a great pity that this word should be so frequently used in connection with pavements. It would certainly be better in future cases to state explicitly what is a permanent pavement.

In compliance with the provisions contained in the previously

mentioned argument, in the spring of 1892 plans and specifications for paving the track allowance on King, Queen, Yonge and other streets were prepared, and on June 28, 1892, the street railway company laid down a temporary track on King St., west of Simcoe St., and the contractor for the pavements commenced work. The work of changing the tracks and constructing permanent pavements on these streets was carried on continuously until winter set in (with the exception of a week's intermission during the time of the Industrial Exposition). The amount of track taken up and relaid that season was 29.9 miles. The rail adopted by the company and approved of by the city was a 6½-in. steel girder rail, weighing 70 lb. to the yard, and having a web ⅜ in. thick and a base 4½ in. wide. A slight alteration was afterward made in the size of the base, it being made 5 in. instead of 4½ in. The rail now weighs about 73 lb. to the yard. From experience since gained a heavier section of rail should have been used. The following are the quantities of materials and weights required to build one mile of single track:

128 tons of rails.
5.85 tons of fish plates, 17 lb. per pair.
1,800 cedar ties.
1 ton of spikes, ¾ lb. each.
1 ton of bolts and nuts, 1 lb. each.

The work of constructing these pavements and of laying new rails was carried on continuously until the work was practically completed in 1894, there being only a few extensions constructed since. In constructing these new pavements the street railway company took up the old rails, tamped the gravel under the ties, put down new rails and lined and leveled them and the paving contractor did the rest of the work.

It may be of some interest to give the amount of work done in each year, the average cost per lineal foot (the width paved being 15 ft. for a double track), the average rate of progress per day, and the different classes of paving material:

1892—29.9 miles single track cost.....$322,555.00
1893—26.1 miles single track cost..... 302,030.00
1894— 9.8 miles single track cost..... 116,942.61

The average cost per lineal foot of double track for the different classes of pavement during these years was:

Asphalt $5.23
Granite 2.43
Brick 4.21
Cedar blocks 3.83

This includes the cost of stone or scoria toothing. Where granite was used the contractor was permitted to use the blocks that were on the street.

The average amount done per day was:

Asphalt .....131 lin. ft. of double track
Granite ..... 56 lin. ft. of double track
Brick ..... 73 lin. ft. of double track
Cedar block ..... 96 lin. ft. of double track

In 1894, on McCaul St., the method of construction was slightly altered as to the system of laying the granite or scoria toothing. It was found that when the blocks were laid as headers and stretchers the water lodged next to the block and assisted in destroying the asphalt. To prevent this it was decided to lay scoria blocks, 4 x 5 x 9 in., with their length parallel to the rail and then lay the asphalt. The practice had been to lay the first 6 in. of concrete up to the bottom of the rail, then lay the scoria blocks in mortar and finally put in the remainder of the concrete. On this street a change was also made in this respect. The whole of the concrete was put in at once and while it was still wet scoria blocks were pounded into it and left to consolidate with the concrete before the asphalt was laid down. In any extension constructed since 1895 wooden ties have been dispensed with and steel tie bars, 2 x ⅜ in., placed 6 ft. apart, have been used, the rails being laid on a solid bed of concrete 8 in. in depth by 20 in. wide. This method of construction is much superior to the first type adopted and is largely used in other cities.

After an experience of six years with the different materials used, it is evident that with the conditions existing in Toronto, asphalt is not a suitable paving material to be used between street railway tracks. After having been down only four years, the asphalt commenced to disintegrate. This was at first more noticeable where the asphalt joined the toothing, but it was not long before the rest of the material between the rails commenced to wear into holes. This was due probably to the following causes:

The lack of a proper foundation under the ties, which was shown by the settlement of the rails in several places. The impossibility of properly tamping the asphalt; and the constant watering of the asphalt, rendered necessary by the dust caused by the passage of the cars, and also by climate conditions. Upon King St., which was the only asphalt pavement laid without toothing, a rut was soon formed, rendering constant repairs necessary. The fact of the lip of the rail not being quite as high as the head and the gage of the track being 4 ft. 10⅞ in. instead of 4 ft. 8½ in., probably had a great deal to do with the forming of this rut.

As previously mentioned, the first pavements were laid in 1892 and in 1897 it became necessary to commence tearing up the asphalt and replacing it with granite, scoria or brick, depending upon the amount of travel upon the street, and by 1900, all the asphalt between the rails will have been replaced by a more permanent material. Up to the present time 7¼ miles of this work had been done. At first as these asphalt pavements were guaranteed for five years, arrangements were made with the contractors whereby they substituted brick for this asphalt, and were paid $1.50 per sq. yd., but afterward when the guarantee expired the price paid for substituting scoria for asphalt averaged about $2.40 per sq. yd. This includes taking up the old asphalt and also 4 in. of concrete. The amount of money spent up to the present time in substituting a more permanent material for asphalt is $137,340.19. In putting in blocks in place of asphalt, the asphalt was first taken off and then the concrete had to be picked out so as to afford room for the blocks, which were bedded on a cushion of sand. Fortunately on most of the streets the concrete was put in between the rails just to a depth of 4 in., and it was not a very difficult operation to take this out. Granite is no doubt the most durable material to use between street railway tracks, but owing to the very strong opposition of the cyclists not so much of it was used as the department would have liked, and scoria blocks, imported from England, were used instead. On streets where there was not a great deal of travel, Canadian bricks were used. Cement grout was used almost entirely for this work; some filling was done with paving pitch, but cement was found to be the more satisfactory. Owing, however, to the impossibility of stopping street car traffic while this work was in progress, it was very difficult for the filling to become properly set. On King St., during the past summer, where scoria block was substituted for the asphalt, a portion of the pavement between the tracks was laid with concrete. It has been down now for some two months, but not long enough to know the results.

WATER GUARDS FOR TROLLEY POLE AND ROPE.

The accompanying illustrations show the trolley rope water guard and the trolley pole water guard invented by Mr. Thomas Hawken, superintendent of the Rockland, Thomaston & Camden Street Ry., of Rockland, Me. Fig. 1 is the pole guard; it catches the water which is discolored by the corrosion of the trolley wire, and prevents it from running over the roof

FIG. 1.

FIG. 2.

of the car and down the sides and discoloring the paint. Fig. 2 is the rope guard which prevents water from the overhead wires from running down the trolley rope and dripping onto the platform and the clothing of the passengers. Mr. Hawken states that both of these devices have been tested and their usefulness demonstrated on the road under his charge.

IN THE POWER HOUSE.

This department is devoted to the construction and operation of electric railway power houses. Correspondence from practical men is specially invited. Both the users and makers of power house appliances are expected to give their views and experiences on subjects within the range of the department.

ACCIDENT AT THE BIRMINGHAM (ALA.) POWER HOUSE.

An accident occurred last month at the power house of the Consolidated Electric Light Co., of Birmingham, Ala., which shut off the city's lights and stopped the electric railway system for some time. The 52-in. belt on one of the engines parted and one end of it flew over against the piston rod of another engine, bending it and breaking the piston head. In this way both engines were disabled at once. The accident occurred about the time that people began returning to the city from the state fair, and the number of heavily loaded cars on the line is thought to be the cause of the belt breaking. As soon as the accident occurred the management put quite a number of dummies into service, which gave a fair schedule on part of the line. The feed wires of the Birmingham Traction Co. were also tapped, from which sufficient power was obtained to run eight cars on one of the lines. It required a large force of men from the time the accident occurred until the next morning to repair the damages.

MANIPULATION OF WATER RHEOSTATS IN TESTING GENERATORS.

Mr. Edward J. Willis, in a paper before the American Institute of Electrical Engineers, giving the results of tests of a 300-kw. railway generator, gives the following information concerning the rheostat used: "The water rheostat was composed of two sheets of boiler plate 5 x 6 ft. each. By means of soda the conductivity of the liquid was brought to the desired point. With light loads and before the water commenced boiling completely, there was some fluctuating in amperage, but after the water got to boiling thoroughly, the load could be maintained perfectly steady. At 500 amperes there was about 15 sq. ft. of each plate submerged. The water evaporated by the boiling was replaced by a hose connection and the water level in the rheostat tank thereby maintained constant. The writer would state that in his experience with rheostats of any size, if a steady load is required, it is better to let the water come to a boil and the plates remain steady, replacing the evaporated water with a running connection, than to attempt the continual raising and lowering of the plates."

DISCREPANCY BETWEEN COMMERCIAL AND EXPERIMENTAL RESULTS IN BOILER TESTS.

The final result sought by manufacturers, in initiating tests of steam or other machinery in actual use, is the value of the work done measured in dollars and cents. In some cases the broad question is raised as to the saving that may be accomplished by installing improved boilers, engines, or other machinery; but more generally it is desired to ascertain what can be done to produce saving with the apparatus already in place under the actual conditions that prevail at the particular location. In both these cases it is necessary to ascertain the average cost of the work done commercially previous to the test. Frequently, in fact, generally, this important fact will not be ascertained by an elaborate trial, for the reason that everything will be put in order for the test, and all details of the trial be conducted so carefully that the losses due to average carelessness or want of skill in the past will be eliminated, the engineer making the test will not receive proper credit, and the owners, on seeing the report, may conclude that they are already doing very well, and perhaps continue old methods with fancied security. If the cost of the output of the factory for a given time were ascertained in terms of the coal burned during the same time, and compared with the corresponding cost for the time of the trial, the latter would frequently be found to be one-eighth to one-third less than the former, and it might not be possible to tell what had caused the difference; for instance, whether it was due to putting in order the machinery prior to the tests, to greater care exercised by the fireman under the spur of careful watching, or whether, as is usually claimed, the coal was different, etc., etc. The losses are generally due in the main to the carelessness of the firemen. It follows, therefore, that the cost of the power under average conditions must be obtained in some quiet way preliminarily. Frequently the comparison of the output of the factory with the coal burned will not be sufficiently accurate, and it will be necessary to devise some corresponding check which will not interfere with the regular routine of the establishment. The work of the boilers may be checked by arranging a meter so as to continuously measure the feed water; and its record, compared with the total weight of coal purchased, will frequently give the check desired. Such a check becomes more difficult when it is desirable to ascertain the performances of particular boilers, and the coal supply is common to all boilers; but by assigning particular weighed carloads of coal to the particular boilers, without any intimation to the firemen that they are being watched, it may be possible to ascertain the average performance of the boilers used for the particular purpose. Preliminary experiments of this kind conducted without notice to employes, and continued through a long period, will furnish a basis for comparison with elaborate tests, and it will then be possible to point out clearly where the several losses have taken place, and the testing engineer will get the credit for the saving shown.—Appendix XXV, Proposed Revised Code for Boiler Tests, American Society of Mechanical Engineers, by Dr. Charles E. Emery.

FRICTION OF STEAM PACKINGS.

Read before the American Society of Mechanical Engineers by C. H. Benjamin.

It is generally conceded that one of the most serious frictional losses in engines and pumps is that due to the rubbing of piston and valve rods in their stuffing-boxes, and that this loss varies with the kind of packing employed, the steam pressure, and the judgment of the engineer.

The writer is not aware, however, that any experiments have been described which would show the extent of this loss and the law of its variation. The experiments described in this paper were made at the laboratories of the Case School by senior students, under the direction of the writer. The apparatus used was constructed by Mr. E. O. Lieghley of the class of '98, and a few experiments made by him.

During the past year, Mr. G. S. Beckwith, of the class of '99, made a large number of tests with different varieties of packing, and the results seemed of such interest as to justify their presentation to this society.

The general character of the apparatus is shown in Fig. 1. It consists of a cast-iron cylinder, 6 x 13 in. inside, fitted at each end with a cover and stuffing-box suitable for a 2-in. rod. The proportions of the gland, etc., were taken from those of a well-known engine. The rod was given a reciprocating motion by means of a slotted cross-head and crank; a pulley on the crank was connected by a belt with the pulley of a transmitting dynamometer; steam was admitted to the cylinder by the vertical pipe shown in the figure, and the water of condensation was drained off from time to time at the bottom.

A steam gage attached to the cylinder showed the internal pressure at each instant. The adjusting nuts of the glands were usually

tightened only by the fingers, but when a wrench was used, it was turned by a spring balance and the turning moment noted.

The travel of the rod was 4.25 in., and the usual speed about 200 r. p. m., giving a piston speed of about 140 ft. per minute. Seventeen different varieties of packing were tested, made by nine different manufacturers. The materials present were rubber, asbestos,

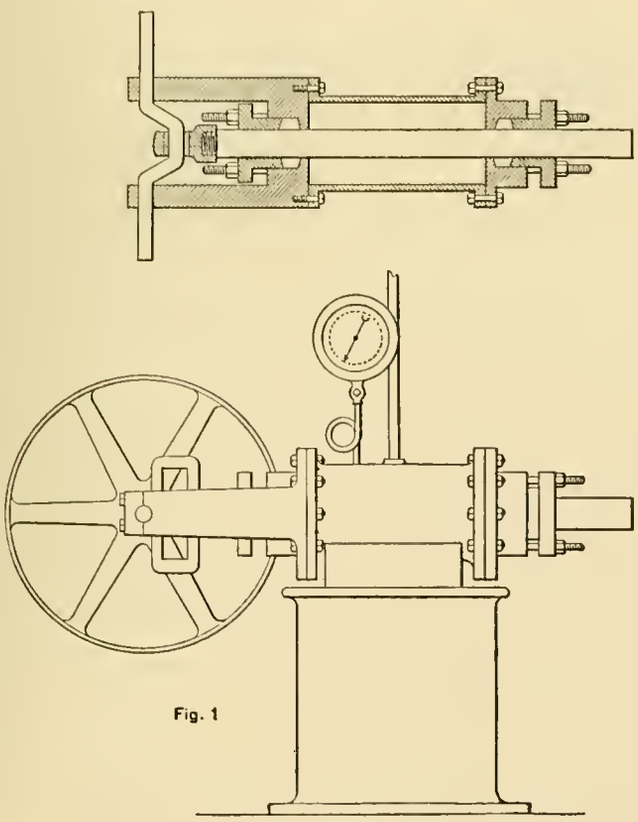

Fig. 1

TESTING APPARATUS.

cotton, flax or hemp, lead, mica, graphite, and paraffin. No metallic packings, strictly so called, were tried.

The following brief description will show the general characteristics of each variety:

1. Square, ring, 7/8-in. Layers of canvas and rubber, saturated with graphite and oil.

2. Sectional, ring, 7/8-in. Composition similar to No. 1. Each ring consists of an inner and outer cone, fitting together, and so wedging under pressure as to fit tightly to rod and box.

3. Similar in shape and composition to No. 1.

4. Metal face packing. Alternate soft and metallic rings. The metallic rings contain lead band, backed by rubber and flax, the whole wound with cotton braid.

5. Two kinds: (a) a sleeve composed of woven flax, rubber, and canvas; (b) a spiral packing of woven flax backed with rubber.

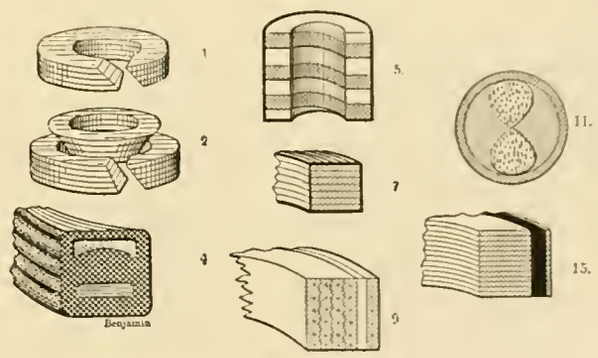
6. Spiral, square, 7/8-in. Alternate layers of rubber and canvas.

7. Spiral, square, 1/2-in. Layers of canvas and rubber, saturated with graphite and oil.

8. Similar to No. 7, but of a different make.

9. Spiral, square, 1/2-in. Composed of rubber and asbestos compound, with elastic rubber inset. Slightly impregnated with graphite.

10. Spiral, circular, 7/8-in. Red rubber core, wound with layers of rubber and flax, and coated with graphite.



PACKINGS TESTED.

11. Spiral, round, 1/2-in. Two wedge-shaped strands of woven flax in center, and two strands of canvas, the whole surrounded by a woven cover saturated with graphite and oil. There seemed to be also some paraffin present.

12. Spiral, round, 1/2-in. A rubber core, around which are braided three thicknesses of hemp or flax, soaked in oil. The whole coated with paraffin.

13. Spiral, round, 1/2-in. A rubber core, surrounded with layers of woven cloth and rubber, impregnated with ground mica.

14. Square, 1/2-in., pump packing. Alternate packing. Alternate layers of canvas and rubber. No lubricant.

15. Square, 1/2-in. Similar to preceding, but having a rubber back about 1/8 in. thick.

16. Square, 1/2-in. Alternate layers of rubber and canvas. No lubricant.

17. Spiral, square, 1/2-in. Woven flax, soaked in oil. As at first constructed, the gland was adapted for packing 7/8 in. thick. The flat

ring and sectional packings of this size, such as Nos. 1, 2, and 3, worked well, but it was found that no spiral packing 7/8 in. thick, would coil easily around a 2-in. rod. Accordingly, the box was bushed and a new gland made to accommodate ½-in. packing.

In cutting and inserting each kind of packing, careful attention was paid to the accompanying directions, and an endeavor was made to ensure the most favorable conditions. It was not practicable to make endurance tests, but each packing was allowed to remain in the box long enough to get into fair working order.

The routine of each trial was about as follows: The apparatus was first tested empty of packing to determine friction.

The packing was then inserted and adjusted in each end, according to directions, and the steam turned on. The very least pressure which would prevent leakage was used on the gland nuts. The packing was then tested under various steam pressures, each run lasting from fifteen to forty minutes. The nuts were then tightened to various pressures, and other sets of readings taken. Cylinder oil was next applied to the rod, the only lubrication in the tests so far having been that contained in the packing itself. Finally, a last run was made with the boxes empty, as at first. A Flather recording dynamometer was used on a few of the runs, so as to determine the nature of the variations in power. The majority of the tests were made with a Webber box gear dynamometer, readings being taken at short intervals and averaged.

TABLE I.

Kind of Pack'g.	No. of Trials	Total Time of Run in Minutes.	Average Horse power Consumed by Each Box.	Horse-power Consumed at 50 Pounds Pressure.	Remarks on Leakage, etc
1	5	22	.091	085	Moderate leakage.
2	8	40	.049	.048	Easily adjusted; slight leakage

Table I. gives a summary of the results, showing the average horse-power consumed by each packing box at varying pressures and, for purposes of comparison, the power at 50 lb. pressure of steam. The friction of the machine has been deducted.

Table II. shows the effect of tightening the gland nuts on the friction of the packing and also the effect of oiling the rod.

In most of the experiments detailed in Table I. the nuts were tightened with the fingers only, and then just enough to prevent leakage, and no lubricant was used except that incorporated in the packing itself. With some of the dry rubber packings it was necessary to use oil from the first. A good quality of cylinder oil was applied.

The effect of varying the steam pressure is best shown graphically, as in Tables III. and IV. The numbers at the ends of the

TABLE III.
VARYING STEAM PRESSURE
SCALE 1 INCH = 0. 1 H. P.

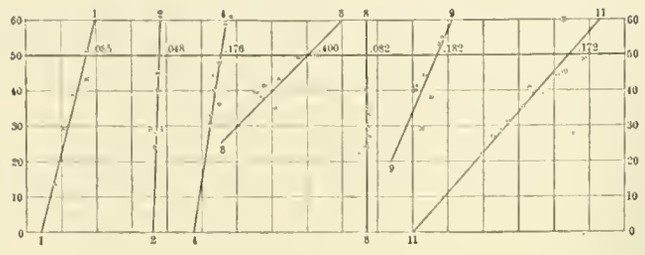

TABLE IV.
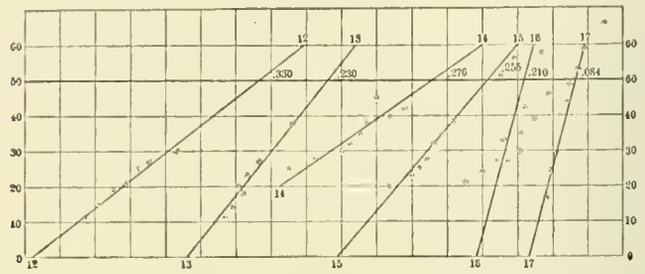
VARYING STEAM PRESSURE
SCALE 1 INCH = 0. 1 H. P.



lines correspond to the numbers used in the other tables. The ordinates indicate the steam pressures observed, while the abscissas represent the horse-power consumed by each box. The points where these lines cut the line of 50 lb. pressure are those used for comparison of the different packings. It will be seen that the friction varies with the pressure in approximately straight line ratios in many of the cases.

GENERAL CONCLUSIONS.

1. That the softer rubber and graphite packings, which are self-adjusting and self-lubricating, as in Nos. 2, 3, 7, 8, and 11, consume less power than the harder varieties. No. 17, the old braided flax style, gave very good results.

2. That oiling the rod will reduce the friction with any packing.

3. That there is almost no limit to the loss caused by the injudicious use of the monkey-wrench.

4. That the power loss varies almost directly with the steam pressure in the harder varieties, while it is approximately constant with the softer kinds.

The diameter of rod used—2 in.—would be appropriate for engines of from 50 to 100 h. p. The piston speed was about 140 ft. per minute in the experiments, and the horse-power varied from .036 to .400 at 50 lb. steam pressure, with a safe average for the softer class of packings of .07 h. p.

At a piston speed of 600 ft. per minute, the same friction would give a loss of from .154 to 1.71 with a working average of .30 h. p., at a mean steam pressure of 50 lb.

It is the intention of the writer to make a series of tests with water packings, and also to try some of the standard forms of metallic packings. He would be glad of any criticisms and suggestions from builders and users of pumps and engines, in regard to any further experiments.

A large consignment of cars went through the New Haven (Conn.) freight yards last month bound west. The trains which came from the Laconia Works in New Hampshire were about 40 cars long, each freight car containing a trolley car.

On November 21st the Western Society of Engineers visited the Lewis Institute, Chicago, at the invitation of the trustees and faculty. The different departments of the Institute were visited in the afternoon and at 6 o'clock an informal dinner was given in the Institute building. The after-dinner speeches were on the subject of technical education in general and a general discussion followed in which many of the guests took part. During the evening the work of the night classes, in which over 900 students are enrolled, was explained.

ELECTRICITY ON CANALS.

Up to within the past year or two, canals have been very much neglected since the introduction of railroads, and no attempts have been made to introduce modern engineering methods upon them.

Some of the most modern canals are to found in Germany, which country has taken a leading part in the development of canal traffic. It is evident that in order to compete with the railways boats of considerable tonnage must be used. The old English canals were at first built for vessels of from 30 to 80 tons only, and later ones were designed for ships of 100 to 150 tons. To still further reduce freight rates by increasing the size of vessels, the Prussian government adopted a canal profile capable of taking ships of from 600 to 800 tons burden. The first of these larger size canals is the one now completed from Dortmund to Emshafen, a description of which is given in the Electrical Review, of London. The latest advances in engineering are to be found in the mechanical devices upon this canal, all of which are expected to have an important influence on the cost of transportation of goods. Electricity plays an important part in the equipment of this canal whose principal cargoes consist of Sweedish iron ores and Westphalian coal.

At the terminal harbor of the canal at Emden, a central station has been erected by Siemens & Halske, which supplies a 500-volt continuous current for power and a 3-wire system, of 220 volts on each side, for lighting. A battery of accumulators serves for subdividing the voltage for lighting. The central station in course of

CANAL TOWING BY ELECTRICITY.

construction will contain three sets of machines each of 100 h. p., two sets of which are already erected. In the harbor there have been erected three traveling cranes driven by electricity, each of which is capable of lifting 2,500 kg. Other cranes are projected, also a floating dock with pumping machinery operated by electricity.

The work at the locks is all done by electricity. Motors with switches are placed in iron casings at each side of the gates. These open and close the sluices for connecting the lock with the upper or lower canal, work the lock gates and pull ships into and out of the lock by means of capstans. The motors may be driven from a switch at the motor, or from a steering house, from which the whole lock can be overlooked, and all the movements of gates, etc., be operated by levers. The power being supplied by a small turbine is very cheap.

The towing locomotive recently introduced by Siemens & Halske it is thought will contribute greatly to the economy of canal traffic. This machine has been thoroughly tested in several places. For medium size and small canals one rail is sufficient, the stability of the machine being secured by slightly loading latteral wheels which run on the ground. A general view of this machine is shown in the accompanying illustration, and an important feature of the invention is the remarkable economy which is claimed for it. It is estimated that for a traffic of 10,000,000 tons per annum, a saving of from 40 to 50 per cent as compared with steamers would be effected, besides which, the great destruction of the canals by the back wash of steamers is entirely avoided.

Considerable attention has recently been drawn to the neglected condition of the Erie canal in New York, and a company has been experimenting for some time on various kinds of traction machines for towing vessels economically. It has recently been given out by members of this company that two machines have been experimented upon by them, one of which is shortly to be put to practical service on the canal. This traction machine is operated by means of storage batteries and is somewhat in the nature of an automobile, as it runs upon the tow path without the use of any track. The other machine is similar to the one manufactured by Siemens & Halske, running upon a single rail and receiving its energy by means of the overhead trolley system.

It is understood that the storage battery traction motors are being manufactured in considerable quantities and will be put in practical operation next season when the canal opens.

ANOTHER FAKE ACCIDENT OPERATOR.

For several months past a man calling himself James Neary, has been endeavoring to secure money from different street railway companies and insurance companies by pretending to have received injuries when alighting from cars. In an eastern paper of June 18th last the following details were given concerning Neary's career since March:

"Fell from trolley car, Paterson, N. J.; injured kneecap; threatened suit for $10,000 damages against New Jersey Electric Railway Co.; settled for $50.

"Two weeks later was knocked off a Main St. trolley car in same city; threatened suit against the Paterson Railway Co., and secured $50 in settlement.

"One week later somersaulted from a trolley car in Newark, N. J., again injuring his kneecap; settled with Union Traction Co. for about $50.

"Two weeks afterward was jolted from a car of the New Jersey Electric Railway Co., at Jersey City, and seriously injured. Made affidavit that he had never been in an accident before or received money for an injury. Company refused to settle and encouraged damage suit, but Neary detected the trap laid for him and failed to appear in court at the trial.

"Three weeks ago (May 23d) changed the scene of operations to New York City; injured hip while alighting from car of the Metropolitan Railway Co.; started suit for $10,000 damages; company doctors found injury to be an old fatty tumor, which Neary doubtless had for 20 years. Secretary John J. Scanlan, of the New Jersey Electric Railway Co., was in court at the trial prepared to reveal the real identity of the injured man, but the latter failed to appear. His lawyers were disappointed.

"Present whereabouts unknown."

In October last doctors representing the Travelers' Insurance Co., of Hartford, and the Fidelity & Casualty Co., of New York, were searching for Neary in Scranton, Pa., he having given them an address in that place. He had made two applications to the New York company, alleging that he had sustained injuries in alighting from a street car, and one to the Hartford company. The insurance people stated that they had information that Neary had successfully played his game no less than 15 times.

GRADE CROSSING ACCIDENT IN CHICAGO.

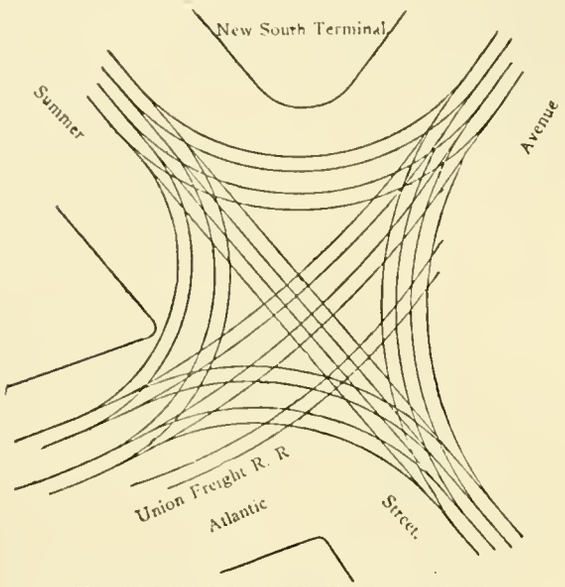
A train on the Wabash R. R. struck an electric car of the Chicago City Ry. as it was crossing the Western Indiana tracks at 31st St., at 5:45 p. m. December 4th. About 25 passengers were on board, 11 of whom were injured, one fatally. The conductor of the electric car, finding the crossing gates open, went ahead, and as the approaching train was two blocks away signalled the car to cross. When on the crossing the trolley left the wire and the car was struck by the approaching train. The crossing flagman claims that he attempted to warn the motorman of the electric car not to attempt the crossing.

It is stated that $100,000,000 will be required to complete the various underground electric systems now building to give London rapid transit.

The Philadelphia Electric Co. has been incorporated at Trenton, N. J., with a capital of $25,000,000. This concern is to absorb the Pennsylvania Manufacturing, Heat, Light & Power Co. and the National Electric Co., of Philadelphia. The incorporators are Edward Hand, jr., of Germantown; J. Morton Fulz, of Frazer, Pa., and Wm. H. Jolley, of Camden.

COMPLICATED SPECIAL WORK IN BOSTON.

The Boston Elevated Railway Co., which has a great many extensive and complicated pieces of special work in its surface tracks, has recently completed its most important installation of curves and crossings. At Dewey Sq., near the new Southern Terminal Station, the Summer St. tracks and the Atlantic Ave. tracks cross, the latter being curved at this point; both tracks are connected by double curves and in addition the crossing is intersected by a single track of the Union Freight R. R., making the layout shown in the illustration. The contract for this work was let to Wm. Wharton, jr., & Co., of Philadelphia, in February last, for, it is stated, about $15,000. Wharton & Co. did not receive the working plans until about September 1st, and considering the crowded condition of



TRACK LAYOUT AT DEWEY SQ., BOSTON.

the works the promptness with which this order was filled is remarkable.

There are 183 points of intersection of the track lines and the crossing when made consisted of 190 rails, frogs and switch pieces, the whole weighing about 170 tons; mangenese frog centers are used. The tracks were all put together at the Wharton works before shipment. Seven freight cars were required to transport this crossing to Boston, where it arrived on November 17th. The work of laying was begun on Saturday evening, November 18th, and practically completed with cars running by the following Tuesday. Men were worked in three gangs, over 200 being on the job.

The Wharton company is also making layouts for the crossings and junctions at Broad and High Sts., and at Atlantic Ave. and Beach St.

TRAMWAYS IN NORTHERN SPAIN.

Julius G. Lacy, United States consul-general at Barcelona, sends the State Department the following data concerning the tramways of northern Spain.

The Compania Anonima de Tranvias de Barcelona, now under the management of J. Kennedy, is the pioneer company of Spain and began operating about 25 years ago with a 99-year concession from the city. In May last this line was changed to electricity, the Dickinson overhead trolley being used. The power house equipment and the electrical car equipment were purchased in the United States. The company has 12 miles of track and 85 motor cars. The fare is 1½ cents for a ride of 5 or 6 miles. The capital stock of the company is $2,400,000, mostly owned in England.

The Compania de Tranvias de Barcelona a San Andres has 5 miles of line. The motive power is soon to be changed from steam to electricity and two extensions, one of 10 miles to the manufacturing town of Sabodell, and one of 5 miles to Horta, built. The manager is Oscar Schmidt-Corr. The present capital is $520,000.

The Compania de Tranvias de Barcelona a Sans has a 3-mile line to the suburb of Sans now operated by mules, but application to change to electricity has been made. The capital of this company is $470,000. Manager, Francisco Esdeve.

The Compania de Tranvias de Barcelona a Badalona is a steam line 6 miles long connecting Barcelona and Badalona. The capital is $320,000. Manager, F. Gillis.

The Compania General de Tranvias has a steam line 4 miles long connecting Barcelona and the suburb of Sarria; electricity is soon to succeed steam.

The Ferrocarril de Barcelona a Sarria, the only double track railroad in Spain, about 3 miles long, has made application for permission to change the motive power to electricity.

The Campania del Tranvia Electrico de San Sebastian has 5 miles of track running through the town of Pasages, the commercial port of San Sebastian, to the manufacturing town of Rentiri. The electric plant is of Swiss make and the cars Spanish. The president is D. Antanasio Osacar and the manager M. L. Carlier.

There is one electric tramway in Bilbao with an aggregate length of 19 miles. Last year 2,700,000 passengers were carried.

At Valencia all the city and suburban tramways have been bought by a French company and a plant for operating by electricity is now being erected.

SAFETY THIRD-RAIL TEST.

A test of a new third-rail system was made in New Britain, Conn., before a party of electrical engineers and railway promoters last month on a stretch of about 300 ft. of track in the yard of the New York, New Haven & Hartford Co. The system is known as the McElroy-Grunow safety third rail and is applicable to roads built for steam service. It comprises a third rail divided into sections which may be of any desired length, the sections slightly overlapping each other side by side, and each section being connected to an automatic magnetic circuit closer of special design. Each of the latter automatically switches the current upon its respective section as the motor car passes upon it and cuts off the current from it as the car leaves the section. During the test the manner in which the current was switched on and off each section was shown by the lighting and extinguishing of incandescent lamps connected to the third rail. A special shoe is used upon the car for collecting the current from the rail and the overlapping of the sections allows the shoe of the motor car to carry current from one section to the next, the contact box responding to the presence or absence of the shoe. The operation of the contact box machinery, which is an electro-magnetic circuit closer, weighing about 16 lb., is through two plates or disks one above the other, the contact of the shoe with the overlapping part of the third rail bringing the lower plate in contact with the upper one by magnetic attraction. Whenever the connecting shoe passes from the section controlled by any particular contact box, contact ceases, the lower plate drops with a click by gravity, the energy has left the section and gone to the next succeeding one, each section being provided with a contact box which thoroughly controls the feed of current from the power house to the rail.

The showing made by this test was in every way favorable to the system, and its inventors claim that it is specially applicable to street railways, as by putting the contact boxes only as far apart as the length of a car no current would ever be upon the surface of the streets except upon the section of rail directly under the car.

LONDON STRIKE ENDED.

The strike of the employes of the London (Ontario) Street Ry., which was inaugurated early last spring, has finally died a natural death. The claims of the men had neither reason nor right to support them, and had it not been for the sympathy extended by the city council for personal political reasons, would have been short lived. Encouraged by this, acts of violence were resorted to, and supported by a local newspaper the fight has been waged for months. Citizens and the city have suffered much pecuniary loss, business has been diverted to other places and the former employes are still looking for jobs.

Modern Mexico says: "The city of Mexico will enter the new year riding in her new electric cars and automobile coaches."

SIGNALS ON THE DOVER TRAMWAYS.

An interesting description of a novel method of signalling between turnouts on the single track railway in Dover, England, is given in the London Electrical Engineer, from which the following is gathered. The details of the system are due to Mr. H. E. Stilgoe, the borough engineer, and the object is to maintain the schedule time of the cars and to avoid the vexatious delays at crossing places.

The streets of Dover at the harbor end of the town are so narrow that there is hardly room for a single line of tramway at some places. The route of the railway is also so circuitous that it was

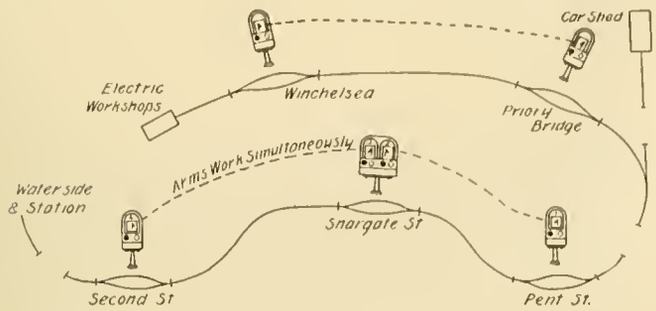


FIG. 1.

impossible to arrange the turnouts within sight of each other. The result of this was that the conductors in certain places were obliged to run on in front of the car to see if the single track was clear, which caused considerable delay to the cars which is quite unnecessary with the present system. The position of the signalling points on the road are shown in Fig. 1, while Fig. 2 illustrates the connections of a pair of instruments controlling one of the single-line sections. It will be seen from the first illustration that there are three of the single-line sections, the turnouts of which are so situated that a car entering cannot see the whole of the line to the next turnout. At these points, therefore, signalling pillars, with switch gear, have been erected on the footpaths. The signals at either side of a single section are so connected that they work simultaneously, and are either both up, indicating that the section is being used by a car, or both down, signifying that the section is

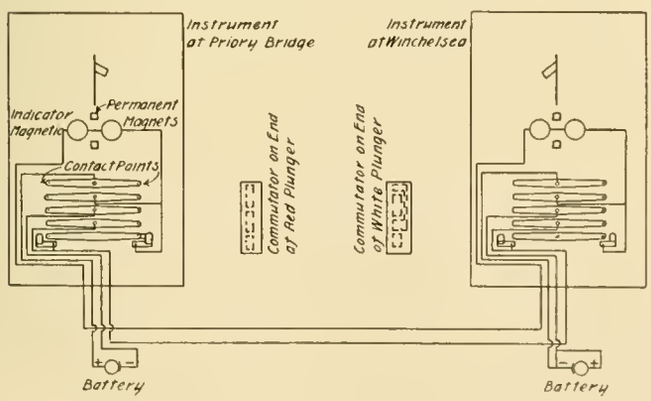

FIG. 2.

clear. The method of working is as follows: On the arrival of a car at the Pent St. section, if the driver finds the signal up he has to wait till a car arrives from Snargate St. As soon as this car has passed, the driver of the first car can proceed, but when he gets to the Snargate St. signal, No 2, he presses the white plunger, which lowers both signals 1 and 2, indicating that the section is free. If the signal No. 3 is down, he can proceed at once after having pushed the black plunger to prevent a car coming on in the opposite direction. Then on passing the fourth signal at Strond St. he will have to press a white button to liberate the signals. It will be seen therefore that in crossing at Snargate St. it is often unnecessary for the drivers to get down to work the signalling apparatus, but that at all the other points he has to unlock the door of the containing case and push a button. This, it would seem, would cause considerable delay, but this is really not the case, as the signals are placed at points where the cars generally have to stop for passengers. In the diagram of connections, Fig. 2, the method of connecting up the apparatus is shown, and it will be seen that no current is used except at the instant the signal is sent. The signal arms are moved by means of a polarized armature between electromagnets. This system has been found to work exceedingly well at Dover, so much so that each car is able to make two more complete trips, or four times the full length of the line, per day more than could be made before these communicators were fixed. Mr. Stilgoe estimates that this is equivalent to an extra profit of at least £1 per week, as the earnings on the two extra trips thus made have not to be debited with any increased labor charge. The other route on which the signals are applied—between Winchelsea and Priory Bridge—is not used so much as the route through the main street, and hence the saving is not quite so much. It is found, however, that the cars can be kept much more closely to their schedule time.

CONESTOGA TRACTION CO.

The Pennsylvania Traction Co., which has been operated under a receiver, was sold under a decree of the United States Circuit Court on November 15th, being purchased by a number of gentlemen from Lancaster, Columbia, Philadelphia and Williamsport. In all probability, after the sale is confirmed by the court, the company will be reorganized under the title of the Conestoga Traction Co., with William B. Given as president, and Samuel R. Shipley, of Philadelphia, president of the Provident Life & Trust Co.; John D. Skiles, president of the Fulton National Bank, Lancaster, Pa.; J. W. B. Bausman, president of the Farmers' National Bank, Lancaster, Pa., will be among the directors. It is contemplated that lines will be built from Lancaster to New Holland, 14 miles; Lancaster to Manheim and Ephrata, and extended to connect with the Reading & Northwestern Ry. at Adamstown, Pa. A line has also been surveyed from Lancaster to Strasburg, eight miles, and the Columbia & Donegal division will be extended from Marietta to Maytown, and in all probability via Elizabethtown to connect with the Harrisburg system.

Frank S. Given, general manager of the road, will continue in the same capacity.

The Pennsylvania Traction Co. operated the following roads: Lancaster City Street Ry., Lancaster & Lititz Ry., Lancaster & New Holland Ry., Lancaster & Millersville Ry., Lancaster & Columbia Ry., Columbia & Ironville Ry., Columbia & Donegal Ry.

TESTING THE SPEED OF STREET CARS.

Several weeks ago the common council of Racine, Wis., passed an ordinance regulating the speed of street cars within the city limits at not to exceed the rate of 8 miles an hour on single tracks and 10 miles an hour on double tracks. It has been claimed that the street railway company has been violating the ordinance. To determine the facts a test was arranged.

Two city officials boarded a car and accompanying the car was a third official mounted on a bicycle provided with a cyclometer, the two officials in the car acting as time keepers.

According to the test made the general speed of cars between stops was never less than 12 miles an hour, and at several places it reached 20 miles an hour, while in one instance it reached as high as 26 miles an hour.

Since these tests were made warrants have been issued against the respective motormen running cars above speed, and the penalty for each and every offense is a fine of from 5 to 25 dollars, or a jail sentence of from 10 to 60 days. Since this test by the chief of police was made there has been a noticeable decrease in the speed of cars throughout the city.

What the Racine authorities should do is to repeal their foolish speed limitations and take their city out of the list of slow going towns.

The Union Elevated Railroad, of Chicago, reported a surplus November 30th of $83,430. This taken in connection with previous reports and the 4 per cent dividend paid indicates a surplus for the 12 months ending Nov. 30, 1899, of $121,355, which is 2.77 per cent on the outstanding stock.

SURFACE CONTACT SYSTEM AT TOURS.

An interesting surface contact system of electric railways has been in operation for several months in Tours, France, which is the first practical application of the Diatto surface contact system with underground conductors. These lines have run uninterruptedly since they were opened for traffic and their operation is reported to have given entire satisfaction. The Tours tramways comprise a number of urban lines having an aggregate length of 12 km., approximately, and suburban lines to Luynes, Saint Avertin and Vouvray. The Diatto system is installed only in the heart of the city, the remainder of the lines being equipped with the overhead trolley system. The power house contains four boilers having a heating surface of 165 sq. m. each, giving 2,000 kg. of steam per hour. There are three simple condensing engines of 300 h. p., belt connected each to a generator of 200 kw. capacity, giving currents of 550 volts pressure. The system of distribution, which is described in La Nature, is comprised of cables buried directly in the ground from which are connected all the branches which operate through the surface contacts.

On the surface of the road, between the rails, are placed surface contact blocks at short intervals apart, each having in its center a metallic piece E, Figs. 1 and 2, which is slightly raised above the surface. In the interior of the block is a pipe connected with the

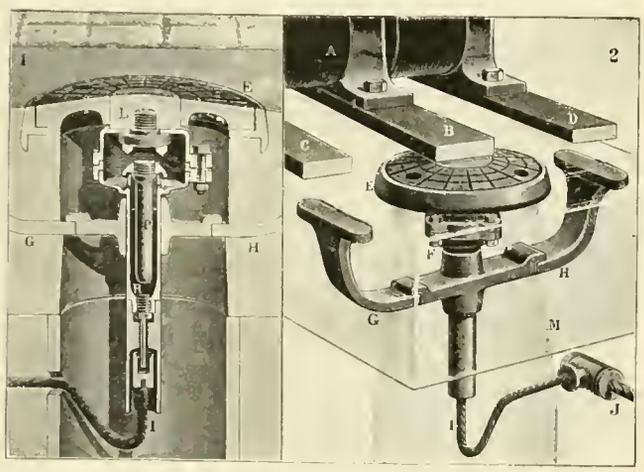

FIG. 1. FIG. 2.

branch I from the cable J coming from the power house. The car carries an electromagnet A which magnetizes the pieces B, C and D. These in gliding over the metallic surface piece attract a movable piece in the interior of the pipe which establishes electrical communication between the bar B on the car and the cable J from the station. The blocks are thus put in electrical connection with the cable only at the moment that the magnet bar of the car is above them, and the circuit is broken as soon as the car has passed. The blocks are placed sufficiently close together so that the magnet bar is always over one of them and the electrical connection between the cable and the car remains continuous. The contact block forming part of the pavement is made of asphalt, as shown in the transparent design, Fig. 2, the middle of it being hollow and the opening to the surface containing a tube. At the upper part is a fixed plug E, of anti-magnetic metal having at its center a cylinder of soft iron L. A little below this is a pair of iron brackets G, H, embedded in the block, which support on their ends an ebonite cup filled with mercury. In the bottom of this cup is screwed a copper plug carrying a small copper rod, which is immersed at its lower end in another small cup of mercury. The latter is connected through the cable I to the cable J from the station. In the mercury which fills the ebonite cup floats an iron plunger P, the weight of which is properly adjusted. The head of the plunger is formed of a truncated cone of homogeneous and very hard graphite and the axis of the iron L also carries a piece of the same kind of carbon which is hollowed out to perfectly fit the cone on the plunger. These two pieces of carbon join accurately and make an excellent electrical contact. The place where this contact is made is enclosed, as shown in the illustration, in a special chamber.

The magnet bars B, C, D, are connected by horizontal electromagnets A which make the central bar B a north pole and the bars C and D south poles. The magnetic circuit is thus established from the bar B through the plunger P and the bracket G to the bar C, and a similar circuit is established on the other side of the bar D. The magnetism draws the plunger P to its upper position. Each electromagnet carries two windings, one of which is traversed by the current which operates the motors and the other by a current from a small storage battery giving 5 amperes at 30 volts. At the moment of starting it is the current from this battery which energises the magnets and raises the plunger. Arcing is avoided when the current is broken at the carbon contacts by reason of the good quality of the carbons, and the rear end of the electromagnet bar is slightly raised in order to avoid a two sudden breaking at the contact. The blocks are set in the paving, so that no water can possibly penetrate beneath them. The return current is carried to the power house by the track rails, and it may be added that defective blocks can be removed and replaced within a few minutes.

OFFICIAL REPORT A. S. R. A.

Secretary Penington with his usual promptness had his official report ready for distribution in exactly one month from the adjournment of the Chicago convention. It makes a neat volume of 220 pages, and contains several new features, one of which is a reproduction of the banquet menu in the same colors as the original. The usual steel engraving of the president is an excellent likeness of Mr. Sergeant. The classification of names of attendants is conveniently arranged and a complete index in the front of the report is specially acceptable. The report is altogether the neatest and best arranged in the history of the Association.

CONTRACTS FOR MANHATTAN ELEVATED, NEW YORK.

November 29th, President Gould, of the Manhattan Elevated, New York City, announced that the Westinghouse Electric & Manufacturing Co. had been awarded the contracts for the power house generating machinery and sub-station apparatus. The contract includes eight three-phase alternating generators of 6,650 h. p. each, together with such step-down and converting devices for the sub-stations as will be necessary to transform the alternating current generated in the power house into a direct current at 500 volts, which direct current will be fed to the third rail of the elevated system.

CONSOLIDATION AT ALBANY, N. Y.

On November 29th the Albany Ry., the Troy City Railway Co. and the Watervliet Turnpike & Railroad Co. arranged for a consolidation as the United Traction Co. with a capital of $4,000,000. The 40,000 shares of stock are apportioned as follows: Albany Ry., 26,760; Troy City Ry., 13,000; Watervliet company, 240.

The amount of the present securities of the united companies is $4,000,000 stock and $3,474,000 bonds. The companies lease and own about 59 miles of street railways. The earnings for the year ending July 1st, last, were $1,250,000.

These officers will serve until the first election in June, 1900: President, Robert C. Pruyn, Albany; vice-president, Charles Cleminshaw, Troy; secretary and treasurer, John W. McNamara, Albany.

The consolidation of these railroads companies, under the controlling influence of the Albany Ry., places under the jurisdiction of what now constitutes that company the direction of the lines of street surface railway operating in and connecting Albany, Troy, Cohoes, Watervliet, Lansingburg, Rensselaer, Green Island and Waterford, and constitutes one of the largest street surface railway systems outside of Greater New York.

Beginning December 1st the following rates of street railway fare were put in effect at Tiffin, O., by order of the city council: Regular fares, 5 cents; strips of 6 tickets, 25 cents; books of 30 tickets, $1.00, good between the hours of six and eight in the morning, and five and seven in the evening.

DOUBLE DECK CARS FOR SOUTH AMERICA.

La Capital Tramway Co., of Buenos Ayres, is putting in service a new type of car recently completed by the J. G. Brill Co. and shown herewith. These cars differ quite materially in details from Brill cars recently built for export to Europe and South Africa, the principal difference being in the protection for the motorman by the gangway leading to the stairs. He is so placed as to be under a hood. Owing to the warm climate it is not found necessary to bulkhead the ends of the upper deck nor to provide stationary sides.

The body is 18 ft. long, 6 ft. 1 in. wide at the sills and 6 ft. 9½ in. at the posts. The platforms are 5 ft. in length, making a length over the dashers of but 28 ft. The car is equipped with two G. E. 1,000 motors and is mounted on a Brill No. 21-E truck with a 6 ft. 6 in. wheel base and 33-in. wheels.

BRILL CAR FOR BUENOS AYRES.

The seats are longitudinal both on the lower and upper decks and are of cherry and maple slats. One feature of the imperial made necessary by the hot climate is a lambrequin around the top, materially increasing the amount of shade, and adding greatly to the comfort of the passengers. The hand rails around the roof and at the stairs are made very high to give ample protection. The car weighs without motors 13,195 lb., and the truck alone weighs 4,590 lb.

These cars were put together complete, painted, taken apart and shipped in sections. The details of this design have been worked out with much care and they are especially adapted to the peculiar conditions of South American street railway service.

ANOTHER NIAGARA ROAD.

The commissioners of Victoria Park, on the Canadian side at Niagara have given the Fort Erie Ferry & Niagara Falls Electric Railway Co. the right to build an electric road between Fort Erie and Chippewa, Ont., over the 66-ft. strip along the upper river, which is controlled by them. When the company builds, it is provided that it shall at the same time construct a carriage-way 40 ft. wide, with ditches on each side not less than 4 ft. deep, which road must be properly graded and kept in repair. The company will also contribute to the revenue of the park by the payment of an annual rental, but how much is not stated. When this road is built it will be possible for Buffalonians to travel up or down on either side of the Niagara. It is expected to have the road in operation next year.

The night of November 25th fully 2,000 ft. of trolley wire was cut from the lines of the Northern Electric Ry., Chicago, and carried away by thieves.

It is thought by the Rapid Transit Commissioners of New York, from the number of blank specifications called for, that there will be considerable competition in the bidding on the underground lines. At least a half a dozen bids are expected.

THE PHILADELPHIA-ATLANTIC CITY STREET RAILWAY.

The plans of the Delaware River & Atlantic Railway Co., which have been previously mentioned in the "Review," have been gradually matured up to the point where the company was ready to start work on the line; but the company is now confronted with local obstacles which again threaten to postpone the completion of the road for an indefinite time. The first legal obstruction had only recently been overcome by changing the right of way when the company was again confronted with a writ restraining it from completing any of its new plans until after the New Jersey Legislature convenes. The opponents of the road believe that they now have the company in a position where it will be impossible to complete the road at all. The company was incorporated under the laws of New Jersey with a capital stock of $9,000,000. The road was to be 52 miles long. Under the New Jersey law the company is required to deposit with the state treasurer $2,000 per mile before a certificate of incorporation can be issued. This has already been done.

The route of the road as planned is a straight line between the termini and will be built with a double track the whole distance and operated on the third-rail system. The trains will consist of standard railroad coaches equipped with all the modern luxuries and are intended to be run every 15 minutes or half hour during the day. The trip is scheduled to be made in one hour including the ferriage across the Delaware River, and the fare is to be 50 cents.

In order to maintain this rapid schedule with safety the block signal system is to be installed along the road. The roadbed is to be 100 ft. wide with double tracks 8 ft. apart, and each side of the right-of-way is to be protected by a fence to keep out cattle, vehicles, etc., and to avoid collisions. The road as planned was to contain neither curves nor grade crossings, every wagon crossing being either depressed or elevated. No stops will be made between the termini, but the company contemplated eventually building a third track to accommodate local traffic, upon which track frequent stops will be made. Plans for the power house, which is to be situated at Winslow Junction, have been completed.

The directors of the company are as follows: Gustav A. Muller, W. M. Boyer, E. E. Pennock, Richard Y. Filbert, Virtue C. Sweatman, C. William Bergner, all of Philadelphia; Louis Kuehnle, H. S. Scull, Atlantic City; Ernest Longstreth, Elias Davis, Camden; Hon. Albert R. Talman, Swedesboro; Rudolph V. Kuser, Trenton; James B. Reilly, Atlantic City.

NEW WATCH AND CLOCK FACE.

The serious consequences sometimes resulting from an error on the part of street railway or steam railroad employes when reading the time from a station clock or their watches have led to the designing of the watch and clock dial shown herewith, and which is intended to do away with a number of the errors most frequently made. The Arabic system of numerals is used instead of the Roman and each minute of the hour is numbered separately; this, it is believed, will prevent the mistakes of reading time five minutes too early or too late, as for instance, taking 1.29 for 1.24, as is often done with the ordinary dial. With the new face the minute hand rests upon the minute figure.

The Railway & Engineering Review, to which we are indebted for the above information, states that the dial is the design of R. D. Montgomery, watch inspector for the Atchinson, Topeka & Santa Fe R. R., and has been adopted as standard on that system.

The Indiana Electric Railway Co. is arranging to carry mail between Goshen and South Bend, Ind., a distance of 26 miles, on its trolley cars beginning January 1st. Elkhart, Mishawaka and other intermediate points will be served.

HOW TO TIE A ROPE.

The Massachusetts Institute of Technology has made a number of tests on different kinds of rope for the purpose of determining the relative strength of various forms of knots for uniting two end. Cotton rope ⅞ in. in diameter and manila rope of three strands 2 in. in circumference were tested, each in a dry condition, the length of the rope between holdings being 4 ft., with the knot in the center. In each case the specimens broke in the twists of the center knot.

From a summary of the tests published in a recent issue of the Railway & Engineering Review, the following figures are taken:

With cotton rope, whose strength was taken at 4,420 lb., four tests on the Englishman's tie gave 2,520 lb. as the maximum load at breaking, and 2,410 lb. as the average strength, an efficiency of 55 per cent for the knot; four tests with a square knot gave 2,470 lb. as maximum, and 2,330 as average, an efficiency of 53 per cent; four tests with a weaver's knot gave 2,460 lb. as maximum and 2,090 lb. as average, an efficiency of 47 per cent; three tests with on open knot gave 2,240 lb. as maximum and 2,110 lb. as average, an efficiency of 48 per cent.

Fig. 1.—Square Knot.

Fig. 2.—Open Hand Knot.

Fig. 3.—Weaver's Knot.

Fig. 4.—Englishman's Tie.

Fig. 5.—Ordinary Tie.

FORMS OF KNOTS TESTED.

With manila rope in seven tests with an Englishman's knot the maximum load at breaking was 3,540 lb., the average strength 2,910 lb., and the efficiency of knot 61 per cent; in five tests with an "ordinary tie" the maximum load was 2,910 lb., the average strength 2,700 lb., with an efficiency for the knot of 57 per cent; in six tests with a square knot, the maximum load was 2,680 lb., the average strength 2,480 lb., and the efficiency of the knot 52 per cent; in five tests with an open hand knot, the maximum load at breaking was 2,370 lb., the average strength 2,180 lb., and the efficiency of the knot 46 per cent.

NEW RAILWAY PLANT FOR READING, PA.

The United Power & Transportation Co., which owns electric railways in a number of cities and of which John A. Rigg, of Reading, is president is about to build a large machine shop and foundry in Reading. It is proposed to introduce the most improved machinery adapted to the company's requirements. All cars or trucks used on any of the company systems will be equipped at these shops and all rebuilding and repairing of electrical street railway machinery will also be done here. This company intends to turn out in this shop everything which is necessary for the repair of the street railway. There will also be established storage battery cars of about 4,000 ampere-hours capacity.

The new machinery shop will give employment to several hundred mechanics and all apprentices will be taught mechanical and electrical engineering in a school maintained by the company in which motormen, conductors and other employes will be instructed in their respective branches. The plant is estimated to cost in the neighborhood of $300,000.

It is announced that parties intimately connected with the Wheeling (W. Va.) Ry. have purchased a controlling interest in the Moundsville, Benwood & Wheeling Ry., a 9-mile suburban line.

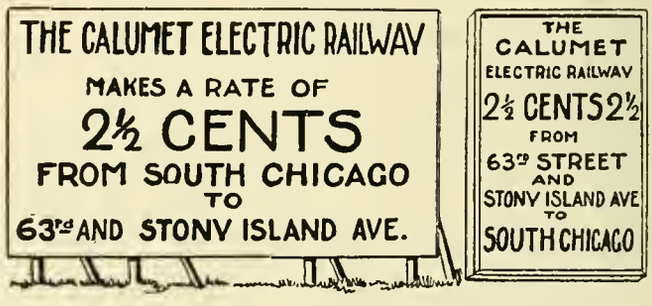
ANALYSIS OF A NICKEL.

President Vreeland, of the Metropolitan Street Railway Co., of New York, in his school of instruction for motormen and conductors recently gave the following analysis of a nickel, which is made in accordance with the company's bookkeeping records. The proportions of a nickel are divided as follows: Labor, .0195 cent; materials, .0048½; taxes, .0026½; interest, .00144; total, .0414; leaving for stockholders, .0086 cent. It will be seen that less than ⅞ of a cent out of every 5-cent carfare goes to the stockholders of the property.

Another point of interest is shown in the fact that out of every dollar spent in operating the system 80 cents goes for wages and only 20 cents for material.

2½-CENT FARES ON THE CALUMET.

Gen. John McNulta, receiver of the Calumet Electric Street Railway Co., on December 1st, ordered that special emergency tickets good for passage between South Chicago to 63d St. be sold at the rate of 2½ cents each. This cut was not intended as the beginning of a rate war, but as a necessary measure for keeping the road's traffic. The Calumet road formerly crossed the Calumet River on a bridge at 95th St., in South Chicago, which collapsed sometime since. Strenuous efforts had been made to get permission from the South Chicago City Ry. to use its tracks and cross at 92d St., and these having failed, General McNulta decided to provide a ferry at 95th St. and cut the rate of fare on this line. The receiver reserves the right to stop the sale of emergency tickets at any time without notice. The low fare was widely advertised by handbills and on bill boards; one of the latter is shown in our illustration.



The Youngstown (O.) & Struthers Electric Ry. was opened for public traffic on November 11th. It is expected that this line will soon be extended to Lowellville and New Castle and will eventually form a part of a through electric railway from Cleveland to Pittsburg.

BUFFET CARS FOR TROLLEY PARTIES.

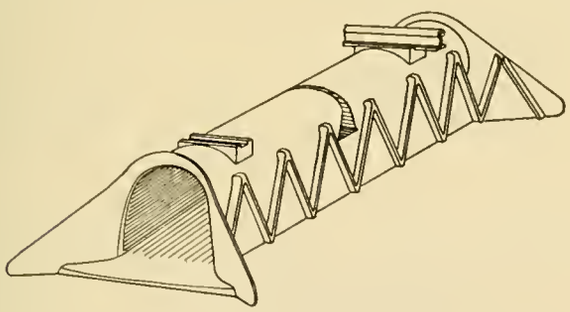
Messrs. J. T. Thompson and George J. Atkins, of Chicago, were recently in Indianapolis in consultation with several local financiers in regard to a new electric road which they are promoting in the northern part of the state. No details of the road have been made public, but in connection with their plans they have mentioned an inovation in the way of an electric car equipment which is calculated to promote a class of trade not now touched by interurban railroads.

They propose to bring into Chicago a large number of passengers from the neighboring cities, and the car mentioned has been devised with the object of making theatre parties from outlying towns into Chicago more popular than they have been in the past. In addition to having large and comfortable cars they will be provided with a dining and cafe service in which out-of-town parties may enjoy a first class supper after the theatre while on their way home, and at no greater expense than would be involved in dining at a restaurant in Chicago. The projectors think it would be greatly to the advantage of the passengers to have a first class restaurant at their disposal without being compelled to stay in Chicago until a late hour before starting home.

It is understood that arrangements were made with the Union Traction Co. for running some of these cars on its lines to Anderson, Muncie and Marion, over which it is expected there will be a considerable theatre traffic.

CULVERT CROSSINGS.

A portable metal culvert built especially to meet conditions arising in electric railway construction work is made by Wm. A. Nichols, of Philadelphia. In cities having surface drainage or wherever it is necessary to lead a small stream or a sewer under the roadbed, this culvert will be found an economical substitute for the ordinary round pipe, brick, wooden or stone crossing. The opening is wider at the bottom than at the top and this with the outwardly diverging wings or approaches effectually prevents leaves,



NICHOLS CULVERT.

driftwood or other obstructions from becoming lodged and causing overflow and washouts. These features will be particularly appreciated in times of floods and freshets.

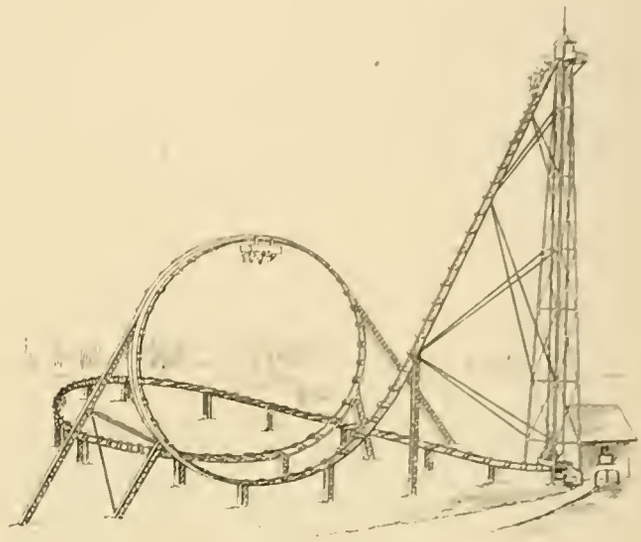
The culverts are made of steel or iron plates, or of cast iron, means being provided at the top, bottom and sides for anchoring or otherwise securing them firmly in position. They are capable of withstanding severe strains in all directions. The model shown herewith has a transverse conduit to permit the passage of a cable or electric conductor and is also provided with supports for holding the rails in position where the railway crosses the culvert at grade. Other types are made to suit various requirements.

RAILWAY TO PAY FOR CHANGING GRADE.

Judge Yerkes, of Bucks County, Pa., has recently rendered a decision to the effect that the Bethlehem-Nazareth electric railway must bear the expense of changing the grade of the highway to conform to the grade of the railway. The county has contracted for rebuilding the highway and the extra cost due to making its grade conform to that of the railway is about $10,000.

CENTRIFUGAL RAILWAY FOR PARKS.

A Toledo man has invented a startling device for pleasure resorts which consists of a monorail track operated by gravity. The car runs upon a single rail with two additional guide rails which prevent it from leaving the track whatever its position. The same can



CENTRIFUGAL RAILWAY.

hardly be said of the passengers who at a part of the trip are seated heads down with only centrifugal force to keep them in their seats. Should for any reason the car fail of its maximum speed the results might be disastrous. The elevator is designed for 80 ft. high; the loop 40 ft.

EXTENSION OF THE UNION TRACTION CO.

The Union Traction Co., which is largely controlled by Mr. Chas. L. Henry, of Anderson, Ind., and his associates, has at present about 100 miles of electric railway in actual operation and also has contracted for the building and buying of 65 miles more. The territory covered by the present lines lies between Anderson, Muncie, Marion, Alexandria, Elwood and other neighboring cities. The company is to build at Anderson what it is stated will be the largest and most complete power house in the world outside of that at Niagara Falls.

The company has devised a new plan for handling the express business, and at the same time adding to its passenger receipts. The arrangements which are being made with the leading stores in Indianapolis are to deliver purchases made by out-of-town people to any town upon the entire system. The plan is to make the rate for delivery just sufficient to cover the cost of handling the business, with the expectation that in this way a large number of passengers will be carried to Indianapolis. The company will erect offices and waiting rooms in each town along its lines, the one in Indianapolis to be fitted up very elaborately.

SODUS BAY R. R.

The Sodus Bay R. R., a new electric line now building between Rochester, N. Y., and Sodus Bay, will be 38 miles long. On portions of the line there are numerous curves and grades. The main power house will be on the east side of the bay and there will be two sub-stations; the line voltage will probably be 625 volts. The road is single track with turnouts; two figure 8 trolley wires will extend the entire distance.

The Decatur (Ill.) Traction & Electric Co. has purchased the property rights and franchises of the City Electric Ry. of that city and proposes to rebuild the line in the spring and add one-half mile of new track. Contracts have been closed for cars, motors, trucks, etc., and in the spring the company will probably build a new power station.

ELMER MORRIS ENTERTAINS.

Elmer Morris, treasurer of the Morris Electrical Co., gave a dinner to members of the press and friends, at the Bingham House, Philadelphia, November 14th, to celebrate the unusual event of a 50-car train of terra cotta ducts for electrical conduit work. The ducts were manufactured by the Potomac Terra Cotta Co., Washington, D. C., and were sent to Philadelphia via B. & O. Ry. to be included in the ship load of materials which the Morris company is purchasing for the railway construction work in Havana. The shipment is probably the largest single shipment of one commodity for electrical purposes ever exported from this country.

Mr. Morris presided in his usual graceful manner at the dinner which was an elaborate repast, there being present the following: W. H. Antrome, Philadelphia Record; A. B. Umstead, Earn S. S. Co., Philadelphia; W. E. Harrington, Camden; manager City & Suburban Ry.; D. A. Hegarty, Railways Company General, Philadelphia; Geo. F. Porter, Kerite Co., New York; Geo. E. Pratt, Hubbard Brake Co., Chester, Pa.; C. C. H. Bent, superintendent B. & O. Ry.; U. B. Macafee, Railway Company General, Philadelphia; S. H. Harrington, New York; George Mason, Potomac Terra Cotta Co., Washington; Edward S. King, Philadelphia; C. B. Fairchild, eastern representative "Street Railway Review"; W. K. Beard, Street Railway Journal; T. B. Franklin, and J. L. B. Haehulen, B. & O., Philadelphia; S. Goddard, Electrical Review; and Franklin Stevens, Keystone Electric Co., Philadelphia.

After a hearty welcome by the host, toasts were responded to by several of the guests. Mr. Macafee speaking on "The Future of the Electric Railway Industry"; Mr. Bent, of the B. & O., on "The Future of Electric Traction in the Field of Steam Railway Practice"; Stephen Goddard for the "Technical Press"; C. B. Fairchild, of the "Street Railway Review" on "The Present as Compared with Early Street Railway Work"; and Geo. F. Porter on "Electric Conductors." Speeches were also made by Mr. Mason of the Potomac Terra Cotta Co., and Mr. Hegarty.

The occasion was a highly enjoyable one, the menu carefully selected and nicely served, and all present hope that Mr. Morris will have 50-car trains of material at frequent intervals.

MAGNETIC BLOW-OUT CASE.

Judge Thomas in the United States Circuit Court, Eastern District of New York, has decided in favor of the defendants in the case of Thomson-Houston Electric Co., vs. Nassau Electric R. R. Co., for alleged infringement of patent No. 283,167, issued to Elihu Thomson in 1883 for a magnetic blow-out device. The suit was in reality defended by the Lorain Steel Co., of Lorain, O.

Judge Thomas said in part:

"It is certain that the influence of a magnet upon an arc was well known long before the complainant's patent.

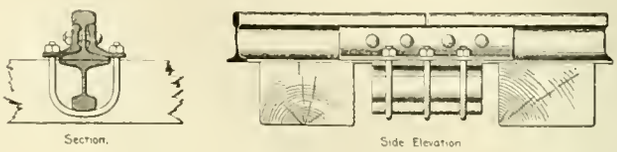
"Long afterwards (after the issue of Thomson's patent) the operation of trolley cars required the quick extinguishment of electric arcs, on a scale not before contemplated. Thereafter Prof. Thomson devised a structure, which involved the use of a magnet to extinguish electric arcs. He had formerly embodied this old art in a patent, and in consequence at the later period sought to monopolize it, without any legal justification, as it appears to the court. Since the letters in truth reveals no use, function, mode of operation, or manner of application new in the art, the complaint should be dismissed."

NEW COUNCIL BLUFFS COMPANY.

The controversy between the Omaha, Council Bluffs & Suburban Railway Co. and the Omaha & Council Bluffs Railway & Bridge Co. as to their rights to lay tracks over certain tracts of land has been amicably settled, both companies getting locations satisfactory to all parties. A number of suits have been brought to have the franchise of the Suburban company forfeited.. On November 28th articles of incorporation of a new company, the Lake Manawa & Manhattan Beach Railroad Co., were filed with the recorder; the directors of this company are the men controlling the Omaha & Council Bluffs Railway & Bridge Co., and they propose to build a summer resort at Lake Manawa.

TORREY RAIL JOINT.

The accompanying illustration, for which we are indebted to the Engineering News, shows the rail joint designed by Mr. A. Torrey, chief engineer of the Michigan Central, and which is being laid on a portion of the Canada Southern Division. It has four-bolt angle bars and a piece of inverted rail under the joint; this piece is 10



TORREY RAIL JOINT.

or 11 in. long and slightly cambered so that there is at the ends about 1-16 in. clearance between it and the base of the rails. The angle plates do not touch the ties; they project beyond the bottom flanges of the rails and have holes to receive the U bolts for clamping the inverted rail section in position.

DUTIES AND RIGHTS.

In the course of what is a short sermon on obedience by Mr. Alsop Leffingwell, of Trinity Parish House, Toledo, published in pamphlet form under the title "Another Message to Garcia," this quotation occurs: "The trouble with the working classes is they aren't half so anxious to do their duty as to claim their rights." The author then discusses the Cleveland strike as follows:

"As a matter of personal curiosity, I would like to know how many men in the late Cleveland car strike, for instance, fulfilled the injunction: First do your duty, then claim your rights. How many had really done their duty, their whole duty, and nothing but their duty, and were now claiming their rights?

"Not knowing, myself, I ask the question merely for information, and to get a concrete illustration of the principle. How many men had a right to smash up the street cars, tear up the rails, and block the way? How many were right in injuring the new employes, and even the officers of the road?

"Supposing you had asked:

"'What is your purpose in thus destroying and wounding?' Why, every mother's son of them would have promptly replied:

"'To compel the company to acknowledge our rights, of course!'

"Very good, perhaps the company, with just as much justice, might have retorted:

"'Yes, but haven't we some rights, too? And isn't one of them to operate cars on our lines whenever we please? And if you don't stop interfering, haven't we a right to compel you to acknowledge our rights by smashing you, just as you smash us and our company?'

"Permit me to repeat that I don't profess to know anything about it. All I do know is, there are always two, and often a half dozen sides to every question, and what I am after is the principle —first, do your duty; then, claim your rights."

TERRE HAUTE-BRAZIL LINE.

The Terra Haute (Ind.) Electric Co. has completed the surveys and begun grading on the 15-mile electric line between Terra Haute and Brazil. The route is along the National Road (Washington to St. Louis) but the track will be laid at one side of the right of way where the ordinary road traffic will not interfere with it. The company will lay 60-lb., 60-ft. T-rails.

The Terre Haute Electric Co. will build a new car house and power station in the spring and abandon the present plant. The installation contemplated will include four 300-kw. direct connected units, one for the railway and three for the lighting.

The Massachusetts Street Railway Association held its monthly meeting on November 8th, at which the subject of discussion was "The Best Design for Electric Cars." Ex-Mayor Sears, of Quincy, and C. E. Foster, of the Lynn & Boston R. R., were guests of the Association and spoke upon "The Relations of the Public to the Corporations."

A SUCCESSFUL PASSENGER AND FREIGHT INTERURBAN.

The constantly growing interest in the transportation of miscellaneous freight on electric lines makes a study of the Chicago, Harvard & Geneva Lake Railway Co. a timely and instructive one. This road, which was completed during the past summer, extends from Harvard, Ill., to the shores of Lake Geneva, in Wisconsin, passing through the towns of Big Foot, Ill., Walworth and Fontana, Wis. It not only makes a short cut to this popular resort, saving from 30 to 90 miles travel each way for some 200,000 people residing in the large manufacturing towns to the west and northwest, but is the only means of rail transportation for the territory through which it passes, the nearest steam line being some eight miles distant, or quite inaccessible on account of high and very steep hills.

Lake Geneva is conceded to be one of the most beautiful bodies of water in the whole country, being entirely spring fed, and the water, which is very clear, reaching a depth of 300 ft. in places. Along its 37 miles of wooded shores extends a fine gravel beach, and here the wealthy residents of Chicago have expended over $10,000,000 in elegant mansions and park improvements. During the summer season the lake is thronged by thousands to enjoy the clear bracing air for which this region is famous; and its blue waters are covered with sailing craft of every kind, and some 40 superb steam yachts. The Yerkes Observatory is also here and an object of interest to hundreds of visitors from our own country and abroad.

The country traversed by the electric line is densely settled for a farming community, and is one of the largest dairy districts in the country. Every foot of land is under cultivation or in use for herds, and farms sell for $100 an acre. From this territory thousands of pounds of butter and cheese are shipped daily, and thousands more of milk sent into Chicago. The country is like one great garden, and to travel over it in summer presents a picture of rare beauty.

The road has conditions in some respects unlike any yet constructed. Most interurbans either connect two large towns or cities, or terminate in one of considerable size. In this case the largest town on the line has but 3,500 population and the combined population of the others and the local residents within walking distance of the line does not exceed 6,000 more. As the road is operated throughout the year, the freight problem as a feature of the winter business is an important one.

The line, which is 12 miles in length, occupies one side of the public highway except for about one mile of private right of way. It is built under highly favorable franchise conditions, and its grants run for the full term of 50 years in both states; the portion in Illinois having been constructed under the Allen law, now repealed. It is incorporated under the general railroad acts of both states, and its franchises particularly authorize it to carry not only passengers, mail and express, but all kinds of freight. This latter feature is rapidly becoming an important one, not only to the road, but to the community it serves. Piece freight includes dressed veal, eggs, spring water, milk, vegetables, and other farm products going out. An elevator has been erected and is shipping out grain from Fontana. Track connection with an important steam line enables it to receive heavy freight, such as lumber, coal, etc., in the original cars and these are hauled to destination. Our illustration shows a car which contained 42 tons of coal, and was the largest ever brought into the county. It was taken out 12 miles to a coal yard recently established at the terminus of the line. Several of these coal yards have been opened by local parties, and as many lumber yards, one alone of which will pay the road $1,500 in freight the present year. The company has erected ample stock yards and is daily shipping all kinds of live stock, of which there will be some 300 carloads this winter. In general local such a line works as a feeder to a steam road, and as a creator of business may be mentioned a recent shipment of a car load of baled hay, which was sent into Chicago, but which it would not have paid the farmers to have

FREIGHT TRAIN ON THE C., H. & G. L.

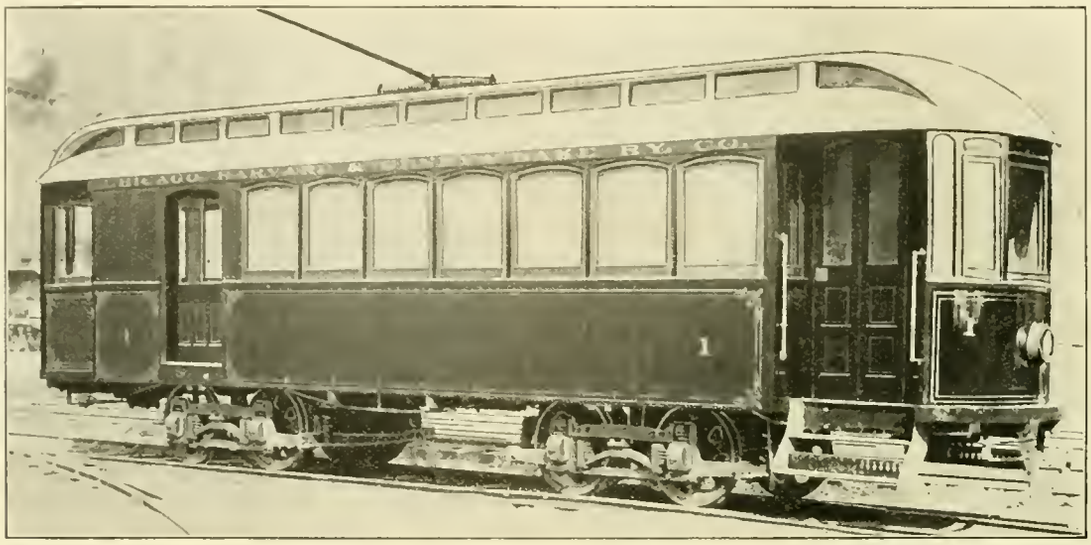
hauled 10 miles into town to the nearest market, even had there been a demand there for any such amount. The same with milk: a farmer cannot afford the time and expense of hauling his milk 8 and 10 miles to a railroad shipping point, so has been delivering it to local factories; but since the electric line opened nearly every farmer along the line has erected a platform in front of his house, and here are set out the cans of milk which the milk car picks up and delivers to the steam road at 7 a. m. each day. At 10 o'clock, just four hours from the time it left the farm it is in Chicago and being delivered to consumers. As the city price is considerably in excess of that paid by the local country factories, the benefit to the producers amounts to a very considerable sum in the course of the year. Other farm products have been raised and shipped which never before were possible on account of lack of rail transportation, and the variety and volume of this business will increase largely each season. Another advantage is the improved mail service: two mails each way daily to Chicago against one, one way, when the service was furnished by teams. The daily papers were quick to take advantage, and a hundred copies of Chicago papers are now distributed at 7 a. m. each day where previously they arrived 24 hours old and consequently few were taken. Thus it will be seen the

POWER HOUSE—CHICAGO, HARVARD & GENEVA LAKE RY.

freight business, which has only been mentioned in a few of its most important branches, is destined to constitute a large part of the winter earnings, and there is no reason to doubt that within a few months the revenue from the milk freight alone will pay the entire bond interest of the road.

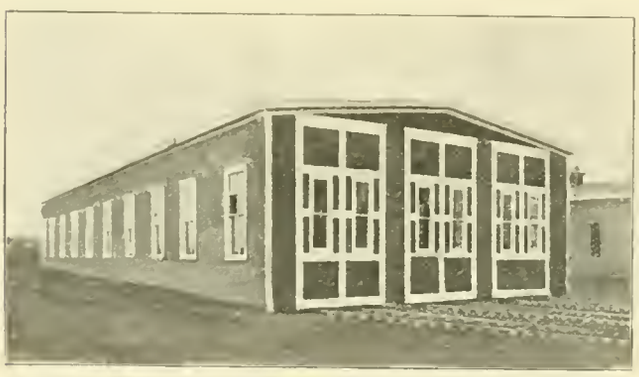
As to its physical construction, little is left to be desired. The Lorain Steel Co. furnished the rails, which are 60-lb. T in 62-ft. lengths, laid on ties spaced 20 in. c. to c. The rails are bonded with Atkinson bonds. Quite fortunately there were no other roads or streams to cross. The switches were made by the Paige Iron Works, and are automatic. The overhead work is extra strong; the trolley wire furnished by the Western Electric Co. is 00 and the feeders 0000. The brackets were from the Ohio Brass Co., side pole construction being used except through towns where the track is laid in the middle of the street. Trains are operated on a telephone dispatching system from the main office which is at the power station in Walworth.

The car seats 36 passengers and leaves ample room for trunks, light freight and express. These cars are equipped with two G. E. 57 motors and have a rated speed of 40 miles an hour, although this has been considerably exceeded on occasion. Two 40-ft. passenger cars with G. E. 1,000 motors on McGuire trucks, and one double truck parlor car and two 24-ft. single truck motor cars complete the passenger motor equipment. The freight locomotive is on McGuire trucks and hauls 100 tons at a load. All the motor cars are equipped with Christensen air brakes and whistles. There are also six open trailers for excursion business in summer. Although it was impossible to complete the line in time for much excursion business the past summer, several were handled, one of 1,000 passengers. The Meaker portable fare register is used.



COMBINATION CAR FOR REGULAR SERVICE.

The power house is a substantial brick structure 50 x 100 ft. with a fire wall separating the boiler and engine rooms. A battery of two boilers made by the Murray Iron Works supply two engines; one a 200-h. p. high speed Ball and the other a 300-h. p. Providence Greene Corlis. The generators are 200 and 220-k. w. Westinghouse, belt connected. At the swichboard 600 h. p. is easily indicated. The car house is a frame building adjoining, 50 x 125 ft., with three tracks. It is connected with the station by a system of



CAR HOUSE.

both water and steam pipes for fire protection. The repair shop is also frame and is 40 x 50 ft. in dimensions.

In the power house and along the line are some 20 Garton lightning arresters.

The equipment includes both summer and winter cars. There are two combination baggage and passenger cars 40 ft. long on Brill trucks and Griffin wheels, built by the Jackson & Sharp Co.

At the lake terminal four acres on the shore have been secured and large docks built from which all the public steamers on the lake sail. Restaurant and depot buildings have been erected here with facilities for taking care of large crowds.

While the travel and freight are at all times sufficient to pay operating expenses and interest, the summer travel to the lake coming from Chicago and the surrounding cities and country will tax the road to its utmost. Owing to delay in completing the line on account of difficulty in getting construction material shipped, only a small part of the business offered could be handled last summer, and that after two of the best months were past. Notwithstanding this, the road with two passenger cars as its entire available rolling

DELIVERING COAL—42 TONS.

stock, in six weeks not only paid operating expenses for that period, but cleared 10 months bond interest, and this with the further handicap of construction work still in progress. The earnings for the lake period next summer is conservatively placed at $20,000. While the road has cost nearly $150,000 to build, it has been bonded for only $100,000. These bonds run 20 years, and are first mortgage gold bonds drawing 5 per cent. With interest charges of only

$5,000, and operating expenses of $10,000 per year, the expectation of the projectors that the line will clear 10 per cent on its capital stock of $150,000 has every prospect of being realized.

Quite a considerable business arises from children and young people going into town to attend the public and high schools and business college. For these a school ticket has been placed on sale so arranged that at time of sale as many rides are punched out as equal the holidays, etc., in the month for which it is sold. This saves printing a different ticket for each month. A similar arrangement is made to carry whole families from their farms to the several churches along the line and is found to work very nicely and secures a large amount of riding which otherwise would be lost. The local cash fare over the line is 30 cents each way; round trip, 50 cents; 10-ride commutation tickets 40 cents for the round trip.

The construction has been a wonderful stimulus to everything along its line. Farm properties have advanced in value; the people now attend the theater and other gatherings, and social visits of both individuals and societies along the line are rapidly increasing. At Walworth where the power station is located, over 30 new dwellings have been built during the past 90 days and the demand is still larger than the supply.

The company also has valuable lighting and power grants, and it will put in a lighting plant to supply some 2,000 incandescent lamps at the lake for the coming summer.

The construction work was in charge of H. T. Windsor, who is now managing the road. The president is W. F. Furbeck, of Chicago, for many years vice-president of the Yerkes lines in this city; and the treasurer, A. L. Dewar, of Chicago.

BRITISH JOTTINGS.

(From Our Own Special Correspondent.)

The notices published last month of intended applications to Parliament for powers to build light railways or tramways (all such notices are required to be published during the month of November) number about 70. Most of the applicants are municipalities and in all cases electricity is the motive power specified. Extensions in Manchester, Liverpool and several Yorkshire towns are the largest schemes. Manchester is buying the local tramways and these with the proposed lines will require 600 cars. Fully as many cars will be required by the adjoining towns which will work their own lines. Current will be distributed to sub-stations on the three-phase system at 6,500 volts, similar to the plan adopted at Glasgow where also 600 electric cars will be provided.

The London County Council is seeking light railway orders for a number of new lines, but it is thought that they will not be granted because of the opposition of parish authorities and railway companies.

The underground schemes now before Parliament are confined to short extensions to authorized lines, applications for an extension of time for completion, and for the electrical equipment of the Metropolitan and District underground steam roads.

One of the applications is for a Behr monorail road from Manchester to Liverpool. (For a description of this system see St. Ry. Rev., July, 1898, p. 429.)

It is proposed to equip a number of short steam roads for electrical working.

The few private companies seeking powers wish to build interurban electric lines, the most notable being for roads in South Lancashire and the valley of the Clyde, below Glasgow.

A uniform 2-cent fare has been inaugurated on the cable tramway in Birmingham (three miles long) with the result that the traffic has increased enormously, requiring cars to be run on a headway of 1½ minute. The gross receipts have also increased. The tramway company would gladly equip all its lines with electricity were it not that the city insists on taking over the road when the lease expires a few years hence.

The tramway committee of the Glasgow council has recommended that the Westinghouse company be awarded the switchboard contract for the main power station for £33,593.

ACCOUNTANTS' REPORTS.

Secretary Brockway has mailed to all the members of the Street Railway Accountants' Association a printed copy of the proceedings of the third annual convention, held at Chicago, Oct. 17-20, 1899. The report, which has been put through the press without delay, is typographically all that could be desired and contains a list of the Association's officers, all the papers and reports presented at the meeting, together with a complete verbatim report of all the discussions and remarks, a list of those in attendance, the constitution and by-laws, etc. Mr. Brockway is to be congratulated upon the promptness with which he prepared his report.

There has been such a demand for the proceedings of the organization meeting of this Association held in Cleveland, March, 1897, that the Association has decided the reprint the proceedings of this meeting in a style uniform with the other reports.

PENNSYLVANIA REPORT.

The annual report of the Pennsylvania Bureau of Railroads, of which Maj. Isaac B. Brown is superintendent, shows that there were 380 street railway corporations in Pennsylvania at the close of the fiscal year ending June 30th last. The total capital stock outstanding of operating street railway corporations is $103,122,319; bonded indebtedness outstanding, $31,139,149; current liabilities, $13,139,149. There was a reduction of the bonded indebtedness of operating street railway companies during the year of $1,131,425. The reduction in current liabilities was $1,090,342. From the total income received by operating companies amounting to $31,646,808, there was paid out during the year in the way of disbursements for operating expenses $10,519,810, or substantially 50 per cent of the income. There was paid in dividends during the year, $9,133,647. The total mileage of street railways operating in Pennsylvania is 1,493.21. The total compensation for the year to employes was $6,596,904.

MONEY COST OF OVER CROWDED STREETS.

In his address before the Society of Arts, London, last month, Sir John Wolfe Barry attempted to roughly estimate the annual money loss suffered by the people of London because of the delays in congested thoroughfares. Countings were made in October and he found that in one hour 992 vehicles passed Cheapside, 1,228 the Strand, 1,497 Piccadilly, and 661 Tottenham Court Road, the number of pedestrians varying from 3,910 at Piccadilly to 6,358 at Cheapside. Similarly, he found by another enumeration that the number of omnibuses varied from 384 an hour at Cheapside to 487 at the junction of Oxford St. and Tottenham Court Road.

On three of these streets the overcrowding was for about 9 hours per day and on Piccadilly about 11 hours; the retardation in different parts of these streets varied from 10 to 44.8 per cent. Taking 20 per cent as the average, and the retardation of pedestrians (25,514 individuals per hour on all four streets) at one-third as much, with conservative estimates as to the value of the time, the annual loss due to the crowded condition of these four streets is as follows: Trade interests, £900,000; vehicular traffic, £1,180,000; pedestrian traffic, £65,000; total £2,154,000.

John Feeny, a former motorman on a Brooklyn road, whose mind had become unbalanced by reason of brooding over his misfortunes, the loss of a leg in a trolley accident and inability to get work, on November 29th opened fire with a revolver and very slightly wounded a fellow passenger on the car on which he was riding. He then attempted to shoot himself but failed.

MECHANICAL DEPARTMENT

MAINTENANCE AND REPAIR OF ROLLING STOCK.

BY J. W. GREER, GENERAL MANAGER YOAKUM TEX. IMPROVEMENT CO.

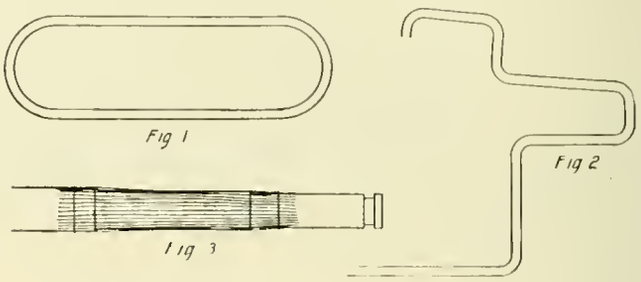
PART V.

In order that no one may be misled by the statement made in a previous paper that five men and two apprentices are all the men needed in the shops of a 100-car road it would perhaps be as well to explain that in the operating department of street railways it is usually the custom to designate a road by the regular number of cars constantly in operation; thus while a road operating 20 cars continually would be known as a "20-car road," the equipment of such a road would probably be 22 closed cars, 22 open cars, and at least 6 trail cars, making (from the shop man's point of view) a 50-car road. Those not familiar with the details of shop practice will, therefore, please bear in mind that the statement made refers not to a road operating daily, continuously, 100 cars, but to the total equipment of a road owning 100 cars, the work on which must be done in the shops at some time during the year. The equipment of the road which the writer had in mind (and which has been operated for the past seven years with the labor roll enumerated) consisted of 40 closed motor cars, 40 open motor cars, and 20 open trail cars; as 10 cars were kept constantly in the shops (five cars out of season being given a thorough overhauling, and five seasonable cars held in reserve for minor repairs) it will be seen that 35 cars were or could be operated continually. When motors were very high priced, it was customary with some roads to have a double equipment of car bodies only, shifting the trucks and motors as the seasons required; this is a practice not to be recommended, as with the full equipment under all the cars there will be sufficient increase in the gross receipts, by being able to run an increased number of cars on special occasions to more than offset the interest on the investment. Of course if there are roads which still practice the semi-annual change of trucks and motors from open to closed cars and vice versa, the work can be greatly simplified and expedited by the use of the simple and efficient air hoist previously described.

Three ground, and one overhead hoist, the cylinders of which are constructed as detailed in a previous paper, have been in successful daily operation for more than two years in the shops of the S. A. & A. P. Ry. Co. (a 700-mile subdivision of the Southern Pacific) in this city. The writer has seen car bodies lifted from the trucks with a level made of 4 x 6 in. scantling 20 ft. long; he has also observed the operation as performed with four screw jacks, and has occasionally witnessed the performance of a chain hoist, the modus operandi of which involved the use of two or four pair of differential pulley blocks.

The writer (who is a street car builder by trade) after years of daily experience with compressed air, pefers it for all purposes of the nature previously described and for the reason heretofore given.

In discussing the practical work relating to this subject, let us begin at the wheels and axles, and go up. *We all know that wheels will flatten and flanges break; one wheel will have a hollow face, while its mate gets too much bevel; one flange will wear thin, while that on its mate is abnormally thick; one wheel will get loose on the axle, while the mate remains tight. The axle will break at one end, next the hub or at the key seat, whichever happens to be the weakest point, etc., through all the ills to which wheels and axles are subject. It is an axiom among medical men that if you remove the cause the disease will disappear. The same thing applies largely in mechanics. The cause of your troubles with wheels and axles and a great many other troubles with your rolling stock, is the fact that one side of your track is longer than the other, and that you never turn your cars around to equalize the strain caused thereby. In street railway practice the wheels are made of exact size, and pressed rigidly on the axle; with these rigid wheels and axles as a base the whole structure is built, and it follows that undue or unnecessary strains or torsion put upon the base must affect the whole structure. Since we cannot prevent one side of a street railway track from being longer than the other, and since it is equally impossible to make two wheels of the same size on a rigid axle travel different distances simultaneously without slipping and torsional strain, let us at least double the life of the parts affected by turning the cars, and causing both sides of all the parts to bear their proportionate share of the insurmountable strain. But you say I operate a belt line and my cars are turned every trip! Glance at



the belt line shown in the sketch, Fig. 1, and see how much further your outside wheels will have to travel than your inside ones. Buy a turntable or put in a Y (the latter is preferred), and if you operate only in one direction over your belt, turn your cars each trip. It is much better, however, if possible, to run your cars both ways around a belt, and turn them only every other trip. This gives you the strains in reverse each trip on the same side of the car and tends more nearly to neutralize the bad effects than when the wheels go only in one direction over the track though different sides are turned each trip. If you are operating a single track line do not overdo the thing by putting a loop or Y at each end of the track, and turning the car each half trip, for while you get the sides of the car changed relative to the track you keep the wheels turning in one direction all the time. Turn the cars only at one end of the line, thus allowing them to go back and forth over the same inequalities and irregularities. Even if you have a track which is perfectly straight, it is better to turn the cars at one end of the line each trip to counteract "hammer" due to constantly striking the same joints and irregularities, and the result of which is eventually to crystallize the axles and flatten the wheels.

Some years since the writer kept a careful record extending over a period of three years and embracing the cars operated on two divisions of the system, of the relative life of wheels and axles on a line where the cars were turned once each round trip, and on a line where they were never turned. The track conditions and loads were slightly in favor of the line where the cars were never turned, but the result showed the axle breakages to be five to one, and the cast-off wheels to be three to one in favor of the line where the cars were turned. The axles would of course break on the T. H. cars at the key seat, and on the Sprague cars at the wheel seat next the inside end of the hub, these being their respective weakest points. Instead, however, of tinkering with a new style key, or enlarging the wheel seat, we sought the origin of the trouble and eradicated it as far as possible. As long as street railways continue to operate there will be some broken axles and some flat wheels; we can only hope to minimize the number. When the cars are properly operated and the track conditions of the best, still the hammer blows due to passing over the joints will eventually crystal-

lize the axle, and it will break at the weakest point, unless the average length of life has been ascertained as it should be on each division separately and the axles be removed before the danger point is reached. A coil spring placed between the frame of the truck and the top of the oil box directly over the bearing, tends greatly to lessen the severity of the hammer, and lengthens the time necessary to produce crystallization. The life of wheels which have soft spots in them, is greatly lengthened also by this, as the flattening of such wheels is largely due to hammer.

A prolific source of flat wheels is "skidding" them by the too sudden application of the brakes, or by reversing the motor when the car is at speed and heavily loaded, the wheels of course cease to revolve under such conditions, but the momentum of the car carries it forward, greatly to the annoyance of the passengers and the detriment of wheels and rails. It is almost impossible to get two wheels with the chill of the same depth on each, and the metal the same degree of hardness, consequently under the best conditions the face of one wheel will wear off faster than that of its mate. Wheels should therefore be trammed for size every time the truck is removed from the car for cleaning the motors, and if a material difference (¼ in. or more) in the circumference of a pair on the same axle is observed, they should be re-mated to prevent torsional stress on the axle, and the eventual flattening of the large wheel.

The writer is not an advocate of grinding wheels to make them mate, but rather inclines to keeping a good assortment of extra wheels, partially worn on hand, and pressing off one or the other of the two wheels which no longer mate, and substituting another. It is a saving of labor and often results in getting together a pair of wheels so nearly the same in quality as to never again give trouble until both are completely worn out. Whereas, if two wheels that have worn unequally are ground to again mate, the trouble will surely recur.

The wheel makers have brought the state of their art to a degree of perfection not hoped for a few years since, and by their combinations of different grades of iron, are enabled to turn out a product which they guarantee for a life of 60,000 miles. Careful experiment and close record have convinced the writer that proper attention to the details as given in this paper will enable one to get as high as 150,000 miles out of these same wheels. Don't abuse your wheel and axle maker till you have given his product a chance by trying to operate your cars properly.

In tramming wheels for size, it is better to use a "traveler" such as is used by blacksmiths, than to use a steel tape or string measure, as is usually done. Make a chalk mark on the tread of the wheel, another on the side of the traveler, and put the two marks even, roll the wheels along the track, if on the axle, or run the traveler around them if off the axle, make a mark on the traveler when it returns to the mark on the tread; try the other wheel, and the difference between the stopping marks on the traveler is the difference in circumference of the wheels.

The cause of much flange breaking is lack of knowledge on the part of the track foreman in setting switches, or on the part of the engineer who designs them. The throat of the switch and its mate will be designed to give just enough room for the flange to pass through and the track which is usually spiked to a gage ¼ in. greater than the width between wheel flanges (which is proper), is brought to exact gage at the switch.

The engineer has designed the throat of the switch a close fit for the flange, in order to prevent vehicle wheels from catching in it. The track man very properly spikes the switches to exact gage in order to get the wheels to pass through, but there is an element neither of them sees, or knows about; it is almost impossible to bore a perfectly straight hole through wheels of different degrees of hardness and keep the hole at right angles with the face of the wheel all round. A variation of 1-32 in. from a right angle will throw a 36-in. wheel 5-16 in. out of plumb, and in a pair of wheels might make the difference in the wheel gage ⅝ in.

Wheels in this condition passing through switches set as above described, will either break the flanges or spring the axles. Guard rails for leading a car round curves or into switches, for the same reason should never be used on both sides of a track, and the space in the mate at a switch should always be such that a variation in or out of ¼ in. is allowed for inwheel wabble. Another serious trouble with wheels is the nicking of the face edge of the tread, due largely to the fact that in a mistaken effort to save power the manager has adopted a wheel the tread of which is 2¼ in. when it should have been 3 in. or more

Theoretically, if the ball of the rail is 2 in. wide, and you use a wheel the tread of which is 3 in., you have 1 in. overhang on the dirt or pavement adjoining, and a greatly increased current consumption to pull a given load in consequence. Practice, however, shows that narrow-tread wheels have a greater tendency to spread the track, and that where the track is bad will fall in quicker; and with wider treads that after two or three trips over the road the pavement and dirt will conform to the height of the rail, and no increase in consumption of power is perceptible

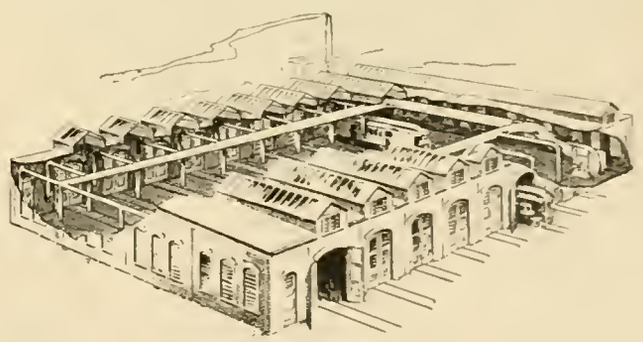
Nicking results where the track is spread, not enough to let the wheel fall in, but enough so that the whole load carries on the edge of the rim. Put a little more metal in your wheels and avoid both "nicking" and track troubles. Very few small street railway shops have a first class wheel boring machine; the writer does not advocate acquiring one, but strongly recommends that boring wheels be not attempted in a small shop. It is better to buy the axles slightly larger than needed and turn the wheelfit on the axle; set your calipers the exact size of your wheel bore, and then make a spring fit (i. e., screw the calipers up tight, and turn off the axle till the spring of the calipers will allow them to pass by shoving hard), this will give you a fit requiring from 40 to 60 tons pressure to put the wheel on.

If you have a wheel which is loose or has been turning on the axle, and you desire to use it again, don't rag the axle with a round nose chisel or shim the hub with tin, but take some hard drawn steel wire, No. 20 to No. 16 gage, cut it in lengths 6 in. longer than the hub of the wheel, place these wires lengthwise, and ¼ in. apart around the wheelfit (see Fig. 2) of the axle; let 3 in. extend back of the point of the hub, and 3 in. in front of the hub; pass a wire round the journal to hold the bundle of wires in place around the wheelfit, and another wire around the other end of the wires; then press the wheels on in the usual way and you can rest assured that you have one wheel that will never get loose again. The small hard wires imbed themselves, half in the softer steel of the axle, and half in the cast iron of the hub and act as so many keys to hold them from turning.

The writer would like to see the beveled tread abandoned and the tread made slightly concave; this would render track repairs materially less and give better wheel life results.

HEATING AND VENTILATING CAR PAINT SHOPS.

The efficient heating and ventilating of a car paint shop greatly increases the capacity by reason of the more rapid drying of the paint and is therefore one of the important things to be considered in designing such a building. The blower system whereby heated air is forced throughout a building by means of a fan is well adapted



PANHANDLE PAINT SHOP.

for buildings of this class, though the usual method of distributing the air horizontally from overhead outlets is not practicable. The illustration shows the blower system of ventilation and heating as applied in the passenger car paint shop of the Pittsburg, Columbus, Cincinnati & St. Louis Ry. at Columbus, O. Here the apparatus is located in one corner of the building, and the air is distributed through an overhead system of galvanized iron piping, extending entirely around the inside of the building at some distance from the walls. Between each pair of tracks pipes are brought down, so as

to deliver the air very near the floor, where it naturally spreads, and whence it gradually rises in a well-distributed mass.

This plant was installed by the B. F. Sturtevant Co., of Boston, Mass., and is the arrangement recommended as best for buildings of this class. In the "Review" for July last, page 484, we illustrated the Sturtevant company's system of heating street car barns.

ADVANCE IN COST OF MATERIALS.

In the fall of 1897 one of the large street railways rebuilt a number of cars, keeping a careful record of the materials and cost. In October, 1899, comparisons were made between the prices obtaining in 1897 and in 1899, with the following result:

Material.	Advance, per cent.
Wages	10
D. T. glass	20
Clear dry ash	10
Clear white oak	20
Whitewood	10
Maple	15
Georgia pine flooring	10
Common pine lumber	20
Wrought iron	118
Cast iron	12.5
Mild steel	110
Brass screws	85
Iron screws and iron nails	100
Carriage bolts	60
Machine bolts	100
Stove bolts	25
Sheet steel, No. 14	67
Brass tubing, ½-in.	50
Brass trimmings	66
Curtains	15
Ducking, 8-oz., 72-in.	25
Bell cord	12
Rubber belting (for tread) and sash rubber	50
White lead	5
Russet leather	10

BENDER FOR T-RAILS.

The Q & C Co., of Chicago, is introducing under the trade name of the "Samson," a new bender for T rails, which is claimed to be an improvement over the ordinary forms of jim crow benders in that the power is applied at the end of the rail, instead of at the

Q & C RAIL BENDER.

center. In most machines of this nature, the rail is held at two points, and pressure is applied by means of a screw at an intermediate point, but in the new type the rail is held by a claw on one end of a heavy lever, and pressure is applied by a capstan-headed screw at the other end. The screw is fitted with a cap, which bears against the head of the rail, and in which the end of the screw revolves on a roller bearing.

The frame is made of an open hearth steel casting, and the screw is of steel working in a bronze nut and is provided with anti-friction washers. The weight of the machine is 113 lb.

The Metropolitan Street Railway Co., of New York, has notified the Continental Telephone Co., that its conduits would be placed at the Telephone company's disposal for telephone purposes of the combined independent companies. The territory now covered by this combination, which is a rival of the Bell company, reaches from the Ohio River to the lakes and from New York to the Mississippi.

PROPOSED MILWAUKEE ORDINANCE.

A special committee appointed for the purpose has reported a street railway ordinance to the city council of Milwaukee which is designed to define the rights of the city and the Milwaukee Electric Railway & Light Co. to the satisfaction of all parties. The principal features of the ordinance are:

The company is given certain additional streets.

If the city limits are extended the company is to extend all lines running to the old limits to the new limits if there shall be any reasonable need thereof.

All rights and franchises in the streets are to terminate Dec. 31, 1934.

The rates of fare shall be 5 cents, except children under 10 years of age, for whom the rate shall be 3 cents or two for 5 cents. One free transfer is to be given when desired. Tickets shall be sold 6 for 25 cents and 25 for $1, good from 5:30 to 7:30 a. m. and from 5 to 6:30 p. m. each day till Jan. 1, 1905, and at all hours after that date. Passengers presenting tickets are to have the same transfer privileges as those paying cash fares.

The company shall provide a clock in each car.

The city shall have the option to purchase the property of the company during the year 1934, paying therefor its actual value (excluding franchises) as a going concern as may be determined by mutual agreement or by a board of arbitration, two chosen by each party and the four to choose a fifth. The decision as to whether the city will purchase must be made between July 1, 1930, and Jan. 1, 1931. If the city does not purchase all franchise rights expire Dec. 31, 1934.

The company is to furnish electric power to operate the drawbridges crossed by it.

The company is to carry policemen in uniform and detectives free of charge.

HEAVY SPECIAL WORK FOR CHICAGO.

The accompanying engraving shows one of a lot of 10 crossings made by the Paige Iron Works, of Chicago, for the Chicago City Ry., to be used on 63d St. where the street railway lines intersect the P. C. C. & St. L. R. R. The crossings are built in accordance with the standard specifications of the Chicago City Railway Co.,

PAIGE CROSSING FOR CHICAGO CITY RY.

and are made of 100-lb. T-rails, fitted with extra heavy "Q" bars. The entire lot when completed weighed 28 tons. This is the third order for heavy crossings given this season to the Paige Iron Works by the Chicago City Ry.

OSHKOSH INAUGURATES FUNERAL SERVICE.

The first funeral at Oshkosh to use an electric car instead of carriages took place on November 16th. A long interurban car having two compartments was utilized for the service, the casket being carried in the baggage compartment and the mourners riding in the other. Funeral cars will hereafter be a regular feature on the lines of the Citizens' Traction Co., of Oshkosh, of which E. E. Downs is general manager.

FOREIGN FACTS.

Electric lines will probably be constructed by the Bath (Eng.) Town Council.

An electric railway will be constructed at Patras, Greece, by the Greek Electrical Co., of Athens.

The street railway running from Kozu to Ooiso, Japan, known as the Odawara Street Ry., is being equipped with electricity.

St. Petersburgh may soon have a new system of electric trams, a commission having been appointed to investigate the subject.

Para, Brazil, will have seven miles of new electric railway. The tramways at this place are owned by the Compania Urbano.

The electric lighting and tramway system of Szakadka, Austria, has been purchased by the Reuni Tramways Co., of Brussels.

A commission to enquire into the advisability of electric tramways for Tokio, Japan, has been appointed by the authorities of that city.

The Glasgow Tramways has given an order for $500,000 worth of steel rails, special work, etc., to the Federal Steel Co., of America.

It is stated that the city of Moscow has been offered a loan of 20,000,000 rubles by a Berlin bank, for the purpose of building electric tramways.

A bill will be introduced in Parliament asking for power for the Barnsley Town Council to construct and operate tramways for the borough and suburban districts.

The District Council of Aston, England, has decided to purchase and operate the tramways owned by the Birmingham & Aston and City of Birmingham Tramways Cos.

An electric tramway will probably be built at Teneriffe, Canary Islands, by the Electric Tramway Co., of Teneriffe, which has been organized by capitalists at Brussels.

Messrs. Kincaid, Waller & Manville, of Westminster, have been asked to prepare plans and estimates for an electric railway to be built by the Town Council of Cambridge, England.

Dawson City, in the Klondike, is to have an electric railway. According to newspaper reports, a line is now being built through the city, and will be extended across the Klondike River to Klondike City.

The Ceylon Government Railways is asking for bids until Jan. 4, 1900, for the constructing of 200 miles of light railways. Information can be secured from the Crown Agents for the Colonies, London, England.

The first section of the Seville (Spain) Tramways Co., Ltd., has been opened to traffic. This road has just been changed from horse traction to electricity, and several extensions built, by the General Electricity Co., of Berlin.

A resolution was passed some time ago by the Dewsburg (Eng.) Town Council agreeing to promote a bill in Parliament, in conjunction with other authorities, to obtain powers to construct a local scheme of tramways.

Frankfurt, Germany, has been empowered to purchase the existing tramways in the city, extend them in several directions and equip them for electrical operation. It is stated much new material will be contracted for at once.

The owners of the Federal District street railway in Mexico City have purchased the street railways of Guadalajara for $700,000 after prolonged negotiations. The same company has purchased the street railway in the city of Puebla.

The Seine Municipal Council will grant permission to the Compagnie des Tramways Electriques de la Rive Gauche de Paris to build two electric railways from Boulogne-sur Seine to Vincennes, and from Montreul to Boulegne, France.

The Buenos Ayres Tramway Co. at a recent meeting declared a dividend of £25,875 and increased its capital stock £100,000. The City of Buenos Ayres is asking for bids for the construction of electric tramways to certain suburbs.

Most of the surface lines of Berlin, Germany, are operated by a company with a franchise still having 20 years to run. The policy of granting no more franchises has been decided upon, and hereafter the city will build all new roads itself.

Sanction for an electric tramway 15 miles long connecting York, England, with Cliffe Common Station, has been given by the Light Railway Commissioners, and a permit for the construction of the line will probably be issued at once to the Escrick and Riccall Rural District Councils.

A school of instruction for inspectors has been established on one of the Berlin Tramways, and all employes of this class will be required to take a three weeks' course of lessons on the care and repair of car equipment, so as to be able to make minor repairs in cases of breakdowns and thus avoid prolonged blockades of the line.

Consul Millner, of Calais, under date of Oct. 30, 1899, informs the department that a company organized at Paris is arranging to establish an electric railway in Calais. The equipment has not yet been purchased, and the consul thinks that United States manufacturers may wish to bid. The old tram cars now in use are of American make.

The city of Mannheim, Baden, Germany, is about to establish a new system of electrical tramways, to be owned by the municipality. It is announced bids on equipment and installation will be asked for in the near future. The municipal council has appointed as director of the system Otto Lowitt, who is now general manager of the tramways at Basel, Switzerland.

A new company has purchased the property of the Tramway & Omnibus Co., of Bordeaux, France, and will immediately proceed to improve the lines and substitute electricity for horse power. Further particulars can be obtained from M. Breterton, managing director Tram & Omnibus Co., Rue Tivoli, Bordeaux, France. The chairman of the board of directors is M. Mercet, 10 Rue de Londres, Paris.

The Port Stanley Electric Street Railway Co. is the title of a concern which is to build and operate an electric railway from Port Stanley to London, Ontario, a distance of about 26 miles. The former place is a popular summer resort on the north shore of Lake Erie and is the summer place of residence of a great many St. Thomas and London people. The railway will follow the route known as the London and Port Stanley gravel road, and a charter has already been obtained from the Ontario government.

Consul Skinner writes that the Paris, Lyons, and Mediterranean Railway Company, headquarters at 88 rue St. Lazare, Paris, has undertaken the construction and operation of an electric railway between Fayet and Chamounix, at the foot of Mont Blanc. The line is to be in operation within twenty months, and it is to be presumed that the company will be interested in propositions for machinery and equipment. Power is to be furnished by the River Arve. Contracts for the road bed and water power have been let.

United States Minister Herbert W. Bowen, Persia, writes the department as follows: "The only tramway lines existing in Persia are those in Teheran, which were laid 10 years ago, and are the property of a mixed society of Belgians and Russians, although at the present time most of the stock is held by the firm of Poliakoo, of Moscow. The lines are about six miles in length, and are laid with ordinary rails." He adds: "Until some better and more expeditious means of communication has been provided, it will be impossible for American manufacturers to compete with Russia for the supply of tramway materials."

TWO NEW ROADS NEAR HAMILTON, ONT.

The Hamilton Electric Light & Cataract Power Co., Ltd., intends to build an electric railway from Hamilton to Guelph, a distance of 30 miles, and also one from Hamilton to Waterloo, through the cities of Galt and Berlin, a distance of 44 miles. The power for both these lines will be supplied by the Cataract Co., and will be derived from DeCew Falls, about 35 miles from Hamilton, so that the total transmission in the longest case will be 75 miles. The roads will be built with 80-lb. rails, and there will be no grade over 2½ per cent, the intention being to run at 60 miles an hour and give an hourly service between Hamilton and Guelph.

The Cataract Co. now owns the large power plant at DeCew Falls, the Hamilton Electric Light & Power Co., the Hamilton Street Ry., the Hamilton & Dundas Electric Ry., and the Electric Power & Manufacturing Co., of Hamilton.

COMBINATION CARS FOR PEORIA, ILL.

The Peoria & Pekin Terminal Railway Co. will soon place in operation on its 10-mile line connecting Peoria and Pekin several combination cars of the type shown in the accompanying engraving, for which we are indebted to the Railway Age. The cars were built by the American Car Co., of St. Louis, and are 43 ft. in length, with baggage and express compartment. They have a seating capacity of 40 passengers, and are mounted on double trucks with a 25-h. p. motor on each of the four axles. The cars are run in trains consisting of a compartment car and a passenger trailer 43 ft. in length with a seating capacity of 48.

The company also do a freight business over the same tracks by means of steam locomotives, having three 60-ton Baldwin dummies and large modern freight cars for this service.

NEW PUBLICATIONS.

THE ELECTRIC STORAGE BATTERY CO. has reprinted the article on "The application of Storage Batteries in Railway and Power Plants" that appeared in the electric railway number of Cassier's Magazine and is sending it to interested parties as Circular No. 55.

THE RIDGWAY DYNAMO & ENGINE CO., of Ridgway, Pa., has recently issued a very handsomely printed pamphlet of over 100 pages devoted to illustrated descriptions of the Thompson-Ryan dynamo and the McEwen automatic engine, which are made by this company.

COPP'S SETTLERS' GUIDE, the 21st edition of which is before us, is a popular exposition of our public land system in the United States. The work is by Henry N. Copp, of Washington, D. C., and is sold at 25 cents. Mr. Copp desires the address of all Union settlers who make entries before June, 1874, of less than 160 acres. The chapter on surveys tells how to decipher township and section corners and the book gives the latest rulings on homestead and other laws.

CONSTRUCTION AND REPAIR OF COMMUTATORS is the title of a 29-page illustrated pamphlet by L. C. Sharp, of Omaha, Neb., which treats of the electrical and mechanical repairs of commutators. The work shows the operation of a commutator making by a series of illustrations which are accompanied by lucid explanations which clearly explain the method of commutator building. The work contains 14 illustrations and is sold for 50 cents.

COMBINATION CAR FOR PEORIA & PEKIN TERMINAL RY.—AMERICAN CAR CO.

GARCKE ELECTRICAL DIRECTORY.

The Garcke Manual of Electrical Undertakings for 1900 is just out, and it will be welcomed by all who are interested in the development of tramways and other electrical industries in Great Britain and her colonies. It is a volume of 1,036 pages, comprising a directory of all companies and manufacturers that pertain to the following subjects: Telegraphs, telephones, electricity supply, traction and manufacturing. Also a directory of all officials, including directors and engineers of corporations.

The work is published under the direction of Emile Garcke, of the British Electric Traction Co., Donington House, London, England. It is evident that the data have been compiled with great care, and the directory is certainly the most complete ever published in England. The Manual sells for $3 net, and may be obtained through C. H. Perrine, 825 Monadnock Building, Chicago, Ill.

The Chicago City Ry. has declared its usual 3 per cent quarterly dividend payable December 30th.

THE ARTICLES announced to appear in the Engineering Magazine for 1900 include papers from the pens of some of the ablest writers on engineering subjects on both sides of the Atlantic, including such authorities as J. Slater Lewis, Sir B. C. Browne, J. H. Biles, Philip Dawson, Dr. Louis Bell, and others.

"NEW TYPE SUNBEAM" is the title of a handsome pamphlelt by the Western Electric Co., describing the "Sunbeam" lamp for which it is exclusive agent. A complete new type has been developed, and the styles of the same are shown in the illustration in the catalog.

THE LIGHT RAILWAY & TRAMWAY JOURNAL is the name of a monthly published at London and devoted to tramway interests in Europe. The issue for November contains several articles of unusual interest, including a description of the Carlisle Electricity Works and the Darwen Electricity Works, Notes on the Light Railways and Tramways of London, and shorter articles dealing with live operating problems.

PERSONAL.

MR. W. C. HELLER, formerly of Montgomery, Pa., has assumed the duties of general manager of the Rapid Transit Ry., of Xenia, O.

MR. THOMAS E. MITTEN, general superintendent of the Milwaukee Electric Railway & Light Co., has returned from an extensive trip in the East.

MR. JOHN M. ROACH was on November 20th chosen vice president of the Chicago Union Traction Co., succeeding Mr. Walter H. Wilson, who resigned.

MR. A. K. BAYLOR, MR. H. F. PARSHALL AND MR. ROBERT W. BLACKWELL, the well-known electrical men of London, arrived in this country last month.

MR. N. C. DRAPER has left the Central Railway Co., of Peoria, Ill., to take up the duties of mechanical engineer for the recently completed Peoria & Pekin Terminal Ry.

MR. J. H. CARSON, formerly president of the Sterling Supply & Manufacturing Co., and now president of the Sterling-Meaker Co., was a caller on the "Review" in Chicago recently.

MR. E. P. SHAW, JR., on December 1st resigned his position as general manager of the Manchester Street Ry., Manchester, N. H., and Mr. J. B. Smith has been elected to fill the vacancy.

MR. CHARLES G. WINGATE has been appointed assistant superintendent of the Metropolitan Street Railway Co., of New York; he was formerly superintendent and chief engineer of the Huntington (N. Y.) Railroad Co.

CORNELIUS JEROME SIMMONS, JR., second vice-president of the Collins Park & Belt R. R., Atlanta, Ga., son of Pres. C. J. Simmons, of that company, is probably the youngest street railway official, being only 12 years old.

MR. HENRY N. RANSOM, purchasing agent for the International Traction Co., of Buffalo, was married on November 21st to Miss Alice Gillet. The "Review" joins with Mr. Ransom's many friends in heartiest congratulations.

MR. JAMES BOYD, well known to many of our readers through his former connection with the "Review" as assistant editor, has been admitted to the Chicago bar and opened an office at 1218 Ashland Block. We wish him the deserved success we feel sure he will attain.

MR. C. J. REILLY resigned his position as chief engineer and superintendent of motive power of the Chicago City Ry. on November 1st, to become superintendent of the Sandusky Portland Cement Co., at Syracuse, Ind., where the company is now building an extensive cement mill. The new mill will be operated throughout by electricity, the three-phase system being used.

COL. G. B. M. HARVEY, who has been placed at the head of the extensive publishing interests of Harper & Brothers, is financially connected with a number of important street railway properties in the United States and Cuba. He has been associated on several occasions with Mr. W. C. Whitney in the latter's railway enterprises, and is at the head of the Harvey syndicate, which owns the street railway system of Havana.

MR. JOHN PATTERSON, of Hamilton, Ont., is known as the "electrical man" of that city, and in this field he has achieved great success. In the 80's he began to develop the electric undertakings which have since done so much for the city. In 1895 the electric line around the beach to Burlington was completed and the next year Mr. Patterson organized the Cataract Power Co. to develop power at DeCew's Falls and transmit it to Hamilton. This company now has a capital of $3,750,000 and controls the Hamilton Electric Light & Power Co., the Hamilton Street Railway Co., the Hamilton & Dundas Electric Ry., the Hamilton Radical Electric Ry., and the Electric Power & Manufacturing Co., of Hamilton.

MR. W. J. JOHNSTON, the well-known publisher, now making a tour of the world, was given a complimentary dinner at Tokyo, Japan, while visiting that city by Professor I. Fujioka, president of the Tokyo Electric Co., and Mr. S. Katom, editor of the Electrical Friend. The dinner was served in true Japanese style, with the usual accompaniment on such occasions of singing and dancing by geisha girls.

MR. ALFRED FAIRBAIRN, for several years paymaster of the Montreal (Can.) Street Railway Co., has been appointed comptroller of the West India Tramway Co., Kingston, Jamaica.

OBITUARY.

MR. F. J. O'DONOGHUE, superintendent of the Nashua (N. H.) Street Ry. and well known in street railway circles in the East, died on November 10th.

VICE-PRESIDENT HOBART, who died November 21st, was quite as prominent in financial circles as in politics, and among his wide interests were large investments in street railway properties. Mr. Hobart was president of the Paterson Railway Co., of Paterson, N. J.

MR. V. C. TURNER died at his home in this city on December 2d, of apoplexy. Mr. Turner was born in Malta, Saratoga County, New York, Feb. 25, 1823; he came to Chicago in 1848 and engaged in the practice of law. In 1860 he became interested in North Chicago City Ry., and was president of the company from 1867 to 1886.

MR. ROBERT F. FOX, who was for some time superintendent of the Scranton (Pa.) Railway Co., and more recently general manager of the Wilmington & Chester Traction Co., of Wilmington, Del., and the Chester (Pa.) Traction Co., died last month at his home in Meadville, Pa., after an illness of several weeks. Before going to Scranton, Mr. Fox held the position of assistant engineer of the Brooklyn (N. Y.) roads.

MR. J. H. VANDERVEER, superintendent of shops of the Brooklyn Heights Railroad Co., died at his home in Bay Ridge, N. Y., December 3d, of typhoid fever. Mr. Vanderveer had an extensive experience in both railroad and street railway work and was considered an expert on the subject of maintenance of rolling stock. In November he read a paper on "Care of Car Equipment" before the American Street Railway Association at Chicago. He was at various times connected with the Central Railroad of New Jersey, the Erie R. R., and the street railway lines at Scranton, Pa., leaving this latter position in 1893 to enter the engineering department of the Brooklyn City R. R., where he remained through the various consolidations, and was finally promoted to the office of superintendent of shops.

FIRST HONORS FOR PANTASOTE.

The highest award, a silver medal and diploma of merit, was conferred by the National Export Exposition, of Philadelphia, upon the Pantasote Co., for products exhibited in competition. The committee of award was appointed by the Franklin Institute, which has an enviable reputation for impartial and thorough investigations.

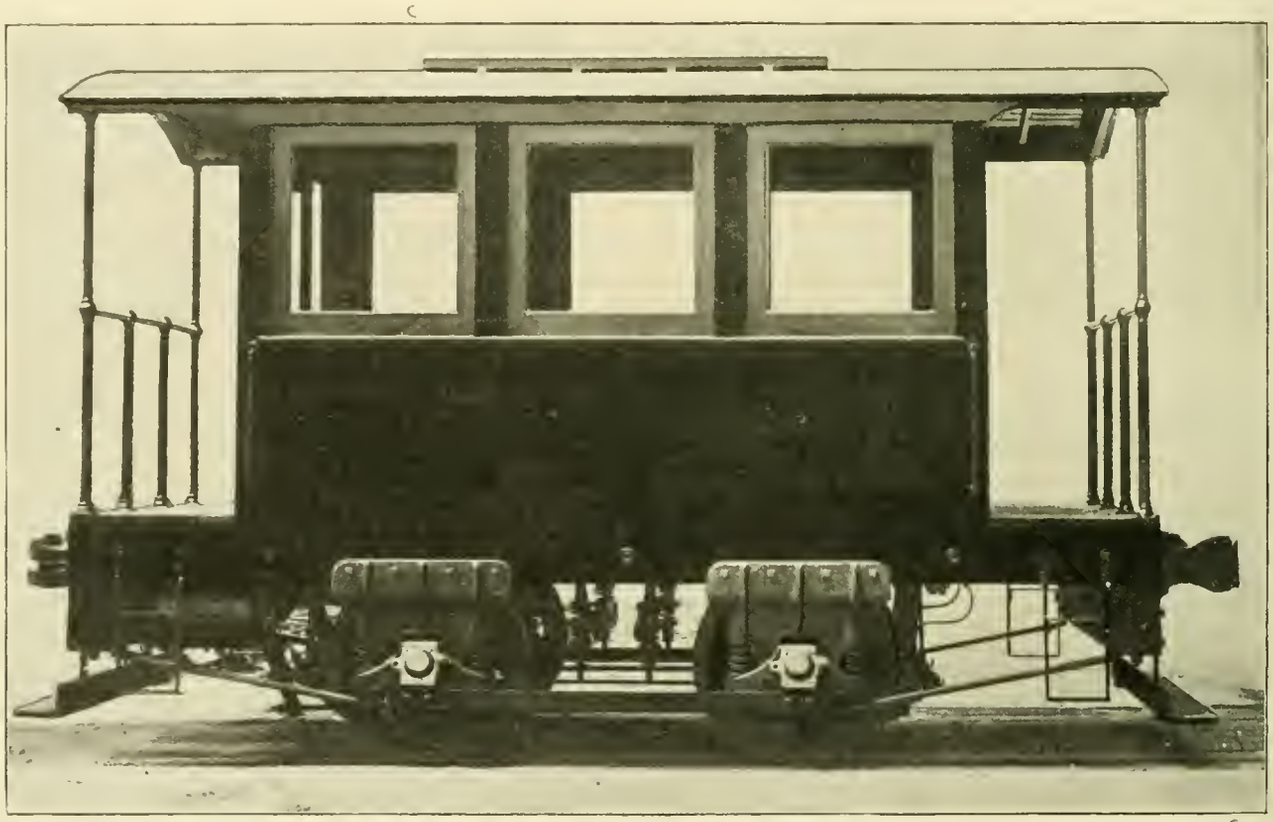
The award thus obtained will doubtless be exceptionally gratifying to the recipients whose products have attained a widespread popularity and sale in this country and in Europe as materials for upholstering car seats, furniture, carriages, etc., and for car curtains. The fact that the United States Government, during the Spanish War, adopted Pantasote for all ambulance upholstering and for other army uses was a high testimonial to its merits. Its freedom from liability to rot, peel or crack, its non-inflammable quality and the fact that it is germ proof makes it extremely desirable for the purposes for which it is intended and renders it a most satisfactory substitute for leather, and in some respects its superior.

NEW M'GUIRE LOCOMOTIVE.

The McGuire Manufacturing Co. has just delivered to the General Electric Co., of Schenectady, N. Y., one of the most compact electric locomotives that this company has yet turned out. It is only 14 ft. over all and weighs complete about 22 tons. It is fitted with Westinghouse automatic air brakes, Trojan couplers, chime whistles, General Electric air compressors, and two G. E. 51 electric motors of 150 h. p. each, giving the machine a capacity of 300 h. p.

The largest one of these locomotives yet turned out by the McGuire company weights 60 tons, and is in operation at Yonkers, N. Y., for hauling steam cars through the tunnel at that point, and the company has made several weighing only 4 tons, for mining purposes. The McGuire company is busy this month with orders for points so widely separated that it is noticeable. It is building 60 trucks for San Francisco, 120 for Havana, Cuba, 30 pair for the Australian Government, and finishing the order for 300 for the Northwestern Elevated of Chicago, with smaller orders from every part of this country. It is just closing up the largest snow plow business the company has ever done in one year, with two orders. 10 for Washington, D. C., and 15 for St. Louis, besides a large number of single orders, among them being one for Spokane, Wash., and one for Burlington, Vt.

Plans are being prepared for an additional building to be added to the McGuire plant this winter. It will cover the piece of ground on the corner of Kinzie and Morgan Sts., being 116 ft. on Morgan by 166 ft. on Kinzie. This building will be five stories high and devoted entirely to sweeper, electric locomotive, and sprinkler woodwork. The McGuire company will introduce a new sprinkler the coming year, which will be distinctive in design and construction. It is to be equipped with sweeper as well as a sprinkler, which for traction purposes will certainly be a great advantage and will be appreciated by managers who realize the economy of having a clean rail.



McGUIRE LOCOMOTIVE FOR GENERAL ELECTRIC CO.

The city council of McKeesport, Pa., passed an ordinance last month placing a tax of $100 a year on all street railway cars in the city used for carrying express packages.

KANSAS CITY-TOPEKA ROAD.

The Kansas City Lawrence & Topeka Railway Co. was organized in September last under the laws of the state of Kansas, with an authorized capital of $2,000,000. The company has authorized the issue of $1,500,000 of 5 per cent first mortgage bonds. It has purchased the Lawrence & Emporia Ry., known as the Carbondale road, and also the Kansas City, Bonner Springs & Topeka road, the Lawrence Street Car line and the East Side Circle Ry., at Topeka. The line between Kansas City and Topeka will be 68 miles in length and the company expects to make arrangements with the Metropolitan road at Kansas City to use the latter's tracks as an entrance to the city; also with the city line at Topeka for enrance to that city. It is now constructing the road the whole distance between Kansas City and Topeka. The officers of the company are: President, Henry G. Pert, of Kansas City Mo.; vice-president, C. C. Baker, Topeka, Kan.; treasurer, W. A. Bunker, Kansas City; secretary, Geo. J. Kensinger, Kansas City, The directors include the four officers and J. D. Bowersock, Lawrence, Kan.; W. C. Endsley, Kansas City; J. W. McDanield, Bonner Springs, Kan.; J. W. Hirst, Omaha, Neb.; Willard E. Winner, Lansing, Kan.

FOREIGN AGENCY DESIRED.

Messrs. E. H. Cadiot & Cie., 12 Rue St.. Georges, Paris, France, who make a specialty of general electric supplies, wish to become the French representatives of American companies making steel rails and street railway poles, and desire that such companies will enter into correspondence with them.

PAVING THE DEVIL'S STRIP.

The Hamilton (O.) & Lindenwald Electric Transit Co. is required to pave between the rails and 8 in. outside, and it contends that its portion of the devil's strip between double tracks is only 16 in. The company recently sued to restrain the city treasurer of Hamilton from collecting for more than for the 16 in. of this strip, and the court granted the injunction.

ECHOES FROM THE TRADE

THE CHRISTENSEN ENGINEERING CO., Milwaukee, through its European agent, J. S. Hamlin, has sold the Compagnie Generale de Traction, of Paris, 180 sets of air brake equipment.

THE CLING-SURFACE MANUFACTURING CO., of Buffalo, N. Y., reports rapidly increasing sales of "Cling-Surface," both domestic and foreign. A recent letter from the Union Traction Co., of Philadelphia, Pa., says: "We herewith order a second can which is evidence that we consider 'Cling-Surface' entirely satisfactory."

THE GARL ELECTRIC CO. has completed its new factory at Akron, O., and recently elected new officers as follows: Hugo Schumacher, president; and M. Garl, superintendent. An office has also been established in Chicago, at 1015 Monadnock Building. The specialties manufactured include electric supplies and a full line of telephone material and equipment.

THE JOSEPH DIXON CRUCIBLE CO. announces that from this time forth it is an out and out "expansionist." The reason is that one mail recently brought five orders from Manila for Dixon's graphite pencils, graphite crucibles and graphite lubricants. The company believes that the "open door" will swing easier if the hinges are lubricated with Dixon's graphite.

THE HUNTER ILLUMINATED CAR SIGN CO., Cincinnati, is now working upon several large orders which will keep its factory busy for five months to come. The company has recently received orders from the Washington Water Power Co., Spokane, Wash.; Holyoke, (Mass.) Street Railway Co.; Metropolitan Street Railway Co., Kansas City; Decatur (Ill.) Traction & Electric Co.

THE SCARRITT FURNITURE CO., St. Louis, is rapidly securing the trade in car seats, not only because its product affords so large a variety to select from, but because its prices are attractive. Its location in the largest street car building city in the world also has a tendency to favor the Scarritt Co., as the car builders do not have to wait for annoying delays in shipment of seats by freight. The popularity of the Scarritt seat is unquestioned.

JUDGE PUTNAM, of the United States Circuit Court, on Oct. 4, 1899, in the case of the Duff Manufacturing Co. v. Norton, at final hearing, again sustained the Barrett lifting jack patent 455,993 of July 14, 1891, as valid and infringed by Arthur O. Norton, of Boston. He ordered the preliminary injunction granted last spring against Norton made perpetual. In so doing, the judge followed the several decisions made at Pittsburg, Philadelphia and Kalamazoo.

THE BIBBER-WHITE CO., which was some time since temporarily embarrassed by having furnished a large amount of construction material to a road which failed to meet its payments, has arranged with its creditors for payments on installment plan, which will soon clean its accounts up, and is now doing a large and prosperous business. The many friends of the gentlemen engaged in the company will be pleased to learn of their good prospects.

THE CHICAGO MICA CO., miner, importer and manufacturer of mica for all purposes, has just moved into its new factory at Valparaiso, Ind. The main building is a three-story structure 100 x 60 ft., and a second building 100 x 40 ft. is arranged for making "micabond" cloth, paper and "Champion" compound. The steam plant occupies a separate building. This company was organized a year ago and has been remarkably successful. The officers are: President, Milton A. Snider; vice-president, J. W. Sefton; secretary, W. F. Hatch; treasurer, Henry E. Miller.

THE CARPENTER STEEL CO. is one of the largest manufacturers of crucible steels, which it makes with the greatest care from the best and purest iron to meet the demand for superior fineness and durability. The executive offices are at No. 1 Broadway, New York; the works are at Reading, Pa., and sales offices and warehouses are maintained at New York, Chicago and Toledo, where large and well assorted local stocks are carried, enabling prompt shipments to be made. The Chicago office is at 9 Canal St., and is in charge of F. W. Lane. A recent publication is a 30-page pamphlet descriptive of Carpenter steels, which will be sent on application.

THE Q & C CO., Chicago, under date of November 27th, sends us the following notice which will be of interest: "Referring to the articles now appearing in the mechanical papers pertaining to litigation on pneumatic tools, and in order to make clear the position of the Q & C Co., we wish to distinctly state that we are not in any way involved in this controversy. The line of tools manufactured by us are protected by our own patents, unique and broad in themselves and absolutely clear from any infringement. Full protection will be given to any purchaser of our tools from any liability on account of their use. We also wish to state that we have completed our line of pneumatic tools and in addition to hammers and riveters will shortly offer for sale pneumatic drills, both for metal and wood work, and pneumatic hoists, and trust that you will investigate the advantages of our devices before purchasing any tools of this description."

THE WESTERN ELECTRICAL SUPPLY CO., of St. Louis, has recently taken the exclusive territorial agency for the Multiplex Reflector Co. It claims these corrugated reflectors and headlights to be an entirely new departure and the latest and best thing in the reflector line yet produced, and that they produce 300 per cent more light than any other plain or parabolic reflector on the maket. Comparisons are invited to substantiate this claim. They are especially adapted for street railway work and certainly deserve the consideration of anyone on the market for a first-class and strictly up-to-date head-light.

The company makes an electric arc head-light with automatic regulation, which it is claimed is the only self-regulating arc headlight made. These head-lights are so constructed that no amount of jarring or vibration will disturb their adjustment or affect the light in the least. They are always glad to send these head-lights out on trial, or for competitive tests. Printed matter, price lists and full information furnished on application.

E. G. JOHNSON & CO., 1135 Broadway, New York, who make a specialty of electric railway construction and supplies of every description, has lately added to its regular business an agency to supply trolley and cable roads with experienced employes. All men furnished by the firm have had experience in the line that they are engaged for, doing away with the loss of time used in breaking in new and inexperienced men; also loss by damages thus incurred. All men supplied by the firm are known to be skilled and reliable. They always have the following line that can be furnished at short notice: engineers, firemen and oilers for power house; section foremen and laborers for track work; electricians, linemen and helpers for overhead work; motormen, conductors and inspectors for operating all kinds of cars and motors. No charge is made the roads for the help engaged through this agency except for strike work; terms for this will be given on application. This firm also handles second hand cars, trucks, armatures, etc.

THE M'GUIRE MANUFACTURING CO. has recently shipped one of its snow sweepers to the Wheeling (W. Va.) Railway Co.

THE FACTORY of the United States Carbon Co., of Cleveland, was badly damaged by fire on November 17th. It is believed the loss on the structure and stock will reach $10,000.

MR. GEORGE S. HASTINGS, one of the best known and most popular sales agents in the field, has resigned his position as western representative of the Brill Co. and accepted a connection with the Christensen Engineering Co., Milwaukee.

THE JACKSON & SHARP CO., Wilmington, Del., has received the contract to build 100 trolley cars to be used on the Paris Exposition grounds. The company is said to be bidding on orders aggregating more than 1,500 for various European cities.

THE REVIEW OF REVIEWS for December is a particularly interesting number; it discusses the significance of the elections, the progress of the two wars now pending and several other questions now exciting controversy in American political circles.

THE STERLING VARNISH CO., of Pittsburg, Pa., has just issued, under the title of "Sterling Extra Insulating Varnish," a little book of 84 pages with 70 reproductions of letters received by the company from different customers, each letter being either an order or a warm testimonial.

THE ORIENT ELECTRICAL CO., of Youngstown, O., points out that it is good luck to buy the Orient incandescent lamps when replenishing stock, in a little eight-page circular just issued. The company's watchword while making these lamps is, "Quality has precedence over all other factors."

THE WALWORTH MANUFACTURING CO. is sending out with its compliments a pocket map of the Philippine Islands, which contains much valuable information concerning our new possessions. The company also announces that on December 1st it moved into its new store at 130-136 Federal St., Boston.

THE H. C. ROBERTS ELECTRIC SUPPLY CO. is the title of the successor to the Franklin Electric Supply House, of Philadelphia, the Roberts company having purchased the good will, stock and fixtures of the latter company on November 14th. The new concern will have its headquarters at 831 Arch St., Philadelphia.

THE BULLOCK MANUFACTURING CO., of Cincinnati, is now advertising for bids to extend its main building 200 ft., making the machine shop 101 x 500 ft. The tremendous volume of business that has come to the company from all parts of the world during the last six months makes it imperative that this work be completed with all possible haste.

HENRY PELS & CO., of Berlin, with New York offices at 66 Broad St., have issued an artistically printed folder describing the Werner patent portable punching and cutting machines, for which they are agents. These tools are for punching and cutting by hand power, beams, channels, angle and flat bar iron, etc., and can be used to advantage in constructing bridges, viaducts, elevated railroads, roofs, buildings or other iron and steel structural work.

THE CENTRAL ELECTRIC CO., of Chicago, is well pleased with the volume of business received during the past few months, and with the outlook for the future. This company carries in stock an absolutely complete line of electrical supplies, including the smallest parts, and is therefore prepared to save street railway companies considerable expense by being able to ship everything required in the different departments at one time. The company expects to announce shortly that it has taken several new important agencies.

THE AMERICAN CAR CO., St. Louis, has recently shipped the first 20 cars of an order for the New Orleans & Carrollton Railroad Co., New Orleans, and they were put in service December 4th. The cars were built after the plans and specifications of Ford, Bacon & Davis, engineers for the railroad, and are 31 ft. long mounted on "Lord Baltimore" single trucks with two G. E. 1,000 motors. The cars are very handsomely finished both outside and inside.

THE FILER & STOWELL CO., of Milwaukee, has been so crowded with work during the past year that it has decided to enlarge its plant by building an addition to cost $60,000. In order to get room in which to erect wider buildings the company has petitioned the city to vacate the street bounding its plant on the east; the street in question has never been used as a thoroughfare. The Filer & Stowell Co. is the second largest engine building concern west of the Allegheny Mountains.

THE FAIRMOUNT CONSTRUCTION CO., of 723 Walnut St., Philadelphia, has increased its capital stock to $200,000. The present directors are: Clarence P. King, president; Josiah B. Seybert, treasurer; John G. Vogler, Frederick H. Treat, all of Philadelphia, and Hon. Robert S. Clymer, of Woodbury, N. J. The company has constructed a number of electric railways and electric light plants, and has lately secured two contracts for electric railways, which it will proceed to build at once. Joseph MacCarroll, former president, has disposed of his interest in the company.

GATES & RANDOLPH are doing a large business with their Waverly automobiles and it will pay all street railway men to see their rigs at No. 15 Monadnock Block, Chicago. The Waverly people have worked out the automobile problem on the basis of street car practice, which has been thoroughly threshed over. Gates & Randolph also report a very large trade in Le Valley carbon brushes, which, though the most expensive brushes made, give such perfect satisfaction that the price cuts no figure. Their business in street railway generators of the Triumph Electric Co's. make is also very satisfactory.

THE WESTERN ELECTRIC CO., of Chicago, has recently issued a small four-page bulletin on annunciators, in which is given a list of its latest style D hotel annunciators and return call push button board. There are also listed a line of smaller annunciators and elevator annunciators. This bulletin is numbered 22 A. The company has also a neat circular describing the pendant push button switch. The purpose of these switches is to connect chandeliers, fan motors, or other devices, with the switch by means of a drop cord, allowing the switch to hang within easy reach. They are made in two sizes, viz., 5 amperes and 10 amperes.

THE SARGENT CO., Chicago, has mailed to the trade a six-page folder which is intended to be gummed into the M. C. B. book of rules for car interchange and repairs. Four pages are devoted to an index of Rules 3 to 9 and two pages to a reproduction of the "Sargent Co. Knuckle Chart." Concerning this folder a prominent superintendent of motive power recently wrote the Sargent Co. as follows: "I have your circular regarding supply of Index to M. C. B. code of rules and beg to acknowledge receipt of the form, which is certainly a big improvement on the rules. They will serve as a guide and ready reference which will be much appreciated. I have placed it in the hands of our employes entitled to the M. C. B. rules."

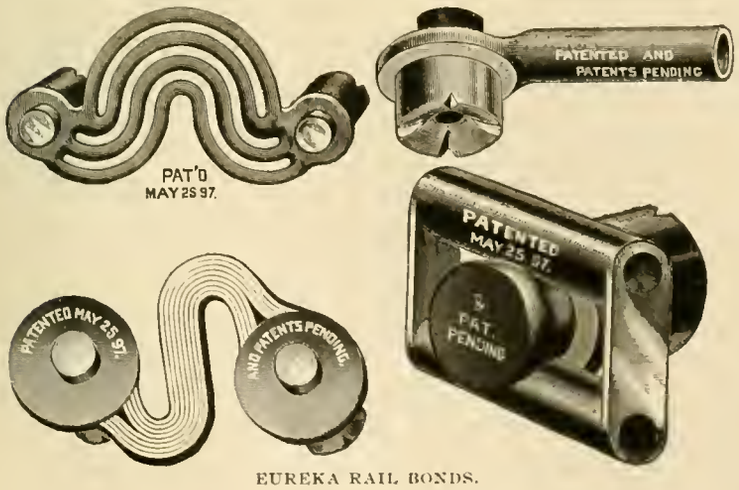
Shoveling out snow drifts commenced early this year. The Westbrooke, Windham & Naples Electric Railroad Co. had a crew out on November 11th cutting through snow drifts several feet high.

In tearing up a street in Johnstown, Pa., recently, workmen have unearthed the ties of the old horse car line which traversed that part of the city previously to the flood several years ago. The old ties, which are in a good state of preservation, are nearly 2 ft. below the surface now.

The International Traction Co. has completed the laying of tracks on the Riverway between Falls St. and Niagara St. at Niagara Falls. The erection of poles and wire will soon be finished and then there will be a belt line about the gorge.

THE EUREKA RAIL BONDS.

The Eureka Tempered Copper Works, of North East, Pa., is the maker of a great variety of the electrical specialties now in use and has lately added to its list a new rail bond, patented by James McLaughlin, of Chicago, who is well known to the electrical trade.



EUREKA RAIL BONDS.

It is claimed that the simple manner of attaching these bonds to the rail saves to the purchaser in labor alone nearly one-half the ordinary cost of rail bonds, or from 10 to 15 cents upon every bond used. The important feature of these bonds is the steel expanding pin cast solid in the head and projecting about 3-16 in. These pins are formed so that driving them flush swedges the copper into perfect contact, and turns a flange on the opposite side of the rail, making a perfect lock connection and perfect contact on both sides. The bond being a solid pure copper casting, leaves no opportunity for any waste of current. This concern makes any desired style of bond with wire or flexible cable. It also makes connectors for attaching supplementary return wires to the rail in the same manner. These bonds are on exhibition at the company's Chicago office, Monadnock Block, and also at the office of the W. R. Garton Co., No. 315 Dearborn St., Chicago. The accompanying illustrations give a better idea of these bonds to the practical mechanic than would any description. These bonds attracted much attention at the A. S. R. A. convention.

PARK FOR LEXINGTON, KY.

The Lexington (Ky.) Railway Co. has purchased the 125-acre tract of land known as Mansfield, formerly the property of Henry Clay, and will make the place into a public park and summer resort. The lines of the company will have to be extended about two miles to reach the park, and this work will be undertaken in the spring. The price paid for Mansfield was $14,000.

INDUSTRIAL CONSOLIDATION.

The Sterling-Meaker Co. is the name of a new organization which has recently been formed by the union of the Sterling Supply & Manufacturing Co., of New York, with the Meaker Manufacturing Co., of North Chicago, Ill. J. H. Carson is president, J. W. Meaker, vice-president, and W. L. Brownell, secretary and treasurer. The headquarters of the company will remain at 141 East 25th St., New York, while Mr. Meaker will have charge of the Western department with headquarters in Chicago. The company will continue to make the Sterling fare registers and the Meaker registers as well as the Sterling safety brake and general railway supplies the same as were produced by the Sterling company before the consolidation. For the present the goods will be made in both establishments as formerly, but it is contemplated that in the near future the register business will be centered in New York. The street railway fraternity is to be congratulated upon the fact that the principals in the two companies will remain in the field and jointly conduct the business.

NEWS NOTES.

ALBANY, N. Y.—The Hudson River Waterpower Co., with a capital stock of $2,000,000, has been incorporated for the manufacture and sale of gas and the sale of electricity for heat, light and power. The company proposes to dam the Hudson. The directors are: Eben H. Gay, Walter H. Trumbull, of Boston; Elmer J. West, Chas. E. Parsons, and Eugene L. Ashley, of Glens Falls, N. Y.

ALLENTOWN, PA.—At a meeting of the directors, on November 17th, the seven electric railways centering in this city were consolidated under the name of the Allentown & Lehigh Valley Traction Co. President, Albert L. Johnson; vice-president, Tom L. Johnson; secretary and treasurer, J. E. Kenney.

ALLEGHENY, PA.—Surveys have been completed for an electric line to connect Allegheny and Perrysville. The line will be five miles long and will cost about $80,000, of which $27,000 have been subscribed. Among those interested are: Geo. B. Hill, M. K. McMullen, Jas. W. Preston and Fred Schwitter.

ANDERSON, IND.—Twelve new buildings, including power buildings, car sheds and station houses, will be constructed in the early spring by the Union Traction Co., at Elwood, Pendleton, Yorktown and other places on the route. C. L. Henry, manager, Anderson, Ind.

ANACONDA, MONT.—The common council of this place has granted the street railway company a franchise for an electric road for the purpose of hauling ore and other feight, its principal object being to haul the ore from the Stewart mine to the Butte Reduction Works. The franchise is for 30 years. The company must give a bond of $25,000 to indemnify the city from all damage by reason of the construction of the line.

ATHOL, MASS.—The parties interested in the construction of an electric road between Gardner and Templeton have under consideration a plan for extending the line to Athol. P. S. Hirsch, of New York City, is one of the promoters of the plan, which would include a nine-mile extension from Templeton to Athol.

BAY CITY, MICH.—An electric railway is being projected from this place to Port Huron, by way of Caro. Ex-Mayor U. S. Boynton, of Port Huron, who is interested in the road, states that the road will be built and the only local aid asked by the company is the right of way, much of which has been secured.

BERKELEY, CAL.—The Oakland Railroad Co. has been granted a new franchise to replace a part of one granted to it last September, which it wished rescinded. The new franchise makes some changes in the route and gives the company a loop through a part of Berkeley not touched at present by any line.

BUFFALO, N. Y.—The engineers of the Buffalo & Erie Railway Co. are at work on the survey of the route, and the matter of securing franchises and rights of way from property owners along the line of the road is now well under way. Work of grading and track laying will begin early in the spring of 1900.

CHARLOTTE, N. C.—The company which is developing the water power of the Catawba River, it is announced, may interest itself in another street railway system to be built in Charlotte and suburbs. Messrs. Dekker, Mason & Co., of New York, are connected with the enterprise.

CHATTANOOGA, TENN.—The Chattanooga Rapid Transit Co. will extend its railway to St. Elmo, at the base of Lookout Mountain, and to Chickamauga Park, 10 miles from Chattanooga. W. B. Royster, secretary of the Chattanooga Rapid Transit Co. Capital for the improvements, it is reported, will be furnished by a Philadelphia syndicate, represented by Clarence P. King.

CHESTER, PA.—The Philadelphia, Swarthmore & Morton Trolley Co. has made application to the Chester city officials for the assignment of the franchise of the Media, Middletown, Aston & Chester Traction Co., the latter having rights over certain streets not occupied by the Chester Traction Co. The new company proposes to connect Chester with its line now building.

CHILLICOTHE, O.—The directors of the Chillicothe, Clarksburg & Mt. Sterling R. R. were granted a franchise on November 6th to construct and operate an electric road along the Chillicothe and Clarksburg pike and as far as the Pickaway County line.

CHILLICOTHE, O.—The commissioners of Ross County have granted a franchise to the Chillicothe, Clarksburg & Mt. Sterling Electric Co., to construct and operate an electric railway for 25 years, along the Chillicothe and Clarksburg pikes, and thence to the county line. A bond of $2,000 was given. The capital for the road is ready as soon as the right of way is secured.

CINCINNATI, O.—The Cincinnati, Lawrenceburg & Aurora Street Ry. is about to build a branch line from Valley Junction to Harrison. The ties for the line have been received.

CINCINNATI, O.—The board of directors of the Cincinnati, Newport & Covington Railway Co. have decided to push the work on an electric street car line running from this city to Crescent Springs and Highland Cemetery. Almost the entire right of way has been secured and the people along the proposed line have subscribed a bonus. The new road will begin at Bromley and run over Pleasant Run road to Crescent Springs and thence across the country to the Highland Cemetery on the Lexington pike.

CLEVELAND, O.—The work of converting the Superior St. and Payne Ave. cable lines into electric roads will begin next spring and will be completed in six months. The overhead trolley system will be installed. Superintendent Mulhern, of the Little Consolidated Co., states that the change to the new electric equipment will cost about $500,000.

CLEVELAND, O.—M. J. Mandelbaum & Co., F. D. Pomeroy, D. H. Kimberly, A. E. Akins and other Cleveland capitalists are behind a project to run a trolley railroad from Cleveland to Cincinnati. H. R. Newcourt, Jacob Mandelbaum and E. G. Tillotson have been elected directors. The capitalization of the company will exceed $2,000,000.

CLEVELAND, O.—The city council, November 6th, granted the application of P. J. Kassulker, Bernard Schatzinger and others that steps be taken to build a cross-town line, starting at Doan street. It is the intention of the promoters to extend the line to Garfield Park, also from Doan street to Glenville.

CLEVELAND, O.—The Cleveland & Eastern Railroad Co. has given a mortgage for $1,000,000 to the Cleveland Trust Co. The money will be used in building extensions.

COLUMBUS, O.—The Brice Syndicate proposes to purchase all the street railway franchises which the city of Columbus may have to sell. The company will invest $3,000,000 in the enterprise, giving a bond of $200,000 to secure the performance of its contract. J. T. Adams, of Toledo, represents the purchasing syndicate.

COLUMBUS, O.—The Scioto Valley Traction Co. proposes the construction of an electric railway from the Union Depot, Columbus, through Circleville to Chillicothe, and perhaps to Portsmouth. Rights of way have been agreed from Kingston to Chillicothe. W. J. Weaver, Scioto Valley Traction Co., Columbus, O.

COLUMBIA, S. C.—It is announced that the Columbia Electril Railway Co. will build several miles of new lines in the suburbs in addition to making improvements to the present system. W. B. Smith Whaley is president of the company.

DANVILLE, ILL.—The Danville Street Railway & Lighting Co. has been incorporated, with T. R. Samuel, Orville Cannon, and Frank Lindley as incorporators. This is a reorganization of the present railway company, and plans are in view for making considerable extensions of the railway system.

DES MOINES, IA.—President Polk and Manager Hippee, of the Des Moines City Railway Co., have just returned from the East, where they went to finance a large interurban railway scheme. They announce that they will next year build a line from Des Moines southwest to Winterset, 25 miles, thence southwest to Macksburg, Greenfield and Creston, the whole making about 75 miles. Capital for the enterprise is assured.

DOVER, DEL.—The Consolidated Public Works Co., of Philadelphia, chartered to secure possession of and interests in steam and electric railways, water works, light and power systems, etc., was incorporated on November 23d, with a paid-in capital stock of $150,000.

FAIRMONT, W. VA.—A company has been formed to build an electric railway from Fairmont to Fairview, a distance of 11 miles, for which surveys have been made and the right of way secured. Among the stockholders are Thomas W. Fleming and W. H. Fleming, of Fairmont; Wm. McKinley and J. C. Whitla, of Pittsburg.

FALL RIVER, MASS.—A company has been formed known as the Fall River & Brockton Air Line Street Railway Co., which proposes to lay 15 miles of track from Fall River through Freetown and Rochester. The capital is to be $150,000. Geo. R. Phillips of New Bedford is clerk and treasurer. The promoters are Abbott P. Smith and H. L. Smith, of New Bedford; C. H. Wilson, of Brookline, and Fred C. Hinds, of Newton.

FORT WAYNE, IND.—The Indiana & Ohio Traction Co. will construct an interurban electric railway, 80 miles in length, from Hicksville, O., to Marion, Ind., via Fort Wayne. The directors are: James H. Simmons, president; John D. Olds, vice-president; William Kaough, secretary; and John W. White, treasurer.

HAMILTON, O.—The Hamilton & Lebanon Street Railway Co. has applied to the county commissioners for a franchise to build its road over the Princeton pike to the east county line.

HARRISON, O.—A branch of the Cincinnati, Lawrenceburg & Aurora Street Ry. is to be built to this place. Several carloads of ties are already on the ground.

HEMPSTEAD (L. I.), N. Y.—The Mineola, Hempstead & Freeport Traction Co. was granted a franchise on November 10th to operate a trolley road through this town. President Newton, of the company, is quoted as stating that the company will begin work within 10 days, and proposes to connect with the North Shore trolley line.

HESPELER, ONT.—The Galt, Preston & Hespeler Railway Co. will build a new station at this place.

HOLLYWOOD, CAL.—A franchise has been granted to Philo J. Beveridge, for an electric road from the main line of the Colgrove-Sherman road, through Hollywood, and around to the main line again. The loop will be about four miles in length. The road must be started within 10 days from December 10th, and the citizens of Cahuenga Valley subscribed a bonus of $15,000 provisional upon the speedy construction of the road.

INDIANAPOLIS, IND.—Daniel Leslie and A. W. Moore, of Indianapolis, have secured a franchise for the Columbus, Brownstown & Salem Electric Ry., to be built through Cortland, Honeytown, Brownstown and Vallonia.

KANSAS CITY, MO.—Willard E. Winner, of Kansas City, is securing the rights of way for an electric railway which he will build from Kansas City via Leavenworth to St. Joseph, Mo.

KANSAS CITY, MO.—A new electric railway is projected to connect Kansas City, Independence, Lee's Summit, Lone Jack and Warrensburg.

KINGSTON, N. Y.—The Delaware & Kingston Valley Railway Co. has been incorporated to construct and operate a steam or electric railway from Kingston to a point in Sullivan County, opposite Lackawaxen, Pa. Capital stock $2,500,000. Directors: Samuel D. Ceykendall, of Kingston; Edward L. Fuller, of Scranton, Pa.; Walter Ferguson, of Stamford, Conn., and others.

KINGSTON, N. Y.—The Delaware Valley & Kingston Railway Co. was incorporated November 11th at Albany, with a capital stock of $2,500,000. The road will be operated by electricity and will be 81 miles long, running from Kingston to a point on the state boundary line in Sullivan County. Samuel D. Kay Kendall, of Kingston, is interested.

KNOXVILLE, TENN.—L. D. Dillon is interested in a proposed electric line between Knoxville and Lyons View, in the suburbs. The County Court has granted the company right of way.

LARCHMONT, N. Y.—The Larchmont Horse Railway Co., which has operated a line in this village for several years, yesterday filed a certificate of extension of its route in the County Clerk's office at White Plains. According to the papers, it is proposed to construct several branches.

MACON, GA.—The North & South Macon Railway Co. has been formed to build a street railway in the suburbs. W. B. Sparks and H. C. Bacon are promoting the enterprise.

MANCHESTER, N. H.—The Manchester Electric Co. has purchased one of the largest water powers in the state of New Hampshire. This power is located at Garvin Falls, and is at present undeveloped. The falls will develop 6,000 h. p. in seasons of the greatest drouth. The power of the falls will be immediately developed, and a large fire-proof brick power house is to be constructed. The company will do business under the name of the Garvin Falls Power Co., and the officers are as follows: S. Reed Anthony, of Boston, president; Nathan Anthony, treasurer; J. Brodie Smith, of Manchester, general manager.

MARLBORO, MASS.—J. F. Shaw, railway contractor, and one of the promoters of the proposed electric trunk line from Worcester to Boston, has made a formal proposition to buy the Marlboro Street Ry., Marlboro & Hudson Street Ry. and Marlboro, Southboro & Framingham Street Ry., and run them in connection with the new line from Worcester to Boston.

MOBILE, ALA.—A franchise has been requested of the city council for a line which would make a complete belt around the city, by Messrs. D. R. Burgess, G. S. Ohear, W. H. Mackintosh, G. B. Thamer and Jos. C. Rich.

MONMOUTH, ILL.—The street car company of Monmouth has authorized the statement that it will build an electric railway to Oquawka with branches to touch Kirkwood and Little York. Promoters of the Galesburg-Monmouth line say it is certain to be built. Both companies expect to have lines running next season.

MONTGOMERY CITY, MO.—The Montgomery City, Bellflower & Middletown Electric Railway Co. has been organized with a capital of $80,000, with John W. Schowengerdt as president, and Howard Ellis, secretary. The road is to be 22 miles long.

MT. PLEASANT, W. VA.—Right of way is being secured for the proposed electric railway between Mt. Pleasant and Bridgeport.

MUNCIE, IND.—The electric railway which is to run from Muncie to Hartford City and Dunkirk, passing through the smaller towns en route received its franchise to run through Muncie, November 6th. The franchise contains the provision that the company must be financially responsible for all damage to pipes resulting from electrolysis.

MUNCIE, IND.—Mr. Brownell, superintendent of the Muncie Interurban Railway Co., has accepted a franchise from the town of Dunkirk, which gives this company free use of the streets for 30 years. This is the last franchise necessary for the completion of the right of way of the road, which, when completed, will extend from Muncie to Hartford City. It is probable that work on the road will not begin before spring.

NASSAU, N. Y.—The Nassau Belt Line Traction Co. has applied to the Nassau County Board of Supervisors for a franchise to furnish electric railway connection to the villages in the town of Hempstead, from Mineola to Long Beach. Paul K. Ames, president.

NEW ALBANY, IND.—The construction of an electric line from this place to Paoli is being agitated. The citizens of Paoli held a public meeting recently and appointed a committee to confer with the New Albany Commercial club relative to devising ways and means to promote the enterprise. The proposed line is 42 miles long and passes through the towns of Mooresville, Galena, Greenville, Palmyro, Fredericksburg, Hardinsburg, Rego and Chambersburg.

NEW BRUNSWICK, B. C.—It is understood that work will be soon commenced on the proposed tramway station and shed for the British Columbia Electric Railway Co.

SHELBYVILLE, IND.—Chas. W. Taylor, promoter of the proposed electric railway between Indianapolis and this city, has asked the city council for a 50-year franchise. Mr. Taylor says the road will be built whether the franchise is granted or not, as a private right of way has been secured along the north side of the city. The line will run from Indianapolis to Bethel and Acton, and will then parallel the Big Four R. R. The money has been secured and work will begin in the spring.

NORTHAMPTON, MASS.—The Northampton & Amherst Street Railway Co. will extend its line from Hatfield to Greenfield, the projected route involving the construction of a bridge.

NORTH ADAMS, MASS.—It is reported that C. F. Richmond, a millionaire banker, and owner of the Hoosick Electric Ry., of North Adams, Mass., is one of the principals in a movement for an electric railway system to be constructed to connect Troy with Grafton, Petersburg and Williamtown, Mass.

OSHKOSH, WIS.—It is reported that preliminary steps have been taken towards the construction of an electric interurban road between Oshkosh and Omro and the intermediate towns. It will be under the control of the Citizens Traction Co., of Oshkosh, which operates the Oshkosh-Meenah interurban line.

OTTAWA, ONT.—The Ottawa Car Co. has purchased a property on Albert St. for the purpose of building an extension to its car shops.

PERU, IND.—Aaron N. Dukes, of Peru, has purchased 30 miles of the line of the old Wabash and Erie canal between Lagro and Fort Wayne, which purchase will complete his control of the entire line from Lafayette to Fort Wayne, a distance of 108 miles. A new interurban electric railway will be built upon the property.

PHILAEDELPHIA, PA.—The Union Traction Co. has secured a franchise to build the Germantown & Fairmount Park R. R. between Manayunk and Germantown. J. B. Parsons, president and manager, Philadelphia.

PINE BLUFF, ARK.—M. Roberts and John Georgian, of Independence, Mo., have offered to construct an electric street railway, also a lighting plant, at Pine Bluff, on certain conditions. It is probable that the charter will be granted.
