Perpetuity: a future contingent interest in property, real or personal, which is not to become a vested interest until a period so remote as to be obnoxious to law. The term is also, though improperly, employed to describe any future estate, whether vested or contingent, in which the absolute power of alienation is suspended for an improper length of time. It is in the latter sense that the term is used in New York and some other States. In the former sense, the Rule against Perpetuities is a rule against remoteness; in the latter, it is a rule against restraining alienation.

The prohibition of perpetuities was only one of a number of devices adopted at various times by the courts of common law, to restrain within reasonable limits the control of the living by the dead; to limit the power of the present owner to control the enjoyment and disposition of his property by those who should come after him. The English doctrine of tenures and estates in land, whereby a man might create any number of future interests to be enjoyed in succession, apparently opened the way for an indefinite control of property by the present owner; and the feudal notion of family permanence, fostered under the influence of Primogeniture (*q. v.*), was a powerful incentive to the great landowners, to avail themselves of this opportunity. The history of our law of property is in large measure a record of a long warfare between the landlords, assisted by Parliament, on the one side, attempting to make good this posthumous control of their property, and the lawyers, backed up by the courts, on the other side, forever attempting to set the present owner free from such posthumous control. In this contest the courts were finally successful, and the Rule against Perpetuities is one of the monuments of their success.

When this rule was devised, the efforts of the landowners to "tie up" their estates for their remote posterity had already been checked in other directions. Estates tail had been rendered alienable, and the creation of contingent remainders had been restrained by the artificial rule which forbade the limitation of "a possibility upon a possibility"—as, for example, a gift to the offspring of an unborn person. There remained only those future estates known as executory uses and devises, and it was to meet the abuse of these limitations that the Rule against Perpetuities was adopted. It provided that all limitations of estates by way of springing or shifting use or executory devise must take effect within the period of a life or lives in being at the time of creating the limitations and twenty-one years afterward. Thus A may, by his will, give his property to his son, B, for his life, and then to his grandson, C, for *his* life, and then (if C has been born when the will takes effect, at the death of A) to the eldest son of C, when such eldest son shall attain the age of twenty-one years. Here the estate must finally vest within twenty-one years after the extinction of the two lives, B and C, both of which are in being at the time when the will takes effect. It is therefore within the rule. On the other hand, if an estate be given to A, a bachelor, for life, and after his death to his eldest son, when the latter shall marry, the latter limitation is void under the rule. A's son may not marry until more than twenty-one years after the death of A; and the circumstance that he does in fact marry within that period will not alter the case, as the validity of the gift is not determined by the actual event but by the possibilities of the situation at the time of the original limitation. If there is a possibility that the future estate may not vest within the period prescribed by the rule the limitation of that estate is void from the beginning.

In this form the rule is in force to-day in England, and generally wherever the common-law system of England prevails. In only a few of the U. S. has it been modified in any important respects. In New York and three or four other States, however, the common-law rule has been completely changed by statute, and converted into a rule forbidding the suspension of the absolute power of alienation for a longer period than two (or more) lives in being at the time of the limitation. In most of those States (though not in New York) the further period of twenty-one years allowed by the English rule may also be added.

For a fuller treatment of the subject, see Prof. Gray's *Rule against Perpetuities.* George W. Kirchwey.

Perpignan, pār'pēēn'yaăn': capital of the department of Pyrénées-Orientales, France; on the Tet, 7 miles from the Mediterranean (see map of France, ref. 9–F). It is a fortress of first rank, and commands the passage between France and Spain. It has a cathedral and a Moorish-Gothic bourse dating from the fourteenth century, a college, a palace of justice, distilleries, bell-foundries, and manufactures of leather, cork, and woolen fabrics, and an active trade in oil, wine, grain, silk, and fruits. Perpignan belonged to Aragon from 1172 to 1475, when it was taken by France. It was given to Spain in 1493, but retaken by France in 1642. Pop. (1896) 35,088.

Perrault, pā'rō', Charles: author; b. in Paris, France, Jan. 12, 1628; studied at the Collège de Beauvais, but left it in a moment of irritation and with a comrade finished his studies without instructors. He prepared for the bar by a rapid reading of the *Institutes* of Justinian, but did not practice long; became next clerk for his brother and cultivated letters. His verse won him some reputation and an election to the Academy (1671), and he found a protector in Colbert, whom he aided in the foundation of the Academy of Arts and who advanced him to the head of the bureau of royal buildings. In 1687 he read before the Academy a poem entitled *Le Siècle de Louis le Grand*, praising modern writers at the expense of the ancients, and this offended the admirers of antiquity and precipitated the quarrel of the "ancients and moderns." To this quarrel he owed his chief notoriety, being severely attacked by Boileau. His position was more fully stated in the *Parallèle des anciens et des modernes* (1688–96), a series of dialogues comparing Homer and Vergil with the French poets. Of more permanent value are the notices of men of letters composing the series *Les Hommes illustres qui ont paru en France pendant ce siècle* (1696–1701), and especially the volume of fairy stories, *Contes de ma mère l'Oye* (1697), containing *Cinderella*, *Blue Beard*, and others, by which alone he still remains popular. D. May 16, 1703. He left *Mémoires*, which were published in 1749, and two comedies. His *Œuvres Choisies* were published by Collin de Plancy (Paris, 1826); the *Contes* by Lefèvre (Paris, 1875). A. G. Canfield.

Perron, Anquetil, du: See Anquetil du Perron.

Perrone, per-rō'nā, Giovanni, D. D.: theologian; b. at Chieri, Piedmont, 1794; studied at Turin; entered the Society of Jesus at an early age; taught at Orvieto; spent

most of his life at Rome as professor of theology; taught at the Roman college till 1853; visited England during the Roman revolution of 1848–49; d. at Rome, Aug. 29, 1876. He exercised considerable influence on Catholic theology in the first half of the nineteenth century, and his lectures at Rome were followed by numerous students from both sides of the ocean. He had a large share in the preparation of the papal bull that defined the Immaculate Conception, and in the preliminary labors for the Vatican Council. He was also a consultor of several Roman congregations, theologian to a number of cardinals, etc. His best-known work is the *Prælectiones Theologicæ* (9 vols., 1835 ff.), which contains the summary of his professorial teaching. It had reached its fortieth edition at his death, and the *Compendium* of the same work, equally successful, is yet much used. His other writings are chiefly polemical. The best of them is his *Protestantism and the Rule of Faith* (3 vols.). As a theologian he represents the positive doctrinal and the polemical element, as distinguished from the historical and the metaphysical school. JOHN J. KEANE.

Perrot, pā′rō′, GEORGES: archæologist; b. at Villeneuve-Saint-Georges, department of Seine-et-Oise, France, Nov. 12, 1832; studied from 1855 to 1858 at the French school in Athens; made in 1861 a journey of exploration in Asia Minor; dwelt for some time at Ancyra investigating the famous inscription on the temple which the Galatians built there in honor of Augustus; became Professor of Rhetoric in the Lyceum Louis le Grand, Paris, in 1863; Professor of Greek Language and Literature in the higher normal school in 1872; Professor of Archæology in the Faculty of Letters in 1877; appointed director of the higher normal school in 1883; wrote *Exploration archéologique de la Galatie et de la Bithynie* (Paris, 1863–72); *Souvenirs d'un voyage en Asie Mineure* (1864); *Essai sur le droit public et privé de la république athénienne* (1867); and other works, and with C. Chipiez, *Histoire de l'art dans l'antiquité* (5 vols., 1881–89).

Perry: city; Dallas co., Ia. (for location, see map of Iowa, ref. 5–F); near the Raccoon river; on the Chi., Mil. and St. P. and the Chi., Rock Is. and Pac. railways; 34 miles N. W. of Des Moines. It is in an agricultural and coal region, and contains 7 churches, 3 public-school buildings, a business college, water and electric-light plants, a national bank with capital of $50,000, a State bank with capital of $50,000, and a semi-weekly and 3 weekly newspapers. Pop. (1880) 952; (1890) 2,880; (1900) 3,986.
EDITOR OF "CHIEF."

Perry: village (incorporated in 1814); Wyoming co., N. Y. (for location, see map of New York, ref. 5–D); at the outlet of Silver Lake; on the Silver Lake Railway; 40 miles S. S. W. of Rochester. There are 7 churches, united free academy and union school, a national bank with capital of $50,000, a State bank with capital of $50,000, a school library, a weekly newspaper, and salt and reaper works and a knitting-mill. The lake affords good power for manufacturing. The Silver Lake Assembly, a noted summer resort with over 200 cottages and a population of more than 2,000 in the height of the season, is 2 miles from the village. Pop. (1890) 1,528; (1900) 2,763. EDITOR OF "HERALD."

Perry: city (settled in 1893); capital of Noble co., Okl.; on the Atch., Top. and S. Fé Railroad; 30 miles N. of Guthrie, 60 miles S. of the Kansas border (for location, see map of Oklahoma, ref. 2–D). It contains a U. S. land-office, several churches, public and private schools, a board of trade, a State bank, 2 private banks, and 3 daily and 3 weekly newspapers. It has a large general trade, as nearly all settlers within a circle of 50 miles do their outfitting here. Pop. (1900) 3,351.

Perry, ARTHUR LATHAM: economist; b. at Lyme, N. H., Feb. 27, 1830; graduated at Williams College 1852; became Professor of History and Political Economy there in 1854, and in 1875 pastor of a church at Williamstown. He wrote *The Elements of Political Economy* (1865), an exponent of free-trade doctrines; *Introduction to Political Economy* (1877); and *Williamstown and Williams College.*

Perry, EDWARD DELAVAN: Sanskrit scholar; b. at Troy, N. Y., Dec. 20, 1854; educated at Columbia College, and at the Universities of Leipzig and Tübingen; successively tutor in Greek, instructor in Sanskrit, and Professor of Sanskrit in Columbia College. His chief works are *Indra in the Rigveda* (in *Journal American Oriental Society*, vol. xi.), and *A Sanskrit Primer* (1885; 2d ed. 1886). B. I. W.

Perry, ENOCH WOOD: See the Appendix.

Perry, MATTHEW CALBRAITH: commodore; b. at Newport, R. I., Apr. 10, 1794. Known as an upright and energetic naval officer, he was intrusted by President Fillmore in 1853 with a letter to the ruler of Japan, its object being to establish international relations, especially with the view of protecting shipwrecked mariners. By an employment of the "gunboat policy," but happily without having to resort to actual bloodshed, he induced the frightened Japanese to sign their first foreign treaty at Kanagawa Mar. 1, 1854. Shimoda and Hakodate were opened to trade with the U. S., and good treatment was promised to shipwrecked crews. Perry died in New York, Mar. 4, 1858. See Perry and Hanks, *Narrative of the Expedition of an American Squadron under Commodore Perry*, and Griffis, *Matthew Calbraith Perry* (Boston, 1887). J. M. DIXON.

Perry, NORA: poet; b. at Dudley, Mass., in 1841. She was Boston correspondent of *The Chicago Tribune* and of *The Providence Journal*, and published *After the Ball and Other Poems* (1875); *Book of Love Stories* (1881); *For a Woman*, a novel (1885); *New Songs and Ballads* (1886); and other works. D. May 13, 1896. H. A. B.

Perry, OLIVER HAZARD: naval officer; b. at South Kingston, R. I., Aug. 23, 1785; entered the U. S. navy as midshipman, Apr. 7, 1799; cruised with his father, a naval officer, in the West Indies 1799–1800; was engaged in the war against Tripoli 1804–05; became lieutenant Jan. 15, 1807, and at the outbreak of the war of 1812 was in command of a flotilla of gunboats on the Atlantic coast, when in Feb., 1813, he was transferred at his own request to serve under Commodore Isaac Chauncey on Lake Ontario. He took an active part in the attack upon Fort George; was appointed to fit out a squadron upon Lake Erie, which he successfully accomplished at Presque Isle (now Erie), Pa.; and having equipped nine small vessels, attacked and captured the British fleet near Put-in-Bay, O., Sept. 10, 1813. This action, known as the "battle of Lake Erie," or more commonly as "Perry's victory," obtained him an immense popularity, partly attributable to the sententious manner in which it was announced by the famous dispatch, "We have met the enemy, and they are ours." Congress rewarded him with a vote of thanks, a medal, and the rank of captain. Perry co-operated with Gen. Harrison in his operations at Detroit and at the battle of the Thames, Oct. 5, 1813, and in the following year was employed upon the Potomac and in the defense of Baltimore. He commanded the Java in Decatur's squadron in the Mediterranean 1815; was sent to the Spanish Main in command of a squadron, June, 1819; ascended the Orinoco to Angostura in July; was seized with yellow fever, and died at Port Spain, on the island of Trinidad, the day of his arrival there, Aug. 23, 1819. His remains were removed to Newport in a ship of war by order of Congress, and buried in the cemetery of that city, Dec. 4, 1826, where an imposing obelisk was erected by the State of Rhode Island. In Sept., 1860, a marble statue of Commodore Perry was erected at Cleveland, O., and on Sept. 10, 1885, a fine bronze statue was unveiled at Newport, R. I. See the *Life*, by Capt. Alexander S. Mackenzie (2 vols., New York, 1843).

Perry, THOMAS SERGEANT: critic; b. at Newport, R. I., Jan. 23, 1845; graduated at Harvard in 1866 and was for some years instructor there in English and German. He has resided much abroad, and has studied at French and German universities. His writings are mainly contributions to literary history, biography, and criticism, and include *Life and Letters of Francis Lieber* (Boston, 1882); *English Literature in the Eighteenth Century* (New York, 1883); *From Opitz to Lessing* (Boston, 1885); *The Evolution of the Snob* (1887); from 1872 to 1874 he edited the *North American Review.* H. A. BEERS.

Perry, WILLIAM STEVENS, D. D. (Oxon.), LL. D., D. C. L: bishop; b. in Providence, R. I., Jan. 22, 1832; graduated at Harvard College in 1854; studied at the Virginia Theological Seminary and privately in Boston, preparatory for orders; ordained deacon in Mar., 1857, at Newton, Mass.; priest in Boston, Apr. 7, 1858; was rector of churches in Nashua, N. H., Portland, Me., Litchfield, Conn., and Geneva, N. Y., 1858–76; was Professor of History in Hobart College, Geneva, N. Y., 1871–73, and president of that institution for a few months in 1876. He was unanimously elected Bishop of Iowa in May, 1876, and was consecrated to the episcopacy in Trinity church, Geneva, Sept. 10; refused the bishopric of Nova Scotia in 1887. He was for nearly twenty years occupied in general church work in addition to his

parochial labors. He was deputy from New Hampshire in 1859; from Maine in 1862; assistant secretary to the House of Deputies in 1862; secretary in 1862–74; was appointed historiographer of the American Church in 1868, and retained that position until his death, in Dubuque, Ia., May 13, 1898. He declined the foreign secretaryship of the board of missions in 1876; also the presidency of Kenyon College. Besides degrees received from seven institutions of learning in the U. S. and Canada, he received that of D. D. Oxon., at the encenia of the University of Oxford. In 1894 he received the degree of LL. D. from the University of Dublin. His writings, chiefly historical, number more than one hundred. Among them are *Journals of the General Conventions of the Protestant Episcopal Church* (Philadelphia, 1861) and *Documentary History of the Protestant Episcopal Church in the United States of America* (2 vols., New York, 1863–64), in which he was aided by Dr. Francis L. Hawks; *Historical Collections of the American Colonial Church* (1871–78); *Some Summer Days Abroad* (Davenport, Ia., 1880); *The History of the American Episcopal Church, 1587–1883* (2 vols., Boston, 1885); *Life Lessons from the Book of Proverbs* (4th ed. 1885). He was an associate editor of *Johnson's Universal Cyclopædia*. S. R. J. Hoyt.

Seph'one, or **Proserpina** (in Gr. Περσεφόνη, Κόρη): in Grecian mythology, a daughter of Zeus and Demeter, the wife of Hades. Along with Hades she ruled over the shades of the dead and the monsters of the lower world, and listened to the curses of men. When, as a maiden, she was gathering flowers near Enna, in Sicily, she was seized by Hades with the consent of Zeus and carried in his chariot to the realm of the dead. In pity for the grief of Demeter (see Ceres), who vainly sought her daughter the world over, Zeus sent Hermes to bring Persephone back; but as she had tasted a pomegranate (the symbol of marriage), offered to her by Hades, it was decreed by Zeus that she should remain one half of the year with Hades and the other half with Demeter. Persephone is thus the symbol of life and death in the vegetable kingdom, and because the decay and death of the corn must precede a new and more fruitful life, she became in the Eleusinian Mysteries (*q. v.*) the symbol of the immortality of the soul. For a discussion of Persephone in art, see the article *Demeter und Kora* in Baumeister's *Denkmäler*. J. R. S. Sterrett.

Persep'olis: the Greek name of the ancient capital of Persia, whose Persian name is not known. It stood in a vast and fertile plain (now called Merdusht), 35 miles N. E. of Shiraz, near the Medus (now Polwár), about 14 miles above its confluence with the Araxes (now Bendemir). Of the age and history of the city very little is known. It was not the residence of Cyrus, who had his palace at Pasargada, unless this be the same city, as assumed by some antiquarians; but Xerxes, Darius Hystaspes, and others of the Achæmenidæ resided here, and in their time the city was known to the Greeks as a wonder of splendor and magnificence. It was said to be completely destroyed by Alexander the Great, and it is mentioned in history only once afterward, when Antiochus Epiphanes visited it for the sake of plunder (2 Macc. ix. 1). Of the city itself no traces can now be found, though it is probable that it occupied the same site as afterward the Mohammedan fortress Iṣṭakhr; but of the palaces some very interesting ruins are still extant, known by their local name, *Chehel Minár* (Forty Columns), or Hall of Xerxes. They consist of a stupendous substructure of cyclopean masonry, forming a platform about 1,500 feet long, about 800 feet wide, and divided into three terraces, to which magnificent flights of stairs give access. Of the buildings, a magnificently sculptured staircase, the entrance to a propylæum, and a number of columns, 60 feet high, are still standing. See Fergusson's *Palaces of Nineveh and Persepolis Restored*; Rawlinson's *Five Great Monarchies*; and *Persepolis* (Berlin, 1882), by Stolze and Noldeke.

Per'seus (in Gr. Περσεύς): in Grecian mythology, the son of Zeus and Danaë, daughter of Acrisius, King of Argos; was driven into exile together with his mother, and educated in Seriphos, one of the Cyclades; conquered Medusa, by the aid of Hermes and Athene, and cut off her head; returned after many adventures to Argos, from which Acrisius fled to Thessaly; settled afterward at Tiryns and founded Midea and Mycenæ. In ancient art he is represented as similar to Hermes. See Andromeda, Grææ, Gorgon, and Pegasus.
Revised by J. R. S. Sterrett.

Perseus: the last king of the Macedonians; son of Philip V.; b. about 212 B. C.; succeeded to the throne in 179 B. C., and confirmed the treaty which his father had made with the Romans. After a preparation of seven years he commenced war against Rome with an excellent army, a full treasury, and important alliances. P. Licinius Crassus, the consul, was sent against him, but was defeated, and the Romans were generally unfortunate throughout the war. Perseus, however, lacked the energy to follow up his victories and the war dragged on for several years without decisive result. At last, L. Paulus Æmilius was sent as commander-in-chief to the theater of war. He arrived in March, began active operations in June, and finished the war, after a campaign of thirteen days, by the battle of Pydna, 168 B. C. The Macedonian army, although fighting with great valor, was completely routed, and Perseus fled with his money-chest to Samothrace. He was afterward delivered up to the Romans, and held in captivity at Alba, in Italy, where he died a few years later. F. M. Colby.

Persia [= Lat., from Gr. Περσίς, from O. Pers. *Pārsa* (> Pers. *Fars*, or *Pārs*), a province of Persia]: a country of Western Asia, called by the natives Eron or Iran. It lies between lat. 25° and 39° 45′ N. and between lon. 44° and 63° 20′ E. By the Treaty of Turkomanchai the boundary between Russia and Persia, W. of the Caspian Sea, follows the bed of the river Araxes, from near Little Ararat to lon. 48° E.; thence southward the line has an irregular course to the Caspian near Astara. By the same treaty Persia renounced her right to float ships of war on that sea, thus virtually making the southern shore of the Caspian a boundary. The river Atak (Etrek) and the Domine Kuh, by acknowledgment of Russia, form the boundary on the N. E. The border-line of Afghanistan and Baluchistan was long a matter of dispute, but the question was referred to Great Britain for arbitration, and, after surveys, a decision and settlement was made by which Seistan proper and part of Baluchistan were given to Persia. The Arabian Sea, the Gulf of Ormuz, and the Persian Gulf give a continuous seacoast to Persia on the S. The boundary between Persia and Turkey was unsettled until 1880, when Turkey accepted the decision of a commission which had been appointed by Great Britain and Russia, and had made extensive surveys. The area of Persia has been estimated at 640,000 sq. miles. The greatest extent from N. to S. is 973 miles, and from E. to W. about 1,042.

Physical Features.—The topographical outline is that of a vast plateau surrounded by mountain ranges. The plateau consists of elevated plains separated from one another by mountain spurs and ridges. The central portions are the most elevated, where the plain of Hamadan attains an altitude of 6,000 feet above the level of the ocean. Ispahan, Shiraz, Tabriz, and Oroomiah (Urumeyah), towns widely separated, have each an altitude of 4,200 feet, and Teheran 3,500 feet. The great ranges of mountains on the N. are the network of the Kara Dag and the Elbruz. The latter rises near the steppe of Mogan, and in a well-defined range follows the contour of the southwestern shore of the Caspian and thence pursues an eastward course through Northern Persia. On the E. are the Domine Kuh, the Shamshire, and the chain extending southward from near Mashhad. The Cotrells are rugged cliffs near the Persian Gulf, cut and worn by the drainage of the great plateau. In the S. E. the Zagros, in many parallel ranges, run diagonally S. by E. from the mountains of Kurdistan, which form a rugged border on the N. W. The highest peaks are Damavand, the cone of an extinct volcano, 18,600 feet above sea-level; Savalan, 11,000 feet; Sahund, 10,000 feet; and Elvand, 9,500 feet. There are no great rivers in Persia. The Kizil Uzen, or Safeed, in the N., the Zanda Rud in the interior, and the Karun and Khirkah in the S. W., are small rivers, but are the chief streams of the country. The Euphrates, the Araxes, and the Helmund are rivers of the border. Many streams flow from the mountains to the desert of Khorassan, where they form kabeers or salt marshes, and disappear in the hot season. The only inland seas worthy of note are the Shahee Sea (Lake Urumeyah) in the N. W., and Niris and Mahala Seas in Farsistan. Nearly all the interior of Persia is described as desert, but nearly every part of the land, except Khorassan and Kerman, is so inhabited that the term desert applies properly to parts of those provinces only. The desert of Khorassan is 200 by 400 miles in extent.

Geology and Mineral Products.—The most common rocks are trap, shale, and limestone in nearly vertical strata. The beds of the valleys are to a great depth composed of gravel and clay and loam. Bituminous coal is found in the Elbruz

Mountains, and mines of it are worked near Casveen and Damavand. White and green marble are found in Khorassan; sulphur on Damavand; lead at Bast; gold near Nikpey; and iron and copper ores in several places. Rock salt and gypsum are abundant. The turquoise mines of Madan, near Nishapur, have been long considered the best mines of that gem.

The climate is distinguished by dryness, except along the seacoast, where moisture is excessive, by equability, salubrity, and heat. The greatest degree of cold on the plain of Teheran is 8° to 10° F. The cold of the northern sections is intense in winter on the elevated plains, and on the mountains. Malaria is excessive in widely irrigated sections and where drainage is deficient. The prevalent diseases are malarial fevers, typhoid, pneumonia, ophthalmia, and cutaneous diseases. Smallpox and measles are seldom of a malignant type.

Soil and Products.—The soil of the plains is a loam very fertile when irrigated. The northern slopes of the Elbruz are covered with pine, spruce, and olives; the lowlands on the border of the Caspian are noted for dense growth of forest, in which the oak, sycamore, boxwood, orange, and sugar-cane abound. Date-palms grow in the southern sections. In the interior the vine, pomegranate, mulberry, fig and olive trees flourish, also the peach, apple, quince, and other fruit-trees. The desert blossoms in many places with the poppy and rose. The chief agricultural crops are wheat, barley, rice, hay, cotton, tobacco, opium, and a great variety of cucurbitaceous and leguminous plants.

The fauna is much the same as that of Southern Europe, but the lion is found in the S., and the tiger and leopard in the N., and wild asses frequent the desert. Domestic animals include the camel (in all sections), horse, ass, and buffalo. Of the birds, besides those commonly found in like latitudes, may be mentioned the flamingo, stork, and nightingale. Brook trout abound in the mountain streams and salmon in the waters of the Caspian coast. Vipers, scorpions, tarantulas, and centipedes are numerous.

Population.—The people of Persia are of many races, Iranian, Turkish, Kurd, Arabic, Armenian, and Hebrew. The dominant races, however, are the Iranian or Persian and the Turkish, the latter of many tribes. The population was estimated in 1872 at 5,000,000; in 1881 at 7,653,600; in 1891 at 9,000,000; in 1894 at 10,000,000. In the absence of any census, for none is ever taken by the Government, these estimates are only approximate. The people are chiefly occupied in agricultural and pastoral pursuits, though a few are engaged in manufacturing woolen, silk, and cotton fabrics. Many are soldiers, but few are engaged in maritime pursuits. A large part of the population is nomadic, and robberies and insurrections are frequent.

Political and Administrative Divisions.—No survey and accurate territorial division has ever been made. The country has through many ages been divided into several great provinces, but these are not now necessarily administrative divisions. They are Khorassan (202,872 sq. miles, including Seistan), Astrabad (28,980), Mazanderan (9,660), Gilan (4,830), Azerbaijan (38,641), Irak-Ajemi (94,182, including Ardelan), Luristan (19,253), Khuzistan (28,981), Fars (57,963), Laristan (19,321), and Kerman (135,317, including Kohistan and Mekran). A subdivision of provinces is into mahäls, formed by grouping together villages or tribes. The administrative divisions are changed often to suit local interests or the wish of a governor.

Principal Cities.—These are Teheran (pop. estimated at 210,000), Tabriz (180,000), Mashhad or Meshed (60,000), Ispahan, Kashan, and Barfurush (each about 50,000), Kerman, Yezd, and Casveen or Kasbin (each about 40,000), and Hamadan, Shiraz, Kom, Bushire, and Resht (each from 25,000 to 30,000).

Education.—There is, strictly speaking, no educational system. Private schools are formed by the mollahs (priests) for teaching the Koran and writing. There are schools for the education of mollahs, usually built and sustained by a patron. The shah sustains a college in Teheran where students are taught, in part, the curriculum of European schools, and receive an allowance of clothing and funds.

Religion.—The national religion is Mohammedanism, of that branch of the Sheahs known as Athna Ashara, or the *Twelve*, but there are many other sects. Of non-Mohammedans there are Jews, Armenians, Guebers, and Nestorians, in regard to the number of whom no two authorities agree. Missions in Persia are sustained by the American Presbyterians, Church of England, and Roman Catholics. The religious and social customs are intimately connected—religion is associated, in form at least, with every phase of life. Each sect has its own social laws and customs. All have in common certain customs distinguished as Oriental; these, however, are being modified by the introduction of European civilization and manners. The chief national observances are the mourning of Moharram, the fast of Ramazan, and the feast of No Ruz, or the New Year's Day of the secular and solar year. Both the Mohammedan era and the era of Yezdegird are observed.

Government.—This is an absolute monarchy. The reigning monarch, called shah, is Nasr-ed-din, who ascended the throne soon after the death of his father, on Oct. 20, 1848. He is assisted by a privy council, appointed and dismissed at his own pleasure. There is no representation of the people. The affairs of the general Government are supervised by a number of ministers, and departments of state are created and abolished at the shah's pleasure, and are constantly changing in number. The most permanent heads of departments are Ministers of the Interior or Finance, of War, of Foreign Affairs, and of Public Works, and Master of the Mint. The office of Prime Minister is periodically created and as frequently abolished. The governors, called *hoikim*, are appointed by the shah, as are many of his subordinates. Mollahs may exercise the judicial function, and their court is termed Sharah, or religious law. The Imäm Jumah and Sheik ul Islam are appointed by the shah under honorary titles, but they have no authority over other mollahs, except in their own mosques. The standing army is formed in general, as far as possible, on the European system of organization, and officers of the Austrian, French, and other armies are employed as drill-masters or commanders. Theoretically, the number of troops is 100,000, but it is rarely the case that the regiments have their complements. Arms are repaired and manufactured in Teheran, but most of the equipments are imported.

Finance.—The chief sources of revenue are the taxes—paid in money or produce—rents, presents, and customs. The tables or statistics of revenue are deficient in omitting known sources of income; also imperfect by reason of reckoning some of the income of districts separately, and also in the totals of provinces. In the course of fifteen years the maximum of revenue was £1,950,000, and the minimum £1,368,000. Under ordinary conditions the income slightly exceeds expenditures. The money of the country until 1889 was gold and silver only. At that date a bank was authorized by the shah. It now has branches in the principal cities and issues paper money.

Trade and Commerce.—The exports are wheat, cotton, tobacco, rice, opium, fruit, oil (olive), wood, wool, hides, silk, and carpets. The imports are chiefly cotton and woolen goods, tea, coffee, sugar, petroleum, and notions. The great routes of traffic and communication are, in the north, the caravan road viâ Mashhad, Teheran and Tabriz, thence to Erzeroum, and N. from Tabriz to Tiflis; the route from Resht on the Caspian viâ Teheran, Kom, Kashan, Ispahan, and Shiraz to Bushire on the Persian Gulf. Another route is from Mohammerah, at the head of the Persian Gulf, to Teheran viâ the Karun river. A route pursued by the pilgrims is from Teheran to Bagdad. The only wagon roads are from Teheran to Kom, and from Teheran to Casveen. Concessions have been made from time to time by the shah for the construction of a railway from Resht to Teheran, but though offered to companies to be formed under British, French, Austrian, or American auspices, no one has ventured to prosecute the plan. A company is (1894) undertaking the work under Russian protection. There is a railway 12 miles long (with extensions) from Teheran to the village of Shah Abd al Azim.

History.—A sketch of the early history of Iran is given in the article IRANIANS (*q. v.*). Since the Mohammedan conquest in the seventh century the Persians have been governed almost wholly by alien dynasties—Ommyiad, Abbassid, Ghiznevid, Mogul, Timurid, Suffavean, and others. During this period the boundaries of Persia were often changed. It was sometimes a province of a larger empire, and sometimes divided between two or more independent states. The present (Kajar) dynasty began with Aga-Mohammed, a eunuch, in 1795. His nephew, Fath-Ali, lost in wars with Russia the provinces of Georgia, Armenia, and Erivan. Mohammed Shah, the next ruler, failed to regain Herat on account of the resistance of Great Britain. Nasr-ed-din, the present shah, also failed for the same reason, but succeeded in extending his territories to the S. E. During his reign Eu-

ropean improvements have been introduced to some extent. See Parsees, Mohammedan Art, Persian Language, etc.

Bishop's *Journeys in Persia and Kurdistan* (2 vols., New York and London, 1891). For Persian history, see Sir John Malcolm's *History of Persia* (2 vols., 1815); the histories by R. G. Watson and Clements Markham; Rawlinson, *The Seventh Great Oriental Monarchy* (1876); Nöldeke's *Aufsätze zur Persischen Geschichte* (1887); Gutschmid's *Geschichte Irans* (1887). James Bassett.

Persian Berries: See French Berries.

Persian Gulf: an inlet of the Arabian Sea through the Gulf of Oman and the Strait of Ormuz, and between Arabia and Persia. It is 650 miles long, 250 miles broad, receives the water of the Shat-el-Arab, and contains many islands, most of which are barren and desolate. The pearl-fisheries along the Arabian coast are celebrated.

Persian Inscriptions: See Persian Language and Cuneiform Inscriptions.

Persian Insect Powder: See Feverfew.

Persian Language: in its broadest sense, the speech of the greater part of Iran from the period of the Achæmenian kings, five centuries before the Christian era, down to the present time. When no qualification is added, Persian is usually employed to designate simply the modern speech. Three stages in the history of the language may be recognized: (1) The language of the Old Persian inscriptions, (2) Middle Persian or Pahlavī, (3) Modern Persian.

1. *Old Persian inscriptions* (b. c. 521–335) are the great monuments of the Achæmenian dynasty preserved in cuneiform rock-cuttings, tablets, on vases and on some seals. These records are the oldest remains of the language of Western Persia, and they present an Iranian tongue closely allied to the idiom of the Avesta (*q. v.*). The closeness of the relationship may be illustrated by such a sentence as this in Old Persian: *þātiy Dārayavauš ḫšayaþiya, ima tya adam akunavam vašnā Auramazdāha āha*, which would be represented in Avestan by *saŋhaiti Dārayaţvaŋhuš ḫšaþryō, imaţ yaţ azəm akərənaom vasna Ahurahe Mazdāo aŋhaţ*—"saith Darius the king: that which I have done was accomplished by the grace of Ahura Mazda." In its phonology the ancient Persian is characterized by a tendency to drop final consonants, e. g. Old P. *abara*, Av. *abaraţ*, Skt. *ábharat*, Gr. ἐφερε (τ), he bore, Old P. nom. sing. *puþra*, Av. *puþrō*, Skr. *putrá-s*, son; most of the phonetic features resemble the Avesta. (See Iranian Languages.) The declensional system is like the Avestan and the Sanskrit, though less complete; the dative, for example, is missing in Old Persian, the genitive having to assume its functions; in syntax the Old Persian is somewhat less perfect than the two languages mentioned.

The ancient Persian inscriptions are written in wedge-shaped characters. The oldest and most important monument is the noble rock-record of the great deeds of Darius, an inscription of a thousand lines engraven on the side of a mountain which rises 1,700 feet above the plane at Behistan, near Ecbatana. This record is inscribed in three languages: (1) In Old Persian, (2) in a language variously designated as Scythian, Median, or better New-Susian, and (3) in Assyrian. There are also tablets and inscriptions at Persepolis, Van, Susa, and elsewhere in Persia, preserving briefer memorials of Cyrus, Xerxes, and Artaxerxes; but the later monuments, especially those of the last Artaxerxes (Ochus), b. c. 335, show distinct signs of a decadence of the ancient speech. On the deciphering of the Old Persian inscriptions, see Grotefend.

2. *Middle Persian or Pahlavī.*—After the fall of the Achæmenidæ and the triumphant invasion of Alexander the Great there follow five centuries during which Iran was under the dominion of the Seleucidæ and of the Parthian Arsacids. From this period we have no literary remains of the Persian language other than a few names or words preserved on coins or in some similar manner. Toward the close of the Parthian sway and on the rise of the Sassanian dynasty (a. d. 226) the national spirit of Persia revived and there succeeded a period from the third to the seventh century of our era during which the Persian is represented by the Pahlavī with its literature of no inconsiderable extent. (See Pahlavī.) This period shows a form of language much worn down as compared with the ancient Persian, and characterized by a very considerable infusion of Semitic (Aramaic) words; the presence of this foreign element is more apparent than real, as discussed in the article Pahlavī (*q. v.*). The stage of the language during the Sassanian period is nearer the Modern Persian than it is the ancient Persian.

3. *New or Modern Persian.*—The Mohammedan conquest of Iran in the seventh century was linguistically to Persia what the Norman conquest was to the English speech. The decay of the inflectional side of the tongue was still further hastened, and there was a large influx of Arabic words which tended to increase rather than to decrease with time. The oldest form of the Modern Persian is represented by Firdausī (*q. v.*), the tenth century epic poet. The native purism of Firdausī in his *Shāh Nāmah* is not kept up in later writers, yet, in spite of the Semitic admixture of Arabic elements, Modern Persian has remained a true Iranian speech, just as much as English has remained true Germanic. The language has not preserved any more of its inflections than has the modern English, consequently Modern Persian in its syntax has passed from the synthetic stage of the inscriptions into that of an analytic speech. In phonetics a marked change from the Old Persian tongue may be noticed, e. g. Old P. *puþra-*, Pahl. *pusar*, Mod. P. *pusar*, boy; Av. *mahrka-*, Pahl. *mark*, Mod. P. *marg*, death; Old P. *naiba-*, Pahl. *nēvak*, Mod. P. *nēk*, beautiful; Av. *Vəhrka-* (cf. Old P. *varkāna-*, Hyrcania), Pahl. *gurg*, Mod. P. *gurg*.

The alphabet employed in writing Modern Persian (the *ta'lik* character) is a modification of the Arabic script (*neškhi*); there is current also a more running style of handwriting known as *šikastah*. The modern vernacular of Persia shows a number of dialects, among which is the antique Darī dialect, still preserved by the Zoroastrian guebers of Iran. (See Parsees.) Consult also Cuneiform Inscriptions, Pahlavī, and Iranian Languages and Literature.

Bibliography.—On the Old Persian inscriptions, consult Rawlinson's *Cuneiform Inscriptions* (in the *Royal Asiatic Society's Journal*, London, 1846); Spiegel, *Die altpersischen Keilinschriften* (Leipzig, 1881); Weisbach and Bang, *Die altpersischen Keilinschriften* (Leipzig, 1893–). (For references to Pahlavī, see under that language.) Modern Persian grammars are by Lumsden (Calcutta, 1820); Sir William Jones (ed. Lee, London, 1828); Chodzko (Paris, 1852); Vullers (Giessen, 1870); Fleischer (Leipzig, 1875); and Salemann and Shukowski, *Persische Grammatik* (Berlin, 1889). Dictionaries are: Richardson, *Persian and Arabic Dictionary* (London, 1852); Vullers, *Lexicon Persico-Latinum* (Bonn, 1855–64); Palmer, *Concise Dictionary, Persian-English English-Persian* (London, 1875); Steingass, *Persian-English Dictionary* (London, 1892); and Horn, *Grundriss der Neuperischen Etymologie* (Strassburg, 1893). On the dialects, consult Browne, *A Year among the Persians* (London, 1892), pp. 187, 388, where bibliography is given. In Geiger and Kuhn's *Grundriss d. iran. Philologie* (Strassburg) Shukowski is to treat the subject of Modern Persian dialects. A. V. Williams Jackson.

Persian Literature: in the broader sense, all literary records, monuments, and writings of Iran from the earliest times to the present; the more ancient forms of the literature are discussed under Avesta, Pahlavī, and Persian Language. In the more usual and restricted sense Persian literature in its modern form may be said to date from about the ninth century of our era, although the real beginning is to be sought earlier, as there was no actual severing of the link between Pahlavī and Modern Persian by the Mohammedan conquest of Iran.

Modern Persian literature can justly boast of having fine examples of the epic and lyric poetry, of the romantic, the satiric, and of mystic poetry; the drama, however, is practically wanting, being a growth of the nineteenth century. As to the real origin of the national poetry of Persia, we are in uncertainty; the invention of metre and rhyme is attributed by legend to the popular Sassanian monarch Bahrām Gōr, or Bahrām V. (a. d. 420–439). Almost all modern Persian literature, even history, as in the case of the Arabs also, is written in verse.

Modern Persian Historical Literature.—For the history not only of Persia, but of the whole Eastern world, Persian literature possesses the amplest materials. Under the monarchs of the Sassanian dynasty (beginning 226 a. d.) materials had been collected for a history of Persia, and Yezdigird I. early in the fifth century ordered an abstract of them

to be made. This was translated from the Pahlavī, and continued by later princes up to the account of the Mohammedan conquest. From these old records the poet Firdausī (b. 940 A. D.; d. 1020) composed the *Shāh-Nāmah* or Book of Kings, for the conqueror Mahmūd of Ghazni. This is a magnificent epic of 60,000 couplets, embracing the whole of the legendary history of Persia from the remotest times until the death of Yezdigird. See FIRDAUSĪ.

The oldest of the prose historians is Tabarī (b. 838 A. D.; d. 922), who wrote a history of Persia down to the times of the khalifate. His work has been translated for the Oriental Translation Fund. (*Chronique d'Abou Djafar Muhammed Tabari*, by Zotenberg, Paris, 1867–74.) The book was originally written in Arabic, but only the Persian version of it exists in a complete state. In the fourteenth century Yahya ibn Abd-ul-latif, Cazwini (d. 1351 A. D.), published a comprehensive general history entitled *Lubb-et-tawarikh*, or Pith of History. Mohammed ibn Khavand-shāh Mirkhond (b. 1433; d. 1498 A. D.) was author of the *Rauzat us Safa* (Meadow of Purity), a history of Persia from the Creation to A. D. 1471. (See MIRKHOND.) His grandson, Khavandamir, who was attached to the court of Bāber soon after the invasion of India (1528), wrote an abridgment of this work under the title *Khulasat el Akhbar* (Abstract of Information). It is in ten books, and is an excellent epitome of Eastern history. The *Habib us Siyar* (Biographer's Friend) is another esteemed historical work by the same author. There is a very excellent history of Persia, written about 1300 A. D. by Wassāf of Shīrāz; an account of it is given by Sir Gore Ouseley in his *Notices of Persian Poets* (Oriental Translation Fund, London, 1846), where, among other extracts from the work (p. 232), he gives a story which is the exact counterpart of the well-known English legend of Whittington and his cat. Besides these general histories, there are a great many histories of particular reigns and periods.

All these are purely Persian works, but there is in addition a large number of works written in that language in India, and relating for the most part to the affairs of that country. Of these, the most important are the *Ayin i Akbari* (Institutes of Akbar the Great, Emperor of Hindustan); *Tarikh i Ferishta*, a general history of India by Muhammed Kasim Hindu Shah (d. about 1612 A. D.), who was surnamed Ferishta, ed. by Gen. Briggs (2 vols., Bombay, 1831), translated by A. Dow (London, 1770–72), and by Gen. Briggs (4 vols., London, 1829); and the *Siyar ul Mutaakkherin* (Modern Biography), a history of India down to recent times (Eng. trans. by Gholam Hossein, 3 vols., Calcutta, 1789, and by J. Briggs, London, 1832). A complete account of the native historians of Persia is given in *A Descriptive Catalogue of the Historical Manuscripts in the Arabic and Persian Languages preserved in the Library of the Royal Asiatic Society of Great Britain and Ireland*, by W. H. Morley (London, 1854).

Poetry.—Of the various forms of Persian poetry the most important are—(1) the *Masnavī* (rhyming couplets), which answer to our own "heroics," epic, narrative, and didactic pieces being generally written in this meter. (2) The *Ghazal* (ode). These are for the most part ostensibly anacreontic songs, love and wine being the constant theme, but they are really highly metaphorical religious writings, expounding the peculiar theosophic views of the most extraordinary sect the East has ever produced, the Sūfī dervishes. (3) The *Kasīdah* (idyl), which is generally employed in panegyric. Among the principal poets of Persia is Rūdagī. He lived in the reign of Nasr, grandson of Ismael Samani, founder of the Samany dynasty (about 940). He was born blind, but wrote magnificent lyrics, some few of which have come down to us. (See RŪDAGĪ.) Firdausī has already been mentioned in the account of the historians. In addition to his great work, the Shāh-Nāmah, he wrote a bitter satire on his ungrateful master, Mahmūd, which is usually prefixed to the epic itself, and a poem entitled *Yūsūf u Zuleïkha* (The Loves of Joseph and Potiphar's Wife), a favorite subject with the Persian bards. (See FIRDAUSĪ.) One of the most original and extraordinary poets of Persia was Omar Khayyām (d. 1123). He was a great astronomer and mathematician, and to him we owe the work called *Aljebr u el Mukabileh*, on the science which still bears the name "algebra" which he gave it. His poems consist entirely of *rubāiyat*, or quatrains. They breathe a spirit of advanced free thought, which sometimes, indeed, verges on atheism; but they have at the same time a strange admixture of refined sentiment, philosophical cynicism, and manly feeling which makes them unlike any other composition of the kind. (See OMAR KHAYYĀM.) Omar Khayyām in his youth was an intimate friend of Hasan Sabah, the original "Old Man of the Mountain" and founder of the celebrated sect of Hashashin or Assassins. Auhad-ud-dīn Anvarī (d. about 1200) attracted the notice of Sultan Sanjar, the sixth of the Seljukian dynasty. He was an astrologer as well as poet, but having predicted a terrific storm on the occasion of the conjunction of the seven planets in Libra (Sept. 16, 1186), and failed signally, he relinquished the former profession. His principal works are *Kasīdahs* (odes), which enjoy even now a great reputation in Persia. They are full of fine and even sublime conceptions, nervous and elegant language, and original conceits. The whole *dīvān* or "collected works" of Anvarī were lithographed at Tabriz during the reign of Nasr-ed-dīn. (See ANVARĪ.) Sa'dī Muslih-ud-dīn of Shīrāz (b. about 1184 A. D.; d. 1291–92 A. D.), next to Hāfiz enjoys the greatest reputation of any Persian poet. He is a master of elegant style, and many of his works are marked by a very high tone of moral sentiment. That by which he is best known in Europe is the *Gulistān* (Rose-garden), a beautiful collection of moral stories in prose and verse. Mention should also be made of his *Būstān* (Fruit-garden.) (See SA'DĪ.) Ferīd-ud-dīn Attār (d. at a very advanced age 1230 A. D.) was an eminent Sūfī and poet. His principal work is a collection of tales and parables in verse entitled *Mantik ut Tair* (The Language of Birds).

Abū Mohammad ibn Yūsuf, generally ealled Shaikh Nizāmī of Ganjah (d. 1203 A. D.), wrote a *Khamsah*—i. e. a collection of five didactic poems embodying Sūfiistic doctrines. Of these the most celebrated are perhaps the *Laila u Majnūn*, an Arabian love-story, and the *Sikandar-Nāmah* (History of Alexander the Great). Nizāmī's style is terse and rather difficult, but at the same time very forcible. Few poets contain more subtle thoughts and pregnant expressions; and while other Persian poets generally err on the side of verbiage and prolixity, Nizāmī frequently falls into the opposite extreme. Besides the five poems above mentioned, Nizāmī wrote a *dīvān*, or collection of odes, elegies, etc. (See NIZĀMĪ.) Maulavi Rumi, Jelāl-ud-dīn Rūmī, the founder of the sect of Mevlavī dervishes (b. 1207; d. 1273), is the great exponent of the mystic doctrines of the Sūfīs. He was a contemporary of Sa'di, the author of the *Gulistān*. His immortal work, the *Masnavī*, consists of six long books in rhyming couplets. It contains a complete exposition of the Sūfī doctrines, and forms a perfect *répertoire* of all the tales, legends, fables, and apologues current in the East. This narrative portion of the work is written in a lively, unaffected style, but the long speculative digressions, to which the stories serve merely as introductions, though instructive and often beautiful, are somewhat tedious to a European reader. So highly is the book esteemed throughout the Mohammedan world that it has acquired the title of the *Koran of Persia*. In addition to the *Masnavī*, Jelāl-ud-dīn wrote a *dīvān* of beautiful lyrics. The collection of Maulavi Rumi's minor poems is generally known in India by the name of *Kulliyat Shems Tabriz*, Shems Tabriz being his *takhallus* or *nom de plume*. (See RŪMĪ.) To the fourteenth century belongs the famous lyrical poet Hāfiz, or Shams-ud-dīn Mohammed, of Shīrāz. His poems for the most part are short odes, or *ghazals*, and the collection of these, under the title *Dīvān i Hāfiz*, is the best known in literature. His death occurred in 1388. (See HĀFIZ.) Jāmī (b. 1414 A. D.; d. 1492 A. D.) wrote a *Khamsah* in imitation of Nizāmi, including a *Sikandar Nāmah*, a History of Alexander the Great, and *Yūsuf u Zuleïkha*, a subject also treated by Firdausī; it is by the last-named poem that he is best known. Jāmī also published a *dīvān* of lyrical odes. His poetry is much more light and elegant in character, and more full of feeling, than Nizāmī's, but it lacks the stately grandeur and profound thought which distinguish the latter. (See JĀMĪ.) Hatifi (d. about 1520 A. D.) was a nephew and pupil of Jāmī, and wrote many beautiful poems, among them one entitled *Laila u Majnūn*, which has been edited by Sir William Jones (Calcutta, 1787); his works gave promise of peculiar excellence, but he died prematurely. Khāḳānī, Afzal-ud-dīn Ibrahim (d. 1199 A. D.), was perhaps the most forcible writer in the Persian language, and his poetry is distinguished by a peculiar loftiness of thought and sublimity of style. He is best known by his odes and satires, and by a charming poem containing an account of the countries through which he passed on his way to Mecca, and called *Tuh fat ul Irāḳain* (A Present from Persian and Arabian Irak). Amir Khosru of Dehli (b. 1253 A. D.; d. 1324 A. D.) was of Tartar origin, be-

ing sprung from the tribe of Hazara Lachin, near Balkh. He went to Hindustan, and settled at Puttiala, near Dehli, where, thanks to the influence of his father-in-law, he obtained an important post at the court of Tughlak Shah in Dehli. He was a very voluminous writer, and his poetry is marked by great wit and exuberance of fancy. He is best known by five Sūfiistic romances after the model of the *Khamsah* of Nizāmī. We must not omit to mention the wild and stirring improvisations of the robber-poet Kurroglou, who flourished about the middle of the seventeenth century, and who, although writing in a half-Turkish *patois*, may yet be considered as a representative of the rustic muse of Persia. The reign of Nasr-ed-dīn produced a poet of no mean pretensions, Hakim Kaani, poet-laureate to the shah. His poems have been printed at the imperial press at Teheran, and form a large folio volume. Kaani has an astonishing command of language and rhythm, and while following closely the ancient traditions of Persian poetry as to the form, he has not disdained to infuse into his works a spice of modern learning which imparts a novel and pleasing character to his style. There is an immense crowd of minor poets in the ranks of Persian versifiers, but those mentioned above are the most important ones.

The aim of the Oriental poets is not, as with our own, to discover and produce new conceits and new trains of thought. Indeed, the introduction of an entirely novel and original simile is considered rather a breach of good taste than otherwise. Upon the other hand, the wealth of the language enables them to clothe a single idea in an almost infinite variety of forms of expression, and it is in this direction that their ingenuity and invention are exercised. In order, then, to become able to read any fresh poet with ease, it is necessary for the learner to adopt the native method, and make himself perfectly acquainted with all the minutiæ of the works of *one* of the standard classical writers, and this will give him a ready key to all the rest. Dr. A. Sprenger's *Catalogue of the Arabic, Persian, and Hindustany MSS. in the Library of the King of Oudh* (vol. i., Calcutta, 1854), and Rieu's *Catalogue of the Persian MSS. in the British Museum* (3 vols., London, 1879–83), contain short biographical notices and accounts of the works of all the principal Persian poets.

Ethics, Science, Fiction, and Miscellaneous Works.—The number of these works which Persian literature contains is so numerous that it would require a large volume to give anything like an adequate account of them. The modern Persians, like other Oriental nations, have been stimulated into intellectual activity in recent times by their increased communications with the West, and the result has been that a number of useful works on educational and scientific subjects have been translated from the various European languages. The old standard authors, however, still hold their ground, and are studied with as much ardor as ever. The most esteemed and best-known miscellaneous works are *Akhlak i Jelali*, a treatise on Persian moral philosophy, by Jelāl-ud-dīn, translated by W. F. Thompson (1839); the *Akhlak i Muhsini*, by Hussein Vā'iz Kāshifī (translated by Keene, Hertford, 1852), another much esteemed work on the same subject, the *Gulistān* of Sa'dī, already mentioned in the notices of poetical works; the *Anwar i Suheili*, the Persian version of the fables of Bidpai, by Hussein Vā'iz Kāshifī; the *Dabistān i Mazahib*, by Muhsin Fani, an interesting account of the rise, progress, and doctrines of various religious sects throughout the East. It contains, among others, a history of the ancient religion of Persia, of Hinduism, and of the different sects of Mohammedanism (translated by Shea and Troyer, Paris, 1843). The *Behāristān*, or Spring Garden, of Jāmī, is a charming collection of tales, anecdotes, and aphorisms, and contains, besides, short biographies of twenty-eight of the principal poets of Persia. One of the most interesting works in Persian is the *Tezkerah i Ahuara*, or Memoirs of the Poets, by Daulat Shah, who finished it about 1486 A. D. It is divided into a preface and nine chapters, each chapter containing biographies of about twenty poets, written in a most entertaining style, with extracts from and criticisms upon their works. It is also filled with historical details of great interest and importance, and displays great research and critical acumen in its compilation. It forms the groundwork of von Hammer's *Geschichte der schönen Redekünste Persiens.* E. H. Palmer.
Revised by A. V. Williams Jackson.

Persigny, pār'sēn'yee', Jean Gilbert Victor Fialin, Duc de: statesman; b. at St.-Germain-Lespinasse, Loire, France, Jan. 11, 1808; entered the army, but was discharged in 1830 on account of insubordination; became a contributor to the *Temps*; founded in 1834 *L'Occident français*, a Bonapartist organ; became very intimate with Louis Napoleon; took part in the affair of Strassburg, from which he escaped, and about which he wrote *Relation de l'Entreprise du Prince Napoléon-Louis* (London, 1837); took part also in the descent on Boulogne, where he was captured and imprisoned for several years, during which time he wrote *Utilité des pyramides d'Égypte* (1844), a rather singular performance, in which he tried to demonstrate that those gigantic structures had been reared in order to defend the Nile valley against the sand-flights; was restored to liberty by the Revolution of 1848, and at once set himself to work in the interest of Napoleon, who, on becoming president, appointed Persigny his aide-de-camp. In 1849 he was elected a member of the Legislative Assembly; played an important part in the *coup d'état* of 1851, and was Minister of the Interior from Jan., 1852, to Apr., 1854, and again from Nov., 1860, to June, 1863, having in the interval been ambassador to Great Britain. He was created a duke in 1863. D. at Nice, Jan. 13, 1872. The letters on public affairs which he now and then published are believed to have been inspired by Napoleon himself. See Delaroa's *Le Duc de Persigny et les Doctrines de l'Empire*, 1865, and Delord's *Histoire du Second Empire*, 1868–75. F. M. Colby.

Persim'mon [from Virginia Ind. name]: a tree of the U. S., the *Diospyros virginiana*, of the order *Ebenaceæ*, and its fruit. The common persimmon-tree has a fruit which is excessively astringent until over-ripe, but after hard frosts have brought it to the verge of decay it is a very sweet and agreeable fruit. The wood is used for last-making and other turnery. The kaki or Japanese persimmon (*D. kaki*) is the leading fruit-tree of Japan. It is now planted in California and the southern parts of the U. S. in many varieties, and its fruit is becoming of importance. See Diospyros. Revised by L. H. Bailey.

Per'sius, Aulus Persius Flaccus: satirist; b. at Volaterræ, in Etruria, Dec. 4, 34 A. D., of a rich equestrian family; received a careful education in the schools of Rome; became a pupil of Cornutus the Stoic; moved in the most elegant circles of the capital; was acquainted with Lucan and Seneca. D. Nov. 24, 62. Six satires by him, comprising 650 hexameter lines, are extant, edited by Jahn in 1843 and by Heinrich in 1844; and it is probable that he wrote no more, and even left these in an unfinished state, as he wrote seldom and slowly. They were edited after his death by his friend the poet Cæsius Bassus, to whom the sixth satire is addressed. In antiquity these satires were read and appreciated more than any other production of Latin literature; they were studied and quoted, not only by the pagan authors, but also by the Christian Fathers, such as Augustine, Lactantius, and Hieronymus. In the darkest periods of the Dark Ages they were still read, and their present standing is indicated by the circumstance that there are fourteen English and twenty French translations of them. They are, nevertheless, not easy to understand. The language is obscure and pedantic, the metaphors often grotesque, the connection of ideas difficult to follow. Much is borrowed from Lucilius and Horace, and there is a constant straining after novel and piquant effects. On a more intimate acquaintance, however, a pure, enthusiastic, and earnest soul reveals itself, which, feeling itself fettered by the corruption and depravity of the age, fights the foe as best it can. There are later editions, with English commentary, by Gildersleeve (New York, 1875) and by Conington with an English translation (3d ed. revised by Nettleship, Oxford, 1893); revised text with Juvenal, by Bücheler (Berlin, 1893). Revised by M. Warren.

Personal Equation: See Equation, Personal.

Personal Property: See Property.

Person and Personality [*person* is viâ O. Fr. from Lat. *perso'na*, theater-mask, part (in a play), personage, person; loan-word from Gr. *πρόσωπον*, mask, face, adapted to presumed etymology of *per*, through + *sona're*, sound (i. e. speak)]: the word person is still sometimes used to denote the corporeal appearance of a man rather than his inner attributes, as when we say that he possesses an agreeable person, or is personally repulsive. Later, the relations that a man might sustain in the world as a "personage," *personam agens*, or *gerens*, became prominent, and later still the spiritual functions became the essential content of the notion. In common parlance to-day "person" means an individual

man in his typical completeness as uniting a human body to a free and rational soul. From this point of view personality has been denied to pure spirits and to the souls of the departed awaiting the resurrection, because they are bodiless; also to idiots because they are irrational; to maniacs because they are not free; and to animals, however intelligent, because they are not human. By emphasizing one feature of the conception or another, psychology, ethics, law, and theology have all developed the conception of personality in different ways.

In psychology "personality" designates individuality, or what is called "personal identity," and various opinions have been held concerning the foundations of this. It is either an ultimate and self-subsistent principle at the core of a man, or it is a result derived from other principles. Already in Hindu philosophy we have this opposition in the contrast between the Sankhya system, with its absolute plurality or independent finite souls, and the Vedanta system, for which there exists only one self, the supreme Drahman, with whom all particular selves (Atman) are really coidentical, but (until they are redeemed by knowledge) dwell in the illusion of finite personality through not distinguishing themselves from the organisms with which they are severally conjoined. These organisms have their psychic as well as their physical side. Their grosser body is resolved at death into its elements, but a finer body, together with the senses and active powers, the *manas*, or organ of consciousness and will, the breath, and the *karma*, or moral worth acquired, form principles of continued individuality which ever enter into other bodies, so that through an indefinite series of transmigrations the finite personal life is kept up. The *modern theosophists'* doctrine of personality is derived from the Vedantic system.

Among the Jews the spiritual principle of personality was the "spirit" (*Ruach*) or warm breath of life which animated the dust, when breathed thereinto by Jehovah. This breath-spirit, which we find as the ruling conception in all primitive thought, maintains its place in both Greek and Christian philosophy, developing into the more physiological conception of "animal spirits" on the one hand, and into the Pauline doctrine of the "Spirit," or *pneuma*, on the other. The animal spirits filling the arteries, nerve-tubes, and brain cavities were supposed to mediate between the rational soul and the body; the theological "spirit" mediates between God and the soul or *psyche*.

In the Greek philosophy, passing over the confused utterances of the pre-Socratic masters, we find the *pneuma* or fiery air-current to play a great part in the systems of the *Stoics*. Being of a nature both material and immaterial, it was well calculated to serve as the animating principle of the world at large as well as of the individual person in it. *Plato and Aristotle* subordinated the principle of the breath to the immaterial and rational *psyche*. In Plato we find the germ of later spiritualistic conceptions of personality. The man is composed of two almost hostile principles, of which the soul is the one that is essential, being superior to Nature, pre-existing to the body, and possessing an immortal destiny to be attained by a course of rational and moral development. The body here is the soul's vessel or prison, and, although its necessary servant, is also the source of its errors and faults. This dualistic view was in Aristotle's psychology developed into that wonderful conception of soul as "form" and body as "matter" which dominated all Christian philosophy until the time of Descartes. For Aristotle the person is this organic unity of form and matter, this animated body in its completeness, this subject of biology and psychology in one; and nutrition becomes a function of the soul as much as thinking is. *Scholastic peripateticism* here, as elsewhere, elaborated the Aristotelian ideas into greater hardness and articulateness. Soul and body, separately taken, are incomplete substances. Only their union is a concretely *subsistent* substance, *suppositum* or *hypostasis*; and since in the case of the human soul the nature of the substance is rational, the *suppositum rationale* thus composed is what is meant by *person*. *Individua substantia naturæ rationalis* is the definition of "a person," often quoted from Boethius.

It is not till Descartes's time that we find consummated with perfect sharpness the distinction, now so familiar to us, of Consciousness and the Unconscious. In the Cartesian philosophy the Conscious and the Extended, having absolutely nothing in common with each other, were raised to the rank of two mutually exclusive substances, and the commerce of soul and body in the human person, mediated for Descartes himself by the animal spirits, had to be carried on for Malebranche and other Cartesians by a perpetual miracle of "divine assistance." The person was thus broken in two, or rather became a purely spiritual entity, while the rest of nature, including the body, was materialistically treated. In Cartesianism, however, as in Peripateticism, the finite souls still constitute a multitude of distinct substances, and are not, as with Spinoza, lost in the one substance of God. Personal identity, in a word, is *real* —a principle, not a result.

In Locke's *Essay Concerning Human Understanding* the great revolution toward empiricism begins. Personality is now explained as a result, and not assumed as a principle. It is not something which, by simply being, gives rise to consequences, but something which is made from moment to moment by a cause which can be assigned. Locke believes, indeed, in souls as substances and in their identity; but the mere ontological self-identity of such a soul would, he says, make no *personal* identity unless a recollecting consciousness were joined thereto. "Consciousness" is what makes a *person*, when it remembers past experiences, as having been also its own. If the same consciousness with its memories could migrate from one soul to another, we should have personal identity without identity of substance. And conversely, if one man were to have distinct incommunicable consciousness at different times, he would make different persons. As personality is annexed to consciousness, so punishment ought to be annexed to personality, and in the great day, wherein the secrets of all hearts are laid open, no one should be made to answer for what he knows nothing of, but should receive his doom, his conscience accusing or excusing. The importance of Locke's doctrine lay in this, that he eliminated "substantial" identity as transcendental and unimportant, and made of "personal" identity (the only practically important sort) a directly verifiable empirical phenomenon. Where not actually experienced, it *is* not. Hume went beyond Locke in discarding substances, whether spiritual or material altogether. Our sense of *gradual* change in the succession of our particular "ideas," in which "there is properly no simplicity at one time nor identity in different," is what Hume means by our personal identity. Locke's and Hume's views have been carried out both in Germany and England by the *associationist psychology*, which in consequence has been dubbed a "psychology without a soul."

Since Kant's time the consciousness of subjection to moral law, and the autonomy and freedom implied by such a consciousness, have often been referred to as the specific marks of personality. On this view "person" means a being with inner ideal ends, to which it freely acknowledges responsibility. Here the psychological notion passes over into the ethical and juridical conceptions of personality.

Recent psychology has, in the main, elaborated itself on Lockian lines. The succession of associated ideas inwardly held together by memory is regarded by all schools to constitute the content of the *empirical self*. For some writers these ideas themselves are compounds of simpler psychic units, so that the psychic person is a purely secondary result, with no special principle of unity. Others contend for such a primordial principle, either in the shape of a real spiritual being or soul, which owns the ideas, or in that of a "transcendental Ego" which performs their synthesis.

Multiple Personality.—That something beyond the mere contemporaneous connection of many ideas with one organism is needed to make one personal consciousness result, is shown by certain phenomena which psychologists are but just beginning to study with care. In a variety of ways one and the same "man" may successively or simultaneously have different consciousnesses that are, in Locke's words, incommunicable. The most familiar cases of this are ordinary forgetfulness, absence of mind, and rapid oblivescence of dreams, where subsequent recollection proves the apparently lost ideas to have been there all the time. In somnambulism, either natural or "hypnotic," the rule is for the subject to forget on waking all that he has done, but to remember it again on re-entering the somnambulistic state. He may thus live two alternating personal lives with a distinct system of memory in each. It was first proved by Edmund Gurney that the memories of the hypnotic consciousness may coexist, after waking, with the normal consciousness of the subject, but be unknown to the latter. Taking subjects to whom it had been "suggested" in trance that they must perform certain acts after waking when a signal should be given (see HYPNOTISM), but whose waking

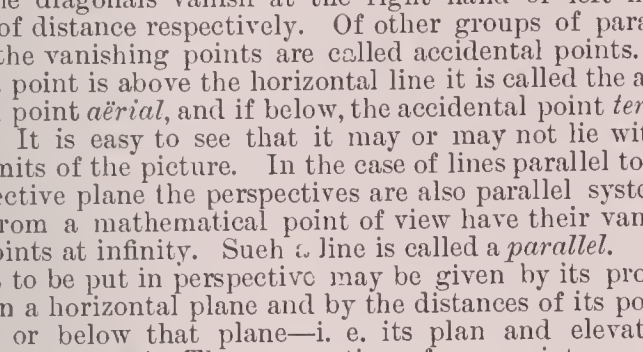
consciousness ignored the suggestion, he set their hands, when they woke, upon a *planchette* and got the order automatically and "unconsciously" written, while their normal consciousness was occupied in reading aloud, or in conversation. At about the same time Janet, Binet, and others found phenomena in connection with the anæsthetic surfaces of hysteric patients, which proved the anæsthesia to be relative only to the subject's principal consciousness, another consciousness appearing present which took cognizance of the apparently lost sensations. Thus one patient's anæsthetic hand can feel her toilet articles and handle them skillfully; in others, if the attention be distracted, the anæsthetic hand adapts its movements to objects that are placed in it, as scissors, matches, etc. Or if figures be traced on the anæsthetic palm, the patient will *see* them, vicariously, as it were; but the chief proof, as with Gurney, is by automatic writing. Janet used what he calls the "method of distraction" in these cases. In this the patient is kept absorbed in conversation with a third party, while the operator, approaching her quietly, whispers questions in her ear. The consciousness engaged in talking ignores the questions, but, if a pencil be placed in the hand, answers to them are automatically written. It is as if one consciousness animated the speaking mouth and another the writing hand, both, however, using the ear. Myers has given the name of *subliminal selves* to consciousnesses supernumerary to the principal one; and Janet and others have found that painful reminiscences split off from the principal consciousness, persisting thus subliminally and revealing themselves in the hypnotic trance, are prime factors of the hysteric condition. Cases of *alternating personality*, in which the man or woman passes at intervals into a "second" state with its own peculiarities, of which the normal state, when resumed, knows nothing, have been recorded at great length. "Léonie," "Felida X.," "Lurancy Vennum," "Ansel Bourne," and "Louis V.," may be named as types. In the last-named case there were as many as five different personalities with exclusive systems of memory and peculiarities both of bodily sensibility and character. A very large number of men and women can readily become *automatic* writers, either with *planchette* or pencil. The writing hand becomes sometimes anæsthetic, sometimes not; and there are all degrees of detachment of the principal consciousness from what is written. In no case, however, is the subject's "will" felt to be concerned. These writings tend in most cases to assume the character of messages from spirits who sign their names; and in its most developed degree automatic writing passes into *mediumistic trance* and may be succeeded by "*speaking under control*." Here again there are degrees; but the medium's normal consciousness usually remembers nothing of the trance-utterances, which may assume a character very unlike the medium's own. (See SPIRITUALISM.) The phenomena of *demoniacal possession*, so rife in ancient times and in primitive societies, seems to be essentially the same thing as our trance-mediumship, obeying, however, a different inspiration as regards its moral content. In both phenomena the "attacks" are short, no memory of them remains, and the patient between them is well. The subjects have nothing in common with the insane, technically so called.

All these facts have brought the question of what is the unifying principle in personality to the front again. It is certain that one human body may be the home of many *consciousnesses*, and thus, in Locke's sense, of many *persons*; but much in the temperament of the secondary persons seems unaccountable if they are only accidental improvisations, produced by certain groups of the patient's "ideas" separating from the rest and leading a quasi-independent life. They have a generic similarity in many cases, as in automatic writing and trance-speaking, which suggests some common cause as yet imperfectly known, or at any rate a context which if explored might make the phenomena, with their peculiar regularity, appear more rational. It is clear already that the margins and outskirts of what we take to be our personality extend into unknown regions. Cures and organic effects, such as blisters, produced by hypnotic suggestion show this as regards our bodily processes; while the utterances of mediums and automatic writers reveal a widespread tendency, in men and women otherwise sane, to personifications of a determinate kind; and these again, though usually flimsy and incoherent in the extreme, do, as the present writer believes, occasionally show a knowledge of facts not possessed by the primary person. The significance and limits of these phenomena have yet to be understood, and psychology is but just beginning to recognize this investigation as an urgent task.

BIBLIOGRAPHY.—For opinions before Locke see all the histories of philosophy, especially Siebeck's *Gesch. d. Psychologie*; and for Hindu ideas, see Deussen's *System des Vedanta*. Locke's statements are in book II., chap. xxvii. of his *Essay*; Hume's in part iv., § vi. of his *Treatise on Human Nature*. In modern psychology Ladd's *Physiological Psychology*, part iii., and James's *Principles of Psychology*, chap. x., may be referred to, the one defending a Real Being as the principle of personal unity, the other placing it in the function of memory. General defenses of the spiritual view are A. W. Momerie's book *Personality*, and F. A. Shoup's *Mechanism and Personality*. The theosophic doctrine is conveniently expressed in Blavatsky's *Key to Theosophy, passim*. Binet's *Altérations de la Personnalité* and various essays by Myers in the *Proceedings of the Society for Psychical Research* give the facts of multiple personality in much detail. WILLIAM JAMES.

Perspec'tive [from Lat. *perspi'cere*, look through; *per*, through + *spi'cere*, look]: the art of representing an object upon a plane surface, so that the representation shall exhibit the same appearance as the object itself. To conceive what is meant by the perspective of an object, imagine a transparent plane to be placed between the eye and the object, and let straight lines be drawn from every point of the object to the eye. Each of these lines will intersect the transparent plane in a point; and if each small area determined by an assemblage of such points is properly tinted, the resulting picture will present the same appearance as the object itself. The art of perspective is thus divided into two parts: (1) the correct delineation of the lines of the object, (2) the proper shading and coloring of the picture, so as to produce the desired effect of distance and tint. The first, which alone is considered here, is called *linear perspective*, and the second *aërial perspective*. The importance of attending to perspective becomes apparent if we consider the appearances presented by objects under certain conditions. For instance, two parallel rows of objects of equal size, if seen from a point midway between the rows, seem to converge as well as to grow smaller and smaller; and a circle, if seen obliquely, appears to be an ellipse. In what follows we suppose the perspective drawing to be made upon a vertical plane between the eye and the object. This plane is called the perspective plane, and any object lying on the same side as the eye is said to be in front of the perspective plane, and any object lying on the other side is said to be behind. The lines that are drawn from the different points of the object to the eye are called *visual rays*; all the visual rays that are drawn from a right line or from a curve in a plane passing through the eye make up a *visual* plane; and all the visual rays that are drawn from any other curve make up a visual cone. The art of linear perspective consists in passing visual planes and visual cones through the principal lines of the object, and finding their intersections with the perspective plane. The method of proceeding depends upon a few simple principles of geometry, of which the following are most frequently used: (1) If two lines are drawn through any point of an object their perspectives intersect, and the point of intersection is the perspective of the given point; (2) if visual planes are passed through any number of parallel lines of the object, they intersect each other in a visual ray parallel to the given lines, and the point in which this ray intersects the perspective plane is a point, called the vanishing point, common to the perspectives of all the given lines. If the perspective plane were made of glass, a sketch made on it by following with a pencil all the lines and shades of the objects seen by the observer would give a representation in absolute perspective; but this method is not practicable for various reasons. A series of rules, founded on observation and experience, has been formed by which painters are enabled to copy nature faithfully. After the objects to be introduced into the picture and the distance from which they are to be viewed have been determined, it is necessary to draw certain lines upon the perspective plane, (1) the *base line*—that is, the base line of the sketch—which is the boundary nearest the observer of the objects to be represented; (2) the *horizontal line*, representing the ordinary position of the horizon. It is supposed to be level with the observer's eye. When the latter is on a level with the horizon it is generally drawn at a height of about one-third of the entire height of the picture, but it will rise together with an increase in the elevation of the observer; (3) the *vertical*

line; it is perpendicular to both the other lines and meets the horizontal line in the *point of sight*. This point is generally placed so as to be the center of the picture—that is, on a line half way between the two sides. All lines in nature perpendicular to the perspective plane, called *perpendiculars*, are represented by lines intersecting in the point of sight, which is thus their vanishing point. The points of distance are two points on the horizontal line, twice as far apart as the eye is from the picture; they are equidistant from the point of sight when the horizontal lines, called *diagonals*, of which they are the vanishing points, are inclined to the base line at an angle of 45°. As a visual ray parallel to a system of diagonals inclines to the right or the left, the diagonals vanish at the right hand or left hand point of distance respectively. Of other groups of parallel lines the vanishing points are called accidental points. If such a point is above the horizontal line it is called the accidental point *aërial*, and if below, the accidental point *terrestrial*. It is easy to see that it may or may not lie within the limits of the picture. In the case of lines parallel to the perspective plane the perspectives are also parallel systems, and from a mathematical point of view have their vanishing points at infinity. Such a line is called a *parallel*. The object to be put in perspective may be given by its projection on a horizontal plane and by the distances of its points above or below that plane—i. e. its plan and elevation. (See PROJECTION.) The perspective of any point may be most easily determined as the intersection of the perspectives of a diagonal and a perpendicular passing through the point; and the perspective of the shadow of a point upon a horizontal plane may be determined as the intersection of the perspectives of a ray of light passing through the point and of the projection of that ray upon the given plane. As an illustration, let us find the perspective of a cube and the perspective of the shadow which it casts on the horizontal plane of its base, the rays of light being parallel. Take the perspective plane through the front face of the cube, and let A B represent the intersection of the plane of the lower base of the cube with the perspective plane. Let C be the center of the picture, and let D C, parallel to A B, represent the horizon; also let D be the left-hand vanishing point of diagonals, R the vanishing point of rays of light, and R′ the vanishing point of horizontal projections of these rays; R′ is in a perpendicular through R to A B, and also in the line D C. Construct the square H L to represent the front face of the cube, and it will be its own perspective. The edges of the cube that pierce the perspective plane at H, K, L, and M are perpendiculars, and their indefinite perspectives may be found by drawing lines from these points to C. The diagonal through the upper left-hand vertex of the back face pierces the perspective plane at M and M D in its perspective; the point O in which M D cuts L C is therefore the perspective of this vertex. The edges of the cube parallel to L M and K H are parallel to the perspective plane, as are also the edges parallel to L K and M H, and consequently their perspectives are parallel to the lines themselves. Hence, if we draw O N and O P parallel to L M and L K, and then construct a square on these lines, it will be the perspective of the back face of the cube. The figure H O is then the required perspective of the given cube.



To find the perspective of its shadow on the horizontal plane A B, we draw M R, which will be the perspective of the ray of light through M, and H R′, which will be the perspective of the horizontal projection of that ray; the point S in which these lines intersect is the perspective of the shadow of the point M, and H S is the perspective of the shadow of H M. The shadow of the edge M N is a perpendicular; hence, we draw S C and N R, intersecting at Q; then is S Q the perspective of the shadow cast by M N. The shadow of N O is a parallel; hence, we draw Q T parallel to O N, and limited by a line from O to R; then is Q T the perspective of the shadow cast by N O. The line T P is the perspective of the shadow cast by the edge O P. The perspective of the shade and shadow of the cube, so far as they are visible, are indicated by the shaded part of the drawing. Revised by R. A. ROBERTS.

Perspiration: See SWEAT.

Per Stirpes: See DESCENT.

Perth: county-town of Perthshire, Scotland; at the foot of the Grampian Mountains, on the Tay; 43 miles N. N. W. of Edinburgh (see map of Scotland, ref. 10–H). It is a handsome city, with several fine buildings, including St. Ninian's Episcopal Cathedral and St. John's church, an old cruciform Decorated structure restored in 1891. The principal industries are dyeing, brewing, and manufactures of ink and linen. The salmon-fisheries are important. Pop. (1891) 30,525; (1901) 32,872

Perth: capital of the colony of Western Australia: on the Swan river, 12 miles above its mouth (see map of Australia, ref. 6–B). It is the financial center of the colony, and is connected by rail with Albany. The town was constituted a city in 1856, is the seat of Anglican and Roman Catholic bishoprics, and has a number of fine public buildings. Pop. (1892) 10,040.

Perth Amboy: city (incorporated in 1784); port of entry; Middlesex co., N. J. (for location, see map of New Jersey, ref. 4–D); at the mouth of Raritan river; on Raritan Bay, Staten Island Sound, and the Cent. of N. J., the Lehigh Valley, the Penn., and the Staten Island Rapid Transit railways; 21 miles S. W. of New York. It is in a fire-clay and kaolin region; has a large and excellent harbor; and contains 5 terra-cotta works, 2 large dry-docks, 4 machine-shops, iron-foundry, oil-refinery, chemical-works, emery-works, cork-factory, and immense coal and freight shipping dépôt and wharves of the Lehigh Valley Railroad. There are a Young Ladies' Seminary, a State bank with capital of $50,000, a savings-bank, and a daily and 3 weekly newspapers. Pop. (1880) 4,808; (1890) 9,512; (1900) 17,699.

EDITOR OF "MIDDLESEX COUNTY DEMOCRAT."

Perthshire: a central county of Scotland. Area, 2,528 sq. miles. It is greatly diversified by mountains, forests, valleys, rivers, and lakes. It is largely occupied by the Grampian Mountains, whose highest peak, Ben Lawers, rises 4,000 feet. Hardly a fifth of the surface is in tillage, the rest being pasture, woods, deer-forests, grouse-moors, etc. Pop. (1901) 123,255.

Per'tinax: a Roman of humble birth who rose to a position of the highest esteem in military and civil life during the reigns of Marcus Aurelius and Commodus. On the assassination of the latter he was chosen to succeed him as emperor, Dec. 31, 192 A. D., but was himself murdered less than three months later (Mar. 28, 193 A. D.).

G. L. H.

Perturbations [from Lat. *perturba'tio*, disturbance, deriv. of *perturba're*, disturb greatly; *per*, through, thoroughly + *turba're*, disturb]: deviations in the motion of a planet from its elliptic orbit, produced by the attraction of other planets upon it. Were a planet attracted by no body except the sun, it would, in accordance with Kepler's laws, describe an ellipse, having the sun in one of its foci. In consequence of the attraction of other planets, every planet deviates from such an ellipse, and these deviations are called perturbations. Periodic perturbations are those which, in the long run, tend to compensate each other. Secular perturbations are those changes in the form of the orbit which go on in the same direction from century to century. The mathematical theory of perturbation forms the most difficult subject in astronomy, and has taxed the powers of the greatest mathematicians in modern times. Laplace's *Mécanique Céleste* and other works of this kind are mostly devoted to the subject. S. NEWCOMB.

Pertz, GEORG HEINRICH: historian; b. at Hanover, Mar. 28, 1795; studied at Göttingen; published in 1819 a learned monograph on the Merovingian *majores domus*; was appointed in 1823 secretary of the royal archives at Hanover, and devoted the rest of his life to the collection and critical editing of the oldest sources of German history. In the execution of that great work, whose results appear in the famous *Monumenta Germaniæ Historica*, he was supported by the King of Hanover and other German princes. Among his other works is a biography of Stein (Hanover, 1849–54). D. at Munich, Oct. 7, 1876. F. M. COLBY.

Peru': a republic in the western part of South America, bordering on the Pacific, between Ecuador on the N. and Chili on the S. In the N. a tract of about 90,000 sq. miles, on both sides of the Marañon or upper Amazon, is held by Peru, but is claimed by Ecuador. Tacna and Arica, formerly southern provinces of Peru, are held by Chili. It is impossible to calculate the area even approximately; the estimate of Reclus is 378,000 sq. miles.

Mountains.—The great mountain system of the Andes follows the coast, northwesterly, in two parallel chains—the Cordillera, with its base generally about 20 miles from the coast; and the Andes, 70 to 110 miles farther inland. Between these is a region of plateaus and high valleys, varied by numerous spurs from both chains, and cut by the Vilcañota Knot or cross range near lat. 14° 30′ S., and the Cerro de Pasco Knot near lat. 9° 15′ S. From Cerro de Pasco the Andes give off an eastern branch, sometimes called the Eastern Cordillera. The Cordillera proper has two crests in many parts, especially toward the S.; between them is a cold, arid table-land or *puna* over 13,000 feet high. The Cordillera is unbroken, and forms the divide between the short rivers which flow to the Pacific and the large ones which unite in the Amazon. Near the Ecuadorian frontier few of the mountains in either range exceed 10,000 feet in height; but from lat. 8° S. there is a succession of snowy peaks, with passes often 15,000 feet high. The highest summits are near lat. 10° S. in Ancachs; according to Hindle the Cerro de Huascan attains 22,050 feet. The limit of perpetual snow is from 15,500 to 16,500 feet.

Regional Divisions.—The parallel mountain ranges divide Peru into three habitable regions called the Montaña, the Sierra, and the Costa. The Montaña includes the lower eastern slopes of the Andes, together with the vast plains bordering the upper Amazon and its tributaries in the N. E. Here there are very heavy and frequent rains and a luxuriant forest growth. The few civilized inhabitants are gathered near the great rivers. The Sierra includes all the region between the Andes and the Cordillera. The southern part, to the Vilcañota cross range, is included in the Titicaca basin; it is nearly 13,000 feet high, and so cold that corn will not ripen. Between the Vilcañota and Pasco cross ranges is the finest and most thickly populated part of Peru, and the ancient center of Inca civilization; a wonderfully varied region of plateaus, mountain-slopes, and fertile valleys, from 3,000 to 12,000 feet high. The northern part of the Sierra includes the deep gorge of the upper Marañon and the head of the Huallaga valley, a wild and rather thinly settled region of difficult access. Rains are never abundant in the Sierra, and there is no true forest; but the valleys are well watered by streams from the mountain snows. The Costa, the narrow strip between the Cordillera and the Pacific, is a terrace a few hundred feet high, abutting on the coast in cliffs and varied by spurs and isolated headlands. It is an almost rainless desert, but crossed by valleys of great fertility wherever a stream comes down. The climate is temperate rather than tropical, and the winter months (May to October) are characterized by frequent thick mists (*garruas*), sometimes with a light drizzling rain, which brings out a sparse growth of herbs on the desert lands. Peru has few well-sheltered harbors, the most important being Callao. Several groups of small rocky islands—the Lobos, Chinchas, etc.—adjoin the coast; they are important only as shelters and for their deposits of guano, now nearly exhausted.

Volcanoes and Earthquakes.—The Peruvian volcanoes, only three or four of which are active, are all gathered in the southern part of the Cordillera; among the best known are Misti, Omate, and Ubinas. The region about them, with the whole of the Costa, is subject to frequent and sometimes severe earthquakes. Lima and Callao have been nearly destroyed four times, the most disastrous shock being that of Oct. 28, 1746. Arequipa and the coast cities have suffered even more, notably in 1868 and 1877. In the Sierra earthquakes are much less frequent and severe, and in the Montaña they are almost unknown.

Rivers and Lakes.—The short rivers of the Pacific slope are all unnavigable. E. of the Cordillera the streams at first follow the axes of the mountain-chains, generally N. or N. N. W.; ultimately they break through the Andes in deep gorges, and reach the northeastern plains, where they become navigable. The principal trunks are the Marañon or upper Amazon, the Huallaga, and the Ucayali. The Javary is a river of the plains on the boundary of Brazil: and the Madre de Dios, one of the four great branches of the Madeira, rises not far from Cuzco. These rivers, owing to the difficulty of communication over the mountains, are used only for the small commerce of the Montaña, but they form the shortest routes from Peru to Europe. Lake Titicaca (*q. v.*), between Peru and Bolivia, is navigated by small steamers, forming part of the mixed route from La Paz to the Peruvian coast. There are several small lakes in the Sierra.

Fauna and Productions.—The Montaña animals are similar to those of Brazil. The mountain region has many peculiar animals, the most noteworthy being the domesticated llama and alpaca (the former used as a beast of burden, the latter for its fleece), with their wild congeners, and the condor, the largest bird of flight. At present rubber and cinchona are about the only utilized products of the Montaña forests. Coca, quinoa, and the potato grow wild, and are cultivated at higher altitudes. The Sierra and coast valleys, and nearly all the Montaña, are very fertile; owing to the diversity of climate almost any plant can be raised, but the principal agricultural products are sugar-cane, cotton, grapes (used for brandy), and tobacco in the Costa; maize and coca in the Sierra, with potatoes and quinoa at higher altitudes; and maize and manioc in the Montaña. Peru is pre-eminently a country of minerals, almost every department being rich in deposits, but in its output it is surpassed by Bolivia and Chili. Heretofore the silver mines have been the most important; the veins occur principally in the Cordillera. The celebrated mines of Cerro de Pasco yielded about $475,000,000 worth of silver from 1630 to 1850; the yield in 1877 was 1,427,592 oz. Gold is found principally on the eastern slope of the Andes, and the washings have been only slightly developed. Other important metals are quicksilver (now but little mined), copper, and lead. Coal (Jurassic) is now mined near the coast, and occurs inland; extensive petroleum deposits have been found in the northwestern department of Piura, and are worked to some extent. The guano deposits have been a source of great wealth; from 1853 to 1872 8,000,000 tons were taken from the Chincha islands alone. The known residue is only a few hundred thousand tons, and has been transferred to a private company. See Peru in the Appendix.

People and Government.—The population in 1894, besides some 150,000 wild Indians, was about 3,100,000. Most of these are descended from the ancient Kechua tribes or, in the Titicaca basin, from the Aymaras. In the cities there is an intermixture with Spanish blood, and a comparatively small proportion is of pure Spanish descent. The educated and ruling class includes portions of all these. Negroes (descended from the slaves who were finally liberated in 1855) are nearly confined to the coast, where, also, there are many Chinese. Spanish is the common language in the coast cities, but Kechua is still universally spoken in the Sierra, where many of the Indians retain their tribal organization under the Peruvian Government. The wild tribes are nearly confined to the Montaña, and few of them are hostile. The constitution now in force was adopted in 1859–60, but has been somewhat amended. Peru is a centralized or unitarian republic, all the principal powers being concentrated at Lima. The president is elected for four years, is not eligible for immediate re-election, and is assisted by a council of responsible ministers. Congress consists of a Senate and a House of Deputies. The state religion is the Roman Catholic, and the public exercise of other cults is forbidden. The University of San Marcos at Lima is the oldest in the New World, and is still well attended. The Government supports *colegios*, or high schools, in the principal cities, but popular education is still very backward. The better class of Peruvians are intelligent, well-read, generous, and sociable, but they are somewhat impulsive, and commonly hot partisans. See Spanish-American Literature.

Commerce, etc.—The leading exports in the order of their value are sugar, silver ore, cotton, wool, and hides. More than half the trade is with Great Britain, and hardly one-fifteenth with the U. S. The total exports in 1899 were valued at 33,615,311 sols, total imports at 21,230,183. There are some 1,000 miles of railways, the most important being the Oroya route from Lima over the Cordillera (projected to Cerro de Pasco and the Montaña), and that from Mollendo to Arequipa and Lake Titicaca. The old Inca roads are still used in parts. There is telegraphic communication between the principal cities and by cable to other countries. The metrical system of weights and measures is legalized, but the old Spanish ones are used. The principal coin, the *sol*, is nominally worth a dollar, but really about forty-nine cents.

Finances.—In Jan., 1890, the whole of the foreign debt, then amounting with arrears to £22.998,651, was, by agreement, assumed by the Peruvian Corporation, a private company; in return, the state railways and other public works, and nearly all the remaining guano, were transferred to the company for sixty-six years, the Government agreeing to pay the bondholders £80,000 sterling annually for thirty years. The internal liabilities were estimated in 1900 at 46,003,000 sols.

History.—Vague traditions relate that a powerful dynasty, the Pirua, held the highlands of Peru and Bolivia in very ancient times; to it are ascribed the remains at Tiahuanaco and some near Cuzco. The Pirua empire is said to have been broken up about A. D. 1000. The INCAS (*q. v.*) established their power at Cuzco about 1230, and at the beginning of the sixteenth century ruled the Andean highlands and the Pacific coast from lat. 35° S. to beyond the equator. The empire was weakened by its division between Huascar and Atahualpa in 1525, and a civil war in which the former was defeated. PIZARRO (*q. v.*) reached Peru in 1527; he invaded it in 1532, captured and killed Atahualpa, and easily conquered the country, securing an immense booty. This led to the conquests of Quito (Ecuador), Southern New Granada, Charcas (Bolivia), and Chili. Pizarro founded Lima as his capital in 1535; a formidable uprising of the Indians was repressed in 1537; and after the rebellions led by the ALMAGROS, GONZALO PIZARRO, and GIRON (*qq. v.*) Peru settled down under the quiet rule of the viceroys. It was the most valued of the Spanish possessions, but few improvements were introduced, and the riches of the country were constantly drained into the Spanish treasury. The viceroyalty embraced the whole of Spanish South America and Panama, with audience divisions corresponding, in part, to the modern republics. The separation of New Granada (1718) and La Plata (1776) reduced the rule of the viceroy to Peru proper, Chili, and Quito (Ecuador), with full powers only in the first. In 1781 the formidable Indian rebellion under Tupac Amaru was repressed with unspeakable cruelties. Peru, the center of Spanish power in South America, was the last region to throw off the yoke. Independence was declared at Lima, July 28, 1821, and the victory of Ayacucho, Dec. 9, 1824, practically ended Spanish rule in South America. Ecuador and Chili had already separated, and Bolivar's rule in Peru ended in 1827. The country, under military rulers, was distracted by civil wars. Santa Cruz, president of Bolivia, interfered, conquered Peru 1835–36, and united the two countries; but Gamarra and other malcontents, aided by Chili, overthrew him in 1839 and re-established the old division. Gamarra, made president, invaded Bolivia, and was defeated and killed in 1841. A firm government was finally established by Ramon Castilla in 1845. His successor, Echenique, was deposed after a civil war, in 1855, and Castilla was again president until 1862. Prado, by a bloodless revolution, usurped the Government in 1865, but was deposed in 1868; meanwhile a Spanish fleet, sent to enforce alleged claims, was brilliantly repulsed at Callao, May 2, 1866. The rich proceeds of the guano and nitrate beds induced a spirit of extravagance; railways and other vast works were undertaken by the Government, and the public debt was enormously increased; interest payments were suspended in 1876, but with constantly increasing revenues and more economical administrations the future seemed secure. This hope was destroyed by the disastrous war with Chili. That country suddenly claimed the coast lands of Bolivia and Southern Peru, and refusal led to a war for which neither Peru nor Bolivia was prepared. Their united armies were disastrously defeated in the south; the Peruvian navy was annihilated after a gallant struggle; by two bloody battles the Chilians took Lima, Jan. 17, 1881; public buildings, including the fine library, were sacked, and the rural districts were desolated. At length Iglesias, as nominal president, agreed to a peace by which Tarapacá was unconditionally ceded to Chili, the provinces of Arica and Tacna were ceded conditionally, and a great share of the guano beds was given up; the ceded territory included all the nitrate deposits. The Chilians evacuated Lima in Oct., 1883. Cáceres, who was the constitutional president, refused to acknowledge Iglesias, seized Lima Dec. 1, 1885, and, his claim being ratified by election, became president. Since then the country has been slowly recovering. The "revolutions" frequently chronicled by newspapers have been slight disturbances connected with elections.

HERBERT H. SMITH.

Peru: city; La Salle co., Ill. (for location, see map of Illinois, ref. 3–E); on the Illinois river at the head of navigation, the Illinois and Michigan Canal, and the Burlington Route and the Chi., Rock Is. and Pac. railways; 17 miles S. of Mendota, 100 miles W. S. W. of Chicago. It is in a coal-mining region, is an important trade center, and has several manufactories, a national bank with capital of $50,000, a State bank with capital of $25,000, and a daily and a weekly newspaper. The river is navigable to this point at all seasons, and is here crossed by a railway bridge. Pop. (1880) 4,632; (1890) 5,550; (1900) 6,863.

Peru: city; capital of Miami co., Ind. (for location, see map of Indiana, ref. 4–E); on the Wabash river, the Wabash and Erie Canal, and the Lake Erie and West. and the Wabash railways; 56 miles W. S. W. of Fort Wayne, 75 miles N. of Indianapolis. It is in an agricultural region, and contains a woolen-mill, carbon-works, flint-glass works, basket-factory, artificial-ice works, bagging-mills, carriage-factories, foundries, a brewery, 2 national banks with combined capital of $200,000, and 2 daily and 2 weekly papers. Pop. (1890) 7,028; (1900) 8,463. EDITOR OF "JOURNAL."

Peru Balsam: a balsamic exudate obtained from a handsome tree (*Toluifera pereiræ*) of the natural order *Leguminosæ*, growing in San Salvador, Central America. Portions of the bark are bruised by beating with blunt instruments, and subsequently charred by flame. A week or so later the injured bark comes away, and the balsam, which now begins to exude from the exposed wood, is collected on cloths, from which it is afterward separated by gentle boiling in water. Peru balsam is a dark-brown, viscid substance, like thick molasses, of a rather fragrant odor, and a warm, bitterish taste. It is insoluble in water, but mixes perfectly with absolute alcohol and chloroform. It is combustible, giving forth white fumes and a fragrant balsamic odor. It contains a resin, a volatile oil, and cinnamic and benzoic acids. Balsam of Peru was probably introduced into Europe as a medicine about the year 1524, and was considered of great value in bronchial and other respiratory affections, and locally upon ulcers or wounds; but its medicinal virtues are feeble, and in the U. S. other balsams have almost completely superseded it in practice.

Revised by H. A. HARE.

Perugia, pā-roo'jăă (anc. *Perusia*): city; in the province of Perugia, Italy; 11 miles from the historic Lake Trasimenus (now Lake of Perugia); on a hill near the right bank of the Tiber, 1,600 feet above the sea-level (see map of Italy, ref. 5–D). The air is healthful, and the surrounding country is picturesque from the old towns, churches, and castles everywhere scattered over it. It is well walled, and entered by gates mostly mediæval or modern; but among them is one of the Etruscan period, bearing the inscription "Augusta Perusia," placed on it by Augustus. Some remains of the old Etruscan walls also still exist. The streets, though often steep, are broad, and the squares are flanked by imposing public and private edifices. In the Piazza del Duomo there is a superb fountain, the work of Niccolò and Giovanni Pisano, and a statue of Pope Julius III. (1555). Among the numerous churches are the Cathedral of San Lorenzo, a Gothic building in the plan of a Latin cross; San Domenico, a Gothic edifice rebuilt in 1632, containing a monument of Benedict XI. by Giovanni Pisano, and San Pietro de' Casinensi, a basilica with a triple nave and walnut stall-work designed by Raphael. Some of the palaces contain choice works by renowned artists, especially the Palazzo del Collegio del Cambio, which is rich in frescoes by Perugino. The Palazzo Publico has a fine Gothic façade dating from the fourteenth century. From many of the suppressed convents and other sources a valuable collection of pictures by the best masters of the Umbrian school, such as Perugino, Raphael, etc., has been brought together in the Academy of Fine Arts near the university. Perugia has always been renowned for love of art and literature, and its university (established in 1307) had (1891) 21 teachers and 179 students. Without the gates there are some remarkable

antiquities; among others, the Torre di S. Manno, on which is a celebrated Etruscan inscription. The chief industry of the city is silk-manufactures; there are also manufactures of woolens, liqueurs, wax candles, etc. Perugia was one of the oldest of the twelve chief Etruscan cities, and one of the last to fall before the Romans. In the quarrel between Anthony and Octavianus this town espoused the cause of the former, and was cruelly punished by the latter, who afterward rebuilt it. During the Middle Ages it was alternately independent and subject to the papacy. It is said to have been an episcopal see from the earliest Christian times, and continues such to the present day. Though always restive under the papal yoke, this town was not united to the kingdom of Italy till 1860. Pop. (1893) 54,500.

Perugia, Lake of (anc. *Lacus Trasimenus*): a lake of Central Italy; in the province of Perugia. It is 30 miles in circumference, and is surrounded by beautifully wooded hills. Here Hannibal defeated the Romans in 217 B. C.

Perugino, pā-roo-jec'nō, PIETRO VANNUCCI: called Perugino, or the Perugian; painter; b. in Castello della Pieve, a dependency of Perugia, 1446. It is disputed who his teacher was, probably Verroehio. He became a remarkably skillful painter and a master of technical execution, and was one of the first Italians to use oil-painting freely. A gentle and rather meaningless grace and sweetness characterizes his female heads, and his whole composition is rather formal and deliberate than truly inventive. His great celebrity is caused by his having preceded Raphael in some of that great painter's peculiarities; and, indeed, Raphael was his pupil for a time. D. probably at Perugia in 1523. Among his important existing pictures are, at Florence, in the Uffizi Gallery, a *Madonna with Saints*; in the Academy, an *Assumption of the Virgin*, with many figures; in the Pitti Palace, a *Pietà* and a *Madonna Adoring the Infant Christ*; in the National Gallery in London a *Virgin and Child with the Archangels Michael and Raphael*; and in Rome, in the Sixtine Chapel, a large fresco of the *Delivery of the Keys to St. Peter.* RUSSELL STURGIS.

Perunite, or **Terrorite**: See EXPLOSIVES.

Peru, Upper, or **Alto**: See BOLIVIA.

Peruvian Bark: See CINCHONA.

Peruvians, Ancient: See INCAS and INDIANS OF SOUTH AMERICA.

Peruzzi, pā-root'see, BALDASSARE: painter and architeet; b. at Accajano, near Siena, Italy, in 1481. His early training in art was received in Siena, but he became noted in Rome in the beginning of the pontificate of Julius II. He is sometimes supposed to have been a pupil of Raphael, with whom he became intimate, and whose manner of painting he emulated, especially in his designs for holy families and his fresco-painting. The chapel of the high altar at Sant' Onofrio, Rome, is one of his most important works. He designed the Villa Farnesina, and probably the Farnesino palace also, for Agostino Chigi, and decorated certain parts in fresco. The *Sybil Preaching to Augustus*, in the Church of Fontegiusta at Siena, is one of his most admired compositions. He succeeded Raphael as architect of St. Peter's, and has higher rank in architecture than in painting. D. in Rome in 1536. W. J. STILLMAN.

Peruzzi, UBALDINO: statesman; b. in Florence, Apr. 2, 1822; was educated at the École des Mines in Paris; and in 1848 was appointed gonfalonier of Florence. He was a Liberal in politics, and strongly in favor of the unity of Italy under the house of Savoy. After the overthrow of the grand duke in 1859 (to which Peruzzi himself contributed) he was elected member of the Tuscan Assembly; afterward deputy from Florence to the Italian parliament. In 1861 Cavour offered him the post of Minister of Public Works, an office which he retained until the fall of the Ricasoli ministry. While Rattazzi was in power Peruzzi threw himself into the opposition, but under the presidency of Minghetti he took the portfolio of the interior, and thus became a member of the ministry which negotiated with Napoleon III. the convention of Sept. 15, 1864, for the transfer of the capital from Turin to Florence. Peruzzi succeeded Count Cambray Digny as syndic of Florence, and showed great energy in suggesting and executing important projects for the improvement and embellishment of the city. In 1882 he was president of the commission appointed to examine the project of a commercial treaty with France. D. at Florence, Sept. 9, 1891. F. M. COLBY.

Pesado, pā-saa'dō, JOSÉ JOAQUIN, de: poet; b. at San Agustín de Palmar, province of Puebla, Mexico, Feb. 9, 1801; d. in the city of Mexico in 1861. His youth and early manhood were passed at Orizaba. As a young man he took an active part in public affairs, being Minister of the Interior in 1838, and Minister of Foreign Affairs in 1846. With advancing years he became more conservative in politics and more intensely Catholic in belief; and in 1854 he withdrew from office to take the chair of Belles-lettres in the University of Mexico. As a poet he was the chief representative in Mexico of the sentimental neo-Catholicism which in France began with Lamartine and reached its perfection in Montalembert and de Maistre. He delighted in biblical subjects, though he was perhaps quite as much an artist in his descriptions of nature. Three editions of his poems have appeared in Mexico, *Poesías originales y traducidas*, in 1839, 1840, and 1886 (the last much the fullest and most satisfactory). A. R. MARSH.

Pesarese, SIMON, da: See CANTAVIUS, SIMONE.

Pesaro, pā'saă-rō (anc. *Pisaurum*): town; in the province of Pesaro and Urbino, Italy; on the right bank of the Foglia, 1 mile from the Adriatic and 37 miles by rail N. W. of Ancona (see map of Italy, ref. 4–E). Pesaro is strongly walled and commanded by a citadel, and from the promenade upon the ramparts the view embraces the neighboring hills dotted with castles and villas, the distant peaks of the Apennines and the near Adriatic. The streets are broad and well paved, and the town contains many churches and private palaces of interest. The cathedral is remarkable as showing by its three superimposed pavements the great changes of level which have taken place on this coast. Rossini, who was a native of Pesaro, left all his fortune to found a musical lyceum here. The maritime trade of Pesaro is of some importance, and there is an active traffic in fruits, grain, beans, silk, and hemp. There are manufactures of leather and majolica. Pesaro is probably of Pelasgian origin, was enlarged and adorned by the Romans, and had a bishop as early as 251 A. D. It suffered from barbarian invasions, and its mediæval life was much agitated. Pop. (1893) 24,500.

Pesellino, pā-sel-lee'nō, FRANCESCO: painter; b. at Florence, Italy, in 1422; grandson of Francesco Peselli, who gave him his artistic training. He is supposed to have been a pupil also of Fra Filippo Lippi. He painted for Santa Croce a beautiful altarpiece now in the Louvre, representing St. Francis of Assisi receiving the stigmata and St. Dominic visiting a sick man. His works are in private collections for the most part, and are distinguished by great beauty of color and delightful invention. He died in Florence in 1457. W. J. STILLMAN.

Peshaw'ar: a town in the Punjaub, India; on the border of Afghanistan, opposite the mouth of the Khyber Pass (see map of N. India, ref. 3–C). It is a British defensive military station, famous as "the bulwark of the Indian empire against Afghanistan." Pop. (1891) 84,181. C. C. A.

Peshi'to, or **Peshitto** [from Syriac *peshīttā*, simple]: the standard Syriac translation of the Old and a part of the New Testament. It was probably made in the second and third centuries of the Christian era, and is now generally believed to be the work of Christian Jews. It is a generally faithful and scholarly piece of work. Jude, 2 Peter, 2 and 3 John, and the Apocalypse are wanting, as they are not in the canon of the Syriac Church, but were translated into Syriac in much later times. The Peshito of to-day is a revision of a primitive text, of which the Gospels were discovered in the convent of Mt. Sinai in 1892 by Mrs. Agnes Smith Lewis, and published in London, 1894.

Revised by S. M. JACKSON.

Pessimism [from Lat. *pes'simus*, worst]: in popular usage, a term often applied to any doctrine or opinion, or even to any mood, which appears to be predominantly gloomy, especially when such a view or state of feeling leads the one who possesses it to make an unhappy forecast of the future.

Philosophical Pessimism.—In technical philosophical usage pessimism denotes any doctrine concerning the universe, and especially concerning the life of man as a whole, which leads to an explicit condemnation of the world, and of life, as being essentially and radically evil. Philosophical pessimism has almost always laid considerable stress upon the assertion that pain, as a most obvious and important form of evil, is predominant in the world; but it is by no means a logical necessity that a pessimist should

condemn the world merely because of the supposed prevalence of painful experience involved in its existence. The moral ideals of philosophers have varied widely, as well as the æsthetic criteria that have governed their judgments of reality, and it would be quite possible that one should be a philosophical pessimist not at all because of his belief in the painfulness of conscious existence, but solely because he was assured that the highest ideal (e. g. the ideal of rationality of life) which his doctrine recognized was doomed to such disastrous defeat in the actual world as to warrant his condemnation of the real, because of its radical opposition to this ideal. As a fact, while the painfulness of existence has played a large part in pessimistic literature, few pessimists have given this painfulness as the *sole* reason for their criticism of reality. Philosophical pessimists have frequently coördinated with the painfulness of life the necessary failure of finite beings to attain satisfactory knowledge; and this inevitable "ignorance" has been a fruitful source of pessimistic condemnation of existence. Yet some thinkers, not pessimists, have made pain a prominent and, in fact, a predominant feature in finite existence, as such, and have nevertheless explicitly defined the universe as essentially good, on the ground that the realization of the ideal, at least in some due measure, is possible, despite, or even through, the very presence of pain in the world. Such views, for instance, are represented in the doctrine of Hegel.

In any case, in order to avoid numerous vulgar misapprehensions, it is well to remember that no one is a pessimist merely because he calls life painful, but rather because he regards life as a "failure." Pessimism depends, then, upon first assuming or maintaining some sort of ideal of what life ought to be or to become, and upon then asserting that this ideal can not be attained, owing to the radically evil constitution of the world.

Hindu Pessimism.—Pessimism as a universal doctrine is first known to us in Hindu thought. In the post-Vedic period of Brahmanical speculation a belief that all finite existence is an evil, from which some sort of "deliverance" is required, became a prominent notion of the Hindu mind —a notion which early received philosophical expression, and which has continued, as a sort of insistent national idea, ever since, leading to developments of great importance for the history of religion. The doctrine of transmigration associated itself with Hindu pessimism from the outset, and the endless succession of births through which every one must pass unless he should be "delivered" is constantly made use of by Hindu teachers to emphasize the weariness of existence, and the need of the "deliverance" itself. The radical evil of finite existence, from which one needs to be "delivered," is very often defined as pain; but it is also often defined as ignorance; and the fault of all finite life appears, even in the very early philosophical and religious writings called the *Upanishads*, as in large measure due to the fact that, in this consciousness of ours, knowledge is necessarily sundered from its objects, so that nobody here knows the true "Self," or Absolute, whom to know would be peace. Hence the essential restlessness and worthlessness of all definable life. Deliverance from particular existence thus appears as identical with absolute knowledge, which no one can reach who remains in this world, or who retains the life that belongs to the world. (See Transmigration.) In Buddhism the philosophical formulations of the earlier Hindu schools were neglected, and the doctrine of deliverance was given a more distinctly practical form; but the essential pessimism still remained, and in fact was even more decidedly emphasized than before. Life is always an evil, being full of pain. The deepest root of pain is desire. Desire once "seen through" and absolutely negated, the peace of Nirvana is attained; and hence comes the release both from the endless succession of births and from all the other intolerable responsibilities of our world.

Pessimistic Tendencies in Greek Philosophy.—In European thought pessimistic tendencies were never prominent until after the Christian era. Classic Greek philosophy was acquainted, in a measure, with some portions of the problem of evil, but, except in a few scattered passages, does not appear disposed to regard the highest good as out of human reach; but after the Christian era the Neoplatonic school, with which the history of ancient philosophy closes, comes nearer to a consciousness of something essentially evil about finite existence, and seeks a deliverance through an union with the absolute—a notion which reminds one in many ways of the thoughts current among the Hindus. Plotinus, the leading Neoplatonic thinker, explicitly declares that the finite world, although indeed a world with much evil in it, is an emanation from the highest good itself, and is therefore as good as the nature of its own finitude will permit; yet he declares that no wise man can remain content to live as a finite being, but, finding all more or less evil here, longs for superconscious union with the divine "One," which union is above all explicit knowledge or definition, although the "One" is the source of all things.

Christian Mysticism.—While it would be wrong to call this doctrine of Plotinus pessimism in the strict sense, its historical importance lies in the fact that the severe condemnation of finite existence in which the Neoplatonic thinkers indulged was later influential in determining the formulations current among the Christian Mystics, who all followed Neoplatonic traditions; and, as a fact, Christian mysticism has very frequently made use of language nearly as pessimistic as that of the Hindus. Mysticism, widely represented both in the Catholic and later in the Protestant branches of the Christian Church, has often indeed tended toward actual heresy; but even in its more orthodox or less heretical forms it has often insisted upon the doctrine that, in order to get into real "union with God," one has to "despise," or to forsake, every possible form of finite existence, not only as represented in this present lower world, but also as represented in any future or heavenly world. All "creatures," so the Mystics of the Church have often been disposed to say, must first be regarded as "naught" or as "worthless," or even as "evil"; else one can never learn to love God aright, and to attain the final superconscious oneness with him.

General Relations between Christianity and Pessimism.—Much stress has been laid, both by supporters and by opponents of pessimism, upon the assertion that the condemnation of all finite existence thus insisted upon by the Mystics was really involved, as a conscious motive, in the fundamental ideas of orthodox Christianity itself; and there can indeed be no doubt that the tendency to condemn and forsake "the things of this world," which has always formed one motive of Christian piety, has been easily confused in some minds with an actually pessimistic condemnation of the whole finite universe; and it is necessary to mention this confusion here, from the light that it tends to throw upon the history of modern pessimism; for there can be no doubt, in any case, that the importance given to the problem of evil by the whole Christian consciousness has had much to do with making pessimism a prominent topic of discussion in the recent generations of religious unrest.

Pessimism in Earlier Modern Philosophy.—In modern thought Leibnitz is well known as the author of a carefully considered reflective doctrine which he intended as a "theodicy," or proof that the present world was chosen by its creator as "the best of possible worlds." This optimism of Leibnitz was a favorite topic of discussion in the eighteenth century, and was satirized, together with other less philosophical forms of optimism, by Voltaire in *Candide*. Kant, although upon ethical grounds an optimist, still, during his critical period, regarded all attempts at a theoretical theodicy as necessarily doomed to failure. In his own analysis of the worth of life Kant lays stress upon the necessary prominence of the painful in our sentient existence, and distinctly asserts that, viewed as a mere experience, our life is full of conflict, and has no abiding worth. Its true worth, however, lies in what our free will can give it—namely, conformity to a moral ideal, which we seek without any reference to happiness. This worth, the worth of a "good will," is indeed absolute. Meanwhile it is a "postulate" of our moral faith that in an immortal life happiness will be apportioned according to desert.

The ethical optimism of Kant, joined as it was with a strong realization that, viewed merely as sentient experience, life is rather an evil than a good, determined the interesting syntheses of ethical and religious optimism with a frankly avowed pessimism concerning life viewed as mere finite experience, which were above referred to as present in the doctrine of Hegel. The life in union with the moral ideal, or with the knowledge of the absolute, is good; but finite life, as such, apart from its union with the ideal, is essentially painful and worthless; this is the classic doctrine of German idealism, in which many still see the solution of the whole problem.

Schopenhauer.—It was reserved, however, for Schopenhauer, while actually building on the basis of the general tendencies of the idealism of his country, first to deny the rationality of the world-principle, or absolute, and then, in

consequence of the first denial, to affirm that the evil of all existence is radical. Schopenhauer is consciously affiliated with Hindu pessimism. The world is the expression of an irrational and blind principle called the Will, similar in tendency to the "desire" of the Buddhists, but defined in more explicit and positive metaphysical terms. The expression of this Will is a world of insatiable striving and longing, which, being in the main planless, can come to consciousness only as a desire to change whatever it finds into something else, and so to enter into an endless conflict with itself, and pain is simply the experience of unsatisfied desire. The only remedy for the life of the Will lies in a certain transcendent form of self-possessed knowledge, only attainable by a sort of supernatural accident, an absolute resignation, identical with the insight that led Buddha to Nirvana. This resignation Schopenhauer called "the denial of the will to live."

Von Hartmann.—More recently von Hartmann, in his *Philosophy of the Unconscious* and in other of his numerous philosophical essays, has attempted, with great ingenuity, an exposition of pessimism whose metaphysical basis lies in an union of Schopenhauerian with other elements, largely Hegelian in their source, while the method undertakes to be mainly one of induction. Schopenhauer's proof for pessimism is in great measure rejected by von Hartmann, and a more empirical estimate of the "balance" of pleasure and pain in life is substituted. The result of this estimate is, however, once more the condemnation of all conscious life. The escape from the world-evil can be attained only in the far-off future, when, in the course of evolution, consciousness, wise enough to see the necessary evil of existence, becomes predominant in the universe. Then, by the general consent of conscious beings, who will then be wise enough to have the springs of existence under their control, a common act of self-denial can annihilate not only the then existent sentient life, but its whole physical basis, and so bring the world to an end.

The minor defenders of pessimism are numerous, and its influence upon modern literary tendencies is considerable. For a fuller account the reader may be referred to James Sully's *Pessimism: A History and a Criticism* (2d ed. 1891).

JOSIAH ROYCE.

Pessi'nus (now *Bala Hissar*): ancient city of Galatia; in Asia Minor; on the Sangarius; the center of the worship of Rhea or Cybele, mother of the gods. The almost shapeless stone image of the goddess, fabled to have fallen from heaven, was kept in her chief temple and attracted worshipers from all over the eastern world. The temples and public buildings of Pessinus then surpassed in magnificence those of any other city in Asia Minor. The image of Cybele was taken to Rome in consequence of an oracle which foretold that the Roman state would endure forever if once possessed of it. Thereupon Pessinus rapidly declined and is not mentioned after the sixth century. Its splendid and extensive ruins have been identified by Texier. E. A. G.

Pestalozzi, JOHANN HEINRICH: educational reformer and chief founder of modern pedagogy; b. at Zurich, Switzerland, Jan. 12, 1746. Always enthusiastic and philanthropic, he studied first theology, then law, and, finally, his health somewhat impaired, turned to farming. In 1767 he bought a farm near the village of Birr and built a house, Neuhof. Hither in 1769 he brought his bride, Anna Schulthess, after one of the strangest and frankest courtships ever recorded. The farming was a failure, the firm that advanced the money withdrew from the enterprise, and finally in 1775 Pestalozzi, who from the first was deeply impressed by the abject condition of the peasantry and had been greatly interested by the doctrines of Rousseau's *Émile*, started a kind of pauper school. He housed, boarded, and clothed the children in return for such work as they gave in the field. By 1780 this experiment had failed. His wife's fortune was now exhausted, and the next eighteen years were a period of great distress. He turned now to writing, and in 1780 published *Abendstunde eines Einsiedlers* (Evening Hour of a Hermit); in 1781 appeared *Lienhardt und Gertrud* (Leonard and Gertrude), a simple tale of life in a Swiss village, which shows incidentally and strongly the effects of right education. The book was an immense success, and on it Pestalozzi's fame as an author mainly rests. The vicissitudes of war settled Pestalozzi in 1798–99 in charge of an orphan asylum in Stanz, where from stern necessity in one year the main elements of his educational system were developed. In 1799 he joined Krüsi in opening a new school in Burgdorf Castle, for which he obtained Government aid in 1802. In 1801 appeared the result of his educational experience in his work *Wie Gertrud ihre Kinder lehrt* (How Gertrude Teaches Her Children). In 1802 he was elected a member of the deputation sent by the Swiss people to Paris. In 1804 he was obliged to remove his school to Münchenbuchsee. The chief authority here being given to Fellenberg, the same year he moved on to Yverdun. The Yverdun Institute very soon had a worldwide reputation. His chief helpers here were Niederer, Ramsauer, Schmid, Steiner, and Krüsi. Schmid, though a famous teacher of mathematics, was not calculated to appreciate his leader, or his methods. He ultimately obtained complete ascendency over Pestalozzi's mind, finally causing the departure of the other masters and the downfall of the institute. In 1825 Pestalozzi retired to Neuhof. He died at Brugg, Feb. 17, 1827, and is buried near the schoolhouse at Birr, where, Jan. 12, 1846, on the 100th anniversary of his birth, a memorial was erected to him. It is impossible to summarize Pestalozzi's services to education, for he rather set on foot ideas than originated methods. He was pre-eminently a man of feeling and imagination. He would never admit that he had a carefully thought-out system. Judged by ordinary standards, he would have been considered anything but a good teacher. His true function was to educate ideas. Raumer sums up the services Pestalozzi did for education in these words: "He compelled the scholastic world to revise the whole of their task, to reflect on the nature and destiny of man, and also on the proper way of leading him from his youth toward that destiny." Doubtless the best single biography in English is *Pestalozzi, his Life and Work*, by Roger De Guimps. A very interesting and valuable biography is *Pestalozzi, his Life, Work, and Influence*, by Hermann Krüsi, son of Pestalozzi's assistant (New York, 1875); *Pestalozzianism*, by Henry Barnard (New York, 1862), contains a great amount of valuable material selected from Barnard's *Journal of Education*. See also Quick's *Educational Reformers* and Williams's *History of Modern Education*. German literature on the subject is extensive. C. H. THURBER.

Pesth: See BUDAPEST.

Pestilence: See EPIDEMICS and PLAGUE.

Petals: See FLOWER.

Petalu'ma: city; Sonoma co., Cal.; at the head of navigation on Petaluma Creek; on the San Fran. and N. Pac. Railway; 16 miles S. of Santa Rosa, 42 miles N. by W. of San Francisco (for location, see map of California, ref. 7–B). It is in an agricultural, stock-raising, and wine-making region; has a daily line of steamers to San Francisco; and contains 8 churches, high school, 3 grammar schools, Ursuline convent, an academy, a public library (founded in 1867), a national bank with capital of $200,000, 3 State banks with capital of $600,000, and 2 daily and 3 weekly newspapers. There are flour, planing, silk, and woolen mills, tannery, and fruit drying, canning, and distilling works. Pop. (1880) 3,326; (1890) 3,692; (1900) 3,871. PROPRIETOR OF "IMPRINT."

Petasos: See HEAD-DRESS.

Petau, pe-tō', DENIS (*Dionysius Petavius*): chronologist and Catholic theologian; b. at Orleans, France, Aug. 21, 1583; became professor at Bourges in 1603, in Rheims 1612, in La Flèche 1613, in Paris 1617; died there Dec. 11, 1652. Following in the footsteps of Sealiger, but equipped with a profounder mathematical knowledge, he endeavored with singular success to systemize and harmonize the numerous chronological eras of the ancients by ascertaining with the aid of mathematics the various cycles upon which they were based. The results of his labors are laid down in his *Opus de doctrina temporum* (2 vols., 1627), and in the more famous *Uranologium* (Paris, 1630). Both are combined in the Verona edition of 1734. His *Tabulæ chronologicæ* (Paris, 1628) and the *Rationarium temporum* (1633; new ed. 1849) remained standard schoolbooks for centuries. He is also the author of a celebrated theological work *De theologicis dogmatibus* (5 vols.). The best edition is by Thomas (Bar-le-Duc, 1864). See F. Stanonik, *Dionysius Petavius* (Gratz, 1876). ALFRED GUDEMAN.

Petch'ora: a river of European Russia, rising in the Ural Mountains. It flows through wild forest regions to the Arctic Ocean, which it enters through a large estuary in lat. 68° N. and lon. 53° E.

Peter, SAINT [*Peter* is via Lat. from Gr. Πέτρος, liter., masc. form of πέτρα, rock, stone]: the first in the list of the twelve apostles; b. in Galilee, at Bethsaida, on the shore of

the Lake of Gennesaret, whence he removed to the adjoining village of Capernaum. He was a fisherman, like his brother Andrew, and, like him, he was probably a disciple of John the Baptist, but he followed Christ immediately when called. His original name was Simon, which Christ changed, declaring, "Thou art Peter, and upon this rock I will build my Church" (Matt. xvi. 18). From his call to the office of apostle, and up to the time of the apostles' council in Jerusalem, the events of his life are told in the Gospels and the Acts, and are familiar to all. His personal character is so distinct and strongly marked that there probably are no readers of the Bible who have not a vivid conception of it, or any two whose conceptions differ very much; but after the apostles' council in Jerusalem (50 A. D.) he is only heard of at Antioch (52), when his inconsistency exposed him to Paul's stern rebuke (Gal. ii. 11), and in 57, when he is incidentally referred to by Paul (1 Cor. ix. 5). From that point on tradition is the only authority, and the circumstance that the papal see rests its whole claim of primacy on events related by this tradition has caused it to be very much doubted by Protestants. Jerome (*De viris illustribus*) relates that Peter was Bishop of Antioch for several years, preached in Pontus, Galatia, Bithynia, and Cappadocia, and spent the last twenty-five years of his life in Rome, where he suffered martyrdom; but Paul makes no reference to such a fact in his Epistle to the Romans, and the long residence can only be maintained by denying a tradition that both Paul and Peter suffered martyrdom there under Nero. At the time of the Reformation it was even contended—for instance, by Spanheim—that Peter never was in Rome; but at present most critics, Protestant as well as Roman Catholic, agree in accepting the tradition in its principal traits—namely, the residence of Peter in Rome and his suffering martyrdom there—though it has not been possible to establish an agreement with respect to the dates of these events. The most probable date is 66 or 67. Ramsay maintains that he survived the Neronian persecution and was living in 80. Revised by S. M. Jackson.

Peter I., the Great: Czar of Russia; b. at Moscow, June 12, 1672; son of the czar Alexis Michailowich; in 1682 succeeded Feodor, but Ivan V., Peter's brother and the lawful heir, was soon after announced as joint-sovereign through the efforts of their sister Sophia, who for several years directed the affairs of the empire. After seven years of tutelage Peter thrust the princess-regent into a convent, where she died twenty-two years later, and the inactive Ivan in 1689 abdicated his share of the government. The new czar aided by his able minister Le Fort (*q. v.*) reorganized the army; built a small navy; went to sea in person on Dutch and English ships, so as to learn the practical part of navigation, and took Azof from the Turks 1696, thus realizing his ambition of gaining for Russia a port on the Black Sea. He lived abroad (1697–98), chiefly at Saardam in the Netherlands and at Deptford and London; worked as a shipcarpenter and blacksmith, and for some months studied the sciences. In 1698 he took 500 English mechanics, engineers, etc., to Russia, and in the same year, the Strelitzes having revolted, he ordered them all to be put to death, and assisted the executioners with his own hands; but pardoned a few upon the scaffold, noteworthy among whom was the young Orloff, founder of the princely house of Orloff. The czar now reformed the calendar, founded schools, introduced arithmetic (hitherto unknown in Russia), compelled rich merchants to engage in foreign commerce, and enacted rules for dress and deportment; entered upon a war of conquest against Sweden, supported by Denmark and Poland, 1700, and in the same year was defeated by Charles XII. at Narva; founded St. Petersburg 1703; invaded Courland 1705; overthrew the Swedes at Pultava 1709; seized the Baltic provinces 1710, and Finland 1713; married Catherine I., his mistress, 1707, and declared her czarina 1711; waged an unsuccessful war against the Turks 1711; finally gave up most of Finland in the peace of 1721; made the tour of Europe 1716–17, and returned with many books and works of art; put to death his son Alexei 1718, on the ground of treasonable conduct; conquered three Caspian provinces from Persia 1722. D. Feb. 8, 1725. He was succeeded by Catherine I., his wife. Peter was the first Russian to take the title of emperor 1721. See Eugene Schuyler's *Peter the Great* (2 vols., 1884).

Peter II., Alexeievitch: Czar of Russia; b. at St. Petersburg, Oct. 22, 1715; a grandson of Peter the Great, a son of Alexei; succeeded Catherine I. in 1727. The most prominent features of his short reign were the desperate intrigues between the families of Mentchikof and Dolgoruki. The czar was only twelve years old and completely under the sway of Mentchikof, who had him betrothed to one of his own daughters and jealously kept him away from the court and all business; but the Mentchikofs were overthrown by the Dolgorukis, who planned a marriage between the czar and a daughter of their house; this was prevented by Peter's death, which occurred Feb. 9, 1730.

Peter III., Feodorovitch: Czar of Russia; b. at Kiel, in Holstein, Jan. 29, 1728; a son of Peter the Great's daughter Anna, who had married a duke of Holstein; was designated as heir to the Russian crown in 1742 by his aunt, the Empress Elizabeth; married, in 1745, the Princess of Anhalt-Zerbst, afterward Catherine II.; ascended the throne Jan. 5, 1762. He had two very prominent passions—admiration of Frederick II., with whom he immediately made peace, restoring to him the conquered provinces, and hatred of the royal dynasty of Denmark, against which he was on the point of waging war when a revolution, headed by his wife, broke out at St. Petersburg. Taken completely by surprise, he was deposed, and Catherine was proclaimed empress. He was strangled in his bed at Ropscha by the brothers Orloff, July 17, 1762.

Peterboro: town; Hillsboro co., N. H.; on the Contoocook river, and the Boston and Maine and the Fitchburg railways; 18 miles E. by S. of Keene, 33 miles S. W. of Concord (for location, see map of New Hampshire, ref. 10–E). It contains several cotton and woolen mills, iron-foundries, and shoe-factories, and has a town library (founded in 1833), a national bank with capital of $100,000, a savings-bank with deposits of over $875,000, and a weekly newspaper. Pop. (1880) 2,206; (1890) 2,507; (1900) 2,527.

Peterborough: town; capital of Peterborough County, Ontario, Canada; on the river Otonabee, and on the Grand Trunk and Canadian Pacific railways; 85 miles N. E. of Toronto (see map of Ontario, ref. 3–F). It is handsomely built on a fertile plain; has good water-power, manufactures of lumber, leather, machinery, castings, farm implements, etc. It has a good trade in grain, pork, lumber, and flour. A handsome bridge connects it with the village of Ashburnham. There are 2 daily and 2 weekly newspapers, and a monthly periodical. Pop. (1881) 6,812; (1891) 9,717.

Peterborough: city; partly in Northamptonshire, partly in Huntingdonshire, England; on the Nen, 76 miles N. of London (see map of England, ref. 9–J). It is celebrated for its beautiful cathedral, built between 1118 and 1528, chiefly in the Norman style. Its length is 476 feet; the height of the nave to the ceiling 81 feet, and of the lantern-shaped tower 135 feet; its breadth is 202 feet across the transept. The Early English west front, consisting of three arches, is one of the grandest products of mediæval architecture. The town has a large trade in agricultural produce, coal, and malt. It is the seat of a bishopric and returns one member to Parliament. Pop. (1891) 25,172.

Peterborough, Charles Mordaunt, Earl of: soldier; b. in England about 1658; joined Narborough's fleet in the Mediterranean; won distinction in Cloudesley Shovel's engagement with the dey's fleet off Tripoli; took part in the defense of Tangier, and on returning to England became an active politician, working in the Whig interests. He joined William, Prince of Orange, and accompanied him to England in 1688. He was appointed First Lord of the Treasury and created Earl of Monmouth, but retired from office Jan., 1690. He fell into disfavor with the court, and in 1697 was imprisoned in the Tower by order of Parliament, on an accusation of complicity in Sir John Fenwick's plot against the king's life. In the same year he succeeded to the earldom of Peterborough by the death of an uncle. Restored to favor on the accession of Queen Anne, he was placed in command of the land forces sent to the aid of the Archduke Charles of Austria in asserting his claim to the Spanish crown, and sailed for Spain in May, 1705. His chief exploit was the capture of Barcelona, to which against his judgment he had been obliged to lay siege. Early in September the siege was about to be abandoned as impracticable, when Peterborough obtained leave to undertake a seemingly desperate night-assault upon the citadel of Monjuich, one of the strongest fortresses in the world. This was successfully executed, and led to the capture of Barcelona. He then began a brilliant campaign, overran Catalonia, Aragon, and Valencia with the greatest rapidity, and successfully defended Barcelona against the formidable army of Philip

V. (1706), but resigned in 1707, in consequence of dissensions with his associate commanders. Employed for some years in diplomatic posts, he became governor of Minorca 1713, sided with the Tories during the last years of Anne, lived in retirement during most of the reigns of George I. and George II., was an associate and friend of the chief literary celebrities of the time, and became general of the marine forces of Great Britain 1722. D. at Lisbon, Oct. 25, 1735. Peterborough was a chivalrous and eccentric character, of vast military genius, and considerable literary taste, as shown by several occasional publications. He wrote his own *Memoirs*, but they were destroyed by his widow, the celebrated singer, Anastasia Robinson. See Macaulay's *Essays*, Lord Mahon's *History of England*, and Eliot Warburton's *Memoir of Charles Mordaunt, Earl of Peterborough* (1853), which contains selections from Peterborough's correspondence. Revised by F. M. Colby.

Peter, Epistles of St., The First: one of the catholic or general epistles; was written from "Babylon" (perhaps symbolical for Rome, but more likely the name of the actual city, which contained many Jews), about 64 A. D. Ramsay maintains that it was not written till 80 A. D.; cf. his *Church in the Roman Empire*, pp. 279, *seq.* It is evidently the product of perilous times and inculcates the duty of patience under suffering. It is a practical epistle, and addresses itself to various classes of readers, to each assigning the appropriate duty. It is the subject of one of the great religious classics—the commentary by the saintly Archbishop Leighton.—Peter, Epistle of St., The Second, has suffered more from doubts as to its authenticity than any other book of the New Testament. It is directed against heretics and corrupt men, and the second chapter, in which they are described, bears a striking resemblance to the Epistle of St. Jude. There is, however, no good reason to abandon the Petrine authorship. The author claims to have been a witness of the transfiguration, and uses Petrine expressions. Upon both epistles a good commentary is that by J. Lillie (New York, 1869). Revised by S. M. Jackson.

Peter, Gospel and Revelation of: two apocryphal writings contained in very fragmentary form in a Greek MS., found in a tomb of a monk at Akhmim in Egypt, the site of Panopolis, and not far from Assiout, by U. Bouriant in the winter of 1886–87. The MS. dates from the eighth century. The writings were previously only known by allusions in early Christian literature. Of the Gospel, the fragment is but about 150 lines long, and gives only, and that very imperfectly, the passion and resurrection history of Jesus. The date of original composition is the early part of the second century; the place is somewhere in Western Syria. The Revelation fragment is still shorter, only about 131 lines, but dates from the same time and place. It is mostly a description of a revolting character of the punishments of hell. Naturally most attention has been given to the Gospel, which is valuable. See for text and translation J. A. Robinson and R. J. Montague, *The Gospel according to Peter and the Revelation of Peter* (London. 2d ed. 1892); H. B. Swete, *The Akhmim Fragment of the Apocryphal Gospel of St. Peter* (1893); H. von Schubert, *The Gospel of Peter, Synoptical Tables with Translations and Critical Apparatus* (Edinburgh, 1893); *The Gospel according to Peter*, by the author of *Supernatural Religion* (London, 1894). Samuel Macauley Jackson.

Pe'terhead: a seaport and burgh in the district of Buchan, Aberdeenshire, Scotland; 44 miles by rail N. N. E. of Aberdeen (see map of Scotland, ref. 6–J). It stands on a narrow peninsula, across which a canal has been cut connecting its three rock-hewn harbors. The town is irregularly built, chiefly of granite. Among its buildings may be mentioned the town-hall, built in 1788, with a spire 125 feet high, the parish church, with a spire 125 feet high, a free library and museum, and an academy. It was formerly the chief seat in Scotland of the seal and whale fisheries, and is now noted for its herring-fishery, in which over 500 boats and 5,000 persons are employed. An immense harbor of refuge was begun, chiefly for their benefit, in 1886, and will be finished in 1921. The chief industries of the place are woolen manufactures, boat-building, and granite-polishing. Peterhead unites with Elgin, Banff, Cullen, Inverurie, and Kintore in sending one member to Parliament. Pop. (1891) 12,198. R. L.

Peterhof: an imperial palace in the government of St. Petersburg, Russia, on the Bay of Cronstadt, built by Peter the Great. It contains a fine collection of pictures, and is surrounded with beautiful parks and gardens. A small town has grown up around it.

Petermann, pā'ter-măn, August: geographer; b. at Bleicherode, in Prussian Saxony, Apr. 18, 1822; received a gymnasium education and entered (1839) the geographical institution of Prof. Berghaus at Potsdam, where he assisted in the preparation of Berghaus's *Physical Atlas*, and prepared the maps to A. von Humboldt's *Asie Centrale*; in 1845 went to Edinburgh to superintend the English edition of the *Physical Atlas*, and in 1847 to London, where he became a member of the Royal Geographical Society, and wrote a number of geographical essays and articles; in 1854 returned to Germany as director of Justus Perthes's geographical institution in Gotha, and (1855) began the publication of *Mittheilungen*, a monthly which is considered as the central organ and the highest authority in present geographical literature. D. by suicide (like his father and brother before him) at Gotha, Sept. 25, 1878.

Peters, Christian August Friedrich: astronomer; b. in Hamburg, Germany, Sept. 7, 1806. On the foundation of the Pulkowa Observatory he became one of the principal astronomers, and published noteworthy papers on the parallaxes of stars, the constant of nutation, etc. In 1849 he resigned and went to the Königsberg Observatory, but left to become director of the observatory at Altona and editor of the *Astronomische Nachrichten*. He continued the publication of this journal until his death, at Kiel, May 8, 1880. S. N.

Peters, Christian Henry Frederick, Ph. D.: astronomer; b. at Coldenbüttel, Schleswig, Germany, Sept. 19, 1813; graduated at the University of Berlin; engaged in scientific researches, after which he settled in the U. S.; was employed upon the Coast Survey; became Professor of Mathematics and Astronomy at Hamilton College 1859, where he took charge of the Litchfield Astronomical Observatory, and made very extensive investigations concerning comets and asteroids, discovering more than forty of the latter bodies; catalogued 16,000 zodiacal stars, and recorded over 20,000 solar spots. He took a prominent part in the observation of the total solar eclipse of Aug. 7, 1869, at Des Moines, Ia.; was chief of the party sent by the U. S. Government to New Zealand to observe the transit of Venus of Dec. 9, 1874, and was the only observer on that island who had complete success, having obtained 237 photographs of the transit. D. at Clinton, N. Y., July 19, 1890. Revised by S. Newcomb.

Peters, John Charles, M. D.: b. in New York, July 6, 1819; studied homœopathy in Europe, and returned to New York to practice his profession. He edited the *North American Journal of Homœopathy* (1856–61), was one of the translators of Rokitansky's *Pathological Anatomy*, and was the author of medical treatises. S. T. A.

Peters, Phillis (*Wheatley*): a Negro poet; b. in Africa about 1750; was taken as a slave to Boston 1761; was taught to read by the family of her master, John Wheatley; made rapid progress in letters; soon displayed so much poetical talent, stimulated by the reading of Pope's *Homer*, that a volume of her verses was printed in London 1773, with a copperplate portrait and a dedication to the Countess of Huntingdon. She visited England in that year; wrote some notable verses to Gen. Washington. Her poem was printed by his direction in the *Pennsylvania Magazine* for Apr., 1776. She married a Negro named John Peters, who seems to have fallen into great poverty during the Revolution. D. at Boston Dec. 5, 1784. Her *Letters* were printed in 1864. Revised by H. A. Beers.

Peters, Richard: judge; b. at Belmont (now part of Philadelphia), Pa., Aug. 22, 1744; after graduating from college, studied law, and became a successful lawyer, distinguished for wit and brilliant social qualities; was a captain in the Revolution; secretary to the continental board of war 1776–81; was in Congress 1782–83; was U. S. district judge 1792–1828, and his decisions upon admiralty questions (published in 2 vols. in 1807) had much influence in shaping the admiralty law of the U. S. D. at Belmont, Pa., Aug. 21, 1828.—His son, Richard Peters (b. at Belmont, Aug., 1780; d. May 2, 1848), succeeded Mr. Wheaton as reporter of the U. S. Supreme Court, and published *Reports of the United States Circuit Court, Third Circuit, 1803–1818* (17 vols.); *Condensed Reports of Cases in the United States Supreme Court to 1827* (6 vols.); *Digest of Cases in the United States Supreme Court and District Courts to 1847* (2 vols.); and *Case of the Cherokee Nation against the State of Georgia* (1831). He also edited *Chitty on Bills* (1819),

Washington's Circuit Court Reports (*Third Circuit, 1803–27*; 4 vols.), and the *United States Statutes at Large*.

Revised by F. Sturges Allen.

Peters, Samuel: clergyman; b. at Hebron, Conn., Dec. 12, 1735; graduated at Yale College in 1757; went to England for ordination, and returned in 1760 to become the Church of England minister at Hartford. He fled to Boston in 1774 to escape molestation at the hands of the Sons of Liberty on account of his aggressive Toryism, and from Boston, in October, he sailed to England, where he obtained a small pension from the crown, and remained until 1805. In 1781 he published *A General History of Connecticut from its First Settlement under George Fenwick, Esq.*, etc., as being written "By a Gentleman of the Province," which book gave rise to the widespread misconceptions concerning the Connecticut Blue Laws (*q. v.*). In 1794 he was chosen Bishop of Vermont, but the Archbishop of Canterbury and the bishops of the American Church refused him consecration. On his return in 1805 to the U. S. he published *A History of Rev. Hugh Peters* (New York, 1807), alleged by him to be his granduncle, and also a short history of Hebron; in 1817 he endeavored to get possession of a tract of land in what is now Minnesota. D., in great poverty, in New York, Apr. 19, 1826. Peters was notorious for his habit of falsification, and his autobiography was wholly untrustworthy. He wrote his name variously Samuel Peters, Samuel Andrew, and Samuel A., and appended to it the letters LL. D., although how he came by the right to the title is unknown. Some books of reference make him D. D., and some books make him both D. D. and LL. D. He is the Parson Peter in Trumbull's *McFingal*.

F. Sturges Allen.

Petersburg: city (laid out by Abraham Lincoln in 1835); capital of Menard co., Ill. (for location, see map of Illinois, ref. 6–D); on the Sangamon river and the Chi. and Alton and the Chi., Peoria and St. L. railways; 20 miles N. W. of Springfield. It is in an agricultural, timber, coal-mining, and stock-raising region, and has medicinal springs, waterworks, public square, 2 flour-mills, a national bank with capital of $50,000, 2 private banks, and 2 weekly papers. Pop. (1890) 2,342; (1900) 2,807. Editor of "Observer."

Petersburg: town; capital of Pike co., Ind.; on the Evansville and Terre Haute Railroad; 20 miles S. E. of Vincennes, 44 miles N. N. E. of Evansville (for location, see map of Indiana, ref. 10–B). It is in a coal, dairy, tobacco, and stock-raising region, and has flour and woolen mills, brick and tile works, lumber-working and other factories, a State bank with capital of $25,000, and three weekly newspapers. Pop. (1880) 1,193; (1890) 1,494; (1900) 1,751.

Petersburg: city in Virginia (settled in 1733, incorporated in 1748, reincorporated in 1781); port of entry; formerly in Chesterfield, Dinwiddie, and Prince George Counties, but now independent; on the Appomattox river at the head of tide-water, and the Petersburg, the Norfolk and Western, the Richmond and Petersburg, and the Seaboard Air Line railways; 12 miles W. of the confluence of the Appomattox and James rivers, 22 miles S. of Richmond (for location, see map of Virginia, ref. 7–H). It is the third city in population in the State, is built on the declivities of a hill sloping to the river bank, and derives abundant power for manufacturing from the falls in the river. There are 38 churches, 2 high schools, 9 public-school buildings, public-school property valued at over $75,000, the Southern Female College, the Bishop Payne Divinity School (colored), 2 libraries containing over 13,000 volumes, 2 public parks, a national bank with capital of $100,000, 2 State banks with capital of $300,000, and a quarterly, 2 daily, and 4 weekly periodicals. The city has a copious supply of pure water for domestic purposes, has two telephone companies, electric-lighting and street-railway plants, and is the most important shipping-point for manufactured tobacco in the U. S. The census returns of 1890 showed that 223 manufacturing establishments (representing 56 industries) reported. These had a combined capital of $3,879,151, employed 5,315 persons, paid $1,283,612 for wages, and $4,200,936 for materials, and had products valued at $6,876,352. There are 6 large tobacco-warehouses, 13 tobacco-factories, 5 cotton-mills, 5 corn and 3 flour mills, 4 foundries and machine-shops for the manufacture of heavy machinery, silk-mills, 4 trunk factories, granite-quarries, and other industries. The city is on the site of an Indian village burned by Nathaniel Bacon in 1676; was twice occupied as headquarters by British commanders during the Revolutionary war; received the popular name of "Cockade City" from President Madison because of the gallantry of its company of volunteers in the war of 1812; and has been called the "last citadel of the Confederacy" from its heroic defense in the war of 1861–65. The Army of the Potomac, under Gen. Grant, being induced by the result of the second battle of Cold Harbor to abandon its advance upon Richmond by the line of the Chickahominy, crossed the James river below City Point June 14–16, 1864, and made formidable assaults on Petersburg June 15, 16, 17, and 18, carrying portions of the exterior lines on each of the first three days; but, being generally unsuccessful in the assaults of the 18th, the ground occupied at the close of the day was intrenched and held up to the close of the war, forming part of the line of investment. The Union loss in killed, wounded, and missing was 10,586. The siege began on June 19, and was continued by constantly gaining and intrenching ground to the left and moving against the railways with a view to isolating the city, combined with the explosion of a mine under one of the works, with the resulting "battle of the crater," and numerous other actions. The siege was continued until Apr. 2, 1865, when, the place being no longer tenable, Lee withdrew his army, the Union troops taking possession on Apr. 3, the surrender at Appomattox occurring Apr. 9. Pop. (1900) 21,810.

Petersen, Dory: See the Appendix.

Petersen, pā'ter-sen, Johann Wilhelm: theologian; b. at Osnabrück, Hanover, June 1, 1649; studied theology at Giessen, Rosbach, and other German universities; became a disciple of Spener, with whom he met at Frankfort in 1675; was in 1677 appointed superintendent of Lübeek and in 1688 of Lüneberg. In the meantime he had made the acquaintance of Juliane von Asseburg, who claimed that the Saviour often revealed himself to her in visions and spoke to her of his second advent. Petersen, who was a strong and outspoken chiliast, put implicit confidence in those revelations, and laid them in a solemn manner before the German clergy. The municipal council of Lüneburg, however, took another view of the case. He was deposed in 1692, and lived afterward at Thymer, near Zerbst, where he died Jan. 23, 1727. Of his works, which are very numerous, the principal are *Wahrheit des herlichen Reiches Jesu Christ* (Magdeburg, 1692–93, 2 vols.) and *Geheimniss der Wiederbringung aller Dinge* (Frankfort, 1700–10, 3 vols. fol.). He also wrote exegetical works, Latin and German poems (the former edited by Leibnitz, who also showed great sympathy for Juliane von Asseburg), and an autobiography (2d ed. Frankfort, 1719). See H. Corrodi, *Kritische Geschichte des Chiliasmus* (Frankfort, 1871; 2d ed. 4 vols., Zurich, 1794).

Revised by S. M. Jackson.

Petersen, Niels Matthias: scholar; b. at Sanderup, island of Fünen, Denmark, Oct, 24, 1791; studied philology and history, and became Professor of the Ancient Scandinavian Language and Literature in 1845 at the University of Copenhagen. His works relating to ancient Scandinavian mythology, literature, history, and language, *Det Danske, Norske og Svenske Sprogs Historie* (1829), *Den Nordiske Mythologi* (1849), *Danmarks Historie i Hedenold* (1834), *Haandbog i den gammelnordiske Geographi* (1834), etc., though now superseded, exercised a great influence at the time of their appearance. His *History of Danish Literature* (5 vols., 1853–64; 2d ed. 1867–70) is the most elaborate work on that subject, and is the standard authority. D. at Copenhagen, May 11, 1862. Revised by D. K. Dodge.

Petersilea, Carlyle: See the Appendix.

Peterson, Frederick, M. D., Ph. D.: neurologist and poet; b. in Faribault, Minn., Mar. 1, 1859; studied medicine at the University of Buffalo, New York, graduating M. D. in 1879; Professor of General Pathology, University of Buffalo, 1882–84; lecturer on nervous diseases, New York Polyclinic, 1888–91; instructor in nervous and mental diseases, College of Physicians and Surgeons, New York, from 1888; Professor of Neurology, University of Vermont, 1893–94. He has published two volumes of poems: *Poems and Swedish Translations* (Buffalo, 1883); *In the Shade of Ygdrasil* (New York, 1893); and is the author of important monographs on neurological subjects.

Peterson, Peter Archibald, D. D.: b. at Petersburg, Va., Sept. 28, 1828; received only common school training; served as a lieutenant in Company E, First Regiment, Virginia Volunteers, in the Mexican War, 1846–48; in 1852 joined the Virginia Conference; was a member of every general conference from 1866 to 1890; served as chaplain in

the Confederate army 1861–62; delegate to Œcumenical Conference, Washington, 1891. His last pastorate was in Trinity church, Richmond, Va., where he died Oct. 6, 1893. He published *Handbook of Southern Methodism* (1882 and 1891). A. Osborn.

Peter's Pence, or **Romescot**: an ancient tax for the benefit of the pope, probably first levied as a tax for the support of the English school at Rome. (See Lappenberg's *History of England under the Normans.*) Peter's Pence was paid the pope, with some interruptions, until 1534, during the reign of Henry VIII., when it was finally abolished. The levy of Peter's Pence was customary in various other countries at different times. During the nineteenth century it has been revived as a voluntary popular contribution, and is one of the chief sources of the pontifical revenue, especially since the establishment of the Italian monarchy. See Cancellieri, *La visita de' sacri limini ed il danaro di S. Pietro* (Rome, 1821); Paul Fabre, *Étude sur le Liber Censuum de l'Église Romaine* (Paris, 1892).

Revised by J. J. Keane.

Peter's, St.: a basilica in Rome. It consists of a Latin cross 613 feet long and 450 feet across the transept, surmounted by a dome which rises 434¾ feet above the pavement with a diameter of 195½ feet. The façade is 368 feet long and 145 feet high. The building was begun under Pope Nicholas V., after a plan by Rosselini, in 1450, but the work was neglected for nearly half a century. Under Julius II., Bramante prepared a new plan, which was subsequently followed out in the main. Raphael had charge of the building for some time. Michelangelo designed the dome and nearly completed its erection. The façade is by Carlo Maderno, the colonnade by Bernini. The church was consecrated by Urban VIII. Nov. 18, 1626, the 1300th anniversary of the day on which St. Sylvester consecrated the basilica which originally occupied the site. This was built by Constantine the Great on the spot where, according to the tradition of the Roman Catholics, the apostle Peter suffered martyrdom. St. Peter's is the largest church in Christendom, and is exquisitely proportioned. See Fontana, *Tempio Vaticano*; Cancellieri, *De Secretariis Vaticanis*; Letarouilly, *Le Vatican et la Basilique de Saint Pierre* (Paris, 1882). Revised by J. J. Keane.

Peter the Hermit: religious leader; b. at Amiens in the middle of the eleventh century; was educated in Paris and Italy; served in the army in Flanders, but gave up the military career and married; became a monk after the death of his wife, and finally a hermit; made in 1093 a pilgrimage to Jerusalem, and, deeply impressed by the indignities and cruelties inflicted on the Christian pilgrims by the Mohammedan rulers of the city, he began immediately on his return to Europe, and with the authority of Pope Urban II., to preach a general war for the delivery of the holy sepulchre. His preaching in Italy and France stirred up the whole populace, and a crusade was actually determined upon by the Council of Clermont in 1095. Peter himself led the first army toward the Holy Land—an undisciplined and disorderly swarm, containing as many women and children as men. After unspeakable sufferings on their way through Hungary, Bulgaria, and Constantinople to Asia Minor, they were routed and massacred at Nice by Sultan Solyman. Next year a regular and brilliant army, comprising the flower of European chivalry, undertook the second crusade, under the command of Godfrey of Bouillon. Peter accompanied also this expedition, and after the conquest of Jerusalem in 1099 he preached to the crusaders on the Mount of Olives. Shortly after he retired to Belgium, where he founded a monastery, at Neu-Moutier, near Liége, and died there July 7, 1115. Some consider the story of his activity in inciting the crusades as unauthentic, and deny that Peter ever was in Palestine prior to his expedition. See H. Hagenmeyer, *Peter der Eremit* (Leipzig, 1879).

Revised by S. M. Jackson.

Peterwardein: city of the county Syrmia, Austria-Hungary; formerly capital of the Slavono-Servian military frontier; a strong fortress on the Danube with barracks for 10,000 men (see map of Austria-Hungary, ref. 8–H). Here (1096) Peter the Hermit reviewed the first crusade and (1716) Prince Eugene of Savoy disastrously defeated the Ottomans under Damad Ali Pasha. Pop. 3,603. E. A. G.

Petigru, James Lewis: lawyer; b. in Abbeville co., S. C., Mar. 10, 1789; graduated at Columbia College (now the University of South Carolina) in 1809; after his admission to the bar in 1812 settled in Charleston, S. C., and rapidly rose to the leadership of the bar in his State. He was a decided adherent to the principles of the Federal party, and in the days of nullification he was the acknowledged leader of the Union party. He opposed the doctrine of secession, but, by reason of his sincerity, integrity, and ability, retained the respect and esteem of his fellow-citizens, and held various public and private positions of trust. Upon the secession of South Carolina he remained loyal to the State, although he took no active part in the work of secession. He was appointed by the State Legislature to codify the laws of South Carolina, and completed the work a short time before his death, in Charleston, Mar. 3, 1863. See his *Biography*, by W. J. Grayson (New York, 1866), and the *Memorial* (1867) containing the proceedings of the Bar of Charleston, S. C., shortly after his death.

F. Sturges Allen.

Pétion, pā'ti'ōn', Alexandre: soldier and politician; b. at Port-au-Prince, Haiti, Apr. 2, 1770. He was a quadroon, the son of a wealthy planter; was educated in Paris; served with the French army in Haiti; joined the revolt of 1791, and was commandant of artillery under Toussaint Louverture, but went over to Rigaud in 1799, and was forced to leave the island with him in 1800. Going to France he was attached, as colonel, to Leclerc's expedition, destined to subdue Haiti; he did efficient service, but at the end of 1802 joined the new revolt of those who feared that slavery would be re-established. On the death of Dessalines, Christophe seized the government of the northern provinces, but the rest of Haiti remained in the hands of the mulatto party, which declared a republic and made Pétion president Mar. 10, 1807. He was re-elected in 1811 and 1815. Christophe and the black party, who still held the north, waged an almost continual war against Pétion, whose many enlightened measures were often defeated by ignorance and malice. He protected whites and opened the ports to all flags. D. at Port-au-Prince, Mar. 29, 1818. Herbert H. Smith.

Petit de Julleville, pe-tec'de-zhül'veel', Louis: historian; b. in Paris, July 18, 1841; graduated at the École Normale; studied in the French school at Athens; was instructor in the Collège Stanislas, Paris; then professor in the faculty of letters of Dijon; and in 1886 was called to a professorship in the faculty of letters of Paris. His best-known works are in connection with the dramatic history of France, *Histoire du Théâtre en France: Les Mystères* (2 vols., 1880); *Les Comédiens au moyen âge* (1885); *La Comédie et les moeurs en France au moyen âge* (1886); *Répertoire du Théâtre comique en France au moyen âge* (1886); *Le Théâtre en France* (1889). A. G. Canfield.

Petition of Right: (1) a celebrated English statute passed early in the reign of Charles I. (3 Car. I., c. 1, A. D. 1627) for the purpose of restraining and limiting the acts and prerogatives of the crown, and securing the personal and civil liberties of the subject. Although a legislative act, yet, as it does not profess to establish any new rule, but simply to reaffirm those already in existence, it is in the form of a petition, and is entitled, "The Petition exhibited to His Majesty by the Lords and Commons, etc., concerning divers rights and liberties of the subjects, with the King's Majesty's royal answer thereto in full Parliament." After reciting the most important provision of Magna Charta and certain old statutes passed in the reigns of Edward I. and Edward III., which prohibited unlawful taxes and assessments, and forced loans, and illegal arrests and imprisonments, and quartering of soldiers upon private citizens, and a resort to martial law in civil cases; and after reciting in detail the various acts done by or in the name of the king which violated all of these prohibitions—viz., his unwarrantable levies of taxes, his forced loans, his arbitrary arrests and imprisonments, his quartering of soldiers in private houses, and his commissions authorizing the use of martial law—the Parliament prays that all these acts and proceedings should be discontinued and not repeated, recapitulating the violations of law above mentioned in detail, and concluding in the following language: "That you would be pleased to declare your royal will and pleasure that in the things aforesaid all your officers and ministers shall serve you according to the laws and statutes of this realm, as they tender the honor of Your Majesty and the prosperity of this kingdom." The king's assent, given in full Parliament, is indicated by the formula, "*Soit droit fait come est desiré*" (Let right be done as prayed). This declaration of the legislature is justly considered one of the fundamental and

constitutional guaranties by which civil and political liberty is secured to the British people. Although it does not contain in express terms the statement of broad principles, but rather deals with particular instances of executive wrongdoing, yet it is regarded as including and establishing the principles of personal right and liberty in the most comprehensive manner.

(2) A common-law proceeding by which a subject sought to establish his title to and recover possession of property which was held by the crown. (See INQUEST OF OFFICE.) As the sovereign is not liable to an ordinary suit at law, a petition setting forth the facts of the case and praying for the proper relief is presented to him, upon which he indorses the words "*Soit droit al partie*" (Let right be done to the party), and delivers it to the law officers of the crown. The subsequent proceedings resemble those in an ordinary action between subject and subject; the issues are tried before a court, and judgment is rendered for or against the petitioner according to the merits of the case. The Petitions of Right Acts (20 and 21 Vict., c. 44; 23 and 24 Vict., c. 34; and 36 and 37 Vict., c. 69) provide an alternative remedy for the claimant in these cases. Revised by FRANCIS M. BURDICK.

Petit Mal: See EPILEPSY.

Petit-Thouars: See DUPETIT-THOUARS.

Petoskey: village; Emmet co., Mich.; on Little Traverse Bay, Lake Michigan, and on the Chi. and West. Mich. and the Grand Rapids and Ind. railways; 60 miles N. N. E. of Traverse City, 120 miles N. by E. of Reed City (for location, see map of Michigan, ref. 3–I). It is in an agricultural region, has lime-kilns and leather and woodenware factories, is connected by a line of steamers with Chicago, Detroit, Escanaba, Buffalo, and other lake ports, and is a popular summer resort. There are a State bank with capital of $50,000, a private bank, and a monthly and three weekly newspapers. Pop. (1880) 1,815; (1890) 2,872; (1900) 5,285.

Pe'tra [= Lat. = Gr. Πέτρα; cf. πέτρα, rock]: the Selah of 2 Kings xiv. 7, taken from the Edomites by Amaziah (839–810 B. C.), in the hands of the Moabites about 700 B. C., and the capital of the Nabathæans (descendants of Nebaioth, the eldest son of Ishmael) about 300 B. C., when the Greeks first knew it as Petra. During the reign of Trajan (in 105 A. D.) it was conquered by the Romans; is mentioned several times by Eusebius and Jerome as an ecclesiastical metropolis, but is not heard of after about 536 A. D. Whether destroyed by the Mohammedans in the seventh century, or previously by the hordes of the desert, is not known. Its identification, suggested by Ritter on the basis of facts gathered by Seetzen in 1807, was established by Burckhardt in 1812. A good description of the ruins may be found in Robinson's *Biblical Researches* (Boston, 1841), as also in Murray's (Porter's) *Handbook for Syria and Palestine* (London, 1875), and with numerous illustrations in E. L. Wilson's *In Scripture Lands* (New York, 1890). The little valley, now called *Wady Musa*, is about 28 hours N. E. of Akabah, the eastern head of the Red Sea. The ruins, shut in by cliffs from 150 to 300 feet high, occupy an area of about half a mile square, are approached through a narrow and dark cañon, and burst upon the traveler in a way never to be forgotten. A stream still flows through the valley. The ruins of tombs, a theater, and a building supposed to have been a temple are exceedingly picturesque, as all these were cut from the living rock, and not built. The Bedouins who infest Petra have a bad reputation, and dragomans are afraid to conduct small parties thither.

Revised by S. M. JACKSON.

Petrarch (Ital. *Petrarca*), FRANCESCO: Italian poet and scholar; b. at Arezzo, July 20, 1304; d. at Arquà, near Padua, July 18, 1374. At the time of the poet's birth his family was in exile from Florence, his father, Petracco (name later modified to Petrarca by the son), being, like Dante, one of the White Guelphs banished in 1302. The first seven years of the boy's life were spent with his mother at Incisa; in 1310 he went with the family to Pisa, where he began his studies under Convenevole da Prato; but in 1313 his father decided to settle in Avignon, in France, then the papal residence. For many years this last city was Petrarch's real home. From 1315 to 1319, however, he was studying at Carpentras under his old master, then removed to France. His father now destined him for the career of jurisprudence, and he went first to Montpellier (1319), then to Bologna (1323), to study for this. His tastes were all for letters, however, and he had already conceived that passion for the Latin classics which was to make him the first of the humanists, the true initiator of the intellectual life of the Renaissance. In 1326, after the death of his father and mother, the young man returned to Avignon, and there entered the Church, receiving, however, only minor orders. He continued his favorite studies, and also took part in the gay and licentious life of the place.

At Avignon, on Good Friday, Apr. 6, 1327, as the poet himself tells us (but in 1327 Good Friday was Apr. 10), occurred an event that affected his whole after-life. In the Church of Sta. Clara he saw for the first time the woman he was to celebrate in verses of more lasting fame than was to be obtained by any other product of his pen. Few literary questions have been more discussed than that of the reality or unreality of this lady, Laura, as the poet calls her. Like Beatrice, she has been made out to be almost every form of poetical abstraction; but, in spite of all, the probability remains that she was Laura de Noves, wife of Hugues de Sade, a lady of whom we know that she died in 1348, having been the mother of eleven children. Whoever Laura was, there can be no doubt that the poet's love for her was profound, and that it deeply affected his whole spiritual life. It did not, however, prevent him from intrigues of a lower kind or from bringing into the world illegitimate children by a nameless mother.

It was not long after he had first seen Laura that Petrarch began to feel that restlessness which for many years made him a constant traveler. We can not follow his many peregrinations, but the reader will find them briefly and clearly enumerated by d'Ancona and Bacci in their *Manuale della letteratura italiana*, vol. i., p. 361–372 (2d ed., Florence, 1893). Suffice it to say that before he died he had visited the most notable cities of Italy, France, and Southern Germany, and had even been as far as Prague in Bohemia. These journeys, however, did not impede his study of the classics; they rather helped it. Wherever he went he was ever on the lookout for manuscripts of his favorite authors, and he first rescued from oblivion Cicero's *Letters to Atticus* and several of his orations, as well as a considerable portion of Quintilian. He also inspired all those with whom he came in contact with a passion for collecting similar manuscripts, and thus he began the necessary task of gathering together the productions of the ancient world in order that they might really be studied and known. His letters, of which a great number are preserved to us, show us how eagerly and consistently throughout his mature life he labored for the restoration of classical learning, and how abundant were the results of his efforts.

Naturally the encyclopædic scholarship of the poet, as well as the remarkable beauty of his Italian verse, speedily brought him great fame. In 1340, while he was at his favorite retreat of Vaucluse, near Avignon, he received a striking evidence of this renown in the form of simultaneous invitations from the University of Paris and from Rome to accept the laurel crown. He decided in favor of Rome, and Apr. 8, 1341, he was with great solemnity crowned upon the Capitol. The next years of his life were spent in many places, mostly in Italy, though he several times returned to Avignon and his beloved Vaucluse. In 1353, however, he abandoned Avignon forever, and his last years were spent in Italy—in Milan, Padua, Venice, and other places. In 1370, full of rejoicing at the return of the papal curia to Rome, he undertook a journey thither, but fell ill on the way, and retired to Arquà, in the Euganean hills, twelve miles from Padua. Here he lived till the day when his friend Lombardo da Serico found him dead in his study, with his head reclining upon the pages of a book.

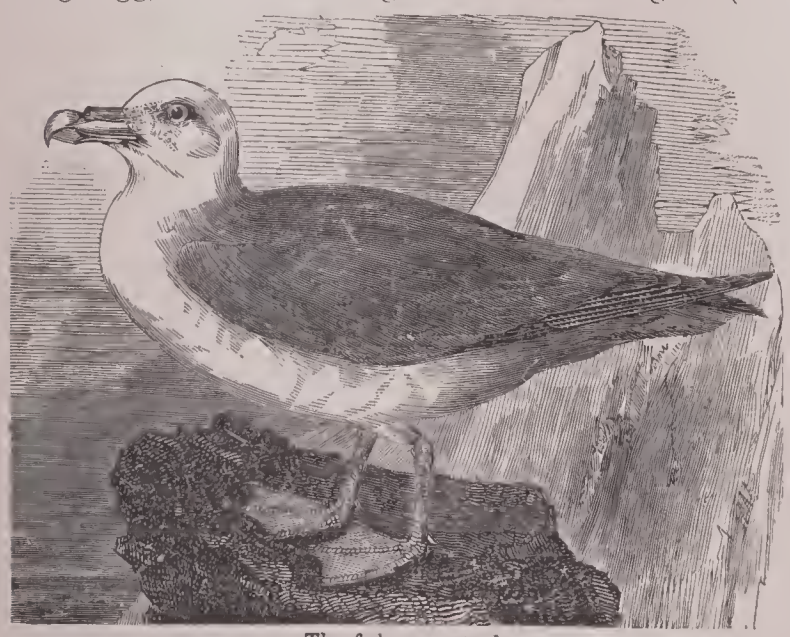
It is rare that a man obtains fame as great as Petrarch's in two distinct fields. It is chiefly as the poet, the singer of Laura, that he is known to the world at large; and, in fact, though he is far from having the high seriousness of Dante, it would be hard to exaggerate his importance in the history of Italian literature. Yet this is perhaps not his best title to the memory of men, but rather the fact that in him we have the initiator of the movement which has had such profound consequences for the modern world—the movement of return to the classics, to humanism, to the life and art of the natural man. Both he and his contemporaries were guilty of much exaggeration and misapprehension as to the true character of this movement. His own firm belief, for instance, in the superior excellence of his Latin epic, *Africa*, has not been justified by the judgment of posterity; and yet it is certain that from the huge mass of his Latin works have come influences of deeper im-

port than any that the *Canzoniere* gave rise to. The very titles of these works, however, are forgotten, except by the professed students of the Renaissance, and can be mentioned here only in the most cursory way. They fall into three groups—works of erudition, works of criticism or invective, and works of a personal or moral character. To the first group belong *Rerum memorandarum libri IV.*, *Itinerarium Syriacum*, *De viris illustribus*. In the second group fall *Invectiva in medicum*, *Invectiva in Gallum*, *De sui ipsius et multorum aliorum ignorantia*. The last group contains the poetical *Carmen bucolicum* (twelve eclogues) and *Epistolæ metricæ*, and the prose treatises *De contemptu mundi*, or *Secretum*, *De vita solitaria*, *De otio religiosorum*, *De vera sapientia*, *De remediis utriusque fortunæ*. Most of these last are in dialogue form. Finally should be mentioned the letters, *Epistolæ*, of which Petrarch himself made several collections.

The literature about Petrarch is now enormous, and can be found best enumerated in Willard Fiske, *A Catalogue of Petrarch Books* (Ithaca, N. Y., 1882). There are countless editions of the Italian poems, *Canzoniere*, e. g. edited by C. Pasqualigo, Venice, 1874. The Latin poem *Africa*, edited by F. Corradini, is printed in the volume *Padova a Francesco Petrarca nel quinto centenario dalla sua morte*, 1874. Of the other Latin works there is no good edition, the best being still that in folio, Basel, 1554. Of the *Epistolæ de rebus familiaribus* and *Epistolæ variæ* there is the excellent edition of G. Fracassetti (3 vols., 1859–63), and the same scholar has published an Italian translation of these and the remaining letters (7 vols., 1863–70). For Petrarch's life and literary character, see the following: A. Mézières, *Pétrarque*, etc. (Paris, 1867); L. Geiger, *Petrarka* (Leipzig, 1874); G. Koerting, *Petrarcas Leben und Werke* (Leipzig, 1878); G. Voigt, *Die Wiederbelebung des classischen Alterthums* (2d ed. 2 vols., Berlin, 1880); A. Bartoli, *Storia della letteratura italiana* (vol. vii., Florence, 1884); P. de Nolhac, *Pétrarque et l'humanisme* (Paris, 1892).

A. R. Marsh.

Pet'rel [from Fr. *pétrel*, dimin. of Lat. *Pe'trus*, Peter]: any member of a family (*Procellaridæ*) of sea birds belonging to the order *Tubinares*. The name was originally applied to the smaller species which, like the Mother Carey's Chicken (*q. v.*) flutter over the water with their feet just touching the surface, seeming, like Peter, to walk upon the sea. Petrels have long, narrow, pointed wings, hooked beaks with the nostrils opening in a tube. The plumage is thick, soft, rather oily, and has a peculiar, ineradicable musty smell. These birds feed on almost any animal matter, but are particularly fond of fat, and when captured not only defend themselves with beak and claw, but eject from their mouths a thick, oily, ill-smelling liquid. They dwell in communities and breed in holes, rarely laying more than a single egg, and come to and go from the nest at night. (For



The fulmar petrel.

a description of the nest of the fork-tailed petrel, see Nests of Birds.) Petrels are pre-eminently sea birds, only coming ashore to breed, and are found in all oceans, very sparingly in the tropics, most abundantly in the colder portion of the south temperate zone. The largest species is the giant fulmar (*Ossifraga gigantea*), frequently called the Cape-hen by sailors, a bird about 3 feet long and 7 feet in spread of wing, of a sooty color, lighter below. The bill is whitish. This species ranges N. in the Pacific to the coast of California, but the southern seas are its true habitat. The fulmar (*Fulmarus glacialis*) is the best known in the northern hemisphere, the Cape-pigeon (*q. v.*; *Daption capensis*) in the southern. Those petrels belonging to the genus *Puffinus* and related genera, which have a short nasal tube and rather slender beak, are commonly termed shearwaters, but it is rather a "book name." The Albatross (*q. v.*) is a near relative of the petrels.

F. A. Lucas.

Petrie, W. M. Flinders: Egyptologist; b. June 3, 1853; educated privately; engaged in mapping and measuring ancient British earthworks 1874–80; devoted much labor to the theory of the recovery of ancient measurements from monuments; has made several exploring expeditions in Egypt, in the third of which he discovered the city of Naukratis. Author of numerous works on Egyptology and archæology, among the most important being *Stonehenge: Plans, Descriptions, and Theories* (1880); *Tanis* (1885); an article on *Weights and Measures* in the ninth edition of the *Encyclopædia Britannica* (1887); *Historical Scarabs* (1888); *A Season in Egypt* (1888); *Hawara, Biahmu, and Arsinoe* (1889).

Petrifactions: a general name applied to fossils in reference to the mineralization of the organic tissues which were buried in the muds and sands from which the rocks were made.

Petrog'raphy [from Gr. *πέτρα*, rock + *γράφειν*, write]: that branch of natural science which has for its object the study of rocks. The terms *lithology* and *petrology* have thus far usually been used as synonyms with *petrography*, but some authors, as A. H. Green and Wadsworth, have attempted to differentiate their meanings. From their derivation it would be natural to divide these three terms so as to reserve *lithology* for the study of stones or rocks as hand specimens, especially with reference to their constituent minerals; *petrography* for the description of rocks both as mineral aggregates and in their broader field relations as geological bodies; and *petrology* for the philosophical discussion of questions of origin, relationships, metamorphism, etc., which can only follow a considerable advance in the two foregoing departments. Petrography is the most generally employed of these three terms to cover the entire field of rock study. See Rocks.

The investigation of rocks as a separate department of Geology (*q. v.*), though by no means new, dates its modern importance from the successful application of the polarizing microscope to the study of rock sections, cut thin enough to be transparent, the way to which was first pointed out by Sorby in 1858. Petrography includes the investigation of the nature, origin, composition and structure, genetic relationship, and secondary alterations in all rocks. The subject is one whose importance was clearly recognized at the dawn of geologic science, but for a long time it yielded no satisfactory results because of the lack of adequate appliances. It is now possible not merely to identify under the microscope (the most valuable appliance) the constituent minerals of even the finest-grained rocks, to determine their optical and other physical constants, and to make out their relative ages, modes of growth or the rock structures which they produce, but by means of various high specific-gravity solutions and the electro-magnet these constituents may be separated in a pure state and subjected to a complete chemical analysis. Much has also been done in the way of rock synthesis.

Rocks of a highly crystalline character have been most studied, both because, in the nature of the case, they are best suited to yield definite optical and chemical results, and because they are without those palæontological and stratigraphical aids to geological correlation which the sedimentary deposits possess. Field and laboratory study of rock masses have furnished and are still furnishing material for the comparative study of petrographic provinces, as well as for conclusions regarding the cause, extent, and nature of rock alterations, which promise to throw light on the darkest chapters of our earth's history.

George H. Williams.

Petro'leum [Gr. *πέτρα*, stone, rock + Lat. *o'leum*, oil]: the fluid form of bitumen, distinguished from maltha by its lessened viscidity, and its occurrence, in even its most dense forms, free from water. It is known also by the names rock-oil, mineral oil, and others. For its origin, see the article Bitumen.

History.—Although petroleum has been known in Persia, China, Japan, and other countries since the earliest times, the U. S. led in the production till 1898, when it was passed by Russia. In China it was obtained from artesian borings before the dawn of history. In Japan and Burma dug wells have been employed for centuries. In Persia it has been obtained from springs from a very remote period. Springs of petroleum early attracted the attention of travelers in the far East. Herodotus in 500 B. C. wrote of the springs of Zante, which are still flowing; and he describes how the oil was collected on a myrtle branch dipped into the spring. Pliny and Dioscorides mention the oil of Agrigentum, which was used in lamps under the name of "Sicilian oil." The wells of Amiano formerly supplied oil for lighting in the city of Genoa. At Point Apscheron, near Baku, on the Caspian Sea, at the eastern end of the Caucasus Mountains, springs of petroleum have been known from very early times. At Yenangyoung (earth-oil river), on the Irawadi, a heavy sort of petroleum has long been obtained from dug wells or pits, and sold under the name of "Rangoon tar."

The earliest reference to petroleum in North America is found in Sagard's *Histoire du Canada* (1632), in a letter in which a Franciscan missionary—Joseph de la Roche d'Allion—mentions the springs in what is now Alleghany co., N. Y. The oil of these springs, as well as that of Oil Creek, now in the State of Pennsylvania, was used by the Indians for medicinal and other purposes, and was sold under the name of Seneca oil. The early settlers in Northwestern Pennsylvania dug pits about the springs and curbed them.

From 1790 to 1820 numerous wells were drilled along the western slope of the Alleghany Mountains for brine, from which to manufacture salt. These were located along the Alleghany, the upper Ohio, the Muskingum, between Marietta and Zanesville, the Kanawha, above Charleston, the Big Sandy, and the head-waters of the Tennessee and Cumberland rivers. In all of these localities wells were occasionally drilled that yielded petroleum, and in some of them the amount was sufficient to spoil them for brine. One of these abandoned wells was drilled in Wayne co., Southeastern Kentucky, in 1819, and it has flowed a small quantity of black petroleum ever since. Another drilled on Little Rennox Creek, near Burkesville, Cumberland co., Ky., in 1829, was the first important flowing well in the U. S. The oil flowed out of the creek and into the Cumberland river, where it covered the water and was finally set on fire, burning for a distance of 56 miles. It ceased flowing in 1860, after other wells had been drilled in the vicinity. For many years the product ran to waste, but it was finally put up in bottles and sold as "American Medicinal Oil, Burkesville, Ky.," throughout the U. S., and in Europe.

As early as 1834 Selligue had manufactured in France shale oil that was used for lighting purposes. In 1850 James Young, of Scotland, introduced into commerce paraffin oils, made from the Torbane Hill shale, commonly known under the name of "Boghead coal." This industry soon extended to other European countries and to the U. S. Abraham Gesner in 1854 took out several patents in the U. S. for a process and apparatus for the manufacture of "kerosene." The manufacture of this article rapidly developed in the U. S. into an important industry. On the Atlantic coast of New England in 1860 there were forty establishments using Boghead coal, imported from Scotland, and albertite from New Brunswick. W. of the Alleghanies the rich cannel coals of Breckinridge co., Ky., those found at Cannelton on the Kanawha river, and at Canfield and Newark, O., were distilled for oil. The most extensive works for this purpose in the U. S. in 1859 were the Lucesco works in Westmoreland co., Pa., with a capacity of 6,000 gal. per day. The advent of petroleum finally caused all these concerns in the U. S. to abandon coal and take up petroleum. The Pennsylvania Rock-oil Company was organized in 1854 for the purpose of procuring petroleum on Oil Creek, Pa. After many vicissitudes, by 1858 this company had leased its land near where Titusville now stands to a portion of the stockholders, who employed Col. E. L. Drake to drill an artesian well. Drake first attempted to dig a well in one of the old timbered pits; but quicksands thwarting him, he drove an iron pipe 36 feet to the bed-rock. The following season men were engaged to drill, and, on Aug. 29, 1859, after many vexatious delays, the drill struck a crevice, into which it fell 6 inches. The next day the well was found to be nearly full of petroleum. Oil was struck in this well only 69 feet from the surface.

The success of this well was the signal for a grand rush. Speculators came from all directions, and in the next few years hundreds of wells were drilled along the tributaries of the Alleghany river. The farmers along Oil Creek, who could not have realized more than a few dollars an acre for their farms, suddenly found themselves wealthy. As the wells in one locality failed new ones were drilled to take their places, until they had exhausted the valley land in the neighborhood of Oil City, Tidioute, Titusville, and Franklin. Then borings were made on the table-land between Oil Creek and the Alleghany river, and at other places, without regard to the present configuration of the country. Test-wells were bored all over the country E. of the Mississippi river wherever an oil or gas spring rendered the production of oil possible. While a great many such enterprises proved fruitless, there were opened up a number of minor fields at some distance from the so-called "oil-regions of Pennsylvania," where the famous Pithole excitement was at its height. In Beaver co., Pa., the Smith's Ferry field was opened up, and in Ohio the Mecca district in Trumbull County, the Belden district in Loraine County, and the region that extends from the northern part of Washington co., O., southward through Pleasants and Ritchie into Wirt co., W. Va. Another locality in West Virginia was found along the Great Kanawha river, above Charleston, in Kanawha County. Still another region was developed in the southeastern part of Kentucky, near Glasgow, in Barren County. With the exception of the Mecca and Kanawha districts, which have been practically worked out, all of these localities are (1900) producing oil. From 1865 to 1875 operations in Pennsylvania gradually extended down the Alleghany river into Butler and Clarion Counties, and N. E. into Warren and McKean Counties. The Butler and Clarion, or "Southern Country," was at its height of production in 1872–75; then began the development of the Bradford field, which reached its height in 1880–81. In 1885–86 the Washington and Greene Counties, Pa., fields were opened up, and later the region in Alleghany and Washington Counties W. of Pittsburg.

In the northwestern counties of Ohio, particularly in the vicinity of Findlay in Hancock County, and Lima in Allen County, natural gas had been known since the settlement of the State. In drilling wells for gas in 1884 oil was encountered, often in such quantities as to prove troublesome. Wells for oil were first drilled in Lima and its vicinity in 1885, and their success soon led to the development of a large production over a wide area in Northwestern Ohio and Northeastern Indiana, known as the Trenton limestone or Lima oil-field.

On the Pacific coast another area next in importance has been developed in the Coast Ranges of Southern California. For more than a century bitumen has been observed floating upon the sea in the Santa Barbara channel. Exploration of the mainland E. of Point Conception and S. of the line forming the northern boundary of Santa Barbara County showed that an immense amount of bitumen was reaching the surface in the form of maltha that soon became asphaltum upon exposure to the elements. In 1865 companies were formed in New York, Philadelphia, and San Francisco, but their wells were improperly located, and failed to produce oil. In 1880–87 their properties passed into the hands of men of large experience in the oil-regions of Pennsylvania, and after several unsuccessful attempts, and a careful examination of the stratigraphy of the country, wells were obtained, principally in Ventura and Los Angeles Counties, which have produced steadily since. Other locally valuable regions are found in Wyoming and in Southeastern Colorado.

Outside the U. S. the regions furnishing petroleum to commerce are those of Russia, which extend along the Caucasus Mountains; those of Galicia and the Danubian principalities, Wallachia and Moldavia; and a small area in Peru. The Russian oil-fields are chiefly confined to a small area of very productive territory near Baku, which yields wells remarkable for their enormous output and for the long time during which it is discharged. Operations have been carried on here since 1873. The Galician and Roumanian oil-fields have been worked in a rude way for more than a century. Although attempts have been made for many years to utilize Peruvian petroleum, it is only quite lately that it has been imported in tank-steamers into San Francisco and sold in competition with the oils of California. See the article PETROLEUM AND NATURAL GAS, GEOLOGY OF.

Properties.—Petroleum is a liquid varying in color from

a light straw, through amber, red, and brown, to black; oils from the same locality are usually of nearly the same color. The Trenton limestone oils are very black; those of Oil Creek, Colorado, South America, Russia, Germany, Japan, and India are brown; the Bradford oils and those of the lower Alleghany and the vicinity of Washington, Pa., are amber-colored, as well as that of Amiano in Italy. The oil found at Smith's Ferry is a very light amber, and in a few instances natural petroleum has been obtained almost colorless. The colors given above are observed when the light is transmitted through the oil. The same oils, from the lightest to all but the darkest shades, when viewed by reflected light, are tinged with green. Hence petroleum is said to be dichroic, or of two colors. In specific gravity it varies from ·7 to 1·2, water being 1. As it escapes from the earth it is usually accompanied by water and a varying amount of gas, which latter it holds in solution. It is insoluble in water, but itself dissolves about 2 per cent. of water. It is partially soluble in all of the varieties of NAPHTHA (*q. v.*), in all varieties of alcohol, ether, chloroform, bisulphide of carbon, turpentine, and the other solvents of bitumen. The lighter colored varieties are highly refractive.

The chemical composition of petroleums varies greatly. Taken together they are found to contain nearly all the members of all the series of HYDROCARBONS (*q. v.*) known; but no single variety contains nearly all of them. The Trenton limestone oils of Canada and the U. S. consist of members of the paraffin and olefine series, holding in solution small quantities of more complex compounds, into which either nitrogen, sulphur, or oxygen enter as constituents. The oils obtained in the Devonian and Subcarboniferous rocks of Eastern Ohio, New York, Western Pennsylvania, and West Virginia are mixtures of paraffins and olefines, with only a trace of nitrogen or sulphur compounds. They are the most easily refined into commercial products of any petroleums known. The oils of Kentucky and Tennessee partake of the characteristics of both the Trenton and Devonian oils. The oils of Colorado contain paraffins. Those of the Pacific slope apparently consist of members of the benzole series, holding in solution considerable though varying amounts of pyridins and chinolins (basic oils containing nitrogen), combined with an acid resembling hippuric acid, in the form of an *ester* or compound ether. These nitrogen compounds make these oils very difficult to refine, and by their decomposition from natural causes cause the oils to pass rapidly into maltha and asphaltum. Russian oils consist of a mixture of the hydrides of the benzole series; Burmese petroleum (Rangoon tar) consists of a mixture of olefines and benzoles.

Development of Oil-territory.—The successful location of oil-wells on any proved territory requires sound judgment and experience. Each owner of a tract is likely to drill along the border of it, in order to draw oil from beyond the border. If the drilling is done under a lease, it is customary to give the owner of the land a royalty of a certain sum per barrel, or a certain proportion of the oil, or a certain percentage of the gross receipts. One well to 5 acres is considered a proper ratio, but they have been drilled as closely as five to an acre. Wells drilled so closely exhaust the oil-sand more rapidly; they have sometimes been exhausted in a few months.

Great differences are found in the oil-sand of different localities. The pebble sands of the Alleghany river and its tributaries are masses of rounded or flattened white quartz pebbles of the size of beans or grapes, that adhere at their points of contact, constituting a friable rock with large interstitial spaces. It varies in thickness from 10 to 125 feet. The Warren sand is blue, fine-grained, and muddy. The Bradford and Washington sands are coarse sandstones of a brown color. In California the sand is fine-grained, blue sandstone of marine origin. In Russia the sand is a sort of quicksand, very fine and blue in color. It often accompanies the oil in its outflow. It has been proved by experiment that the Venango pebble sand will hold about 1,000 barrels per acre for every foot in thickness.

For the method of drilling wells, see WELL-DRILLING. When an oil-well is drilled into a firm rock it is customary to introduce into the bottom of the well from 2 to 15 gal. of nitroglycerin and explode it by causing a mass of iron to drop on a fulminating cap. The effect of generating in the limited space a large volume of gas is to drive the oil, gas, etc., back into the rock until an equilibrium is established; then a reaction follows, and the expansion of the compressed gases forces everything before it up the drill-hole in a geyser of oil until the expansive force subsides. Torpedoes are not used in the oil-regions of California. After a well has been torpedoed it is prepared for flowing by introducing into it a 2-inch pipe, at the lower end of which is attached a strainer. At some point below the casing the pipe is arranged with a joint in such a manner that the portion above the joint will slide on that below. The joint is secured by a cylindrical mass of India-rubber, called a packer. The weight of the upper portion of pipe presses the rubber against the well in such a manner as to plug the drill-hole around the pipe, and prevent any oil or gas from escaping from the rock except by ascending the pipe. So long as the pressure of gas within the rock is sufficient to force the oil to the surface, the well will flow. When the well ceases to flow a pump is introduced, and the oil lifted to the surface until it ceases to be remunerative.

In the early days on Oil Creek the oil was transported in barrels holding 42 gal. each; along rivers bulk-barges were employed. In 1871 wooden tanks on flat cars came into use, and later these were followed by plain iron cylinders, holding about 5,000 gal. each, which are still used for transporting crude and refined oil in America and Europe. Crude oil is also transported by means of pipe-lines, which are best described in connection with the means employed for storing the oil. Every well is supplied with a tank holding 250 barrels, from which a 2-inch pipe connects with a larger tank holding perhaps 10,000 barrels. This large tank is connected by a 4-inch pipe, through a pumping-station, with a general system of 6-inch pipes, extending often for hundreds of miles. At convenient points along these main lines storage-tanks are placed, holding 35,000 barrels each; and pumping-stations are located about 40 miles apart. These pipe-lines are made of wrought iron, the sections screwed into couplings, the whole of which is tested to a pressure of 2,000 lb. to the square inch. Pipe-lines extend out of the oil-regions to Chicago, Cleveland, Buffalo, Jersey City, Philadelphia, and Baltimore. In California they extend from the wells in the mountains to Santa Paula and Ventura. In Russia a line has been laid from Baku on the Caspian Sea to Batum on the Black Sea, a distance of about 600 miles.

Petroleum in Commerce.—Petroleum, suitable for refining into illuminating oil, enters the market in enormous quantities through the pipe-lines. The more dense oils, which are suitable for use as lubricating oils in the crude state, and also as reduced oils, are handled in barrels and tank-cars. The handling of oil in pipe-lines has rendered banking in oil possible. This business is conducted as follows: When oil is run into the pipe-line the owner receives for it certificates, which, having been properly indorsed, are negotiable after the manner of certified checks. Certificates for 1,000 barrels are negotiable on the Stock Exchange, like any other declaration of indebtedness, and their purchase and sale makes speculation in oil possible. Certificates for less than 1,000 barrels are sold to consumers of oil. The oil is held against these certificates in storage-tanks, holding 35,000 barrels each, to the amount of millions of barrels, under regulations that insure its proper care.

Technology of Petroleum.—The apparatus employed for distillation consists of an iron still connected with a condenser of wrought-iron pipe, which is submerged in water. The first products of distillation are gases; at ordinary temperatures they pass through the condenser and escape. By cooling the condenser with ice and salt the very volatile liquid rhigolene is obtained; and by using a condensing-pump a still more volatile liquid, cymogene. The first fluids that condense at ordinary temperatures have a gravity of about 95° B.; in most establishments it is customary to run the product into one tank until the gravity of the distillate reaches 65°–58° B. This product is known as crude naphtha, and is subsequently separated by redistillation into gasoline and A, B, and C naphthas. When the stream of oil has a gravity of 59° B. it is run into the kerosene-tank until the gravity reaches about 38° B. or until the color becomes yellow. After taking off this second fraction, the kerosene, the stream is run into the paraffin-oil tank until there remains in the still only a thick, heavy tar, called residuum. The last products have a gravity of about 25° B. The paraffin oil is put into barrels and chilled, to crystallize the paraffin, and is then put into cloths and pressed, in order to remove the oil. The solid paraffin is purified by repeatedly melting it in naphtha, chilling, and pressing.

While this is a general outline of the process by distillation, it should be remarked that refiners differ in the de-

tails of the operation. A single firm at Rochester, N. Y., distill their oils in a vacuum, producing what are known as vacuum oils. Formerly very large stills were in use; at present the largest hold about 1,200 barrels. In these, by slow distillation, the heavier lubricating oils are "cracked" into lighter oils, so that the refiner need not produce any heavy oils, but only crude naphtha, illuminating oil, and residuum. The naphthas, burning, and lubricating oils are deodorized and decolorized for market by treatment, which consists in thoroughly agitating the crude distillate with strong sulphuric acid and allowing the mixture of the acid and the impurities of the oil, called sludge, to subside; the oil is removed, and then agitated with a solution of caustic soda, ammonia, or lime; this removes any free acid, along with any other impurities not removed by the acid. After treatment the burning oils are sprayed, in order to remove any light vapors that might render the oil unsafe. The lubricating oils, or reduced oils, produced by partial distillation, are sometimes treated and sometimes filtered through animal charcoal, to remove both color and odor; they are sometimes distilled with superheated steam. The residuum is distilled in small stills, and yields a large quantity of paraffin and paraffin oil, and a solid residuum that is run out of the still while it is hot, called coke-pitch, as it always contains a considerable percentage of coke. A variety of solid and semi-solid preparations are made by filtering the melted materials through animal charcoal; vaseline and various light-colored lubricating oils are examples. Nearly every natural petroleum is found to possess some peculiarity that renders some modification of this general technology necessary. Russian petroleum yields a second grade, as compared with the best American illuminating oil, excellent lubricating oil, and white solids, that are not paraffin, sold under the name of "Alboline." No first-class illuminating oil has ever been made from California petroleum, and very little, if any, is now being manufactured from that material. In the few refineries of the Pacific coast the articles turned out are gasoline, naphthas, lubricating oils, and several grades of both fluid and solid asphaltic residuums. These residuums resemble in some respects the natural asphalts; but in others they are very unlike. The dense black California petroleums are also reduced, and the fluid residuum is found to be especially valuable for use as an asphaltic flux in the preparation of street-paving.

The yield of these different products varies greatly with the variety of oil and with the refinery. The following is a fair average for Pennsylvania oil of about 45° B.:

	Per cent.
Gasoline	1½
Naphthas	14
Kerosene	55
Lubricating oil	17½
Paraffin	2
Loss, gas, and coke-pitch	10
Total	100

By cracking, the same oil could be made to yield:

	Per cent.
Naphthas	20
Kerosene	66
Loss, gas, and coke-pitch	14
Total	100

Kerosene is the most important product of petroleum. It is a mixture of many hydrocarbons, and has the consistency of the essential oils, a burning taste, and aromatic odor. It is nearly colorless by transmitted light, and slightly fluorescent by reflected light. Its density should be from 43°–45° B. At ordinary temperatures it should extinguish a match as readily as water. It should not evolve an inflammable vapor below 110° F., and should not take fire below 125° F. As kerosene containing even a small percentage of naphtha is very dangerous, it is almost universally required by law that kerosene be tested before it is sold. A suitable apparatus is required, consisting of a cup to hold the oil, surrounded by a vessel of water, which is heated by a small spirit-lamp. The bulb of a thermometer is immersed in the oil, not far below the surface. The oil should be heated very slowly; the temperature should not rise faster than 2° per minute. The oil should be stirred before applying the flame. The flashing test determines the lowest temperature at which the oil gives off an inflammable vapor. The burning test fixes the burning-point of the oil, or the lowest temperature at which it takes fire. One per cent. of naphtha will lower the flashing-point of an oil 10° without materially affecting the burning test. The burning-point of an oil is from 10° to 50° higher than the flashing-point. The flashing test should therefore be the only test mentioned in laws framed to prevent the sale of dangerous oils.

Uses of Petroleum.—The earliest use of petroleum, both in Europe and in the U. S., was as a therapeutic agent, in diseases of the skin of both men and animals, in rheumatism and consumption; it is still largely a constituent of embrocations in popular use. A filtered paraffin residue, under the name of vaseline, cosmoline, or petroleum ointment, is very extensively used, not only as a basis of medicated ointments by the apothecary, but very generally in households. Rhigolene has been used as an anæsthetic; cymogene has been used in ice-machines.

Various products of petroleum besides kerosene are used for purposes of illumination. Gasoline is used in large quantities in carburetors. These are machines in which air is made to bubble through the gasoline and dissolve a sufficient amount of the volatile liquid to form a combustible mixture, which may be burned like ordinary illuminating gas. Illuminating gas has been made by causing crude petroleum to drip into a retort upon red-hot coke. Naphtha is burned like gas in an apparatus in which it is vaporized by the heat generated during its combustion. A product of petroleum known as gas-oil, which consists of the naphtha and kerosene distillates run together without treatment, is used to enrich gas deficient in illuminating power. Astral oil is an oil of high flash-point, especially prepared with reference to illuminating power and safety. Mineral sperm" is an illuminating oil of very high flash-point, for use in lighthouses and on locomotives.

The paraffin and other lubricating oils prepared from petroleum, in innumerable brands, have largely superseded animal and vegetable oils throughout the world, while for coarse and heavy bearings the use of crude petroleum has become universal. Crude petroleum is used very extensively in Russia and on the Pacific coast of the U. S. for fuel, chiefly for steam purposes. The residuum of the refineries is also used on steamers on the Volga and the Caspian Sea, and on locomotives throughout Southern Russia. It has also been successfully used in the Eastern U. S. for steam purposes, but the low price of coal in the Mississippi valley renders competition impossible. On the Pacific coast coal is scarce and high-priced, and petroleum is used extensively for stationary boilers, petroleum having the advantage over coal in freedom from dirt, and the small expense for labor attending its use. Gasoline is very widely used for domestic heating and cooking, notwithstanding the well-known danger attending its use. It is more satisfactory than kerosene, which is also used for the same purpose, and, like gasoline, in stoves especially constructed for its combustion. The most volatile products of the distillation of petroleum are used for explosion in the cylinders of motors, after the manner in which gas is exploded in the cylinders of gas-engines. The asphaltic residues of California petroleum, as well as coke-pitch, are used for coating paper and in the manufacture of varnishes, paints, lacquers, etc.

The influence of petroleum and its products upon civilization is hardly less potent than that of the steam-engine and electricity. While thousands of wells have ceased to produce, and many localities in all of the regions that contribute to the world's supply have ceased to be important factors therein, still the aggregate amount appears to be sufficient to meet all of the enormous and varied demands; and, from a careful survey of the prospective supply, there seems to be no reason to fear that these demands of commerce will not be adequately met for an indefinite period.

The following statistics, from the *Mineral Resources of the United States for 1899*, show the annual production of petroleum throughout the world, in barrels of 42 gallons:

PRODUCTION OF PETROLEUM.

Appalachian Field	33,050,076
Lima-Indiana	20,225,356
Southern California	2,642,095
Florence, Colorado	390,278
Kansas and Texas	738,713
Wyoming	5,560
Other fields in the U. S.	18,722
Total barrels for the U. S., 1899	57,070,850

PRODUCTION OF PETROLEUM—CONTINUED.

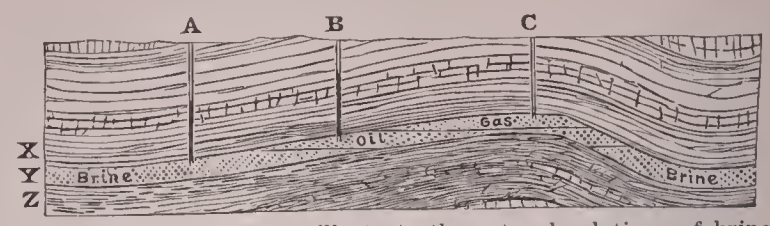
Russia, Baku, 1899	66,452,240
Russia, elsewhere, 1899	2,300,000
Austria-Hungary, 1899	2,600,000
Roumania, 1899	1,470,000
Peru, 1899	891,666
Sumatra, 1899	861,610
Canada, 1899	704,794
Java, 1898	582,903
India, 1898	542,068
Japan, 1898	265,389
Germany, 1899	192,232
Italy, 1898	14,489
Other countries (estimated)	400,000
Total number of barrels	134,348,241

S., vol. x., *Petroleum*, by S. F. Peckham; Reports of the Geological Survey of Ohio, *Economic Geology*, vol. vi., by E. Orton; *Mineral Resources of the United States* (1882–93). S. F. PECKHAM.

Petroleum and Natural Gas, Geology of: Petroleum and natural gas appear to be inseparably connected. Wherever large supplies of the one exist the other is in almost all cases not far distant. Hence any statements concerning the geology of the oil are equally applicable to that of the gas. Then, too, the flow of large petroleum-wells is always accompanied by an immense output of natural gas, which doubtless is dissolved in the oil under the great pressure of its rock reservoir.

The quantity of gas occurring immediately with the oil varies greatly, depending upon the depth of the oil-reservoir below the surface and the permeability of the overlying rocks. When the rock reservoirs lie near the surface, as at Volcano, W. Va., Mecca, O., and Franklin, Pa., most of their volatile contents escape into the air, leaving a heavy or lubricating oil, with little or no gas present, while if the reservoir lies upon the surface, or its included oil is transported to the surface in any manner, evaporation and oxidation reduce the liquid to the condition of asphaltum, as in the island of Trinidad and at many places in Kentucky, Tennessee, and the Western States and Territories of the U. S. In Ritchie co., W. Va., a vertical fissure from 2 to 3 feet wide and extending down to the oil-sand group has been thus filled with grahamite. From this universal occurrence of oil and gas together, or in close proximity to each other, it is evident that they have had a common origin, and that natural gas is one of the by-products in the genesis of petroleum. Until 1884 geology played a very insignificant part in guiding the drill in its search for oil and gas deposits. Since that date, however, the laws of oil and gas distribution and occurrence have been quite thoroughly worked out, and it is now possible to predict from geological structure the general regions where productive areas of oil and gas may be found, as well as to define the boundaries of nearly all those regions where a search for either must prove fruitless. These laws have been formulated under three heads—*Structure*, *Reservoir*, and *Cover*.

Structure.—All of the great areas of petroleum and natural gas occur along lines of disturbance in the rocks, where anticlinal arches have tilted the strata and thrown them into considerable relief, thus permitting the gas, oil, and salt water occurring in all porous sedimentary rocks to separate themselves in the order of their specific gravities, the water occupying the synclines and lower slopes of the strata, the oil coming next above the water and extending upward until it is in turn succeeded by natural gas higher up the slope and across the crowns of the anticlinals, if the rocks are continuously porous. (See diagram.) Hence when



Ideal diagram of strata to illustrate the natural relations of brine, petroleum, and gas in a porous bed (Y) contained between impervious beds (X, Z). A well at A yields only brine. A well at B yields first petroleum and afterward brine. A well at C yields first gas and afterward petroleum and brine.

the rocks are nearly horizontal over a wide area, structure would condemn such a region as not likely to furnish large supplies of either gas or oil. Structure also teaches that it would be useless to bore for gas in a syncline, unless it should be a subordinate feature of an anticline.

Structure would also condemn all regions for gas or oil where the rocks are highly contorted and the folds of great height, since these fissure the strata deeply, bring the reservoirs themselves to the surface, and permit the escape of the oil and gas they may once have contained.

Reservoir.—When petroleum was first discovered in large quantity, many people imagined that it existed in underground lakes, filling large caverns in the strata, and it was so represented even in leading text-books on geology. Petroleum does not occur in caverns, as thus depicted, but in the rocks themselves, disseminated through the minute cavities and spaces between the sand-grains and pebbles of fragmental deposits, while in limestones it occurs in the crystalline cavities formed by the partial replacement of pure limestone by dolomite. In slates it probably exists mostly in fissures. All sedimentary beds are porous to some extent, but the finer elastic materials, like slate, shales, and ordinary limestone, are so slightly permeable to liquids that unless much fissured they make poor reservoirs for either oil or gas, and hence the geological structure may be favorable, but if porous rock reservoirs be absent from the underground strata we can not expect to find any large supplies of oil or gas. The rate of production of any oil-well appears to depend largely upon the porosity of its rock reservoir. When this is a mere bed of gravel, like the famous fifth sand at McDonald, Pa., we may have a well like the Matthews or Mevey, putting out 15,000 barrels daily, and when the pebbles are not consolidated, as in the Baku district of Russia, the wells may flow even 50,000 to 60,000 barrels daily, while if the reservoir is compact and close-grained, wells penetrating it are non-productive. If the reservoir rock changes its character suddenly a well practically dry may exist close beside one that is highly productive. A non-productive well was drilled within 300 feet of the Mevey well at McDonald, Pa., at the time the latter was yielding 15,000 barrels daily. The porosity or quantity of reservoir space in good oil or gas rock in the Pennsylvania fields varies between one-fifth and one-tenth of the volume of the rock.

Cover.—However coarse or open the rock reservoir may prove, it must be roofed over with an impermeable cover, else the oil and gas will escape to the air, and the drill will find the original reservoir practically empty, or filled with fresh water. Soft shales or slate make such an excellent cover that even where the rocks are bent at an angle of 30° to 60°, as along the Volcano, W. Va., anticlinal, they have still retained a considerable quantity of petroleum in its subterranean reservoirs, though from the sands which lie nearest the surface much of the oil and nearly all of the natural gas has escaped. In any region, then, where unaltered sedimentary rocks have been gently tilted, and contain coarse or porous beds overlain with a considerable thickness of shale, clay, or other impermeable rock, we may expect to find deposits of petroleum and natural gas.

Dr. Orton believes that the terrace, or monoclinal structure, which is really a suppressed or arrested anticlinal, is the most favorable for accumulation of petroleum, since this peculiar arrangement of the rocks, as first noted by Minshall, is so common in the oil-fields of Ohio. It is also prevalent in most of the oil-fields of Pennsylvania and West Virginia.

The pressure under which oil and gas are found in porous rocks is hydrostatic, and identical with that of artesian wells. In any field newly opened, or in a field the wells of which are kept closed until a condition of static equilibrium

is restored, it is approximately measured by the pressure of a column of water rising from the same reservoir at another point. If, in the case illustrated by the diagram, the brine in well A rises half way from the reservoir to the top, the oil in well B, being lighter than water, will rise to a higher level, and the gas in well C will sustain a pressure measured by that part of the column of oil in B which is above the surface of oil in the reservoir, or approximately by that part of the brine in A which is above the oil-surface in the reservoir. This law of pressures has been demonstrated by Dr. Orton for the Trenton limestone reservoirs in Ohio and Indiana, and the same rule holds true for the oil-sands of Pennsylvania and West Virginia. An important corollary is that in the same "oil-pool" the liquid must occupy about the same level in the rock, since it is subjected to practically the same pressure in every portion of the pool. Hence when one good well is found in any field, the proper direction to go in search of others is along the *strike* of the rocks, and as the strike of the oil-sands is nearly the same as that of the surface rocks, the latter may be used in tracing out the probable course of oil-belts in advance of the drill. In this is found the philosophy of the 45°, 35°, or 22½° lines which in different oil-fields have proved so popular with the practical oilmen. These are strike lines in the several regions where used.

Geological and Geographical Distribution.—Petroleum and natural gas are not confined to any particular geological horizon, but occur in rocks of all ages from the Lower Silurian up into the Quaternary, as will be seen by the following remarks on distribution in the U. S.

The Trenton limestone of the Lower Silurian is the lowest and oldest known horizon for productive oil and gas wells. This horizon was first discovered near Findlay, O., and has proved one of the most prolific sources of oil and gas that is yet known in the U. S. Very large areas in Ohio, Indiana, and also in Canada contain petroleum and natural gas. Dr. Orton has shown that the productive areas of the Trenton limestone are confined to domes and terraces in this rock, where it has been rendered porous by the presence of dolomite.

The Hudson river beds seem to have furnished the first flowing well on the continent in the salt-well of Cumberland co., Ky., bored in 1829. This formation is petroliferous at many points in Kentucky and Tennessee, but none of the wells are very productive, as the rocks are close-grained. The Clinton series has proved, according to Orton, a rich repository of gas in the vicinity of Lancaster and Newark, and in other parts of Ohio, having also some oil. It is also, according to the same authority, the probable oil and gas horizon in the Barren County oil-field of Kentucky, where a great many small producing wells have been found. The producing stratum is a sandstone in Ohio, and probably the same in Kentucky.

The Corniferous limestone, Devonian, appears to be the principal oil horizon in the Canada petroleum-fields, and it has also produced oil in several borings of Eastern Kentucky, though always in small amounts. The Marcellus shale is the source of considerable natural gas in New York, and doubtless at many points in Ohio, but the wells are always small. The Chemung series (including the Portage, Chemung, and Catskill formations) has so far proved the most prolific oil and gas horizon in the U. S. The Portage beds are always low in porosity and, so far as known, have yielded gas and oil only sparingly, the localities being at Erie, Pa., and elsewhere near the shore of Lake Erie. In the Chemung and Catskill rocks, however, we find coarse sandstones and conglomerates, which are very porous, and both of these series have proved great reservoirs of oil and gas along the western slope of the Appalachian Mountain system from the southern portion of New York across Pennsylvania, and down into Ohio and West Virginia. The great Bradford oil-field, as well as the Southern New York region, derives its oil and gas from the Chemung beds proper, and that from Kane, Sheffield, Warren, Cherry Grove, Speechly, and adjoining regions, comes from the same source. The Catskill rocks appear to be even more prolific in oil than the Chemung, since the Venango oil-sand group of Pennsylvania, with its first, second, third, fourth, and fifth sands, from Venango County down through Clarion, Butler, Armstrong, Mercer, Lawrence, Beaver, Allegheny, Westmoreland, Washington, and Greene, belongs wholly in the Catskill beds, with the possible exception of its basal members. This Venango group has furnished practically all of the oil and gas of Western Pennsylvania, and has proved prolific at Macksburg, O., and at Eureka, Wellsburg, Mannington, Big Isaac, and many other points in West Virginia. Two of the largest gas-wells ever struck were found in a member of the Venango group at Big Isaac, in Doddridge co., and near Joetown, Marion co., W. Va.

The Cleveland shale, which, according to Orton, is the black shale of Southern Ohio and Eastern Kentucky, is also a member of the Venango or Catskill series, and contains some petroleum and gas wherever its outcrop extends. The gas-wells near Brandenburg, Meade co., Ky., occur in this stratum, and they have proved large enough to pipe to Louisville, 25 miles distant. Dr. Orton reports the shale as shattered and fissured at this locality, and its reservoir capacity has thus been increased to a large extent.

The next higher member of the geologic scale, the Pocono sandstone (Lower Carboniferous), No. X., or Vespertine of Rogers, is also one of the great petroliferous horizons. It is so far the principal oil and gas horizon of West Virginia, the Mt. Morris, Doll's Run, Peddler's Run, Jake's Run, Fairview, Mod's Run, and Mannington oil and gas fields being found at this horizon. The great Sistersville oil-field is found in the same rock, while it was the principal producing horizon at Volcano, White Oak, and Burning Springs. The gas-wells of the Great Kanawha, Guyandotte, and Big Sandy rivers are found in these beds. It is the Slippery Rock oil-sand in Pennsylvania, and the Mecca sand in Ohio, while through Kentucky, Tennessee, and Alabama it carries more or less oil, gas, or asphalt. The Mountain limestone series next above the Pocono is also petroliferous at many points in Kentucky, where the Keokuk and Chester divisions contain some massive sandstones. The tar-springs of Breckinridge and Grayson Counties come at this horizon. The Pottsville conglomerate also holds hydrocarbons, when covered sufficiently to prevent their escape. It holds large quantities of gas in Southwest Pennsylvania and Northern West Virginia, and also considerable oil along the Volcano anticlinal of the latter State. This series also carries oil in Southern Ohio, Eastern Kentucky, and at some localities in Illinois and Indiana.

The sandstones of the lower coal-measures, No. XIII., hold oil and gas in West Virginia, the Freeport sandstone being the one most generally petroliferous. This rock appears to hold gas over a wide area in Central West Virginia.

The Mahoning sandstone, at the base of No. XIV. in the Barren measures, is also widely petroliferous, and at one locality near Dunkard creek, Greene co., Pa., has produced a large quantity of oil. It is also the "Cow Run" sand of Southern Ohio and the Williamstown district of West Virginia, in both of which regions it has produced a considerable quantity of oil.

The highest stratum geologically that has ever produced oil in the Pennsylvania field is the Morgantown sandstone, 200 feet below the great Pittsburg coal-bed. In the Dunkard region of Pennsylvania a large well was struck in this sandstone.

The natural gas at Paola, Kan., and the Kansas City region probably comes from the coal-measures. A small quantity of oil is found in the Triassic beds of North Carolina.

The oil and gas of the Western States and Territories are found in newer rocks than those of the Appalachian region. The Florence oil-field near Cañon City, Col., is in the Cretaceous beds, while the same rocks are petroliferous through Wyoming, Dakota, Montana, and New Mexico. The oil of California, Mexico, the West Indies, and much of that of South America, occurs in the Miocene. That of Trinidad and Peru is reported to occur in the Eocene. The natural gas near Salt Lake City, Utah, is derived from Pleistocene lake-beds; that of La Moile, Ill., from glacial gravels.

In England a small quantity of petroleum has been found in the coal-measures. In the valley of the Rhône and in Savoy it occurs in the Jurassic limestones. That of the Apennines, Dalmatia, Albania, Roumania, Galicia, the Caucasus, and Baku is mostly from rocks of Eocene age, as also that from the Punjaub and Burma. Oil and gas are also found in Persia, Hindustan, China, Japan, Java, Australia, and Africa, and in all these cases the oil zones appear to lie parallel to the principal mountain systems of the several countries, as they do in America, thus indicating the connection of oil deposits with rock structure.

Available Store.—From this review it will be perceived that petroleum and natural gas, like coal, are distributed quite generally over the world and through rocks of all ages, from the Lower Silurian up to the Quaternary. The process of exhaustion is a slow one, many individual wells

in the Pennsylvania field having yielded oil in paying quantities continuously for a period of more than thirty years. New districts and new horizons are constantly being discovered, so that there is no immediate prospect of the exhaustion of petroleum. Not so with natural gas, however, which can be removed from the rocks so much more rapidly and completely than oil. In regions like Pittsburg, where several hundred wells have been drilled to the gas horizons, rapid exhaustion must certainly follow, but in other regions, where only a few wells are drilled, the supply may be counted upon for an indefinite time, since large gas-springs like those in the Caucasus have been burning for centuries. For other information, see the articles PETROLEUM and NATURAL GAS.

Soc. of America, vol. iii., 1892). I. C. WHITE.

Petrol'ogy [from Gr. πέτρα, rock + λόγος, discourse]: the science of the mineralogical composition of rocks. See PETROGRAPHY.

Petromyzon'tidæ [Mod. Lat., named from *Petromy'zon*, the typical genus; Gr. πέτρα, rock, stone + μύζων, sucking in. The name is given in allusion to the manner in which these animals remove small stones from their breeding-grounds]: the single family of the order *Hyperoartii*, comprising the forms known as lampreys and lamprey eels. The form is eel-like; the skin naked; in the adult the head is elongated, with branchial and antebranchial regions nearly equal; eyes well developed, not far in front of the first branchial aperture; mouth with a subcircular suctorial disk armed with teeth which are horny, each resting on a soft papilla, and simple or multicuspid; the branchial apertures are always seven in number and lateral; dorsal, anal, and caudal fins represented to a greater or less extent by a continuous or interrupted membrane; pectorals and ventrals not developed; the intestine has a spiral valve. Such are the characters of the adults, but all the species undergo a metamorphosis, and a very different form is possessed by the young or larvæ. This stage was formerly regarded as representing a peculiar mature form, and described under the name *Ammocœtes*; in this stage the front region of the head is little developed, the eyes are wanting, and the mouth is represented by a longitudinal slit, and is without teeth. The species are, to some extent, parasitic, and fasten themselves by their suckers to fish, whose flesh they consume by abrasion. Revised by D. S. JORDAN.

Petro'nius Ar'biter: the author of a Latin romance, *Satiræ*, also called *Satiricon*, which in a half-comical manner gives a description of the vices and debauchery of Roman society under the first emperors, now in prose, now in verse, sometimes witty, occasionally obscene. Of the work, which seems to have been very large, only fragments are extant, from the fifteenth and sixteenth books. One of these, the *Supper of Trimalchio* (*Cena Trimalchionis*), was first discovered in the middle of the seventeenth century, and published at Paris in 1664. Several attempts have been made to deceive the public by spurious manuscripts of the lacking portions of the book; thus, in 1693, Francis Nodot published a complete *Satiricon* from a manuscript which he pretended to have found in Belgrade. The best editions of the true fragments are that by Burmann (Amsterdam, 1743) and that by Bücheler (Berlin, 1862, and in a third smaller edition 1882). A minute and thorough collation of the MSS. was made by Charles Beck (Cambridge, 1863). Of the author of this book nothing is known, but there are strong reasons for identifying him with the Petronius of whose character and life Tacitus (*Annales* 16. 18) gives an amusing sketch, the *maître de plaisir*, *elegantiæ arbiter*, at the court of Nero, the authority and model in matters of taste and fashion in dress, manners, and sensual enjoyment. The scene of the *Supper of Trimalchio* is laid in a town of Campania, probably Cumæ or Puteoli, and under Nero, although other scholars put it under Augustus or in the last years of Tiberius. There is an excellent edition of the *Cena* with German notes and translation by Friedlaender (Leipzig, 1891). See also C. Beck, *The Age of Petronius* (Cambridge, Mass., 1856); Haley, *Quæst. Petron* (Harvard Studies, ii.); A. Collignon, *Étude sur Petrone* (Paris, 1892). Revised by M. WARREN.

Petropaulov'ski [Harbor of Peter and Paul]: a strong Russian naval station on the east coast of Kamchatka, commanding the Northern Pacific (see map of Asia, ref. 2–J). Pop. about 500, besides the garrison. It is the chief town of the peninsula.

Petrop'olis: capital of the state of Rio de Janeiro, Brazil; in a valley of the Organ Mountains, 2,300 feet above the sea; 35 miles N. of Rio de Janeiro and connected with it by a mixed railway and steamboat route (see map of South America, ref. 7–G). Originally a German colony, it became a favorite summer residence of wealthy residents of Rio, and the Emperor Pedro II. had a summer palace here. During the naval rebellion of 1893–94 the state government removed from Nictheroy to Petropolis, which was made the permanent capital in Oct., 1894. The climate is delightful and the scenery is magnificent. Pop. 8,500. H. H. S.

Petrosilex: See FELSITE.

Petrozavodsk': capital of the government of Olonets, European Russia; on the Onega Lake (see map of Russia, ref. 5–D). It was founded in 1703 by Peter the Great, who discovered the rich iron ore which the neighborhood contains. It is the see of an archbishop, and has many educational institutions, a good harbor, and a large cannon-foundry. Pop. 11,500.

Petrus de Apono: See ABANO, PIETRO, d'.

Petrus Lombardus: See LOMBARD, PETER.

Pettenkofen, AUGUST, von: genre and military painter; b. in Vienna, Austria, in 1821; member of the Vienna Academy 1866; member of Munich Academy 1867; knighted 1876. D. in Vienna, Mar. 20, 1889. His pictures, which are generally of small size and depict episodes in the soldier and peasant life of Hungary, are painted with marvelous exactness of detail, and at the same time are broad and complete in general effect. *A Rendezvous* is in the Vienna Museum, and *Hungarian Peasants' Halt in the Puszta* and *After the Duel* are in the Fedor Museum, Amsterdam. *The Ambulance Wagon* and *Hungarian Volunteers* are in the collection of Mrs. W. H. Vanderbilt, New York, and *Hungarian Artillery on the March* is owned by Henry G. Marquand, New York. WILLIAM A. COFFIN.

Pettenkofer, MAX, von, M. D.: chemist and sanitarian; b. at Lichtenheim, Bavaria, Dec. 3, 1818; graduated from the University of Munich in 1843; became a professor of chemistry in Munich in 1847. In 1866 he initiated the first practical instruction in hygiene in Germany, and has been intimately associated with the advance in hygiene since that date. As a chemist his researches in the affinities of gold, the preparation of platinum and of hydraulic lime, the process of obtaining illuminating gases from wood, and of the characteristics of oil-colors, were of signal commercial advantage. His announcement made in 1855 that the ætiology of cholera was an equation with three unknown quantities—x, a specific germ disseminated by human intercourse; y, a factor dependent on place and time, that might be called local disposition; and z, the individual predisposition—has been substantiated by the facts discovered in later years. He was coeditor of the *Zeitschrift für Biologie* from 1865–82. Among his important works are *Untersuchungen und Beobachtungen über die Verbreitungsart der Cholera, nebst Betrachtungen über Massregeln, derselben Einhalt zu thun* (Munich, 1855); *Ueber die Verlegung der Gottesäcker in Basel* (Basel, 1864); *Ueber die Kanalisirung der Stadt Basel* (Basel, 1866); *Boden und Grundwasser in ihren Beziehungen zu Cholera und Typhus* (Munich, 1869); *Zum gegenwärtigen Stand der Cholerafrage* (Leipzig, 1877). S. T. ARMSTRONG.

Pettigrew, CHARLES, D. D.: bishop; b. probably in Pennsylvania about 1750; removed with his family to North Carolina; became a teacher at Edenton 1773; was ordained in the Protestant Episcopal Church in London 1775; was chosen first Bishop of North Carolina 1794, but was prevented by accident from receiving consecration. He took a leading part in establishing the University of North Carolina. D. at Bonarva, near Lake Scuppernong, N. C., in 1807. Revised by W. S. PERRY.

Petty, Sir WILLIAM: political economist; b. at Romsey, Hampshire, England, May 26, 1623; was the son of a clothier; educated in the school of his native town and at Caen in France; was for a time an officer in the English navy; afterward studied medicine at Paris; obtained from Parliament in 1647 a patent for his invention of a "penta-

graph " or copying-machine; practiced medicine at Oxford, where he became assistant to the professor of anatomy; obtained a fellowship at Brasenose College 1648; chosen Professor of Anatomy in the University of Oxford 1651; Professor of Music in Gresham College 1651; became physician to the army in Ireland and secretary to Henry Cromwell 1652; was made surveyor of forfeited lands in Ireland; entered Parliament 1658, and at the Restoration was knighted and made surveyor-general of Ireland. He was one of the founders of the Royal Society; made several curious inventions and discoveries in physics; lost much by the fire of London, but afterward acquired a large fortune by successful speculations, and was author, among other works, of *The Political Anatomy of Ireland* (1691), *Treatise on Taxes and Contributions* (1662), *Political Arithmetic* (1691), a treatise on money entitled *Quantulumcunque* (1682), which have procured him the reputation of being the principal founder in England of the science of political economy. D. at Westminster, Dec. 16, 1687.

Petunia [Mod. Lat., from Braz. *petun*, tobacco]: a genus of annual, biennial, or perennial plants of the family *Solanaceæ*, natives of the hot regions of America. The *Petunia nyctaginiflora* and *P. violacea* are cultivated in European and North American gardens, and have afforded numerous hybrid and other varieties, some of which are very beautiful.

Peutinger, poi'ting-*er*, Konrad: antiquarian; b. at Augsburg, Oct. 14, 1465; d. Dec. 24, 1547; wrote several works on antiquities, and was the possessor of the so-called *Tabula Peutingeriana*, a map of the military roads of the West Roman empire from the fourth century. It was first discovered in a Benedictine monastery at Tegernsee, and remained there for nearly two centuries in the family of Peutinger, but in 1814 was bought by Prince Eugene, who presented it to the imperial library of Vienna, where it is now preserved. Published by Scheyb (Vienna, 1753); by Mannert (Leipzig, 1824), who also gives an interesting account of the vicissitudes which this unique monument of ancient literature has gone through from the fourth to the nineteenth century; and in *Recueil d'Itinéraires anciens*, by Fortia d'Urban (Paris, 1845). Cf. Paulus, *Erklärung der Peutinger Tafel* (1867). Revised by A. Gudeman.

Pew [from O. Fr. *pui*, *poi*, rising ground, hill, high place < Lat. *po'dium*, height, elevated place, emperor's gallery in the circus, appar. liter., foot-rest. Cf. Gr. *πόδιον*, dimin. of *πούς*, *ποδός*, foot]: an inclosed seat in a church. In England the exclusive and perpetual right to a particular pew in the parish church may be held as a kind of Heirloom (*q. v.*) by a parishioner as an appurtenant to his messuage (dwelling-house), such ownership arising either from prescription—that is, long-continued use—or from a grant by the ordinary or bishop. All the other pews not so claimed, except that appropriated to the minister's family, are under the control of the churchwardens, acting on behalf of the ordinary—i. e. the bishop of the diocese. Every parishioner is entitled to a sitting, and may enforce his right by suit in the proper court. This is the law applicable to churches built before 1818; with regard to those built thereafter acts of Parliament provided for the existence of some free seats and the manner of letting the rest. Pews in the Established Church in Scotland are held under a similar system. In the U. S., where the Church and state are separate, the method of holding church seats is regulated by the rules of the various churches. Occasionally the trustees or vestry, or other officers of the corporation or society, retain the entire custody of the church edifice, and the seats are free to all comers during divine service. Sometimes the pews are leased for a year only at a specified rent; on the other hand, they are often conveyed by an instrument in the form of a perpetual lease, reserving an annual rent. In the latter case the right of the pew-holder is peculiar; it is property, and may be transferred, but is generally exempt from sale on execution; in some States it descends to the heirs as real estate, and in others it passes to the administrator as personal estate. It is, however, limited, and subject to the ultimate control of the trustees or vestry, who may, under restrictions not affecting the pewholder, convey the church edifice, rebuild, repair, or remodel it at their discretion. Revised by F. S. Allen.

Pewee: See Phœbe-bird.

Peyer's Glands: small sacculi peculiar to the mucous membrane of the small intestine, termed *glandulæ solitariæ* when scattered singly, and *glandulæ agminatæ* when collected in groups. Also called *Peyer's patches*, from Peyer (1653–1712), who first described them. See Histology.

Peyron, pā'rōn', Vittorio Amadeo: philologist; b. at Turin in 1785; d. 1870. He was a pupil of Tommaso Valperga di Caluso, and succeeded him in the chair of Oriental languages. He was a member of the Turin Academy of Sciences and foreign member of the French Institute. He rendered important services to the study of Greek and of Coptic; translated Thucydides anew into Italian; published a critical essay upon the Hellenic constitution, prefixed to the *Scene Elleniche* of Brofferio; some Greek texts, partly inedita, of Empedocles, Parmenides, Theodosianus; and fragments of the *Orations* of Cicero for Scaurus and Tullius and against Clodius. He has also the merit of having founded the study of Coptic by his *Lexicon Linguæ Copticæ* and his *Grammatica Linguæ Copticæ*.

Revised by A. Gudeman.

Peyronnet, pā'rō'nā', Charles Ignace, Comte de: statesman; b. at Bordeaux, France, Oct. 9, 1778; studied law, and practiced as an advocate in his native city; became very conspicuous during the first and second Restorations as an ultra-royalist and stanch adherent of the Bourbons, and was Minister of Justice 1821–28. In 1822 he carried a law by which all press cases were deprived of trial by jury and referred immediately to the royal courts, which were empowered to suspend and suppress any publication which seemed hostile to the public peace, the established Church, and the royal authority. In 1825 he carried another law by which profanation of any object consecrated to the public worship was punished by forced labor for life. In 1822 he was created a count; on May 16, 1830, he again entered the Government as Minister of the Interior in the cabinet of Polignac, and as such he signed the notorious ordinances of July 25, 1830, which occasioned the Revolution of 1830 and the fall of the elder line of the house of Bourbon. Arraigned before the House of Peers for high treason, he was sentenced to imprisonment for life and confined in the fortress of Ham, but Oct. 17, 1836, he was pardoned. D. Jan. 2, 1854, on his estates in the Gironde. He wrote a *Histoire des Francs* (2d ed. 1846) and *Satires* (2d ed. 1854). F. M. Colby.

Pfleiderer, Otto: German Protestant theologian; b. at Stetten, near Cannstatt, Würtemberg, Sept. 1, 1839; studied under Baur at Tübingen 1857–61; became pastor at Heilbronn 1868; superintendent and Ordinary Professor of Theology at Jena 1870; Professor of Theology in Berlin 1875. He belongs avowedly to the school of Baur, and defends his views with logical power and eloquence. He has twice appeared as a lecturer on English foundations—once as Hibbert lecturer in London (1885) and once as Gifford lecturer in Edinburgh (1894), and both courses were published in English—*Lectures on the Influence of the Apostle Paul on the Development of Christianity* (London, 1885) and *The Philosophy and Development of Religion* (2 vols., 1894). Besides these there are in English, *Paulinism: a Contribution to the History of Primitive Christian Theology* (2 vols., 1877); *The Philosophy of Religion on the Basis of its History* (4 vols., 1886–88); *The Development of Theology in Germany since Kant and its Progress in Great Britain since 1825* (1890). Samuel Macauley Jackson.

Pflü'ger, Eduard Friedrich Wilhelm, M. D.: physiologist; b. at Hanau-on-the-Main, June 7, 1829; studied medicine first in Marburg, then in Berlin, where he was a pupil of John Mueller and of Du Bois-Reymond; graduated M. D., University of Berlin, in 1855; elected Professor of Physiology at the Bonn University in 1859; established and edited the *Archiv für die gesammte Physiologie des Menschen und der Thiere* in 1868. Among his important works are *Die sensorischen Functionen des Rückenmarks der Wirbelthiere*, etc. (Berlin, 1853); *Untersuchungen über die Physiologie des Electrotonus* (Berlin, 1859); *Wesen und Aufgaben der Physiologie* (Bonn, 1878). S. T. Armstrong.

Pforz'heim: town: in the grand duchy of Baden, Germany; at the confluence of the Nagold, Enz, and Würm; 20 miles by rail S. E. of Carlsruhe (see map of German Empire, ref. 6–D). It has large manufactures of jewelry, chemicals, and linens, iron-works, tanneries, and oil-mills, and an active trade in timber, which is cut in the neighboring Black Forest. Pop. (1895) 33,345.

Phacochœ'ridæ [Mod. Lat., named from *Phacochœ'rus*, the typical genus; *φακός*, lentil seed, wart + *χοῖρος*, pig]: a family of even-toed ungulates comprising the wart-hogs, and closely related to the true hogs, with which they are

combined by some zoölogists. The milk dentition is I. $\frac{1}{3}$, C. $\frac{1}{1}$, P. M. $\frac{3}{2}$, M. $\frac{3}{3}$; but many of the teeth are lost as growth proceeds, and in the adults frequently none are present but the canines and last molars. The structure of the molars is peculiar, as they consist of about twenty upright columns of dentine coated with enamel and united by cement, each column having its own pulp-cavity. See WART-HOG.

F. A. LUCAS.

Phædra (in Gr. *Φαίδρα*): in Greek legend, the wife of Theseus and the stepmother of Hippolytus, with whom she fell desperately in love. When he refused to comply with her wishes, she accused him to his father of an attempt upon her honor, but when she heard that he had perished in consequence of his father's wrath, she confessed her guilt and committed suicide. The tragedies on this subject by Sophocles and Euripides are lost, but there is a celebrated one by Racine. Revised by J. R. S. STERRETT.

Phæ'drus: author; b. in Thracia; was taken to Rome as a slave, but was made free by Augustus, and was the first to raise the fable to the dignity of a special branch of Roman poetry. He wrote five books of fables, now extant but incomplete, containing ninety-three fables in all, many of which, however, are only versifications of the fables of Æsop. The style is easy and fluent, and the book often very pleasant to read. There are editions by Orelli (Zurich, 1831), L. Müller (Leipzig, 1868), and a larger critical edition, containing appendix of additional fables, 1877. See L. Hervieux, *Les fabulistes latins* (Paris, 1884), and Hartman, *De Phædri fabulis* (Leyden, 1890). Revised by M. WARREN.

Pha'ëthon [= Lat. = Gr. *Φαέθων*. Cf. *φαέθων*, shining]: in Grecian mythology, the son of Helios. He obtained one day permission of his father to drive the chariot of the sun across the heavens, but the horses ran off, and the chariot was just about setting heaven and earth on fire when Zeus struck down the unfortunate driver with a thunderbolt. He fell into the Eridanus, and his sisters, the Heliades, who stood mourning by his corpse, were transformed into poplars and their tears into amber. Revised by J. R. S. STERRETT.

Phaëton'idæ [Mod. Lat., named from *Pha'ethon*, the typical genus, from Gr. *Φαέθων* (see PHAËTHON), in allusion to their tropical habits]: a family of birds belonging to the order *Steganopodes*, and containing the TROPIC BIRD (*q. v.*).

Phagocyto'sis [Mod. Lat., from Gr. *φαγεῖν*, eat + *κύτος*, a hollow vessel]: a word first used by Metschnikoff to express the destruction of bacteria and other injurious substances by means of white blood-corpuscles. In accordance with this view of Metschnikoff, the leucocytes, which in inflammation leave the vessels and enter into the tissue, play an important and useful part, their function being to eat up and destroy bacteria and other injurious solid substances. Metschnikoff found on inoculating an animal with certain organisms that after inflammation was produced the bacteria became included in the leucocytes, and when this was the case they were apparently destroyed or rendered innocuous, and the inflammation subsided.

It was found from the experiments of Nuttall, Buchner, and others that the destruction of the bacteria is not due to this action of the leucocytes, but to destructive effects of substances contained in the blood serum, and the bacteria are already destroyed when they are taken into the cells. These substances in the blood serum, which are destructive to the bacteria, are either present naturally, in which case the animal has an immunity to the disease inoculated, or they arise during the course of the disease, and with their presence in the blood in sufficient amount the disease subsides. There is no doubt, however, that although the process has not the full bearing and importance which was ascribed to it by Metschnikoff, it plays an important *rôle* in disease. Not only are dead bacteria removed by the leucocytes, but foreign particles of all sorts, including necrotic cells and portions of tissue. These substances are taken into the body of the leucocytes, and there undergo a complete or partial digestion, and are rendered soluble and thus absorbed. In other cases they may be carried off while still in the body of the leucocytes. This is the case when particles of pigment are placed in the skin as in tattooing. The presence of the leucocytes in such places is always due to the presence of a chemical substance which has a powerful action in attracting the leucocytes. This substance is known to be of an albuminous character, and it is found in all cases where dead cells of whatever nature, whether bacteria or the tissue cells themselves, are present. W. T. COUNCILMAN.

Phalan'ger: a common name for a marsupial of *Cuscus*, *Phalangista*, or a related genus of the family *Phalangistidæ*, popularly known in Australia as an opossum. The phalangers are about the size of a cat; have a rather small, somewhat pointed head; long, bushy, prehensile tail; and are clad in thick, woolly fur. They are arboreal and nocturnal in their habits, and live on fruit and leaves. They are found in Australia and Tasmania, and are eaten by the natives and to some extent by the settlers. The vulpine phalanger (*P. vulpecula*), which is of fox-like aspect, and gray above, whitish below, with white ears and a black tail, is a well-known species. The flying phalangers, of the genus *Petaurus*, have, like the flying squirrels, a fold of membrane running from the fore to the hind leg, which serves as a parachute and enables them to take long leaps. The genus ranges from New Ireland to New South Wales. F. A. LUCAS.

Phalangida [from Gr. *φαλάγγιον*, spider + *εἶδος*, like]: a group of Arachnida, including those long-legged spider-like forms familiarly known as harvestmen or daddy-long-legs. They have small bodies consisting of an unsegmented anterior portion (cephalothorax) and a six- or eight-jointed abdomen. They have usually a single pair of eyes; they breathe by means of air-tubes (tracheæ), and so-called lungs are absent. The legs are usually extremely long and slender, the distal portion (foot or tarsus) being many-jointed. Some 250 to 300 species have been described, South America being especially rich in species. The harvestmen live in damp places, crawling over leaves, etc., by means of their long legs, and being protected from enemies by a pair of "stink glands," which open on either side of the cephalothorax. They are largely nocturnal, and feed upon small insects, etc. American species have been described by Wood (in *Proceedings Essex Institute*, vol. vi., 1870) and Weed (in *American Naturalist*, 1888–93). J. S. KINGSLEY.

Phalangist'idæ, or **Phalangeridæ** [*Phalangistidæ* is Mod. Lat., named from *Phalangis'ta*, the typical genus, from Gr. *φάλαγξ*, phalanx, bone between joints of the fingers or toes. So called from the peculiar joining of the phalanges]: a family of herbivorous marsupials containing the members of the genera *Cuscus*, *Phalangista*, *Belideus*, and their allies. The dentition is somewhat variable, I. $\frac{3}{1}$, C. $\frac{1}{1}-\frac{1}{0}$, P. M. $\frac{2}{1}-\frac{3}{3}$, M. $\frac{4}{4}=\frac{3}{3}$. The fore and hind limbs are of nearly equal size, all with five toes. The first toe of the hind foot is opposable to the others, the second and third are slender and united by skin as far as the claws. The stomach is simple; a cæcum present and usually large. See CUSCUS, KOALA, and PHALANGER. F. A. LUCAS.

Pha'lanx [= Lat. = Gr. *φάλαγξ*]: in the military organization of ancient Greece, the tactical unit of the heavy-armed troops, a body of foot-soldiers armed with spears and shields. The number of men was various. They were arranged from four to sixteen men deep. In later times the great phalanx under the Macedonians comprised 16,384 men, and was composed of four minor phalanges, each of which had two *merarchies*, or halves. Each merarchy was composed of two *chiliarchies*, each of these of four *syntagmata*, and each syntagma of 256 men. The phalanx was, as compared with the Roman legion, a cumbrous arrangement of men.

Revised by J. R. S. STERRETT.

Phal'aris: proverbially the most cruel tyrant known to antiquity; the ruler of Agrigentum in Sicily for about sixteen years, in the middle of the sixth century B. C. Of his history hardly anything is known with certainty, most of it being enveloped in fables. A prominent feature in these fables is the brazen bull, invented by one Perillus, in which Phalaris roasted his enemies, inaugurating the ingenious instrument of torture by the roasting of its inventor. This story perhaps originated in the worship of the Phœnician Baal with human sacrifices, and after the abolishment of this cult its practice would seem to have been associated with the memory of the odious tyrant. The famous *Epistles of Phalaris*, 148 in number, first printed at Venice in 1498, and afterward often reprinted and translated, give quite another picture of the man's character, and were read through many centuries with great edification, until Bentley proved that they were spurious, a product of a much later time. Revised by G. L. HENDRICKSON.

Phalarope, făl'a-rōp: any one of three species of small wading birds resembling sandpipers, but having the toes lobed, or furnished with scallop-like margins, which enables these birds to swim and dive with great ease. They are found in the northern hemisphere and breed far north. On

their breeding-grounds they are usually found in couples about some body of fresh water, but during their migrations they often occur at sea in considerable flocks. They feed on seeds, insects, and minute crustacea. Wilson's phalarope (*Phalaropus tricolor*) is peculiar to North America. *P. lobatus* and *Crymophilus fulicarius* are found in Europe and Asia as well. F. A. Lucas.

Phalaropod'idæ [Mod. Lat., named from *Phala'ropus*, the typical genus; Gr. φαλαρίς, coot + πούς, ποδός, foot]: a family of aquatic birds of the order *Limicolæ*, containing the phalaropes. The bill is slender, straight, about as long as the head, and with the sides of the upper mandible grooved for nearly the whole length; nostrils near the base, linear, and in the lateral groove of the mandible; wings long and pointed; tail short and rounded; legs rather posterior, with the tarsi moderate, the anterior toes united at the base and with lobate sides, and the hind toe elevated and with a narrow membrane. F. A. Lucas.

Phallic Worship [*phallic* is from Gr. φαλλικός, deriv. of φαλλός, penis; probably cognate with Germ. (dial.) *bulle*]: originally the adoration of the reproductive and regenerative powers of nature, represented after a time by a figure of the phallus, or male generative organ, or in some instances by a straight column or by the pistil of a flower, as in India at the present day. This worship, whatever of symbolism it may have had at first, rapidly became a most corrupt practice. It prevailed in India (as at present), in Chaldæa, Egypt, Syria, Phrygia, Greece, and Rome, as in later days among some of the American savages, notably the Seminoles of Florida. The forms which this abomination assumed were innumerable. Dionysus, Hermes, Venus, Priapus, Pan, Isis, and other gods were worshiped at Rome by phallic symbolism.

Phana'riots, or **Fana'riots** [from *Fanar*, one of the quarters of Constantinople where they dwell; from Gr. φανάριον, the "beacon" there situated]: a body of Constantinopolitan Greeks who claim a noble Byzantine descent. Spared by the Turkish conquerors, they artfully insinuated themselves into public affairs, and until 1822 held many important civil, military, and naval positions, in which they displayed, as a rule, selfish and ungenerous qualities. Their power as a class is now completely broken.

Phaneroga'mia, Phan'erogams [*phanerogamia* is Mod. Lat., from Gr. φανερός, apparent, visible (deriv. of φαίνειν, φανῆναι, show) + γάμος, marriage]: the highest branch of the vegetable kingdom, the flowering plants. The less objectionable terms Anthophytes (*q. v.*) and Spermaphyta are displacing the older ones in recent botanical works. See Vegetable Kingdom. Charles E. Bessey.

Phanocles: Greek elegiac poet of the Alexandrian period who wrote a cycle of elegies on the boy-favorites of the gods and heroes (Ἔρωτες ἢ καλοί). The fragment preserved by Stobæus, *Floril.*, 64, tells of the love of Orpheus for Calaïs, son of Boreas, and the death of the singer at the hands of jealous women. Ed. by Schneidewin in his *Delectus* and Bergk in his *Anthologia Lyrica*. B. L. G.

Pha'raoh [Egypt. *Per-āa*, great house; Heb. *Phar'ōh*, Gr. Φαραώ]: the royal title of the Egyptian kings, used generally alone in the Bible, rendering it impossible to distinguish between successive sovereigns. Only in the later periods were other names added, as Pharaoh-Necho and Pharaoh-Hophra. The etymology given above is the one usually accepted, though several others have been proposed. It is often compared to the Turkish Sublime Porte. For contrary views, see Renouf, *Proceedings of the Society of Biblical Archæology*, vol. xv., p. 421 f. C. R. G.

Pharaoh's Hen: See Egyptian Vulture.

Pharisees [from Lat. *Pharisæ'us* = Gr. Φαρισαῖος, from Heb. *pᵉrūshīm* (plur.), deriv. of *pārash*, to separate]: a political and religious party among the Jews, originated during the time of the Maccabees in opposition to the invasion of Greek ideas and Greek customs which took place especially during the reign of Antiochus Epiphanes. While the Sadducees and the ruling aristocracy had yielded to the idea of a distinction between religion and politics, between Church and state, the Pharisees still maintained the old and genuinely Jewish view of a theocracy; and while the Sadducees adhered rigorously to the literal conception of the words of the sacred books, the Pharisees adopted the tradition as a means by which to interpret Scripture. Thus the Pharisees stood at the time of Christ at once as the national party in politics and as the progressive school in theology, and their influence with the mass of the people seems to have been very great. The sources of our knowledge of them are the New Testament, Josephus, and the Mishna. Modern scholars seem inclined, however, to look at them under a milder view than that in which they appear in the New Testament, though it is only natural when the importance which they ascribed to the observation of all minutiæ of the law led to hypocrisy and falsity.

Pharmacopœ'ia [Mod. Lat., from Gr. φαρμακοποιΐα, preparation of medicines; φάρμακον, drug, medicine + ποιεῖν, make]: a book containing formulas and directions for preparing and compounding drugs for use in the treatment of disease. Such a book may be the outcome of individual enterprise or the execution of an order of the government. In many European states the *Pharmacopœia* is issued by the authority of the Government, and penalties are attached to failure on the part of the pharmacist to observe its directions. In the U. S. the *Pharmacopœia* is not prepared under authority of the general Government, but observance of its provision is, in certain States, required by special law. The first pharmacopœia published in the U. S. was issued at Philadelphia in 1778 for the use of the hospital of the U. S. army, at Lititz, in Pennsylvania. This was published in Latin. In the second edition, Dr. William Brown was named as its author. In 1805 a pharmacopœia was issued for the use of New England. Another pharmacopœia was issued in 1815 for the use of the New York Hospital. In 1817 Dr. Lyman Spalding, of New York, proposed a plan for the formation of a *National Pharmacopœia*, and circulars being issued to a large number of medical societies, these sent delegates to Washington in 1820 to prepare the first *National Pharmacopœia*, which was issued Dec. 15, 1820, in Latin and English. Since that time at certain intervals conventions have been held by representatives of the medical profession and pharmacists, which have revised and altered the *Pharmacopœia*, so as to incorporate in it new drugs or new formulas which had come to be recognized as useful, and to exclude others which had fallen into disuse or been found unworthy of a place in such a work. The issue of the *Pharmacopœia of the United States of America* called the seventh decennial revision was prepared by a convention which met at Washington in 1890. It was printed at Philadelphia, and became official on Jan. 1, 1894. It contains descriptions of drugs and the mode of preparing them for use, and a great variety of information on subjects collateral with these. The following is an example of the description of a drug: "Acidum Carbolicum. Carbolic Acid. C_6H_5OH–93·78. (Phenol.) A constituent of coal-tar, obtained by fractional distillation, and subsequently purified. Carbolic acid should be kept in dark amber-colored, well-stoppered vials." After this follows a full description of the chemical and physical characteristics and properties of carbolic acid. In the preparation of compound remedies the *Pharmacopœia* gives the name in Latin, then in English, then a description of the preparation, then its constituents with their proportions, followed by a description of the method of compounding them. Works of this kind are of the greatest value in producing uniformity in the preparation of drugs, and in securing reliability as to strength and genuineness of their ingredients. In the U. S. there is no general law compelling physicians or pharmacists to follow the directions of the *Pharmacopœia*, but it is recognized as the best guide in regard to the preparation and compounding of drugs, and is the basis of all intelligent teaching on pharmacy. Charles W. Dulles.

Pharmacy [from Gr. φαρμακεία, use of medicines, pharmacy, deriv. of φαρμακεύειν, administer medicines, deriv. of φάρμακον, drug, medicine]: the art of preparing, preserving, compounding, and dispensing remedies for disease. The modern idea of pharmacy includes only the art of one who acts as an agent for the physician, and in so far differs from the theory and practice of the ancients. This definition corresponds fairly to the present actual relation of the dispensers of drugs to practitioners of medicine, although many who claim the name of pharmacists prepare remedies according to formulas which they make public or conceal, and sell these with indications for their use and directions how to employ them. This practice is not regarded as commendable by physicians, on the ground that, while sometimes useful, it may at times be damaging to those who avail themselves of it.

The origin of pharmacy is very ancient. In the earliest medical times it was carried on by physicians who prepared

their own remedies and directed their administration. The earliest history of medicine, which is that of the Egyptians, contains records in the Leipzig and Berlin papyri of the preparations of remedies by the priestly class, who were the physicians. The earliest Greek physicians (the Asclepiadæ) prepared their own remedies, and were in the original sense of the word pharmacists. About the time of the Christian era there was a class of persons called rhizotomes (root-cutters), who collected drugs and sold them to physicians. In a rude way these were the first pharmacists in the modern sense of the word. After this, with the increase of medical practice, there arose a class of persons who made it a business to collect drugs and prepare them for the use of physicians, and accordingly this work became more specialized. There were certainly drug-shops among the Romans, for one has been unearthed at Pompeii; but it was not until the end of the Middle Ages that pharmacy became much of an art, receiving a distinct recognition from the great Emperor Frederick II., who was the patron of the University of Salerno in the thirteenth century. At present it is made an object of study in institutions devoted to it alone, and is regulated by law in most civilized lands. Some of the most celebrated schools of pharmacy are found in the U. S., where men of great learning have contributed to elevate the standard of education of pharmacists, until the art is now sometimes erroneously spoken of as a profession. The intending pharmacist is instructed in chemistry, botany, physics, animal physiology, materia medica, toxicology, and pharmacology. The result of education and of cultivating the niceties of the art of pharmacy has been the preparation of many remedies, beautiful in appearance and pleasant to take, and at the same time of proper efficiency. The French pharmacists have unusual skill in the manufacture of what are known as elegant preparations. The U. S. is especially distinguished for what may be called neat pharmaceutical preparations.

The shop of the modern pharmacist is supplied with many things besides drugs, such as various surgical appliances, plasters, bandages, and even instruments, with many articles of convenience or of cosmetic usefulness. The enterprise of modern pharmacy secures, in the large cities, everything, no matter how rare, that is of approved value in the treatment of disease, and has led to the actual discovery of useful remedies. See APOTHECARY. CHARLES W. DULLES.

Pha'ros (in Gr. *Φάρος*): an island off Alexandria, in Egypt, celebrated for its lighthouse. Alexander the Great connected the island with Alexandria (a distance of 7 stadia) by a dike.

Pharyngobran'chii [Mod. Lat.; Gr. *φάρυγξ*, throat + *βράγχια*, gills]: a group of fish-like vertebrates, so named from the perforation of the pharynx for the gill-slits. It is equivalent to the class LEPTOCARDII (*q. v.*), which is the generally used term.

Pharyngog'nathi [Mod. Lat.: Gr. *φάρυγξ*, throat + *γνάθος*, jaw]: name applied to an artificial combination of fishes originally established by Johannes Müller for the reception of those teleosts in which the two lower pharyngeal bones form a single solid piece. The group thus distinguished was recognized as an order by Müller, and to it were referred some of the spiny-rayed fishes (*Labridæ*, *Cichlidæ*, *Embiotocidæ*), as well as some with soft rays (*Scomberesocidæ*). These forms have, however, on the one side no close affinity with each other, and on the other side they are severally related to other types in which the lower pharyngeals are separated; again, there are fishes of other families, as the drumfishes (*Aplodinotus* and *Pogonias*) among the *Sciænidæ*, which have the lower pharyngeals as much united as in the typical *Pharyngognathi* of Müller. On account of these inconsistencies the order, though formerly generally adopted, is now discarded by the best ichthyologists.

Revised by D. S. JORDAN.

Phar'ynx [Mod. Lat., from Gr. *φάρυγξ*, throat, pharynx]: a musculo-membranous sac situated at the base of the skull, immediately behind the mouth, nose, and larynx, and in front of the cervical vertebræ, extending as far down as the fifth, where it is continuous with the œsophagus. It has the following openings into it: Two from the nose, the posterior nares; two Eustachian tubes, which communicate with the middle ear; the mouth, larynx, and œsophagus. It is lined by mucous membrane, which is continuous with that lining the various cavities opening into it. Beneath this mucous coat is a fibrous layer known as the pharyngeal aponeurosis; and beneath this, again, is a muscular layer, composed of the superior, middle, and inferior constrictor muscles; they diminish the capacity of the pharynx, and by their successive contraction from above downward the food is carried along into the œsophagus. The pharynx is freely supplied with glands, which are situated in the mucous membrane, and there is considerable lymphoid tissue in various parts. This is similar in structure to the tonsil gland. The function of the pharynx is to give passage to the food in deglutition and to the air in respiration. The pharynx is a common seat of catarrhal inflammations, occurring acutely as "colds" or as more chronic affections. Those who smoke tobacco or drink strong alcoholic beverages, as well as those whose occupation requires public speaking and especially that in the open air, are liable to a peculiarly obstinate form of inflammation of the pharynx.

Revised by W. PEPPER.

Phascolomy'idæ [Mod. Lat., named from *Phasco'lomys*, the typical genus; Gr. *φάσκωλος*, pouch + *μῦς*, mouse]: a family of marsupial mammals containing the wombats (see WOMBAT), and distinguished by their rodent-like dentition. The body is stout and large; the head large; nostrils widely separated behind, but converging forward; upper lip cleft; dentition, I. $\frac{1}{1}$, P. M. $\frac{1}{1}$, M. $\frac{4}{4}$, all of which are rootless, more or less incurved, and grow upward, like the incisors of the placental rodents; the limbs are nearly equal, short and stout, and with five toes to a foot; anterior toes, with broad and little-curved nails; the innermost toe of hind foot small, at nearly right angles with the rest, and destitute of a nail; the second, third, and fourth toes are connected, and they, as well as the fifth, have long curved nails; tail rudimentary; stomach simple, with a special gland situated to the left of the cardiac orifice; cæcum short and wide, with a vermiform appendage. Revised by F. A. LUCAS.

Phasian'idæ [Mod. Lat., named from *Phasia'nus*, the typical genus, from Lat. *phasia'nus*, pheasant; cf. *Pha'sis*, name of a river in Colchis. See PHASIS]: a family of birds including most of the gallinaceous fowls. They all have the bill moderate, with the sides compressed, and with the culmen arched toward the tip, which is curved over the lower mandible; the wings are moderate and more or less rounded; the tail variable in development; the tarsi are robust, and covered with transverse scales in front, smaller ones behind, and still smaller ones on the sides, and in the cock generally armed with one or more spurs; the toes are moderate, three in front united at base by a slight membrane, and a hinder one short and elevated. The family has been made the subject of a beautiful monograph by D. G. Elliot. Revised by F. A. LUCAS.

Pha'sis [= Lat. = Gr. *Φᾶσις*]: the ancient name of the *Rion* or Faz river; in the Russian province of Transcaucasia; considered by the classical geographers as the boundary between Europe and Asia. The Argonauts were fabled to have landed at its mouth.

Pheasant [from Lat. *Phasianus* (sc. *avis*), the Phasian bird]: a name said to have been given by the ancients to the best-known species of pheasant (*Phasianus colchicus*), from the fact that it was brought from the vicinity of the river Phasis, in Colchis. It is now used as a general name for the long-tailed gallinaceous birds related to the common pheasant, and forming the sub-family *Phasianinæ*, and is extended to a number of other game-birds. In the U. S. it is applied to the ruffed grouse (*Bonasa umbellus*), in those sections of country where the quail (*Colinus*) is termed partridge. *Phasianus colchicus* originally inhabited Western Asia about the Caspian Sea, and Southeastern Europe, but it has been introduced in other localities, especially in England, and in the U. S. is very commonly known as the *English* pheasant. It is nearly 3 feet long, half of this being due to the tail. The plumage is rich and variegated. The head and neck are glossy green, the lower neck, breast, and sides reddish brown with a purple luster, the feathers being edged with black. The rump is coppery red, wings striped with brown and red, tail gray with black bands and brown edges. The female is smaller, of a general grayish brown, and she is shorter and without the long central tail feathers. These long feathers, so characteristic of the males of the true pheasants, reach their maximum in Reeve's pheasant (*P. reevesii*), in which they attain a length of over 5 feet. Two species of pheasants closely related to the common pheasant, the Mongolian pheasant (*P. torquatus*) and the green pheasant (*P. versicolor*), have been introduced into Oregon, as has also the beautiful golden pheasant (*Chrysolophus pictus*). The fire-back pheasants (*Euplocamus*) are so called on ac-

count of the glowing red upon the rump of the males of some species. To this genus belongs the Macartney pheasant, *E. ignitus*, of Siam. The impeyan pheasants (*Lophophorus*) are large birds of rich metallic colors, distinguished by their tails being flat and rounded instead of compressed and pointed. They inhabit the slopes of the Himalayas. The horned pheasants, or tragopans (*Ceriornis*), are distinguished by a little pointed wattle on either side of the head. Their general color is dull red with white spots, and they too dwell on the slopes of the Himalayas. Pheasants are ground-frequenting birds, and feed on grubs, insects, seeds, and grain. They are mostly polygamous, and the numerous eggs are deposited in a very rude nest. With the exception of *Phasianus colchicus* they are confined to Asia and some of the large adjacent islands, and Japan. A beautiful monograph of the group has been issued by D. G. Elliot, under the title *A Monograph of the Phasianidæ, or Family of Pheasants.* A more accessible work is Tegetmeier's *Pheasants: their Natural History and Practical Management.*

F. A. Lucas.

Phelps, Austin, D. D.: clergyman and author; b. at West Brookfield, Mass., Jan. 7, 1820; graduated at the University of Pennsylvania 1837; studied divinity at Andover and New Haven; was pastor of the Pine Street Congregational church, Boston, Mass., 1842–48, and was Bartlett Professor of Sacred Rhetoric in the Andover Theological Seminary 1848–79. He published *The Stilt Hour* (1859); *The New Birth* (1867); *The Theory of Preaching* (1881); *Men and Books* (1882); *My Portfolio* (1882); *Engtish Style in Public Discourse* (1883); *My Study* (1885); *My Note-book* (1890); and numerous articles in the religious journals. With Prof. Park and Dr. Lowell Mason he edited the *Sabbath Hymn-book* (1858). D. at Bar Harbor, Me., Oct. 13, 1890. See his *Life* by his daughter, Mrs. Ward (1891).

Revised by G. P. Fisher.

Phelps, Edward John: lawyer; b. in Vermont, July 11, 1822; graduated at Middlebury College in 1840; was at Yale Law School 1842–43; a lawyer in Vermont from 1844; second comptroller of the treasury 1851–53; member of Vermont constitutional convention 1870; Democratic candidate for Governor of Vermont 1880; became Kent Professor of Law in Yale College in 1881, and lecturer on constitutional law in Boston University in 1882. He was a Webster Whig till that party broke up, and then became an independent Democrat. He was U. S. minister to Great Britain 1885–89, and one of the counsel for the U. S. in the Bering Sea tribunal of arbitration in 1893. D. March 9, 1900.

Phelps, Elizabeth S.: See Ward, Elizabeth Stuart.

Phelps, Thomas Stowell: See the Appendix.

Phelps, William Walter, LL. D.: statesman; b. in New York city, Aug. 24, 1839; graduated at Yale College 1860 and at Columbia Law School 1863: member of Congress 1873–75; U. S. minister at Vienna 1881–82; again in Congress 1883–89; one of the U. S. commissioners to negotiate the Samoan treaty with Germany 1889; U. S. minister at Berlin 1889–93; appointed a judge of the New Jersey Court of Errors and Appeals 1893. D. at Teaneck, N. J., June 16, 1894.

Phenacetin: a drug which occurs in colorless needles, slightly soluble in water. Its general action on the system is almost identical with that of antipyrin and antifebrin, but it is thought by many physicians to be safer than those remedies. In nervous headaches and other nerve pains, in doses of 10 grains, it frequently affords great relief.

Phenakis'toscope: See Stroboscope.

Phenic Acid: See Phenol and Carbolic Acid.

Phenicin, or **Phenyl Brown**: a coloring-matter first prepared by Roth in 1865 by the action of nitrosulphuric acid on phenol (carbolic acid). It is a brown amorphous powder, slightly soluble in water, very soluble in alcohol, ether, and acetic acid. With alkalies it forms a fine violet-blue solution, which is changed to brown by the slightest excess of acid. It dissolves also in lime-water. It consists of two coloring-matters—one yellow dinitro-phenol, the other a black, humus-like body, both possessing the same tinctorial properties. Phenicin was at one time used for coloring leather, but it has given way to other dyes.

Revised by Ira Remsen.

Phe'nol ($C_6H_6O = C_6H_5OH$), **Phenic Acid**, **Carbolic Acid**, **Phenyl Hydrate**, **Phenylic Alcohol**, or **Coal-tar Creosote** [*phenol* is from Gr. *φαίνειν*, show, named from its yielding derivative colors]: a substance discovered in coal-tar by Runge, produced by the dry distillation of salicylic acid and a number of other substances. The urine of the cow, horse, and man yields it in small quantities. Commercial creosote often consists entirely of phenol, but the true creosote from wood is a totally different substance.

Preparation.—Phenol is prepared from coal-tar. The tar is separated by fractional distillation into (1) light oil of coal-tar, crude coal-tar naphtha; (2) heavy oil of coal-tar, "dead oil"; (3) anthracene oil; (4) pitch which remains in the still. From the light oil the phenol is most easily prepared. The oil is rectified by distilling with a current of steam, and leaves behind a portion known as naphtha tailings, which contain about 15 per cent. of phenol. From dead oil it is more difficult to obtain pure phenol, owing to the presence of much cresol. But the mixture of the two, which is better than pure phenol for disinfecting purposes, is readily obtained. Dead oil contains from a trace to perhaps 12 per cent. of the tar acids, phenol, cresol, etc., according to the part of the distillate it represents, the entire product of dead oil averaging about 5 per cent.

Properties.—Phenol occurs in long colorless needles or in white crystalline masses, sp. gr. 1·065, melts at 93°–95° F., and boils at 368°–370° F. The crystals deliquesce on exposure to the air by absorbing a trace of water. Phenol smells like wood-tar creosote, and attacks the skin like that substance. It dissolves in about 20 parts of water, and mixes in all proportions with alcohol, ether, and strong acetic acid. The aqueous solution of phenol coagulates albumen and preserves animal substances from decomposition. It even removes the fetid odor from meat which is already in a state of decomposition. Fish and leeches die when immersed in the aqueous solution, and their bodies subsequently dry up on exposure to air, without putrefying. These properties have led to the extensive use of phenol as an antiseptic and disinfectant. It is used in all grades of purities—dead oil for privy vaults, sewers, cattle-yards, and cars, and purer forms for street-gutters, cellars, water-closets, dwellings, clothing, etc. All grades except dead oil should be mixed with 20 to 50 parts of water before they are applied, or they may be mixed with dry slaked lime, sawdust, clay, etc., and applied in powder; the first-mentioned mixture is sold under the name of carbolate of lime. Many mixtures of carbolic acid are advertised as disinfectants which are practically worthless. A mere odor of phenol is not sufficient to prevent putrefaction. (See Disinfection and Fermentation.) Phenol is highly poisonous, except in an extremely dilute solution. The best antidote is olive oil, administered in large quantities. Sulphuric acid converts phenol into phenyl-sulphuric acid. Strong nitric acid converts it into trinitro-phenic acid, Picric Acid (*q. v.*), an important dye, $C_6H_3(NO_2)_3O$. On heating the soda compound of phenol in carbonic acid half the phenol distills off, leaving a sodic salicylate, which is now the source of the valuable salicylic acid. For phenol in its relations to medicine, see Carbolic Acid.

Revised by Ira Remsen.

Phenol Colors: an important class of artificial dyes derived from coal-tar. The most important are (1) Picric Acid (*q. v.*); (2) *dinitro-cresot*, known as *Victoria yettow*, *aniline yettow*, etc.; (3) *aurin*; (4) *rosotic acid* (the last two are described in the article Rosolic Acid); (5) *azutine*; (6) *phenicin*; (7) *pæonine*. The phenols combine with phthalic acid to form another class of colors, known as the phthalic-acid colors; and they also combine with azo-compounds. See Azo-colors.

Revised by Ira Remsen.

Phenology: See Climate.

Phenols: a class of compounds of which ordinary phenol is the best-known example. They are closely related to the alcohols. The latter are derived from the paraffins by the substitution of hydroxyl (OH) for hydrogen, while the phenols are derived from the aromatic hydrocarbons (see Hydrocarbons) in the same way. As benzene is the simplest of the aromatic hydrocarbons, so the substance called phenol is the simplest representative of the class to which it belongs. Its relation to benzene is shown by the formulas:

C_6H_6	$C_6H_5(OH)$
Benzene.	Phenol.

Cresol is derived from toluene in the same way that phenol is derived from benzene:

$C_6H_5.CH_3$	$C_6H_4<\begin{matrix}CH_3\\OH\end{matrix}$
Toluene.	Cresol.

There are phenols derived from the hydrocarbons by the substitution of two hydroxyl groups for two atoms of hydrogen. These are called di-acid phenols. Of these, hydroquinone, resorcin, and orcin are examples. Tri-acid phenols are derived from the aromatic hydrocarbons by the substitution of three hydroxyl groups for hydrogen. Pyrogallic acid is the best-known example of the tri-acid phenols. The phenols have a somewhat more acid character than the alcohols. This is shown by the ease with which they form salts when treated with strong bases such as sodium hydroxide, NaOH, potassium hydroxide, KOH, calcium hydroxide, $Ca(OH)_2$, etc. They readily undergo decomposition when treated with oxidizing agents, and, unless pure, they are slowly decomposed by contact with the air, the change being shown by change in color. IRA REMSEN.

Phenyl (C_6H_5): a univalent radical which exists in aniline, phenol, etc.

Phenylic Acid: See PHENOL.

Phe'ræ (in Gr. Φεραί): an ancient city of Thessaly; in a fertile plain near Mt. Pelion; 10 miles W. of its port; on the Pagasæan Gulf; on the site of the modern *Velestino*. Jason, son of Polyphron, succeeded to the throne of Pheræ in 378 B. C., and subdued the greater part of Thessaly up to Pharsalus. Pheræ now became a splendid and prosperous town, and under the government of the nephew of Jason, Alexander, who was notorious for his cruelty, it became the controlling power of the whole of Thessaly and played a conspicuous part in Greek politics. The treachery of Alexander induced the Thebans (see PELOPIDAS and EPAMINONDAS) to aid the oppressed Thessalians, and after the battle of Cynoscephalæ his dominion was again confined to the city and district of Pheræ. He was, nevertheless, still strong enough to land troops in Attica and plunder Piræus. In 358 B. C. Alexander was murdered, and in 352 B. C. Pheræ passed with the rest of Thessaly into the hands of Philip of Macedon. Revised by J. R. S. STERRETT.

Pherec'rates (in Gr. Φερεκράτης): poet of the Old Attic comedy, whose strength lay in his invention. A few fragments—one of considerable length—may be found in Meineke's and Kock's collections. B. L. G.

Pherecy'des (in Gr. Φερεκύδης) OF LEROS: a Greek logographer of the fifth century B. C. who lived in Athens. Of his great work on Greek mythology, often quoted by ancient writers, though under different titles, the existing fragments have been collected and edited by Müller, *Fragmenta Histor. Græcorum*, vol. i., 70–99, and vol. iv., 637–639. B. L. G.

Pherecydes OF SYROS: Greek philosopher of the sixth century B. C. He was considered by some the earliest Greek prose writer; was a rival of Thales and the teacher of Pythagoras. Of his work, which bears the mystic title Ἑπτάμυχος, and seems to have been a product of poetical intuition rather than of philosophical reasoning, some fragments are extant, and have been edited by Sturz (2d ed. 1824). See Ueberweg-Heintze, *Grundriss der Geschichte der Philosophie des Alterthums*, p. 31. B. L. G.

Phid'ias (in Gr. Φειδίας): the greatest sculptor of Greece; b. at Athens 500 B. C.; was taught by Hegias and Ageladas. His career as a sculptor (he gave but brief attention to painting) began under Cimon, but reached its glory under Pericles, with whose splendid epoch his name is indissolubly associated. He was a man of lofty soul, majestic intellect, consummate knowledge of the principles of his art, and wonderful skill in design. The buildings that crowned the Acropolis at Athens are believed to have been erected under his direction, and much of the work—how much can not be known—may be ascribed to his hand. The great statue of Athene in the Parthenon, of gold, ivory, and precious stones, was, there is little room for doubt, executed by him. It was finished 437 B. C. Later, he completed the colossal statue in gold and ivory of Zeus in the temple of Olympia at Elis. It sat enthroned in the temple for 800 years, and was finally destroyed by fire about 475 A. D. Of these works, which commanded the admiration of all Greece, and have given the master an immortal renown, nothing but the fame remains. The traditions concerning the life of Phidias are conflicting. That he met great changes of fortune from the fickleness of his countrymen, that he shared the popularity and the unpopularity of his patron, Pericles, was accused of crimes against the state, embezzlement, and even impiety, and imprisoned, may be believed. He is supposed to have had a long life, and to have died from poison about 432 B. C. See de Rouchand, *Phidias, sa vie et ses ouvrages* (Paris, 1861); Petersen, *Die Kunst des Pheidias*, etc. (Berlin, 1873); Waldstein, *Essays on the Art of Pheïdias* (Cambridge, 1885); Collignon, *Phidias* (Paris, 1886); Brunn, *Geschichte der Griechischen Künstler* (Brunswick, 1853; 2d ed. 1889), i., pp. 157–210; Overbeck, *Geschichte der Griechischen Plastik* (Leipzig, 1893), i., pp. 344–385; Mitchell, *History of Ancient Sculpture* (New York, 1888), i., pp. 299–364; Collignon, *Histoire de la Sculpture Grecque* (Paris, 1892), i., p. 517 ff.—vol. ii., which has not appeared in 1894, will continue the subject. Revised by J. R. S. STERRETT.

Phigali'a (in Gr. Φιγαλία): a city in the southwestern corner of Arcadia, near the frontier of Messenia, now Pavlitza. It was celebrated chiefly for the temple of Apollo Epicurius at Bassæ, on the top of Mt. Cotylium, some miles from Phigalia. The temple was built by Ictinus, one of the architects of the Parthenon, at Athens. Thirty-six columns and their architraves are still standing The frieze, made up of sculptures now called the Phigalian marbles, is in the British Museum. One half of it represents a battle of the Greeks and Amazons, the other half the struggle of the Centaurs and Lapiths. The sculptures are of almost the best style of early Greek art. See Stackelberg, *Der Apollotempel zu Bassæ* (1826); Donaldson, *Antiquities of Athens and other Places in Greece* (London, 1830), vo.. iv.; Cockerell, *The Temple of Jupiter Panhellenius and Apollo Epicurius at Bassæ* (London, 1860). See the histories of Greek art cited under PHIDIAS. Revised by J. R. S. STERRETT.

Philadelphia: See ALA SHEHR and AMMAN.

Philadelphia [from Gr. φιλαδελφία, brotherly love, deriv. of φιλάδελφος, loving one's brother; φίλος, friendly, loving (but for meaning, cf. φιλεῖν, to love) + ἀδελφός, brother]: city; coextensive with Philadelphia co., Pa.; on the west bank of the Delaware river, 103 miles from its mouth, on both banks of the Schuylkill river, which joins the Delaware near the city's southern boundary, and on the Penn., the Phila. and Reading, the Lehigh Valley, and the Balto. and Ohio railway systems; area, 129⅛ sq. miles: extreme length, 20 miles; extreme width, 10 miles; water frontage, 38 miles (for location, see map of Pennsylvania, ref. 6–J). It is the most important city in Pennsylvania, and the third city in population in the U. S.

Plan of the City.—The streets running N. and S. are numbered (as First, Second, Third, etc.) from the Delaware westward; these are crossed at right angles by streets running E. and W. that are named from trees and the counties and Governors of Pennsylvania, and a few main thoroughfares cross diagonally the square blocks thus formed. The principal streets are from 50 to 120 feet wide. The houses are numbered N. and S. from Market Street, and W. from the Delaware, 100 to the block or square, though the block or square may not contain 100 buildings. Numerous streams formerly flowed through the comparatively level land on which the older parts of the city stand. Dock Street shows the winding course of Dock creek. Others have been converted into sewers. The Poquessing, Pennypack, Wissinoming, Frankford, Gunner's, Cohocksink, Hollanders, and Bow creek empty into the Delaware, the Wissahickon and Mill creek into the Schuylkill.

On Dec. 31, 1900, there were 1,510 miles of streets, of which 1,090·62 miles were paved. The streets are lighted every night in the year by 8,569 arc lights, 20,174 gas lamps, and 13,966 gasoline lamps. Between 1855 and 1900 141·22 miles of main sewers and 670·24 miles of branches were constructed. Most of the main streets are traversed by trolley cars. The Schuylkill is spanned by bridges at Penrose and Gray's ferries, at South, Walnut, Chestnut, Market, and Callowhill Streets, and at Girard Avenue and the Falls of Schuylkill, and by seven railway bridges. The most beautiful bridge in the city limits is the stone one of the Reading Railroad over Wissahickon creek. Ninety-four per cent. of the water-supply is drawn from the Schuylkill, the rest from the Delaware. There are 6 pumping-stations and supplementary high service at Roxborough, Mt. Airy, Belmont, Chestnut Hill, and Wentzfarm, and 11 reservoirs and 2 tanks, also four stand pipes, with a total capacity of 1,417,966,400 gals. The police force numbers 2,779 men and 18 matrons. There are 34 station-houses, 10 sub-stations, 3 police tug-boats, and 31 patrol stations.

Public Buildings and Places of Interest.—Among the buildings of historic importance Independence Hall stands first. The Old Swede's church, Christ Episcopal church, where Bishop White preached, Washington worshiped, and Franklin and Robert Morris are buried; Carpenters' Hall,

in which the first continental congress met; the old building on South Street which was the first American theater; William Penn's house, which stood in Letitia Street and has been removed to Fairmount Park; St. Joseph's, Willing's Alley below Fourth, the scene of the pathetic meeting of Evangeline and Gabriel; Mt. Pleasant, the home of Benedict Arnold, in East Fairmount Park; the modest house at No. 239 Arch Street, where Betsy Ross made the first American flag for Washington; and the site of the house at Seventh and Market, where Jefferson wrote the Declaration of Independence, are a few of the city's possessions rich in historical associations. The principal Government buildings are the U. S. mint, the post-office, and the custom-house, Naval Asylum and Hospital, and two arsenals. Among the parks are Stenton, once the property of James Logan, and Bartram's Garden, the first botanical garden in America. The Schuylkill and the romantic Wissahickon, along the latter of which dwelt Kelpius, the mystic, and Henry Bernhard Koster, the Chiliast of the seventeenth century, flow through Fairmount Park. Included in Fairmount Park are the residence of John Penn, the last colonial governor; the estate of the witty Judge Peters, the Revolutionary Secretary of War, and the country-seat of Robert Morris. The Zoölogical Garden, of 33 acres, is on the west bank. In the lower Schuylkill section of the park are 500,000 trees and shrubs, including 3,400 forest trees, some of them 27 feet in circumference. Of flowering shrubs and flowers there are 500 genera and 700 varieties. The park contains one-sixth of all the known minerals of the U. S. Fifteen species of fish inhabit its waters, and 77 species of birds its woods and valleys. There are 50 miles of carriage drives, and 100 miles of byways and bridle-paths. Steamboats ply for 6 miles through the park on the Schuylkill, and the course for row-boats on the Wissahickon is 2 miles in length.

Among the more notable works of art are the equestrian statue of Washington, made for the Pennsylvania Society of the Cincinnati by Rudolph Siemering, costing $225,000; the Reynolds and McClellan statues in front of the city-hall; the statues of Gen. Meade, Lincoln, Grant, Garfield, and Jeanne d'Arc in Fairmount Park; and that of Benjamin Franklin at the post-office building. The Smith Memorial entrance, in memory of officers of the civil war, is now being erected in Fairmount Park at a cost of $500,000. The city-hall, at Broad and Market Streets, has cost $24,000,000. The tower, completed in 1894, is surmounted with a bronze statue of William Penn, 37 feet in height and 547 feet above the pavement. The length of the north and south front of the city-hall is 470 feet, and of the east and west front 486½ feet. The Masonic Temple is on North Broad Street, opposite the city-hall.

There are some fifty prominent clubs, among them the Philadelphia, founded in 1834, the Manufacturers', the Rittenhouse, the Union League, the Penn, the Art, the Sketch, the University, the Pen and Pencil (of newspaper-workers), the New Century (for women, whose drawing-room seats 600), and the United Service. The State in Schuylkill, founded in 1732, is said to be the oldest club in the world. There are over 50 hotels, and 18 theaters.

At the State penitentiary, on Fairmount Avenue, opened in 1829, the separate system of confinement was first introduced. Each prisoner works in his own room. The system has been adopted in several European countries. The Philadelphia Bourse, erected in 1894, at a cost of $2,000,000, is primarily intended as a place for the display and sale of everything made in Philadelphia's widely scattered mills and factories. The great hall is 250 feet by 125 feet. There are 400 offices, and a room 130 feet square for the exhibition of machinery with or without power. It has also all the conveniences of a great club-house.

The site of the navy-yard at League island, including nearly 1,000 acres, was presented to the U. S. Government by the city in 1862. There are many cemeteries, of which the best known is Laurel Hill, where many famous men are buried, including Dr. Kane, the Arctic explorer, Gen. Meade, and Gen. John C. Pemberton.

Educational Institutions.—Penn's plan of government provided for the erection of public schools and the encouragement of useful sciences and laudable inventions. In 1689 the William Penn Charter School, still one of the most flourishing in the city, was formally opened. The Assembly charter, granted in 1711, provided for the instruction of poor children in "reading, work, languages, arts, and sciences." In 1740 subscriptions were raised for a charity school, and the site was purchased in that year. On Feb. 1, 1749, the lot and buildings were conveyed to James Logan and twenty-three other trustees, the plan having been enlarged to include a college. This movement of 1740 was the beginning of the University of Pennsylvania. See PENNSYLVANIA, UNIVERSITY OF.

The medical colleges comprise the University, Jefferson, the Woman's, the Hahnemann, the Medico-Chirurgical, and the Philadelphia Polyclinic and College for Graduates. There are 3 colleges of dentistry, 1 of pharmacy, and one of veterinary surgery.

Philadelphia has over $16,000,000 invested in public-school property, and in 1901 the 428 public schools, taught by 3,700 teachers and maintained at an expense of $3,426,416, exclusive of $593,912 for permanent improvement, were attended by 155,000 pupils. At the head of the public-school system are the Boys' High School, the School of Commerce for Boys, the Girls' High School, the Girls' Normal School, the Commercial High School for Girls, and a School of Pedagogy. There are 2 manual-training schools, 2 schools of practice, an industrial art school, 13 cooking-schools, 13 grammar schools, 64 combined grammar and primary schools, 32 consolidated, 142 kindergartens, 147 primary, 84 night schools, 2 special schools for truant children, 5 vacation schools, and 70 summer playgrounds. One hundred and seventy-five prize scholarships are open to public-school students in the University of Pennsylvania, Bryn Mawr College, and other higher institutions. The Pennsylvania Institution for the Deaf and Dumb at Mt. Airy, the Asylum for the Blind, and the Pennsylvania Working Home for Blind Men are prominent local charities. The Academy of the Fine Arts, founded in 1805, is the oldest art institution in the country. The School of Design for women was founded in 1853. The Drexel Institute, founded by A. J. Drexel, imparts industrial education to both men and women. It was opened in 1891. The Pennsylvania Museum and School of Industrial Art was incorporated in 1876. Its valuable collection of fabrics, metals, curios, etc., has been maintained in Memorial Hall, the permanent building erected by Pennsylvania at the Centennial Exhibition of 1876. The Spring Garden Institute aims to cultivate the industrial side of art education. The Williamson Free School of Mechanical Trades, founded by I. V. Williamson, is near Media. Girard College, to found which Stephen Girard left about $7,000,000, in 1900 contained 1,510 orphan pupils, 114 officers and pupils, and 268 employees. The Temple College, with a faculty of 40 members and 3,000 students, has an evening department for the instruction of working-people at a nominal charge, and a day and afternoon department for all grades of scholars. The Wagner Free Institute of Science, begun in 1847 by Prof. William Wagner, has a lecture-room seating 640 people, a library of 7,500 volumes, a natural history museum, and provides free lectures on scientific subjects. The Franklin Institute was founded in 1824 for the promotion of the mechanic arts and manufactures. Its library contains 40,000 volumes, 25,000 pamphlets, 20,000 maps and charts, and 1,000 classified and catalogued photographs. The library is strictly scientific and technical in character. The institute maintains a drawing-school, publishes a monthly journal, and awards each year medals for meritorious discoveries and inventions. The American Philosophical Society, which was made famous in the eighteenth century among scientists by the attainments of Rittenhouse, the great astronomer, and with the general public by the more popular experiments of Franklin, and which included among its members Godfrey, the inventor of the mariner's quadrant, Mason and Dixon, who ran the boundary-line between Pennsylvania and Maryland, and many other celebrated men, was founded in 1743. Its reference library contains 50,000 volumes. There are over 100 libraries open to the public, the oldest being the Philadelphia Library, founded in 1731; its Ridgway branch, under the will of Dr. James Rush, received a legacy of $1,000,000. With the Philadelphia Library is the Loganian Library, begun in 1699, founded by James Logan, the secretary of Pennsylvania, who provided that the librarian should always be one of his male descendants, thus creating what is said to be the only hereditary office in the U. S. The Mercantile Library was founded in 1821. The library of the Carpenters Company was established in 1736, the Friends' Library in 1742. The city is rich in special and reference libraries, among the most important being those of the Pennsylvania Historical Society (30,000 volumes), the College of Physicians, the Law Library, the Hurst Free Law

Library, and the library of the Academy of Natural Sciences. The Apprentices' Library and that of the City Institute, the latter being the first free library in the city, are free. The Free Library of Philadelphia, founded in 1891, consists of a main library, which includes a department for children and a department for the blind, and fifteen branches which have been established in different parts of the city. It contains over 230,000 volumes, and its circulation during the year 1900 reached a total of 1,826,637 volumes, the largest attained by any library in the U. S., if not in the world. The Academy of Natural Sciences, founded in 1812, has the largest collection of shells in existence. Its ornithological cabinet holds 27,000 mounted specimens and 5,000 unmounted skins. Here are the Gould collection of Australian birds, the Bonaparte collection of European birds, and the Verreaux collection of African and Asiatic birds. In fossils, especially in invertebrates, the collections are particularly rich. The academy gives a scientific education to a number of young persons without charge. At the Historical Society are the most complete collection of colonial laws in the U. S., the Dreer collection of autograph letters, and a wealth of historical material.

The churches number 773; the Sunday-schools 682, with 18,376 teachers and 204,046 scholars. The first Sunday-school in the world, of which there is now a record, was conducted at Germantown. There are 72 hospitals and dispensaries. The oldest hospital in America is the Pennsylvania, founded in 1751. The Philadelphia City Hospital is the largest in the U. S. in capacity. Each of the great medical schools maintains a hospital, and most of the hospitals have training-schools for nurses. The Nurses' School of the Lying-in Charity, founded in 1828, is the oldest in America and the second oldest in the world. The Wills Eye Hospital was founded in 1832 for the relief of the poor. The Young Men's Christian Association is the third in the world in size and equipment.

The Municipal Government.—The municipal life of Philadelphia begins with the charter to William Penn of Mar. 4, 1681, and the government of the provincial council, the county court, and the grand jury. Under the proprietary charter of 1691, Humfrey Morrey became the first mayor. Penn in 1701, before his departure to England, granted a second proprietary charter to Philadelphia, and this lasted until the Revolution. From 1776 to 1789 the government of the city rested in the justices of the peace and the legislative commissions. In 1789 an act of the Legislature incorporated the city, which remained under this charter until 1854. During the greater part of this period the government was administered practically by the different committees of the city council, although at first an effort was made to concentrate power and responsibility in the executive. In 1854 the many outlying districts which previously had their separate governments were consolidated with the city, which became coterminous with the county. The old city had extended from Vine to South Streets, and from the Delaware to the Schuylkill. The charter created by the Bullitt Act of 1885 concentrates executive power in the mayor, elected for four years. He appoints a director of public safety, whose department includes the police, fire, electrical, health, building inspection, city property, and boiler inspection bureaus; a director of public works, whose department includes the bureaus of gas, highways, street-cleaning, lighting, surveys, and water; and a president and four directors of the department of charities and correction. The receiver of taxes and city solicitor are city officers elected in the spring for terms of three years. The city treasurer and city comptroller are county officers elected for three years in November, the city and the county of Philadelphia being identical geographically, but having a separate political existence. There are a central board of education, consisting of a representative from each ward, and local boards in the different wards. The sinking fund commission is composed of the mayor, city comptroller, and one member elected by the city councils. The park commission is composed of the mayor, the presidents of select and common councils, chiefs of the bureaus of surveys, water, and city property, and ten citizens appointed for five years by the judges of the common pleas courts. The public buildings commission, created by the Legislature in 1870, had charge of the erection of the new city-hall until 1901, when it was abolished, and the building placed in charge of the bureau of city property. The park commissioners have charge of Fairmount Park and Hunting Park. The other forty small parks of the city, of which twenty-five, with a total area of 86 acres, are improved, while the rest are used as children's play-grounds, are under the control of the bureau of city property of the department of public safety. The legislative branch of the city government is composed of the select and common councils. Each of the forty-one wards is represented by one select councilman elected for three years, and by common councilmen, the number varying in the different wards, elected for two years. There is one common councilman for every 2,000 names on the completed canvassers' list of the year in which the election is held. The judiciary consists of fifteen judges af the court of common pleas, four judges of the orphans court, and, in 1901, twenty-eight magistrates. The Supreme Court of the State sits for a large part of the year in the city-hall. The U. S. circuit and district courts sit in the post-office building. The city is represented in the Legislature by eight members of the State Senate and thirty-nine members of the House of Representatives. Philadelphia had in 1901 five representatives in Congress.

The assessed value of real estate, about two-thirds of the actual value, is $880,935,265. The tax-rate is $1.85 on every $100 of assessed valuation. The total city debt on Jan. 1, 1901, was $56,503,333, an increase during the year of $3,024,253; amount in the sinking fund, $17,708,125; cash in the treasury, $11,389,783; and taxes due and collectable, $2,601,264. These assets amounted to $28,527,055, leaving the total debt above cash assets, $27,976,278. The real estate owned by the city is appraised by the board of revision of taxes at $58,413,394. The total receipts for the year ending Dec. 31, 1900, were $32,972,187.51; expenditures, $30,628,246.25—excess of receipts, $2,343,941.26.

Banking and Insurance.—In 1900 there were 40 trust companies with a combined capital of $28,600,000, and deposits of $135,500,000. These companies afford facilities that in most cities are furnished by banks, and, with a capital larger than that of the banks, control most of the market for collateral loans. There are 35 national and 3 State banks with an aggregate capital of $20,131,000 and deposits of $125,349,000. There are 8 savings-banks with deposits of $77,566,286. The field for these institutions is limited on account of the great number of building and loan associations, 600 of which have offices in this city, have investments of $50,000,000, and receive annually $10,000,000.

There are 20 joint-stock fire and marine insurance companies, with a capital of $8,652,875, a surplus of $9,133,007, and total assets of $35,902,673. There are 3 life-insurance companies of more than local standing.

Manufactures.—The census returns of 1890 showed that 18,166 manufacturing establishments (representing 330 industries) reported. These had a combined capital of $375,249,715, employed 260,264 persons, paid $135,917,021 for wages and $311,645,804 for materials, and had products valued at $577,234,446. The minimum yearly products of all Philadelphia's manufactures have been estimated at $763,820,400, the number of distinct establishments at 22,500, and the number of employees at 350,000.

Ship-building.—In ship-building from 1710 to 1894 Philadelphia led all American cities. From 1781 to 1790 162 vessels aggregating 18,000 tons register were constructed in Philadelphia. From 1790 to 1812 New Bedford and Nantucket whalemen frequently had their vessels built at the Philadelphia yards. In 1790 John Fitch made regular trips between Philadelphia and Trenton with the first American steamboat. In 1794 Joshua Humphreys, a Philadelphia ship-builder, designed the Constellation, President, Constitution, and the Congress, and himself superintended the building of the United States at Philadelphia. The purchase by the East India Company in 1830 of two Philadelphia ships built for the China trade resulted in the closing of the British market to American-built ships. Cramp's ship-yard was founded in 1830, and there were then fourteen ship-building firms along the Delaware front of the city. Two of these are still in existence. In seventy-one years the Cramps built 282 ships for the public service. The new Atlantic liners and the Newark, New York, Columbia, Indiana, and Philadelphia, among other vessels of the new navy, were built at this yard. The company recently completed a cruiser for the Japanese navy, another for the Russian navy, and has made a contract to build still another for Turkey. The Russian battleship Retvizan is now in course of construction, as is also the battleship Maine and the cruisers Pennsylvania and Colorado for the U. S. navy. The Neafie and Levy yard has three destroyers

and two cruisers under construction for the U. S. navy. The New York Ship-Building Company in 1900 completed a large, modern yard at Camden, N. J., opposite Philadelphia, and has a number of important contracts for merchant ships. The application of electrical labor-saving devices has in this yard reached its highest development.

Commerce.—There are 7 steamship lines from Philadelphia to European ports, 5 to Jamaica and the West Indies, and 6 coastwise. The International Navigation Company, owner of the New York, the Paris, the Berlin, the Chester, the St. Louis, and the St. Paul, is capitalized and controlled in Philadelphia.

In 1753 Philadelphia exported 125,000 barrels of flour and 175,000 bush. of wheat. In 1793 its domestic exports were $7,000,000; in 1796, $17,500,000; in 1806, $31,000,000. In 1843 the exports had fallen to $2,300,000; in 1880 they reached $56,500,000. In 1900 the imports were $49,186,877; exports, $81,145,966. The immigrants arriving at the port were in the same year 16,516.

Railways.—The railway systems entering the city are the Pennsylvania, controlling 13,136 miles of road, of which 2,279 is Baltimore and Ohio, and 921 B. and O. Southwestern; the Philadelphia and Reading, 2,302 miles; the Lehigh Valley, 1,398 miles. The terminals of the Pennsylvania and the Reading railways, in the heart of the city and reached by elevated viaducts of brick, stone, and iron extending to the outskirts, are among the finest in the world. At the Broad Street and Camden stations of the Pennsylvania line an average of 631 trains and 54,111 passengers arrive and depart daily, and 230,391 trains and 19,750,508 passengers yearly. The terminal of the Pennsylvania Railroad extends on Broad Street from Market 306 feet to Filbert Street, and with the train-shed along Market and Filbert Streets westwardly for 812 feet. The train-shed has an arch of iron and glass with a clear span of 304 feet. The Reading terminal, at Market and Twelfth Streets, is of pink granite to the second floor, with pink-tinted brick and white terra-cotta above. It cost $10,000,000. Here and at the other Reading stations in the city 433 trains and 38,000 passengers arrive and depart daily. The Pennsylvania Railroad has stations in Philadelphia at which freight is received and distributed. Two grain elevators at Girard Point have a total capacity of 1,900,000 bush. The Philadelphia and Reading Railroad has 53 freight-stations in the city. The Port Richmond grain-elevator has a capacity of 1,500,000 bush.; another elevator at Washington Avenue has a capacity of 400,000 bush. At Port Richmond are the great coal-wharves of the Reading Company, and the great modern freight terminus. The coal-wharves of the Pennsylvania Company are at Greenwich Point. A short distance above the mouth of the Schuylkill, at Point Breeze, is the terminus of the pipe-lines of the Standard Oil Company, where tank steamers receive about 35 per cent. of all the oil exported from the U. S. The Schuylkill Canal, 108 miles, is controlled by the Reading Railroad. In 1894 city councils appropriated $10,000 for a preliminary survey of a ship-canal across New Jersey to the ocean.

Delaware River Improvements.—From 1836 to 1900 inclusive the Government appropriated $3,542,500 for the improvement of the channel of the Delaware river, and $3,935,000 for the harbor between Fisher's Point and Kaighn's Point, a distance of 5 miles. In 1894 Smith and Windmill islands were removed, as part of a plan to contract the Delaware river immediately in front of the city from a width of 2,400 feet to one of 1,900 feet by an extension of the wharves on the Philadelphia side to a length of from 500 to 600 feet, which would permit the widening of Delaware Avenue from 50 to 150 feet. To obtain the desired depth of 26 feet at mean low water and 32 feet at high water for a width of 1,000 feet from the harbor line, the excavation of 25,000,000 cubic yards of material and the expenditure of $3,500,000 were required. Councils have appropriated $685,000 for improving the river-channel below the harbor, and $1,500,000 for the widening of Delaware Avenue. The Girard estate also has a fund of about $1,000,000 available for the latter purpose.

History.—Queen Christina of Sweden in 1636 sent a little band of Swedish colonists to the village of Wiccaco, now a part of the city. An Indian town previously stood within the present city limits. In 1677 the Swedes erected a log church, which also served as a fort. In 1700 this was torn down and a brick structure erected on the site, known as the Old Swedes' church, which still stands in the southern part of the city on the banks of the Delaware. Services in the Swedish language were continued until 1818. The Dutch vessel Onrust, Capt. Hendrickson, explored the Delaware in 1623, and near New Castle the Dutch in 1651 built Fort Casimir, which was captured by the Swedes in 1654, retaken by the Dutch the same year, captured by the English in 1664, surrendered to the Dutch in 1673, and given over to the English by the treaty of 1674. William Penn's deputy governor and cousin, Capt. William Markham, arrived at Philadelphia in Oct., 1681, and Penn's commissioners in the early summer of 1682. Penn himself, with a large company of Friends or Quakers, reached New Castle on the Delaware on Oct. 27, 1682. The city of Philadelphia had been named, surveyed, platted, and the lots occupied by some settlers in July, 1682. The Dutch and German pioneers, who had been invited by Penn to remove to Pennsylvania, arrived at Philadelphia Oct. 6, 1683, and settled Germantown, now a ward of the city. This immigration is notable because four of the immigrants, Gerhard Hendricks, Dirk Op den Graeff, Francis Daniel Pastorius, and Abraham Op den Graeff, on Apr. 18, 1688, sent to the Friends' meeting the first public protest ever made in America against the holding of slaves; because in 1690 the first paper-mill in America was erected by William Rittinghuysen, a Dutch immigrant, where was made the paper used by William Bradford, the earliest printer in the middle colonies; and because Sower, the German printer of Germantown, printed in German three quarto editions of the Bible before an edition in English had been printed in America.

The principal political events of the colonial period were the attempts, extending over many years, to wrest the political control of the colony from the Quakers and Germans, and the contests between the Assembly and the proprietary interests. Benjamin Franklin was active in the efforts to alienate the Germans from the Quakers, but was himself defeated when a candidate for the Assembly. These political struggles had an important influence upon the attitude of the colony in the contest with Great Britain. The religious and civil liberty encouraged by Penn's government caused the Quakers and the Germans to feel a strong attachment to the proprietors, whose rights they saw would be imperiled by revolution. The leaders of society in Philadelphia were not clergymen, as in Massachusetts, but lawyers, like John Dickinson, who had received a thorough legal training at the Inns of Court in London, who had great respect for law, and who thought that the legal methods for settling the difficulties should be exhausted before force was resorted to. Opposition to the Stamp Act took form in 1765. The act of Parliament imposing duties upon paper and tea was resisted in 1768, and when in 1773 the news reached Philadelphia that the tea-ships were on their way, the people met in the State-house on Oct. 17, and adopted resolutions which were unanimously readopted by the Boston meeting on Nov. 5. The tea-ship Polly, Capt. Ayres, from London, anchored near Philadelphia two days after Christmas, but was not allowed to discharge her cargo. Carpenters' Hall was the meeting-place of the first Continental Congress of 1774, and the State-house that of the second Congress, which met May 2, 1775, and which, on July 2, 1776, agreed to the resolution declaring that the united colonies "are, and of right ought to be, free and independent States." On July 8 the Declaration of Independence was first publicly read by John Nixon from the platform of the observatory, which then stood in the square back of the hall, and the bell, now called the Liberty bell, in the State-house steeple fulfilled the prophecy of its inscription—"Proclaim liberty throughout the land unto all the inhabitants thereof."

The city was soon to become the center of stirring events. The battle-fields of Trenton, Brandywine, where more troops were engaged than on any other battle-field of the war, the scene of the attack upon and escape of Wayne at Paoli, where he occupied a perilous position by Washington's orders, and Valley Forge, are only an hour's ride from the city; while Germantown, where the losses were heavier than in any other battle of the war, is now a ward of Philadelphia. Lord Howe entered the city Sept. 26. The Congress had fled to York. Count Donop, with 2,500 men, was defeated at Red Bank by Col. Christopher Greene with one-sixth of that force Oct. 22, 1777. The British naval attack on the same day also ended in disaster. Fort Mifflin, on Mud island, after a gallant defense of six days, was abandoned on Oct. 16, by which time the earthworks had been leveled by the British fire. On Dec. 8 Howe declined a battle with Washington at Whitemarsh. The British evacuated Phila-

delphia in June, 1778, and Congress returned. The convention which framed the Constitution of the U. S. met at the State-house in May, 1787, and adjourned Sept. 18. Under the Constitution Philadelphia was the capital of the U. S. from 1790 to 1800, and in the building, still standing, at the southeast corner of Sixth and Chestnut Streets George Washington was inaugurated as President for a second term and John Adams and Thomas Jefferson as President and Vice-president.

On the invitation of the Pennsylvania Abolition Society a convention was held in Philadelphia Jan. 1, 1794, of delegates from the different abolition societies of the country. The nineteenth century was marked locally by the opening of the water-works Jan. 1, 1801; the completion of the Schuylkill Canal in 1825; the opening of the Germantown Railway in 1832; the lighting of the streets with gas Feb. 18, 1836; the abolition riots of 1834, 1835, and 1838; the burning of Pennsylvania Hall by a mob on May 17, 1838; the anti-Catholic riots of May and July, 1844; the civil war period; and the Centennial Exhibition from May 10 to Nov. 10, 1876, which was carried through entirely by Philadelphia capital, with the exception of a Government loan that was repaid in full.

Philadelphia's services to the Union cause during the civil war (1861–65) were important. One of her sons, Gen. George B. McClellan, organized the Army of the Potomac, and, with a brief interruption, commanded it from June 22, 1861, until Nov. 7, 1862. Another Philadelphian, Gen. George Gordon Meade, commanded it from June 28, 1863, a few days afterward winning the battle of Gettysburg, until the army was disbanded in 1865. Gen. Andrew A. Humphreys, a descendant of the designer of the famous vessels which won the brilliant naval victories on the sea in the war of 1812, was famous as chief of staff of the same army and as commander of the Second Corps at the time of Lee's surrender. Gen. David Bell Birney, another corps commander, was also a Philadelphian, and Admiral Porter, who at Fort Fisher commanded the largest armada the world had ever seen, was a native of a Philadelphia suburb. The city sent eighty regiments to the field. The Union Volunteer and Cooper Shop refreshment-saloons fed all the Union soldiers from the North and East, passing to the front and returning home, until the end of the war, the total number thus cared for being over 1,000,000. Philadelphia was the headquarters of the U. S. Christian Commission, which expended $2,524,512 in caring for the soldiers, and distributed stores valued at $2,953,767, besides Bibles, hymn-books, etc. The Sanitary Fair held in Logan Square in 1864 netted $1,080,000 for the sick and wounded soldiers. During the war the house of Jay Cooke & Co. placed $3,000,000,000 worth of Government securities without direct profit to the firm. In the Mexican war E. W. Clarke & Co. placed one-third of the war loan, Stephen Girard furnished the funds for the war of 1812, and Robert Morris was the financier of the Revolution. For a number of years the Bank of the United States, of which Nicholas Biddle was the head, was the center of the financial currents of the country, its position being destroyed when President Andrew Jackson vetoed the bill to recharter it, and ordered the removal of the Government deposits.

There are 16 daily newspapers, 99 weekly publications, 114 monthly, 7 fortnightly, 15 quarterly, and 7 bi-monthly periodicals. In the last quarter of the eighteenth century Robert Bell, one of whose clerks was Thomas Paine, introduced English literature to the people of the U. S., publishing *Rasselas*, Goldsmith's *Traveller* (1768), Robertson's *Charles V.* (3 vols., 1771), Blackstone's *Commentaries*; the poems of Milton and Thomson, and other standard works. For sixty years of the nineteenth century the Philadelphia magazines, from *The Portfolio* to *Graham's Magazine*, were the best in the U. S.

Population.—(1800) 65,787; (1820) 114,445; (1850) 360,305; (1870) 674,022; (1880) 847,170; (1890) 1,046,964; (1900) 1,293,697.

Authorities.—Westcott, *History of Philadelphia*; Allison and Penrose, *Philadelphia 1681–1887, a History of Municipal Development.*

Phi'lae [= Lat. = Gr. *αἱ Φίλαι*; Egypt. *P-alek*, the island of the end; Copt. *Pilak*, or *Pelak*; mod. *Jeziret Anas-el-Wojond*]: a sacred island in the Nile, a little S. of the first cataract (about 24° N. lat.), devoted principally to Isis and Osiris, who were worshiped here for seventy years after the edict of Theodosius, in 381 A. D., prohibiting the native cult. It was regarded as one of the graves of Osiris (*q. v.*), and was hence a resort of pious pilgrims. On its west side is located a large and irregular temple of Isis, built by Nectanebo II. and extended by the Ptolemies and the Roman emperors down to Diocletian. A small but exceedingly beautiful temple to Isis is also located on the east of the island. It was built by Nerva Trajanus, and is usually known as Pharaoh's Bed. Charles R. Gillett.

Philaret, Basil Drosdoff (*Vasily Drozdov*): Metropolitan of Moscow; b. at Kolomna, 63 miles S. S. E. of Moscow, Jan. 6, 1783; was educated in the theological seminary in Moscow; became tutor of the Greek and Latin languages; preacher in the Sergian monastery of Troizka 1806; entered the monastic life, and became archimandrite (1811), and later rector (1812) of the St. Petersburg Theological Academy; Bishop of Reval (1817), Archbishop of Tver and Yaroslav (1891), Metropolitan of Moscow 1821. D. in Moscow, Dec. 1, 1867. He was renowned as an orator, a theologian, and a statesman. He was learned and remarkably broad-minded. To him is attributed the emancipation of the serfs. He was the constant adviser of his sovereign, and the most venerated and beloved man in the Russian empire. His writings enjoyed the highest reputation, and one of them, his *Longer Catechism of the Orthodox Catholic Eastern Church* (rep. by Schaff, *Creeds*, ii., 445–542, in Blackmore's translation), was sent to all the Eastern patriarchs and unanimously approved by them, and since 1839 has been generally used in the Russian schools and churches. A selection of his sermons in English translation, with a short biography, appeared in London 1873. His greatest work was his history of the Russian Church (Moscow, 1850–59; German trans., 2 vols., Frankfort, 1872).

Samuel Macauley Jackson.

Philbrick, John Dudley, LL. D., D. C. L.: educator; b. at Deerfield, N. H., May 27, 1818; graduated at Dartmouth 1842; taught the next ten years in Boston; was principal of the State Normal School, and State superintendent of schools in Connecticut four years; superintendent of public schools in Boston 1857–74 and 1876–78; for ten years member of Massachusetts board of education, and its agent in 1875; president of State educational associations of Connecticut and Massachusetts and American Institute of Instruction, and National Teachers' Association; was editor of Connecticut *Common-school Journal* and *Massachusetts Teacher*; educational commissioner of Massachusetts to Vienna Exposition 1873, serving as member of international jury; U. S. commissioner of education and member of international jury at Paris 1878, receiving the decorations of the cross of the Legion of Honor and the gold palm of the University of France. He was the author of nearly fifty public-school reports of great value, and of *City School Systems in the United States* (U. S. Bureau of Education 1885), a comprehensive and valuable study. D. at Danvers, Mass., Feb. 2, 1886. Revised by C. H. Thurber.

Philel'pho, or **Filelfo**, Francesco: humanist; b. at Tolentino, Italy, July 25, 1398. Having studied at Padua, he was appointed professor at the age of eighteen. The next year (1417) he was invited to Venice to teach eloquence and moral philosophy. Here he remained two years, becoming a citizen of Venice and being treated with great respect. In 1419 he was appointed secretary to the Venetian consul-general (bailo) at Constantinople, and in 1420 he arrived there. He at once took up the study of Greek under John Chrysoloras, brother of the more famous Manuel (*q. v.*), and became a favorite at the imperial court. In 1427 he returned to accept the chair of Eloquence at Venice; but in 1428 we find him in Bologna, and in 1429 in Florence. In 1434, however, as a result of a bitter quarrel with the scholars of Florence and of rash participation in the intrigues against Cosimo de' Medici, he had to remove to Siena. After four years' residence here he was invited by Filippo Maria Visconti to Milan, where he was treated with great respect, and enabled to live in the luxurious and vainglorious fashion he loved. After the death of Filippo Maria (1447), however, and the seizure of Milan by Francesco Sforza, he found his position an uneasy one. At last, in 1474, he was tempted to accept a professorial chair at Rome. Things went badly here, and in 1476 he posted back to Milan. In 1481 he was called to the chair of Greek Literature in Florence, and died two weeks after his arrival there, July 31, 1481. He was conceited, jealous, passionate, and absolutely without principle. Yet he extorted from his contemporaries almost unbounded respect and admiration. He was perhaps the first modern to know Greek and Latin

equally well, and this knowledge seemed at the time almost a miracle. The works he has left, apart from his translations, have almost no interest beyond that attaching to the ingenuity of their scurrility. See *Francesci Philelfi Epistolarum Familiarum libri xxxvi.* (Venice, 1502); *Satyrarum Hecatosticha* (Venice, 1502); *Orationes Franc. Phil. cum quibusdam aliis eiusdem operibus* (Paris, 1515); É. Legrand, *Cent-dix lettres grecques de François Filelfe . . . d'après le Cod. Trivul. 873* (Paris, 1892); *Convivia Mediolanensia* (Spires, 1508); C. de Rosmini, *Vita di Franc. Filelfo* (3 vols., Milan, 1808); G. Voigt, *Die Wiederbelebung des klassischen Alterthums* (2d ed. 2 vols., Berlin, 1881).

A. R. Marsh.

Phile'mon (in Gr. Φιλήμων): Greek comic poet; b. at Syracuse, or at Soli, in Cilicia, about 361 B. C.; lived mostly in Athens, where he was a successful rival of Menander, but spent some time in Alexandria. D. at Athens in 262 B. C. The *Mercator* and *Trinummus* of Plautus are adapted from Philemon, and fragments of his plays are to be found in Meineke's and Kock's collections. B. L. G.

Philemon, Epistle of St. Paul to: a letter written at the same time as the Epistles to the Ephesians and Colossians. It is a private letter, begging forgiveness and acceptance as a brother beloved for a runaway servant, Onesimus, who had been converted through the apostle's teachings. It is stated by tradition that the letter was written from Rome. Others suppose Cæsarea was the place. One tradition makes St. Philemon a Bishop of Colossæ, and in the Roman missal he is commemorated on Nov. 22. See Pauline Epistles.

Phile'tas (in Gr. Φιλήτας): Greek grammarian and poet of the island of Cos; tutor of Ptolemy Philadelphus; master of Theocritus, teacher of Zenodotus. A great light in his day, and much admired by his imitator, Propertius. Scant fragments are given in Schneidewin's *Delectus* and Bergk's *Anthologia Lyrica*. See Couat, *La Poésie Alexandrine*, pp. 68–80. B. L. G.

Phil'idor, François André Danigan: composer and chess-player; b. at Dreux, Eure-et-Loire, France, Sept. 7, 1726; received his musical education in the royal chapel, afterward in Holland and Germany, where he resided from 1745 to 1754; composed between 1754 and 1774 a number of operas, comic and serious, which were well received; but became most famous as an unrivaled master of chess-playing. His book, *L'Analyse du Jeu des Échecs* (London, 1777), was for many years considered the code of the game. D. in London, Aug. 24, 1795. See Allen's *Life of Philidor* (Philadelphia, 1864).

Philip: the fourth called to the apostleship by Christ; b. at Bethsaida. He is often mentioned in the Gospels, especially by John (vi.; xii. 20–22; xiv. 8), but must not be confounded with Philip the Evangelist, mentioned in Acts vi., who had four virgin daughters who prophesied (Acts xxi. 8, 9). By the Fathers they are so confounded that it is impossible to separate them. Thus Theodoret reports (*Com. on Ps.* cxvi.) that he preached in Phrygia, which is likely; Clement of Alexandria (*Stromata*, iii., 6 [*Ante-Nicene Fathers*, ii., 390]) that he was married and had married daughters, which again is likely, but the statement may come from the confusion noted above; Eusebius (*Ch. His.*, iii., 31; Eng. trans., pp. 162–163) states that he died at Hierapolis, in Syria, but, as the context shows, he confounds him with the evangelist. His festival is celebrated by the Latin Church on May 1, by the Greek on Nov. 14. The *Acta Philippi* are apocryphal.—Philip the Evangelist was one of the seven deacons (Acts vi. 5); persecution drove him to Samaria, where he confounded Simon Magus (Acts viii. 5). He was instrumental in the conversion of the Ethiopian eunuch (viii. 2 *seq.*); afterward preached in Cæsarea (viii. 40), where Paul met him (Acts xxi. 8), and Greek Church legends make him Bishop of Tralles, in Lydia. Revised by S. M. Jackson.

Philip (in Gr. Φίλιππος): the name of five Macedonian kings, of whom two became very celebrated. Philip II. (359–336), b. at Pella in 382, a son of Amyntas II.; spent while a youth three years as a hostage at Thebes, in the house of Epaminondas, where he became familiar with Greek tactics and politics. When he ascended the throne Macedonia was attacked from two sides by external enemies, the Illyrians and the Athenians, and in the interior it was torn by four pretenders and their factions; but in less than two years the young king repelled the Illyrians, bought off the Athenians, defeated and killed the pretenders, and established himself firmly in the kingdom. He immediately began to work at the realization of his much-cherished plan, the acquisition of the supremacy over all Greece, and by his energy and shrewdness, his talents and unscrupulousness, he succeeded at last. He conquered Pydna and Methone, two Athenian possessions on the coast of Macedonia, the peninsula of Chalcidice, with the prosperous cities of Olynthus, Potidæa, Amphipolis, etc., all Athenian colonies or allies; and a part of Thrace, with the rich gold mines, and the town of Crenides, which soon became a flourishing city under the name of Philippi. In spite of Demosthenes's thundering against him, he achieved these conquests without occasioning any serious breach with Athens, for he understood how to bribe and how to deceive. Meanwhile he had also defeated the tyrant of Pheræ and reduced the whole of Thessaly, and during the two sacred wars in 346 and 339 he acquired a foothold in Greece proper, called in by the Greeks themselves—in the first case, by the Thebans against the Phocians; in the second, by the Amphictyonic Council against the Locrians. Alarmed at his successes, Athens made a coalition with Thebes and other Greek states against him, but he routed the allied army at Chæronea in 338, and after this victory became the master of Greece. By his admission as a member of the Amphictyonic Council shortly after the First Sacred war he and the Macedonians were recognized as belonging to the Greek nation, and by the congress at Corinth (in 337) he was chosen commander-in-chief of all the Greeks under a projected invasion of Persia; but the realization of this vast plan he had to leave to his son Alexander; during his preparations he was assassinated at Ægæ by Pausanias.—Under Philip V. (220–179), b. in 237, Macedonia relapsed into insignificance. He dreamt, like his subjects, only of the re-establishment of the empire of Alexander. His whole attention was taken up by the East, by Pergamus, Bithynia, Syria, etc., and meanwhile the danger arose from the West, from Rome, which already held possessions in Illyria. The offers of alliance which Hannibal made he treated slightingly, and the war with Rome, which began incidentally, the first Macedonian war (210–205), he carried on without energy, though generally successfully. In 200 the war began again, the second Macedonian war, in consequence of Philip's aggressive policy toward Pergamus and the Achæan association, now allies of Rome. The Macedonian army was completely routed by Titus Quintius Flamininus at Cynoscephalæ in 197, and the country reduced to a submissive ally of Rome, relinquishing all its conquests in Europe and Asia, surrendering its fleet, and paying a tribute. Revised by J. R. S. Sterrett.

Philip: the name of six kings of France. Philip I., b. 1052, son of Henry I. and a Russian princess, Anna, came to the throne in 1059, ruling at first jointly with his father, after whose death in 1060 Philip possessed the undivided sovereignty. In 1071 he married Bertha of Holland, by whom he had three children; but in 1091, having fallen in love with Bertrade of Montfort, the wife of the Count of Anjou, he repudiated the queen and married Bertrade, in spite of the vehement opposition of the Church. The Archbishop of Lyons, who was papal legate for France, excommunicated Philip and Bertrade at the Council of Autun, 1094, and in the following year, 1095, at the Council of Clermont, Pope Urban II. in person renewed the excommunication. Philip, however, continued to live with Bertrade, and after the death of Bertha the Church lost its principal argument against him. Nevertheless in 1100 the legates of Paschal II. compelled him to acknowledge his eldest son, Louis, as coregent, and from that time begins really the reign of Louis VI. D. July 29, 1108.—Philip II., Augustus, b. in Aug., 1165, son of Louis VII. and Alice of Champagne, ascended the throne Sept. 18, 1180, after the death of his father. His reign was eminently successful. In the controversies which took place between Henry II. of England and his sons Philip invariably took the part of the latter, and not without profit, though he afterward found among them his bitterest and most formidable enemy, Richard Cœur de Lion. Richard ascended the throne of England in 1189, and in the following year he and Philip joined in their famous crusade. They quarreled in the Holy Land, and Philip returned to France, stopping at Rome on his way to ask the pope to release him from the oath that he had taken not to attack Richard's possessions in his absence. The pope denied his request. Nevertheless, as soon as he heard of the imprisonment of Richard by the Emperor Henry VI., Philip made an alliance with John,

began the attack, and seized a portion of the English king's territories in France. After the liberation of Richard and his reconciliation with John, war broke out in which fortune decided now on this side and now on that; but at the death of Richard in 1199, Philip was the gainer, and, under John, England lost most of its remaining possessions in France. He was equally successful in his many controversies with Flanders, Brittany, etc., with the feudal lords of the realm, and with the clergy. He sent his ambassadors to the great Council of the Lateran in 1215, and he promised to give one-fourth of his revenues to a new crusade, but he absolutely refused to take any part in the war against the Albigenses. When Amaury of Montfort proposed to cede to him those domains in Languedoc which the Council of the Lateran had given to his father, he declined the offer, well knowing that by keeping aloof from this whole business, with its horrible crimes, the French crown could not fail finally to harvest the fruits. The general character of his government was decidedly aristocratic. The tribunal of the barons, which afterward played a conspicuous part in the history of France, was his creation, and, though he was very careful to make conspicuous distinctions between the king and the feudal lords, he sought and found his principal support among the latter. Nevertheless, few kings have done so much for the security and prosperity of the cities as he. A great number of places in France were provided with walls and other kinds of fortifications during his reign, and those works were generally executed at his expense. Paris especially owes much to his munificence. He gave its university—which already attracted not only the nobility of France, but also that of England and Germany—many privileges and a more independent position beside the Church. He continued the Cathedral of Notre Dame, which had been begun under Louis VII., and he built the churches of St. Sulpice, Ste. Geneviève, etc. He also laid the first foundation for the palace of the Louvre. D. July 14, 1223.—Philip III., b. Apr. 3, 1245, was second son of Louis IX. and Margaret of Provence, and became heir-apparent to the crown after the death of his older brother, Louis. He embarked on a crusade with his father, and followed him to Tunis, but he was stricken by the plague. Upon the death of his father he was immediately recognized as king, and after some minor battles he made peace with Tunis and returned to France. An armistice of ten years was established, all Christian slaves were liberated without ransom, freedom of worship was granted to the Christians, and 210,000 gold pieces were paid to France. The rest of his reign was quiet and peaceful. D. Oct. 5, 1285.—Philip IV., The Fair (1285–1314), b. in 1268, a son of Philip III., was an avaricious, haughty, and even cruel man, but courageous and eminently successful in extending the boundaries of France and consolidating the power of the crown. In order to procure money the king taxed the clergy. The pope, Boniface VIII., forbade the clergy to pay the tax, and the king answered by forbidding the exportation from France of money or other valuables, thereby cutting off one of the richest sources of the papal revenue. The pope sent a legate, who remonstrated in an insolent manner with the king, and the king threw the legate into prison. Philip now convoked the States-General, and having ascertained that the French people would stand by him even if he were excommunicated, he pursued his own course and confiscated the property of those prelates who sided with the pope. Meanwhile Boniface assembled a council at Rome and excommunicated the king, but a French army under William de Nogaret captured Rome and imprisoned the pope. In 1304, at the election of Clement V., the papal residence was transferred to Avignon, and for a long time the papal authority was merely a weapon in the hands of the French king. Clement V. also sold the Knights Templar to Philip IV., who treated them in a cruel and unjust manner, in order to get possession of their wealth. (See Templars.)—Philip V. (1316–22), the second son of Philip IV., based his claims to the throne on the Salic law. His brief reign was uneventful.—Philip VI. (1328–50), the founder of the house of Valois, b. in 1293, a son of Charles of Valois, brother to Philip the Fair; was first proclaimed regent of France on the death of Charles IV. in 1328, but when the queen-dowager, who was pregnant at the death of her husband, shortly after gave birth to a daughter, who, according to the Salic law, was excluded from the French throne, Philip assumed the royal dignity and was crowned at Rheims. Edward III. of England, a grandson of Philip the Fair, laid claim to the French throne, and when Philip undertook to support David Bruce of Scotland, the English king made an alliance with Flanders and declared war in 1337, thus opening that terrible contest between the French and English dynasties which lasted for 100 years, exhausted England, and devastated France. The two prominent events of the war during the reign of Philip VI. were the battle of Cressy (1346), in which the French army was totally routed, and the capture of Calais by the English (1347). In the following year the plague, the so-called Black Death, entered France and made fearful ravages: but in spite of all these calamities the king, who was bigoted and debauched, went on with his carousals, squandering the money which was extorted from the people by heavy taxes and ruinous government monopolies.

Revised by F. M. Colby.

Philip: the name of five kings of Spain, of whom two deserve a special notice.—Philip II., b. at Valladolid, May 21, 1527; succeeded his father, Charles V., in the Netherlands in 1555, and in the other possessions of the Spanish crown Jan. 16, 1556. Charles's attempts to procure for his son the imperial crown of Germany and the Austrian possessions had failed, and Philip's marriage with Queen Mary did not have the anticipated effect of making England the ally of Spain, but Philip II. was nevertheless, on his accession to the throne, the most powerful monarch of Europe. He ruled over Spain, its vast dominions in America, the East Indies and Africa, the two Sicilies, and Milan, Burgundy, and the Netherlands, to which in 1581 he added Portugal; and these countries were at that time the principal centers of European civilization and wealth. From his father's reign he inherited a war with France, the pope, and the Turkish sultan, who had made an alliance for the purpose of depriving the Spanish crown of its Italian possessions; but the Duke of Alva, Viceroy of Naples, drove the French out of Italy and compelled the pope to sue for peace under the walls of Rome, while the brilliant victories of St. Quentin and Gravelines, won by Egmont, enabled Philip to conclude an advantageous peace with France at Câteau-Cambrésis, Apr. 2, 1559. Nevertheless the forty years' reign which now followed was a period of decline. The countries under his scepter sank into degradation or rose in rebellion. On leaving the Netherlands he confirmed the political privileges of the provinces, but he refused to repeal his father's ordinances against heresies. On the contrary, he would enforce them, and immediately set to work to extirpate heresy in the Netherlands by means of the Inquisition. He met with energetic resistance, and the Duke of Alva was sent as governor to the country, with an army of Spanish veterans. Egmont, Horn, and other prominent men were executed and horrible cruelties perpetrated; but the result was just the opposite of that which had been expected. The resistance, instead of dying out, grew into a revolution, and under the organization and leadership of William of Orange the union of the seven provinces was formed at Utrecht in 1579, and a protracted war was carried on against Spain by land and sea. When Philip died Spain was exhausted, but the provinces were not reduced to obedience. In his wars against the Turks or the Mohammedans in general he gained a brilliant success by the battle of Lepanto, Oct. 7, 1571. After this victory it would have been possible to incorporate the northern coast of Africa into the political systems of the civilized world, and Don John of Austria entertained some such idea; but Philip felt a jealous distrust of his illustrious half-brother, and the situation of the Mediterranean pirates remained the same after the battle as it had been before. The destruction of the Invincible Armada was a mortification which he bore with dignity, but the unfortunate war against Henry IV. of France and the disadvantageous Peace of Vervins (May 2, 1598) he felt as a deep humiliation. After a lingering and painful disease he died in his palace of the Escorial in Sept., 1598, leaving Spain exhausted almost to prostration, with its industry, commerce, and other material resources greatly impaired and disturbed, and the proud, adventurous spirit of its people curbed by despotism and influenced by fanaticism. He was four times married—with Maria of Portugal, Mary of England, Elizabeth of France, and Anne of Austria. By his first wife he had a son, the unfortunate Don Carlos; by his fourth wife he had another, Philip, who succeeded him. (See Prescott, *History of Philip II.* (3 vols., 1856–59), and Motley, *Rise of the Dutch Republic* (3 vols., 1856).)—Philip V. (1701–46), the founder of the house of Bourbon in Spain, b. at Versailles, Dec. 19, 1683, the second son of the dauphin Louis, son of Louis XIV. by the Spanish princess

Maria Theresa; was declared heir to the Spanish throne by the will of Charles II., who died childless Nov. 1, 1700. There was, however, another claimant to the throne—Archduke Charles of Austria—and war began almost immediately. (See Succession Wars, Spanish.) By the Peace of Utrecht (1713) Philip retained the Spanish crown, but he was compelled to surrender his possessions in Italy and the Netherlands to Austria, and Gibraltar to England. He was indolent, weak-minded, and always controlled by his advisers. Under his first marriage, with Louisa Maria of Savoy, the Princess Orsini had the predominant influence; after his second marriage, in 1714, with Elizabeth Farnes of Parma, the queen, Cardinal Alberoni, the adventurer Ripperda, and others held the reins. The policy of the queen was concentrated on the acquisition of the former possessions of Spain in Italy for her sons, for which purpose Spain waged several wars. (See Succession Wars, Austrian.) Meanwhile the king became weaker and weaker. Jan. 10, 1724, he abdicated in favor of his eldest son, but as the young king died Sept. 6, 1724, Philip was persuaded to assume the government once more, though he had become almost idiotic. At last he would not leave his bed, and nothing would arouse him from his mental stupor but the songs of Farinelli. D. in Madrid, July 9, 1746.

Revised by F. M. Colby.

Philip, or **Metacom**, usually called **King Philip**: youngest son of Massasoit, sachem of the Pokanoket Indians of Massachusetts. Philip succeeded to the chieftainship on the death of his brother Alexander 1662, when he visited Plymouth and promised friendship to the colonists; but in 1675 he headed the war that is known by his name, and in which thirteen towns were destroyed and 600 colonists killed. Philip was killed at Mt. Hope Aug. 12, 1676, by a party under Capt. Benjamin Church, after his tribe had been nearly annihilated.

Philip, John W.: See the Appendix.

Philippeville: town (founded in 1838); in the province of Constantine, Algeria, on the Gulf of Stora (see map of Africa, ref. 1–D). It forms the port of Constantine, is well built, and has a fine harbor and large fishing, manufacturing, and trading interests. It is the seat of a bishopric. Pop. (1891) 21,962.

Philip'pi [Lat.; in Gr. *οἱ Φίλιπποι*; mod. *Filibi*]: an ancient town of Macedonia; built, or at least enlarged, by Philip, from whom it received its name. It became very famous as the place where the battle was fought in 42 B. C. between Brutus and Cassius on the one side, and Antony and Octavius on the other. Brutus and Cassius were totally routed. The apostle Paul founded a Christian church here (Epistle to the Philippians). J. R. S. Sterrett.

Philippians: See Pauline Epistles.

Philip'pics [from Gr. *Φιλιππικός*, pertaining to Philip, deriv. of *Φίλιππος*, Philip]: a name properly belonging to three splendid and spirited orations of Demosthenes against King Philip of Macedon. The first was delivered in 351 B. C., the second in 344, the third in 341. There is a fourth philippic, which is assigned by some to the year 340, and which is generally pronounced either a forgery or a patchwork. The fourteen orations of Cicero against Mark Antony are also called philippics. They were delivered in 44 and 43 B. C., mostly in the senate, but the second and severest and most famous was written and not delivered. The name is applied to any severe personal attack in speech or print.

Revised by B. L. Gildersleeve.

Phil'ippine Islands: See the Appendix.

Phil'ippins [from Philip Pustoswiät, one of their former leaders], or **Staroverski** (old-faith men): name of a sect of Russian origin settled since 1700 in East Prussia and Lithuania. They reject oaths and the priesthood, refuse to do military service, rebaptize all converts from other sects, and have a celibate eldership. They are peaceable and industrious citizens, but have at times fallen into wild, fanatical excesses. They cling persistently to the ancient liturgy of the Russian Church, which has been officially discountenanced for more than 200 years. The Philippins are a branch of the Raskolniks (*q. v.*).

Philippop'olis (Bulg. *Plovdiv*): chief city of Eastern Roumelia (South Bulgaria); picturesquely situated on five granite hills close to the Maritza in the middle of the great Roumelian plain (see map of Turkey, ref. 3–C). It is a center of trade in attar of roses, grain, tobacco, wool, and wine, and does an extensive banking business. The inhabitants are enterprising. Pop. (1890) 33,442. E. A. G.

Philippoteaux, fĕĕ'lĕĕ'pō'tō', Henri Emmanuel Félix: painter; b. in Paris, France, in 1815. He was a pupil of Léon Cogniet, and worked with him on the painting of the *Battle of Mount Tabor* for the Museum of Versailles. He adopted the historical and descriptive manner of painting, and his work, though not of very high rank as fine art, is of great interest as illustration. Late in life he painted several remarkable panoramas. D. Nov. 9, 1884. Of his important pictures there are in the South Kensington Museum *Before the Battle of Fontenoy* and the *English Squares at Waterloo*; at Versailles, *The Chevalier Bayard defending the Bridge at Garigliano. The Siege of Antwerp in 1832*, and the *Battle of Montebello, 1859*; at the Luxembourg, *Louis XV. on the Field of Fontenoy*; and in the Gallery of Marseilles, *The Last Banquet of the Girondins.* R. S.

Philips, Ambrose: poet; b. in Leicestershire, England, about 1671; educated at St. John's College, Cambridge, and graduated 1696; settled in London as a writer; was an associate of Steele, Addison, and their circle; wrote six *Pastorals*, which appeared in Tonson's *Poetical Miscellany* (1709) along with others by Pope—a circumstance which led to a bitter rivalry between the two poets; produced on the stage three tragedies, *The Distressed Mother* (1712), *The Briton*, and *Humphrey, Duke of Gloucester* (1721); began in 1718 the publication of a serial paper, *The Free-thinker*, which attained great popularity; became secretary to the primate and to the chancellor of Ireland 1726; was chosen a member of the Irish Parliament; became registrar to the prerogative court 1734; returned to London, where he published a collection of his poems, 1748. D. there June 8, 1749. Revised by H. A. Beers.

Philipsburg: borough; Centre co., Pa.; on the Moshannon river, and the Penn., the Beech Creek, and the Altoona and Philipsb. Connecting railways; 20 miles N. of Tyrone, 38 miles N. by E. of Altoona (for location, see map of Pennsylvania, ref. 4–E). It is the center of the bituminous coal region, has a large lumber trade, and contains a national bank with a capital of $50,000, a private bank, and a daily, a semi-weekly, and two weekly newspapers. Pop. (1880) 1,779; (1890) 3,245; (1900) 3,266.

Philip the Bold: Duke of Burgundy; b. Jan. 15, 1342, a son of John, King of France. He distinguished himself in the battle of Poitiers (1356), where he saved his father's life and received the surname of *Le Hardi*. Sept. 6, 1363, King John gave him, as a fief of the French crown, the duchy of Burgundy, which had become vacant by the extinction of the elder ducal line in 1361. Philip married Margaret of Flanders, heiress of Flanders, Artois, Rethel, and Nevers, and founded the younger ducal line, under which Burgundy became one of the most prominent powers of Western Europe. During the minority and subsequent insanity of Charles VI., Philip the Bold assumed the regency of France, which involved him in many feuds with his brother, the Duke of Anjou, and his nephew, the Duke of Orleans, but which he held to his death, Apr. 27, 1404.

Philip the Good: Duke of Burgundy; b. at Dijon, June 13, 1396, a grandson of Philip the Bold. He succeeded his father, John the Fearless, after his assassination on the bridge of Montereau in 1419, and married in 1424 Jacobæa of Holland, heiress of Holland, Brabant, Zealand, and the rest of the Low Countries. In order to avenge the murder of his father, which had been perpetrated at the instigation of the dauphin, afterward Charles VII., Philip allied himself closely with England, and acknowledged by the Treaty of Troyes (1420) the English king as the legitimate heir of the French crown after the death of Charles VI. The arrogance of the English, however, provoked him afterward to break the alliance, and in 1435 he concluded a separate peace with Charles VII. and aided him in expelling the English from France. He governed his extensive possessions with great wisdom, and, in spite of several risings in Ghent and Bruges, occasioned by heavy taxation, he was much loved by his subjects. D. at Bruges, June 15, 1467.

Philip the Magnanimous: landgrave of Hesse; b. in Marburg, Nov. 13, 1504; succeeded his father, William II., with his mother as regent, in 1509; married in 1523 a daughter of George the Bearded, Duke of Saxony. In 1531 he participated in the formation of the Smalcald League, and was subsequently one of its two leaders, the other being the elector John Frederick. In the battle of Mühlberg,

Apr. 24, 1547, the league was defeated by the Emperor Charles V., and Philip was retained as a captive until the treaty of peace was signed at Passau, Aug. 2, 1552, when he was released on payment of a large indemnity. He was secretly married in 1540 to Margaret von der Saale, his wife being alive at the time, and the assent of Luther and Melanchthon to the act caused great scandal. D. in Cassel, Mar. 31, 1567.

Philis'tines [from Lat. *Philisti'ni*, from Heb. *Pᵉlishthīm*, Philistines. See PALESTINE]: a people who occupied the southern seacoast of Palestine during most of the period of biblical history, and were almost constantly at war with the Israelites. The Old Testament speaks of them as immigrants into Palestine from the Egyptian region known later as Caphtor (Gen. x. 14; 1 Chron. i. 12; Amos ix. 7; Jer. xlvii. 4). Once, apparently, they are called Caphtorim (Deut. ii. 23). The immigration occurred early, as they were in or near the region in the time of Isaac (Gen. xxvi. 1, 8, 14, 15, 18), and probably earlier, in the time of Abraham (xxi. 32, 34). The accounts of the conquest under Joshua seem to imply that the region was then occupied partly by Philistine and partly by Canaanite communities (Josh. x. 29–34, 40, 41; xi. 16; xii. 11–15; xv. 11, 38–47, etc., compared with xi. 22; xiii. 2, 3).

In the phrase "whence the Philistines came out" (Gen. x. 14), the adverb denotes the region whence they came, not the race. The passage gives no indication as to whether the Philistines were Hamitic by race. Perhaps the evidence indicates that they were either Semites or Aryans who became thoroughly Semiticized in language. Some have tried to connect the twelve to fifteen names and titles we know as Philistine with Sanskrit and Greek, but a Semitic derivation fits better in every case. The ending *ath*, which is found in many names (Goliath, Achusath), is Egyptian, and indicates an emigration from Egypt. The land of the Philistines was the low plain called the *Shefelah*, and their superiority in the arts of war and in the possession of weapons several times enabled them to conquer the Israelites. The five chief cities of the Philistines, Gaza, Ashdod, Ashkelon, Gath, and Ekron, had their several princes, who were united in a confederacy. The chief divinities of the Philistines noticed in the Bible are Dagon, Ashtaroth, and Baal-Zebub. The Philistines shared the fate of the Israelites in successive subjection to Assyria, Babylon, and Egypt, and disappeared altogether from history previous to the Christian era. Revised by WILLIS J. BEECHER.

Phili'stus (in Gr. Φίλιστος): Greek historian; b. about 435 B. C.; was a general in the service of Dionysius the Elder and Dionysius the Younger, and wrote a history of Sicily from the beginning to 362 B. C., in which he showed practical sense and insight as well as groveling servility toward his masters. Thucydides was his model, and he imitated him in condensation of style, in the strictly chronological order of his narrative, and in the use of speeches; hence he was called by Cicero *pusillus Thucydides*. The fragments are to be found in Müller's *Fragmenta Historicorum Græcorum*, vol. i., pp. 185–192; iv., p. 639 foll.
B. L. GILDERSLEEVE.

Phillimore, JOHN GEORGE, LL. D.: b. in Oxfordshire, England, in 1809; educated at Westminster School and at Christ Church College, Oxford; called to the bar at Lincoln's Inn 1832; became an eminent jurist and (1851) queen's counsel and professor at the Middle Temple; M. P. 1852. Besides a number of pamphlets on legal topics, he wrote an *Introduction to the Study and History of the Roman Law* (London, 1848); *Private Law among the Romans*; *Principles and Maxims of Jurisprudence*; and began the publication of a history of England during the reign of George III. (vol. i., 1863). D. at Shiplake House, Oxfordshire, Apr. 27, 1865.—His brother, Sir ROBERT JOSEPH PHILLIMORE, D. C. L., b. in London, Nov. 5, 1810, graduated at Oxford in 1831. He also was a distinguished lawyer and writer; sat in Parliament 1853–57; and held the offices of judge-advocate-general (1871), judge of the arches court 1867–75, judge of the high court of admiralty 1867–83. He was made a baron in 1881. D. Feb. 4, 1885. His most important works are *Commentaries on International Law* (3d ed. 1879–89); *The Ecclesiastical Law of the Church of England* (1873; largely taken from Burn's *Ecclesiastical Law*); also, besides other works, the *Memoirs and Correspondence of George Lord Lyttelton from 1734–73* (1845). Most of his works were published under the name of Robert, or Sir Robert, Phillimore. Revised by F. STURGES ALLEN.

Phillips, ADELAIDE: singer; b. in Stratford-on-Avon, England, Oct. 26, 1833, and went with her parents to the U. S. in 1840. On Sept. 25, 1843, she made her first appearance in public in the Boston Museum in a part in *The Spoiled Child*, in which she sang and danced. In 1850 she was advised by Jenny Lind to cultivate her voice under Manuel Garcia, and the great singer herself headed the subscription list with her check for $1,000. On Dec. 17, 1854, Miss Phillips made her first appearance in opera in Milan as Rosina in *The Barber of Seville*. She returned to Boston in Aug., 1855, and sang in several English ballad-operas in that city. She made her *début* in Italian opera in New York, Mar. 17, 1856, as Azucena in *Il Trovatore*, and was successively re-engaged for five seasons in the Academy of Music. Then she went to Havana, Paris, Madrid, Barcelona, Hungary, and Holland, with success everywhere. From 1865 to 1868 she sang in California, New York, and Philadelphia. She was also a very much admired oratorio singer. She sang many times with the Boston Handel and Haydn Society, and also with other choral societies. Her last public appearance was in Cincinnati in Dec., 1881. Her health began to fail, and the next summer she went to Carlsbad, where she died, Oct. 3, 1882. Her remains were sent to Boston and interred at Marshfield. Her voice was a contralto of great compass (two and a half octaves) and remarkable quality. She left a sister, Mathilda, also a contralto singer, who had been educated by her. See *Adelaide Phillips, a Record*, by Mrs. Robert C. Waterson (Boston, 1883). D. E. HERVEY.

Phillips, CLAUDE: See the Appendix.

Phillips, GEORG: historian; b. in Königsberg, Germany, in 1804, of English Protestant parents; studied law at Berlin and Göttingen under Savigny and Eichhorn; was successively professor at Berlin, Innsbruck, and Vienna; became a Roman Catholic with his wife in 1828, and retired from teaching to live at Salzburg. The great epochs of the Middle Ages, the times of Charlemagne, Innocent III., and St. Louis, exercised a powerful charm over the mind of Phillips, who saw in them the highest flowering of Catholicism. He wrote much on the imperial and constitutional history of Germany, but he will be best remembered by his monumental work on canon law entitled *Das Kirchenrecht*, of which seven volumes (Manz, Regensburg) appeared from 1845 to 1872, in which year he died. The work has been taken up by Prof. Vering, of Prague, who printed in 1889 the first part of the eighth volume; a compendium of it exists in German and Latin for the use of seminaries. He was a man of very great erudition in mediæval matters, possessed a sure and sober judgment, and rigorously adhered to the historico-critical method in his great canonical work. See Adolph Tardif's *Histoire des sources du droit canonique* (Paris, 1887), p. 370. He co-operated with Görres and others in founding the *Historisch-politische Blätter*, a Roman Catholic monthly review of history and politics.
J. J. KEANE.

Phillips, HENRY: author; b. in Philadelphia, Pa., Sept. 6, 1838; educated at home and abroad, and admitted to the bar in Philadelphia, but did not practice law actively, because of delicate health. He became widely known, both in the U. S. and in Europe, as an authority on archæology, philology, and numismatics. He was a member of many scientific societies. He published *History of American Colonial Paper Currency* (Albany, 1865) and *History of American Continental Paper Money* (1866), the first works published on their subjects; *Pleasures of Numismatic Science* (Philadelphia, 1867); *Poems from the Spanish and German* (1878); *Faust*, from the German of Chamisso (1881); and four volumes of translations from Spanish, Hungarian, and German (1884–87). D. in Philadelphia, June 6, 1895.

Phillips, JOHN, LL. D.: benefactor; b. in Andover, Mass., Dec. 6, 1719; graduated at Harvard 1735; was for a time a preacher, but became a successful merchant of Exeter, N. H., where in 1781 he founded Phillips Exeter Academy at a cost of $134,000; gave $31,000 to Phillips Academy, Andover, besides liberal sums to Dartmouth College and Nassau Hall, New Jersey. D. at Exeter, N. H., Apr. 21, 1795.

Phillips, JOHN: geologist; b. in Marden, Wiltshire, England, Dec. 25, 1800; was a nephew and pupil of William Smith, called "the father of English geology"; became Professor of Geology in King's College, London, in the University of Dublin, and finally in the University of Oxford; and made important researches in geology, electricity, mag-

netism, astronomy, and meteorology; author of *Illustrations of the Geology of Yorkshire* (1829–36); *A Treatise on Geology* (2 vols., 1837–38), and other writings on geology. D. at Oxford, Apr. 24, 1874.

Phillips, John Arthur: See the Appendix.

Phillips, Wendell: orator and anti-slavery leader; b. in Boston, Mass., Nov. 29, 1811; the son of John Phillips, the first mayor of Boston; graduated at Harvard College in 1831 and at the Cambridge Law School in 1833, and was admitted to the Suffolk bar in 1834. When he entered upon his professional career the anti-slavery movement was attracting serious attention. In 1835 occurred the attack on William Lloyd Garrison by a Boston mob, and two years later the murder of Lovejoy, the editor of an anti-slavery newspaper in Alton, Ill. His sympathy with the Abolitionists was strengthened by these acts of violence, and at a meeting held in Boston to condemn Lovejoy's murder he delivered a speech of great fire and eloquence, condemning what he characterized as the cowardly spirit of those who would submit without protest to so gross a violation of the liberty of the press. From this time he was the foremost orator of the Abolitionists. He gave up his commission as a lawyer on the ground that he could no longer hold himself bound to obey the Constitution, which recognized the existence of slavery and protected the slaveholder in his rights. Refusing to accept money for his services, he devoted himself with unfailing energy to the advocacy of the anti-slavery cause, for which he maintained that even the disruption of the Union was not too high a price to pay. Believing that the war would lead to emancipation, he supported the North throughout the contest, and when that side triumphed he still continued as president of the Anti-Slavery Society his work on behalf of the Negroes, contending for their possession of equal civil rights with the whites. With the passage of the Fifteenth Amendment the Anti-Slavery Society found its objects attained, and it accordingly dissolved, but by this time Phillips's fame as an orator had won wide recognition, and he made frequent and much-applauded speeches on other topics. In addition to his anti-slavery championship he was an advocate of women's rights and a supporter of the temperance movement, and he occasionally lectured on subjects that had no relation to his aims as a reformer. A well-known lecture of this sort was that *On the Lost Arts*, which was very frequently repeated by him. He also lectured and wrote on financial subjects, and on the relations between capital and labor. He advocated prohibitory legislation in regard to the sale of liquors, maintaining that the attempt to govern great cities on the basis of universal suffrage had been a failure owing to the influence of the dram-shop. He urged that the national banks be deprived of the right to issue bills, and that the Government furnish all the national currency, separating it wholly from any coin basis, and let the currency rest solely on the credit of the Government. D. in Boston, Feb. 2, 1884. Revised by F. M. Colby.

Phillipsburg: city; Warren co., N. J.; on the Delaware river, and the Cent. of N. J., the Del., Lack. and West., the Lehigh Valley, and the Penn. railways; opposite Easton, Pa., 50 miles N. N. W. of Trenton (for location, see map of New Jersey, ref. 2–C). It is in an agricultural, iron-ore, and limestone region, and is noted for its extensive iron-works and their productions. There are six public-school buildings, public-school property (over $60,000), a national bank with capital of $200,000, and a daily and a weekly newspaper. Pop. (1880) 7,181; (1890) 8,644; (1900) 10,052.

Philoch'orus (in Gr. *Φιλόχορος*): the most important of the writers of special histories of Attica (*Ἀτθίδες*); flourished in the first half of the third century B. C. Fragments are in Müller's *Fragmenta Historicorum Græcorum*, vol. i., pp. 384–412, and iv., pp. 646–648. B. L. G.

Philocte'tes (in Gr. *Φιλοκτήτης*): in Grecian mythology, son of Pœas and Demonassa. He was educated in archery by Heracles, whose bow and arrows he inherited from his father, Pœas, who received them from Heracles, because he had set fire to the pyre of that hero. Philoctetes started to Troy with seven ships, but having been bitten on the island of Chryse by a snake sent by Hera because of the service rendered to Heracles, he was abandoned on the island of Lemnos by his fellows, who could not endure the stench of his wound and his agonized wailings. He lay on Lemnos for more than nine years, when he was brought to Troy by Odysseus and Diomedes, or Neoptolemus, because an oracle had declared that Troy could not be taken without the arrows of Heracles. He was healed by Machaon, killed Paris, and Troy was taken. See the tragedy of Sophocles entitled *Philoctetes*. J. R. S. Sterrett.

Philode'mus (in Gr. *Φιλόδημος*) of Gadara: Greek philosopher of the first century B. C., fragments of whose writings have been discovered at Herculaneum, some of them of great importance for our knowledge of the Epicurean school, to which Philodemus belonged. See Ritter and Preller, *Historia Philosophiæ* (1888), p. 447 foll.; Gomperz, *Philodem* (1891), and Sudhaus, *Philodemi volumina rhetorica*. A number of amatory epigrams by Philodemus are contained in the *Anthologia Palatina*.

Phi'lo Judæ'us [= Lat., liter., Philo the Jew]: theologian; b. at Alexandria about 20 B. C.; spent his whole life there, with the exception of two journeys he made—one to Jerusalem and one to Rome. Of his life very little is known. He was of a wealthy family, and occupied a conspicuous position in his native place. In the year 40 A. D. he was chosen a member of the embassy which the Jews sent to Rome to Caius Caligula. The embassy stayed in Rome over half a year without being admitted to the presence of the emperor; but during the reign of Claudius a learned defense of the Jews, written by Philo, was read in the Roman senate. The embassy he has described in his *Legatio ad Cajum*. In Alexandria he devoted all his time to study, and although as a philosopher he is without original genius, the peculiarity of his situation as mediator between Greek and Oriental wisdom, between Platonism and Judaism, between polytheism and monotheism, gave his writings a great influence in his own time, and makes them interesting to ours. He was a very religious man, and believed himself to be an orthodox Jew; but yet is the first representative of those of his countrymen who accommodated the faith of their ancestors to the new circumstances. His writings, which are in the Greek language, may be divided into three classes—those defending his countrymen, *Contra Flaccum*, *Legatio ad Cajum*, *De Nobilitate*; those interpreting and explaining the sacred books of the Jews, *De Opificio Mundi* (ed. L. Cohn, Breslau, 1889), *Legis Allegoriarum Libri III.*, *De Monarchia*, *De Præmiis Sacerdotum*, *De Posteritate Caini*, *De Cherubim*, *De Pœnitentia*; and those treating metaphysical subjects, *De Alternitate Mundi* (ed. F. Cumont, Berlin, 1891), *Quod Omnis Probus Liber*, *De Vita Contemplativa*. Of these three classes, the second and third are the most interesting with respect to his standpoint. His method of interpretation is the allegorical. The texts of the sacred books are not made subjects of positive criticism, but employed as opportunities for the development of theories. With him matter is an eternal principle. His idea of God is thoroughly monotheistic, but between God and matter he finds a convenient place for the ideas of Plato transformed into the angels of the Old Testament. These ideas, or powers, or angels form the medium through which God reveals himself to the world, and they are all gathered together in a divine world-spirit, a divine intellect, the *Logos*, which, however, in the speculation of Philo, remained a cosmic, naturalistic power without any real personality. D. about 50 A. D. The latest complete collection (8 vols.) was published at Leipzig in 1893. There is an English translation by C. D. Yonge in Bohn's Ecclesiastical Library (4 vols.). Cf. J. Drummond, *Philo Judæus, or the Alexandrian Philosophy in its Development and Completion* (2 vols., London, 1888). Revised by S. M. Jackson.

Philola'us (in Gr. *Φιλόλαος*): Pythagorean philosopher; contemporary of Socrates. The genuineness of the extensive fragments written in Doric dialect was maintained by Boeckh in his *Philolaus* (Berlin, 1829). See Ritter and Preller, *Historia Philosophiæ* (1888), p. 57 foll. B. L. G.

Philology: See Language and Comparative Philology.

Philome'le (in Gr. *Φιλομήλη*): in Grecian mythology, daughter of Pandion, King of Athens, and sister of Procne, the wife of the Thracian king Tereus, who lived at Daulis, in Phocis. Tereus loved Philomele, and having concealed Procne in the country that he might lie with Philomele when she came to visit her sister, he accomplished his purpose, and having cut out the tongue of Philomele, that she might not inform against him, he announced to Procne that her sister was dead; but Philomele, having discovered the truth, wove the story of her wrongs into a mantle and sent it to Procne. The two sisters then killed Itys, the son of Tereus by Procne, and served him up to Tereus for dinner. The sisters fled, Tereus pursued, and when he had

overtaken and was about to slay them, the gods, at the prayer of the sisters, turned all three into birds; Procne into the swallow, Philomele into the nightingale, and Tereus into the hoopoe. J. R. S. STERRETT.

Philopœ'men [= Lat. = Gr. *Φιλοποίμην*]: soldier and statesman; b. at Megalopolis, Arcadia, in 252 B. C., of a noble family; was carefully educated; distinguished himself greatly in the battle of Sellasia (221 B. C.) as leader of the horse; lived subsequently for several years in Crete, and was chosen commander-in-chief (*strategos*) of the Achæan League in 208 B. C., a position which he held eight times. It was his policy to put down rigorously all internal dissensions and feuds in order to deprive the Romans of any opportunity of interfering in Greek affairs; and although his plan was finally baffled by the fickleness of his countrymen and the meddlesomeness of the Roman senate, in details he achieved many brilliant successes; thus he compelled the Spartans to join the league, which was an important step toward the establishment of a united Greece. He was in Greek history the last character of an heroic cast. When the Messenians revolted against the league, he was seventy years old and sick in bed, but he rose immediately and put himself at the head of the army of the league. In the ensuing battle he was captured, and the hostile commander sent to him a cup of poisoned wine, which he drank (183 B. C.). J. R. S. STERRETT.

Philosophy [viâ O. Fr. from Lat. *philoso'phia* = Gr. *φιλοσοφία*, liter., love of wisdom; *φίλος*, loving + *σοφία*, wisdom]: a term the introduction of which is currently attributed to Pythagoras on the authority of Cicero (*Tusc.*, v., 3) and Diogenes Laertius (i., 12; viii., 8), but the oldest writer known to use it is Herodotus (i., 30). The Seven Wise Men of Greece were called *σοφισταί*, to denote their practical sagacity rather than their knowledge of science as such. Socrates, however, who left behind him no writings of his own, is said to have called himself a philosopher in order to reprove the Sophists of his time, he being only a seeker of wisdom—they, self-styled possessors of wisdom.

Definition.—Many noteworthy definitions of this science may be culled from its writers. While the Stoics made it include "a striving after virtue in the sciences—physics, ethics, and logic"—Epicurus declared it to be the rational pursuit of happiness. Plato had already designated philosophy as the acquisition of true knowledge (*ἐπιστήμη* = scientific knowledge), and Aristotle had defined it as the science of being as being (*τὸ ὂν ᾗ ὄν*). The relation of cause and effect furnishes the basis of the definitions of the earlier among modern philosophers (Descartes, Bacon, Hobbes, Leibnitz). Wolf returns substantially to the Aristotelian basis by defining it to be the science of possible existence in so far as possible, thus referring to the logical conditions of existence. Fichte makes it the science of sciences (*Wissenschaftslehre*); and this conception is very generally adopted, with slight modifications, by later thinkers. Whenever man attempts to refer all of his cognitions to one he begins to philosophize. Each nation's philosophy is an endeavor to solve the problems of the world, as they appear to it from the standpoint of its national life, by some one principle. This principle may be any cognition selected from the realm of nature or from that of mind. The systems of philosophy of a given nation or time may differ as to the one principle chosen as the explanatory one, but they are certain to agree in the elements of the problem to be solved. For the philosophy of a given epoch endeavors to state in ultimate terms the elements of the problems of its epoch. A philosophic solution of a problem consists in the reduction of the immediate and contradictory elements, as they are given in life, to the ultimate terms or expressions which indicate the universal and necessary conditions out of which those elements have arisen. Hence every philosophy has two factors: (1) The temporal and finite one, which includes the empirical elements to be explained—that is, the then present world of man and nature, which involves problems to be solved; (2) an eternal and infinite element, or the permanent and unchangeable ultimate idea through which the solution is wrought out and by which the temporal and finite is explained: this element is the conception of the absolute as it finds expression in the solution. Thus the different systems of philosophy start from different phases of life (because its phases, from one age to another, are perpetually changing), and yet they arrive at substantially the same result if they are complete systems. The difference, therefore, between the systems of philosophy of different peoples appertains rather to the empirical factor than to the character of the general terms in which the solution is expressed and contained. It has been pointed out (see GENERALIZATION) that in the most rudimentary form of knowing—i. e. in sense-perception—there is a synthesis of the two extremes of cognition: (1) The immediately conditioned content, which is the particular object as here and now perceived; (2) the accompanying perception of the self or Ego which perceives—that is, the activity of self-consciousness, the knowledge that it is I who am subject in this particular act of perception. Thus in sense-perception two objects are necessarily combined: (*a*) The particular object here and now presented; (*b*) the universal subject of all activity of perceiving. This universal subject, which is thus its own object in all forms of knowing, appears in two characters if we reflect upon it: (1) It is absolutely particular—i. e. present in this special moment now and here, and in this special act of perception; and (2) it is absolutely universal, retaining its self-identity under the constant change or flux which essentially belongs to the process of the immediate now and here, or present moment. The present now is a point in time, and thus has no duration except through the synthetical addition of past and future time, which *are* not, but either *were* or else *will be*. Thus such a thing as the perception of a permanent or a *relation of any sort* (for example, the one of identity or of difference, the most elementary and fundamental ones) can not take place without attention on the part of the subject who perceives to the perception of self or to the universal factor which is present in perception. This act of attention to self is reflection, self-perception entering all perceptions. The degree of the power of reflection or of attention to self-consciousness measures the ability to generalize or the ability to think; or, in other words, the strength of thought. For the minimum of this power of reflection admits barely the possibility of combining the perceptions of time-moments that are slightly separated, and hence its results are bare perceptions of identity or difference, without their quantity and quality. Sense-perception increases in richness of knowledge in proportion as the power of synthesis or of combining the successive elements of perception increases. And this power of combining such separate elements is contingent on the power of reflection or of attention to the self-activity in perception. Such reflection has been called "second intention," and is the condition of all generalization. Self-consciousness is therefore the basis of all knowledge; for all predication—from the emptiest assertion, "This is now," up to the richest statement involving the ultimate relation of the world to God as the highest principle—is possible only through a withdrawal of the mind out of the limiting conditions of the particular here and now by means of attention to its own activity, which, as already pointed out, comprehends the two phases of absolute particularity and absolute universal potentiality in one. This is the psychological basis of the general principle laid down regarding the identity of systems of philosophy and their phases of difference. The naïve state of mind of the uncultured human being, alike with the acute philosophical intellect or the intuition of the religious mystic, involves in all its activities and at every moment thereof this phase of attention to the self-activity or to the subject which knows. The naïve or non-philosophical stage of consciousness differs from the philosophical stage in the fact that the latter sets up some one of its cognitions as the highest principle, through which it attempts to explain the totality of said cognitions, while the former makes no such attempt. The philosophical activity of the mind is therefore a *third intention*, or act of attention which has for its object the reference of individual cognitions, whether particular or general, to an assumed supreme principle. This philosophical act, it is evident therefore, is a species of reflection different from that reflection which is implicit in all cognition. It is an act of withdrawal of the mind from immediate cognition, which arises through the first and second intention (or perception and reflection), and a concentration of the attention upon the relation of that immediate cognition (as existing in its separate details) to all cognition as totality. It is therefore systematic knowing. Moreover, as already suggested, it may posit as its supreme principle any one of its cognitions, taking, for example, an empty one lying close to the sensuous pole of cognition, or a concrete one lying close to the pure Ego. Thus it may make matter, or some form of matter, as water, air, fire, or ether, the philosophical principle which is to explain all things, being universal and

particular at the same time; or it may take for this purpose Reason (νοῦς), the Will, the Idea, the Good, *Causa sui*, the self-representing monad, or some form nearly approaching the pure Ego, for its principle; but the psychological presupposition underlying all philosophy, whether materialistic or spiritualistic, is the fact of withdrawal or abstraction of the mind from its first stage of cognition, and the contemplation of the same under the form of relation to a single principle—i. e. to an absolute totality. This contains the remarkable result that in this species of knowing the mind views its first principle, or the primitive existences by which it explains things as self-activities; which means that mind sees under its knowledge its own form as the ultimate truth of all. Take the standpoint of materialistic philosophy, for example: Matter is the ultimate principle, the whence and whither of all. Matter is thus posited as a universal which is the sole origin of all particular existences, and also the final goal of the same. Hence matter is active, giving rise to special existences, and also changing them into others with all the method and arrangement which we can see in natural laws. For matter must contain in it potentially all that comes from it. Hence matter is creative, causing to arise in its own general substance those particular limitations which constitute the differences and individuality of things. It is negative or destroyer in that it annuls the individuality of particular things, causing to vanish those limitations which separate or distinguish this thing from that other. Such a principle as this "matter" is assumed to be, which causes existences to arise from itself by its own activity upon itself and within itself, entirely unconditioned by any other existence or energy, is self-determination, and therefore analogous to that factor in sensuous knowing which was called the Ego or self-consciousness—an activity which is universal and devoid of form, and yet incessantly productive of forms, and destructive of the same. All this is implied in the theory of materialism, and exists there as separate ideas, only needing to be united by inferences; but "matter" as such idea is a cognition which arises only through reflection; it is perceived by "second intention," for first intention only refers or relates to immediate particular objects, and not to general objects like "matter," which is only a term for the persistent activity which recurs in the perception of whatever object it apprehends in time and space. As cognition of the mind, therefore, "matter" is a product of "second intention," but as philosophic principle it is more than this: it is this special cognition of matter posited as the absolute or as the totality and entirety of cognition, and hence not as limited through other particular cognitions, but as containing within itself a limiting power necessary for the particularization of other cognitions. Hence it is a pure Ego in so far as the possibility of all special ideas are concerned, and an active process so far as actual particular existence arises from it. Thus the position even of materialistic philosophy implies the thought of a totality which is purely universal, and a pure activity originating particular existences at the same time. Here we meet the most important distinction which belongs to the definition of philosophy. The degrees of consciousness are various, and differ through the completeness with which they grasp the determinations of the self-activity of the Ego. On the stage of philosophy consciousness grasps determination as a totality, and hence as self-determination; but this may happen in all shapes, from the emptiest up to the fullest and concretest. Even in materialism the attempt to explain the world through an ultimate principle indicates the certitude of the mind of the objectivity of its principle of self-determination, and it therefore implicitly asserts and presupposes that the truth of things is self-determination. Yet it may under this form so far contradict itself as to represent its content, "matter," to be a mere spatial existence, thinking under the term a vague abstraction as the origin of all immediate particularity and as the final cause thereof, without distinctly defining to itself these attributes as belonging to matter as highest principle. There are, then, various forms of philosophy, differing in the degree of completeness in which they consciously define their highest principle as the concrete Universal which originates the particular by its self-activity, and thus realizes itself in its own externality.

The distinction of philosophy from religion (which would be thought at first to be a reduction of all special beings to an absolute principle, God, in the same manner as defined for the province of philosophy) lies in the fact that while philosophy attempts to comprehend the totality of things through its absolute principle, religion *represents* its absolute in the historical relation of Creator of the world, and thus while it does subordinate all knowledge to one of its own principles, the mind in religion is not active in its third intention, but only in its first and second intentions. Religion offers its teaching to the lower and lowest stages, as well as to the highest stages of theoretical consciousness; for its revelation, although of the highest essence, is not immediately addressed to the theoretical reason, but rather to the Will. Hence it presents its absolute, not for assimilation, but for practical reconciliation with the individual. The relation of theosophy or mysticism to philosophy is here to be defined. Setting out from the standpoint of religion, and positing the absolute of religion as not only the principle of human action, but also of theoretical cognition, the religious mystic explains the world of nature and of history through it. This constitutes theosophy. It purports to arise through special illumination of the mind through the Absolute, and may be very profound and complete in its theory of things, but will of necessity use categories borrowed from religion, and consequently tinged with pictured representations, while philosophy uses its thoughts abstractly, and derives them from the activity of reflection.

The province of literature is to be distinguished from philosophy through the fact that its works seek an æsthetic unity of form, rather than a unity in the principle portrayed. It may happen, as in the poem of Lucretius, *De Rerum Natura*, that a philosophical treatise assumes an æsthetic form, but such form does harm to the requirements of scientific method. The essay and the literary criticism may offer profound reflections, but they are necessarily hampered through their form when it is literary rather than scientific.

The sciences, finally, are more difficult to distinguish from philosophy, especially the mental sciences. Indeed, philosophy is sometimes made synonymous with mental science, or with psychology. While religion agrees with philosophy in content (the relation of the Absolute to the world), it differs from it in form (employing the prineiple of faith or authority instead of logical necessity); the sciences, on the contrary, agree in form, but disagree in content. They treat of the systematic arrangement of materials within special provinces, rather than the reduction of the same to the first principle of all. The province of philosophy may include those of all special sciences, and even those of art and religion, jurisprudence and ethics, psychology and ethnology, in so far as those provinces are made elements of the problem of the universe to be solved by a first principle.

Method.—Philosophy alone can cognize methods, whether of other provinces of mental activity or of its own procedure. First and most obvious is the analytic method, which proceeds by resolution of a whole into its parts, and is a method of invention or discovery, inasmuch as it concentrates indefinitely the power of the mind upon a subject by attacking its details singly. This method is in philosophy what the microscope is in anatomy and kindred physical investigations. It proceeds from the vague to the distinct and clear. Then there is the synthetic method, which proceeds by combination or composition, and is a method of generalization or of principles—a method of explanation rather than of discovery. Besides these species of method, their union gives rise to higher species of method: (1) Deductive method, proceeding from the necessity of the whole to the necessity of the parts; (2) inductive method, proceeding from particulars contingently given to their necessary unity; (3) dialectic or genetic method, which by the analysis of its object discovers its essential dependence upon other objects and its unity with them; again, considering the new object, which has arisen synthetically through the discovery of dependence in the first object upon other objects, it discovers by analysis a new form of dependence, which leads to a new synthesis, etc. It is a method of ascent toward a first principle by the discovery of presuppositions, and by their addition to the object considered. It is contrasted by Plato (*Repub.*, bk. vi., ch. xiii.) with the mathematical method (that of simple deduction), as the method which removes its hypothesis (i. e. its first object) and ascends toward a first principle (ἐπ' αὐτὴν τὴν ἀρχήν), while geometry and the kindred sciences use fixed hypotheses (i. e. *assumed* first principles), and are unable to show their necessity as the dialectic method does by the discovery of presuppositions. The method of Aristotle is dialectic in the same sense as that of Plato, differing only in this, that he makes it more exhaust-

ive by laboriously collecting and discussing all the inadequate phrases that fall under each subject, exhibiting at last the true archetype or adequate realization of the species, as though he had empirically discovered it by careful investigation. The dialectic method contains the process of analysis in union with that of synthesis. Its analysis proves to be a synthesis because it reveals dependence, and hence the relation of the part to a whole. It must be present under all forms of necessary thinking, even when the thinker is unconscious of his method; as, in fact, he may be even of all method, and still think philosophically. The inductive and deductive methods, so called, unite analysis and synthesis also, but in the former the side of analysis is partly suppressed, in the latter that of synthesis. Again, the dialectic method is skeptical when it lays chief stress on its negative side, on that of the destruction of its hypothesis through the discovery of dependence, and speculative when it subordinates the negative phase to the total result, which is constructive of a more comprehensive and deeper thought —hence of a truer thought.

Classification.—(A) From the foregoing definition of philosophy it is evident (*a*) that there is one province of thought which belongs partly in the domain of philosophy and partly in that of religion—to wit, theosophy or mysticism. In it the dogma is partially rationalized, and therefore belongs to the realm of cognition instead of faith. Theosophy is the first form of philosophy, therefore, inasmuch as it makes its appearance as an outgrowth from religion, the effort being made to realize the content of religion as truth. (*b*) Thought perfectly independent from religion, and intent on constructing a rational view of the world and on reducing its common notions to consistency, may originate systems of materialism. This happens when it is not yet sufficiently disciplined to seize consciously its higher cognitions (those of the soul, for example) as first principles with which to explain the world; it therefore posits a cognition lying close to its ordinary experience and most familiar to it, as the explanation of all. (*c*) By continued reflection it gradually discovers what it has implied by endowing a principle with the power of originating all things, and comes to adopt, step by step, more spiritual principles until it reaches pure idealism and recognizes the world of sense-perception as phenomenal manifestation of absolute mind. This first series is founded on the "third intention of the mind" and constitutes dogmatic philosophy. (B) Above this standpoint begins the series of systems founded on perception of method (the fourth intention of the mind, making for its object the operations of the mind in its third intention, or ordinary philosophizing). (*a*) The first system founded on perception of method is skepticism, which breaks the link between subject and object, between the mind and the truth, by calling attention to the process or method of the mind in philosophizing, and exhibiting the modifying effect of mind upon truth. It shows that the activity of the mind enters and constitutes an element of truth, and therefore invalidates it. (*b*) The second system founded on the perception of method is the system of critical philosophy, giving to it the name which Kant gave his own system. On it is founded the third phase of philosophy which we may call Absolute Idealism, giving it the name given to its best type, the system of Hegel. (C) As the second phase of philosophy is skeptical when it perceives philosophic method only in glimpses, so when it comes to make an exhaustive study of method and to learn all of its possibilities, as in the critical philosophy of Kant and Fichte, then it arrives at the insight that the object of the third intention—namely, mind as the first principle or absolute, is also the presupposition of all psychological method. After this skepticism becomes impossible. This third phase of philosophy is founded on the fifth intention of the mind and perceives the positive side of method, and its necessary universality as principle of existence or as logical condition of the world. This last system is sometimes called pure science, science of ideas in and for themselves, ontological logic, science of knowledge, absolute idealism, etc. Examples of each of these five systems may be found in the subdivision *History of Philosophy*.

Departments.—The old division of Wolf makes four departments in philosophy: (*a*) Ontology, (*b*) rational psychology, (*c*) cosmology, (*d*) theology. This may be modified to meet the present development of philosophy thus: (*a*) Pure science or logic or methodology—dialectical discussion of general ideas; (*b*) science of nature, corresponding to rational cosmology; (*c*) science of spirit, including numerous subordinate spheres, such as (1) psychology, (2) ethics, (3) politics and history, (4) æsthetics, (5) theology (natural). This corresponds nearly to the division of the ancients into (*a*) dialectics, (*b*) physics, (*c*) ethics.

History of Philosophy.—The history of philosophy, according to the definition discussed in this article, will contain the record of all thinking which refers the manifold of experience to an ultimate principle; this explanatory principle being materialistic on the one hand in the elementary stages of thought, and idealistic in the more advanced stages, while it becomes a principle of method (or a principle at once ontological and psychological) in the highest thinking.

The Orient has generally been excluded from the domain of the history of philosophy, on the ground that its thinking is not emancipated from religious authority. Religion and philosophy are mingled in a species of theosophy in Asia, but are worthy of study as a phase of transition containing the embryonic shapes and metamorphoses that become fully developed and distinct in the literature, religion, and philosophy of the Western peoples. The Chinese systems of Lao Tsŭ (604 B. C.) and Confucius (550 B. C.) posit a first principle (called *Tao* by the former, and *Tai-ki* by the latter), an abstract indeterminate substance, whence arise masculine and feminine principles that beget all things.—The Indian caste system gives rise to limitations so irksome and galling that the great problem in Indian thought is emancipation; it seeks relief from the rigid particularity of the distinctions (tedious ceremonial observances) which it encounters in life, by flight to the indefinite, vague, and empty ground of substance of all things, and finds solid satisfaction in contemplating Brahm—i. e. the pure identity wherein neither caste-differences, nor the bewildering luxuriance of tropical nature, nor even the prolific creations of its own active fancy and teeming intellect, any longer find subsistence to vex and weary it. Besides the Saukhya or rational system, there are reckoned the Nyaya, or logical system of Gautama, and its modification in the atomic system of Kanada, called the Vaiseshika Philosophy: the Vedic system, full of mysticism, including the elder school of commentary called *Purva Mimansa*, founded by Jaimini, and a later one, called *Uttara Mimansa*, founded by Krishna Dwaipayana; but the philosophic principle is the same in all these, namely, the doctrine that the absolute is Pure Being devoid of all attributes, and that all phases of mind and matter are only illusion (Maya).—The philosophic standpoint of the Persian consciousness is considered to be an advance upon those just considered, in that it gives greater validity to the negative element—that of limitation or finitude, the principle of individuality or particularity. It posits a process, the conflict of light and darkness or of good and evil, the positive and negative, as the explanatory principle of the universe.—The worship of Hercules and of Adonis in Syria and of Osiris in Egypt indicates a progress over the standpoint of Zoroaster, in that the principle of particularity is still more highly prized. Purification through pain reconciles the finite and infinite, and it is not necessary to annihilate the former. Immortality of the individual becomes explicable, and the Egyptian mind is mostly occupied with this thought.—Western Asia (including Egypt) occupies itself with the problem of individuality and its essential inherence in the absolute. Its influence appears in the Ionic philosophy, particularly in the teachings of Anaximander and Heraclitus; in the Pythagorean philosophy; in Neoplatonism; in gnosticism; in the mysticism founded on the *Cabbala*; in the early Christological speculations of the Church; in Arabian mysticism.—The history of philosophy in the Occident, beginning with Greece, has to do with independent thinking, and is no longer obliged to seek its material in systems that are partly religious, partly ethical, and partly speculative. Greek philosophy begins with the Ionic school in Asia Minor, Thales, Anaximander, Anaximenes, and Heraclitus being its chief names. They set up material principles—(*a*) water, (*b*) the indefinite (matter), (*c*) air, and (*d*) fire—as the origin of things. Pythagoras, born in Ionia and taught in its school of philosophy, founded a society in Lower Italy, and proclaimed numerical harmony as his principle. The Eleatic school (also of Lower Italy) set up the principle of pure being, thus arriving for the first time at a principle entirely above and beyond experience, a principle seen only by pure thought acting *a priori*; it included Xenophanes, Parmenides, and Zeno. Empedocles of Sicily taught that love and hate are the ultimate principles, while Anaxagoras at Athens announced the important doctrine that Reason

(*νοῦς*) arranges and orders all things. Leucippus and Democritus of Thrace founded the atomic philosophy. The Sophists, of whom the most important were Protagoras, Gorgias, and Prodicus, discovered and applied the principles of ratiocination, or the dependence of conviction upon grounds or reasons. Socrates investigated universals, seeking ultimate grounds for conviction in order to establish moral principles on a firm basis. The *νοῦς* of Anaxagoras becomes with the Sophists individual reasoning—with Socrates, universal reason as conscience. Plato, continuing the investigation, finds the theoretical universals, the ideas or archetypes, antecedent to and dominant over the world of experience. Aristotle, finally, takes an empirical inventory of the world, and completes the demonstration that *νοῦς* is the principle of things in detail, being their final cause. He finds that all universals are phases of one universal Reason (*νοῦς ποιητικός*), which is the highest principle. His doctrine of first and second entelechies defines the relation of individuals to this absolute Reason and the grounds of the immortality of man. He maps out the paths of the several particular sciences, and makes important investigations in many of them. His pupils, Eudemus and Theophrastus, and his commentators, Alexander of Aphrodisias, Porphyry, Themistius, Simplicius, and, later, Avicenna and Averroës, deserve mention in any notice of Greek philosophy, however brief. The Stoic school of Zeno of Citium, whose system is ethical in its tendency, the school of Epicurus, whose system is an atomic materialism, belong to the decline of Greek philosophy. (This brief summary of the first phase of Greek philosophy may be supplemented by reference to special articles in this cyclopædia, such as Thales, Parmenides, Zeno of Elea, Heraclitus, Pythagoras, Sophists, Socrates, Plato, Aristotle, Stoics, Zeno the Stoic, Teleology, Form, Matter, Substance, Idea, Simplicius, Sextus Empiricus, and Lucretius.) The revival of Greek philosophy at Alexandria after the Christian era was occasioned by the contact of Greek thought with Orientalism. Alexandria was the focus or center for the East and the West. Neoplatonism, accordingly, is the struggle to define the relation of Greek thought to spiritual religion. Its distinguished names are Ammonius Saccas, Plotinus, the two Origens, Porphyry, Iamblichus, and Proclus. Its principle is the transcendence of the Deity, and it labors to explain how the world emanates from a primal One which is in nowise related to it, and is devoid of all antithesis, and therefore unthinkable. Boëthius, through his *Consolatio* and his translation of a portion of the *Organon*, and by his commentary on the *Isagoge* of Porphyry, transmitted almost all that was known of Greek philosophy by the Christians in the West for several centuries. (See articles on Plotinus, Porphyrius, Iamblichus, Proclus, Gnostics, Mysticism, and Philo Judæus.)—Within Christianity, Gnosticism arose in the second century as an attempt to construct a philosophy on a Christian basis. Philo had already speculated on the Logos. Valentinus made the *νοῦς* the "only-begotten" and the source of the Logos. Origen and Clement endeavored to assimilate some of the Gnostic doctrines. After the Council of Nice had given definition to the orthodox faith, more attention was given to the philosophic justification of its dogmas. Athanasius, Gregory of Nyssa, St. Augustine, Synesius, Æneas of Gaza, Philoponus, and the pseudo-Dionysius the Areopagite contributed to this work. In the ninth century it was the translation of the writings of the pseudo-Dionysius, evidently a Neoplatonist, by Scotus Erigena that gave rise to scholasticism. The controversy of nominalism and realism, in which Roscellinus, Anselm, Abelard, and William of Champeaux were the chief disputants, occupied the first period of scholasticism. The mastery of Aristotle and the refutation of the pantheistic commentary of Averroës were the chief business of the second period, in which appeared the great theologians Alexander of Hales, Bonaventura, Albertus Magnus, Thomas Aquinas, and Duns Scotus. Aristotle became the "*precursor Christi in naturalibus*," as John the Baptist "*in gratuitis*." Besides Averroës should be named Avicenna, Alfarabi, Alkendi, and Algazel among the Arabians, and Avicembron, Ben David, and Moses Maimonides among the Jewish philosophers. Roger Bacon and William of Occam did not follow the prevailing tendencies, the former being an experimenting physicist born before his time, and the latter an invincible opponent of the logical realism current. Nominalism under Occam destroyed the tendency to rationalize the dogma, and scholasticism went down altogether. (See articles on Scholasticism, Nominalists, Realism, Idealism, Immortality, Necessity, Occam, Duns Scotus, and Aquinas.) The fall of the Eastern empire brought many learned Greeks into the West, and kindled at Florence and elsewhere the direct study of Plato and Aristotle in the original Greek, whereas hitherto the interpretation of commentators had been generally accepted. Distinguished translators and new commentators, such as Ficino, Pomponatius, Scaliger, appeared. (See Ficino.) The naturalistic opponents of the traditional philosophy of the schools at this period, Nicolaus Cusanus, Jerome Cardan, Telesius, Patritius, and Ramus, prepared the way for an epoch of emancipation from authority, in which the leading spirits were Giordano Bruno, Francis Bacon, and René Descartes. The first of these attacked the ecclesiastical authority in matters of science; the second founded the empirical method of philosophizing; the third completed the emancipation from scholasticism by bringing the principles of philosophy to the test of consciousness and by discarding the authority of tradition. Thomas Hobbes applied Bacon's principle to politics; Geulincx and Malebranche explained the relation of mind and matter in the Cartesian dualism; Spinoza avoided the Cartesian dualism altogether by adopting the principle of One Substance with the two attributes, thought and extension. Locke attempted a critical survey of the powers of the mind to cognize truth, and found sense-perception and reflection to be the sources of all ideas. Berkeley drew from Locke's doctrine the inference that we know only ideas and not the external world. Cudworth, author of the *Intellectual System*, and Henry More the Platonist, Gassendi the atomist, Grotius and Puffendorf, writers on international law, Bayle the pantheist, are among the foremost thinkers of that time. Meister Eckhart, probably a pupil of Albertus Magnus, founded in the fourteenth century along the Rhine the most noteworthy school of theosophy yet known, and with his followers, Tauler, Heinrich Suso, John Ruysbroeck, and the author of *Theologia Germanica*, and Thomas à Kempis, exercised a most potent influence on the growth of thought in Germany and the rise of the spirit that produced the Protestant Reformation. Jacob Böhme, contemporary of Descartes and Lord Bacon, developed another system of theosophy nearly as remarkable as that of Eckhart, and in substantial agreement with it. With Leibnitz, theosophy becomes philosophy. His doctrines were systematized by Wolf, and held sway down to the time of Kant. In his *Monadology* he sets up in opposition to the mechanical system of Deseartes the doctrine of monads, which have no mechanical relation to each other, but only the ideal or psychological one of representing each other. David Hume is the point of departure for the chief systems of philosophy which have appeared during the past hundred years. His criticism on the idea of causality, reducing it to the mere "habit of surveying things constantly conjoined with each other," sapped the foundations of all dogmatic philosophy current at his time. La Mettrie, Voltaire, Rousseau, Condillac, Diderot, d'Alembert, Robinet (who anticipated Darwinism and the Spencerian "evolution"), and Von Holbach are noted thinkers in the same movement in France. Lessing began the struggle for literary independence in Germany, and Kant completed the reaction in philosophy and freed his country from its subservience to French ideas. The *Critique of Pure Reason* established on the ground of their universality and necessity the *a priori* character of causality and other categories, and demonstrated the self-activity of the mind in sense-perception. The *Critique of Practical Reason* showed that God, free will, and immortality are necessarily postulated by all acts of the individual as "regulative ideas"; hence these are the logical conditions of human action. These two *Critiques* rescued religion and morality, and the institutions founded on them, from the attacks of skepticism, but they denied the possibility of theoretical cognition in the realm of objective existence. This inability the later schools of German philosophy labored to remove. Fichte's *Science of Knowledge* showed in a systematic form the origin of the categories in the self-activity of the mind, and proved that the will is therefore presupposed everywhere as a conditioning factor in cognition. The sensuous factor of knowledge is accordingly subordinated, and the moral world is almost the only world that exists for Fichte. Schelling, however, reacts to the opposite extreme, and lays great stress on the evolution of unconscious organism in nature and human history. The central object of his system is therefore æsthetic art, wherein the unconscious reason reaches its completest expression. Schelling's school in-

cludes the distinguished theosophist Baader and the naturalists Oken, Carus, Oersted, Esenbeck, Steffens; the theologians Schleiermacher, Eschenmayer, Blasche, Görres; Schubert the cosmologist, Stahl the jurist, Solger and Ast, æsthetic writers; besides Krause, Troxler, Jacob Wagner, and others. Hegel, in opposition to Schelling's tendency to emphasize unconscious evolution, endeavored to grasp the content of nature and mind with self-conscious method. His "unity of thought and being" means that universal and necessary ideas, being the logical conditions of the world of experience, are as objective as they are subjective, any denial of this principle being self-contradictory, inasmuch as it assumes to pronounce *a priori* upon the objective possibility of existence—the very thing it repudiates. Hegel's philosophy, like that of Aristotle, takes an encyclopædic inventory of the world of nature and man, reconciling and interpreting all phases. The most eminent of the direct expounders of Hegel are Marheineke, J. Schulze, Gans, Von Henning, Hotho, Förster, Michelet, Rosenkranz, Weisse, Göschel, Erdmann, M. Carrière, K. Ph. Fischer, R. Eucken, and Kuno Fischer. All these expound with originality, and sometimes with important deviations.

According to the popular distinction of Strauss, there is a left wing which expounds the Hegelian system as a logical pantheism (panlogism); a right wing which expounds it in conformity with orthodoxy; a center which agrees substantially with the right wing, but introduces many modifications in technique and interpretation. The study of Hegel and of the Kantian movement in his direction has made its way into Great Britain through the original writings and translations of J. H. Stirling (*The Secret of Hegel*), J. Caird, of Glasgow, T. H. Green, E. Caird, and W. Wallace, of Oxford; and further by A. Seth, D. G. Ritchie, B. Bosanquet, E. S. Haldane, E. Wallace, R. Adamson, F. H. Bradley; into France especially through A. Vera, Ch. Benard; into Italy through A. Vera, B. Spaventa, R. Mariano; into the U. S. through the *Journal of Speculative Philosophy*, and the expositions and translations of J. Watson, C. C. Everett, E. Mulford, G. S. Morris, G. H. Howison, H. C. Brockmeyer, D. J. Snider, J. Royce, J. S. Kedney, J. Dewey, W. S. Hough, W. M. Bryant, J. M. Sterrett, R. A. Holland, N. M. Butler, J. G. Schurman, A. T. Ormond. A school has arisen in Germany which, starting from Hegel or Kant, approximates somewhat in methods the English and Scotch schools of empirical psychology. Its most eminent names are J. H. Fichte, Wirth, Zeller, Ulrici, Fr. Harms, Bona Meyer, Liebmann, Volkelt, J. Bergmann, J. Rehmke, W. Schuppe. A materialistic tendency appears in the writings of the "left" Hegelian wing, and becomes pronounced in Strauss, Feuerbach, and some others. Experimental psychology has recently taken new life from researches in anthropology, ethnology, folklore, child-study, hypnotism, spiritism, mind-reading, and other phases of "psychic research," and more especially through the discoveries in the physiology of the brain and nerves made since the success of Broca in fixing the location of the lesion producing aphasia in 1868. In England the names of Carpenter, Maudsley, D. Ferrier, Galton, Lubbock, Romanes, Sully, Spencer, Tylor, J. Ward, G. C. Robertson, A. Bain, are connected with one or another phase of this movement; in America the names of G. T. Ladd, W. James, G. S. Hall, J. M. Baldwin, J. B. Powell, L. F. Ward, G. Mallery, D. G. Brinton, J. Fiske, G. S. Fullerton, J. M. Cattell, E. B. Titchener, E. Barnes, C. L. Franklin, are most distinguished in the several departments of this study; in Italy the criminologist C. Lombroso is eminent; and in Germany, where the movement borrowed its methods, its literature is due to W. Wundt, Helmholtz, A. Horwics, G. T. Fechner, E. Dubois-Reymond, A. Schleicher, E. Haeckel, F. Brentano, H. Münsterberg, H. Ebbinghaus, C. Stumpf, H. Witte, T. Lipps, G. K. Uphues, M. Dessoir, and their colaborers; in France the hypnotic phenomena have received more attention than elsewhere, and the location of psychical activities in the brain has been investigated with much thoroughness. The writings of Th. Ribot, A. Binet, G. Tarde, Ch. Féré, are studied in both hemispheres. Herbart reproduced Leibnitz modified by ideas derived from Kant and Fichte. His school is prolific in distinguished writers, especially in the department of psychology as applied to philology and education. Prominent are the names of Drobisch, Beneke, Exner, Hartenstein, Lazarus, Steinthal, Waitz, Bonitz, Wittstein, A. Fouillée (in France). H. Lotze's system is almost eclectic, being founded on a criticism of the Herbartian system and the later Kantian systems. It has exercised much influence in the U. S. through the writings of B. P. Bowne, G. T. Ladd, and J. Cook. Trendelenburg's system is based chiefly on Aristotle and Kant, and represents a reaction against the logic of Hegel. Schopenhauer revived the Buddhistic system with great penetration and power of exposition, and with caustic criticism of his contemporaries. E. von Hartmann has added to its popularity by his writings, and Frauenstaedt has connected it with the "left-wing" interpretation of Hegel. Other disciples of Schopenhauer are Julius Bahnsen, K. Peters, P. Deussen, P. Mainlaender, the novelist Spielhagen, and the musician Richard Wagner. Italian philosophy counts Galluppi, Gioberti, Rosmini, Mamiani, and the Hegelians (at Naples), Vera, Spaventa, Mariano, Ragnisco. The writings of Rosmini have been translated into English by his disciples, W. Lockhart and T. Davidson, and expositions made of his ideas in psychology and metaphysics. Besides these, there is an active school of positivists in Italy represented by R. Ardigo, A. Angiulli, G. Cesca, G. Sergi, E. Lombroso, Morelli, and Caporali. In France, Laromiguière, Royer Collard, Maine de Biran, B. Constant, Victor Cousin, T. Jouffroy, P. Janet, C. de Rémusat, Saint-Hilaire, Emil Saisset, J. Simon, Ravaisson, represent the spiritual tendency, partly stimulated by the Scotch philosophy, partly by the scholastic traditions of the universities, and partly by the Kantian movement. Saint-Simon, Fourier, P. Leroux, represent the socialistic direction, and Comte and his disciples positivism. Comte has gained followers in all countries. In France, Blignières, Littré (lexicographer), P. Lafitte, many of the physiological psychologists, Taine, are eminent names in this school. In Great Britain Frederick Harrison is the leader of positivism. A reaction against the materialistic followers of Locke begun with V. de Bonald, Jos. de Maistre, and F. de Lamennais. Writers that should not be omitted in a list of French philosophers are J. Reynard, E. Vacherot, E. Carot, Claude Bernard (physiologist), J. M. Guyau, and especially C. Renouvier, whose writings show the influence of Kant. The Scotch school of Reid, Stewart, Brown, and Sir W. Hamilton begins with a reaction against Hume, and tends toward a modified Kantianism (in the system of Hamilton). Dr. McCosh (see McCosh, James) is a later representative. It has exerted a powerful influence in France and the U. S. The writings of Mansell furnished the foundations of Herbert Spencer's doctrine of the unknowable. The school of Locke and Hume has been represented in the nineteenth century by Stuart Mill, Lewes, and Spencer. All these, and especially Herbert Spencer, have exerted a powerful influence upon thinking minds engaged in natural science. German philosophy was introduced to the English-speaking world by Coleridge and Carlyle and later by J. H. Stirling, Jowett, Flint, T. H. Green, J. F. Ferrier, J. Caird and E. Caird. Shadworth Hodgson has criticised the Kantian doctrines of time and space. Whewell, De Morgan, Boole, Jevons, Venn, Bradley, and Whateley have written on logic, and H. Sidgwick, Leslie Stephen, and James Martineau have written on ethics. In the latest period there has arisen in Germany a movement which takes as its watchword "back to Kant." It counts among its leaders Fr. Paulsen, F. A. Lange, O. Liebmann, A. Krause, A. Classen, J. Folkelt, B. Erdmann, H. Vaihinger, H. Cohen, A. Stadler, P. Natorp, K. Lasswitz, and E. König. The following German writers on philosophy in various departments should be added to those already named: Laas, Riehl, and Avenarius as German positivists; A. Zeising, and K. Groos, writers on æsthetics; C. Sigwart, W. Schuppe, and J. Bergmann as writers on logic. American philosophy counts (*a*) in its theological school the names of Edwards, Dwight, Taylor, Tappan, Finney, W. E. Channing, D. D. Whedon; (*b*) in its transcendentalist school, chiefly founded at first on Platonism and the Coleridge version of Kantianism, and later on influenced by French eclecticism, Fichte, and other Germans, Marsh, Emerson, Margaret Fuller, A. B. Alcott, Theodore Parker, J. F. Clarke, George Ripley, O. A. Brownson (who afterward became a Thomist), F. H. Hedge, and H. D. Thoreau; (*c*) in its psychological school (following the Scotch school or the French eclectics), N. Porter, F. Bowen, A. Mahan; (*d*) in its school based on the study of Kant or his successors, L. P. Hickok, C. C. Everett, J. B. Stallo, and nearly all the present teachers of philosophy in the colleges of the U. S. Most of those who have contributed to philosophy by their writings have been mentioned in other connections. (See articles on Idealism, Identity, Knowledge, Reason, Sensationalism, Transcendentalism, Understanding, Descartes, Spinoza, Malebranche, Bacon (Francis), Locke, Leibnitz, Hobbes, Hume, Kant, Fichte, Schelling,

Hegel, Schleiermacher, Schopenhauer, Herbart, Mill, J. S., and Spencer, Herbert. Consult also, on the general problems recurring in the history of philosophy, Generalization, Infinite, Mind, Moral Philosophy, Psychology, Scepticism, Soul, Thought, and Will.) The chief historians of philosophy are Stanley, Bayle, Brucker, Tiedemann, Buhle, Tennemann, Reinhold, Ritter, Hegel, Schwegler, Erdmann, Ueberweg, Cousin, Lewes, Zeller, K. Fischer, L. Ferri, E. Zeller, R. Falckenberg, W. Windelband, Ludwig Noach (*Philosophisches-Geschichtliches Lexikon*). Recent periodicals devoted to speculative philosophy are *Zeitschrift für Phil. und philosophisch. Kritik* (at Halle); *Phil. Monatshefte* (at Berlin); *Die Neue Zeit* (at Prague); *La Filosofia delle Scuole Italiane* (now *Rivista Italiana di filosofia* (at Rome); *Mind, a Quarterly Review of Psychology and Philosophy* (at London); *Revue philosophique de la France et de l'Étranger* (at Paris); *Journal of Speculative Philosophy* (New York); *The Monist* (Chicago); *International Journal of Ethics* (Philadelphia); *The Philosophical Review* (Ithaca, N. Y.); *American Journal of Psychology* (Worcester); *The American Anthropologist* (Washington); *Journal of American Folk-lore* (Boston); *Philosophisches Jahrbuch* (Fulda); *Vierteljahrsschrift für Wissenschaftliche Philosophie* (Leipzig); *Psychological Review* (New York); *The Platonist* (Osceola, Mo.); *The Journal of the American Akademe* (Jacksonville, Ill.); *Rivista Filosofica Scientifica* and *La Nuova Scienza* (organs respectively of Signor Morelli and Signor Caporali, Italian positivists); *Revue de Hypnotisme* (Paris). W. T. Harris.

Philosophy, Moral: See Moral Philosophy.

Philosophy of the Conditioned: See Conditioned, Philosophy of the.

Philos'tratus (in Gr. Φιλόστρατος): a name borne by four Greek sophists of the same family of Lemnos: 1. The eldest Philostratus, son of Verus, lived under Nero and wrote the dialogue of that name (Νέρων), preserved among the writings of Lucian. 2. The next, Flavius Philostratus the elder, a descendant of Verus, flourished under Alexander Severus (222–235 A. D.), and composed, among other things, the *Lives of the Sophists* (Βίοι Σοφιστῶν) and a remarkable romance, *The Life of Apollonius of Tyana* (see Apollonius of Tyana), much used as an offset to the life of our Saviour. 3. The third Philostratus, son-in-law of Philostratus II., wrote a series of descriptions of paintings; and 4. A fourth Philostratus wrote a second series in imitation of the first. Whether and how far these descriptions deal with real works of art is disputed. The works of these various Philostrati are of great importance for an appreciation of the periods to which they belong. There is a text edition of all the works by Kayser, in the Teubner Library (2 vols., 1849), and a separate edition of the *Vitæ Sophistarum*, with a copious commentary by the same scholar (Heidelberg, 1838). A new edition of the *Imagines* of the elder Philostratus was published by the members of the Vienna Seminary in 1893.

B. L. Gildersleeve.

Philox'enus (in Gr. Φιλόξενος): Greek dithyrambic poet (435–380 B. C.) of Cythera; lived long at the court of Dionysius the Elder, about whose poetical performances he used great plainness of speech. One of his dithyrambs suggested the *Cyclops* of Theocritus. Fragments of another, *The Banquet*, are interesting for their rhythmical form and for the account they give of the luxury of the Sicilian table, and are to be found in Bergk's *Poetæ Lyrici Græci*. B. L. G.

Philter [from Lat. *phil'trum* = Gr. φίλτρον, love-potion, deriv. of φιλεῖν, love]: an aphrodisiac preparation. Philters were much used in ancient Greece and Rome, and the Thessalians had special eminence in their preparation. From the accounts which have come down to us, many of their ingredients were harmless, or at most disgusting, and used on account of some purely fanciful efficacy; while others, it would seem, were violent poisons. Thus a doubtful tradition says that the poet Lucretius died in consequence of a strong philter given by his wife; and some hold that Caligula's madness was caused and maintained by his wife's philters. The use of these potions is prevalent in almost all barbarous and half-civilized lands. As of old, magic arts are employed to add force to the supposed natural powers of the drugs.

Phintias: See Damon and Pythias.

Phips, or **Phipps**, Sir William: Governor of Massachusetts; b. in Pemaquid, now Bristol, Me., Feb. 2, 1651; was a shepherd, but when eighteen was apprenticed to a shipbuilder; removed to Boston, where he worked as a shipcarpenter, and subsequently engaged in commerce; went in 1684 to England, and obtained means to fit out a vessel to recover the silver of one of the Spanish Plate fleet wrecked off the Bahamas, but was not successful until 1687, when he obtained treasure worth $1,500,000 (some accounts say $3,000,000), for which he got about $80,000, besides receiving knighthood and the office of high sheriff of New England; headed, in 1690, an expedition which captured Port Royal, Nova Scotia, and in the same year had command of a fleet which unsuccessfully besieged Quebec; was the first royal Governor of Massachusetts 1692–94; built the fort of Pemaquid, Me., 1692; put an end to the prosecutions for witchcraft by organizing a special court of magistrates for the consideration of the cases; was suddenly called to England 1694 to answer charges against him. D. suddenly, of a malignant fever, in London, Feb. 18, 1695. His enterprise and patriotism were remarkable, and his native abilities fair, but he was ignorant, ill-tempered, credulous, and the tool of abler men. He did not learn to read until he was twenty-two years of age. Cotton Mather wrote an eulogistic *Life* of Phips, who was a member of his church. A trustworthy one by Francis Bowen is given in Sparks's *American Biography* (Boston, 1834–37).

Phlebi'tis [Mod. Lat.; Gr. φλέψ, φλεβός, vein + suff. *-itis*, denoting a disease of]: inflammation of the coats of a vein or veins. Phlebitis may occur in any part of the body from direct injury and accidental or surgical wounds. Idiopathic or primary phlebitis occurs chiefly in the lower extremities, especially in the tortuous expansions and dilated pouches of varicose veins. When a vein is inflamed its contained blood coagulates, adheres to the walls of the vessel; a local fibrinous mass or clot (thrombus) obstructs or wholly suspends the circulation. Exceptionally, this thrombus organizes, connecting with the nutritive capillaries of the venous coats. More often it partly or wholly breaks down, disseminating pus when attached by pyogenic (pus-producing) or putrefactive bacteria, and contaminating the blood, or giving off particles which are carried by the blood to the different parts of the body, and may lodge in the small vessels of large organs, occluding them. Such plugs or emboli deprive a tract of tissue of its nutritive blood-supply, and lead to the condition of fatty degeneration or abscess. Phlebitis, if acute, may be announced by chills and febrile disturbance preceding the local inflammation. The affected vessels are hard, tortuous, prominent, visibly elevated if the surface be viewed in profile. There is a dusky redness over and in the immediate vicinity of the vein, with slight tumefaction and redness of an erysipelatous character, shading off into adjacent tissues. Nodular prominences exist at the site of the valves in the veins. The vein is sensitive to touch, and the entire part tender and painful if moved. Œdema or dropsical swelling, evidenced by pitting upon pressure, may result from the obstructed circulation; in the extremities this swelling may be considerable, with sense of great weight, due to accumulated venous blood and serous transudation. Following childbirth, phlebitis occasionally occurs, usually in the lower extremities, due to local thrombi following the perverted blood of the puerperal state, and probably resulting from absorption of septic matter by the open uterine sinuses. This painful condition is known as *phlegmasia alba dolens* (i. e. painful white swelling), and popularly termed "milk leg." Indeed, at present, the infection of the blood by septic matter and local thrombosis as the causes producing phlebitis are generally conceded. Phlebitis and venous thrombosis are chiefly interesting as engendering embolism and similar putrefactive disturbances in other parts of the body, metastatic abscesses. The "multiple abscesses" of the liver follow inflammation of the venæ portæ. Coexisting abscesses in the brain, lung, liver, spleen, and kidneys may develop from a general poison of the blood. When a vein is enlarged and rigid, as in the sinuses of the cranium, the veins of old hæmorrhoids or stricture of the rectum, or the varicose veins of the leg, its inflammation is very liable to infect the system. The treatment of phlebitis is by local antiphlogistics and internal administration of antiseptics and tonics with absolute rest of the part attacked, and prompt evacuation of collections of pus. Revised by R. Park.

Phlebotomy: See Bleeding.

Phlegma'sia [Mod. Lat., from Gr. φλεγμασία, heat, inflammation, deriv. of φλέγειν, burn]: a term synonymous with *phlegmon*, *phlegmous inflammation*, *pseudo-erysip-*

elas, *diffuse abscess*, and now usually replaced by *cellulitis* or *phlegmonous cellulitis*, denoting an acute inflammation of the subcutaneous cellular tissue, tending to suppuration, in which the pus formed has a tendency to become infiltrated through the tissues, instead of collecting into one place as in ordinary acute abscess. The causes of this variety of inflammation are sometimes very obscure. It is always an expression of an infection by pyogenic or pus-forming bacteria, patients being made more liable thereto by exposure, alcoholic excess, wasting disease, etc. It sometimes results from mortifying shreds of tissue in wounds, and complicating injuries, but in by far the greater number of cases it arises spontaneously in debilitated individuals—persons suffering from mal-assimilation, and consequently having a thin and impoverished blood, i. e. which is incapable of producing a healthy inflammatory action. In such individuals it generally occurs in the extremities, especially in the fingers and hands. The symptoms of phlegmasia are those of ordinary inflammation somewhat aggravated—viz., pain, heat, redness, and swelling; there is always some œdema of the affected part, and, as a consequence of it and the swelling, a tense, shining skin; a throbbing, synchronous with the pulse-beats, is one of the chief symptoms of the disease, and generally immediately precedes the suppurative process. In a few days the skin becomes red at one or more points, and fluctuation appears. Sometimes the œdema and swelling exist to such a marked extent that the skin is deprived of blood, and consequently becomes gangrenous; and as a complication immense sloughs of integument often come away, exposing the uncovered muscles and fasciæ beneath. Accompanying these local symptoms there is always a high fever. In the treatment the first indication should be to remedy as far as possible the condition of the system which has acted as a predisposing cause of the trouble: for this purpose aperients and such tonics as quinine and iron should be given. Locally, suppuration should be hastened by warm applications, and as soon as fluctuation appears at any point an exit should be made for the pus by the lancet; should two or more outlets be found to communicate subcutaneously, the sinus or sinuses should be laid open the entire length, and be allowed to heal from the bottom. Sometimes local depletion, if practiced at the outset of the disease, will cut it short. For *phlegmasia alba dolens*, see PHLEBITIS.

Revised by ROSWELL PARK.

Phlegon (in Gr. *Φλέγων*) OF TRALLES in Caria: Greek historian; freedman of the Emperor Hadrian, and author of a much-read historical compend in sixteen books called *Olympiads*, of which several chapters have been preserved. These and fragments of other works of his are to be found in Müller's *Fragmenta Historicorum Græcorum*, vol. iii., pp. 602–624. B. L. G.

Phlogis'ton: See CHEMISTRY and HYDROGEN.

Phlox [Mod. Lat., from Lat. *phlox* = Gr. *φλόξ*, a flower, so named from its bright color, special use of *φλόξ*, *φλογός*, flame]: a genus of a few annual and nearly thirty perennial herbs of the family *Polemoniaceæ*, all but one Siberian species North American. The phloxes cultivated in flower-gardens are mostly artificial varieties of *Phlox paniculata*, *maculata*, *drummondii*, and *subulata*, all natives of the Atlantic U. S. and Texas. Revised by L. H. BAILEY.

Phlox Family: the *Polemoniaceæ* (from *Polemonium*, one of the genera), a family of gamopetalous dicotyledonous plants, mostly herbs, distinguished from allied families by having regular and symmetrical flowers with the parts five each, except the superior pistil, which is of three carpels, forming a three-celled capsule. The seed-coat when wet usually develops mucilage and spiral threads, especially in the large genus *Gilia*. *Polemonium* (the Greek valerian or Jacob's ladder) is the only European genus, but the single European species is also North American, as are the few others and nearly all the rest of the family, except a few peculiar to South America, and one or two extending into Northeastern Asia. The family is rich in plants for ornamental cultivation, but is otherwise of no economic importance, the plants and their watery juice being bland and inert. PHLOX (*q. v.*) furnishes the gardens with numerous handsome perennials and one or two annuals, running into many varieties; *Gilia* supplies many annuals, chiefly Californian, and one or two showy biennials, such as the "standing cypress." A common cultivated climber, *Cobœa scandens*, with compound leaves and tendrils, is an anomalous member of the family from Mexico and South America.

Revised by CHARLES E. BESSEY.

Phocæ'a: the most northern of the twelve ancient Ionian cities of Asia Minor; founded by the Athenians on the Erythrean Cape, 200 stadia N. W. of Smyrna. Remarkable for maritime enterprise, its inhabitants were first of the Greeks to build fifty-oared galleys and to undertake distant voyages, traversing the Adriatic, Tuscan, and Black Seas. Attacked by Harpagus, general of Darius, the Phocæans abandoned their city rather than submit, and after long wanderings reached Gaul and founded Marseilles. Their abandoned city attracted colonists, again became rich and powerful, and desperately resisted the Romans. In the Middle Ages the Genoese founded a city, Phocæa Nuova, on the same spot, and with their ships aided the Ottomans against the Greeks. The present insignificant village of Phokia occupies the ancient site. E. A. GROSVENOR.

Phocas I.: Byzantine emperor (602–610); originally a groom in Cappadocia, then a common soldier, and finally general; was made emperor by the rebellion which deposed Mauritius. Brave before accession though always sanguinary, on the throne he became tyrannical and timid as if demented; was unsuccessful in war against Persia, whose armies marched to Chrysopolis (Scutari). Abhorred as a monster, he was deposed by the people, and put to death with frightful mutilations.—PHOCAS II., or NICEPHORUS II: Byzantine emperor (963–969); before his accession conquered Crete from the Saracens (962), and was decreed a triumph; was proclaimed emperor by the people shortly after the death of Romanus II.; was successful against the Mussulmans in Asia Minor, captured Aleppo and Antioch, made intimate alliance with Sviatoslav, Prince of Kief, and in subsequent wars was victorious throughout Armenia and Mesopotamia. At the height of his successes he was betrayed by his wife Theophania, and assassinated by John Zimisces, her paramour. E. A. GROSVENOR.

Phocidæ, fos'i-dĕe [Mod. Lat., named from *Pho'ca*, the typical genus, from Lat. *pho'ca* = Gr. *φώκη*, seal]: a family of pinniped mammals belonging to the order *Carnivora*, and containing the earless or hair seals. The nose is blunt, there are no external ears, the flippers are developed as swimming-paddles, the hind limbs, which alone are used in swimming, can not be directed forward, and, as a rule, all the digits bear claws, and are always without the cartilaginous prolongations peculiar to the eared seals (*Otariidæ*). With the exception of one genus (*Monachus*) all are inhabitants of the frigid and colder portions of the temperate zones. See SEAL. F. A. LUCAS.

Pho'cion (in Gr. *Φωκίων*): an Athenian general; b. about 402 B. C., of humble descent, but excellently educated; commanded with great success against Philip II. of Macedon in Eubœa, Megara, Byzantium, and other places. In politics, however, he sided with the Macedonian party, and was an unrelenting adversary of Demosthenes. After the death of Antipater he became implicated in the intrigues between Cassander and Polysperchon, fled to Phocis, was delivered up to the Athenians, and by them condemned to take poison (317 B. C.), and his corpse was hurled unburied across the frontier. One year later the Athenians raised his statue and erected a fine monument in his honor.

Revised by J. R. S. STERRETT.

Pho'cis [= Lat. = Gr. *Φωκίς*]: an ancient division of Greece in Hellas proper; was bounded S. by the Corinthian Gulf, E. by Bœotia, N. by Doris, and W. by Locris. It was very mountainous, being almost entirely covered with the famous mountain range of Parnassus. Its northeastern part was traversed by the river Cephissus, which formed a beautiful and fertile valley. Delphi, Elatea, and Cirrha were its principal towns. It derived its chief historical interest from the circumstance that the famous oracle of Delphi was situated in its territory; but this circumstance became at last the cause of its ruin. A verdict of the Amphictyonic Council ordered the Phocians to pay a fine for having used a tract of land which belonged to the oracle. When the Phocians refused to pay, a ten years' war (generally called the Sacred war), from 355 to 346 B. C., broke out, in which they fought bravely, maintaining themselves by the treasures of the temple; but at last they were conquered, chiefly by the strategy of Philip of Macedon, and then their cities, twenty-two in number, were destroyed, and they were scattered in villages, of which none was allowed to contain more than fifty houses.

Phocyl'ides (in Gr. *Φωκυλίδης*) OF MILETUS: Greek elegiac poet; flourished about the middle of the sixth century B. C.

His poems were of brief compass and conveyed moral lessons in more or less humorous forms. A few of these have been preserved. A transparent forgery called *Phocylidea*, in 230 hexameters, once diligently conned as an authoritative code of morals, is, according to Bernays, the fabrication of an Alexandrian Jew; the time is uncertain, but not later than Nero. Both real Phocylides and false in Bergk's *Poetæ Lyrici Græci* (4th ed. vol. ii., pp. 68–109). On the pseudo-Phocylides see the admirable treatise of Bernays in *Gesammelte Abhandlungen* (vol. i., pp. 192–261). B. L. GILDERSLEEVE.

Phœbe: See DIANA.

Phœ'be-bird, or **Pewee**: a well-known fly-catcher of the U. S., the *Sayornis fuscus*, which often builds under old bridges, mills, and at other points near the water. It is easily recognized by its well-known note, whence its name is derived.

Phœ'bus: See HELIUS.

Phœnicia [Gr. *Φοινίκη*. Etymology uncertain, but plausibly connected with *φοινός*, blood-red, a name applied to the people because of their complexion, analogous to the name *Edom*, which also signifies red]: the name given by the Greeks to the narrow strip of coast-land between the Lebanon Mountains and the Mediterranean. Its northern and southern limits were never accurately fixed, but in a general way Phœnicia may be said to extend from the mouth of the Nahr el-Kebir to Mt. Carmel. The breadth varies from 10 to 12 miles. Its excellent harbors gave it a most favorable situation for commerce, and as early as the fifteenth century B. C. the towns that afterward rose to such importance, as Sidon, Tyre, Byblos, Beirut, Acre, are already in existence. How much earlier the settlement of these places began it is impossible to say. The language of the country known among the natives as Canaan was at the time already Semitic (see PHŒNICIAN LANGUAGE), and the Phœnicians whenever they came either adopted or brought with them this speech. The lack of historical monuments makes it impossible to follow the history of the Phœnicians in unbroken sequence. Inscriptions in large numbers have been found both in Phœnicia itself and in the various settlements made by the Phœnicians, but they are generally of a religious or mortuary character, while the historical annals that appear to have been drawn up by native historiographers are lost, beyond a few fragments preserved in Greek writers. Upon the latter, in combination with the important notices found in the Old Testament and in the annals of Egyptian and Assyrian kings, the history of Phœnicia must largely depend for its reconstruction. The earliest notices that we have show the country to be in a state of dependence upon Egypt. Following the campaigns of Thothmes III. in the seventeenth century B. C., governors were stationed at various points along the coast under Egyptian control, whose duty it was to furnish the tribute imposed upon the country. This control, varying in firmness, continued until the fourteenth century, when the Hittites of Northern Syria appeared as formidable rivals to Egypt, and the latter, agitated by internal disturbances, was unable to retain her hold upon her foreign possessions. The centuries following marked the development of the commercial prosperity of Phœnicia, which gave her such an important place among the nations of antiquity. The native industries of dyes and the manufacture of glass were two of the chief factors that furnished the stimulus to her commercial activity, and about the year 1000 B. C. we find the position of the Phœnicians as the mediators between nations assured. At this time the extension of the Phœnicians beyond the mainland begins. The outlying island of Cyprus may have been settled by them even earlier. After Cyprus, the southern coast of Asia Minor and the islands of the Ægean became additional centers of commercial colonies, and about the ninth century the settlement of Carthage on the African coast took place. Other places followed with the growth of commercial interchange. Sicily, Sardinia, the southern coast of Spain, and, farther to the north, Marseilles, were founded by the Phœnicians. There seems to be no reason to question the tradition that Phœnician ships passed through the Strait of Gibraltar into the open sea and reached the English coast, though whether they actually brought back tin from the mines of Cornwall and amber from the Baltic ocean has not been definitely ascertained. Of the internal history of Phœnicia during all this period few details comparatively are known. The commercial spirit was not conducive to the unfolding of either military force or the creation of a strong national feeling. The cities appear to have been independent of one another for the greater part of their duration and only occasionally did the one or the other endeavor to extend her jurisdiction beyond her limits. In consequence of this lack of unity the Assyrian conquerors, when, in the ninth century, they began the serious conquests of the lands lying to the west of the Euphrates, met with comparatively little resistance; but the tribute imposed upon the cities did not seriously affect the commercial activity, which steadily assumed larger proportions, and it was not until the advent of the Greeks after Alexander's conquests that Phœnicia began to lose her importance. The independent existence of Phœnicia ended with the absorption of all of Syria and Palestine into the Roman empire.

The share taken by the Phœnicians in the propagation of the alphabet, which was probably not their invention (see PHŒNICIAN LANGUAGE), entitles them to an honorable place as potent factors of civilization. Their religion shows an eclectic character, such as we should expect in a nation commingling so largely with others. To the substratum of the primitive Semitic cult, elements taken from the Egyptian and Assyrian religions were added, and at a later period Greek ideas also made themselves felt. The chief god Baal was worshiped in many different manifestations, and the combination of the male and female elements was a distinguishing feature of the religious symbolism that led by a natural degeneration to rites, obscene when viewed from the surface, but redeemed by the mystic sense attached to them.

LITERATURE.—Pietschmann, *Geschichte der Phoenizier* (Berlin, 1889); Maspero, *Histoire ancienne de l'Orient*, chap. xi. (Paris); George Rawlinson, *History of Phœnicia* (not reliable; London, 1889); Meltzer, *Geschichte der Karthager* (Berlin, 1879); Duncker, *History of Antiquity* (Eng. trans. London, 1877, book iii.); Sayce, *Ancient Empires of the East* (chap. iii., London, 1884). Among older works Mover's *Die Phoenizier* (3 vols., Bonn, 1841–50) still retains its value, though antiquated in parts. MORRIS JASTROW, Jr.

Phœnician Language: a language belonging to the Semitic group (see SEMITIC LANGUAGES), spoken by the inhabitants of the ancient district of Phœnicia (native name *Canaan*), on the Mediterranean coast, but with the founding of colonies by the Phœnicians diffused through the islands of the Mediterranean and Ægean—notably Cyprus, Rhodes, Malta, Sicily, and Sardinia—along the southern and in part western coast of Asia Minor, the northern coast of Africa, and the southern coast of France. It is natural that in a language spread over so large a district dialectical variations should arise and become more pronounced with the lapse of time. Phœnician, as spoken and written on the African and Spanish coast and adjacent islands, is thus sufficiently marked off from that current in the mother-land and parts nearer to it to perhaps merit the distinct name of Punic—the term itself being only another form of Phœnician. This distinction extends also to a variation in the script, and it is possible even to differentiate within the Punic dialect between old and new Punic, but the differences touch only minor points, pronunciation and orthography rather than morphology proper and syntactical construction, so that the relation between eastern and western Phœnician may be appropriately compared to the divergences existing between the English of Great Britain and that heard in the U. S. As in the latter instance, the constant communication between Phœnicia and her colonies acted as a check to the accentuation of these differences sufficiently to preserve the unity of Phœnician speech. Our knowledge of the Phœnician language is derived (1) from the large number of inscriptions, mostly of a mortuary or votive character, found in Phœnicia itself, but more copiously in the various settlements, notably Carthage and Citium; also the names and phrases found on coins and seals; (2) the Phœnician phrases transliterated into Latin characters occurring in Plautus's comedy of *Pœnulus*: (3) the proper names and occasional words in the Old Testament, in the Egyptian and Assyrian inscriptions, and in classical writers. Of native Phœnician literature proper, which does not seem to have been very extensive, and so far as we know consisted largely of annals, nothing has been preserved beyond some fragments in Greek translation of Sanchuniathon and Hanno.

The inscriptions form naturally the most important source, but covering as they do the period (roughly speaking) from 600 B. C. to 200 A. D., they are not coextensive with Phœnician history, which approached its climax some centuries earlier, while a corrupt Punic dialect survived in Africa as

late as the fifth century of our era. On the other hand, the Phœnician phrases in Plautus, as well as the transliterated names and words revealed through the other sources mentioned, are of great value in determining the more precise form of the language as well as the pronunciation; for the Phœnician script, like all Semitic alphabets (except the Babylono-Assyrian cuneiform and the Ethiopic), expresses only the consonantal framework of the words, without any vowel signs and only a very sparing use of vowel letters. Even with this help, many features in the morphology of the language remain to be determined, even where the meaning of a text is perfectly clear.

It has been definitely ascertained that Phœnician belongs to the northern division of the Semitic group, and bears the closest resemblance to Hebrew (see HEBREW) and Moabitic. Indeed, the variations are so slight that it is regarded by some scholars as a Hebrew dialect. Hebrew and Phœnician may more appropriately be looked upon as two independent branches of some older form of Semitic speech once current in Palestine, and the peculiarities presented by each are due to the different course taken by the two peoples in their political, social, and religious development, just as the still slighter variations between Hebrew and Moabitic are to be accounted for. The more important points of divergence between the Hebrew and Phœnician are (1) the use of *Kûn* for the predicate verb in the latter (as in Arabic) instead of *hāyā*; (2) the more restricted use of the article; (3) the more frequent recurrence of certain suffixes, as *em*; and (4) lexicographical variations involving the common use of certain stems in Phœnician, as *pa'al*, to do, for which in Hebrew quite different ones are brought into requisition. In general, Phœnician betrays a more archaic stage of language than Hebrew, less indicative of phonetic decay, and simpler in its syntactical constructions. The scantiness of the vocabulary is due to the monotonous character of the epigraphical material, which also is disappointing in affording but little light for the history of Phœnicia and her colonies. See SEMITIC LANGUAGES.

The Phœnician script is an interesting and important study because of its position as the direct prototype of the Greek, Roman, and modern European alphabets on the one hand, and of the square character Hebrew, Palmyrene, Arabic, Nabatæan, Syriac on the other, while less directly the Sanskrit and derivatives and the Ethiopic are to be traced to the same source. The variations in the form of the characters are considerable as we pass from one century to another, while upon approaching the Neo-Punic period, the tendency to cursive script results in distortions which give the writing a confused appearance. The oldest specimen of "Phœnician" script being the Moabite Stone (about 850 B. C.), the origin of the alphabet must be placed at 1000 B. C. at the least. The question, however, as to the time and circumstances of its invention is still involved in obscurity. Recent epigraphical discoveries seem to show that in Southern Arabia and along the Abyssinian coast a more archaic form of the alphabet than even that of the Moabite Stone is to be found, and it is more than doubtful whether the Phœnicians, whose entire culture shows little traces of originality, are to be regarded as the inventors of the alphabet. De Rouge's theory, that the alphabet is a derivative of the hieroglyphic writing of Egypt, requires new investigation in the light of the advanced culture that has been shown to have flourished in Southern Arabia and Abyssinia as early at least as 1000 B. C. The contingency of these districts to Egypt and the commercial intercourse between them makes it probable that we must, after all, look to Egypt as the source of the alphabet, if future investigations should bear out the proposition that it originated among the Semites of Southern Arabia, and was by them transmitted to the Phœnicians. See ALPHABET.

LITERATURE.—Schroeder, *Die Phoenizische Sprache* (Halle, 1869); Bloch, *Phoenizisches Glossar* (Berlin, 1891); Stade, *Erneute Prüfung des zwischen dem Phoenicischen und Hebräischen bestehenden Verwandschaftsgrades*, in *Morgenländische Forschungen* (Leipzig, 1875); M. A. Levy, *Phoenizische Studien* (Breslau, 1857–64); Renan, *Histoire générale des Langues Sémitiques* (5th ed. Paris, 1878), pp. 181–211. The most complete collection of Phœnician inscriptions is to be found in the *Corpus Inscriptionum Semiticarum* (Paris, 1881–87), published under the auspices of the Académie des Inscriptions et Belles-Lettres. Previous to this the standard work was Gesenius's *Scripturæ linguæque Phœniciæ monumenta quotquot supersunt edita et inedita* (3 vols., Leipzig, 1887). MORRIS JASTROW, Jr.

Phœnicopter'idæ [Mod. Lat., named from *Phœnicopterus*, the typical genus; Gr. φοῖνιξ, purple red, red + πτερόν, feather, wing]: a family of birds of peculiar organization, whose species are known under the English name flamingoes. In their osseous structure, as in their external characters, they are almost intermediate between the duck-like birds (*Anatidæ* and *Palamedeidæ*) and the stork-like birds (*Ciconiidæ*); there has, therefore, been considerable doubt as to their systematic position, some authors having associated them with the wading birds, and others with swimming birds; on the whole, however, they appear to be most closely related to the swimming birds, although forming a peculiar type or "super-family" by themselves, named by Huxley *Amphimorphæ*. See FLAMINGO.

Phœ'nix [= Lat. = Gr. φοῖνιξ; cf. Egypt. *bennu*]: a fabled bird, whose prototype is found in the Egyptian *Bennu*; sacred to Osiris, and also, particularly, as a form of the rising sun, to Ra, the sun-god. In the hieroglyphs the *bennu* is represented as a heron, but in classical myth, following Herodotus (ii., 73), the phœnix was given the form of an eagle. It was reputed to have its origin amid flame in the top of a sacred tree at Heliopolis. Herodotus represents it as an Arabian bird which arises from its own ashes in Heliopolis once in 500 years, but the myth assumed a variety of other forms. CHARLES R. GILLETT.

Phœnix: city; capital of Arizona and of Maricopa County; on the Salt river, and the Maricopa and Phœnix and Santa Fé railroads; 226 miles N. E. of Yuma (for location, see map of Arizona, ref. 13–L). It is in an agricultural, stock-raising, and mining region, and contains 2 national banks with combined capital of $200,000, 3 incorporated banks with capital of $215,200, a savings-bank with capital of $100,000, a State bank with capital of $50,000, and 3 daily and 5 weekly newspapers. Pop. (1890) 3,152; (1900) 5,544.

Phœnix: village; Oswego co., N. Y.; on the Oswego river, the Oswego Canal, and the Rome, Watertown, and Ogdensburg Railroad; 16 miles N. of Syracuse (for location, see map of New York, ref. 3–G). It is in an agricultural region, and has large interests in stock-raising, tobacco-growing, and dairying. The river and canal afford good water-power, which is utilized by saw and flour mills, and other manufactories. There are a State bank with a capital of $35,000, and a weekly newspaper. Pop. (1880) 1,312; (1890) 1,466; (1900) 1,532.

Phœnixville: borough (founded as a forge in 1792, incorporated as a borough in 1848); Chester co., Pa.; at the junction of the Schuylkill river and French creek; on the Penn. and the Phila. and Reading railways; 28 miles N. W. of Philadelphia, 30 miles E. S. E. of Reading (for location, see map of Pennsylvania, ref. 6–I). It is widely known for its rolling-mills, blast-furnaces, and iron-works, and their products, such as iron bridges, girders, columns, and other heavy work, and for its hosiery-factories. There are gas, electric-light, and water plants, a denominational and 4 public schools, public park, library, 2 national banks with combined capital of $300,000, and a daily and 2 weekly newspapers. Pop. (1880) 6,682; (1890) 8,514; (1900) 9,196. EDITOR OF "REPUBLICAN."

Phonautograph: See ACOUSTICS.

Phonetic Laws: the laws governing the changes of sound in the historical development of a language. When a sound-change like that of Old English *ā* (pron. *aa*) to English *ō* is observed to have taken place in a great number of words widely separated from each other in meaning and use, the possibility of anything like collusion or a conscious regulation of one word according to the sound of another is entirely excluded, and it is evident that the change is a matter of individual sounds and not of complete words as such; cf. O. Eng. *hām* > Eng. *home*; *dāg* > *dough* (*dō*); *hlāf* > *loaf* (*lōf*); *strād* > *strōde*; *cnāwan* > *knōw*; *þās* > *thōse*; *nā* > *nō*, etc. If a matter of individual sounds, this change can not have been subject to conscious direction, because in the natural and unstudied pronunciation of words the individual articulations from which the sounds result are made unconsciously. Except after careful acoustic and physiological analysis the speaker is not aware, for instance, that in the word *judge* he employs the compound consonant *dž* twice (i. e. *džŭdž*). He is not aware that the *g* in *give* differs from that in *got*, or that the *m* in *lamp* is different from that in *lamb*, or that the *th* in *thin* differs from that in *then*; or, if he is, he does not without analysis and reflection know wherein the difference lies. The production of speech, moreover, does not consist in the juxtaposition of a

certain number of definite and complete articulations, but in a current of sound checked, deflected, and guided by organs which are in continuous and generally complicated simultaneous movement. As the organs pass from one point of articulation to another speech goes on, and the number of different sounds produced is really infinite. An absolutely correct analysis of speech has not yet been attained, even by scientific observation and reflection.

In view of such considerations as these, it is evident that the production of sounds is not governed by consciousness. Consequently the assumption of sporadic, in the sense of willful, sound-changes, subject to the speaker's choice or caprice, is untenable. The power of an individual willfully to mispronounce a word is undeniable, but an occurrence like this does not constitute a fact of language history. Language is a *social* institution. If a case could actually be found where the willful and capricious mispronunciation of an individual had by imitation been adopted by a whole speech community and become the unconscious possession of their language, then it would be a case of a loan-word in just the same sense as *rouge* is a loan-word from the French.

Phonetic change is in its inception due to minute and unconscious deviations in the speech of individuals. As speech is a social institution in which intelligibility is of even higher importance than expression, these deviations are continually subject to correction, (1) by the necessity of intelligibility, (2) by the impressions received from the speech of others, as well as the impressions received from the speaker's own more accurate articulations. Before, therefore, any deviation can establish itself in the language of the community, it must do so as the resultant of a practically infinite number of modifying forces. The language of a community is therefore in reality an ideal to which the speech of the individual is always being drawn back, but to which in each single case of speaking it may not absolutely conform.

As the conditions which produce the changes of sounds are not dependent on the particular words in which the sounds occur, it is evident that there can be no reason to expect like-conditioned sounds to be differently treated in different words. On the contrary, we should expect a phonetic change to reach throughout the whole like-conditioned material of the language. This expectation finds more and more confirmation as language comes to be more accurately observed in its natural developments. The principle that the laws of sound suffer no exception was first stated by August Leskien in the introduction to his *Declination im Slavisch-Litauischen und Germanischen* (1876), and has since that time been vigorously attacked, vigorously defended, and widely applied in investigation. Though only a scientific dogma, it constitutes the only safe guide in etymological research, and is theoretically defensible within the limits of the perfectly natural developments of folk-speech in a compact and homogeneous speech-community. When a sound-change is in the act of extending itself from the narrow speech-community where it is native to a wider speech area it undoubtedly seems to progress from word to word—i. e. it manifests itself in some words before others; thus in the case discussed by W. D. Whitney, *Indogermanische Forschungen*, iv., 32 ff. Such cases do not, however, contravene in the least the theory of uniformity in phonetic change. They fall under the head of processes for the unification and solidification of language. Phonetic laws are not laws in the sense of physical laws, but, as may be inferred from the foregoing, are socio-historical in character. As Paul has expressed it (*Principien*, chap. iii.): "Sound-law does not pretend to state what must always under certain general conditions regularly recur, but merely expresses the reign of uniformity within a group of definite historical phenomena."

Delbrück, *Die neueste Sprachforschung* (1885); K. Brugmann, *Zum heutigen Stand der Sprachwissenschaft* (1885). Opposed to the view here maintained are, e. g., G. Curtius, *Zur Kritik der neuesten Sprachforschung* (1885): H. Schuchardt, *Ueber die Lautgesetze* (1885); F. B. Tarbell, *Phonetic Law* (in *Transactions of the American Philological Association*, vol. xvii., 1886).

BENJ. IDE WHEELER.

Phonetics [noun use of plur. of *phonetic*, pertaining to sounds, from Gr. *φωνητικός*, pertaining to sounds or to the voice, deriv. of *φωνή*, sound, voice]: the science of speech-sounds, and, in the usage of some, also the art of representing their combinations by writing. Speech-sounds are such of the phenomena of the resonance of inclosed masses of air variously excited by the organs of speech as are used for communication of thought. The resonance cavities are the larynx, pharynx, nasal passages, and mouth, with various smaller parts. Each cavity has a separate resonance, and each resonance acts more or less in combination with all the others. The action of the resonance for vowels was first (though incompletely) explained by Helmholtz (*Sensations of Tone*; see Ellis's translation, 2d ed., 1885, pp. 103–119, 123, 538–543). It is necessary to distinguish the mode of exciting resonance and the fixed or variable forms of the resonance-cavities.

I. *Mode of Exciting Resonance.*—(1) "Irrespirates," sounds independent of respiration, which may or may not be carried on at the same time through the nose. The air in the resonance-cavities is excited by smacks, clicks, smokers' mouth-puffs, blowpiper's cheek-puffs, or implosion (due to sudden condensation). All these are recognized elements of language. (2) "Inspirates," sounds arising from drawing in air—(*a*) through the mouth only, as in chirps, whistles, sobs, gasps; (*b*) through the nose only, as in snuffling; or (*c*) through both nose and mouth, as in snoring. Common elements of expression, even in English. (3) "Expirates," sounds arising from expelling air from the lungs. These are the commonest and most important elements of speech. (*a*) "Physems" (a name not in general use), or bellows-actions of the lungs, with constant pressure (force, loudness, and much of modern accent), with discontinuous pressure (jerks, the main element of aspiration), or with condensation suddenly relieved (explosions, one element of post-aspiration). (*b*) "Glottids," or actions of the elastic glottis, which, when the vocal chords forming it are wide apart, give either inaudible breath (physem weak) or "flatus"—that is, audible breath (physem strong). When the glottis is narrowed, but not closed, they give "whisper." When the glottis is closed elastically, they give "voice." When the glottis is closed inelastically, they give the Arabic *hamza*, or "check." These actions also, chiefly by various tensions of the vocal chords, produce variety of pitch (musical accent, singing), and by different arrangements regulate the size and distinctness of the periodical puffs of air on which voice depends (original quality of tone, expression), with other effects not so marked. (*c*) "Arytēnads" (a name scarcely used), or actions of the gristly glottis, giving by various actions the Arabic *hha* or wheeze, and *ain* or bleat, and the Danish *r* (?). (*d*) "Hisses" (generally restricted to voiceless sibilants), arising from flatus driven through narrow passages, as for *s*, *sh*. (*e*) "Sonants" (or voiced stops, voiced explosives), arising from driving the voice into closed cavities, where the air rapidly becomes too condensed to sound. (*f*) "Buzzes" (generally restricted to voiced sibilants), arising from driving the voice laboriously through passages suitable for hisses, and hence producing the effect of a mixture of voice and flatus, as for *z*, *zh*. (*g*) "Vocals" (a name hardly used in this narrow sense, but, like "sonant," sometimes applied to all voiced sounds), arising from driving the voice easily through a partially obstructed cavity, or one which may be periodically obstructed and relieved by a vibrating membrane, as for *l*, *r*. (*h*) "Vowels," arising from letting the voice resound clearly in comparatively unobstructed cavities of the mouth separately, or mouth and nose combined, which modify the original quality of tone.

II. *Fixed Forms of Resonance-cavities.*—(*a*) "Oral vowel positions," the uvula, being pressed against the back wall of the pharynx, shuts off the nasal cavities; the tongue, in part or in whole, is raised to different heights within the mouth, but not sufficiently to touch the palate; the throat (pharynx), in whole or in part, is lengthened, shortened, widened or narrowed; the lips are more or less closed or opened; or all these alterations of tongue, throat, and lips are variously combined. The number of possible oral vowels is infinite; fifteen to twenty of them are common in European languages. (*b*) "Orinasal vowel positions," the nasal passages are open to the larynx by the advance of the uvula, and the various membranes of the nose are variously brought into action, at the same time that the various oral vowel positions are assumed. Each oral vowel generates various kinds of orinasal vowels (generally called simply nasal vowels). The four French orinasals in the words *an*, *on*, *un*, *vin* are best known. (*c*) "Oral consonant positions" have the nasal passages cut off, as for oral vowel positions, and either entirely

obstruct the passage of air, flatus, or voice, as (1) for mutes (i. e. voiceless stops or voiceless explosives), *p*, *t*, *k*, positions without sound and rendered effective only by "glides"; (2) for implodents, with a sound due to implosion, as in modern Saxon, *p*, *b* or *t*, *d* (I., 1); and (3) for sonants (as *b*, *d*, *g*, I., 3, *e*); or are only adapted for "hisses" (such as *f*, *s*, *sh*, *th*, I., 3, *d*), "buzzes" (such as *v*, *z*, *zh*, *dh*, I., 3, *f*), or "vocals" (such as *l*, *r*, I., 3, *g*), by the formation of narrow or choked passages, or the introduction of a (possibly) vibrating valve.* Such positions are very numerous. (*d*) "Nasal consonant positions" have the nasal passage open, but the mouth (generally) closed as for mutes, and are generally accompanied by voice (as *m*, *n*, *ng*), but many other forms occur.†

III. *Changing Forms of Resonance-cavities.*—(1) If while a violin-string is bowed the stopping finger is slid on the finger-board from the nut toward the bridge, the result is a series of musical sounds, changing by insensible degrees. The first and last sounds may or may not be of sensible duration. In each case the changing sounds are called "glides." (2) If the extreme sounds have sensible duration and the glide is short, the glide becomes a "slur," to which case the word will be here specially limited, although musically it has a wider signification. (3) When no glide or slur occurs, there is a "break" or silence during change of position. (4) In speech, glides and slurs are the cement by which elements are bound into syllables. Speech-glides were first recognized in Ellis's *English Phonetics* (1854), and slurs in his *Early English Pronunciation* (part iv., 1874, p. 1130). They generally arise from continuing sound during change of resonance-cavity, but there are also (5) "force-glides," arising from continuously variable bellows-action of the lungs; (6) "pitch-glides," from continuous alterations, chiefly in the tension of the vocal chords; and (7) "glottal glides," from continuous alterations in the degree of separation of the vocal chords, changing from flatus through whisper to voice, and conversely; and (8) "arytēnad glides," arising from continuous changing position of the gristly glottis. (9) "Vowel glides" arise from passing from one vowel position to another, and may be "lip," "tongue," or "throat glides," separately or combined two or three together, the results being "diphthongs" and "fractures" of the most diverse character and of great philological importance. (10) "Mixed glides" arise from passing from a consonant to a vowel position, and conversely, and are most remarkable in the case of mutes, as in *peep*, *took*, because it is solely by the glide that the mute becomes effective. When final, the mute often glides on to a click or some flatus (in English), and often (in English and German) flatus is interposed between the mute and the vowel, producing a passing glottal glide, the habits of different nations and individuals being extremely different. In such words as *see*, *cease*, *seize* there are glottal as well as mixed glides. (11) "Consonant glides" occur when we pass from one consonant position to another, of which one at least is capable of flated or voiced resonance, as in *tree*, where there is a consonant glide from *t* to *r*, and a mixed glide from *r* to *ee*. (12) All these glides give rise to slurs, which are more convenient to the speaker than breaks, because breathing is uninterrupted, and hence they constantly occur between syllables. (13) "Breaks" occur where the passage of breath is interrupted by some suspension of expiration, some check of the glottis, or some mute consonant. The study of glides is one of the most important parts of phonetics for clear enunciation, intelligible singing, and comparative philology.

The above analysis of speech-sounds, here merely indicated, results from the most recent physiological and linguistic investigations, and its great complication would apparently involve immense difficulty in the attempt to find a method of representing speech-sounds to the eye. All the accepted alphabets of both ancient and modern times are more or less defective as representations of the phenomena of speech. When the Greeks borrowed the Phœnician syllabary, they gave it a real alphabetic character. It was in this form that the Romans adapted the same Phœnician characters to their needs, and from these two original sources all modern European alphabets are derived. At an early period the Roman alphabetic system became general for most Aryan languages, and was subsequently used for languages of different families, as Basque and Hungarian. The diverse nature of the selection of speech-sounds and systems of glides and accents in use among the different nations of Europe has caused the Roman letters, individually and in groups, to have different significations in the several countries using them, and to be practically increased in number by the addition of various diacritical marks. These systems of writing were in many cases introduced by "clerks" (ecclesiastics), who were satisfied with a rough indication of the sounds of words at remote periods when the sounds of the languages thus reduced to writing were different from those now in use; but there was always an indisposition to make any changes in orthography, and this indisposition has increased since printing became widely used. Hence the groups of letters have in many instances ceased altogether to recall the sounds of the words, and consequently alphabetical writing has in numerous instances almost reverted to ideographical symbolization. This is especially the case in English, where sign and sound are so practically independent, to the great detriment of education, that no one who sees an English word for the first time knows how to speak it, and no one who hears an English word for the first time knows how to spell it.

Missionary enterprise and scientific linguistics have raised the question of a universal alphabet capable of writing all languages. We are still very far from being able to determine what should be the value, number, or form of the separate elementary symbols in such an alphabet, and how their combination should be indicated. Prof. Lepsius, of Berlin, invented the "linguistic alphabet" (German ed. 1855), adopted under the name of the "standard alphabet" by the English Church Missionary Society in 1858 (2d English ed. 1863), and approved by many other missionary societies. It consists of a mixture of Latin and Greek letters, supplemented by a vast complication of diacritical marks, which render its use so laborious that in special adaptations most of these marks are omitted. It requires new fonts of types, and, notwithstanding the number of its symbols (more than 250), it is defective for well-known languages, both in characters for elementary sounds and in the means of representing glides. Prof. Brücke's *Neue Methode der phonetischen Transscription* (1863) with entirely new letters is also inadequate. In A. Melville Bell's *Visible Speech* (1867)* the characters are formed on the principle of picturing the positions of the speech-organs. It embraces a philosophic consideration of vowels as well as of consonants, and although by no means perfect, it was by far the best and most practical attempt yet made. It has been improved by Henry Sweet, who has also provided a corresponding alphabet (revised Romic) consisting of Roman letters and various other signs already used in printing. (See his paper on *Sound Notation*, in *Transactions of the Philological Society* (1880–81), pt. ii., 177–235.) Neither these, however, nor any other system yet proposed can be considered as an entirely satisfactory solution of the problem. For the purposes of Ellis's *Early English Pronunciation* (1869–89) he introduced a temporary system called "Palæotype," because it can be readily printed with ordinary or old types. It is too complicated and confusing, however, for general use.

In the meantime, the question of particular phonetics, or of writing the sounds of a particular language with sufficient accuracy for native use, is comparatively easy. It will be sufficient to mention here four of the proposed methods of writing English on a phonetic basis. 1. Ellis's Glossic; see his article in *Transactions of the Philological Society*, 1870, pt. i., *On Glosik, a neu sistem ov Ingglish speling, proapoa·zd faur konkur·ent eus, in aurder too remidi dhi difek·ts, widhout ditrak·ting from dhi valeu ov our prezent aurthog·rafi*. As this example shows, glossic often uses combinations of letters to express single sounds, but each of such combinations is used always with the same value, and this is in most cases determined by the commonest value of the same combination in the usual spelling of English at the present day. 2. Sweet's broad Romic (less complicated than the revised Romic mentioned above), in which the most important single sounds are now represented by single signs, generally Roman letters used with approximately their original Latin values. See for slightly different forms of it his *Handbook of Phonetics* (1877, pp. 191, 192); *Primer of Phonetics* (1890, pp. 71–82); *Elementarbuch des gesprochenen Englisch* (3d ed. 1891); *Primer of Spoken*

* Ellis's "hisses" and "buzzes" include what are more often called spirants or fricatives; they should be carefully distinguished from aspirates. English *sh* in *shut*, *th* in *thin*, *this*, for example, are in strict phonetic use not aspirates but spirants or fricatives. See ASPIRATE.

† The terminology of phonetics is different with different writers. See the list of terms in the appendix of Jespersen's book mentioned on the next page.

* See also his *Sounds and their Relations* (1881).

English (1890). Similar to this, but more minute, is the system of indicating the pronunciation in the *New English Dictionary* (since 1884). 3. The World-English alphabet of A. Melville Bell; see his *World-English* (1888). 4. The phonetic alphabet proposed in the report of a committee of the American Philological Association in 1877; see that report (in the *Proceedings* of the Association) and *The Spelling Reform*, by Francis A. March in *Circular of Information No. 8*, published by the Bureau of Education in 1893.

In recent years the study of phonetics has been vigorously pursued, and many valuable investigations have been published. Among the books and papers of importance, besides the work of Sweet, are Sievers, *Grundzüge der Phonetik* (4th ed. 1893, excellent; contains also a useful bibliography); Trautmann, *Die Sprachlaute im Atlgemeinen und die Laute des Englischen, Französischen und Deutschen im Besonderen* (1884–86); W. Vietor, *Elemente der Phonetik des Deutschen, Englischen und Französischen* (3d ed., first part, 1893; Victor was also the editor of *Phonetische Studien*, 6 vols., 1887–93, now succeeded by *Die Neueren Sprachen* with the *Beiblatt*, *Phonetische Studien*); P. Passy, *Étude sur les changements phonétiques*, etc. (1890; Passy is the editor of *Le Maître Phonétique*, 1889 and since; earlier numbers beginning in 1886 were called *Dhi Fonètik Tîtcer*); Rousselot, *La méthode graphique appliquée à la recherche des transformations inconscientes du langage* (1891), and *Les modifications phonétiques du langage*, etc., in *Revue des patois gallo-romans* (1891, pp. 65–208. The work of Rousselot is particularly valuable for experimental observations with apparatus); Techmer, *Phonetik* (1880), and articles in *Internationale Zeitschrift für allgemeine Sprachwissenschaft*; Jespersen, *The Articulations of Speech Sounds represented by Means of Analphabetic Symbols* (1889); Sheldon and Grandgent, *Phonetic Compensations* (in *Mod. Lang. Notes*, June, 1888, 354–374, vol. iii.); Grandgent, *Vowel Measuremets* (in *Pub. of the Mod. Lang. Assoc. of America*, suppl. to vol. v., pp. 148 ff.; an excellent description of a method for determining the shape of the oral cavity in the vowels of natural speech); R. J. Lloyd, *Speech Sounds: their Nature and Causation* (in *Phonetische Studien*, iii., 251 ff., iv., 37 ff., 183 ff., 275 ff., v., 1 ff., 129 ff., 263 ff.; see also the bibliography in Sievers. Lloyd considers the acoustic side especially, making investigations similar to those of Helmholtz, and throwing new light on the problems of vowel-sounds); Johan Storm, *Engtische Phitotogie*, i., *Die lebende Sprache, 1. Abteilung : Phonetik und Aussprache* (2d ed. 1892; this is largely devoted to phonetics in general, and contains admirable discussions of some of the most important works on the subject); R. L. Weeks, *A Method of Recording the Soft-palate Movements in Speech* (in *Harvard Studies and Notes in Phitotogy and Literature*, ii., 213 ff.); L. Soames, *An Introduction to Phonetics* (*English, French, and German*) (1891; a good introduction to the subject for English speakers); Bremer, *Deutsche Phonetik* (Leipzig, 1893).

ALEX. J. ELLIS.
Revised by E. S. SHELDON.

Phonograph: an instrument for recording and reproducing sound. The problem of recording sound was solved long before its reproduction was accomplished. In 1807 Dr. Thomas Young pointed out a method by which a tuning-fork might be made to trace a record of its own vibrations, but nearly half a century seems to have elapsed before this hint was put into practice by Wertheim and Duhamel. A light pointed style is attached to the end of one prong of the fork, and made to press against a surface of smoked glass or paper; and this is then moved in the direction across which the prong is vibrating. The combination of these two motions produces a sinuous line, and the character of this curve is determined by the nature of the motion which at the same time impresses the ear as sound. In the phonautograph of Scott and Koenig (see ACOUSTICS) the tuning-fork is replaced by a stretched membrane at one end of a drum, into which the sound is directed, while the tracing of the style is made upon smoked paper encircling a cylinder. The rotation of this cylinder is compounded with lateral motion in the direction of its axis by means of a screw thread cut upon the axial shaft, and moving in a fixed nut when the handle is turned. In Barlow's logograph, constructed in 1873, the drum is replaced by a short trumpet, and to the vibrating membrane a delicate ink-marker is attached. In 1876 Dr. C. J. Blake obtained very fine tracings by employing the tympanum of a human ear for a logograph. In 1878 Prof. E. W. Blake photographed the motion of an elastic disk set into vibration through sound-waves produced by the voice. To the disk a small mirror was attached, and from this a beam of sunlight was reflected upon a moving photographic plate.

All of the contrivances just described may quite properly be called phonographs. This graphic method has been carried to the utmost perfection by Rudolph Koenig, of Paris; but it implies no attempt to produce a talking-machine, however accurately the peculiarities of articulate speech may be registered. An elaborate talking-machine was perfected by the two Fabers, father and son, in Vienna, the outcome of many years of work. This instrument was exhibited in the U. S. in 1883. An air-blast is sent through a rather complicated arrangement of vents, in which the action of the human organs of speech is imitated as nearly as possible. It is indeed a special form of cabinet organ from which articulate words are uttered in a monotone, each word being phonetically spelled out by skillful manipulation of a keyboard. There is no attempt to register speech, but the mechanical manufacture of speech is successfully accomplished without the reproduction of sounds from any articulate source.

In 1877 Thomas A. Edison applied to a telephone disk a style which pressed upon a strip of tin-foil, his object being the attainment of a self-recording telephone. Accidental motion of the indented foil under the style caused a momentary reproduction of the sounds which had actuated the telephone disk. This suggested his invention of the modern phonograph, which was first exhibited in 1878. A telephone mouthpiece was adjusted close to a cylinder, such as is employed with the Scott phonautograph. To the telephone disk was attached a metal point, made to press gently on tin-foil, with which the cylinder was covered. Into the surface of the cylinder a spiral groove was cut, corresponding to the pitch of the axial screw. By motion of the metal point the plastic tin-foil was pressed into the groove beneath it, receiving thus a series of slight indentations, which constituted the registration of the exciting sound. When this line of indentations was made to pass under the metal point again the variable pressure thus given caused the disk to repeat the vibrations originally impressed upon it by the voice; and a talking-machine was thus secured which gave forth articulation, not in a monotone, but with the variations of pitch, loudness, and quality that had characterized the voice of the speaker. The reproduction was not quite perfect, but it was incomparably superior to the outcome of any previous effort to imitate the human voice.

Interesting as was the phonograph, considered as a triumph of ingenuity, it was not found capable of satisfactory commercial use. Modifications of it were devised, of which the most important were the graphophone, by Bell and Tainter, and the gramophone, by Berliner. In the former of these a cylinder of wax, hardened slightly by admixture of paraffin or some other similar waxy substance, was substituted for tin-foil. In Berliner's gramophone, instead of indentations a sinuous line is made, as with Scott's phonautograph; but this is traced upon a horizontal revolving disk of zinc, covered with a thin coating of wax. The plate is then dipped into a solution of chromic acid, so that the line is etched into the zinc. Such a plate when passed again under the style gives lateral motion to this, which is communicated to the disk, resulting in very satisfactory articulate sound.

Since 1886 Edison has improved the phonograph, adopting the use of a wax cylinder, with two separate mouthpieces, having specially prepared styles—one for transmitter, the other for receiver. The elastic disks are made of glass, and great improvement has been secured in distinctness of articulation, but with corresponding loss of loudness. From the receiving disk a pair of tubes are conveyed to the hearer's ears. To secure the utmost regularity in speed of rotation an electric motor is employed to actuate the wax cylinder. Its delicacy and accuracy in reproduction are very remarkable. Not only talking, but also whistling, singing, whispering, and the playing of any musical instrument whatever may be very perfectly repeated by it.

The uses to which the phonograph may be put are manifold, but the actual uses have been thus far somewhat limited. The wax cylinders are capable of ready transportation by mail, the capacity of each varying from 100 to 1,000 words, according to size. Aside from the purposes of entertainment, the phonograph is used in business as an aid to the stenographer and the typewriter.

W. LE CONTE STEVENS.

Phonog'raphy [Gr. *φωνή*, sound + *γράφειν*, write]: any system of writing in which a phonetic spelling is used. The term, however, is used specifically for any system of writing in which the phonetic elements of words are represented by "simple and easily formed signs, which readily enter into every combination required," the same sign never being used to represent more than one sound or articulation. The name "phonography" was first applied to a system of shorthand writing by Isaac Pitman in the second edition of his system, published in London in 1840, but had been applied as early as 1701 to a little work on phonetic spelling by J. Jones, M. D., London. The appearance of Pitman's system (first ed. London, 1837) marked an era in the history of shorthand writing. By the introduction of a more accurate analysis of the vocal elements of the English tongue, and a more systematic presentation of the shorthand art, Pitman did very much to bring the possibility of verbatim reporting within the reach of persons of ordinary adaptability for the practice of the art. His system has been the basis of every subsequent system which has received any considerable degree of public support. The chief of these are Graham's (that presented in this article), Munson's, Bishops', Cross's Burnz's, Lindsley's, and Osgoodby's. Graham's system is now written by about 50 per cent. of the official stenographers; and a large proportion of the other shorthand writers, in the U. S.

FIG. 1.—The consonant signs.

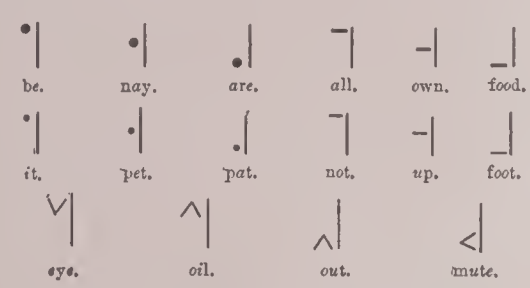

FIG. 2.—The vowel scale.

characters—dots, right-lines, and curves—variously modified and combined. Signs are provided for forty elements in the "working alphabet." The consonants, with their appropriate signs and names, are illustrated in Fig. 1. The vowels are represented by means of dots and dashes. They are written by the side of a consonant stroke, and the vowel-scale is made extensive by giving a different vowel-significance to the dot or dash according as it is written opposite the beginning, middle, or end of the stroke. The vowels are read before or after an adjacent consonant, according as they are written before or after perpendicular or inclined, or above or below horizontal strokes. (See Fig. 2.) They are named by their sound. In rapid writing they are not inserted except to indicate words of unusual occurrence or to vocalize proper names. Indeed, the consonant outlines of words are found to be so legible and suggestive that the vowels are usually left out even in phonographic correspondence. Fig. 3 shows how the consonants are combined in forming words.

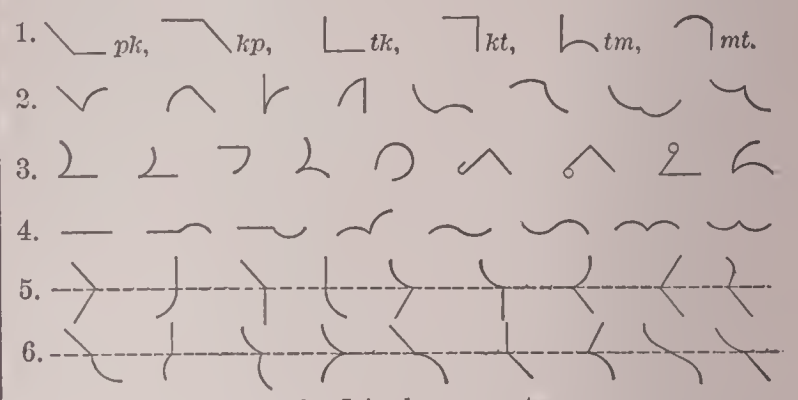

FIG. 3.—Joined consonants.

Modifications of the Consonant Strokes.—The primary consonant strokes are variously modified to indicate the addition of other consonants; thus a small initial hook indicates the addition of *l* or *r*, according to the side on which it is written. A large initial hook indicates the addition *lr* (as in *ler*, *lor*, *lar*) or *rl* (as in *rel*, *ral*, etc.), according to the side on which it is written (see Fig. 4). A small final hook indicates the addition of the sound of *f*, *v*, or *n*; and a large final hook the addition of *shn* (*tion*, *sion*, *cion*, *cian*, etc.) or *tive*, according to the side on which it is written. The *iss* circle when written at the beginning of a stroke (hooked or not) implies that the stroke is preceded by *s*; when written at the end of a stroke (hooked or not), that the stroke is followed by *s*. The *ses* circle occurring initially or finally implies the precedence or succedence of *cis*, *ces*, *sis*, *ses*, *sus*, *sas*, etc. The *steh* loop initial or final indicates *st*. The *ster* loop indicates *str* (as in *ster*, *stor*, etc.), but is not written initially. These circles and loops when written finally, on the side of the *n* hook (by making the hook into a circle or loop), signify the addition of *n-s*, *n-ses*, *cis*, etc., *n-st* or *n-str* to the stroke. The sound of *s* may be added to a stroke modified by an *f* hook by writing the *iss* circle within the hook. *S* may be made to precede a stroke modified by an *l* or *r* hook by writing the *iss* circle within the *l* hook, or by making the *r* hook into a circle. By *halving* a stroke (writing it half length) *t* or *d* is added, according as the stroke is light or heavy; by *lengthening* (writing it double length), *tr*, *dr*, *thr*, or *Thr* is added, according as the stroke is light or heavy; by *widening*, *p* or *b* is added.

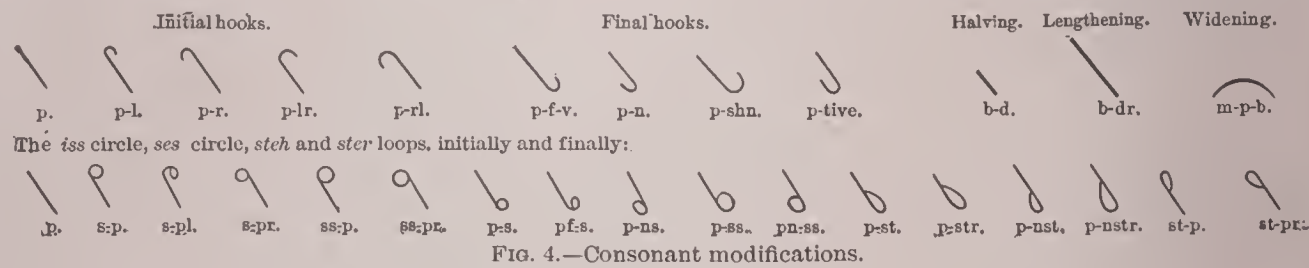

FIG. 4.—Consonant modifications.

Expedients for increasing Speed.—Various other expedients are made use of, as an initial dot or tick or small

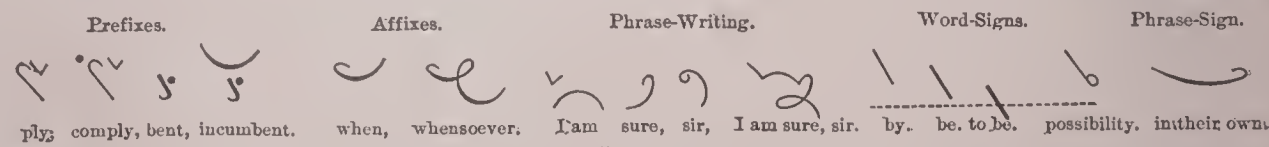

FIG. 5.

circle to imply a prefix, as *con*, *com*, *cog*, *circum*, *contra*, *self-con*, or *self-com*; a final dot or tick (light or heavy), or circle, to indicate the imperfect participle of verbs, an adverbial or other affix, as *ing*, *ings*, or *ly*; *self*, *selves*, *-bleness*, *-fulness*, etc. Other affixes are indicated by an abbreviated termination, as *sv* for "soever" in *whosoever*, *whensoever*, etc.; and the omission of the connecting preposition "of," or of the prepositional phrases "of the," "of a," is indicated by writing two words near together, and the omission of "to" or "two" by writing the following outline just under the line of writing. See Fig. 5.

Two other expedients for increasing speed remain to be noticed—phrase-writing and word-signs. By phrase-writing is meant the junction of several words without lifting the pen. This does not diminish, but rather increases, the legibility of the writing where the words are grammatically closely related, as in the phrase "I am sure." By the term word-sign is meant a primary character, simple or modified, which is memorized as an arbitrary and abbreviated expression of a certain word or words. The principle of word-signs is carried to a great extent, and like phrase-writing is one of the reporter's most important aids for increasing the speed of his writing. See Stenography and Pitman's *History of Shorthand* (1891). Revised by R. Lilley.

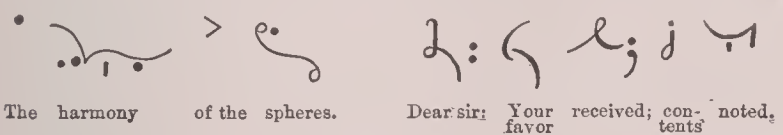

Fig. 6.—The corresponding style.

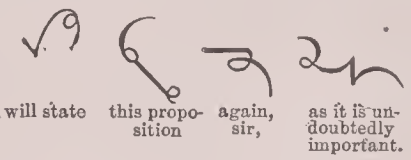

The reporting style.

Phonolite [from Gr. φωνή, sound + λίθος, stone]: a name given by Klaproth to a dense, hard variety of volcanic rock in allusion to its ring under the hammer (German, *Klingstein*; English, *clinkstone*), a property which is much increased by its tendency to separate into thin slabs. Phonolite is an acid igneous rock very rich in alkali, and is to be regarded as the surface equivalent of eleolite-syenite. Its essential constituent minerals are sanidine, nepheline, and an alkaline pyroxene, called ægirite. It also frequently contains minerals of the sodalite-haüyne group, leucite, hornblende, titanite, apatite, and magnetite. Quartz is never present except as a secondary product, since there is too much alkali to allow of the separation of free silica. Zeolites of various kinds are also very frequent alteration minerals in phonolite.

This rock occurs in dikes, flows, and volcanic necks, for the most part of Tertiary age. It is often accompanied by its tuffs, and in many regions, like the Auvergne, Southern Baden, and Bohemia, forms steep and picturesque mountains of small size. Phonolites are also known in Northern Africa, Italy, the Eifel, England, Brazil, the Black Hills, and Colorado. George H. Williams.

Phormion (in Gr. Φορμίων): an Athenian general who distinguished himself in the wars with Samos, but especially at the siege of Potidæa in 432 B. C. He there fought with Perdiccas, King of Macedonia, against the Chalcidians; in 430 B. C. he led the Acarnanians against the Ambraciots; in 429 B. C. he was victorious at Naupactus against the Peloponnesians, after which he once more commanded the Acarnanians. His tomb was near those of Pericles and Chabrias on the road to the Academy.

Phororhachidæ: See the Appendix.

Phosphates: See Phosphoric Acid; also Apatite.

Phosphines: bases corresponding to amines, bearing the same relation to PH_3 that amines do to NH_3. Triethyl phosphine is $P(C_2H_5)_3$.

Phosphorescence [deriv. of *phosphoresce*, shine like phosphorus, deriv. of *phosphorus*]: the emission of light with little, if any, heat, and in most cases with little chemical change. Phosphorus emits light in the dark, and this is due to slow combustion, the change being of the same kind as that which takes place when phosphorus burns actively in the air. Phosphorescence is frequently observed to a very marked degree in sea water. The cause of this is not known, but the phenomenon is believed to be connected with the presence of minute organisms from which the light is given off. Some substances have the power to emit light after having been exposed to a bright light. Prominent among these are the sulphides of calcium, strontium, and barium. According to Becquerel, phosphorescence is a power possessed by all substances, but in most cases it lasts only a very short time. With calcium sulphide it lasts several hours, and the sulphides of strontium and barium have this power to even a greater extent than calcium sulphide. The cause of the phosphorescence in such substances is not known. See also Fluorescence. Ira Remsen.

Phosphoric Acid: the principal acid formed by the element Phosphorus (*q. v.*). It occurs in nature mainly in the form of the calcium salt, calcium phosphate. This is the principal constituent of the ashes of bones. It occurs also as phosphorite and, in combination, in the mineral apatite. It can be made in the laboratory (1) by burning phosphorus which converts it into the oxide, P_2O_5, and then boiling this in water solution; (2) by oxidizing phosphorus with nitric acid. On the large scale it is made from bone-ash or phosphorite, by treating with sulphuric acid, filtering, and evaporating. When its solution is evaporated to the proper consistency the acid crystallizes out on cooling in the form of large crystals having the composition represented by the formula H_3PO_4. This is called *orthophosphoric acid* to distinguish it from two other varieties of the acid to be mentioned below.

Phosphates are the salts of phosphoric acid, or, more especially, of orthophosphoric acid. This acid is tribasic, and therefore capable of yielding a great variety of salts. Each of the three hydrogen atoms contained in its molecule, H_3PO_4, can be successively replaced by metallic elements. Those salts which are derived from the acid by the replacement of one or two of the three hydrogen atoms are called *acid phosphates*. Examples are *mono-sodium phosphate*, H_2NaPO_4; *di-sodium phosphate*, HNa_2PO_4; *secondary calcium phosphate*, $HCaPO_4$; *primary calcium phosphate*, $H_4Ca(PO_4)_2$, etc. The last two salts mentioned are also called *acid phosphates of calcium*. One or both are contained in the preparation commonly called Horsford's acid phosphate. The *normal phosphates*, or *neutral phosphates*, are those that are derived from orthophosphoric acid by the replacement of all the hydrogen by metallic elements. Thus *silver phosphate*, Ag_3PO_4; *tertiary calcium phosphate*, $Ca_3(PO_4)_3$, etc., are normal phosphates. Among the more important phosphates are those of calcium. As has been said, tertiary calcium phosphate is the chief constituent of bone-ash. It forms 85 per cent. of this mixture. Calcium phosphate exists everywhere in fertile soils, and is taken up by the plants, from which in turn it finds its way into the animal body. It is evident, therefore, that it is of fundamental importance, and that a soil must either contain this salt or something from which it can be formed. See Agricultural Chemistry and Fertilizers.

Metaphosphoric acid, HPO_3, is formed when orthophosphoric acid is heated to 400° C. (750° F.). Under these conditions the latter loses water as represented in the equation:

$$H_3PO_4 = HPO_3 + H_2O.$$

This is the more common commercial form of phosphoric acid, being known in the market as *glacial phosphoric acid* (*Acidum phosphoricum glaciale*). Boiled with water it is converted into ordinary or orthophosphoric acid, the reaction above represented being reversed. The salts of metaphosphoric acid are called *metaphosphates*. The acid is monobasic, and it was formerly called monobasic phosphoric acid. Its composition is similar to that of nitric acid, HNO_3, and chloric acid, $HClO_3$.

Pyrophosphoric acid, $H_4P_2O_7$, is formed by heating orthophosphoric acid to 200°–300° C. (400°–600°F.). The change effected is similar to that which takes place in the conversion of the ortho-acid into the meta-acid (see above). It is represented by the following equation:

$$2H_3PO_4 = H_4P_2O_7 + H_2O.$$

The acid is tetrabasic, and was at one time called tetrabasic phosphoric acid. When a secondary salt of orthophosphoric acid is heated to a sufficiently high temperature a pyrophosphate is formed. Thus di-sodium phosphate yields sodium pyrophosphate:

$$2HNa_2PO_4 = Na_4P_2O_7 + H_2O.$$

So also when a primary phosphate, such as mono-sodium phosphate, is heated high enough to decompose it, it yields a metaphosphate:

$$H_2NaPO_4 = NaPO_3 + H_2O.$$

The case with which the acid phosphates and the acid itself undergo change when heated gave rise originally to considerable difficulty in their study. By a masterly investigation of these substances Graham succeeded in explaining the relations between them and the products formed from them, and he thus laid the foundation of the views at present held in regard to acids. IRA REMSEN.

Phosphor-iridium: Holland's compound. See IRIDIUM.

Phosphor'oscope: a device invented by Edmond Becquerel for showing the phenomenon of phosphorescence in bodies which shine but for a very minute portion of time after their insulation. By suitable perforations in a disk revolving over a box in which is the substance to be examined, sunlight is allowed to fall upon it and to be cut off before the observer can see it through another aperture. By giving to the disk a sufficiently rapid rotation observations may be made after an interval of less than $\frac{1}{4000}$th of a second after light has ceased to shine upon the substance. In this way it has been discovered that many substances are phosphorescent (i. e. capable of emitting light) which have never before been known to be so; but there are still a large number of bodies which have no appreciable phosphorescence. Revised by IRA REMSEN.

Phosphorus [Mod. Lat., from Gr. *φωσφόρος*, light-bringing; *φῶς*, light + *φέρειν*, carry, bring. Cf. *Φωσφόρος*, name of the morning star]: one of the chemical elements. In the eighteenth century the name phosphorus was applied to every body that gave light without burning. Gradually, however, the name came to be applied only to the element which was discovered in the latter part of the seventeenth century by Brandt (1669), of Hamburg, who obtained it in experimenting on the distillation of extract of urine with charcoal. Phosphorus is manufactured by first making from bones a soluble acid phosphate of lime through the agency of sulphuric acid, and mixing and distilling this with charcoal in earthen retorts at a red heat. Bone-ash contains nearly 20 per cent. of phosphorus, this being the precise proportion in pure *tricalcic phosphate*; but the amount of phosphorus obtained in practice is only from 8 to 11 per cent. The process is also expensively consumptive of fuel and destructive of apparatus, as well as of the health of the operatives, these facts much enhancing the cost of phosphorus. The importance of phosphorus is, however, so great—chiefly as a material for making matches—that the production is carried on on a very large scale, and the annual production of phosphorus is something over 3,000 tons. There are two principal factories—one in France, at Lyons, the other in England, at Oldbury near Birmingham. Some phosphorus is also made in Sweden and at Philadelphia, Pa.

Common commercial phosphorus is a slightly yellowish body of wax-like consistence, and translucent. It is generally cast into the form of sticks, which, on account of their dangerous inflammability, must be preserved under water. It melts at 44° C. or 111° F. to a liquid of oily consistence, which may be cooled if undisturbed much below the melting-point again without solidifying, but then at once solidifies on agitation. Although flexible and highly sectile at ordinary temperatures, it becomes brittle and breaks with a crystalline fracture at the freezing-point of water. It may be crystallized from bisulphide of carbon, in which it is soluble, the crystals belonging to the regular system. It boils at 290° C. (554° F.), forming a transparent vapor nearly four and a half times as heavy as air. Phosphorus is slightly soluble in ether and in fixed oils, considerably so in benzene and in many essential oils, including oil of turpentine, largely so in bisulphide of carbon.

Red phosphorus or *amorphous phosphorus* is formed from ordinary phosphorus when the latter is long exposed to the light. The same change takes place when phosphorus is heated for a time in an atmosphere free from oxygen, and rapidly when it is heated to 300° C. in a tube hermetically sealed. This variety of phosphorus differs very markedly from the ordinary variety. It is a red powder. It does not emit light. It does not melt at a low temperature. It is not poisonous, and can not be easily ignited. Further, it is insoluble in bisulphide of carbon. When heated to 260° C. in an atmosphere of carbon dioxide it is converted into ordinary phosphorus, and when heated to this temperature in the air it takes fire, and in burning forms the same product that ordinary phosphorus does.

Oxides of Phosphorus.—There are two known oxides of phosphorus: (1) phosphorous anhydride (P_2O_3), a soft, white, readily volatile powder formed by the slow oxidation of phosphorus in a limited supply of dry air; and (2) phosphoric anhydride, or phosphoric pentoxide (P_2O_5), the product of the burning of phosphorus with flame in the air. It appears as a white smoke. This phosphoric pentoxide as made in quantities is a snow-white amorphous powder, which sublimes at a moderate heat below redness. It is highly deliquescent, and when added to water combines with it with great heat and explosive violence.

In addition to the acids mentioned under the head of PHOSPHORIC ACID (*q. v.*) phosphorus yields two other acids. These are *phosphorous acid* and *hypophosphorous acid*. The former has the formula H_3PO_3. Its salts are called *phosphites*. The latter has the formula H_3PO_2; and its salts are called *hypophosphites*. Revised by IRA REMSEN.

MEDICINAL USES OF PHOSPHORUS.—Pure phosphorus is locally an intense irritant and caustic to animal tissues, and taken internally is a virulent poison, whether in large single dose or in repeated administration of small quantities. Even in a single fatal dose, however, the symptoms may not begin till several hours after swallowing the poison, and death does not generally occur till after several days. There are the usual signs of irritant poisoning—viz., nausea, vomiting, and sometimes purging, with abdominal pain, but the latter symptom is not so severe as with other corrosive poisons. A garlicky breath, luminosity of the eructations and sometimes of the secretions, profound disturbances of the nervous system, such as delirium, convulsions, coma, with extreme general prostration, follow, and the individual may die suddenly from collapse and syncope, or more slowly after sinking into coma. Then a peculiar feature of phosphorus poisoning sets in—namely, jaundice, from fatty degeneration of the liver. This symptom is often preceded by a remission in the symptoms, which should not be considered as a favorable sign. After death there is found profound structural disintegration of the tissues, with special tendency to fatty degeneration of many of the organs, and extravasations of blood into their tissue. In chronic poisoning, however, no symptoms occur except a profound general debility, in which condition the subject may sink away and die. The antidotes in phosphorus-poisoning that seem to be of most use are permanganate of potassium and peroxide of hydrogen. Oil of turpentine is worse than useless. Given medicinally in doses of a minute fraction of a grain, phosphorus is sometimes of benefit in conditions of nervous debility, and especially in neuralgias and bone disease. Under its use the patient's general state may improve and the special morbid symptoms abate. Phosphorus is most commonly given in pill form, the minute dose being dissolved by warmth in some form of fat which congeals on cooling. It may also be given in solution in appropriate fluid mixture, but most of these solutions have an excessively offensive taste. As slow poisoning by phosphorus is very insidious, the drug should be taken only under the observation of a physician. Revised by H. A. HARE.

Pho'tius: ecclesiastic; held a high position in the civil service of the Byzantine government, and was distinguished for his learning and literary taste, when in 858, on the deposition of Ignatius, he was hurried through all the ecclesiastical degrees, and installed by the Emperor Michael III. as Patriarch of Constantinople. A council of 318 bishops, held at Constantinople in 861, confirmed the election, but Pope Nicholas I. objected to the irregularities of Photius's elevation, and convoked a council at Rome in 862, which deposed and excommunicated him. Photius then gave the conflict a doctrinal turn, and the Council of Constantinople (867) condemned and excommunicated Pope Nicholas I. because of heretical views, thereby laying the foundation of the schism between the Eastern and Western churches. In 867 Photius was deprived by Basilius the Macedonian of his office and sent into exile, and Ignatius was reinstated; but after the death of Ignatius he returned to Constantinople, and was once more placed on the patriarchal throne. In 886 Leo the Philosopher again exiled him, and he died a few years after in an Armenian monastery. Of his works, the *Myriobiblon* or *Bibliotheca*, a collection of extracts and summaries of a large number of Greek authors in 280 sections (edited by I. Bekker, 1824), the *Lexicon* (edited by Porson, 1822, and by Naber, 2 vols., 1866), the *Nomocanon*, a collection of acts and decrees of councils up to the seventh œcumenical council, and his letters are of great interest. A collected edition is found in Migne's *Patrologiæ Cursus Completus*.
Revised by B. L. GILDERSLEEVE.

Photo-engraving: the term applied to a variety of processes in which the action of light and the use of certain chemical substances supplant the work of the engraver. About the year 1826 Nicéphore Niepce, a Frenchman, discovered that bitumen, under certain conditions, became sensitive to light, losing solubility by its action. He coated a sheet of metal with bitumen dissolved in oil of lavender, exposed it under a drawing to the rays of the sun; the bitumen became insoluble in all those parts except where the lines protected it; the latter were then dissolved away with oil of lavender, and the metal thus laid bare was etched with an acid. Many modern processes are based upon this action of bitumen, but in others different substances, rendered insoluble by light, are employed, being quicker in their action, although the finest results are still obtainable by the bitumen process.

The modern method of producing a photo-engraved metal block is as follows: A collodion negative is first made of the line drawing, giving clear white lines on a black ground. If from a photograph, or a washing drawing, or from any picture or object where there is a *gradation* of color, what is termed a *half-tone* process must be employed. This consists in placing in front of the sensitive plate a transparent screen having a network of fine lines mechanically ruled upon it, which breaks up the image into a mass of fine dots, varying in size according to the amount of light composing the various parts of the image passing through the network. A polished plate of metal, such as zinc, brass, or copper (the last being used for the finest work), is next coated over with the sensitive solution—bitumen dissolved in benzole or albumen rendered sensitive by the addition of bichromate of ammonium or potassium. When this is dry, the plate is exposed to light beneath the collodion negative and afterward treated with the necessary solvent, turpentine being used for the bitumen and water in the albumen process. With the latter method the plate is dried and dusted over with finely powdered asphaltum, the surplus brushed off, and the plate held over a stove until the asphaltum just melts. An image capable of resisting the action of acid etching-fluids is thus produced upon the metal plate. It may be mentioned that with some processes the image instead of being printed direct upon the plate is transferred to it. The plate is next coated over at the back and sides with an acid-resisting varnish, and then immersed in the acid etching-bath. If upon copper, the etching mordant used is perchloride of iron. The action of the mordant is to bite into the metal where unprotected by the image, and in this manner the printing-plate is produced. Such a plate can be printed from in the ordinary printing-press.

Photogravure.—In printing from a photo-engraved plate the ink is taken up and transferred to paper by the raised or unetched parts of the plate, but in photogravure the ink fills up the intaglio engraved on the plate by the acid and is lifted away again by the paper pressed upon it. The process of making a photogravure plate is as follows: From the ordinary photographic negative a positive transparency is made. A piece of carbon tissue (paper coated over with gelatin containing lampblack) is sensitized in bichromate of potassium and exposed to light beneath the positive. A copper plate is dusted over with very finely powdered resin or asphaltum, and heated, which gives it an etching-ground, rendering it capable of holding the ink. The exposed carbon tissue is mounted upon the copper plate and subjected to the action of hot water. This dissolves away the gelatin unacted upon by light, leaving a negative image upon the copper. It is then etched with a solution of perchloride of iron, and the photograph cleared off, leaving a plate that may be printed from in the same manner as a copperplate etching or mezzotint engraving.

Woodbury, *Photogravure* (New York); Geynet, *Photogravure sur zinc et cuivre*, (Paris).

WALTER E. WOODBURY.

Photography [Gr. *φῶs*, *φωτός*, light + *γράφειν*, write]: the art of producing permanent images or pictures by means of the chemical action of light, or, more strictly, of "radiant energy."

Early History.—The first authentic record of an attempt to utilize the action of light for producing pictures appears in the early years of the nineteenth century. In 1802 Thomas Wedgwood, son of the famous potter, published in the *Journals* of the Royal Institution a paper giving an account of a "method of copying paintings on glass and making profiles by the agency of light." The sensitive surface which he employed was obtained by impregnating paper or white leather with a solution of nitrate of silver. When this was exposed to sunlight under a design on translucent material the prepared surface darkened in proportion as the light reached it, with the result that a copy of the design in light and dark was produced. Davy, who worked with Wedgwood, afterward found the chloride of silver more sensitive than the nitrate, and succeeded in reproducing the strongly illuminated images formed by the solar microscope; but no device was found for rendering these results permanent. Exposed to daylight the light parts soon darkened, producing a uniform tint over the whole surface and obliterating the picture. As Davy says of it, "Nothing but a method of preventing the unshaded parts of the delineation from being colored by exposure to the day is wanting to render this process as useful as it is elegant." As it was, the process was of course a failure, and the development of photography was delayed for nearly forty years for want of a solvent for the unchanged chloride of silver.

Niepce's Asphalt Process.—A permanent result was, however, obtained in 1814 by Niepce, of Châlons. Having discovered that asphalt is rendered insoluble by the action of light, Niepce exposed a film of dry asphalt varnish on polished metal under a drawing. The film was then soaked in a mixture of oil of lavender and white petroleum, which dissolved the parts which had been protected, laying bare the metallic surfaces, and thus bringing out a copy of the drawing. By this process Niepce also succeeded in securing pictures of landscapes in a camera, many of which were exhibited by him in England in 1827. Although these "heliographs" were not very satisfactory as pictures, the process still survives in modified form in the asphalt process for photo-mechanical printing. In the heliograph method of Niepce is found the idea which lies at the basis of all successful photographic processes for making camera images—the development of an invisible or "latent" image by treatment after exposure. In 1829 Niepce associated himself with Daguerre, but died in 1833 without arriving at any important results. Daguerre, however, pursued the work, and in 1839 brought out the process known by his name.

The Daguerrotype.—The original daguerrotype process was in outline as follows: A carefully polished surface of silver (plated on copper) received a delicate film of silver iodide by fuming with the vapor of iodine. After exposure in the camera for some time there is no visible change produced; but the action of the light is made apparent by placing the plate over a dish of heated mercury, whose vapor condenses on the parts which were illuminated, and in proportion to the chemical effect producing an image in white amalgam of mercury and silver. The image was made permanent by means of a strong solution of common salt. It was soon found that the plates were more sensitive, and thus the time of exposure shortened by using bromine vapor with the iodine; and also, on suggestion of Sir John Herschel, that hyposulphite of soda (sodium thiosulphate) gave a better solution for "fixing" the image than common salt; while both the appearance and the permanency of the pictures were improved by gilding the silver portions with a solution of gold. The pictures taken by this method were of great fidelity and beauty, and were very popular for portraiture until the invention of the collodion process some twelve years after Daguerre's discovery. The first photographic portraits from life were made by this process by Dr. J. W. Draper, of New York, in 1839. The great defect of the method, from the present standpoint, is that no copies of the original daguerrotype are possible, except by an electrochemical method. Daguerre received from the French Government, on the publication of his process, a pension of 6,000 francs, while Niepce's son, Isidore, who was associated with Daguerre after the death of his father, was given a pension of 4,000 francs.

The Calotype.—While Daguerre was working in France, Fox Talbot, in England, was experimenting on the lines suggested by Wedgwood and Davy. He found that paper soaked in common salt solution and then brushed over with silver nitrate gave a film of silver chloride more sensitive to light than the chloride in the state used by Davy. With this Talbot was able not only to make prints of drawings, lace, ferns, etc., but also to secure images in the cam-

era. Another step was taken with the discovery by Rev. J. B. Reade of the accelerating power of gallic acid, and in 1841 Talbot patented the calotype process. By it a latent image is formed on silver iodide paper and developed by nitrate of silver and gallic acid. The result is a "negative," or picture in which the natural lights and shades are reversed; but, as the paper is somewhat translucent, and can be made more so by waxing, "positive" copies may be produced in indefinite number by exposing sensitized paper beneath it. This method of securing prints by "contact-printing" is essentially the same as that employed now. Among the defects of the calotype process were the lack of transpareney of the paper and the fact that its texture was copied in the positive print. The introduction of glass instead of paper is due to Sir John Herschel, who recognized its value on account of transpareney, rigidity, and indifference to chemical agents. In the first attempts to use a glass support the film of silver salt was formed on it by subsidence from water. It proved, however, to be of little sensitiveness, and did not adhere well to the glass.

The Albumen Process.—Niepce Saint-Victor, seeing the necessity of an adherent substance to hold the silver salts, coated glass plates with albumen (white of egg) containing the iodide and bromide of potassium and common salt. On drying and heating, the albumen became insoluble, and the film was sensitized by a bath of silver nitrate, which reacted with the salts in the albumen, forming the iodide, bromide, and chloride ("haloids") of silver. A similarly prepared albumen surface on paper was used for positive printing. The results were much finer and more brilliant than those of the calotype process.

The Collodion Process.—In 1851 Scott Archer substituted for albumen, collodion, a solution in alcohol and ether of pyroxylin, made by the action of nitric acid on cotton, and closely allied to the explosive guncotton. The collodion process could be worked with greater certainty than the albumen; it displaced the daguerrotype, and in various modifications was practically the only process used for making negatives for over twenty-five years. In this process collodion containing soluble bromides and iodides is flowed over a glass plate, and the film, when partly dry, is immersed in silver nitrate. After exposure the latent image is developed by means of an acid solution of a reducing agent, such as ferrous sulphate or pyrogallic acid. This developer does not affect the silver haloids, but reduces the silver nitrate adhering to the film to metallic silver, which is deposited on those parts on which the light has acted, and in proportion to the amount of that action, so that an image is built up in finely divided silver. This image can be intensified by further application of nitrate of silver and developer, and is fixed by hyposulphite of soda. The negative is then washed to remove all soluble substances, dried, and used for the production of positives in the way already indicated.

Collodion Dry Plates.—In this so-called wet-collodion process the plates must be exposed immediately after their preparation. This inconvenience led to many attempts to impart keeping qualities to the film. The most successful of these modifications consisted in washing off the excess of silver nitrate after the bath in that solution, coating the surface with some "preservative," and drying. The "preservatives" were all organic substances of some description, tannin, morphine, coffee, tea, and tobacco being among those recommended by various photographers. The "dry plates" thus prepared kept for a considerable time, but were much slower than the original wet plates.

Emulsion Processes.—About 1864 a collodion film was used in which the silver salts were contained in the state of emulsion, and in 1871 the first successful attempts with a gelatin emulsion were made. This last process developed in the following seven or eight years into the gelatin dry-plate method, which since that time has been in general use. In both of these emulsion processes the silver haloids formed by double decomposition are emulsified in a mass of the vehicle, the soluble products of the reaction removed by washing, and the emulsion rendered more sensitive, or "ripened," by standing for some time, in the case of collodion; or, in the gelatin process, by boiling or treatment with ammonia. The development of the latent image is effected by means of ferrous oxalate or an alkaline solution of some reducing agent such as pyrogallic acid. The exquisite sensitiveness of the modern gelatin dry plate is due to the mode of development as well as to the nature of the vehicle and the state of the emulsified salts.

The Action of Light and of the Sensitizer.—It has been seen that all successful negative processes depend on the use of salts of silver. The action of light on the silver haloids results in their partial reduction with loss of halogen. This occurs with comparative slowness when the salts are pure; but when they are in intimate contact with some substance which readily takes up the halogen set free by the light, the change goes on with greater rapidity. To the class of halogen absorbants belong silver nitrate, gelatin, tannin, and many other organic substances. These substances act, therefore, as accelerators or sensitizers when associated with the silver haloids. Referring to the various processes which have been outlined, it is seen that in the successful cases some halogen-absorbing substance has been employed. The greater sensitiveness of the calotype paper, as compared with Wedgwood and Davy's preparations, lay in the presence of an excess of silver nitrate. In the albumen and wet-collodion processes, again, it is free nitrate of silver which gives sensitiveness; in the dry collodion, the "preservative"; while in the present dry plate the *rôle* of sensitizer is played by the gelatin, which is an especially efficient halogen absorbant. In the daguerrotype process it is the silver plate itself which aids the action of light by taking up the halogen.

Ripening.—The greatly increased sensitiveness of the ripened gelatin emulsion has been found to depend on a purely physical change in the imbedded particles of silver bromide, which increase in size as the ripening proceeds. This fact is indicated by the color of the light transmitted through the emulsion, which changes as the process goes on from reddish to gray or grayish violet.

Development.—The first attempts in securing the camera image were directed to the discovery of a "printing-out process," as it would now be called; that is, a process in which the delineation of the picture should be complete in the camera. Daguerre's efforts in this direction were unsuccessful, and his discovery of the mercury development is said to have been the happy result of an accidental exposure to mercury vapor of a plate which had been tried in the camera and discarded as a failure. The hint was not lost on the other workers in photography, and from that time all negative processes were by development of the latent and invisible image produced by the light. The most important developers which have been employed are acid solutions of pyrogallic acid or ferrous sulphate in presence of silver nitrate, ferrous oxalate, and alkaline solutions of pyrogallic acid, etc. All developers are reducing agents which carry on the reduction begun by the light. The action of the acid developers has been explained under the collodion process. The result is the formation of an image in relief. With the ferrous oxalate and alkaline developers, on the other hand, the picture is built up by growth from beneath, the silver of which it consists being supplied by the particles of silver haloid underlying and in contact with the material of the latent image. In this case the image is sunk in the film, forming an intaglio. The alkaline developers are much more powerful than the others, and could not be employed in connection with silver nitrate, as in the wet-collodion process, where they would cause a deposit of silver over all the plate. A number of substitutes for pyrogallic acid have been proposed in recent years, among them hydrochinon, para-amidophenol, eikonogen, and methol.

Positive Printing—The Silver-print.—Since the picture obtained by exposure in the camera and subsequent development is a negative, in which the light parts of the object are represented by a dark deposit of silver, it is necessary to combine with this negative process a positive one, which shall give an image whose shading corresponds with that of the original. As already stated, the usual method of accomplishing this is in principle the same as that used by Talbot. The common silver-print is made on paper coated with egg albumen, which has been "salted" with chloride of sodium or ammonium, and sensitized by floating on a strong solution of silver nitrate. The dry paper is usually fumed with ammonia shortly before it is used. After proper exposure to sunlight under the negative, the print is fixed by immersion in hyposulphite of soda. In the fixing bath the picture acquires an objectionable reddish tint, which is corrected by "toning" with a solution of gold. Combined fixing and toning baths are sometimes used. Other silver-printing processes employ gelatin or collodion in place of albumen. After the prints are toned and fixed, all the soluble substances which they retain must be completely removed by thorough washing with water. If this is not effectually done, the photographs become in time faded and

discolored. When dry they are trimmed and mounted on cardboard, and burnished by being passed between heated metallic rollers.

Among the printing processes which depend upon sensitive substances other than silver salts, the more important survivals are those employing potassium or ammonium bichromate in gelatin or other sensitizer, the blue-print process, and the platinotype process.

Carbon Processes.—Gelatin containing bichromate is rendered insoluble in water by action of light, and its "tackiness" destroyed. The first fact is utilized by mixing some pigment with the chromated gelatin, which is removed with the soluble portions during development (in water), leaving an image in pigmented gelatin; the second, by dusting powdered pigment over the film after exposure, when adhesion to the unaffected parts brings out the picture. In the latter case the lights and shades reproduce those of the plate under which exposure was made; hence the printing must be under a transparent positive. Processes of this sort are known as "carbon" processes.

Blue Prints.—Blue prints are made on paper coated with a mixture of a ferrous salt, usually ammonio-citrate of iron, and ferricyanide of potassium. The image is developed and fixed by merely washing in water, which brings the reduction products into reaction with the result that insoluble Turnbull's blue is formed, and dissolves the unaltered salts, leaving a picture in blue on a white ground. This process is largely used on account of its cheapness and simplicity for copying plans, and by amateurs.

The Platinotype.—In the platinum process the paper is coated with ferric and platinum salts. Light reduces the ferric to a ferrous salt, and this, when brought into solution by the developer (oxalate of potassium), reduces in turn the platinum salt, giving an image in platinum black. The platinotype is very soft and beautiful, resembling a fine engraving, and has the additional merit of being absolutely permanent.

Direct Positives.—A thin negative, produced by short exposure or insufficient development, appears as a positive when seen by reflected light against a black background. This fact has been used for making collodion positives directly, as in the "ambrotype," in which the glass plate receives a dark backing, and in the ferrotype, or "tintype," in which the support and background are a plate of enameled iron.

Photo-mechanical Printing.—A number of photographic processes for the preparation of plates and blocks, from which impressions may be made by mechanical printing, have been developed, some of which are of great perfection, and have largely displaced wood-engraving for purposes of illustration. Most of these depend in their photographic part on the behavior of bichromated gelatin toward light, which has already been alluded to. The limits of this article admit only of a brief sketch of one or two of these processes, and the reader is referred for details and descriptions of others to the books on the subject whose titles are given at the end.

The Woodburytype.—In the Woodburytype, development (by hot water) of a bichromated gelatin film gives an image in relief. When dry, the film is stripped from its glass support and forced, face down, by hydraulic pressure on a plate of lead. The gelatin image withstands the enormous pressure, and sinks into the lead surface, producing a mould. From this mould the prints are made. The ink is a mixture of gelatin, water, and coloring-matter. The mould is oiled, and a pool of ink poured on it; then a sheet of specially prepared paper is laid on top and pressed down under a platen, which squeezes out all the ink except that filling the depressions of the mould; this is allowed to set, and on removing the paper adheres to it, forming a relief image whose varying thickness gives gradations of shade.

The Stannotype.—The stannotype process is similar to that just described, but does away with the hydraulic pressure and lead mould. The exposure is made under a positive, so that the gelatin image is itself a mould like that obtained in lead in the last process. It would, however, be destroyed if brought in contact with the ink, and is therefore protected by a facing of tin-foil, and then used for printing in the same way as the lead mould of the Woodburytype.

Photolithography.—In photolithography advantage is taken of the fact that those portions of a bichromated film affected by the light acquire the property of holding greasy lithographic ink. The "artotype" is a form of photolithograph. Other processes give relief blocks for printing by etching with acid the metal which supports the gelatin or asphalt image.

Use of Artificial Light.—While direct or reflected sunlight is generally employed both for the production of the camera image and for positive printing, artificial light may be used to advantage in some instances. The electric arc-light has occasionally served for photographic illumination since the earliest days of the daguerrotype; but the light that has proved most available is that of burning magnesium, which is much used for photographing dark interiors and for the instantaneous "flash-light" pictures. For copying by means of the camera, making negatives of microscopic objects, contact printing on dry plates for transparencies, and on gelatino-bromide paper, gas or oil light is commonly employed.

Chemical Action of Light.—Light from different sources, even if of the same luminous intensity, shows marked differences in its chemical effect. It is well known that ordinary white light is composed of a great number of rays of different colors, and that this difference in color is an expression of a difference of wave-length or vibration-frequency. When white light is passed through a glass prism, its component rays are refracted more strongly as their wave-length is less, so that a narrow beam is spread out in fan shape and produces on a white screen a "spectrum" of color extending from the least refrangible red through yellow, green, and blue to violet. Light and color form but one of the modes in which the radiation from a luminous source or "radiant energy" can manifest itself. Each has in general, besides this power of exciting vision, a heating and a chemical or "actinic" effect. Nor are these effects limited to the visible spectrum; the heat extends far into the region beyond the red, and chemical action is found beyond the violet; moreover, the intensity of these effects is not similarly distributed; luminous intensity reaches its maximum in the yellow part of the spectrum; the greatest heating effect is usually in the infra-red; while the chemical action differs with the substance on which it is exercised, and in the case of the silver salts used in photography is most in the blue and violet, and almost altogether absent in the yellow and red.

This fact has several important consequences. From the moment of making the sensitive emulsion until the negative is in the fixing bath, the material of the film must be protected from all actinic rays except those of the camera image; and the inactivity of the red and yellow makes it possible to conduct all necessary operations in light which has been filtered through glass or paper of red or orange color, instead of in the uncertainty of utter darkness. Again, this fact explains the frequent failure of the photograph to give in its light and shade a truthful representation of the effect of colored objects. Reds and yellows photograph black, while the blues usually appear much lighter than in nature. This difficulty has been in part overcome in the "ortho-chromatic" and "iso-chromatic" plates, in which, by the application of certain dyestuffs (first suggested by Vogel, 1873), the film is rendered sensitive to the usually inactive rays, and a more naturally shaded picture is secured. Finally, the photographic lens has to receive a somewhat different form from that of the optical lens. For light in its passage through lenses suffers dispersion, or separation into color, along with the refraction by which the image is formed. In a single lens this results in the production of a series of colored images, the red one farthest from the lens and the violet one nearest. By the combining two lenses whose dispersive power is opposed, most of this effect can be done away with and a single sharp image formed. It is, however, impossible to bring all rays to exactly the same focus, and in optical lenses the correction is made for the most luminous rays, so that the actinic rays form an image whose position differs somewhat from that of the visible one. Consequently, after focusing sharply with such a lens, the negative would be found blurred. The elements of the photographic lens are therefore ground so that the actinic and the visual foci shall coincide.

Lenses.—The photographic camera is a development of the camera obscura which was described by Porta in the sixteenth century. Light entering a darkened room through a small orifice forms images of the objects without; but a lens in place of this simple opening gives images which are much brighter and sharper. The lenses for this purpose must be of the convex class, as these alone give "real" images which can be caught on a screen. The lenses used

in photography may be grouped in the following classes: (1) single corrected lenses; (2) rapid rectilinear; (3) wide-angle rectilinear; (4) portrait lenses. All except the single lenses consist of two combinations, which differ in detail and are mounted at different distances apart, according to the special work for which they are intended.

The focus of a lens is the point in which rays which enter parallel meet after emergence. The distance from the optical center of the lens to the focus is called the focal distance, or, in the case of compound lenses, the "equivalent" focal distance, being so termed from comparison with a single lens of equal power. The image is formed at a distance from the lens which is greater as the object is nearer the lens; for very distant objects, nearly at the focal distance.

Diaphragms.—Accompanying the lens are a number of diaphragms or "stops," which are brass plates with circular openings of different diameters. Placed in the lens-tube in a slot provided for their reception, the diaphragms cut off the outer rays of the entering beam to a greater or less extent, and, by correcting certain deficiencies of the lenses, increase the sharpness of definition and the depth of focus. Since the light admitted through the diaphragm varies as the area of its opening, or the square of its diameter, the time of exposure must be varied inversely as these diameters. The size of the diaphragm is usually expressed in terms of the focal distance of the lens; thus, $\frac{f}{10}$ means that the diaphragm marked in this way has an opening whose diameter is one-tenth of the focal distance of the lens to which it belongs.

Photographs without a Lens.—Since images are formed by admission of light through small apertures, it is possible to take photographs without a lens. To get clear definition, the diameter of the orifice must be several hundred times less than its distance from the sensitive plate, so that the exposures have to be very long. The images have, however, the advantage of being entirely free from all distortion.

The Camera.—The camera is a light-tight wooden box, or, as in many modern cameras, a framework of wood whose parts are connected by a bellows of leather, so that the camera may be light and occupy little space when closed. In front is fixed the lens, and at the back is a screen of ground glass for focusing the image by an arrangement which serves to shorten or lengthen the camera body. With the camera are one or more plate-holders, usually carrying two plates back to back, and which fit the back of the camera so that the film of one of the plates may occupy exactly the position of the focusing screen. The plates in the plate-holder are protected from the light by a slide which is withdrawn during the exposure. Light is admitted for the exposure either by uncapping and capping the lens-tube, or by means of a mechanical shutter fitted to the tube, which is controlled by a pneumatic bulb, and, in case of "instantaneous" or very brief exposures, is operated by a spring released by air from the bulb.

"Detective" cameras, which are much in vogue, are small boxes with mechanical adjustment for focusing, and a finder, consisting of a small auxiliary lens and ground glass screen for ascertaining the position of the image. In these cameras the film is on a flexible support, as paper or celluloid, in a continuous roll wound on two spools at the back. After an exposure the film is reeled from one spool to the other, a mechanical check indicating when a proper amount of fresh surface is brought into position. The shutter is made to flash across the opening by pressing a button.

Printing.—In printing from negatives, the negative is placed in a "printing-frame," glass side out, and the prepared paper faced down on it and held in close contact with the film by a back secured by springs. The back is in two parts, hinged together so that one part may be opened to examine the progress of the printing, while the paper is prevented from shifting by the other.

Photography in Natural Colors.—One of the earliest dreams of photographers was to fix the natural colors of the camera image. Until quite recently all attempts in this direction were unsuccessful. Within a short time encouraging results have been obtained by Lippmann by a method based on the interference of light. Lippmann's process has been improved by Messrs. Lumière, who are said to have applied it successfully to landscapes and portraits. At present the necessary exposure is long, and no copies can be made, while the picture is clearly visible only when viewed at a certain angle.

Ives's Process.—A process which gives colored images by an indirect method has been brought out by F. E. Ives. In it nature is imitated by a superposition of monochromatic images. Starting with the Young-Helmholtz theory, that all color is the result of three primary sensations responding to red, green, and blue-violet rays respectively, which being excited, singly or together, produce all possible tints, three negatives are made of the colored object, one through a screen which allows only red to reach the plate, a second in green, and a third in blue-violet light. Transparencies from each of these negatives are made, and the three pictures projected by a lantern through red, green, and blue color screens respectively. When the images are superposed on the screen a picture resembling the natural object in tint is produced. This process has also been applied with moderate success to the production of photo-engravings by preparing blocks from the three negatives and printing in superposition with properly colored inks.

Photolithography: See PHOTOGRAPHY.

Photom'eter [Gr. *φῶς, φωτός*, light + *μέτρον*, measure]: an instrument for the comparison of artificial light sources with a standard. All such instruments are based upon the power of the observer to determine by inspection when two contiguous fields of view are equally bright. Reliable judgment of this character can be formed, as has been pointed out by von Helmholtz, only when *the lights illuminating the two fields of view are identical in color—that is to say, in composition.*

The above may be regarded as the fundamental assumption in all photometric operations. The lack of precision in photometry as frequently practiced is indeed due chiefly to the attempt to compare *unlike* sources of light without taking into consideration their differences in quality.

It follows that for lights which differ in composition a class of instruments must be used in which each wave-length in the spectrum of the standard is compared separately with the corresponding wave-length in the spectrum of the light under investigation. Such instruments (spectrophotometers) have, however, not been largely introduced in the commercial measurement of gaslight or of electric lamps. The present article will be confined to the consideration of photometers designed for the comparison of similar light sources.

The earliest of these photometers appears to have been due to Bouguer, although frequently ascribed to Rumford. It consists simply of an upright rod casting shadows upon a

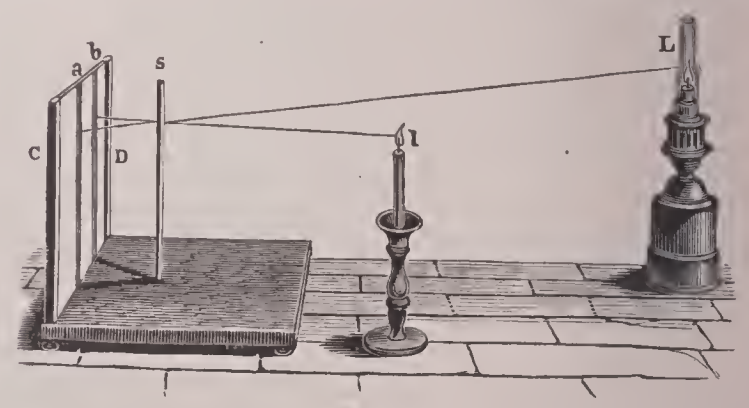

FIG. 1.

white screen placed behind it (Fig. 1). If the only light falling upon the screen come from the two light sources *l* and L, which are to be compared, the spaces occupied by the two shadows which the rod *s* will cast upon the screen will be illuminated respectively by the source to which the shadow in question is not due. The brightness of the two fields within the areas covered by the shadows may now be made equal by adjusting the distances of the two sources of light,

when we have the following simple relation between their intensities and their distances from the screen,

$$\frac{I_1}{I_L} = \frac{D_1^2}{D_L^2},$$

where I_L and I_1 are the illuminating powers of L and l respectively and D_L and D_1 are their distances from the screen. This relationship holds in the use of all photometers based upon the principle stated in the opening paragraph of this article.

Rumford pointed out the conditions under which this instrument will give the best results, the chief of which consists in arranging the apparatus so that the two shadows, instead of being widely separated as in the figure, will be contiguous and separated by a well-defined boundary-line. Thus constructed, the Rumford-Bouguer photometer is as sensitive as any known form when used with lights of *identical* composition. It is, however, more sensitive to slight color differences, and brings out more strongly than many other forms the uncertainties to which the photometric process is subject when we attempt to apply it to dissimilar sources.

Photometers of the above type have been almost entirely abandoned in industrial work because of the greater convenience of a form devised by Robert Bunsen.

The Bunsen photometer is so constructed that the two fields of view, the illumination of which is to be brought into equality, lie between the light-sources, which are placed at the ends of a track or bar (the photometer bar). This bar carries a scale which may be divided equally throughout to advantage in 1,000 parts, or in such manner as to be direct reading in standard candles or in some other unit. The essential feature of the Bunsen photometer, however, is the disk. This in the original form consisted of a piece of unsized paper of considerable thickness, a portion (usually a central circular spot 2 or 3 cm. in diameter) of which had been rendered translucent by treatment with oil or paraffin.

The appearance of the disk by reflected light is that of a dark spot upon a bright ground. A considerable portion of the light which is reflected from the surface of the opaque portions of the paper and serves to render it visible is transmitted by the translucent part. By transmitted light the reverse is true, and when the disk, mounted upon a suitable car, is shifted along the bar between the two lights to be compared it passes through an intermediate stage where the translucent and the opaque portions, whichever side one may view them from, present an almost identical appearance. This happens when the illumination on both sides is alike, and it only remains to note the position of the disk upon the bar and to apply the formula given in a previous paragraph. Sometimes for convenience in preparation the center of the disk is protected by being clamped between two flat, circular pieces of metal or wood, and the whole is dipped into melted paraffin. This gives an opaque spot in the middle of a translucent screen, in which case all the above-mentioned appearances are reversed.

In order to render possible simultaneous observations of the two sides of the disk two mirrors are mounted obliquely on either side, as shown in Fig. 2, in which D is the disk, M M are the mirrors, and A A is the aperture through which the observer looks. The arrows indicate the directions in which the rays come from the two light-sources. Fig. 3 shows the bar or track and the position of the bar between the two sources. L_r and L_l indicate, respectively, the directions in which light comes from its sources.

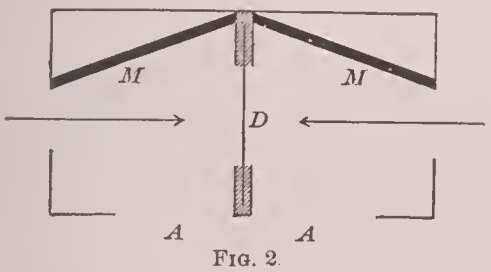

FIG. 2.

Many modifications of the Bunsen disk and substitutes for it have been devised, but only one of these offers such a decided advantage over the original form as to make it necessary to describe it here. This is the photometer of Lummer and Brodhun, in which the rays from the two sources are reflected obliquely from the direction of the photometer bar so as to make an angle of 90° with one another and of 45° with the bar. At the point in which they cross each other a pair of rectangular prisms, cemented together, are placed, as shown in Fig. 4. These would form a complete cube with faces perpendicular to the two rays were it not that a portion of the left-hand prism is cut away, as shown in the diagram.

The result of this arrangement is that a bundle of rays, r_1 r_2, from the observer's right enter the prism b_1 c_1 b_2.

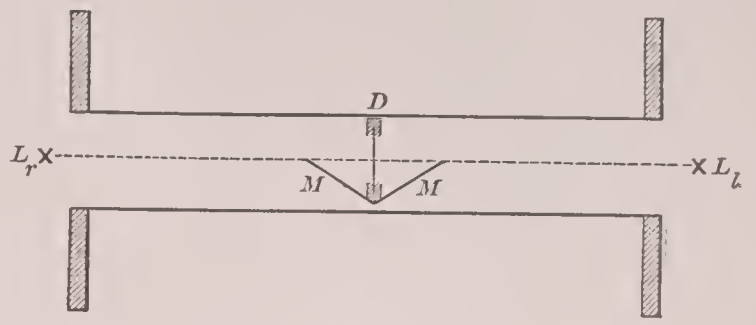

FIG. 3.

Those portions which reach the interface between a_1 and b_2 (also a_2 b_2) are totally reflected, while those between a_1 and a_2 pass through. To an observer at O the appearance is that of a bright ring with a dark center. If, further, the bundle of rays l_1 l_2 fall upon the prism b_1 c_2 b_2, only those which reach the face a_1 a_2 will be transmitted. When the intensities of the two rays are equal the dark center will disappear. When l is brighter than r the center will be brighter than the ring.

This form of photometer possesses a higher degree of sensitiveness than those previously described. Working upon a photometer bar of 1,000 divisions, with similar in-

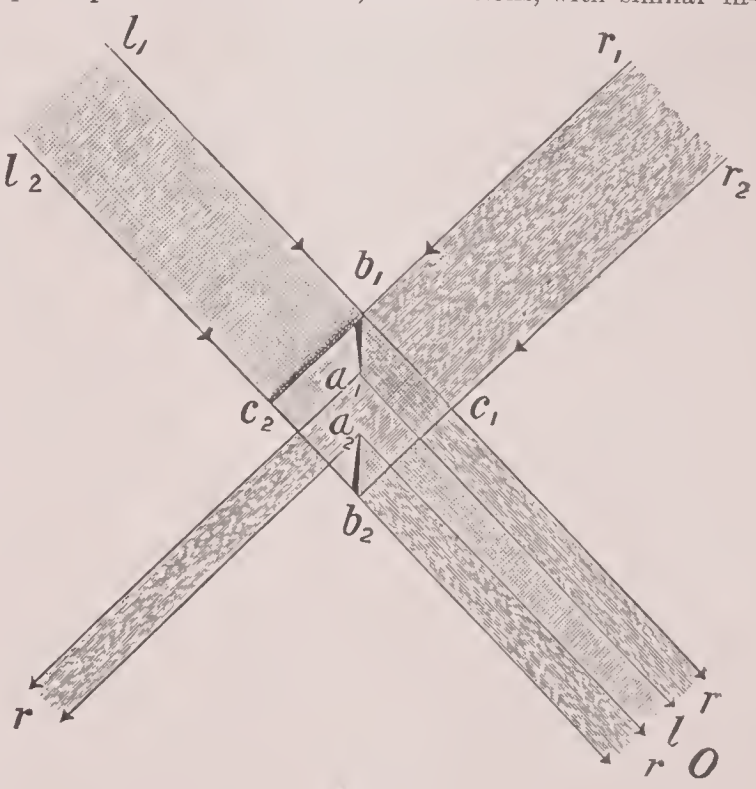

FIG. 4.

candescent lamps at the ends, the lamps being maintained at the same candle-power, a series of fifty readings made with the ordinary Bunsen photometer and with the Lummer-Brodhun photometer respectively gave as the mean error of a single setting:

Lummer-Brodhun	± 0·884 s. d.
Bunsen	± 1·459 s. d.

The sensitiveness to slight color differences is less in case of the Lummer-Brodhun than in other photometers. A comparison with the Bunsen disk, which probably comes second in this respect, gave for the change of voltage to which a 100-volt glow-lamp could be subjected before the color difference between it and a similar lamp at constant voltage with which it was being compared was observable with certainty:

For Lummer-Brodhun	8·6 volts.
For Bunsen	5·76 volts.

This lack of sensitiveness to color differences affords at least some apparent advantage, since the observer is freed from a disturbing element; whether the readings, rendered more concordant on this account, are really of greater accuracy is an open question. The chief advantage of the

Lummer-Brodhun form undoubtedly lies in the fact that observations are made through a telescope, only one eye being employed. The errors thus avoided are not inconsiderable, as will appear from the following experiment:

Ten observers in the physical laboratory of Cornell University (1889) made a series of observations, using the Bunsen photometer and employing the two eyes simultaneously in the customary manner, for the purpose of determining this error. Two lamps of intensities I_r and I_l were placed at the right and left ends of the bar. The ratio $\frac{I_r}{I_l}$ was 1·0032 ± ·0015. The mean of ten readings by these observers, however, gave:

Observer.	$\frac{I_r}{I_l}$	Observer.	$\frac{I_r}{I_l}$
A	1·0590 ± ·0040	F	1·0902 ± ·0057
B	0·9704 ± ·0044	G	1·0733 ± ·0053
C	1·0021 ± ·0022	H	1·0293 ± ·0042
D	1·0191 ± ·0072	I	1·0297 ± ·0050
E	1·0182 ± ·0039	J	1·0220 ± ·0027

It will be noted that all but one of the observers set the disk persistently to the left hand of its true position. The error appears to be analogous to that which arises in the attempt to bisect a straight line by judgment formed in unaided vision. It disappears in those methods in which only one eye is used.

For further information concerning photometers, see PHOTOMETRY; for a discussion of light standards, see CANDLE and CARCEL. The reader is further referred to Palaz, *Photometrie Industrielle.* E. L. NICHOLS.

Photometry [Gr. *φῶς, φωτός*, light + *μέτρον*, measure]: the operation of measuring the intensity of light. In setting such a process on a satisfactory scientific basis, a great difficulty is met with in the fact that the effect measured is not a physical one, but merely an excitation of the optic nerve, the amount of which does not permit of any precise determination. Making abstraction of the different colors of light, and considering only ordinary white light, the principles on which photometric investigations are conducted are these: A comparison of the intensity of two lights can be made only by increasing or diminishing one or both of them until they appear to the eye to be equal. For example, in comparing the light from a gas-jet with that of a candle, we may, by using various instruments, and by putting the jet at different distances, so diminish the light which comes from the latter that the eye shall see side by side the light of the candle and one-fifteenth the corresponding part of the light of the gas-jet; if they then look equal, we shall know that the light emitted by the gas is fifteen times that emitted by the candle. The instruments by which these various comparisons are made are called photometers. See PHOTOMETER.

If all light were of one kind the application of this method of comparing lights would offer no difficulty; but, as explained in the article LIGHT, this agent is a heterogeneous mixture of light of widely varying wave-lengths. No accurate comparison can therefore be made between lights of different colors; in any case the comparison will be a matter of guesswork, and people will guess differently from each other when two lights of different colors appear equal. Yet some system of photometry is not only a necessity in astronomy, but in the practical comparison of different systems of illumination. Let us therefore inquire what view we shall take of the relation between the intensity of beams of light of different colors.

It is shown in the article on LIGHT that, when considered as a physical agent, light is nothing but radiant heat. Hence the only absolute measure of the intensity of a ray of light is the heat or radiant energy which it conveys. If we form its spectrum by dividing it into its prismatic colors, the proper measure of the intensity of each color, or each region of the spectrum between two given wave-lengths, is the amount of heat which is there conveyed; but even the intensity of the heat at a given point of the spectrum will depend on the way in which the spectrum is formed. If we proceed by the units adopted in the article LIGHT, we may classify the parts of the spectrum as follows: That of wave-length between 3 and 4 units; that between 4 and 5; that between 5 and 6; that between 6 and 7, etc.

Of course we could subdivide these regions into as many others as we chose. Then a complete statement of the intensity of the different parts of the spectrum would be merely a statement of how much heat was conveyed by the light between these several limits of wave-lengths. When, however, we refract the light by a prism these four regions spread out unequally. Thus the heating effect in different parts of the spectrum will not give a correct expression even for the amount of heat belonging to that part of the spectrum. It follows that we must correct any determination of the relative amounts of heat thus made, by allowing for the different degrees in which the parts of the spectrum are spread out. There are, however, two insuperable difficulties in the way of reducing photometry to a mere measurement of heat. One is, that the very object of photometry is to determine visibility, and not to measure heat. The eye must therefore be the sole arbiter. Besides this, the eye is so much more delicate than any instrument for measuring heat that it will perceive a ray of light the heat from which could never be detected. What is then really wanted as a basis of photometry is a determination of the relation between the amount of heat carried by rays between each two limits of wave-length and the corresponding visibility of the light. It must not be forgotten that there can be no general comparison for either the heating or the illuminating effect of different parts of the spectrum. In fact, the relative intensity of radiation in different parts of the spectrum depends on the nature of the body from which the light comes, and the absorbing media through which the light has passed. Such expressions as "the brightest part of the spectrum," or "the relative heat in different parts of the spectrum," can be true only of the spectrum of some one body—the sun, for example—or of a given substance at some given temperature—iron at 2,000°, for example.

There are two possible units by which the purely illuminating effect of light of different wave-length can be compared. One is afforded by the determination of the least quantity of light that can be seen. If we agree to take this quantity as a unit at each part of the spectrum it will afford us a basis for comparing the luminosity of light of different colors. Yet another unit would be the smallest amount of light by which the eye could read, or distinguish letters at a given distance. Should we hang up a page containing a few sentences in large print—or, better yet, the test types used by oculists—and then illuminate them with red light, yellow, green, blue, etc., until the eye could just distinguish them, we should have a basis for such a comparison; but from what has already been said it will be seen that the results of this comparison would be incomplete unless the amount of heat carried by these various units of light was also determined. This is quite within the power of science, and, in fact, Prof. Langley has already made researches in this direction. When a table can once be constructed, showing for light of each wave-length what fraction of a unit of heat per second must be conveyed to produce a definite effect upon the human eye, we shall have a scientific basis for photometry. S. NEWCOMB.

Photo-relief Printing: See PHOTOGRAPHY.

Phranza, or **Phranzes**, GEORGE: last of the Byzantine historians; b. 1401, d. 1478; was chamberlain of Manuel II., Palæologus. At the siege of Patras (1429) he saved the life of Constantine, afterward emperor, but was himself taken prisoner and made to endure a harsh captivity. He was protovestiary of Constantine XIII. At the capture of Constantinople by Mohammed II. his entire family were made slaves; his daughter died from her sufferings, his son was murdered in the sultan's harem, but he and his wife escaped to Sparta and thence to Corfu, whence he conducted some diplomatic negotiations. Finally he retired to the monastery of Tarchaniotes, where he wrote his valuable *Chronicon* or Byzantine History. This covers the period from 1259 to 1477, and is interesting and reliable. It was published at Vienna in 1796 in folio. Bekker gave a new edition with Latin translation in 1838. E. A. GROSVENOR.

Phrenology [Gr. *φρήν, φρενός*, faculty, mind + *λόγος*, discourse, reason]: the so-called science of mental faculty as exhibited in the shape, size, and contour of the skull. This mode of investigating the mental capacities of individuals rose into prominence through the "systems of phrenology" of Franz Joseph Gall (1758–1828) and Kaspar Spurzheim (1776–1832). As a method by which the external examination of the "bumps and hollows" of the skull is made to reveal the intellectual and emotional gifts of particular men—so considered, the whole scheme is now known to be worthless. The only semblance of justification it has is found in the facts of brain LOCALIZATION (*q. v.*); but this extends only to the senses and movement, and shows all men to be alike in their localizations. It gives no ground

whatever to the elaborate pretense of the "phrenologists" to describe character. It is possible that morphology may some day show that certain ratios in skull measurements may, in the process of evolution, have come to have some significance for mental faculty in great averages, but even that is forbidden to us in the present state of anthropometric research. See PHYSIOGNOMY. J. MARK BALDWIN.

Phryg'ia (in Gr. *Φρυγία*): a province in the western half of the peninsula of Asia Minor, whose boundaries varied greatly in different epochs. The Phrygians emigrated from Macedonia and founded a powerful empire, whose capital city was situated on a hill across the gulf from Smyrna and within sight of the city. It is now called Tantalis, or city of Tantalus. The Acropolis walls and the tomb of Tantalus still exist. Later on the Phrygians secured a large portion of the crumbling Hittite empire, and removed their capital into the interior. This was the city of the Midases and the Gordiuses. About this city of Midas many remains of the Phrygian civilization still exist near the modern village of Kumbet. (See MIDAS and GORDIUS.) The best account of Phrygia and the Phrygians is in Perrot and Chipiez, *History of Art in Phrygia*, etc. (London, 1892), pp. 1–231, where all the literature relating to the subject is cited.
J. R. S. STERRETT.

Phrygian Language: the language of the ancient Phrygians, located in western central Asia Minor. The language is known to us only through a few glosses and brief inscriptions, but, so far as can be judged from these scanty remains, it was an Indo-European tongue, bearing close relations to the Armenian, and also, though more remotely, to the Balto-Slavic group. According to the reports of Herodotus and Strabo, the Phrygians were anciently regarded as related both to the Armenians and the Thracians. (Cf. Herod., vii., 73; Strabo, c. 47, 295.) The Phrygian glosses are collected in Lagarde, *Gesammelte Abhandlungen*, pp. 283 ff. (1866). See also Fick, *Spracheinheit der Indog. Europas*, pp. 408 ff., and *Zum Phrygischen, Bezzenberger's Beiträge*, xiv., 50 f. BENJ. IDE WHEELER.

Phry'ne (in Gr. *Φρύνη*): a Greek hetæra (see HETÆRÆ) of surpassing beauty, who was employed by Praxiteles as a model for his Cnidian Venus, and by Apelles for his Venus Anadyomene. She was born at Thespiæ in Bœotia in humble circumstances, but when Alexander the Great destroyed the walls of Thebes she offered to rebuild them. When accused of profaning the Eleusinian mysteries, and summoned before the tribunal of the Heliasts, Hyperides, her defender, threw off her veil and exposed her breasts, whereupon the judges immediately acquitted her, and the people carried her in triumph to the temple of Aphrodite.
Revised by J. R. S. STERRETT.

Phry'nichus (in Gr. *Φρύνιχος*): one of the framers of Attic tragedy, the first to bring female characters on the stage, and the first to develop a true dialogue, though the lyric element was still predominant, and Phrynichus was best remembered by his sweet and graceful melodies, which were sung as late as the time of Aristophanes. The most famous of his pieces was the *Phœnician Women*, *Φοίνισσαι*, brought out with great splendor by Themistocles in 476 B. C. to commemorate the victory over the Persians, and soon afterward imitated by Æschylus in his *Persians*. An earlier piece, *The Capture of Miletus* (*Μιλήτου ἅλωσις*), is memorable for the story told by Herodotus that the audience was so moved by the representation of the sufferings of their kindred that they burst into tears, and the poet was fined 1,000 drachmæ —a significant warning against realism in art. Fragments are to be found in Nauck's *Tragicorum Græcorum Fragmenta*. B. L. GILDERSLEEVE.

Phthalic Acid ($H_2C_8H_4O_4 = C_6H_4(COOH)_2$), **Alizaric Acid, Naphthalic Acid** [*phthalic* is a deriv. of *(na)phthalene*]: an acid obtained first in 1836 by Laurent, by boiling naphthalene tetrachloride with nitric acid. It crystallizes in white nacreous laminæ arranged in rounded groups; is slightly soluble in cold water, readily soluble in alcohol and ether. By distillation with an excess of lime it yields benzene and calcic carbonate; with a smaller proportion of lime, calcic carbonate and benzoate. It forms acid and neutral salts, and yields substitution products with bromine, chlorine, nitric acid, etc. By distillation it yields *phthalic anhydride*, $C_8H_4O_3$. When this is heated to 195° C. with resorcin it produces fluorescein. Fluorescein forms a red crystalline powder; crystallizes in yellow needles from methylic alcohol; and its solution in an alkali exhibits a most beautiful and intensely green fluorescence. Fluorescein has become of great industrial importance as a basis for the preparation of the beautiful dye called *eosin*, which rivals safflower and saffronin for dyeing rose-red. Eosin is the potassium salt of tetrabrom fluorescein. Other dyestuffs, also called *phthalic acid colors*, are made by heating phthalic anhydride with other substances belonging to the class of phenols. Besides eosin and fluorescein the more important are *phenol phthalein*, used as an indicator in volumetric analysis, *pyrosin*, which is tetrajod fluorescein, and *gallein*, which is pyrogallol phthalein. Phthalic-acid colors are among the most brilliant of the artificial dyes, and are used on cotton, silk, and wool, for the preparation of lakes, printer's inks, etc. C. F. CHANDLER.

Phthisis: See CONSUMPTION and CLIMATE.

Phycis: See FORKED-BEARDS.

Phycol'ogy [Gr. *φῦκος*, seaweed + *λόγος*, discourse, reason]: the botany of the algæ, or seaweeds, in the broadest sense. It thus includes the green members of the PROTOPHYTES, PHYCOPHYTES, and CARPOPHYTES (*qq. v.*). See also DESMIDS, DIATOMS, FUCOIDS, KELP, RED SEAWEEDS, and STONEWORTS.

Phycomyces: See MUCORACEÆ.

Phyco'phytes, or **Phycoph'yta** [from Gr. *φῦκος*, seaweed + *φυτόν*, plant]: a branch of the vegetable kingdom in which the result of the sexual union of two cells is the formation of a single "resting-spore" (zygospore or oöspore). Phycophytes are the lowest plants which exhibit sexuality, and by this they are easily separated from the PROTOPHYTES (*q. v.*). They are distinguished from the CARPOPHYTES (*q. v.*) by the simple spore which results from the sexual act, in contrast with the many-celled "fruit" of the higher group.

The structure of the plant-body ranges from the simple cell, as in PROTOCOCCUS, DESMIDS, and DIATOMS, to the large KELP and other FUCOIDS (*qq. v.*) with stems and leaves. Phycophytes are separable into two well-marked classes, and seven orders as follows: Class I., *Chlorophyceæ*; Orders, *Protococcoideæ*, *Conjugatæ*, *Siphoneæ*, and *Confervoideæ*. Class II., *Phæophyceæ*; Orders, *Phæosporeæ*, *Dictyoteæ*, and *Fucoideæ*. In the first, second, and third orders some of the families are degraded, chlorophyll-less parasites and saprophytes. All others are independent plants (holophytes), possessing chlorophyll (or an equivalent), although sometimes hidden by brown or smoky coloring matter, as in the Diatoms, Kelps, and Rockweeds. See also EMBRYOLOGY IN PLANTS. CHARLES E. BESSEY.

Phylac'teries [from Gr. *φυλακτήριον*, guard-post, safeguard, amulet, deriv. of *φυλακτήρ*, watcher, guard, deriv. of *φυλάσσειν*, guard, watch]: properly, amulets worn to protect the person from evil influences. In the New Testament the name is given to the leathern cases containing on fine parchment the four passages, Ex. xiii. 1–10; xiii. 11–16; Deut. vi. 4–9; xi. 18–21. They are fastened by leathern straps to the forehead and the arm, and also to doorposts and the like. This custom has been maintained from very ancient times by the Jews, and is based upon a literal interpretation of Ex. xiii. 9, 16; Deut. xi. 18.
Revised by S. M. JACKSON.

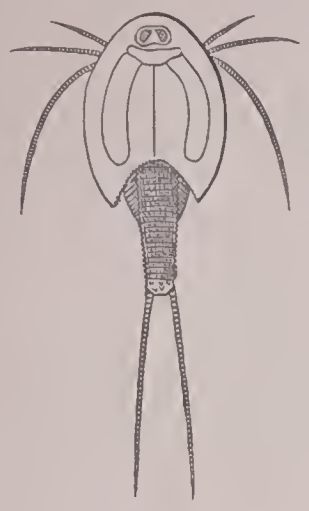
Phy'læ [= Lat.= Gr. *φυλαί*, plur. of *φυλή*, tribe, clan]: the tribes into which ancient Attica was divided. Their number was originally four, but after the expulsion of the Pisistratidæ it was raised to ten by Cleisthenes; two more were afterward added in honor of Antigonus and his son Demetrius. At the head of each tribe was a phylarch, who superintended the registering of the members of the *phyle*, organized the choirs for the festivals, presided over the communal assemblies, and commanded the contingent of cavalry. Afterward, however, the office was divided, the phylarch retaining only the military duties, while the civil duties were transferred to a new office, that of the *epimeletes*. To the Athenian senate each phyle sent fifty members. J. R. S. STERRETT.

Phylar'chus (in Gr. *Φύλαρχος*): Greek historian of the third century B. C.; wrote the history of Greece from the expedition of Pyrrhus against the Peloponnesus down to the death of the Spartan king Cleomenes (220 B. C.), of whom he was a passionate partisan. Fragments are to be found in Müller's *Fragmenta Historicorum Græcorum* (vol. i., pp. 334–358; vol. iv., p. 645). B. L. G.

Phyllo'ma: See MORPHOLOGY (*Vegetable*).

Phyllop'oda [Mod. Lat., from Gr. *φύλλον*, leaf + *πούς*, *ποδός*, foot]: the lowest or most primitive group of Crusta-

cea, embracing segmented forms provided with numerous (ten to sixty, or more) pairs of leaf-like feet. In some the segments are easily seen in the anterior region of the body; in others this portion is covered by a "carapax" formed by a duplication of the skin, which either covers the body like a scale, or is folded so that it forms a bivalve shell, in which the body can be entirely retracted. None are marine; most species live in fresh water, but some are found in strong brine, for example in Great Salt Lake. It is interesting to note that Schmankewitch has pointed out that by transferring fresh-water forms to brine he was able to change not only specific but generic characters. Another fact of interest is that the eggs require desiccation and then reimmersion in water before they will develop. Corresponding to the development of the carapax noted above three families are recognized, the *Branchiopodidæ*, without carapax, the *Apodidæ*, with simple carapax, and the *Estheridæ*, inclosed in a bivalve shell. To the first belong the "fairy shrimps" common in roadside pools in the spring, and the brine shrimps; the second family occurs in North America only, W. of the Mississippi. The *Estheridæ* of the ponds are liable to be mistaken for small bivalve molluscs. To the naturalist these forms possess the greatest interest, as they probably represent the stock from which all other Crustacea have descended. They occur in all geological ages from the Cambrian to the present.



Apus equalis (after Packard).

LITERATURE.—Lankester, *Quarterly Journal Micros. Sci.* (xxi., 1881); Packard, *Monograph of Phyllopoda* (in Twelfth Annual Report U. S. Geological [Hayden's] Survey); Claus, Development, *Arbeiten. a. d. zoolog. Inst.* (vi., Vienna, 1886).

J. S. KINGSLEY.

Phyllostom'idæ [Mod. Lat., named from *Phyllos'toma*, the typical genus; Gr. *φύλλον*, leaf + *στόμα*, mouth]: a family of bats, so named from the leaf-like nasal appendages. The nostrils are in the front part of the cutaneous nasal appendages or open by simple apertures at the extremity of the muzzle; true molars are developed; there are four upper incisors, and the stomach is sacciform.

Phyllotaxy: See BOTANY and LEAF.

Phylloxe'ra [Mod. Lat.; Gr. *φύλλον*, leaf + *ξηρός*, dry]: a genus of plant-lice. There are but few species so far known as indigenous to Europe, but about twenty species have been described from the U. S.

The genus is essentially gall-inhabiting. It is distinguished from the other genera of the *Aphididæ* by the three-jointed antennæ (the third joint much the longest), by the simple venation of the wings, and by these being carried flat on the back, and not roof-fashion, as in the more typical Aphides.

For a long time the term *phylloxera* was known only to the naturalist; but since about 1870 the grape phylloxera, or *Phylloxera vastatrix*, Planchon, a species which injuriously affects the grapevine, has attracted so much attention, particularly in Europe and North America, that it has come to be known as *the* phylloxera. This insect, while it occasionally acquires the gall-making habit, normally dwells underground upon the roots of the food-plant. A native of North America, discovered in New York in 1854 by Fitch, it is found from Canada to the Gulf wherever the grapevine grows, and has doubtlessly existed on the wild vines from time immemorial. Early in the history of grape-culture in the U. S. the gall-making type was observed on the leaves of certain varieties, especially on the Clinton. The more normal root-inhabiting type was not suspected, however, till discovered by Riley in 1871. Meanwhile, about 1865, a peculiar grape-root disease began to attract attention in France. At first noticed in the lower valley of the Rhône, it spread rapidly until the entire destruction of the grape interest was threatened. In 1879 infested vines had been taken up and destroyed from nearly 3,000,000 acres. For several years annual appropriations amounting to almost $200,000 were made by the government for the carrying on of phylloxera investigations, and in 1874 a reward of 300,000 francs ($60,000) was offered for the discovery of an effectual remedy. The study and investigation which this induced soon brought to light the facts that the insect producing the disease was identical with that which is indigenous on American vines, and that it was imported into France from the U. S. in 1863 on vines sent to French nurserymen. It now occurs in all the vine-raising countries of Europe, and has been reported from South Africa, Algeria, New Zealand, and Australia.

Natural History of the Insect.—The species, as already intimated, presents itself in two types—the one (*gallicola*) gall-inhabiting, the other (*radicicola*) root-inhabiting. The former is easily distinguished from the latter (see accompanying figures) by lacking the tubercles or warts on the back. On carefully opening one of the galls we find it to contain the mother-louse and many pale-yellow eggs scarcely one-hundredth of an inch long, and not quite half as thick. The louse is about ·04 inch long, of a dull-orange color, and looks like an immature seed of the common purslane. The eggs hatch in six or eight days, and the young lice differ from their mother in their brighter yellow color and more perfect legs. Issuing from the mouth of the gall, the young lice scatter over the vine, most of them finding their way to the tender terminal leaves. Here they begin sucking the sap, forming galls, and depositing eggs, as their parent had done before. This process continues during the summer until the fifth or sixth generation. Every egg brings forth a fertile female, which soon becomes wonderfully prolific. By the end of September the galls are mostly deserted, and those which are left are usually infected with mildew, and eventually turn brown and decay. The young lice attach themselves to the roots and thus hibernate. It is an important fact that the gall-inhabiting insect occurs only as a parthenogenetic and apterous female form. It is but a transient summer state, and does, compared with the other or root-inhabiting type, but trifling damage.

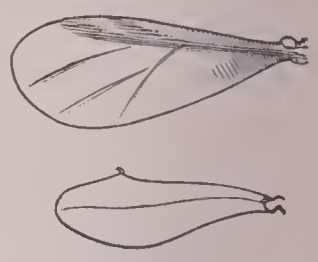


FIG. 1.—Upper and under wings of phylloxera.

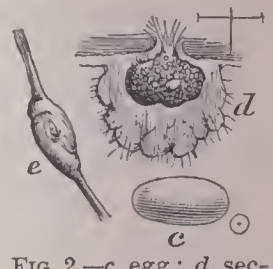

FIG. 2.—*c*, egg; *d*, section of gall, showing mother-louse and eggs; *e*, swelling of tendril; dot and lines showing natural size.

The more normal or root-inhabiting type presents many more forms and many interesting biological traits. The newly hatched lice are precisely like those which hatch in the galls, but, as they develop, rows of tubercles appear on the back where only minute short hairs were observed before (Fig. 5). During winter these young are found, somewhat dulled in color, adhering closely to the roots. As vegetation starts in spring they become active, rapidly enlarge, and soon begin laying unimpregnated eggs, for there are at that time no males. These bring forth females, which in their turn develop and lay unimpregnated eggs, and this virginal reproduction continues for five or six generations, the development increasing in rapidity with the heat, but the number of eggs decreasing. In July some of the individuals show little wing-pads at the sides, and begin to issue from the ground and to acquire wings. These winged individuals become very numerous in August, and continue to appear in diminishing numbers thereafter till the leaves have fallen. They are all females, and carry in the abdomen from three to eight eggs of two sizes, the larger ones about one-fiftieth of an inch long and half as wide; the smaller, three-fourths as long. These eggs are also unimpregnated, and are laid by preference on the under side of the more tender leaves,

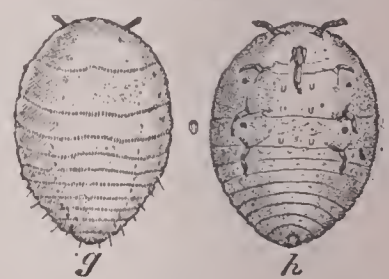

FIG. 3.—Mother gall-louse: *g*, dorsal; *h*, ventral view; natural size indicated between them.

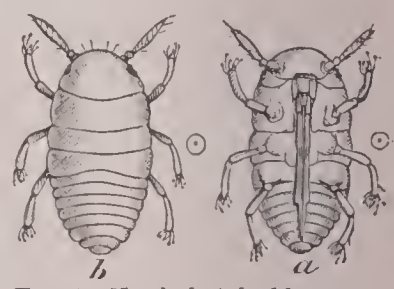

FIG. 4.—Newly hatched larva: *a*, ventral; *b*, dorsal view; natural sizes in circles at sides.

attached by one end amid the natural down. They increase somewhat in size, and give birth in about ten days to the true sexual individuals, the larger eggs producing females, the smaller males. These individuals are born fully developed, and are wingless and without mouth parts. A remarkable fact is that some of the females that never acquire wings, but always remain on the roots, also produce the few different-sized eggs from which males and females hatch. The sexes pair soon after hatching, and the female is delivered on the third or fourth day of a solitary egg, and then perishes. This impregnated egg is never laid on the leaf, but always on the wood, in sheltered situations above ground, or on the roots underground. The young hatching from it is the normal parthenogenetic mother, which lays a large number of eggs, and recommences the virginal reproduction and the cycle of the species' curious life. The impregnated eggs laid early in the season doubtless hatch the same year, but most of the eggs pass the winter before hatching, and from this fact are known as "winter-eggs."

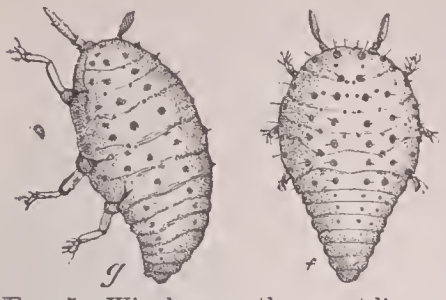

FIG. 5.—Wingless mother root-lice: *f*, dorsal; *g*, lateral view; natural size indicated at side.

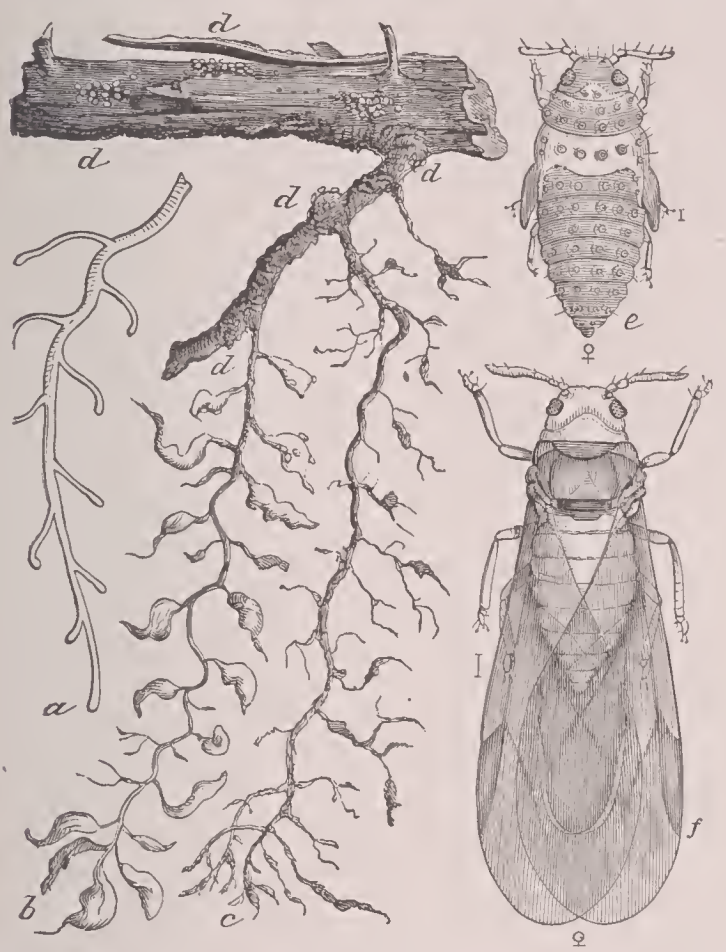

FIG. 6.—*a*, healthy root; *b*, root on which the lice are working, showing the knots and swellings caused by their punctures; *c*, root deserted by them, on which the rootlets have begun to decay; *d d d*, lice on the larger roots, natural size; *e*, female pupa, dorsal view; *f*, winged female, dorsal view, greatly enlarged.

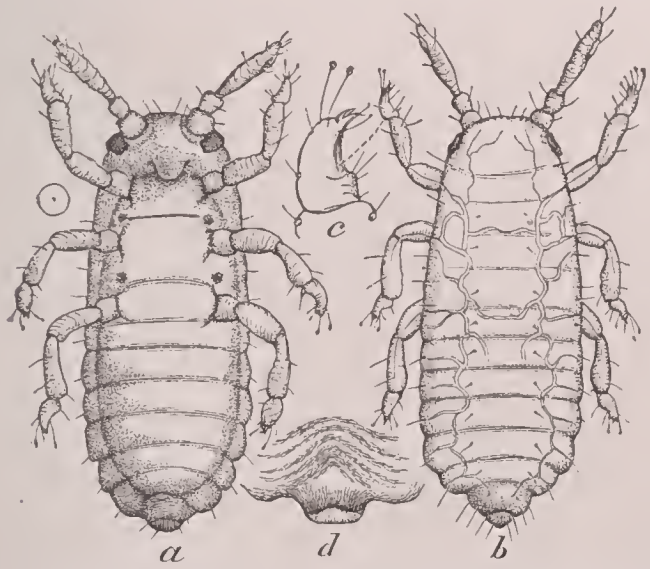

FIG. 7.—True female phylloxera: *a*, ventral view, showing obsolete mouth and solitary egg occupying nearly the entire body; *b*, dorsal view; *c*, tarsus; *d*, contracted anal joints after the egg is laid; dot in circle showing natural size.

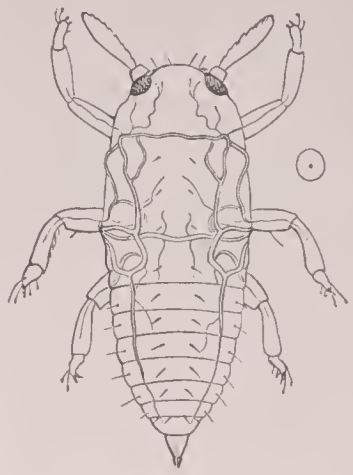

FIG. 8.—Male phylloxera: dot in circle showing natural size.

Appearance of the Phylloxera Disease.—A vine attacked by phylloxera has the more fibrous roots covered with little swellings; and a careful examination of the swellings during the growing season will disclose numerous yellowish lice of different ages, and groups of brighter yellow eggs barely visible to the naked eye. The swellings in course of time rot, and the lice settle on the larger roots. Vines that are more susceptible to the disease generally show external signs the second year of attack in a sickly, yellowish appearance of the foliage and in stunted growth; while the third year they frequently perish, when on examination the lice are no longer to be found—they have left or died—and all the finer roots have decayed and wasted away.

Spread of the Disease.—The wingless phylloxera travels over the surface of the ground from vine to vine, or beneath the ground where roots interlock; while in the winged form it may fly or be carried as many as 15 or 20 miles, and, under exceptional conditions, even more. Through man's agency, by commerce in plants and cuttings, it may be carried to indefinite distances. Hence the importance of precautionary measures in grape-producing countries still free from the scourge, and the wisdom of laws—such as have been enacted by Australia, Algiers, Italy, Germany, and other countries—prohibiting the importation of vines from infested regions.

The Disease more Virulent in Foreign Countries than where it is indigenous.—A certain harmony or mutual adaptation exists between the autochthonous fauna and flora of a country, the result of a long-past "struggle for existence." Plants and animals suffer most from diseases which they have not been accustomed to. American vines, though showing a varying power of resistance to the attacks of phylloxera, are less susceptible than the European vine, which has been so long under cultivation and which is more highly developed and more tender.

Practical Considerations.—Of the many remedies that have been proposed, none is universally practicable or satisfactory. Such an underground enemy is measurably beyond man's reach. Submersion, where feasible, is a sufficient protection. Bisulphide of carbon and sulpho-carbonate of potassium have proved useful, while petroleum emulsions may be used to advantage. Having discovered that the cultivated American vines possess a varying degree of resistance to the disease, there has been an immense demand from Europe for cuttings of the least susceptible of American vines. Many vineyards in France are being replanted with American vines. In 1881 22,000 acres in seventeen departments were so planted, while by 1890 719,500 acres in forty-four departments were covered with American vines. The varieties most employed are Clinton, Taylor, Jacques, and those more particularly belonging to the species *æstivalis*, as Cunningham, Norton's Virginia, Herbemont, Cynthiana, etc.

C. V. RILEY.
Revised by VERNON L. KELLOGG.

Phylogeny [from Gr. *φῦλον*, tribe, race + root of *γίγνεσθαι*, be born]: a term introduced by Haeckel to include the evolution of the race. Ontogeny, the contrasted term, includes the development of the individual from the germ. See MORPHOLOGY.

Phy'salis [from Gr. *φυσαλλίς*, bladder, kind of plant with bladder-like husk or calyx]: a genus of annual or perennial herbs of the family *Solanaceæ* or nightshades, embracing about thirty species, seventeen of which are found in the U. S. The *P. peruviana*, otherwise known as strawberry tomato, ground-cherry, winter-cherry, yellow alkekengi or Cape gooseberry, is cultivated in gardens in England,

France, and the U. S., and bears an edible fruit inclosed in a balloon-shaped netted angular calyx. The *P. alkekengi*, probably a native of Spain or North Africa, bears a brilliant scarlet berry, and is an ornamental garden plant. An American species, *P. philadelphica*, or purple ground-cherry, has a dark-purple berry an inch in diameter, which is sometimes preserved. Revised by CHARLES E. BESSEY.

Physap'oda: See ENTOMOLOGY.

Physeter'idæ [Mod. Lat., named from *Physe'ter*, the typical genus, from Gr. φυσητήρ, blower, bellows, kind of whale, deriv. of φυσᾶν, blow, blow up]: a family of toothed whales, containing the sperm-whale (*Physeter*) and pigmy sperm-whale (*Kogia*). Its members have a blunt head, which projects forward in advance of the jaw; the blowhole well forward, and in the sperm-whale on the left side; there is no back fin. The skull, which is unsymmetrical, has its front upper edges turned upward to form a sort of basin in which rests the cartilage containing the spermaceti. The halves of the lower jaw are anteriorly in contact for some distance, and in the adult teeth are present in the lower jaw only. See CACHALOT. F. A. LUCAS.

Physical Education: the training of muscles and nerves, which constitutes the modern practice of gymnastics. Though the term physical education is of comparatively recent date, and the thought suggested complicated and extensive, the idea itself is older than any records, and the underlying principles and methods which we now apply consciously and understandingly were prehistorically applied, perhaps unconsciously, yet at least effectively, as shown by the physique developed. As we compare the physique of to-day with that of two or three thousand years ago, we find very slight differences. Again, in those races which are still in their childhood as to mental and social development, we find essentially the same physical proportions. This physique has resulted from the physical activity necessitated by the environment of the generations which have preceded.

Ancient Aims and Methods.—In the earliest records we learn nothing of any conscious body training. The early peoples did what they were forced to do, hunted, farmed, or took care of their flocks, each one doing a multitude of things, and thus getting, perforce, a good all-round body training. Their relations to their neighbors were not always pleasant, and it was important to be able to fight effectively; hence the practice with the club, bow, spear, and sword naturally assumed a prominence in the education of the youth. Here we find the first hint of physical education in the training of the body for a definite future end. In all primitive peoples this seems to have been the main factor, and has determined the body training toward endurance of fatiguing travel, running, swimming, and in the use of weapons. The plays of childhood, then as now, tended to the imitation of the most attractive occupations of the parents, so again we have the use of toy weapons as well as spontaneous games which arose from the pure enjoyment of physical activity. Strength meant so much to the more warlike of the primitive peoples that it is not surprising that they worshiped it as an attribute of the gods, and sought to develop it by constant practice, crowning the strongest, bravest man as hero and leader. In studying the early records we find that the ideals of the peoples affected markedly the physical life. Warlike nations tended to skill and endurance in the use of weapons and armor, while others, as in India, prized grace and suppleness.

The Greeks.—Among the early Greeks the ability to wield effectively the sword and spear, javelin and bow, to run, climb, and endure fatigue transcended in practical value all other accomplishments, so it is not surprising to find that the education of the youth consisted essentially of this training. Later the ideals of the Greeks became broader, and we have the conscious training for grace and symmetry. The physical training of the Greeks was of a general character, consisting largely of games and contests, including running, leaping, wrestling, throwing the discus and spear, boxing, use of bow, various games with balls, and swimming. Many gymnasia were maintained for systematic training in athletics and gymnastics. The physical life was considered as of equal importance with the mental in the palmy days of Athens, and at the contests in Olympia and elsewhere the successful competitors were crowned with olive as were the poets and orators. The educational value of gymnastics was recognized by them in addition to the merely utilitarian, and "mens sana in corpore sano" is here first suggested.

The spirit of friendly contest was gradually lost, and professionalism resulted from the lowering of physical ideals, gymnastics and athletics becoming a duty of the slaves for the amusement of their effeminate masters. The Romans borrowed generously from the Greeks in their ideas of body training, outdoing them in building magnificent baths and gymnasia; but in their history is repeated the same change in physical ideals and resulting effeminacy. The barbarians who conquered them possessed the physical power in which they were wanting.

Middle Ages.—Until the invention of firearms military success was dependent upon bodily strength. We find this holding true through the Middle Ages, when the educational side of exercise was ignored and only the utilitarian valued. In contrast to this military attitude was the monkish, in which the body was disowned and the soul only regarded. On the one hand, we have chivalry developed with strength, grace, and beauty as ideals, while in sharp antagonism we have the monasteries filled with men who looked upon the body as a fetter to the soul, a thing to be scourged and starved into subordination. With the advent of gunpowder the utilitarian stimulus to training was lost, for men no longer won battles by brute force, and physical training became a thing of the past, aside from the spontaneous games of childhood and youth.

Beginning of Modern Gymnastics.—Luther began a reaction from this condition, though little was accomplished for many years. A German physician, Mercurialis, published a treatise (*De Arte Gymnastica*, 1573) on the old Greek gymnastics in which he emphasized the hygienic effects of exercise. Similarly an English physician, Thomas Fuller (1654 to 1734), advocated a return to the Greek methods. Montaigne and Locke made strenuous efforts in behalf of a broad education to include physical training, but it remained for Rousseau by his *Émile* (1762) to rouse general public interest in the movement.

Germany.—Basedow, Salzmann, Pestalozzi, Gutsmuths, Vieth, and Nachtigall became successively interested, and established gymnasiums in connection with certain schools. They worked enthusiastically, devising new movements and testing them, selecting and systematizing those which seemed valuable. The movement had not become general, till Jahn, an accomplished gymnast, conceived the idea of nationalizing Germany by educating the youth, and rousing in them the spirit of patriotism. To this end he organized societies for systematic instruction and training in gymnastics and athletics. He also invented many pieces of apparatus, such as the parallel and horizontal bars, and greatly enriched systematic gymnastics by adding new and varied exercises. Jahn is indeed the father of modern gymnastics. His influence spread quickly through Germany; societies were organized in the towns and villages, and the youth became strong, active, brave, and patriotic. Much credit must be given to Spiess, also, for suggesting many features which popularize gymnastics. After the German war for independence the gymnasiums flourished till 1819, when they were suppressed for political reasons, but revived in 1844. The spread of gymnastics in the U. S. and other countries at this time was due to exiled teachers from Germany. In Switzerland a complete system was organized by Clias at the same time Jahn was working in Germany, and this extended throughout the schools and spread to France, Italy, and England. The German influence has been preponderate in the U. S. At Milwaukee a normal school for the training of gymnastic teachers has been maintained by the Turners for years, and their societies are found in all the larger cities supporting well-equipped gymnasiums, constantly used by the enthusiastic members, and always exerting a strong influence for the broader school curriculum which shall include gymnastics. A marked characteristic of the German system is that it grows spontaneously, because it embodies the play instinct, and rouses all the stimulating emotions of play, at the same time giving the needed exercise.

Swedish System.—Ling, the founder of the Swedish system, was familiar with what Jahn and others were doing in Germany and Denmark, but worked out a system of movements from an entirely different standpoint. He analyzed movements into elements, each performed by as few muscles as possible, thus claiming to localize the will and train coordination. After drilling on these elementary movements for "purity" he combined them into groups forming complete exercises. The resemblance to the a-b-c method of learning to read is striking. Ling's aims were hygienic, educational, therapeutic, and military, and he worked out

what must be regarded as the most definite system of physical training that has yet been evolved. He formulated the idea of progression, making it more extensive than the Germans, because he forced all to begin with rudimentary movements, while the Germans built upon what the pupils already knew. Ling made a rigid artificial progression, while with the others the natural power was the guide to progress. He made a "day's order" the unit of work, insisting that all parts of the body should be exercised, and that exercise should begin gradually, reaching a maximum of effort before the end of the work, and finishing with slow easy movements to aid the heart to resume its normal beating. He worked constantly for discipline and initiated each movement by a command, thus keeping the attention fixed. This necessitated the naming of all movements, and has resulted in an extensive nomenclature. Music can not be used with the order movements, and is deprecated by the Swedes. The Swedish work was introduced in the form of "movement cure" by Taylor, of New York, many years ago. Dio Lewis based his "Mutual Help" gymnastics for schools upon the Swedish idea of analysis, but made the valuable addition of resistance in all the movements. Since 1889 a strong effort has been made to introduce the unmodified Swedish system generally into the schools of the U. S.

Physical Training in England.—England's contribution to physical training has been chiefly the development of sports and games, such as archery, football, cricket, tennis, boating, hare and hounds, handball, etc. These furnish undoubtedly as complete and thorough body development as was gotten in the primitive days. Dr. Parke has stated it very strongly: "The national games of English boys are infinitely superior to any system of artificial exercise ever devised." The great difficulty is that such games can not be made available for the proper development of all the children of the nation, owing to lack of time and space. In 1862 Lord Elcho made a strong effort for scientific physical training, and soon after Maclaren began his work at Oxford, which has resulted in such valuable contributions to our knowledge of the hygiene of exercise and training. (*Physical Education*, 1869, and *Training in Theory and Practice*, 1874.)

In the United States.—Between 1821 and 1879 several of the schools and colleges in the U. S. established gymnasiums, chiefly influenced by the Germans. The building of the Hemenway gymnasium in 1879 by Harvard College marks the beginning of an era in gymnastics in the U. S. Its influence may be seen in the rapid increase in the number of gymnasiums, all founded, essentially, upon the Harvard system of measurements and appliances. These now number more than 1,000, including the Y. M. C. A. gymnasiums, and have cost millions of dollars.

The Harvard System.—The Harvard system of developing appliances started in 1869, when Dr. Sargent took charge of the Bowdoin College gymnasium as student-instructor. At this time the equipment of a gymnasium consisted of certain German apparatus, parallel bars, horizontal bar, trapeze, etc., which were used by a few of the students only. The mass of the students were not experts in these exercises, and did little or nothing in the way of gymnastics aside from the enforced military drill, from which they revolted. They were hardy fellows and accustomed to heavy outdoor work, yet few were really well developed, most of them having done work which left its impress in characteristic asymmetry and faulty attitudes. A careful study of the problems thus presented led to the formulation of certain general principles which have since served as valuable guides. It was seen that attitudes necessitated by occupations became fixed habits in ratio to the length of time they were held uncorrected by other attitudes; also that in individuals possessing unequal muscular development faulty attitudes were often the result of the apparent shortening of stronger muscles, the increased tonicity of these muscles exerting a constant pull with the result mentioned. Thus the necessity of supplementing the development due to occupation was clearly seen, and also the rational method of effecting this by the local development of the relaxed weaker muscles. To do this economically and definitely various machines were devised which offered the required resistance. The first of these was the adjustable chest-weight (1869). This exercising-machine enabled one to exercise so much of the body that it was practically universal in its application, and was adopted by the gymnasiums of the U. S. till now it is a staple part of their equipment. The chest-weight was followed by other "developing appliances" as this kind of apparatus came to be called, all from the same motive, to furnish means selectively to build up weak and relaxed muscles to the best advantage. Such developing appliances are the high and low pulleys, leg-machines, wrist and ankle machines, chest expanders and developers, quarter circle, abdominal machine, etc., forty in number, devised chiefly between the years 1869–79. Dr. Sargent's gymnasium in New York was the first to be at all fully equipped with this apparatus (1878), and the Hemenway gymnasium, Harvard University, was the next (1879); this is one of the most fully equipped in the U. S. The developing appliances were devised to supplement other gymnasium work, not to replace it. The movements are practically similar to the Swedish, but differ essentially in that they are all made against external resistance which can be adjusted to strength, hence co-ordination is trained to an economical expenditure of energy in overcoming such resistance. This is an important distinction which serves as one basis for the classification of movements, for in slow free movements, such as the Swedish, much of the resistance comes from the contraction of antagonistic muscles. The individual's need may be made the basis of work, and a clear prescription given specifically directing his work toward the attainment of his ideal form and condition, not only from a physical standpoint, but in relation to his intellectual activity. This makes it important to have a trained physician study the individual and decide the problems presented in each case.

Zander, of Sweden, has devised an elaborate set of apparatus for resistive movements both active and passive, answering much the same purpose as the developing appliances, but too expensive to be generally available.

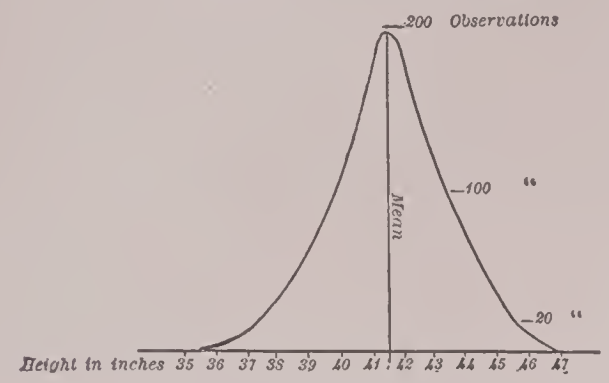
Anthropometry.—Doubtless for ages measurements have been taken as a means for comparing muscular development and recording the progress of an individual while in training. These measurements were chiefly of the height, weight, upper arm, forearm, chest, thigh, and calf, and were made at first with no idea of collecting data, but for immediate limited use. About 1870 anthropologists and ethnologists became interested, and by their suggestions gave an impetus to a broader consideration of the subject. The value of the measurements of a large number of individuals of school and college age was now first realized as contributing to a study of the rate of growth, influences affecting growth, males as compared with females, different nationalities, etc.; all questions of vital importance. To the more obvious measurements taken previously were added bone lengths, joint circumferences, and girths of important parts of the head, trunk, and limbs, together with certain strength tests, as grip, number of times pull-up and push-up, strength of back, leg, and chest muscles, of expiratory muscles, capacity of lungs, and a record of color of eyes and hair, history of diseases and habits, and nationality of parents and grandparents. This list of measurements was definitely selected and methods of taking formulated in 1878, and presented by Dr. Sargent in a report to the American Association for the Advancement of Physical Education in 1886, to insure the general use of the same methods, and hence to make the results of all examinations comparable. Valuable tables of measurements have been contributed since 1869 by Baxter and Gould, army recruits; Galton, of boys, 1875; Bowditch, of school children, *Rep.* State Board of Health, Massachusetts, 1877–79–91; Roberts, *Com. Rep. British Association*, 1878; Hitchcock, Amherst students, 1887–89–90–92; Erismann, Russian factory employees, 1889; Pagliani, Italian children; Wood, Wellesley students, 1890; Porter, school children of St. Louis, 1893; Sargent, Harvard students, etc. The number of persons of whom complete measurements had been charted in percentile grades was 15,000 in 1893.

The method of graphically representing the values of individual measurements relative to the whole mass of measurements by percentile grades, published by Galton in 1885, has been of the greatest assistance in studying the statistics gathered, bringing to light as it has numerous minor problems before overlooked. This method also made possible the charting of tables so that they can be used quickly and conveniently.

Attention is now being directed to the necessity for tests which shall show the condition of an individual as a vital unit, not merely as a mass of muscle and bone; tests of quickness, accuracy, endurance of mental and muscular power, of voluntary muscular control, delicacy of adjustment of automatic control, of circulation general and local,

of respiration, response of circulation and respiration to exercise, fatigue, tone of nervous and muscular systems, etc. These are problems constantly facing one practically interested in physical education, but so difficult of approach that little has yet been done. Mosso, Demeny, Galton, Warner, and others are working on the problems in Europe, and Harvard University has established a laboratory for such research in the U. S.

Charting Measurements.—The classification of large numbers of individuals shows a remarkable uniformity in the distribution of variation of corresponding measurements. The law of this variation is shown by the chart given herewith, of heights of individuals of the same age. It will be



Curve of distribution of 848 observations. Heights of boys five years old. From Bowditch's tables.

seen that at the center we have by far the larger number of observations suggesting for this age a tendency to a "medium" height. All other measurements may be similarly plotted and the means determined. Putting these means together, of all the items measured we may determine the parts of what may be called a medium or normal individual. By a similar method were gotten the data for modeling the statues representing the normal college student, male and female, exhibited by Dr. Sargent at the Columbian Exposition, Chicago, 1893. This medium individual, of course, shows the actual general type prevailing, not the highest type perhaps attainable, and the test of its correctness is the fact that if a number of new measurements of the same class of individuals is added it does not change this type, but merely falls into proper relation to it. Dr. Porter has contributed a valuable study of the relation of weight to scholarship in school children of St. Louis. He has taken weight as an index to strength and development, and has expressed the relation of weight and age to scholarship in percentile grades. This has brought out the fact that large children take higher intellectual rank than small ones in all the grades of the school, and that the rate of growth is practically the same for all grades of intellectual precocity. President Hyde of Bowdoin College has shown that scholarship and physical development in college work go similarly hand in hand. Dr. Bowditch has clearly shown the rate of growth in children of school age, and demonstrated the physical superiority of girls from eleven to fourteen years of age, due to their more rapid development. See Sargent, *N. A. Rev.*, Feb., 1883; *Physical Training in American Colleges and Universities*; Hartwell in *Report of the Commissioner of Education* (1886), p. 663; and J. Stanley Hall, *A Bibliography of Education* (1886). D. A. Sargent.

Physical Geography: the geography of nature, or the science of the surface of the earth and its envelopes. The structure of the earth and the history of the changes to which the structure and surface configuration are due are the field of geology; the general form of the earth as a spheroid belongs to geodesy; its motions and its relations to other planets and the sun belong to astronomy; the distribution of human races on the earth belongs to ethnography; the partitioning of the earth among governmental organizations to political geography; and the redistribution of natural products through human transportation to commercial geography. Physical geography includes physiography, or the classification and explanation of the various elements of the surface configuration; oceanography, or the description and study of the aqueous envelope; meteorology, or the description and study of the gaseous envelope; zoögeography, or the natural distribution of animals; and phytogeography, or the natural distribution of plants. See Geography, Physiography, Hydrography, Ocean, Meteorology, and Geographical Botany. G. K. Gilbert.

Physical Training: See Physical Education.

Physics, or **Physical Science** [*physics* is from Gr. *φυσικός*, natural, deriv. of *φύσις*, nature]: literally, the knowledge of the processes, both mechanical and vital, which occur in nature. In this sense the word physical has the same meaning as natural, but in the development of science the words have been specialized and the former has been used so as to exclude the study of organized bodies and the mineral world. Thus physics lies between pure mathematics—that is, arithmetic, algebra, and geometry—on the one hand, and natural history on the other hand. Chemistry is properly a physical science, but custom has excluded it from the domain of physics. The following is a list of the principal divisions of physics:

I. Mechanics (*q. v.*), which includes kinematics (see Motion), Dynamics (*q. v.*; see also Energy), Statics (*q. v.*; see also Composition of Forces), or the subject may be divided according to the nature of the body studied. Thus we have the mechanics of a particle, of a rigid body, of an elastic body, and of a fluid, the last being subdivided into Hydrostatics (*q. v.*) and hydrodynamics (see Hydraulics).

II. The secondary physical sciences, viz.: Optics (*q. v.*, where its subdivision into different departments, light, etc., is given); Acoustics (*q. v.*; see also Refraction of Sound, etc.); Electricity (*q. v.*); Magnetism (*q. v.*; see also Magnetism of Iron and Magnetism, Terrestrial); and the branches dealing with the action of pressure and heat in changing the volumes and physical states of bodies, for which see Heat, Gas, Liquids, Pneumatics, Thermodynamics, etc. R. A. Roberts.

Physics of Vegetation: See Physiology, Vegetable.

Physiocrats: See Political Economy.

Physiognomy [from Gr. *φυσιογνωμονία*, art of judging a man by his features, deriv. of *φυσιογνώμων*, judging by features; *φύσις*, nature + *γνώμων*, judge]: the art of interpreting the character of man by facial conformation and expression. It was first presented as a systematic study by Lavater in 1775. It was included in the systematic phrenology of Gall and Spurzheim. While much has been, and is still, claimed for physiognomy inconsistent with the facts of the natural history of man and the laws of physiology, the face may be regarded as an index, by facial expressions developed both voluntarily and involuntarily, of the prominent characteristics of intellect, emotion, and will. The physiognomy of infants, while the intellect is latent, expresses only happiness and pain or sorrow. With the training of the tongue and lips in phonation, and the development of the language of expression by the control of the muscles of the eye, the nostrils, and mouth, combinations of facial lines and individuality of features become established. By electrical excitation of muscles and groups of muscles of the face, the various expressions of mirth, sorrow, impotency, power, etc., may be produced irrespective of the mental condition—expressions which the subject's character had never developed. In hypnotic experimentation, also, the state called catalepsy is favorable to the systematic study of the muscles of facial expression. Recent research shows that a large part of facial expression is acquired by unconscious imitation of that of others. See Charles Bell, *The Anatomy of Facial Expression*; Darwin, *The Expression of the Emotions*. Also see Face.

Revised by J. Mark Baldwin.

Physiography [Gr. *φύσις*, nature + *γράφειν*, write]: as a part of physical geography, the science which describes, classifies, and explains the forms of the earth's surface. The features of the earth are conveniently grouped according to form, and also under the processes by which they have been produced. In this article they are arranged primarily according to form, and those of like form are classified by genesis. The processes through which they originate are: 1, diastrophism, or uplift and downthrow; 2, volcanism; 3, erosion and deposition by water; 4, erosion and deposition by wind; 5, erosion and deposition by waves; and, 6, erosion and deposition by glaciers. These are described under *Dynamic Geology* in Geology (*q. v.*).

Features of the Land.—Upon the uneven surface of the earth rests a great body of water which, being gathered in the hollows, divides the surface into a submerged or oceanic portion, and an emergent portion, the dry land. As viewed on the map and in respect to climate and various activities of man, the relation of the land to the ocean is of great importance, and the shapes of the land, as defined by coasts, are distinguished as continents, islands, peninsulas, etc.

Continents are the greatest of the land areas. Their ex-

tent, connections, and peculiarities of outline depend on what may be regarded as an accidental condition—the amount of water on the earth's surface; but they may also be regarded as the summits of the greater prominences of the earth's surface, and these prominences are the result of subterranean processes, the nature of which is little understood. See CONTINENT and EARTH.

Islands are in general small continents, and similarly owe their character to the accident of ocean-level, but something more specific can be said as to their origin than in the case of continents. Some of them are produced by the local and narrowly limited uplift of the ocean-floor; others by the building of subterranean volcanoes whose peaks are finally carried above the surface; yet others are occasioned by the elevation or subsidence of broad tracts of the earth's surface, elevation bringing above water the shoals of the ocean-bed, subsidence causing the sea to overflow the lower parts of the land, leaving plateaus or mountains as islands; yet another class have an organic origin, being formed by the growth of coral reefs which eventually reach the surface. Low and temporary islands are formed along some coasts through the shifting of sands by winds and currents. Out of fresh-water lakes, which usually result from the flooding of tracts previously dry, pre-existent hills and mountains sometimes project as islands, and certain rhythmic factors in the flow of streams cause them to divide their waters from time to time so as to inclose islands. See ISLANDS and RIVERS.

Peninsulas, differing from islands only in their narrow connections with mainlands, may be ascribed to all the causes which originate islands, and in the progressive development of geographic forms there is a constant interconversion of islands and peninsulas. Upon the subsidence of land or rise of water new peninsulas are won from the mainland, old peninsulas are converted into islands, and islands are submerged; by the reverse process new islands emerge from the waters, old islands become joined to the land, and old peninsulas become surrounded by land. A special variety of peninsula, called a *spit*, is built by waves and currents in a peculiar manner. A wind which drives waves against a shore also drifts the water along the shore. Sand and pebbles rolled upon the beach by the waves are carried by the current in the direction of its motion, and wherever the current leaves the shore, as, for example, at a cape, the drifted particles come to rest, being built into a low embankment, chiefly submerged but rising a few feet above the water. Currents from other directions, and especially tidal currents, often curve the spit at its end, and in this way the end sometimes grows broad, as in Sandy Hook, N. J., so as to produce the typical peninsular outline. The barriers or banks of the coast from New Jersey to Texas are of similar character, and are essentially peninsulas, though often temporarily converted into islands. See COAST.

Isthmuses, being only those parts of peninsulas which distinguish them from islands, hardly deserve special mention. In general they express only a relation between a pre-existent surface form and a particular position of water-level; but there is one variety which is a work of construction. Where an island lies close to the mainland or close to another island, the waves and currents usually build a spit from one land toward the other, and the completion of this process unites the two by a natural causeway, which is overrun by the water only during the most violent storms.

Capes also in general express the relations of ancient forms to modern ocean-level. They are original salients of land masses. There is, however, a special type depending on the modifications of shores by waves and currents. An examination of the map of the Atlantic coast from Virginia to Florida will show a series of cusps which are largely independent of the forms of the neighboring mainland. They consist of low bars of sand, and are probably associated with eddies of the oceanic circulation.

Passing now to those interior features of the land which depend upon the slope or relief of the surface, we recognize that certain ones are convex or prominent, others are concave, and yet others are intermediate in character. The principal convex features are plateaus, mountains, hills, and ridges; the concave, basins, valleys, and gorges; the intermediate, slopes, plains, terraces, and cliffs.

Plateaus are broad uplands of somewhat even surface. They may be indefinitely bounded; they may be limited on all sides by cliffs overlooking adjacent areas, or descending cliffs may limit them on one side and ascending cliffs or slopes on the other. Their surface may be continuous, or may be interrupted by stream gorges or by valleys. A plateau traversed by many deep waterways is said to be dissected. Many plateaus, including all the greatest, are produced by the uplifting of plains; others are sculptured from greater uplifted masses, and owe their forms to the presence in those masses of tabular bodies of resistant rock; yet others are produced by the flooding of an upland with lavas which, yielding less rapidly to subsequent erosion, not only themselves survive, but protect the rocks beneath them while the surrounding country is worn down. Plateaus of moderate size, and especially those with lava caps, are called "table mountains," and in the western part of the U. S. the term "mesa" is applied to small plateaus definitely bounded by cliffs. See PLATEAU.

Mountains differ from plateaus by having narrow or acute summits, and they are always bounded by steep slopes. Many are due to uplift along relatively narrow belts, accompanied with folding and faulting of the rocks. Others are built by the heaping of lava and scoria about volcanic vents. Yet others are residua of plateaus which have suffered stream dissection until the extension of gorges and valleys has obliterated the original even top. As the dissection of plateaus proceeds more rapidly in soft rocks than in hard, the residuary mountains usually mark the positions of the harder parts of the great mass originally lifted in the creation of the plateau. See MOUNTAIN and VOLCANOES.

Hills are prominences smaller than mountains. Some of them, like some mountains, are volcanic heaps, and many, like other mountains, are produced by the dissection of plateaus and plains; but none are the direct results of uplift. A large number are occasioned by glacial deposition, and a few by æolian deposition. Hills due to differential wear by rain and streams are partly located by hard rock masses and partly by the positions of minor divides, which often have no relation to rock texture. Where the degrading agent is glacial ice, relative hardness is probably the chief determining condition. Hills of glacial drift are limited to the tracts which were overrun by the Pleistocene glaciers (see PLEISTOCENE PERIOD), and arise from the irregularity of the process by which the detrital load of a glacier is deposited. Hills of æolian origin (see DUNE) are traveling bodies of sand, and are essentially related to the rhythmic process by which the wind transports such material. In general hills are round-topped as compared with mountains; but in arid regions the hills containing cores of hard rock are apt to have acute summits, and in the Western U. S. such hills are partly discriminated by the term "butte."

Ridges, being merely long and narrow hills or mountains, may seem ill entitled to consideration as a separate class; but usage has given them a distinctive name, and several of the processes of their genesis are equally distinct. The greatest of ridges are produced by uplift and are called mountain ranges, and the same process is appealed to in explanation of certain very small ridges measuring but a few yards in height and a few rods in width. Among glacial deposits the moraine, the osar or esker, and many drumlins are ridges. Where streams deposit their detrital loads in deltas the heaviest deposits are made next the banks, so that the water, when at low stage, flows between parallel ridges or natural levees. The spits, barriers, and bars of gravel and sand which are built along coasts by the action of waves and currents are submerged ridges, and if afterward the coast is lifted above water, these appear as ridges of the land. Perhaps the most important of the ridge-producing processes is dissection. When a plain is lifted so high as to be dissected by its streams it often happens that the principal streams run parallel to one another, and as their valleys broaden the intervening tracts are reduced to ridges. Ridges of similar origin on mountain-flanks are called "spurs." When a plateau consisting of folded strata is deeply dissected, as, for example, in the Appalachian district, the ridge is the most important of the resulting features. The original folding and faulting of the rocks causes the outcrops of the various beds to occupy long, narrow, parallel belts; and the unequal degradation of these, dependent on differences in the qualities of the rocks, produces a system of parallel valleys and ridges.

Basins are tracts limited by divides or water-partings. They are thus units with reference to the drainage of the land by rivers. They may be regarded as secondary results of the various causes which produce mountains and other uplands. Their interior shapes depend largely upon the action of streams, which are ever engaged in remodeling the

face of the land, excavating here and filling there. It is a general law of stream sculpture that the upper slopes are steeper than the lower, and basins are therefore in general concave in cross profile, as the name implies. Exceptions to this rule are introduced by local uplift, and other exceptions depend on the great differences among rocks in their ability to oppose and retard the work of water. Thus basins are diversified. See RIVERS.

A special class of basins, those which do not drain to the ocean but are completely encircled by water-partings, deserve separate mention. They are known as interior or closed basins. Many of them, including the greatest, arise from the unequal uplifting of the land, and this process is supplemented, especially in the arid interiors of continents, by local accumulations of alluvium, which gathers with relative rapidity along the bases of mountains. In a region of great rainfall the alluvial process is inoperative, because the entire water-supply of a basin escaping from it at one point constitutes so powerful an agent of transportation that an alluvial dam can not be formed across it. Where the rainfall is so scanty that the rivers are not perennial, the local mountain storm may create at the critical point an alluvial dam which is not immediately removed, and which, once established, tends to grow and become permanent. This is well illustrated in the Great Basin of the Western U. S., where uplift has produced a multitude of ranges trending N. and S., and the storm-swept alluvium from these has partitioned the intervening valleys into many separate basins. Valleys of various kinds are also dammed by lavas and thus divided into basins; and the heaping of volcanic ejecta about a vent walls in a circular basin called a "crater." In districts where the prevailing rock is limestone a considerable part of the drainage is often subterranean, the rainwater finding its way through crevices to stream-bearing channels beneath. Such crevices are in time enlarged, assuming funnel forms, when they are known as "limestone sinks" or "swallow-holes," and they are often afterward clogged at the bottom and converted into basins. The irregular heaping of sand by the wind leads to the inclosure of small basins, and in arid regions basins are sometimes hollowed out by the erosive action of the wind. The action of a stream upon its channel produces a somewhat uneven bed, so that if the water is afterward dried away there remain a series of small basins. On a greater scale ice-streams produce uneven beds, and the great areas overrun by Pleistocene ice abound in lake basins carved from the rock. Most of these are shallow, but a few, like the hollows holding the Laurentian lakes, are deep. Many other basins arise from the obstruction of valleys by morainic drift, and the uneven surfaces of the greater moraines abound in small hollows. The glaciated area is thus characterized by its numerous basins, and as the rainfall is abundant, these are mostly occupied by lakes and ponds. See BASIN and LAKES.

Valleys are lowlands between uplands. Many valleys are individual basins, but others are parts of drainage basins, and yet others belong to several basins. An important class are caused by differential uplift, or perhaps by a local sinking of the land. Another important class are carved out by streams in the dissection of a plateau. The ice of the Pleistocene period was chiefly instrumental in altering the forms of valleys which had been previously created by streams, but such alteration was sometimes of greater importance than the original stream work. The name valley is commonly applied only to those hollows having at bottom lowlands of some width, but in physical geography the term is sometimes used generically for all hollows of the land surface, including valleys proper and gorges. See VALLEY.

Gorges.—The channel occupied by a stream may be excavated from the rock or earth beneath or inclosed by the building of banks with detritus brought by the stream itself. When a stream flows at base-level, it retains a constant depth of channel, building on one bank as much as is cut away from the other. If the tract is lifted into a mountain or plateau, the stream at once cuts its channel deeper, producing a trench or gorge. When uplift is arrested, a limit to down-cutting is eventually reached, and the stream then moves to the right and left laterally, broadening the gorge and producing a valley. The gorge is thus the first step of dissection and the prelude to the valley. Where uplift is unequal or where the rocks traversed are of diverse character, the valley phase is reached earlier by some parts of the stream than by others, and thus many streams traverse alternately valleys and gorges. Gorges are produced also by stream-action in a district the configuration of which has been modified by volcanism or by glaciation, and in general they testify to the recency either of a drainage system or of conditions by which it is affected. The synonomy of the word *gorge* is extensive but chiefly local. The *ravine* is of small size; a *glen* in North America is similar to a ravine, but in Great Britain is a narrow valley; the use of *chasm* is largely poetic, but always implies vertical walls; *clove* is restricted to the Catskill Mountains and neighboring regions; *cañon* is a term widely used in the western parts of the U. S. See GORGE and CAÑON.

Slopes.—The meaning of the word mountain includes the idea of mass; the meaning of valley includes that of volume. If we avoid these implications and give attention only to the surface, we see that it is composed of various facets or slopes—for example, the sides of mountains, the sides of valleys, etc. A special terminology applies to the various features of slopes. Surfaces nearly level are *plains*; a class of fragmentary plains are *terraces*; surfaces nearly vertical are *cliffs*; and certain slopes of intermediate grade have also received names.

Plains.—Tracts of land are rendered approximately level and smooth in various ways. When sediment is deposited beneath a lake or ocean, the agitation of the water tends to prevent it from coming to rest on prominences and thus leads to the filling of hollows, and the ultimate result is an even surface. Many of the great plains have been thus formed beneath the water and afterward lifted into dry land. Other plains are produced by streams, which work toward this result by two processes. (1) A river flowing at base-level, that is, having its surface but little above the body of water to which it discharges, pursues a sinuous course, and washes away the bank on the outer side of each curve, at the same time building up the bank on the inner side. In this way it enlarges its valley, and it also spreads over the bottom of the valley a sheet of alluvium. The surface of this sheet, being overflowed when the volume of water is greatest, is called the flood-plain of the stream. Although the material just beneath the surface of the flood-plain is deposited by the stream, the plain owes its extent primarily to the action of the stream in cutting at the sides of the valley so as to enlarge it. (2) Wherever a stream deposits more than it excavates, so as to build up its bed, it produces a plain by burying all inequalities of the pre-existent surface under its alluvium. Deltas are plains of this character, and wherever the local conditions cause a stream to deposit its load in an interior valley, the result is a detrital plain known as an alluvial cone. Such plains surround the bases of the mountains of the Great Basin. When a tract remains for a very long time with the same relation to the sea, its streams all arrive at base-level and open out broad valleys, and eventually the divides between the valleys waste away so that the whole tract constitutes a single plain. This is called a base-level plain, and when the process of formation is approximately complete, but the positions of some divides are still marked by hills, it is known as a *peneplain*. A few plains have been produced by great floods of lava filling depressions and obliterating previous rugosity of the surface. A more important class are ascribed to the destructive and constructive processes pertaining to coasts. The waves attack promontories, cutting them away and accumulating the material in contiguous bays. Their tendency is thus to render the surface more even; and if a continent is slowly depressed, so as to permit the waves to accomplish their work progressively over the whole surface, there results a subaqueous plain, and this, through subsequent uplift, may become part of the land. It is called a plain of marine denudation. See PLAIN, DELTA, and FLOOD-PLAIN.

Terraces are subordinate and nearly level plains interrupting steeper slopes. Usually they are bounded upon one side or both by cliffs. Where a series of them occur on the same slope, they are comparable to a flight of stairs. Whenever a stream held long at base-level has developed a broad flood-plain, and the land is afterward lifted so that the stream can deepen its valley, the old flood-plain is left as a terrace on the side of the valley. Developing a new flood-plain at the new base-level, the stream may obliterate the terrace, or a second uplift may cause it to abandon the newer flood-plain and thus leave two terraces at different heights. Repetition of the process may produce an indefinite number of terraces on the same valley-side; but a series may also result from the continuous descent of a stream channel toward an ultimate base-level, provided the descent is so slow that it does not prevent a considerable amount of

lateral cutting. When a region occupied by level strata of alternating character is trenched by streams, the sides of the gorges are eaten back by the wash of rains, which removes the rock as fast as it is disintegrated by frost, etc. As some beds are disintegrated more rapidly than others, the valley-side is carved into a series of terraces. Terraces of another type were produced by the Pleistocene glaciers, which at various stages of their recession occupied the lower parts of valleys, and received against their flanks flat-topped accumulations of alluvium which remained after the ice had disappeared. The sloping strands wrought on coasts by the waves, and the deltas built at the mouths of rivers, both appear as terraces if subsequent changes cause the waters to retreat. See TERRACE.

Cliffs are produced directly by uplift when the rock on one side of a fracture rises above the other. The steep faces of some mountains are of this origin. The sides of a gorge are cliffs due to stream-cutting, and in stream valleys a cliff or bluff is produced wherever the meandering current encroaches on the valley-side. In the latter case the cliff is associated in origin with the flood-plains, and in terraced valleys such cliffs sometimes occur in series. The same differential process which develops terraces from level strata of alternating texture also develops cliffs, and cliffs and terraces constitute a stairway. Cliffs are also produced by unequal erosion by glaciers, and at the heads of mountain glaciers the ice eats backward by a sapping process, producing a semicircular cliff known as a cirque or amphitheater. Where waves erode a coast, their direct work is limited to a zone at the water-level, and they undercut higher masses of land, causing them to fall away in cliffs. See CLIFF.

Taluses.—The stability of a precipitous cliff depends on the strength of its material, and it wastes away as rapidly as its rock is fractured by frost or sudden heating. Loosened fragments fall to the base, and there accumulate in a steep slope which eventually extends to the top. Such a sloping heap of detritus, called a talus, is found at the base of every cliff which is not by some process perpetually renewed. Its grade, known to engineers as the earth slope, makes an angle of about 30° with the horizon.

FEATURES OF THE WATER.—By outline, by size, and by relation to land, bodies of water are distinguished as oceans, seas, lakes, bays, straits, etc. The forms of their bottoms are distinguished as deeps, oceanic plateaus, shoals, etc.

Oceans.—The earth's aqueous envelope, collectively known as the ocean, is divided, through the relation of its parts to continents, into a number of parts, likewise called oceans. The ocean basins are but complements of the continental prominences, and are referable to the same unknown cause. It is probable that the ocean-beds are of heavier material than the continents, and that an adjustment of level is prevented by this difference of density, but the cause of the difference is not understood. See OCEAN.

Seas are small oceans, and their basins are referable to the same general cause; but it is generally believed that while the ocean basins are part of the original configuration of the earth, or at least of immense antiquity, some of the sea basins are relatively young, having been produced by the submergence of land basins through the depression of large continental tracts.

Lakes.—The basins occupied by lakes and ponds have already been discussed as basins of the land. Given an interior basin, or cup-like hollow, the existence of a permanent lake is a question of climate. After every storm the water gathers in the bottom of the basin, and a portion of it at least is thence evaporated. The rate of evaporation depends on climate and the extent of the water surface, and the extent of water surface has its maximum determined by the size of the basin at the level of the lowest point of its rim. Thus the special configuration of the basin and the local conditions of rainfall and evaporation determine whether or not it shall contain a permanent lake, and if permanent whether the lake shall have outlet over the rim. The basins of all lakes are slowly filled by sediments washed into them from the sides; the channels of lake outlets are gradually deepened by the outflowing streams; thus in two ways physiographic processes tend to abolish lake basins, and but for the persistence or recurrence of the processes which create them, they would cease to diversify the face of the land. See LAKES.

Bays, the converse of capes, are re-entrants of the land. Some of the larger are called *gulfs*, and some of the least inclosed *bights*. It is possible that some are remnants of the primordial topography of the globe, but the greater number may be ascribed to the local uplift of the promontories that partly inclose them, and to the flooding of basins by the depression of broad continental tracts. Where the submerged hollow of the land was previously a stream valley, the resulting bay is called an *estuary* or drowned river valley, and the name *fiord* is applied to submerged valleys originally shaped by glaciers. The extension of spits into shallow water sometimes partitions off a portion of the sea which is known as a *lagoon*.

Straits, the converse of isthmuses, have a similar history which need not be recited. When the passage between an island and mainland is extensive, it is sometimes called a *channel*, and the word *sound* has a local but not consistent use in the same sense.

The configuration of the bed of the ocean, becoming known only through the plummet, has been little discussed with reference to its causes. Doubtless the greater features, the deeps and oceanic plateaus, result from the same causes which have produced the ocean basins themselves. By comparison with the volcanic peaks which project above the surface, it is easy to infer that many prominences of the ocean-floor are due to eruption. The idea formerly prevalent, that the sea-bottom has become smooth through sedimentation, has been largely dispelled, first, by the discovery that the bed of the deep sea is not more level than the surface of the land; second, by the discovery that the sediments washed from the land are not widely spread, but fall to bottom chiefly near the shore. The submerged belts close to the coast are indeed smoothed and shallowed by sedimentation, but they constitute only a small part of the oceanic area. By reason of their contrasted character they are sometimes called the continental shelves. The points of the ocean-bed which approach the surface are sometimes acute, and are then called reefs; more often they are comparatively smooth, and are designated as shoals or banks. It is probable that most of the shoals are submerged islands or capes whose surfaces have been leveled by sub-aërial processes of sculpture.

DIFFERENTIATION AND INTERPRETATION OF FEATURES.—In the brief outline of the subject here presented only the principal topographic species and their more important genetic varieties have been mentioned, and no attempt has been made to explain how the varieties are discriminated. It is in general true that all the various topographic forms produced by each physiographic agency are essentially distinct from all the forms produced by each other agency, notwithstanding the fact that the resemblances are often so great that the same name may with propriety be applied to results from several processes. Thus certain results from uplift, from aqueous erosion, from glacial deposition, and from littoral deposition have such formal resemblances that they are all called ridges; but comparative study shows that there are details of form by means of which each individual ridge may be referred to its cause. These criteria are supplemented in many instances by differences of material and differences of topographic relation. Through attention to such distinctions an intelligible meaning is found in each feature of the landscape; and each interpretation of a topographic form is a contribution to the history of the globe's surface. To ravel that history the geologist studies the internal structure, the geographer the surface configuration. The earlier history is discovered by the geologist alone; there is an intermediate chapter to which both contribute, and the closing paragraphs belong to the student of geography.

G. K. GILBERT.

Physiologus (Gr. *Φυσιολόγος*): the title given to a Greek treatise composed in the early Christian centuries, in which the habits or qualities of beasts, birds, reptiles, and even precious stones are related as affording allegorical or mystical illustration of Christian truths. The natural history of the book is of the most fabulous kind, as is illustrated by the account of the panther. This beast, says the *Physiologus*, when he has eaten his fill, sleeps three days; then wakes and lifts up his voice, at the same time emitting with his breath a wonderfully sweet odor. Attracted by this, all the other animals from far and near approach, except the serpent, which is the panther's enemy. So Christ, risen from the dead on the third day, gathered about him both Jews and Gentiles; but the serpent is the devil, whom Christ overcame. Still better known than this is the account of the fabulous Phœnix, symbolic of the Resurrection.

There is much uncertainty about the date and circumstances of the composition of the *Physiologus*. It is probable that it was originally written at Alexandria in the second century A. D., and intended for the edification of Christian believers of a mystical turn of mind. It immediately became extremely popular, and for many centuries was a source of allegorical illustrations for Christian writers and preachers. It was translated into many languages—Latin (early fifth century), Ethiopic, Armenian, Syriac, Arabic, Anglo-Saxon, German, Icelandic, English, French, Provençal, Spanish—not all of these, of course, directly from the Greek original. No small part of the remarkable attributions of qualities to animals, so common in all the literatures of Europe, is due to the wide circulation of this treatise in its many forms. The Greek text is best printed by Pitra, in the *Specilegium Solesmense* (vol. iii., 1855); the Latin text, by Cahier, *Mélanges d'Archéologie* (vols. ii.–iv.). For an account of the origin, character, and diffusion of the work, and a bibliography of the editions of the various texts, see F. Lauchert, *Geschichte des Physiologus* (Strassburg, 1889; has also a Greek and a German text). See also the introduction of F. Hommel, in his *Aethiopische Uebersetzung des Physiologus* (Leipzig, 1877). A. R. Marsh.

Physiology [Gr. *φύσις*, nature + *λόγος*, discourse, reason]: that department of natural science which treats of the laws, processes, and phenomena of living organisms. The prominent features of the physiology of the human being are vital force and nutrition. Vitality is the first condition of animal existence—the condition determining growth and maintenance; nutrition supplies the material of the germinal and incipient stages of organism, the mature growth of the body, and constant renewal and regeneration which counterbalance the waste of tissue metamorphosis.

The blood is the circulating nutritive fluid of the body—one-thirteenth of the entire weight, or about 12 lb. It is alkaline, and has a specific gravity of 1·052. It consists of the plasma, or water with albumen, fibrine, and salts in solution, and the solid elements, the red and white blood-cells and blood-plaques. The blood-cells constitute from one-third to one-half of its volume. The white are the largest, but relatively few—one to three or more hundred of the red. The white have active amœboid movements, and probably migrate from the vessels under certain circumstances to form new cells and tissues or for processes of repair. Red corpuscles carry oxygen from the lungs to the tissues; they convey nutritive matters, and bring about changes in certain of the products of digestion. Spectroscopic analysis of red globules reveals hæmoglobin, salts of potash, and many other substances.

The heart is the center of the circulation, propelling the blood into the arteries with a force of 51½ lb.—a force steadily decreasing as the arteries subdivide and approach the capillaries. Capillary circulation is effected chiefly by a remaining element of cardiac force. The veins return the blood to the heart. The veins are more numerous than the arteries—have a much greater capacity; hence, the venous blood circulates with less rapidity than the arterial. Venous return is aided by the compression of the integuments, exercise, and the presence of valves in the veins. In 1553 Servetus discovered the circulation of the blood through the lungs. In 1603 Fabricius demonstrated the valves of the veins; he was Harvey's preceptor at Padua. In 1616 Harvey demonstrated the general circulation of the blood, publishing his researches in 1628. In 1661 Malpighi discovered cells in the blood; in 1673 Leuwenhoeck determined these anatomical elements more definitely; in 1770–75 William Hewson discovered the white blood-cells.

Respiration is a double act of inspiration and expiration, expansion and contraction of the lung. Freshly inhaled air parts with oxygen in the vesicles of the lung, which is taken up by the red corpuscles of the blood, while expired air is loaded with carbonic-acid gas, received from venous blood. Respiration is an involuntary act, formerly regarded as reflex from the presence of impure air in the lung, now established as largely emanating from the cognizance which the medulla oblongata takes of the nutritive demand of all parts of the body for a constant supply of oxygen. Certain lower animals have no lungs, but receive the oxygen by direct surface absorption, or through structures which are the analogues of lungs.

The materials of the blood are supplied by food after preparation by the processes of digestion. Appetite and hunger are also sensations of centric origin, indicative of the nutritive demands of the tissues. Food must be varied in character, and include nitrogenous substances, hydrocarbons, carbohydrates, water, and a proportion of salts. The preliminary steps of digestion are mastication, insalivation, and deglutition. Albuminous substances are digested by the gastric and pancreatic juices, starchy and saccharine substances by the saliva and pancreatic and intestinal juices, and fatty substances by the secretions of the small intestine, pancreas, and liver. Emulsified food is but little absorbed from the stomach, but chiefly by the lacteals of the bowels, and emptied by the thoracic duct into the blood. The lacteals are a part of the general lymphatic or absorbent vessels distributed throughout the body, discovered by Eustachius and Asellius in the sixteenth century. Secretion is the action of special glands in the body, which elaborate elements of the blood for special purposes, as the fluid bathing the pleura and peritoneum, the synovial fluid lubricating joints, mucus to moisten the air-tubes and intestines, saliva, gastric and intestinal juices to digest food. Excretion is a glandular separation from the blood of effete products—the urine, fæces. Fæcal matter is partially *débris* of digested food. Bile is to be regarded secretory so far as it aids digestion. Certain ductless glands—the spleen, suprarenal capsules, thymus, thyroid, pituitary, and pineal glands are specially concerned in the elaboration of the blood. Nutritive waste and supply and glandular activity evolve heat to maintain the normal temperature of the body—in the healthy adult, 98·5° F., with little variation.

The nervous system was divided by Bichat into the cerebro-spinal and the sympathetic. The first comprises the brain, spinal cord, motor and sensory nerves, and nerves of special sense. The brain and cord have gray and white substances; the gray is ganglionic, composed of cells which originate force or receive impressions; the white is tubular, nerve-tracts which transmit motor stimulus from the brain to the muscles or sensory impressions from the body to the brain. The rapidity of nerve action is about 111 feet per second. Motor nerve-fibers terminate in neural plates upon the surface of the muscular fiber. Sensation is received by the tactile bodies of the hands and feet, the sensative papillæ of the skin, taste-buds of the tongue, etc. The brain comprises the cerebrum—the seat of the mind—the basal ganglia, the cerebellum, pons Varolii, and medulla—controlling vital functions. The spinal cord is a column of nerve-fibers connecting the brain with their distributions throughout the body. It possesses a vast number of nerve-cells, and is the seat of independent reflex action; it also has a partial control of co-ordinated action of groups of muscles. The cranial nerves proceed from the brain to their destination without entering the cord; they are partly nerves of special sense—sight, hearing, smell, and taste; the facial nerve governs the expression of the face; the pneumogastric nerve has important connections with the action of the heart, respiration, and movements of the larynx, and also influences the digestive processes.

Speech is produced by movements of the larynx, tongue, teeth, and lips, methodically trained to create sounds, which, by custom, are representative of ideas; it is an artificial method, the invention of man, and slowly developed and perfected. Sight is the impression received by the brain of light and the images of objects, transmitted through the optical media of the eye to the sensitive retina and optic nerve. Hearing is a transmission of sound-waves to the tympanum, and, by the system of ossicles and resonating canals and cavities, to the filaments of the auditory nerve. Generation, or reproduction of definite species and of individual characteristics, is the result of predetermined law. Conception begins with the fecundation of germinal elements, which

develop vitality, motion, and nutritive growth; by successive steps—cellular multiplication, nutritive membrane, nerve-canals, primitive blood-vessels, heart, lungs, glands, lateral walls of the body, inclosing cavities, budding of the extremities, and facial conformation—the embryo progresses to the perfect human being.

Revised by EDWARD T. REICHERT.

Physiology, Vegetable: that branch of science which deals with the activities of the cells, tissues, and organs of living plants. To treat of these exhaustively would far exceed the limits of this article, so only a general outline of the subject is here given. For convenience, the phenomena involved may be considered under five heads, viz., Nutrition, Growth, Reproduction, Physics of Vegetation, and Plant Movements.

NUTRITION includes all those activities which have to do with the supply of matter to meet the wants of living cells. It must be remembered that the life of a cell involves the use of matter, and that as long as a cell is living it must have a continual supply of certain substances. Accordingly we find that every mass of living protoplasm under favorable conditions is continually absorbing watery solutions. Imbibition is one of the most pronounced of the properties of living protoplasm, and its absence is one of the marked distinctions between living and dead cells. Along with the water thus absorbed are taken in the various substances dissolved in it; these may have been solids dissolved in the water, or liquids, or even gases. It appears, however, that solutions are not always absorbed without modification; thus, of a 2-per-cent. solution outside of the cell proportionately more water than dissolved substance may be absorbed, so that the solution in the cell may have a strength of no more than 1 per cent.; or the opposite may occur, and the strength of the solution in the cell may be greater than that outside of it. This selective power may even bring about chemical changes in the watery solutions, when the plant-cells absorb certain constituent parts of the chemical compounds.

Once absorbed, the solutions diffuse through the watery protoplasm and the watery contents of the vacuoles, "cell-sap." This diffusion continues from cell to cell in thin-walled tissues, and is here known as osmosis, the thin cell-walls serving as permeable membranes through which the solutions pass. In laboratory experiments the rate of diffusion varies greatly, and is dependent upon the solution itself, the substance in which it diffuses, and the temperature; thus hydrochloric acid diffuses more than twice as rapidly as common salt, and seven times as rapidly as cane-sugar. This law must hold for solutions in plants also.

Gases also are absorbed directly by living cells, and these are diffused through other gases in the plant, or they enter into watery solutions as described above.

In all the foregoing the plant is simply taking material, but the latter does not yet properly constitute a part of its living substance. It is still unassimilated plant-food, and must undergo considerable changes before the plant can make use of it. One of the best known of the assimilative processes is that by which the plant obtains its carbon, hence called carbon-assimilation, or, on account of its great importance, often spoken of as assimilation exclusively. The term here used, carbon assimilation, is to be preferred, inasmuch as it permits us to speak of other kinds of assimilation in the plant.

Carbon assimilation takes place only in protoplasm which is stained with chlorophyll. When a green mass of protoplasm is supplied with carbon dioxide (CO_2), it is able in the sunlight (or other strong light) to break up this compound and to use its carbon. At the same time some of the water (H_2O) is broken up and its constituents are united with those of the carbon dioxide. The successive steps can not be given with certainty. One of the best-known compounds formed in the series of changes is starch ($C_6H_{10}O_5$), which may usually be detected in the green cells after they have been exposed to the light for some time. The results thus far may be expressed as follows:

$$\begin{aligned} 5 \text{ molecules of } H_2O &= \quad H_{10}\, O_5 \\ 6 \text{ molecules of } CO_2 &= C_6 \quad\; O_{12} \\ \hline 1 \text{ molecule of starch} &= C_6\, H_{10}\, O_5 \\ \text{Excess of oxygen} &= \quad\; O_{12} \end{aligned}$$

Now, while starch is not made in such a direct way, it is worthy of note that in the chemical changes involved there is a setting free of oxygen as required by the expression above. In some cases the carbon compound formed at this stage is not starch, but something equivalent (physiologically) to it, as oil, or possibly glucose ($C_6H_{12}O_6$). These carbohydrates are readily taken into the protoplasm as constituents of its substance, from which in turn it may build a cellulose wall ($C_6H_{10}O_5$), or form glucose ($C_6H_{12}O_6$), sucrose ($C_{12}H_{22}O_{11}$), inulin, gums, oils, acids, etc. The importance of carbon assimilation may be inferred at once from the fact that about one-half of the dry substance of plants is composed of carbon, all of which has been obtained from carbon dioxide by the process outlined above.

Another important assimilative process is that by which nitrogen is obtained. This substance, although not present in such large quantity as carbon, is of high importance on account of its entering largely into the composition of protoplasm, and especially the cell nucleus. Inasmuch as about 80 per cent. of the air is free nitrogen, it might be supposed that plants derive it from this source, but careful experiments show this not to be the case. On the contrary, the nitrogen is derived from compounds in the air and water, chiefly in the form of nitrates of various bases (e. g. soda, potash, lime, ammonia, etc.), or some ammonia salt (e. g. the nitrate, chloride, sulphate, carbonate, etc.). In the higher plants it has been shown that these compounds undergo decomposition and reconstruction in the leaf, the result being the formation of proteid substances; but it is also held that probably every living cell is capable of taking part in these processes.

Of the assimilation of sulphur and phosphorus still less is known than in the case of nitrogen. We know that sulphur is absorbed in the form of sulphates (of ammonia, potash, lime, and magnesia), and some of these are to be found in the cells of plants, but where and how they are broken up is not known. It has been suggested that the crystals of calcium oxalate which occur in many plants are residua of chemical changes by which sulphur was set free from calcium sulphate. If true, this would show that the assimilation of sulphur takes place in all active tissues of the plant. Phosphorus is absorbed in the phosphate of lime, which undergoes decomposition in the tissues, but the details of the process are not known.

A number of other substances—e. g. potassium, calcium, iron, etc.—enter into the proper food of plants as solutions of their salts, which afterward undergo decomposition, thus allowing their assimilation. They are commonly called the "ash" of plants, and are often erroneously regarded as consisting of unassimilated matter. That they enter into the vital activities of the plant has been shown by the experiment of withholding them, with the result that the plant so treated always languishes or dies.

Even after the various substances which constitute plant-food have become assimilated they undergo many chemical changes. Every living tissue, and perhaps every living cell, is the seat of chemical changes in assimilated matter, whose results have in many cases been made out by chemists who have made numerous analyses, but in no case are the details of these chemical changes certainly known. We know that in many of these operations oxygen is absorbed by the active cells, and that as one result of their activity they excrete carbon dioxide. These after-changes of assimilated matter have been known in physiology as metastasis or metabolism.

To the foregoing general account of the nutritive activities of plants should be added the following: In homogeneous-celled holophytes (i. e. green plants whose cells are all alike) every cell performs all the operations noted above; but in heterogeneous-celled holophytes there is a division of labor, some cells or masses of cells engaging in certain activities quite different from those engaged in by other cells or tissues. Thus in a moss the cells of the root-hairs (rhizoids) which clothe the subterranean part of the stem engage in the absorption of watery solutions almost exclusively, and since they do not take part in carbon assimilation they are destitute of chlorophyll. On the other hand, the cells in the leaves are active in carbon assimilation, and have an abundance of chlorophyll. They absorb carbon dioxide and but very little, if any, water or soluble food-matter. The cells of the leaves and stem must therefore obtain their supply of watery solutions from the cells in the soil. The cells contiguous to those which absorb the solutions from the soil absorb from the latter, those next removed now absorb from those newly supplied, and so on from cell to cell to those at the upper extremity of the plant. In this way, by simple absorption from cell to cell, water and solutions are transported to all portions of the plant-body. Now, many of the cells above ground are often in contact with

dry air into which some of their water evaporates. The cells which suffer this loss of water repair it by absorbing water from contiguous cells, and these absorb from still others, and so on. There is thus a general upward movement of water in the moss-stem due to the loss of water from the leaves. Again it is seen that the carbohydrates are formed in the green cells alone, and from these they are diffused and absorbed as solutions from cell to cell throughout the plant. Thus there may be an upward movement of water while there is a downward diffusion of carbohydrates (and probably of other assimilated matters also).

In a plant with a still more complex structure, as, for example, the common sunflower, the cells of the surface of the roots absorb watery solutions, which are then absorbed from cell to cell in the large and numerous roots, finally passing in the same way from cell to cell in the stem and even to the leaves and flowers. The loss of water by evaporation from the leaves is much less proportionately than from the leaves of mosses, the latter consisting of but a single layer of unprotected cells, while the active cells in the sunflower-leaf are protected by a layer of specially modified thick-walled cells (the epidermis) less pervious to moisture. When, however, the stomates (breathing pores) are open for the ingress and egress of gases, much moisture escapes, and this is replaced by absorption from cell to cell as in the moss. The fact that moisture escapes through the open stomates has led to the assumption that they are for the purpose of permitting moisture to escape, and that the leaves of higher plants are "organs of evaporation." On the contrary, the stomates are clearly for preventing as far as possible the loss of water, while permitting the free interchange of gases, and the leaf is rather a skillfully devised structure in which a multitude of thin-walled cells gorged with moisture are exposed freely to the air with a minimum of loss of water by evaporation.

The stomates of the leaves and stem when open admit the external gases to the intercellular spaces of the whole plant, and also allow the internal gases to escape into the air. There is thus a respiration in plants of the high organization of the sunflower, but when examined closely this does not differ in any essential from the simple absorption and excretion of gases by a single-celled plant.

In the hysterophytes (parasites and saprophytes) the solutions absorbed consist partly or wholly of assimilated matter. When this includes the carbon products of assimilation the plant does not develop chlorophyll, as in the dodders, Indian-pipes, broom-rapes, and the vast assemblage of "fungi." When, however, there is little or no absorption of carbon compounds, chlorophyll is present and the leaves are well developed, as in the mistletoe. In the dodders the absorption is performed by suckers (outgrowths) on the stems, and as a consequence the roots do not develop. In these leafless, rootless, and eventually almost stemless plants there is probably little assimilation of any kind; they are nourished much as the flower and fruit-clusters of ordinary plants are. The evaporation of water is probably as rapid in hysterophytes as in holophytes of equal structural complexity and similar habits. The fungi quickly lose their water and become wilted and dried up when their supply of moisture is cut off. On the other hand, among the flowering hysterophytes the absence or small size of the leaves greatly reduces the amount of evaporation. Clearly, also, the respiration of hysterophytes is less than in holophytes, there being little or no absorption of carbon dioxide. Oxygen, however, is absorbed, and carbon dioxide excreted by most if not all hysterophytes.

Growth.—A young cell consists of a nucleus and a solid (continuous) mass of protoplasm closely invested by a wall. During the nutritive processes described above the substance of the protoplasm is increased, and this requires an increase in the area of the wall; these two increments constitute the simple growth of the cell. Later, the absorption of water and the formation of a large vacuole, with or without an increase in the mass of the protoplasm, may require the increase in the area of the wall; this, also, is growth of the cell. In its increase in area the wall is first distended by the internal pressure, and new matter (cellulose) is secreted upon or in it, thus permanently increasing its area.

In simple plants every cell may grow, producing an aggregate growth of the whole plant-body. As each cell reaches a certain size it divides into two, which then grow, and divide again, and so on. Continued growth thus involves the growth of the cell and its fission, and where the plant-body is made up of similar cells the growth is general throughout it. Where, however, the plant-body is made up of dissimilar cells, involving and implying dissimilarity of function, growth is confined to particular masses of cells, occupying definite portions of the plant-body or its organs. In such a case we generally say that growth is confined to the younger cell-masses; this is necessarily true, but conveys little information; it would be more accurate to say that such and such cell-masses have a short growing period, while others retain their power of growth for long periods. The woody stem of an ordinary dicotyledonous shrub or tree consists of masses of different kinds of cells which soon lose their power of growth; thus the wood-cells, vessels, and even the parenchymatous cells of the wood, pith, and bark are soon incapable of growth in size, and retain but little longer the power of growth in thickness of the wall. In the same stem certain other cells (lying between the wood and bark) retain their growing power for many months.

Reproduction.—One of the most important functions of plants is reproduction, or the formation of new individuals from the living cells of those already existing. For a discussion of this subject, see Reproduction (*in Plants*).

The Physics of Vegetation.—Since all parts of plants are composed of matter, it follows that they are subject to physical forces. In a living cell there is no suspension of the action of any force or of any physical law. Every atom of matter in the cell is as much under the control of force as it was before it entered into living matter. In the cell there are many forces, and what we see is the resultant of all, not of one alone, and it is this complex result which sometimes has puzzled us. We can no more reasonably doubt that the matter in living cells is still subject to physical forces because of apparently paradoxical results than we can entertain doubts of the mutual attraction of all matter because smoke rises, or the similar poles of magnets repel one another. It is only when we take a superficial view of such cases that they appear paradoxical.

It is not necessary, even if it were possible, to discuss in detail the action of the various physical forces upon each mass of matter in living plant-cells. It concerns us more in this place to note the behavior of the living cells, cell-masses, or the whole plant under the influence of physical forces of varying intensities.

Heat.—For every cell there is a certain range of temperature in which it is active, culminating in an *optimum* temperature; above this its activity decreases rapidly to its *maximum* temperature, where all activity ceases. In like manner below the optimum temperature activity decreases; not so rapidly, however, until the *minimum* is reached, where activity ceases again. This range of activity is not the same for all plants, and in many-celled plants it often differs considerably for different parts of the plant-body. Prof. Sachs, of Germany, determined this range for the germination of the following seeds:

SEEDS.	Minimum.	Optimum.	Maximum.
Indian corn.....	9·4° C.=48·92° F.	34° C.=93·2° F.	46° C.=114·8° F.
Pumpkin	14·0° C.=57·2 ° F.	34° C.=93·2° F.	46° C.=114·8° F.
Wheat.....	5·0° C.=41·0 ° F.	29° C.=84·2° F.	42° C.=107·6° F.
Barley.....	5·0° C.=41·0 ° F.	29° C.=84·2° F.	37° C.= 98·6° F.

Common observation shows that plants differ much as to the degree of heat necessary for germination, as well as for other activities, but we have little in the way of careful measurements upon anything more than the germination of seeds. Certain experiments appear to indicate that the range in green parts of plants is much greater than has usually been supposed, in some cases approaching 0° C. and in others reaching 50° to 55° C. (122° to 131° F.), or even more. On the other hand, it is certain that other parts of plants will not endure such temperatures; e. g. roots and underground stems.

When the maximum temperature for a plant-cell is exceeded, a point is generally soon reached where by coagulation of the albuminoids or by some other changes the structure of the protoplasm is permanently altered, rendering further activity impossible, even upon the return to a favorable temperature. Such a cell is "dead." Reduction of the temperature below the minimum sooner or later results in a similar permanent alteration of the structure of the protoplasm, with the consequent "death" of the cell. Here it is noticed that watery cells can not endure as low temperatures as those which contain little water; e. g. a dry embryo in a kernel of Indian corn will endure a temperature of 40° or more below 0° C. (−40° F.), but when it has

made a little growth a slight frost (0° C. or 32° F.) will quickly kill it. In many respects the results of too great a reduction of temperature are similar to those produced by too great an elevation; the albuminoids become coagulated and the protoplasm structure is permanently changed. In both cases the power of imbibing water and of rendering the cell turgid is lost, and in ordinary temperatures chemical changes in the free solutions soon set in, resulting in their rapid disintegration.

Light.—Directly or indirectly all plants are dependent upon the light. Although many parasites and saprophytes grow in complete darkness, they do so by using material which developed in the light. We have seen (*supra*) that carbon assimilation is possible in the light only in cells whose protoplasm is stained with chlorophyll. All the carbon of vegetation came originally from chlorophyll-bearing cells, made active by the light. Just how the light affects the green protoplasm in carbon assimilation is not known, nor do we know how light brings about the formation of chlorophyll by the protoplasm. We can only regard light as a force which, acting upon the complex compound protoplasm, produces molecular changes resulting in the secretion first of chlorophyll, and second of a carbon compound. Here it must be remarked that not all cells secrete chlorophyll in the light, although many which are normally colorless become green under its influence; thus while many roots and underground stems become green on exposure to the light, the petals of many flowers, the stems of the dodders, and the cells of fungi when so exposed develop no chlorophyll. It is a fact, however, that some kind of coloring-matter is produced in nearly all cells on exposure to the light, as is well shown by the familiar experiment of growing flowers, fruits, and various fungi in complete darkness, when they are usually much paler or wholly wanting in color. The color of some flowers appears to be independent of the direct action of light, as shown by Prof. Sachs, who obtained perfectly normal flowers of the tulip, iris, squash, and morning-glory when grown in the darkness, although the leaves were completely etiolated.

It has been shown by experiment that light somewhat retards the growth of certain cells. A shoot grown in darkness or deficient light is always longer than one grown in strong light. Even in the daily growth of plants the rate during the day is less than during the night. This has been called by Prof. Vines, of England, the "tonic influence of light." Here we must note that while the stem grows more rapidly in darkness, the leaves grow less rapidly, and in complete darkness remain very small.

Gravitation.—Many cells always grow in a particular direction with respect to the earth's mass (gravitation). Thus the principal roots usually grow toward the earth, while most stems grow away from it. When a seed germinates its roots invariably take a downward and its stems an upward direction, and it does this regardless of its immediate surroundings. This is well illustrated in the experiment shown in Fig. 1, in which seeds are planted half an inch deep in a flower-pot, which is then covered with coarse netting and inverted upon a ring-stand. Below it is placed a mirror, standing at a proper angle to reflect light upon the under surface of the flower-pot. A tall bell-jar is put over the apparatus and water is kept in the dish so as to preserve a moist atmosphere. The whole is now placed in a light room of the proper temperature. Upon germination the stems invariably grow upward, deeper and deeper into the ground and darkness, while the roots grow down, out of the ground, and into the light. If, now, we make another experiment we may understand the matter better. Two small flasks containing a little water are slipped over opposite ends of a wooden rod and retained in place by a coil of wire, as shown in Fig. 2. A sprouted seed is previously fastened to each end of the rod by a stout pin, and the whole is rotated rapidly upon the steel rod *s* by a water or electric motor. As the roots develop they grow outward in the direction of the centrifugal force, and the stems grow inward, or in opposition to that force. Upon slower rotation both roots and stems grow diagonally, the angle depending upon the rate of revolution.

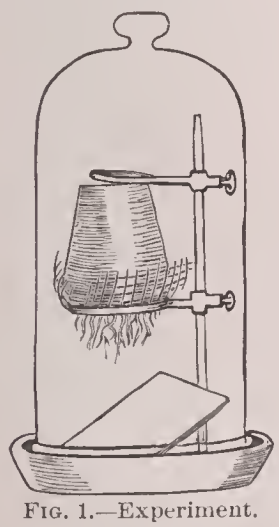

FIG. 1.—Experiment.

In considering the mode of action of gravitation upon parts of plants we can not suppose that the root-cells are more subject to it than the cells of the stem. Perhaps the best statement which we can now make of this matter is that each cell exhibits what we may call "polarity" with respect to the lines of constant force (gravitation, or centrifugal force). When these lines are vertical, as in gravitation, the cells exhibit vertical polarity; when the lines of force are horizontal, the cells exhibit horizontal polarity; and when, as in the experiment above, there are two lines of force acting at right angles to each other, the axis of polarity is diagonal. This general statement, while incomplete, and here applied only to the principal roots and stems, is capable of a far wider application, and doubtless may be useful as a working hypothesis.

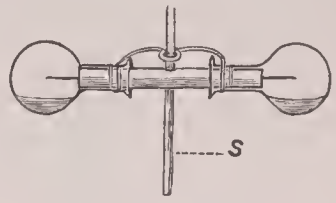

FIG. 2.—Rotating apparatus.

Electricity.—While plants exhibit electrical conditions in common with other material objects, they seem at present to possess no physiological significance. Every chemical change in the cell probably produces some disturbance of its electrical conditions and of those of its neighboring cells. So, too, the considerable amount of evaporation of water from leaves and other aërial parts probably produces electrical disturbances. Various observers have noticed weak electrical currents between different tissues upon making tranverse sections of stems or leaves. None of these appear to be of any importance physiologically, at least as now understood. Strong electrical currents, especially when interrupted, quickly disorganize the protoplasm; weak currents retard or arrest protoplasmic movements, and very weak currents produce no perceptible effect.

Humidity of the Air.—Since the walls of living plant-cells are usually permeable to water it follows that when exposed to relatively dry air they lose a portion of their watery contents by evaporation and soon cease their activity. In many-celled plants this loss is repaired by the absorption of water from contiguous cells not so exposed, and the latter in turn repair their loss by absorption from the surrounding moisture (water or moist earth). The condition of the atmosphere may thus set up many disturbances in the plant, but it must not be forgotten that the loss of water by the plant is a purely physical process.

Supply of Energy to the Plant.—The work done by a plant involves the expenditure of energy. In hysterophytes the decomposition of the chemical compounds absorbed by them affords a supply of energy fully, or nearly, adequate for all their needs. In holophytes the case is far different; they absorb compounds of simple chemical constitution supplying relatively little available energy, but in their chlorophyll-stained cells they are able to arrest the energy of the sunbeam, and divert it to the work of the plant. Doubtless green plants derive some energy from the decomposition of the compounds absorbed by them and perhaps more from the heat to which they are exposed, and possibly to a slight extent from other sources, but the great supply of energy is the light of the sun. It has been shown experimentally that any other bright light, whether produced by lamps of various kinds or by the electric arc, when of sufficient intensity may be a source of energy for green plants.

PLANT MOVEMENTS.—It is one of the essential characteristics of living things that they move, although "motility" and "life" are not synonymous. A complete examination of the motility of plants would include the many kinds of movements exhibited by protoplasm, whether naked (as in zoöspores) or inclosed within walls of greater or less rigidity, and in addition the very slow movements connected with growth and nutrition.

Nutation.—Under this term are gathered those cases in which terminal parts of plants move spontaneously and somewhat regularly in definite directions. It has been observed that the growing ends of climbing plants perform circular nutations; thus in the hop and honeysuckle the free ends of the stems rotate in the direction of the hands of a watch (Fig. 3, *a*), while in the yam, bean, and morning-glory the rotation is the reverse (Fig. 3, *b*). In other cases the nutation is a simple swaying back and forth, as Darwin has observed, in many leaves and growing shoots.

Geotropism.—This term includes all those movements of plants or their parts due directly or indirectly to gravitation, discussed above. In many works the movement toward the earth is termed geotropism, and organs exhibiting it are

said to be geotropic. Organs which move away from the earth, then, exhibit negative geotropism, and are said to be negatively geotropic.

Heliotropism.—In like manner the movements of plants or their parts due to the light are included under the term

FIG. 3.—Twining stem of hop (*a*) and yam (*b*), showing opposite nutations.

heliotropism. Organs which turn toward the light are heliotropic (or sometimes positively heliotropic), while those which turn away from it are said to be negatively heliotropic, and the phenomenon is negative heliotropism. The upper surface of most leaves is positively and the lower negatively heliotropic; yet some leaves have both surfaces positively heliotropic, and their blades are therefore approximately vertical and parallel with the meridian, as is notably the case in the compass-plant (*Silphium laciniatum*) of the prairies of the U. S. The tendrils of many plants are negatively heliotropic, as are also the runners of some others.

The movements of plants with the decrease in the amount of light, as at nightfall, often called the "sleep of plants," are heliotropic in their nature. Some of these are quite marked, as in many of the clovers, beans, peas, and their allies. The species of *Oxalis* are notable for their nyctitropic movements.

FIG. 4.—Ordinary (*a*) and "sleeping" (*b*) positions of leaves of white clover.

Irritability.—Many parts of plants exhibit movements as a result of physieal contact with some object. For this sensitiveness to contact the term irritability has been used. One of the best examples of this is the well-known "sensitive-plant" (*Mimosa pudica*), whose leaflets quickly assume a particular position when rudely touched. A more remarkable example is the Venus's fly-trap (*Dionœa muscipula*), in whieh each lobe of the leaf has three sensitive hairs upon its upper surface; and when these are touched the two halves of the leaf close together quickly. (See INSECTIVOROUS PLANTS.) Many stamens are sensitive to touch, as in the barberry, portulaca, and purslane.

The tendrils of many plants exhibit irritability, and when touched by an object bend toward and eventually coil around it. If after contact and some bending the tendril be freed once more, it will soon straighten out as before, and may be made to bend in the opposite direction by another contact; and this may be repeated a number of times. See, further, BOTANY, PROTOPLASM, and HISTOLOGY, VEGETABLE.

LITERATURE.—The most important of the recent general works on plant physiology are the following, in which may be found full references to books and papers on special topics: Charles Darwin, *The Movements and Habits of Climbing Plants* (2d ed. 1875), and *The Power of Movement in Plants* (1880); W. Pfeffer, *Pflanzenphysiologie* (1881); W. Detmer, *System der Pflanzenphysiologie* (1882); G. L. Goodale, *Physiological Botany* (1885); S. H. Vines, *Lectures on the Physiology of Plants* (1886); J. Sachs, *Lectures on the Physiology of Plants* (Eng. ed. 1887); A. Zimmerman, *Die Morphologie und Physiologie der Pflanzenzelle* (1887); W. Detmer, *Das Pflanzenphysiologische Praktikum* (1888); J. Wiesner, *Elemente der Wissenschaftlichen Botanik* (3 vols., 1889–91); J. Sachs, *Gesammelte Abhandlungen über Pflanzenphysiologie* (1892–93); W. Oels, *Pflanzenphysiologische Versuche* (1893), English translation by D. T. MacDougal under the title of *Experimental Plant Physiology* (1894).

CHARLES E. BESSEY.

Physitheism: See INDIANS OF NORTH AMERICA.

Physopoda: See ENTOMOLOGY.

Physos'tomi [Mod. Lat.; Gr. φῦσα, bellows (i. e. air-bladder) + στόμα, mouth]: those teleostean fishes which are provided with a duct connecting the air-bladder with the intestine as by a mouth, in allusion to which the name has been given. The name has been used with varying limits by different authors.

Phytoph'thires [from Gr. φυτόν, plant + φθείρ, louse]: that group of Hemipterous insects which contains the leaf-fleas (*Psyllidæ*), plant-lice (APHIDES, *q. v.*), and scale-insects (*Coccidæ*), characterized by having usually wingless females, wings when present with few veins and uniform texture, and the body frequently concealed by a waxy or powdery secretion from certain dermal glands. All are parasitic on plants, and cause no little damage to agricultural and horticultural interests. Exceptions to this rule are to be found in the cochineal insect (*Coccus cacti*) the lac-insect (*Coccus lacca*), and the manna-insect (*C. manniparus*), which produce directly or indirectly products of value to man. Among the most injurious forms is the grape PHYLLOXERA (*q. v.*), though many of the scale-insects are serious pests.

J. S. KINGSLEY.

Phytozo'ön, pl. **Phytozo'a** [Mod. Lat., from Gr. φυτόν, plant + ζῷον, animal]: a term sometimes applied to the antherozoids, or male sexual cells of certain cryptogamous plants.

Piacenza, pĕĕ-ăă-chen'zăă (anc. *Placentia*): chief town of the province of Piacenza, Italy; on the right bank of the Po, a little below its junction with the Trebbia; 43 miles S. E. of Milan (see map of Italy, ref. 3–C). Formerly a fortress of considerable strength, it is still surrounded by ramparts and trenches forming a circuit of 4 miles. The streets are broad, the Stradone Farnese being the finest, and the principal square, the Piazza de' Cavalli, in which are equestrian statues in bronze of Alessandro Farnese, governor of the Netherlands, and his son Ranuccio, has a busy aspect. The city in general, however, has a decayed and somber look, owing partly to the mediæval character of many of the buildings. The cathedral, begun in 1122 on the foundations of a much earlier church, is Lombardo-Gothic in style, and in its interior contains numerous frescoes mostly by Guercino and L. Caracci. Among other noticeable churches are Sant' Antonio, once the cathedral, built in 324 (on the spot, it is said, where St. Barnabas first preached to the people), but much altered by restorations, and San Sisto, which is known as giving its name to Raphael's famous Madonna, now in Dresden. The Palazzo Farnese, called La Cittadella, was a splendid structure, but is now a barrack. The Palazzo Comunale (1281), in the main front of the lower story, constructed of marble, presents fine open-pointed arcades. The municipal library contains 120,000 volumes. This town, of Gallic origin, served the Romans as a strong point of defense against Hannibal, and the construction of the great military road of M. Æmilius Lepidus and various large canals raised it to great prosperity. Under the Goths it was allowed to govern itself, and under the Lombards and Franks it had a fendal lord. In 1545 it was united with PARMA (*q. v.*) to form a duchy for Pierluigi Farnese, son of Paul III. In 1859 it was united to the kingdom of Italy. The trade of Piacenza is chiefly in the products of the rich neighboring country—grain, wine, cheese, etc.; the manufactures are silk, cotton and woolen goods, and pottery. Pop. (1892) 37,000. The province has an area of 954 sq. miles. Pop. (1892) 229,039.

Revised by R. A. ROBERTS.

Piacenza, DUKE OF: See LEBRUN, CHARLES FRANÇOIS.

Pi'a Ma'ter [Mod. Lat., fancifully taken from Lat. *pi'a mater*, pious or gentle mother; see DURA MATER]: the innermost of the meninges or membranes covering the brain and spinal cord. It is so named because it serves in nourishing the nerve-centers. It is a fine plexus of blood-vessels covering the brain, dipping down into its convolutions, forming the velum interpositum in the third and the choroid plexus in the fourth ventricle. A small part, over the crura

and pons, is not very vascular, but tough and fibrous. It is abundantly supplied with nerves and lymphatics. The pia mater is liable to inflammatory diseases which are collectively designated meningitis. The pia mater of the spinal cord is less vascular than that of the brain, with which it is continuous. It is partly composed of longitudinal fibrous bundles. It is intimately connected with the cord, of which it is the neurilemma. The tunica vasculosa of the testes is also called pia mater.

Revised by WILLIAM PEPPER.

Pianoforte [= Ital.; *pia'no*, soft (< Lat. *pla'nus*, smooth, whence Eng. plane, plain) + *for'te*, strong, loud]: a musical instrument played by a double row of keys upon a fingerboard, each key being connected with a hammer which strikes a steel string. The principle of the keyboard was applied to a musical instrument, the clavichord, as early as the fourth century, and other instruments of the same class, as the cithara, the harpsichord, and the spinet, were popular down to the eighteenth century. The invention of the pianoforte has been claimed for Germany, Italy, France, and England. The best evidence seems to assign it to Bartolommeo Cristofori, a harpsichord-maker at Padua, Italy, about the year 1710. Marius claimed a similar invention in Paris in 1716, and Christoph Gottlieb Schröter in Germany in 1717. It was not until 1760 that the instrument was manufactured in England by German mechanics; and it was first practically introduced into France by Sébastien Érard. (See ÉRARD.) The firm of Broadwood & Stodart soon took a leading position as English manufacturers, and improvements were rapidly made, the instrument speedily attaining popularity. The grand piano seems to have been first made in 1781, the upright in 1795. Few pianos had been exported to the U. S. when, in 1822, Jonas Chickering began their manufacture at Boston, being thus the pioneer of an important industry. In the form of the instrument called the grand piano the strings are placed horizontally and parallel to the keys. In the "upright" piano they run perpendicularly. The manufacture of the so-called "square" piano has practically ceased, owing to the more convenient form of the "upright," especially where little space is available. The former objection to the "upright" piano—viz., that it soon got out of tune—has been remedied. The piano is essentially the musical instrument of modern times. It has become a household requisite, and as a consequence its manufacturing industry has become a colossal one, extending over the whole civilized world. Outside its own characteristics and powers as a solo instrument, no other can so well represent the orchestra or successions of complex harmonies perhaps originally written for voices. In fact, it is the musician's indispensable assistant in every way. Its own literature, both singly and in combination with other instruments, is the richest, the great composers from Bach and Scarlatti down to the present day having bequeathed to the piano a wealth of their best thought and inspiration. Revised by DUDLEY BUCK.

Pi'arists, called also the **Pauline Congregation**, and popularly known as **Scolopins** [*Piarists* is from Lat. *pi'us*, pious; *Scolopins* is from Lat. *scho'la pia*, religious (liter., pious) school]: a congregation of regular clerks of the Roman Catholic Church, founded in 1599, for the purpose of spreading education, by St. Joseph Calasanctius, who was born at Calasanz, in Aragon, Sept. 11, 1556; studied law at Lerida and theology at Alcala; was ordained a priest in 1582, and settled in 1592 in Rome, where he died Aug. 25, 1648. His remarkable success as a teacher induced him to form an association, which in 1612 had over 1,200 pupils in Rome. The Piarists were confirmed by Paul V. (1617) and by Gregory XV. (1622), when they received the official title of Regular Clerks of the Pious Schools. The congregation was allowed by Gregory XV. to take solemn vows. Alexander VII. brought them back to their original condition, while Clement IX. (1669) re-established them in the state of regulars. They are found chiefly in Europe. See *History of Religious Orders*, by C. W. Currier (1894).

Piassava, or **Piassaba, Fiber** [*piassava* is viâ Portug., from the Braz. name]: a coarse substance used for making brushes and brooms for street-sweeping. It is exported from Brazil, and is produced chiefly from the palm-trees, *Leopoldinia piassaba* and *Attalea funifera*. See CHIQUICHIQUI PALM.

Piatt, JOHN JAMES: poet; b. at Milton, Ind., Mar. 1, 1835; was educated at the Columbus (O.) High School and Kenyon College; removed to Illinois in 1856, and soon after became a contributor to the Louisville *Journal* and confidential secretary to its editor, George D. Prentice. From 1861 to 1867 he was clerk in the Treasury Department at Washington. In 1867–70 he was engaged upon newspaper work at Cincinnati, O. In 1870 he became clerk to the U. S. House of Representatives, and librarian to the House in 1871. He was consul at Cork, Ireland (1882–94); joint author, with W. D. Howells, of *Poems by Two Friends* (1860); with his wife, wrote *Nests at Washington* (1863); sole author of *Poems in Sunshine and Firelight* (1866); *Western Windows* (1868); *Landmarks*, etc. (1871); *Poems of House and Home* (1879); *Idyls and Lyrics of the Ohio Valley* (1884 and 1888), etc.—His wife, SARAH MORGAN (*Bryan*) PIATT, b. at Lexington, Ky., Aug. 11, 1836, and married in 1861, is also distinguished as a writer of verse. She has published *A Woman's Poems* (1871); *A Voyage to the Fortunate Isles* (1874); *That New World* (1876); *Dramatic Persons and Moods* (1880); *The Witch in the Glass* (1889), etc. Revised by H. A. BEERS.

Piauhy, pĕe-ow-ee' (also written *Piauhí*): a northeastern state of Brazil; between Ceará, Pernambuco, Bahia, Maranhão, and the Atlantic. Area, 116,506 sq. miles. It lies entirely in the basin of the PARNAHYBA (*q. v.*), E. of that river; the coast is very short, and the mouth of the river forms the only seaport. The interior consists of table-lands, divided by numerous tracts of lower lands; there is little true forest, the land being open or varied with dry *catinga* woods. The climate resembles that of Ceará in its long dry seasons and occasional severe droughts; the vegetation withers and most of the streams disappear in the dry months. Piauhy is one of the poorest as well as least populous of the Brazilian states. The only important industry is cattle-raising. The exports are hides, cotton, vegetable wax, and a few drugs. Small steamers ascend the Parnahyba. The capital, Theresina, is a small place on that river. Pop. (1894) estimated, 300,609. HERBERT H. SMITH.

Piazza Armerina, pĕe-aat'săă-ăăr-mā-ree'năă: city; in the province of Caltanissetta, Sicily; 39 miles E. S. E. of the town of Caltanissetta (see map of Italy, ref. 10–F). It is situated on a hill surrounded by an undulating country of great fertility. It has a cathedral, built in the eighteenth century, an episcopal palace, and a communal library. Piazza Armerina is a very ancient town, settled, tradition says, by a colony of Greeks from Platææ. Under the Normans it rose to importance: it was destroyed in 1160, but rebuilt three years later. Its prosperity depends on the abundance of grain, wine, oil, chestnuts, and walnuts produced in the vicinity. Pop. of city about 17,040; of commune, 19,600.

Piazzi, pĕe-aat'sĕe, GIUSEPPE: astronomer; b. at Ponte, in the Valtelline, Italy, July 16, 1746. His master was the mathematician Father Giambattista Beccaria, and he himself joined the order of the Theatines. After being professor of philosophy in several of the large Italian universities, he was appointed in 1780 Professor of Mathematics at Palermo, where he promoted the establishment of an observatory, and finally went to France and England to obtain instruments for it. This observatory was opened in 1791, and there Piazzi compiled his famous *Catalogue of the Stars*. On Jan. 1, 1801, he discovered the planet or asteroid Ceres, which opened the way for the discovery of so many others. Piazzi revised the plan of the new observatory at Naples, of which he was afterward for some time the director. D. July 22, 1826. On occasion of the erection of a monument to Piazzi at Ponte, B. E. Maineri published his biography.

Pi-Beseth [Egypt. *Pa-Bast*, dwelling of Bast, the cat-headed deity; Gr. **Βούβαστος**; Mod. *Tell Basta*]: the Hebrew (Ezek. xxx. 17) name of Bubastis, a very ancient city of Egypt; situated on the Tanitic branch of the Nile, about midway between Heliopolis and Tanis. Manetho has preserved a legend which mentions the place as existing as early as the second dynasty, and monumental remains have been discovered which date from the fourth, sixth, twelfth, and succeeding dynasties, as well as others which indicate that it had a continuous history down to Roman times. Specially noteworthy are the remains left by Ramses II. and Osorkon II. It was also a stronghold of the Hyksos, and the name of one of these foreign sovereigns was discovered there by Naville, who reads the hieroglyphics as *Ianra*, corresponding to the Ianias or Annas of Josephus. It may have been the royal residence at the time of Joseph, and in that case it corresponds well with the Biblical narrative in being near to the land of GOSHEN (*q. v.*). See Herod-

otus, ii., 59. 67, 137, 166; Naville, *Bubastis* (London, 1891) and *Festival Hall of Osorkon II.* (London, 1892), being the eighth and tenth *Memoirs* of the Egypt Exploration Fund.
CHARLES R. GILLETT.

Pibroch [from Gael. *piobai-reachd*, pipe music, deriv. of *piobair*, piper, deriv. of *pioba*, pipe, bagpipe, from Eng. *pipe*]: the war-notes of the Highland bagpipe. There are numerous compositions of this kind, scarcely distinguishable from each other by the untrained ear. The use of this pipe in Scottish warfare has been traced back no farther than 1594.

Pic'amar [Lat. *pix, pi'cis*, pitch + *ama'rus*, bitter]: an oily body found in wood-tar.

Picard, pĕĕ'kaar', ALFRED: civil engineer; b. in Paris, France, Dec. 21, 1844; studied at the École de Ponts et Chaussées, graduating in 1864; engineer in chief in 1880; inspector-general of first class in 1891; honorary director-general of the commissions of bridges and roads, of mines, and of railways; president of section of the council of state; president of the consulting commission on railways, and of many other Government commissions; editor of the official reports of the Exposition of 1889; commissioner-general of the Universal Exposition to be held at Paris in 1900; grand officer of the Legion of Honor; vice-president of the international railway congress of St. Petersburg in 1892.

Picard, JEAN: astronomer; b. at La Flèche, department of Sarthe, France, July 21, 1620; accomplished the first exact measurement of a degree of the meridian, between Amiens and Malvoisin; made a number of valuable improvements in the instruments of observation and methods of calculation; was the real founder and constructor of the Observatory of Paris; founded the *Connaissance des Temps*, the French astronomical ephemeris, the publication of which has continued annually for more than two centuries; is noted for the noble disinterestedness with which he aided other astronomers, such as Ole Römer the Dane, Cassini the Italian, etc., and wrote, among other works, *La Mesure de la Terre* (1671), and *Voyage d'Uranibourg, ou Observations astronomiques faites en Danemark* (1680). D. in Paris, Oct. 12, 1682. Revised by S. NEWCOMB.

Picard, LOUIS BENOIT: dramatist; b. in Paris, France, July 29, 1769. At the age of eighteen he became an actor, and in 1789 he produced his first play; thereafter he continued in the double *rôle* of actor and author. He entered the Théâtre Français in 1792; about 1800 became director of the Théâtre Louvois, afterward the Odéon; in 1807 was called to direct the Opera, and returned in 1816 to the Odéon. D. Dec. 31, 1828. He wrote a large number of popular comedies, marked by naturalness, gayety, and fertility of invention. They are partly contained in his *Théâtre* (8 vols., Paris, 1821) and *Théâtre républicain* (1832).

Picards: See BRETHREN AND SISTERS OF THE FREE SPIRIT.

Pic'ardy: an old province of France; bordering on the English Channel. It is now divided into the departments of Somme and Pas-de-Calais; parts of it belong to the departments of Aisne, Oise, and Yonne.

Piccini, pi-chee'nĕe, or **Piccinni**, NICOLO: composer; b. at Bari, Italy, in 1728; received his musical education in the conservatory of Naples; made in 1754 his *début* as a composer with the opera *Le Donne dispettose*; achieved in 1760 an almost unprecedented success by his opera, *Cecchina, ossia la buona figliuola*; went in 1776 to Paris, and engaged in a musical contest with Gluck, brought about by the directors of the Grand Opéra. He composed during this period *Roland, Phaon, Atys, Iphigénie en Tauride*, etc., in all fifteen operas; but, although most of them were received with great enthusiasm, Gluck was victorious, and, other troubles being added to the defeat, Piccini left Paris for Naples in 1791. In Italy he composed several successful operas, *Griselda, Il Servo Padrone*, etc., but the Government suspected him of sympathizing with the French Revolution, and in 1798 he returned to Paris, where Bonaparte gave him a position as inspector of music at the National Conservatory. D. at Passy, May 7, 1800. He was a talented representative of the Italian music of that period, and his productivity was enormous; from 1754 to 1775 he composed 133 operas, besides many pieces of church music, etc.

Piccolom'ini: a celebrated Italian family which flourished in Siena and Amalfi. Its most noted members were ÆNEAS SYLVIUS PICCOLOMINI, afterward Pope Pius II. (1458–64), his nephew, FRANCESCO TODESCHINI, who also became pope, under the name of Pius III., but died in the year of his election, and the general OCTAVIO PICCOLOMINI (1599–1656), who fought in the Thirty Years' war on the Imperial side, joining the army of Wallenstein in 1627, and winning distinction in the battle of Lützen in 1632. Though promoted to a high command by Wallenstein, he turned against and was one of those who conspired to overthrow him, receiving for this service a part of Wallenstein's estates. After this he fought with some success against the Swedes and in the Netherlands; entered the Spanish service in 1643, was recalled by the emperor in 1648, and made marshal.

Pi'cea [Mod. Lat., from Lat. *pix, picis*, pitch]: a genus of coniferous trees including about a dozen species, known as spruces, all natives of the cooler portions of the northern hemisphere. They have four-sided needle-shaped leaves, scattered singly over the surfaces of the twigs, which after the fall of the leaves are covered with the elevated leaf bases. The cones are composed of persistent scales, and hence do not fall away from the axis, as they do in the firs (*Abies*). Six species are natives of North America, the best known being *P. alba*, the white spruce, *P. nigra*, the black spruce, *P. pungens*, Rocky Mountain spruce, and *P. engelmanni*, Engelmann's spruce. The European *P. excelsa*, Norway spruce, is commonly planted in North America as an ornamental tree. CHARLES E. BESSEY.

Pichegru, pĕĕsh'grü', CHARLES: general; b. at Arbois, department of Jura, France, Feb. 16, 1761; was a teacher of mathematics at the military school of Brienne while Bonaparte was a pupil there; entered the artillery service of the Revolutionary army, and rose rapidly; was commander-in-chief of the army of the Rhine in 1793, of the army of the North in 1794; conquered Holland and organized the Batavian republic in 1795; resumed the command of the army of the Rhine, but entered into negotiations with the Bourbons, and falling under suspicion on account of his inactivity and the reverses that his army sustained, he was deprived of his command in 1796. In 1797 he was a member of the Council of Five Hundred, and chosen its president, but, his plottings with the *émigrés* and the Royalist party being discovered, he was arrested, Sept. 4, 1797, and transported to Cayenne. In 1798 he escaped to England, where he formed a conspiracy with Cadoudal, the Polignacs, and others against Napoleon's life. He repaired secretly to Paris, but the conspiracy had in the meantime become known to the police; he was captured, imprisoned, and found strangled in his cell Apr. 5, 1804. See *Lives* by Gassier (1814), Pierret (1826), and Bouziers (1870). F. M. COLBY.

Pichiciago: a name for the little armadillos of the genus CHLAMYDOPHORUS (*q. v.*).

Pichin'cha, La: a volcano of Ecuador; immediately N. of the city of Quito and almost under the equator. It has several peaks and craters; the highest, called the Guagua Pichincha, is 15,916 feet above the sea, and appears to be gradually rising. The crater of Guagua Pichincha, which can be visited without great difficulty, is 2,500 feet deep, or one of the deepest in the world; there have been no violent eruptions since 1660, but vapor issues continually. On the side of this volcano was fought, May 24, 1822, the battle of Pichincha, in which the patriots, under Sucre, defeated the Spaniards and secured the independence of Ecuador. The province of Pichincha (named in honor of this victory) includes the city of Quito and the surrounding plateau. Area, 6,218 sq. miles. Pop. (1890) about 205,000. H. H. S.

Pichler, JOHANN: gem-engraver; b. at Naples, Jan., 1734. He was the pupil of his father, Anton Pichler (1697–1779), and began to cut intaglio-gems while still a boy. He copied many antique gems, and, as he seems to have sold them at low prices and to have done such work to order, it is probable that a great number of supposed antiques are by his hand. At a later time he signed his gems, using commonly his surname in Greek capitals, ΠΙΧΛΕΡ. In 1763 he went to Rome. A head of the Emperor Joseph II. caused him to be ennobled and added greatly to his fame. He was recognized as the first gem-engraver of his time, and undertook the most difficult tasks in the line of his art. Among other subjects he took up the representation of Græco-Roman statues and busts. Besides his intaglio-gems he produced a few cameos. He also painted some pictures and began the engraving of a set of plates after the Raphael frescoes in the Vatican. D. at Rome, Jan. 25, 1791.
RUSSELL STURGIS.

Pichuric Acid: See Lauric Acid.

Pich'urim Beans, or **Sassafras Nuts**: a name given to the seed-lobes of *Nectandra puchury* (properly *Ocotea pichurim*), a South American lauraceous tree. They are used by chocolate-makers and others for flavoring. They have a strong taste, resembling nutmeg as well as sassafras.

Pici [from Lat. *picus*, a woodpecker]: an order of birds containing the woodpeckers and wrynecks. The characteristics are a peculiar modification of the schizognathous palate, no basipterygoid processes, a Y-shaped manubrium, no cæca, and a tufted oil-gland. The fourth toe is turned backward, the first in one genus lacking. Huxley placed the woodpeckers in a group called *Celeomorphæ*, and Dr. Parker, from certain peculiarities in the palate, made them a distinct order, to which he gave the name *Saurognathæ*. Other authors have extended the limits of the group, though not always recognizing it as an order. Thus Fürbringer includes the barbets (*Capitonidæ*), toucans (*Rhamphastidæ*), and indicators (*Indicatoridæ*), and Sharpe—in his *Piciformes*—includes the puff-birds (*Bucconidæ*) and jacamars (*Galbulidæ*). F. A. Lucas.

Pic'idæ [Mod. Lat., named from *Pi'cus*, the typical genus or group, from Lat. *pi'cus*, woodpecker, whence Eng. *pie*, a bird]: a family of birds containing the woodpeckers (see Woodpecker) and wrynecks, although these last are sometimes placed in a separate family (*Iungidæ*).

Pick, Arnold, M. D., Ph. D.: alienist; b. at Gross-Meseritsch, Moravia, July 20, 1851; educated at Iglau, Moravia; became medical assistant in the Asylum for the Insane at Oldenburg in 1875, at Prague in 1877; privat docent at the University of Prague in 1880, and Professor of Psychiatry at the same university in 1886. His works are mainly monographs in psychiatry, neurology, physiological psychology, etc., besides his *Beiträge zur Pathologie u. Pathol. Anatomie des Centralnervensystems* (1879–80), written in collaboration with Otto Kohler. J. M. B.

Pick, Bernhard, Ph. D.: author; b. at Kempen, Prussia, Dec. 19, 1842; educated at Breslau, Berlin, and Union Seminary, New York. After filling pastorates in the Presbyterian Church, entered the Lutheran ministry in 1884, serving a congregation in Allegheny, Pa. He is a contributor to many important publications (McClintock and Strong's *Cyclopædia*, Schaff-Herzog *Encyclopædia*, etc.); has indexed Lange's *Commentaries* and the Ante-Nicene Fathers, and has published a number of translations. H. E. J.

Pickens, Andrew: soldier; b. at Paxton, Bucks co., Pa., Sept. 13, 1739, of Huguenot descent; went with his parents to the Waxhaw Settlement, S. C., in 1752; was a volunteer in Grant's expedition against the Cherokees 1761; was a captain of militia at the beginning of the Revolution; soon rose to the rank of brigadier-general, and shared with Marion and Sumter the honor of the heroic resistance made in South Carolina to the overwhelming numbers of the British and Tory forces. In Feb., 1779, with 400 men, he defeated Col. Boyd with 700 Tories at Kettle Creek, and at the battle of the Cowpens, Jan. 17, 1781, he commanded the militia, which he rallied and brought a second time into action after they had been broken and compelled to retreat; for this service Congress voted him a sword. After the war he was for many years a member of the Legislature; served in Congress 1793–95; was frequently commissioned to make treaties with the Indians; settled at Hopewell in the Pendleton district, which he had purchased from the Indians by the Hopewell treaty. D. there Aug. 17, 1817.

Pickens, Francis Wilkinson: Governor of South Carolina; son of Gen. Andrew Pickens; b. at Togadoo, S. C., Apr. 7, 1805; was educated at South Carolina College, and in 1829 became a lawyer of Edgefield district; was prominent as a nullifier in the State Legislature in 1832; was in Congress 1834–43; opposed the Bluffton secession movement of 1844; U. S. minister to Russia 1858–60; Governor of South Carolina 1860–62, and as such had important connection with the early secession movements of his State. D. at Edgefield, S. C., Jan. 25, 1869.

Pickerel [Mod. Eng. *pikerel*, dimin. of *pike*, pike]: in England the young of the pike (*Esox lucius*); in the U. S. any one of various fishes; thus in many localities the name is given to the small Esocidæ (*q.v.*), and in some places (e. g. the interior lakes of the Northwestern States) to the *Esox lucius*, the word being used as a synonym for pike, although sometimes incorrectly applied to other fishes of similar form. At the beginning of spring the pickerel leaves the larger rivers and ascends the creeks and narrow ditches in order to deposit its spawn. The growth of the young pickerel is extremely rapid, and from its birth it exhibits remarkable voracity. See Pike. Revised by D. S. Jordan.

Pickering, Edward Charles: astronomer; great grandson of Col. Timothy Pickering; b. in Boston, Mass., July 19, 1846; graduated at the Lawrence Scientific School 1865; taught mathematics at Cambridge 1865–67; was shortly afterward elected Thayer Professor of Physics at the Massachusetts Institute of Technology; was a member of the *Nautical Almanac* party which observed the total eclipse of Aug. 7, 1869, in Iowa, and of the Coast Survey party sent to Spain with a similar object in 1870; has conducted extended observations in optics, and especially in regard to the polarization of glass and of the sky, on which subjects he has contributed papers to several scientific journals; and has successfully carried out the laboratory method of teaching physics upon a system exhibited in his work entitled *Physical Manipulation* (1874). His system has been largely adopted in other institutions. In 1873 he was elected a fellow of the National Academy of Sciences. He afterward became director of the Harvard Observatory at Cambridge, Mass., which he raised to be one of the most active in the world in the lines of spectroscopy and celestial photography. He received the gold medal of the Royal Astronomical Society of England in 1886. Revised by S. Newcomb.

Pickering, John, LL. D.: philologist and archæologist; son of Col. Timothy Pickering; b. at Salem, Mass., Feb. 7, 1777; accompanied his father in his visits to the Six Nations of Central New York, deriving from that circumstance his fondness for American philology; graduated at Harvard 1796; studied law in Philadelphia; was attached to the U. S. legations in Lisbon and London 1797–1801; a lawyer of Salem, Mass., 1801–27; city solicitor of Boston 1829–46; was much in the State Legislature, and assisted in revising the statutes; was a laborious philological student and familiar with many languages; president of the American Academy of Arts and Sciences; founder and first president of the American Oriental Society; maintained a correspondence for many years on philological topics with P. S. Duponceau and Wilhelm von Humboldt; author of valuable legal, archæological, and philological papers, including an *Essay on a Uniform Orthography for the Indian Languages of North America* (1820), in which he proposed the alphabet adopted by American missionaries in reducing to writing not only Indian but Polynesian languages; *Remarks on the Indian Languages of North America* (Philadelphia, 1836); *Vocabulary or Collection of Words and Phrases supposed to be peculiar to the United States* (1816); *Greek and English Lexicon* (1826; 3d ed. revised and enlarged, 1846). D. at Boston, Mass., May 5, 1846. Revised by B. I. Wheeler.

Pickering, Timothy, LL. D.: statesman; b. at Salem, Mass., July 6, 1745; graduated at Harvard 1763; was commissioned lieutenant of militia 1766; studied law while acting as selectman, assessor, and town clerk of Salem; admitted to the bar 1768; was prominent in resistance to British aggressions; in 1775 became judge of the maritime and common pleas courts, was elected colonel of militia, and published *An Easy Plan of Discipline for a Militia*, which was made the official text-book in Massachusetts and in the Continental army; joined the Continental army at Morristown, N. J., in 1776 at the head of a regiment raised in Essex County, Mass.; served through the Revolution as colonel with valor and disinterestedness; became in 1777 Washington's adjutant-general, serving as such at Brandywine and Germantown, and member of the board of war in the same year; quartermaster-general 1780–85; became a commission merchant at Philadelphia at the close of the war; was sent in 1786 by the Federal Government to settle the dispute between Pennsylvania and Connecticut over land titles in the valley of Wyoming, Pa.; acquired a large tract of land in that region, settled at Wilkesbarre, and strove with much wisdom to harmonize the conflicting elements, but was seized and imprisoned for twenty days; was a delegate from Luzerne County to the Pennsylvania constitutional conventions of 1787 and 1790; negotiated treaties with the Six Nations of New York in 1790, 1791, and 1794, and with the Ohio Indians in 1793; Postmaster-General 1791–95; appointed Secretary of War 1795, and was instrumental in founding West Point Academy; became U. S. Secretary of State 1795, and was retained by President Adams until 1800, when he was dismissed with the rest of the cabinet; returned to the forests of Pennsylvania and

built a log house for his family, when by sale of a portion of his lands to friends in Massachusetts, he was set free from heavy debts and returned to Massachusetts to settle at Danvers; was made a judge of common pleas 1802; was U. S. Senator 1803–11; made himself unpopular by opposing the Louisiana purchase and the embargo of 1807; also was opposed to the war of 1812, but served as commissioner for the defense of the Massachusetts coast; in Congress 1815–17; declined a re-election to the Senate 1816; was author of able political pamphlets; devoted much attention to agriculture, being president of the Essex Agricultural Society; was an ardent Federalist. (See Essex Junto, The.) He published several occasional addresses and pamphlets: *Letter to Governor Sullivan on the Embargo*, *Addresses to the People*, *Political Essays*, and a severe *Review of the Correspondence between John Adams and W. Cunningham* (1824), etc. D. at Salem, Mass., Jan. 29, 1829. See his *Life*, begun by his son Octavius, and completed by Rev. Charles W. Upham (4 vols., 1867–73); Adams, *Documents Relating to New England Federalism* (Boston, 1877); and the article on Pickering by Lodge, *Atlantic Monthly*, vol. xli.

Pickett, George Edward: soldier; b. in Richmond, Va., Jan. 25, 1825; graduated at the U. S. Military Academy, and entered the army as brevet second lieutenant of infantry July, 1846; engaged in the war with Mexico from Vera Cruz to the capture of the city of Mexico; brevet first lieutenant and captain for gallantry at Contreras, Churubusco, and Chapultepec; on frontier duty 1848–61, becoming captain of Ninth Infantry Mar. 3, 1855. He resigned June 25, 1861, and in September was appointed colonel in the Confederate army, and brigadier and major general in 1862. In the Virginia Peninsular campaign of 1862 he led a brigade, and was severely wounded at Gaines's Mill. Continuing thereafter with the army of Northern Virginia, he participated in the battles of that army, and was conspicuous for his bravery and intelligence. At Gettysburg his division led the assaulting column which suffered so severely July 3, 1863; he also commanded in North Carolina, at the capture of Plymouth. In the campaign of 1864–65 he made the final stand at Five Forks, where his division was broken up after a desperate resistance. D. in Norfolk, Va., July 30, 1875.

Picking, Henry Forry: See the Appendix.

Pickling and Pickles: See Preservation of Food.

Picknell, William Lamb: landscape-painter; b. in Boston, Mass., in 1853; pupil of George Inness in Rome, of Gérôme in Paris, and of Robert Wylie in Brittany; member of the Society of American Artists 1880; member of the Society of British Artists; honorable mention, Paris Salon, 1880. His pictures of sunlight effects are remarkably luminous. *The Concarneau Road* (1880) is in the collection of T. B. Clarke, New York, and works by him are in the Metropolitan Museum, New York; Pennsylvania Academy, Philadelphia; Museum of Fine Arts, Boston; and the collection of the corporation of Liverpool, England. D. in Marblehead, Mass., Aug. 8, 1897.

Pico, pee'kō: one of the Azores Islands (*q. v.*); belonging to the central group; comprises an area of 143 sq. miles, and includes the volcanic mass of Pico Alto, 7,613 feet high, the highest mountain in the group. The island is fertile and well wooded, and produces an excellent wine, of which about 25,000 pipes are annually exported. Pop. 29,000.

Pico della Mirandola, Giovanni, Count of Mirandola and Prince of Concordia: philosopher and mystic; b. Feb. 24, 1463; studied at Bologna, and visited several schools in Italy and France; went to Florence 1484, and there became intimate with the group of Platonizing thinkers known as the "Academy." Seeking to reconcile the Platonic and the Aristotelian systems of philosophy, and, at the same time, to harmonize religion and philosophy, he fell into a vague and mystical method of interpretation. The wide range of his knowledge is illustrated by his offer in 1486 to defend against all comers 900 propositions *de omni re scibili*. They are drawn from theology, dialectics, ethics, physics, mathematics, natural magic, the Cabbalah. As preparatory to the great debate, he prepared a discourse, *De hominis dignitate*, a splendid affirmation of man's capacity to take all wisdom and all truth for his promise. Influenced by Pico's enemies, Pope Innocent VIII. forbade the reading of the propositions, as in part heretical. Pico retired to France, but Alexander VI. in 1493 absolved him from all taint of heresy. D. in Florence, Nov. 17, 1494. By the great scholars of the time he was regarded as the wonder of the world, but posterity has not confirmed their judgment. It is only too clear that his command of the twenty-two languages he was reputed to know (among them Greek, Arabic, and Chaldee) was very superficial; and that in philosophy he was one of those ardent but ineffectual spirits whose supposed discovery of the secret of the universe is but an affirmation of their own lack of clearness. The works of Pico that have come down to us are almost exclusively in Latin. In his extreme youth he had written verses in Italian, but later he foreswore such trifles and destroyed most of those he had already composed. His *Opera* have been printed in folio at Bologna (1496), Venice (1498), Strassburg (1504), Basel (1557, and often after that date). The most important are *Conclusiones philosophicæ, cabbalisticæ et theologicæ* (1486), containing the 900 propositions mentioned above; *Apologia G. Pici Mirand., Concordiæ Comitis* (1489); *Disputationes adversus astrologiam divinatricem libri XII.* (1495); *Heptaplus, id est de Dei creatoris opere sex dierum libri VII.* (already in the hands of friends in 1489); *Aureæ ad familiares epistolæ* (1499). Of his great projected *Concordia Platonis et Aristotelis*, he had completed only the treatise *De ente et uno*, when death interrupted his labors. See Dreydorff, *Das System des Johannes Pico della Mirandola* (Marburg, 1888).

A. R. Marsh.

Picot, pēē'kō', François Édouard: historical and genre painter; b. in Paris, France, Oct. 17, 1786; d. there Mar. 15, 1868; pupil of Vincent; Grand Prix de Rome 1813; member of the Institute 1836; first-class medal, Salon, 1819; Legion of Honor 1852. He was the master of a large number of celebrated painters, including Pils, Cabanel, Bouguereau, and Henner. Among his works are *Meeting of Venus and Æneas* (1819), Brussels Museum; *Cephalus and Procris* (1824), Amiens Museum; several portraits in the Museum at Versailles, and ceilings in the Louvre. W. A. C.

Picotees: See Carnation (the flower).

Picric Acid, **Trinitrocarbol'ic Acid**, **Trinitrophenol**, **Trinitrophenic Acid**, or **Carbazotic Acid**: the acid whose symbol is $C_6H_3(NO_2)_3O$. It is produced by the action of hot nitric acid on phenol, salicylic acid, indigo, aloes, silk, etc.; it is usually prepared from pure crystallized phenol. It crystallizes in beautiful pale-yellow, scaly crystals, or needles; dissolves in eighty-six parts of water at 60° F., and in much less at 212° F.; and is soluble in alcohol, ether, and benzol, and in sulphuric and nitric acids. When heated it melts, and on cooling solidifies to a crystalline mass; at a higher temperature it sublimes; when quickly heated, it explodes. Its taste is very bitter. Its solution in water is yellow, and it imparts a yellow color to the skin and to silk and wool; hence it is used as a yellow dye. By mordanting with argol or alum before dyeing, the color is rendered more stable. It has been common to supply for this purpose the picrate of soda, which is very explosive, and has given rise to serious accidents. A beautiful green dye is made by mixing the picric acid with indigo carmine. The Victoria yellow is trinitro-cresol, not picric acid. Leather is dyed with picric acid, particularly alum-tawed leather for belt lacings. Goods dyed with picric acid resist light well, but are liable to suffer on washing with soap. As vegetable fibers do not take picric acid, it affords a ready method for detecting cotton and flax when mixed with silk or wool. It is said to be used as a substitute for hops in making beer. Many of the salts of picric acid are explosive. A mixture of fifty-four parts of ammonium picrate and forty-six of potassium nitrate has been used as a substitute for gunpowder. Other mixtures for gunpowder are formed of potassium picrate, niter, and carbon. For explosive powder for torpedoes the carbon is omitted. Melinite, one of the most powerful explosives, is said to consist only of compressed picric acid. See Explosives.

Revised by Ira Remsen.

Picrite: See Peridotite.

Picrotoxine [Gr. πικρός, bitter + τοξικόν, arrow-poison, poison]: a poisonous bitter principle found in the *cocculus indicus* of commerce, the berries of the *Anamirta cocculus*. An infusion of the berries has been used against lice, and the alkaloid has been employed to prevent night sweats.

Pictet, Raoul: See the Appendix.

Picton: a port of entry; capital of Prince Edward co., Ontario, Canada; on the Bay of Quinté, 40 miles S. S. W. from Kingston; terminus of the Cent. Ont. Railway (see map of Ontario, ref. 4–G). It is the seat of Ontario College, has fruit-canning factories and a manufactory of fence-wire, and two weekly newspapers. Pop. (1891) 3,287.

Pictou: port of entry; capital of Pictou County, Nova Scotia; on a safe and commodious harbor at the terminus of a branch of the Intercolonial Railway; 114 miles by rail N. N. E. of Halifax (see map of Quebec, ref. 2–C). Steamers ply to Charlottetown, Quebec, and the ports of the Gulf of St. Lawrence. Bituminous coal is mined near by. There are considerable manufactures, also an academy, court-house, and a weekly newspaper. Pop. (1891) 2,998.

Picts: a Celtic tribe, the Caledonians of the Roman writers, inhabiting the lowlands and the eastern part of Scotland; are first mentioned under the name of the *Picti* in a speech addressed by the rhetorician Eumenius to the Emperor Constantius Chlorus on his return in 296 A. D. after the victory over Allectus. They were divided into the Southern and Northern Picts by the Grampian Mountains. The Southern Picts were converted to Christianity early in the fifth century by St. Ninian; the Northern by St. Columba, who began the work of conversion in 563. Their history is obscure, and its details have been the subject of much controversy. Nor are authorities agreed upon what languages they spoke. In the ninth century they were subdued by the Scots, a kindred tribe which invaded the country from Ireland. Kenneth II. conquered the whole of Scotland, made it one kingdom, and took up his residence in the old Pictish capital, Forteviot, in Stratherne. Subsequently attacked on both sides—from the N. by the Scandinavian invaders, and from the S. by the Teutonic inhabitants of England—the Pictish language and nationality gradually disappeared. See Innes, *Civil and Ecclesiastical History of Scotland*; Pinkerton, *Inquiry into the History of Scotland*; Stokes, *On the Linguistic Value of the Irish Annals*; and Rhys, *Celtic Scotland* (1884).

F. M. Colby.

Picture-gallery: a room especially prepared for the exhibition of pictures, the word *gallery* expressing the comparative length and narrowness of most of such rooms. (See Gallery.) Many of the public museums of Europe are housed in ancient palaces whose long rooms are not very skillfully altered to suit the new purposes. New galleries also are often defective in respect to the light-openings. It is required to throw the light more upon the walls than upon the floor, and to have this light come at such an angle that there shall be no flash on the surface of the picture at any ordinary position of the spectator. Sunshine and even the reflection and glow of sunshine upon the glass of the light-openings are to be avoided. It is found in practice that the section of gallery and the position of the light which suits a room of certain dimensions is not suitable to galleries much wider or narrower; not only the height has to be changed, but the relative positions of the light-openings and the wall. See the *Handbuch der Architektur*, published at Darmstadt (part iv., sixth half-volume, fourth number).

Russell Sturgis.

Pidgin- (or **Pigeon-**) **English**: an artificial dialect employed in Hongkong and the treaty-ports of China by foreigners of all nationalities who do not speak Chinese, in their dealings with native servants, merchants, coolies, etc. Its base is corrupted English, with a mixture of Chinese, Portuguese, and Malay words, arranged according to Chinese idiom. Owing to the difficulty the Chinese have in pronouncing consonantal terminations, vowel terminations *-o* and *-ee* abound, as *olo* for old, *wifo* for wife, *talkee* for talk, *catchee* for catch, *muchee* for much, etc. *Belong* takes the place of the verb to *be*: *my* = I, me, mine; *plenty* = very; *topside* = above, upstairs; *that side* = there; *this side* = here; *how fashion* = why; *savey* = know; *man-man* = slow, gently, quietly; *chop-chop* = quick; *maskee* = no matter, never mind; *chow-chow* = food, eat, etc. The word *pidgin* is itself a Chinese corruption of the English word "business."

R. Lilley.

Pied'mont (Ital. *Piemonte*): territory of Northern Italy; bounded S. by the Maritime Alps, W. by the Graian and Cottian, N. by the Pennine Alps, and E. by the river Ticino; area, 11,340 sq. miles. In the twelfth century it became a possession of the house of Savoy, and now it forms, with slightly altered boundaries, a large division of the kingdom of Italy, being subdivided into the four provinces of Turin, Cuneo, Alessandria, and Novara. The greater part of this country is mountainous, covered with spurs of the Alps, between which the numerous affluents of the Po, the Tanaro, Bormida, Clusone, Dora, Sesia, etc., form beautiful and fertile valleys; but toward the E. the country gradually opens into the plain of the Po. Rice, wheat, maize, wine, olive oil, and many varieties of fruits are produced, and extensive dairy-farming and manufacturing industries are carried on. The method of the Piedmontese silk-culture is celebrated and very successful. Pop. (1892) 3,270,988. See Italy, and Sardinia, Kingdom of.

Piedmont Plain or **Plateau**: a term applied by geographers to that portion of the North American continent which lies W. of the Coastal Plain (*q. v.*) and E. of the Appalachian Mountains. These portions are quite strongly contrasted. The dividing line between the two, known as the *fall line*, marks the localities where the streams from the W. leave the region of hard rocks adjacent to the Appalachians and enter the newer and more easily eroded terranes forming the coastal plain. In most instances the fall line also indicates where the streams lose their current and merge with the estuaries formed by the submergence of the lower portions of their channels. In New England the Piedmont plateau is broad but less clearly defined than in the Middle and Southern Atlantic States, where it is a broken, hilly country, composed principally of crystalline rocks, and deeply trenched by the rivers flowing across it. It broadens from New York southward, and reaches its greatest width in North Carolina, where it extends eastward some 300 miles from the Appalachians.

Israel C. Russell.

Pie'per, Franz Augustus Otto: theologian; b. in Pomerania, June 27, 1852; educated at Watertown, Wis., and St. Louis, Mo. After a pastorate at Manitowoc, Wis., 1875–78, he became professor in Concordia Theological Seminary, first as the colleague and afterward as the successor of Dr. C. F. W. Walther. Besides numerous articles in the German language, Prof. Pieper has contributed in English to *The Distinctive Doctrines and Usages of the General Bodies of the Evangelical Lutheran Church* and to *The Presbyterian and Reformed Review*. He is the leader of the Missouri Lutherans.

H. E. Jacobs.

Pierce, Franklin: the fourteenth President of the U. S.; b. at Hillsborough, N. H., Nov. 23, 1804; graduated in 1824 at Bowdoin College, where he was the intimate associate of Nathaniel Hawthorne, his lifelong friend; was the law-pupil of Levi Woodbury; admitted to the bar in 1827, and practiced law with success in Hillsborough and Concord, N. H.; represented the former town in the State Legislature 1827–33; was in Congress 1833–37; in the U. S. Senate 1837–42; was heartily in favor of the union of Texas with the U. S.; twice declined positions in the cabinet of Mr. Polk; served with distinction in the Mexican war, commanding a brigade; was president of the New Hampshire constitutional convention 1850–51; was chosen President of the U. S. in 1852 by 254 electoral votes to 42 for Gen. Scott, the Whig candidate. Mr. Pierce's administration was a period of great political excitement. In his inaugural address, Mar. 4, 1853, he strongly denounced the agitation of the slavery question then going on, and maintained that slavery was recognized by the Constitution, and that the Fugitive Slave law was constitutional and ought to be strictly enforced. Prominent among the events of his administration were the Gadsden Purchase, the repeal of the Missouri Compromise, and the beginning of the troubles in Kansas, during which the President opposed by every means in his power the organization of a Free-State government. He sought to justify the Kansas and Nebraska Act, and in his special message of Jan. 24, 1856, represented the formation of a Free-State government as an act of rebellion. Other important events of his administration were the negotiation of a treaty with Japan by Commodore Perry, the publication of the Ostend Manifesto, the settlement of the dispute over the boundary between the U. S. and Mexico, and Walker's filibustering expedition to Nicaragua. He was an ardent advocate of the State rights doctrine, and during the war of 1861–65 sympathized with the Southern States. D. at Concord, N. H., Oct. 8, 1869. His *Life*, down to his nomination, was written by Nathaniel Hawthorne (Boston, 1852).

Revised by F. M. Colby.

Pierce, George Foster, D. D.: bishop; son of Lovick Pierce, D. D.; b. in Greene co., Ga., Feb. 3, 1811; studied law with his uncle, Hon. George Foster; in 1831 joined the Georgia conference of the Methodist Episcopal Church; performed important pastoral work in Georgia and South Carolina, and presided over literary institutions (Emory College for six years) till 1854, when he was made bishop; was a member of the General Conferences of 1844, 1846, 1850, and 1854; published *Incidents of Western Travel* (Nashville, 1857) and several sermons, addresses, etc. D. near Sparta, Ga., Sept. 3, 1884.

Revised by A. Osborn.

Piero'la, Nicolas, de: politician; b. at Camaná, Arequipa, Peru, Jan. 5, 1839; son of the director of the Lima museum; studied and practiced law in that city, and was a well-known journalist. Under President Balta (1868–72) he was Minister of the Treasury, and consequently was directly connected with the enormous outlays of that period. He led abortive revolts against Pardo 1872 and 1874, and Prado 1877. After the first reverses of the Chilian war, President Prado went to Europe; Pierola then headed another revolt, deposed the vice-president, and was declared supreme chief at Lima Dec. 23, 1879. Owing to the urgent need for a responsible head the republic generally accepted him. He showed great activity, especially in defending Lima; when that city was taken (Jan. 17, 1881) he fled into the interior, convoking a congress at Arequipa, but in the following November he resigned and went to Europe. He tried to seize the presidency again in 1885. Owing to his restless and revolutionary spirit he has several times been banished, but he has a considerable political following in Peru. He was a presidential candidate in 1894. Herbert H. Smith.

Pierre: city; capital of South Dakota and of Hughes County (for location, see map of South Dakota, ref. 6–D); on the Missouri river and the C. and N. W. Railway; 158 miles W. of Huron. It is the principal trading-point for the Black Hills section. Natural gas has been discovered here, and is used in large quantities for power and lighting. It is the seat of Pierre University (Presbyterian, chartered in 1883), and of an Indian industrial school established by the U. S. Government, and contains 3 national banks, with combined capital of $200,000, a State bank with a capital of $50,000, and a daily, 4 weekly, and 3 monthly periodicals. Pop. (1890) 3,236; (1900) 2,306. S. A. Travis.

Pierrepont, Edwards, LL. D., D. C. L.: jurist; b. in North Haven, Conn., Mar. 4, 1817; graduated at Yale College in 1837, and a year later was admitted to the bar; practiced law at Columbus, O., till 1845, when he removed to New York city; in 1857 was elected a judge of the superior court of New York, but resigned that position in 1860, and returned to the practice of law; was engaged by the National Government in 1867 to conduct its case against John H. Surratt, indicted for complicity in the murder of President Lincoln; in 1869 was appointed by President Grant U. S. district attorney for the southern district of New York, but resigned that office in May, 1870; was appointed minister to Russia but declined in 1873; was appointed attorney-general of the U. S. in 1875, minister to England in 1876, resigned in 1877. He received the degree of LL. D. from Columbian College, Washington, and from Yale College, and that of D. C. L. from Oxford University. D. in New York, Mar. 6, 1892.

Piers: See Harbors.

Pierson, Arthur Tappan, D. D.: minister; b. in New York city, Mar. 6, 1837; educated at Hamilton College and Union Theological Seminary; was pastor of the Congregational churches, West Winsted, Conn., 1859–60; Binghamton, N. Y., 1860–63; Norwalk, Conn., 1863; of the Presbyterian churches, Waterford, N. Y., 1863–69; Fort Street, Detroit, Mich., 1869–82; Second, Indianapolis, Ind., 1882–83; Bethany, Philadelphia, 1883–91; supplied the Metropolitan Tabernacle, London, England, 1891–93; and was incumbent of the Duff lectureship in 1892. Besides frequent contributions to periodicals, Dr. Pierson has edited *The Missionary Review of the World* since its inception, 1888 (New York), and has published many evangelistic and missionary works, such as *Many Infallible Proofs* (1886; 2d ed. 1889); *The Crisis of Missions* (New York, 1886); *Evangelistic Work in Principle and Practice* (1887; 2d ed. 1888); *The Divine Enterprise of Missions* (1891); *The Miracles of Missions* (1891); *The Heart of the Gospel* (Sermons, 1891); *The Divine Art of Preaching* (New York and London, 1892); and *The New Acts of the Apostles* (1894). C. K. H.

Piers Plowman: See English Literature.

Pietermaritzburg, or **Maritzburg**: capital of Natal (*q. v.*); at an altitude of over 2,000 feet above the sea; on a fertile plain watered by a tributary of the Umgeni; 73 miles by the main line of the Natal Government Railway System N. of Durban (see map of Africa, ref. 9–F). It is also connected by rail with the Orange Free State and the Transvaal. The chief buildings are the government-house and the office of the colonial secretary; and there is a military camp here which is occupied by the principal division of troops stationed in the colony. The town takes its name from its Boer founders, Pieter Retief and Gert Maritz. Pop. (1891) 17,500, of whom two-thirds are whites, the rest being natives and coolies.

Pietists [from Lat. *pi'etas*, piety, deriv. of *pi'us*, observing what is proper toward parents or God, pious (often implying merely formal or outward observance)]: in Germany, Christians who never formed a sect nor professed distinctive doctrines, but were noted for their preference of practical religion. The movement took place wholly within the Lutheran Church, and may be characterized as an attempt to make even the least important every-day doings expressive of the religious spirit, and eliminate from human life anything—such as dancing, visiting the theater, etc.—which proves hostile to such a modification. The first writers of importance who assumed this ground were Johann Arndt (*Vom wahren Christenthum*, 1605) and Johann V. Andreæ (*Invitatio Fraternitatis Christi*, 1617). The term was first applied in derision to a number of teachers at Leipzig in 1689, chief among whom was A. H. Francke, and was soon afterward employed chiefly as a designation of the followers of Philipp Jakob Spener (*q. v.*). The combined influence of Spener and Francke led to the foundation of the University of Halle, which became a center of the pietistic movement. The rationalism of the close of the eighteenth and beginning of the nineteenth century operated adversely to pietism, but since the overthrow of rationalism it has largely revived in Germany, especially in Berlin, Silesia, and Würtemberg. The general history of Pietism has been written by H. Schmid (Nördlingen, 1863), H. Heppe (Leyden, 1879), and A. Ritschl (Bonn, 1880–86, 3 vols.). Revised by S. M. Jackson.

Pie'tra Du'ra [Ital., liter., hard stone]: a name applied to the better kinds of cameo and mosaic work. See Mosaic.

Piëzom'eter [Gr. πιέζειν, press + μέτρον, a measure]: an instrument for measuring the compression of water and of other fluids under pressure. The first successful piëzometer was that of Oersted, in which the pressure was gauged by the manometer, and the amount of compression of the water was indicated by the use of mercury in a glass tube. Regnault's piëzometer is in principle the same, but it also takes into account the expansion of the tubes under pressure, and consequently gives more accurate results. Where the pressures to be used are beyond the crushing point for glass steel tubes are used and the encroachment of the mercury upon the manometer tube is recorded by gold plating the inner surface of the latter previous to the test, and afterward noting to what height the gold has been amalgamated.

Pig: See Swine.

Pigafet'ta, Antonio: traveler; b. at Vicenza, Italy, in 1491. In 1510 he went to Spain in the suite of the papal nuncio; by special permission he accompanied the expedition of Magalhães in 1519, and was one of those who returned in the Victoria 1522, after the first circumnavigation of the globe. A letter which he wrote to Charles V., describing the voyage, was quickly published in several languages. He prepared a longer account, which was discovered and published at Milan in 1800 as *Primo Viaggio intorno al globo terracqueo*. Pigafetta is the principal authority on this important voyage. D., probably at Vicenza, about 1534. Herbert H. Smith.

Pigeon [= Fr. < Lat. *pi'pio*, a young piping or chirping bird, deriv. of *pipi're*, pipe, peep, chirp]: any member of the order *Columbæ*, a group of birds typified by the familiar domestic pigeon. The characters of the order are given under Columbæ, and although the members of the group present great variations in regard to size and color, yet, with one or two exceptions, they are all readily recognizable. There is popularly supposed to be a difference between doves and pigeons, but it has no existence in nature. Something like 500 species have been described, widely distributed throughout the temperate and warm parts of the globe, but most abundant in the Malay Archipelago, which has about 120 species. Wallace accounts for this abundance by the absence in this region of fruit-eating animals, like monkeys and squirrels. The most aberrant number of the order is the Samoan tooth-billed pigeon (*Didunculus strigirostris*), so named from the notches in the lower mandible. It is the nearest living relative of the extinct Dodo (*q. v.*), but the affinity between the two is not very close. The specific name is in allusion to the hooked upper mandible, which suggests that of a bird of prey. This bird is about a foot long; the head and greater portion of the un-

der parts are glossy greenish black; the larger share of the upper part of the body, including the tail, is chestnut brown, the feathers on the upper part of the mantle tipped with greenish black. It formerly nested on the ground, a fact which threatened to lead to its extermination, owing to the attacks of dogs, cats, and rats, but changed its habits and took to nesting in trees and thus prolonged its days.

The Nicobar pigeon (*Calœnas nicobarica*), from New Guinea and some of the adjacent islands, is another peculiar form, having a remarkable horn-like lining to its gizzard. The plumage, except the tail (which is white), is of various shades of green with metallic reflections, and the lower part of the neck is adorned with pointed feathers much like the hackles of a cock. The brilliantly colored fruit-pigeons, of the genus *Carpophaga* and allied genera, come from Australia, the Malay Archipelago, and the islands of the Pacific. Green is perhaps their predominant color, but some are almost as gay in plumage as any of the parrots. Some of the fruit-pigeons of the genus *Treron*, owing to the spicy fruits on which they feed, are said to surpass all other birds in flavor, and some present very interesting modifications of the gizzard.

The giants of the order are the crowned pigeons, Goura (*q. v.*); the pygmies are found among the little ground-doves (*Columbigallina*, *Geopelia*, etc.), some of which are little larger than a sparrow. Finally we come to *the* pigeon (*Columba livia*) or rock-pigeon, which is found in a wild state over a great part of Europe, breeding upon rocky precipices, especially near the sea. The wings are black at their outer margin, and have a black bar on the secondaries, and a second on the great coverts; the rump is ashy; the tail bluish ash, black for the terminal third, with the lateral feathers white externally for their basal third. This plumage may be seen almost feather for feather in some of the common domesticated pigeons. The blue rock-pigeon is by most authorities considered to be the parent stock of *all* breeds of domestic pigeons, of which there are at least 250 varieties, but other authorities consider that some of the eastern breeds sprang from *Columba intermedia*, a very similar bird. The domestic birds differ not only in color, markings, and size, but even in the number of their vertebræ and ribs, as well as in the shape and proportions of their skulls. Darwin, who made an extensive study of pigeons, divides them into four principal groups, Pouters, Carriers, Tumblers, and Trumpeters, with eleven sub-groups or races. There are at least 150 distinct breeds recognized by fanciers. For a full discussion of the question see Darwin's *Animals and Plants under Domestication*, vol. ii.

The carrier-pigeon is perhaps the best known by name of all domestic breeds, but it is *not* the bird used for carrying messages. Whatever may have been the case formerly, the modern carrier is a mere fancy breed distinguished by a large fleshy caruncle about the base of the bill and a smaller one around each eye. The bird used for carrying messages and for long-distance flying is the homer, which is not bred for "points" and is not essentially different from an ordinary dove-cote pigeon in appearance. By careful selection the pigeon's natural fondness for its own loft has been intensified, while by selection and training birds have been raised which will return home from distances of from 200 to 500 miles, and, very rarely, from 1,000 miles.

The fantail belongs to the short-billed tumbler group, and is characterized by the great number of tail feathers, which should be at least twenty-four, and may be as many as forty, and by having the tail carried more or less erect and open. The head should also be carried well over the back, toward the root of the tail, and breeding has gone so far in this direction that these birds are hollow-backed and some have great difficulty in picking up their food.

For domestic breeds, see Fulton's *Illustrated Book of Pigeons*. There is no modern monographic work on pigeons save the British Museum *Catalogue of Game Birds*, by Ogilvie Grant. See also Evolution, Dodo, Goura, Passenger-pigeon, Jacobin, Pouter, and Trumpeter.

F. A. Lucas.

Pigeon-English: See Pidgin-English.

Pigeon-pea: the pea-like pulse grown upon the leguminous shrubs *Cajanus flavus* and *bicolor*, which are extensively cultivated in many tropical countries, where they are highly valued. The better sorts are very palatable substitutes for the pea.

Pigmentation [from Lat. *pigmentum*, paint, color, deriv. of *pingere*, to paint, to decorate]: in physiology, a discoloration produced by the deposition, especially to excess, of a pigment in the tissues. A certain amount of pigment is one of the normal constituents of the body. The great source of pigment is found in the coloring matter of the red blood-corpuscles, and it is probable that all of the pigments found in the tissues represent various modifications of this. Under normal circumstances the greatest amount of pigmentation is found in the epidermal appendages, especially in the hair. The varying color of this is due to the different amounts and possibly different physical relations to the tissue of the same pigment. The same is true of the eyes, which owe their color to the pigment contained in the iris. A varying amount of pigment is found in the skin. In a section of the Negro skin there is found a line of pigment in and between the cells of the deepest layer of epidermis. The formation of the pigment does not seem to be a function of the epidermic cells, but it is formed by certain cells of the connective tissue, and when formed is taken up by the epidermic cells. The color of different organs of the body is due to the presence of essentially the same pigment. An increased formation of the pigment plays an essential part in various pathological conditions of the body, and a diseased condition of the adrenal glands is associated with an increased formation of pigment. In the skin the greatest formation of pigment under pathological conditions is seen in the pigmented tumors. All these tumors spring from the mesoderm and usually originate in tissues where there is normally a formation of pigment, as in the choroid coat of the eye and in the skin. Another source of pigment is also given when organs are subjected to long-standing congestion, or when hæmorrhage takes place in organs. A number of red blood-corpuseles are then destroyed and their pigment is taken up in the tissues. The pigmentation of the skin which follows a bruise or an injury is due to changes following on a hæmorrhage. W. T. Councilman.

Pigments: coloring matters which when mixed with oil, water, or gum, form paint. They are either mineral or extracted from organic matter. See Paint.

Pigmy: See Pygmy Tribes.

Pigmy Ape: See Barbary Ape.

Pig-nut: See Hickory.

Pigres (in Gr. Πίγρης: Greek poet of the fifth century B. C., brother of Artemisia (*q. v.*), and reputed author of the mock-heroic poem, *The Battle of the Frogs and Mice* (Βατραχομυομαχία), once attributed to Homer. (See editions by Baumeister, 1852, and Brandt, 1888.) To him was ascribed also the *Mœrgites* (Μαργίτης), the hero of which was a blundering Jack-of-all-trades and master-of-none, a phrase which goes back to the Greek original: πόλλ' ἠπίστατο ἔργα, κακῶς δ' ἠπίστατο πάντα. B. L. G.

Pigweed: See Chenopodium.

Pike [M. Eng. *pike*, appar. deriv. of *pike*, a sharp point, etc. Cf. Fr. *brochet*, pike, deriv. of *broche*, spit]: any one of various species of fishes. The English pike (*Esox lucius*) has been supposed to have been "so called either from the likeness of its nose to a pike or spear, or because it moves itself in the water like a spear thrown" (*Richardson*); or with greater probability because of the pointed or pike-like teeth. In the U. S. the name is applied to the same species, and in some places to the smaller species of the same genus —e. g. *Esox reticulatus*, *Esox niger*, etc. These are, however, generally called pickerel. The *Esox mashinongy* is in most sections distinguished under the name muskellunge. All the species agree in the form familiar to most persons from personal acquaintance with some one or other of the species, or from the illustrations in angling books, and differ chiefly in the comparative length of the snout, the

The pike.

extension of scales on the cheeks and opercula, the number of rays in the dorsal and anal fins, and color. The name "pike," either alone or in combination, is also perverted to

species very different from those just considered. In some parts of the U. S., e. g. the species of *Stizostedion* (a genus closely related to *Perca* or the perches) are called walled-eyed pike, or simply pike. See Esocidæ and Fishes.

Revised by F. A. Lucas.

Pike: a spear with wooden handle and metal head, carried by foot soldiers. In the fifteenth century it was from 15 to 20 feet in length, but was gradually reduced to from 10 to 14 feet. It was designed for use as a thrusting, not as a missile weapon. Before the introduction of the musket, about 1525 A. D., the mass of the infantry was armed with the pike. Concurrently with the more general use of the musket the number of pikemen was reduced; but in the latter part of the sixteenth century they still constituted half of each battalion, being massed ten deep in the center, with the musketeers on the flanks. With the introduction of the bayonet in the seventeenth century the use of the pike was gradually given up, although, owing to lack of other arms, it has been used in comparatively recent times, as during the French Revolution. James Mercur.

Pike, Albert: author; b. at Boston, Mass., Dec. 29, 1809; studied at Harvard University; went in 1831 to Santa Fé, N. M., by way of St. Louis, much of the way on foot; reached Fort Smith, Ark., in 1832 in a destitute state; was a journalist at Little Rock 1834–36, after which he became a successful lawyer and a prominent States-rights politician; served as a captain of Arkansas cavalry in the Mexican war; was brigadier-general in the Confederate service during the civil war; editor of Memphis *Appeal*, 1867–68; author of *Prose Sketches and Poems* (1834); 5 vols. of *Law Reports* (1840–45); *The Arkansas Form-book* (1845); *Nugæ* (poems, 1854); a romance (1835); a volume of Masonic statutes and regulations (1859); *Morals and Dogma of Freemasonry* (1870). His *Hymns to the Gods* were originally contributed to *Blackwood's Magazine* in 1839. Privately printed collections of his poems were issued in 1873 and 1881. He was the grand commander of Scottish Rite Masonry of the southern jurisdiction and the chief of the Royal Order of Scotland in the U. S. D. at Washington, D. C., Apr. 2, 1891. Revised by H. A. Beers.

Pike, Zebulon Montgomery: soldier; b. at Lamberton, N. J., Jan. 5, 1779; son of a captain in the U. S. army; became a cadet in his father's regiment 1799; was soon promoted to captain; headed an expedition which penetrated to the head-waters of the Mississippi in the autumn of 1805; in the following year was charged with an exploration of the interior of Louisiana territory, in the course of which he discovered Pike's Peak in the Rocky Mountains and reached the Rio Grande; was detained by Spanish authorities, taken to Santa Fé for examination, and his papers seized. Being ultimately released, he arrived at Natchitoches July 1, 1807, received the thanks of the Government for his services, was rapidly promoted, published in 1810 an account of his two expeditions, became brigadier-general 1813, and commanded the expedition sent against York (now Toronto), Canada, in the assault of which place he was killed Apr. 27, 1813. See his *Life*, by H. Whiting, in Sparks's *American Biography* (2d series, vol. v.).

Pike's Peak: a summit of the Rocky Mountains, named in honor of Gen. Zebulon M. Pike, who discovered it in 1806. Its altitude is 14,147 feet, and as it stands in the Front range it is visible from a wide area of the plains. From 1842 to 1888 it was occupied as a meteorological station by the U. S. Signal Service, and observations were resumed by the Weather Bureau in 1892. In 1890 it was connected by a cog railway with Manitou, and it is a popular resort for tourists. Its lower slopes are covered by a forest of pine and fir, the upper limit being at 11,500 feet, above which the rocks are bare. G. K. Gilbert.

Pilas'ter [from Lat. *pila*, pillar]: a square pillar, attached to a wall, from which it projects but little. It sometimes has the taper of a column, and is sometimes of equal breadth from top to bottom. Its base and capital usually conform to those of the pillars or columns, though this was not the custom among the Greeks. The name pilaster is also given to a projecting pier of rough brick or stone standing on the inside of a wall, and designed to sustain the end of a sleeper for the floor above.

Pi'late, Pontius: the fifth Roman procurator of Judæa and Samaria; entered his office in 26 A. D., residing partly in Cæsarea and partly in Jerusalem, where he inhabited the magnificent palace built by Herod the Great. In 36 he was arraigned by the Samaritans before the Syrian proconsul, Vitellius, on account of his unjust and cruel government, and Vitellius sent him to Rome to answer the accusations before the emperor. The issue is not known with certainty. According to Eusebius, he was banished to Vienne in Gaul, and committed suicide soon after. According to a widely spread tradition, he was beheaded under Nero. A great number of legends, more or less fanciful, clustered naturally around his name. His singular behavior during the trial of Christ, as we read it in the Bible, excited from the earliest time a most vivid interest, and occasioned very different explanations. Tertullian calls him *jam pro sua conscientia Christianum*, and the Æthiopian Church declared him a martyr and a saint. Modern scholars, however, agree generally in considering him one of those frivolous characters which were the natural offspring of the Roman civilization in the Augustan period—capable of receiving a strong impression of the sublime, but utterly unable to act on such an impression. The cruel massacre of the Samaritans at Gerizim, the immediate cause of his downfall, is consistent with that kind of weakness of character which rises from moral indifference. The so-called *Acta Pilati* (of which an English translation is found in the Ante-Nicene Library) give an account of the trial of Jesus, but of course they are spurious, as are also numerous other works either attributed to him, as the *Epistola Pilati*, a letter purporting to be Pilate's description to Tiberius of the resurrection, or describing his subsequent life and punishment. His wife is generally called Procla or Claudia Procula by the Pilate legends, and represented as a proselyte of the gate. Origen, Chrysostom, and Hilary assert that she became a Christian. The Greek Church has made her a saint, and observes Oct. 27 as her day.

Revised by G. L. Hendrickson.

Pilat'ka, Fla.: See Palatka, Fla.

Pilchard: See Clupeidæ.

Pilcomayo, pĕĕl-kō-mī'yō: a river of South America; rises in Bolivia, N. W. of Potosí; flows S. E. through the Gran Chaco, where it separates the Argentine Republic from Paraguay, and joins the Paraguay by several mouths just below Asuncion. Length probably over 1,100 miles. Though most of its course is through a plain, it is so shallow and so much obstructed that it is nearly useless for navigation, at least in the dry season; in some places the channel is almost lost in marshes. H. H. S.

Pile-driver: an apparatus for driving piles into the ground. The common pile-driver consists of a frame having two vertical timbers or guides between which an iron ram is drawn up by a rope passing over a pulley at the top, and then allowed to drop on the head of the pile; the ram weighs from 1,000 to 2,000 lb., its fall is from 10 to 20 feet, and the number of blows per minute is five or more. The steam pile-driver, invented by Nasmyth, has a steam cylinder which can be set at different elevations between vertical guides. The piston in this cylinder is lifted up by steam pressure, and thus the ram, which is attached to the lower end of the piston rod, is raised; the ram weighs from 2,000 to 4,000 lb., falls about 3 feet, and the number of blows per minute is about sixty. In the gunpowder pile-driver, invented by Shaw, a cartridge of powder is placed upon the head of the pile and exploded by the impact of the falling ram; the force of the explosion drives down the pile and throws up the ram, which is caught and held by an automatic device at its highest elevation. In soft soils piles should be driven until the penetration under a single blow of the ram is only 1 or 2 inches. Mansfield Merriman.

Piles (in engineering): See Foundation.

Piles, or **Hæmorrhoids** [*piles* is from Mod. Lat. *pi'læ*, piles, liter., plur. of Lat. *pi'la*, ball]: vascular and fibro-vascular tumors of the lower bowel or rectum—termed *external* piles when below the sphincter muscle and upon the verge of the anus; *internal* piles when above the sphincter. In structure they are due to congestion or dilatation of the hæmorrhoidal veins, which are connected with the portal venous circulation, returning blood from the intestines through the portal vein and liver to the vena cava and the heart. Piles when chronic are dilated veins of the anus and rectum, with fibrous thickening of the tissues and mucous membrane investing them. Hæmorrhoids are caused in the first place by anything which obstructs the outflow of blood from the rectal veins, and in the second place by any local irritation tending to cause congestions or inflammatory processes. They seldom afflict persons who are robust, ab-

stemious, frugal, and engaged in active exercise. They result from excessive eating and drinking, congestion or cirrhosis of the liver, alcoholic excesses, and constipation. Sedentary occupation favors their development. Cavalry officers and railway travelers suffer from piles—in part from constipation, in part from the influence of incessant jarring and hypostatic congestion of the lower bowel. The abuse of harsh and powerful catharties, drinking water impregnated with mineral substances, and too fine, non-laxative diet may develop piles. Pregnant women have piles from pressure of the gravid uterus upon the veins. Internal piles may increase in size, and in efforts of evacuation be protruded from the bowel. By this stretching the hæmorrhoidal tumors in time become pedunculated, and are forced out with every act of defecation. They require to be constantly returned; failure to do this may result in their strangulation, ulceration, bleeding, and even removal by gangrene. External piles when inflamed may also ulcerate and bleed. Hæmorrhoids when inflamed render evacuations of the bowels very painful, and cause suffering in sitting and walking. Patients with hæmorrhoids usually discharge mucus from the anus, and sometimes shreds and patches of organized lymph. Piles are to be prevented, and also treated in their milder forms and stages, by regulated, laxative diet, active exercise, and mild saline catharties. When pedunculated they may be removed by the knife, ligature, or galvano-cautery. When they are strangulated they must be reduced in size by ice or cold water, oiled, and returned. Ulcerated and inflamed piles are treated by cold applications, astringent and anodyne ointments, and free evacuation of watery stools by use of saline catharties. Revised by W. Pepper.

Pileus: See Head-dress.

Pilgrim Fathers: the name commonly applied to the earliest settlers in Massachusetts (*q. v.*). They had separated from the Church of England and sought refuge in Holland, whence they emigrated to Massachusetts in 1620, founding the Plymouth colony. In religion they were Independents, while the Massachusetts Bay colonists were Puritans (*q. v.*).

Pillar: See Column.

Pillar Saints or **Stylites**: in the Eastern Church, chiefly in Syria, a class of ascetics who dwelt each on the top of a lofty pillar, after the example of St. Simeon Stylites (*q. v.*). The practice began to prevail in the fourth century, and in the twelfth was not yet extinct. It never penetrated into the West.

Pillars of Hercules: See Gibraltar.

Pilling, James Constantine: ethnologist; b. in Washington, D. C., Nov. 16, 1846. He attended the public schools and Gonzaga College. At the age of twenty was employed as stenographer in court work, in committee work in Congress, and in the various commissions established by Congress for the settlement of claims resulting from the civil war. In 1875 he joined the survey of the Rocky Mountain region under Maj. J. W. Powell; in 1880 was made chief clerk of the U. S. Geological Survey; in 1891 became ethnologist in the Bureau of Ethnology of the Smithsonian Institution. D. at Olney, Md., July 26, 1895. His publications, which are chiefly bibliographical, range from 1881 to the time of his death, and relate to the languages and literatures of the Eskimo (1887), Siouan (1887), Iroquoian (1888), Muskhogean (1889), Algonquian (1891), Athapascan (1892), Chinookan (1893), Salishan (1893), Wakashan (1894), and other linguistic stocks of North American Indians. Among his earliest works was a *Catalogue of Linguistic Manuscripts in the Bureau of Ethnology* in Washington (1881). This was followed in 1885 by a general work on Indian bibliography entitled *Proof-sheets of a Bibliography of the Languages of the North American Indians*. His latest work, as yet unpublished, was a bibliography of the ancient Mexican language.

Pillory [from O. Fr. *pilori*, pillory; cf. Portug. *pelourinho*, Provenç. *espitlori* < Lat. **specula'rium*, deriv. of *speculum*, mirror. Fr. *pilori* has been influenced in form by *pilier*, pillar]: an instrument of punishment, consisting of a wooden frame in which the offender's head and arms were inserted, he standing, thus confined in a stooping posture, exposed to public ridicule. Something of the kind existed in England previous to the Norman Conquest, and was known as the *halsfang*, or catch-neck. From the reign of Henry III., and especially during the sixteenth, seventeenth, and eighteenth centuries, the pillory was a statute punishment for perjurers, forgers, users of false weights, etc. Its use was abolished by 56 Geo. III., c. 138 (1816), except for perjury and subornation, and was altogether abolished by 7 Wm. IV. and 1 Vict., c. 23 (1837). In France a similar implement, called the *carcan*, was in use until 1832. The pillory was in use in the American colonies, and provision for its use existed on the statute-books of the U. S. until 1839, but it seems not to have been employed after the Revolution. See Stephen's *Commentaries*, Andrews's *Punishment in the Olden Times*, *The Reliquary* for Apr., 1861, and *The Penny Magazine* (ii., 108.) Revised by F. Sturges Allen.

Pillow, Gideon Johnson: soldier; b. in Williamson co., Tenn., June 8, 1806; graduated at the University of Nashville 1827; studied law; practiced successfully at Columbia; was a delegate to the national Democratic convention of 1844, where he was influential in securing the nomination of James K. Polk for the presidency; was appointed brigadier-general of Tennessee volunteers July 11, 1846, during the war with Mexico; took a prominent part in the siege of Vera Cruz; commanded the right wing at the battle of Cerro Gordo, where he was wounded; was made major-general Apr. 13, 1847; took part in the battles of Churubusco, Molino del Rey, and Chapultepec, being severely wounded in the latter; came into collision with Gen. Scott in regard to the convention of Tacubaya, which he disapproved, and at his own request was tried by a military court upon charges of insubordination preferred by Gen. Scott, but was honorably acquitted. He was honorably discharged July 20, 1848, and resumed the practice of law in Tennessee; was a member of the Nashville convention of 1850, where he opposed extreme measures; raised a large force of Tennessee volunteers for the Confederate service in 1861; was appointed brigadier-general; commanded at the battle of Belmont Nov. 7, 1861; was second in command at Fort Donelson in February; escaped before the surrender, and afterward served under Gen. Beauregard in the Southwest. D. in Lee co., Ark., Oct. 8, 1878. Revised by James Mercur.

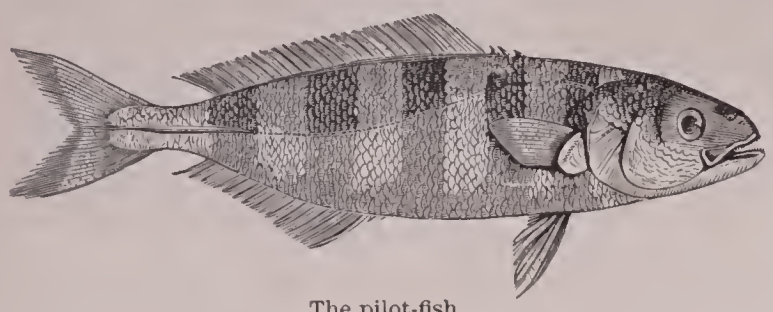
Pilot [from Fr. *pilote*: Ital., *pedoto*, *piloto*: Span. *piloto*, from a deriv. of Gr. πηδόν, oar, πηδάλιον, rudder. The Dutch words *pijloot*, etc., are probably borrowed from Romanic sources]: the steersman of a ship; the officer or person on board ship who has charge of the helm and of the ship's course; in the specific and more usual sense, the person appointed and authorized by law to conduct or steer a vessel through a river, road, channel, etc., or into or out of a harbor or port. *Pilotage* is the service rendered by a pilot; also the compensation received by a pilot.

Pilots of the description last mentioned are rendered necessary by the exigencies of modern commerce by water. In Great Britain the appointment and much of the regulation of pilots is placed in the hands of societies or corporations, either holding ancient charters or existing under statutory authority, and called Pilotage Authorities. The most important of these corporations is that of the Trinity House of Deptford Strand, which has the control of the pilots of the Cinque Ports (*q. v.*). The jurisdiction of pilotage authorities in Great Britain now depends for most purposes, independently of local statutes, upon the Merchant Shipping Act of 1854. In the U. S. the States and the Federal Government have concurrent jurisdiction to pass pilotage laws, the power of Congress being superior to that of the States, and exclusive when exercised (by virtue of Art. I., § 8, of the Federal Constitution). Pilots are licensed in the U. S. either by the Governor of a State, or by a commission, or under federal laws.

Vessels are required by statute to take a licensed pilot, and must pay pilotage to the first pilot offering himself. In Great Britain the Merchant Shipping Act of 1854 provides that no owner or master of any ship shall be answerable to any person whatever for any loss or damage occasioned by the fault or incapacity of any qualified pilot acting in charge of the ship where the employment of the pilot is compulsory by law. In the U. S. the owner is not exonerated from liability for damages resulting from gross mismanagement by the pilot by reason of the employment of the pilot being compulsory. The pilot's fees are regulated by statute, or in Great Britain by the pilotage authorities, or by custom. See Maude and Pollock's *Law of Merchant Shipping*, Abbott's *Law Relative to Merchant Ships and Seamen*, and Parson's *Maritime Law*. F. Sturges Allen.

Pilot-fish, or **Pilot** [so called because it was formerly supposed to act as a pilot to the mariner, and is still sup-

posed to act as such to sharks]: a carangoid fish (*Naucrates ductor*), rarely much more than a foot long, which is found in almost all tropical and temperate seas. These fishes often



The pilot-fish.

follow in the wake of vessels, associating with sharks, and taking the refuse thrown from the ships. They are elongated, symmetrical, fusiform fishes, of graceful form and with seven cross-bands of black, which, however, in part disappear in after-life. They are remarkable for the changes which they undergo with age, which have led to the idea that the young pilot-fish was a species distinct from the adult. Revised by D. S. JORDAN.

Pilot Mountain: See ARARAT.

Pilot-snake: a harmless snake (*Coluber obsoletus*) common in the Eastern and Southern U. S. It is dark brown or black above, mottled or clouded below, and is more heavily built and less active than the true black snake (*Bascanium constrictor*). F. A. L.

Piloty, pēē'lō'tēē, KARL, von: historical painter; b. in Munich, Oct. 1, 1826; d. there July 21, 1886; son of a lithographer, Ferdinand Piloty, from whom he received his first instruction; afterward pupil in Munich Academy. He visited Venice in 1847, painted portraits in Leipzig in 1849, went to Paris and Antwerp in 1852, and thereafter devoted himself to painting pictures of historical subjects. He was appointed a professor in the Munich Academy in 1856 and director in 1874, and had numerous Americans among his pupils. His style is academic. One of his most celebrated works, *Nero on the Ruins of Rome* (1861), is in the National Museum at Pesth; his *Galileo in Prison* is in the Cologne Museum; *The Entry of Godfrey de Bouillon into Jerusalem* (1862) is in the Maximilianeum, Munich; *Columbus Discovering Land* (1866) in the Shack Gallery, Munich; the *Triumph of Germanicus* (1873) in the New Pinakothek, Munich; and the *Death of Alexander the Great* (1886) in the National Gallery, Berlin. His *Wise and Foolish Virgins* (1881) was exhibited in the principal cities of the U. S. in 1887–88. WILLIAM A. COFFIN.

Pilpay, Pilpai, or **Bidpai**: Oriental fabulist; lived several centuries B. C.; the reputed author of a collection of fables not now extant, but contained partially in the PANCHATANTRA (*q. v.*) and to a less extent in the MAHÂ-BHÂRATA (*q. v.*) and the *Hitopadesa*.

Pils, peelz, ISIDORE ALEXANDRE AUGUSTE: historical and military painter; b. in Paris, Nov. 17, 1815; pupil of Picot; awarded Grand Prix de Rome 1838; medals Salons 1846, 1855, and 1857; first-class medal, Paris Exposition, 1867; medal of honor Salon 1861; became officer Legion of Honor 1867; member of the Institute 1868; d. at Douarnenez, France, Sept. 3, 1875. He first attracted attention in 1849 by the exhibition of his picture *Rouget de l'Isle Singing the Marseillaise*, and his battle pictures made his works very popular. They are open to criticism for technical faults, however. He was a Professor of Painting in the École des Beaux-Arts for a number of years. WILLIAM A. COFFIN.

Pil'sen: town of Bohemia, Austria; at the confluence of the Mies and the Beraun; 67 miles by rail S. W. of Prague (see map of Austria-Hungary, ref. 3–D). It lies in a fertile valley, and is surrounded by promenades on the site of the old walls. Among the buildings are the Gothic church of St. Bartholomew (1292) and the Renaissance town-hall. There are large breweries producing annually 9,000,000 gal. of the beer known as Pilsener, and manufactures of leather, pottery, machinery, etc. In the neighborhood are mines of iron, coal, and alum, During the Hussite wars Pilsen was besieged several times, and was stormed by Count Mansfeld at the beginning of the Thirty Years' war. The first printing-press in Bohemia was set up here in 1468. Pop. (1891) 50,693, about equally divided between Germans and Czechs.

Piman Indians: a linguistic stock of North American Indians. The term Pima, which as a tribal name was first used by Father Eusebio Kino as early as 1692, is said to mean "no," and was employed, as now used, through a misunderstanding. The aboriginal name of the Pima proper is *A'kemorl-Oohtam*, signifying river people. According to some authorities, the Piman Indians, as here recognized, form but part of a linguistic group embracing the Shoshonean, Piman, and Aztec or Nahuatl tribes. The relationship of these peoples, however, has yet to be demonstrated.

TRIBES.—With the exception of the Pima Alta or Pima proper, and part of the Papago, the tribes composing this stock inhabit a vast area in Northwestern Mexico, including the greater portions of the states of Sonora, Chihuahua, Sinaloa, and Durango, as well as parts of Jalisco and Zacatecas. Beside the tribes mentioned, the stock embraces the Pima Baja or Nevome, Opata, Tarahumar, Cahita, Cora, and Tepehuan, with their numerous ramifications.

Pima Alta.—According to tradition, the Pima Alta formerly lived in the Salado valley, Southern Arizona, whence they extended their settlements into the valley of the Gila. According to their mythology, a deluge came and left but a single survivor, a chief named Ci-ho, or So-ho, the progenitor of the present Pima tribe. One of his descendants, Sivano, erected as his residence the now ruined adobe structure called CASAS GRANDES (*q. v.*), and constructed numerous other pueblos in the Gila and Salado valleys. The Sobaipuri, an extinct branch of the Pima, attributed these now ruined pueblos to people who had come from Tusayan, or from the north, and this is strengthened by recent research, which tends to show that the culture of the inhabitants was quite similar to that of the ancient Pueblos of the north. Sivano's tribe became so populous that many of its members were forced to emigrate to the Salado valley, where they followed the example of their ancestors of the Gila by constructing extensive irrigating canals and reservoirs, and by building large defensive villages of adobe.

The Pima attribute their downfall to the destruction wrought by foreign tribes from the east. Prior to this, however, a part of the tribe seceded from the main body and settled in the valleys of Northern Sonora, where they became known as Pima Baja, or Nevome, and Opata. When the other natives descended from the mountains and resettled the valley of the Salado, they never rebuilt the substantial adobe dwellings, but constructed dome-shaped lodges of poles covered with thatch and earth, and in such habitations they have since dwelt. In early historic times the Pima were joined by the Maricopa, a Yuman tribe who left the Lower Gila owing to constant oppression by the Cuchan or Yuma. Although speaking distinct languages, the Maricopa and Pima intermarry, and their general habits and customs are similar.

It is probable that the teachings of Father Eusebio Kino and his followers, in the seventeenth and eighteenth centuries, influenced the primitive beliefs of the Pima Alta. They now believe in the existence of a supreme being, known as the "Prophet of the Earth," and also in a malevolent deity. Sickness, misfortune, and death are attributed to sorcery, and medicine-men are employed to overcome the evil influence of the sorcerers.

Marriage among the Pima is entered into with little ceremony, and is never considered binding, and the number of a man's wives is only a question of the husband's ability to support more than one wife. The women perform much of the labor, save the hunting, plowing, and sowing.

The agriculture of the Pima Alta is conducted by irrigation, and antedates the Columbian epoch. Each village possesses an irrigating canal, frequently several miles in length. They cultivate wheat, corn, barley, beans, pumpkins, squashes, melons, onions, and a small supply of inferior short cotton. One of the principal food products of their country is the bean of the mesquite, which is prepared and made into loaves. The fruit of the zaguara cactus (*Cereus giganteus*) is also gathered by the women and made into an intoxicating beverage. The Pima women are expert makers of water-tight basketry, prettily decorated. They also manufacture a coarse pottery, some of which also is decorated.

The Pima Alta, who numbered 4,464 in 1890, are confined, with the Maricopa, to reservations in the Salado and Gila valleys, Arizona.

Pap'ago.—This tribe inhabits the territory S. and S. E. of the Gila river, on Gila Bend reservation, especially S. of Tucson, Ariz., and extending across the desert waste known as the Papagueria into Sonora, Mexico. Like the Pima, the Papago subsist by agriculture, and are frugal and peaceable. An extensive trade in salt, taken from the great in-

land salt-lakes, is conducted by this tribe, and they also manufacture and sell a sirup extracted from the pitahaya. They are tall and dark-complexioned; their dialect differs but little from that of the Pima, and their habits and customs, as well as their traditions, are quite similar. The tribe suffered much from the hostility of the Apache prior to the subjugation of the latter. Within the limits of the U. S. the Papago number about 5,000. There are possibly as many more in Sonora.

Sobaipu'ri.—Allied to the Pima and Papago were the Sobaipuri, a tribe now unknown by that name, but in the eighteenth century occupying the Santa Cruz and San Pedro valleys, and the valley of the Gila between the confluences of those intermittent streams. Probably this tribe was forced from its settlements by the depredating Apache, and compelled to join its nearest kindred, the Papago, by whom they have been absorbed.

Nevo'me.—This term is applied to the Lower Pima, or Pima Baja, and their subdivisions inhabiting the region of South Central Sonora. The social organization and religious system of beliefs and practices of the Nevome, prior to the teachings of Catholic missionaries, were analogous to those of the Yaqui, their southern neighbors, although the dialects of the two branches were so differentiated that intercourse was possible only through a sign-language. The Nevome were agriculturists; they dressed better than most of their kindred, and lived in flat-roofed adobe houses. The Nevome were divided geographically into a northern and a southern branch. These were autonomous, often at enmity with each other, and inhabited a number of independently governed villages. The population is estimated at about 8,000.

O'pata.—Adjoining the Papago and Pima Alta on the S. E. is a large body of Indians whose tribal name is Joyl-ra-wa, and who were formerly at enmity with their northern neighbors, hence the appellation Opata, a Pima term derived from *oop*, enemy, and *ootam*, people, folk.

Physically the Opata are fine specimens of the Indian race. They are generally below the medium size, but are well-proportioned; their complexion is not so dark as that of the Yaqui; their features are regular and agreeable, and their hair is unusually soft. They number about 5,500.

Prior to the advent of the Spanish missionaries the habits and customs of the Opata were akin to those of the Pima and Papago N. and W.; now, however, they have become so thoroughly transformed as almost to have forgotten their native tongue. They are described as of a submissive disposition, with much regard for honesty and morality.

Tarahumár.—The name of this division is derived from *huma*, to run; *tala*, or *tara*, foot = foot-racers, in allusion to the custom of running and driving a wooden ball before them with their feet. Their habitat embraces the headwaters of the principal southern Sonora and Chihuahua streams in the Sierra Madre. They are still very primitive, living in hovels or in caves in the mountain fastnesses and barrancas, and subsisting by hunting deer and smaller game, and by the cultivation of maize, beans, pepper, and potatoes. They are robust, of medium height, and have swarthy complexions and scanty beards, but long, thick, black hair. They formerly tattooed the forehead, lips, and cheeks in various patterns. Their docile character contributed to their reduction by the Spanish settlers, notwithstanding their large number, which is said to reach about 15,000, and by some is even estimated at 40,000. The names of the settlements of the Tarahumar almost invariably terminate in the locative form *chic*.

Cahi'ta.—This division inhabits the southwestern coast of Sonora and the northwestern coast of Sinaloa, extending from lat. 28° to 25° 30′. The Yaqui and Mayo tribes form the most important part of the Cahita division. The men are robust, but well formed; their complexion is dark bronze and their features, though somewhat coarse, are not unpleasant. The women are small and rather thick-set. Owing to the semi-tropical climate their dwellings are unsubstantially constructed of canes and boughs covered with palm-leaves. In the fertile valleys about the mouths of streams they engage in raising corn, cotton, calabashes, beans, and tobacco, and also in cultivating the mescal-producing agave.

The Mayo and the Yaqui have a tribal chief; both are divided into a number of autonomous villages, which combine only in case of warfare. In both groups a system of clans is found, and esoteric orders similar to those of the Pueblos exist. Their religious beliefs are characterized by fetichism, and they recognize no supreme being.

In the first half of the seventeenth century the Mayo and Yaqui probably numbered together about 60,000. There are now about 13,500 Yaqui and half as many Mayo. Like most of the southern tribes of the Piman stock these have largely become Hispanized, except in language. The Yaqui are described as naturally industrious, and are employed as cattlemen, teamsters, farmers, sailors, etc. They are also good miners, and are expert in pearl-diving. They exhibit an unusual talent for music.

Co'ra.—This division, which embraces the Cora, Nayarita, Tecualme, Muntzizti, Teacuacitzisti, Ateacari, and Colotlan, with their sub-tribes, inhabits mainly the territory contiguous to the Rio de San Pedro. Their country, therefore, lies chiefly within the state of Jalisco. They were warlike, living independently in the mountain glens and ravines until 1721–22, when they were subjugated by the Spanish and compelled to follow more civilized ways. The Cora language does not exist in its native purity, having been influenced by contact with civilization. Although hostile, they were agriculturists and manufacturers of coarse woolen blankets. The population is about 20,000.

Tepehuán.—The native name of this tribal division is derived from *tepehuani*, conqueror, victor. They inhabited mainly the state of Durango, but their domain extended also into Southern and Western Chihuahua, Northeastern and Southeastern Sinaloa, Northeastern Jalisco, Northern Zacatecas, and Southwestern Coahuila. Now, however, the tribe is confined to the eastern slope of the Sierra Madre, between lat. 25° and 26°. Their primitive condition resembled that of the Cahita tribes, locally varied through environment. While strictly an agricultural people (cotton and corn being their principal products), they were ever ready to defend the log and stone habitations they had constructed on almost inaccessible crags. In valor they were regarded as foremost among the tribes of Mexico, and chastity they held in high esteem. They wove their cotton into articles of clothing, which they dyed and bartered with neighboring tribes. The population is less than 1,000.

Pimen'ta, or **Pimento** [from Span. *pimien'ta* and *pimiento* < Lat. *pigmen'tum*, paint, pigment, juice of plants]: a name given to the unripe berries of a handsome evergreen tree (*Pimenta officinalis*, family *Myrtaceæ*), growing throughout the West Indies and in Mexico and South America. The fruit is a small globular berry, rather less than a third of an inch in diameter; it is two-celled, each cell containing a single black kidney-shaped seed. The active principles are a volatile oil, contained in the proportion of from 3 to 4 per cent., and a green fixed oil. Both of these occur in largest proportion in the cortical portion of the fruit. Pimenta has a warm, pungent, aromatic taste, and may be used in medicine for the general purposes of the aromatic spices—namely, as stomachics, to improve digestive power, to allay nausea, and correct the nauseating and griping effects of other medicines. It is largely used as a spice in cookery, called allspice or Jamaica pepper. It is obtained in commerce from Jamaica.

Pimpernel, or **Poor Man's Weather-glass**: a common herb of Europe (*Anagallis arvensis*), naturalized in North America, having rather handsome flowers, most commonly scarlet, but often white or blue. It is remarkable that it always closes upon the approach of bad weather. The water-pimpernel is *Samolus valerandi*, found in the U. S. and most other countries. *S. floribundus* and *S. ebracteatus* are found in the Gulf States. The above plants all belong to the *Primulaceæ*. The first-mentioned was thought to have active medicinal powers, and the second was once looked upon as having magical qualities.

Pinar del Rio: See the Appendix.

Pinchback, PINCKNEY B. S.: See the Appendix.

Pinchbeck: a kind of brass formerly much used for making cheap watch-cases, and now used as a substitute for the more costly bronze. It contains over 80 per cent. of copper (the rest is zinc), and has when new a look quite like that of gold.

Pinckney, CHARLES, LL. D.: statesman; b. at Charleston, S. C., 1758; was bred a lawyer, and during a part of the Revolution was held a prisoner by the British, and after the peace represented South Carolina in Congress. He was a prominent member of the convention of 1787 which framed the U. S. Constitution, and one of the drafts submitted to that body was made by him. In 1788 he was president of the convention in which South Carolina ratified the U. S. Constitution, and in 1790 he presided over the convention which adopted the State constitution. He was Governor of the State 1789–92, 1796–98, 1806–08; U. S. Senator 1798–1801; minister to Spain 1802–05: and was again in Congress 1819–21; an ardent and eloquent anti-Federalist. D. at Charleston, Oct. 29, 1824.

Pinckney, CHARLES COTESWORTH, LL. D.: statesman; b. at Charleston, S. C., Feb. 25, 1746; was educated at Westminster, at Christ Church, Oxford, and the Middle Temple, London; studied military science at Caen, France; became a barrister at Charleston 1769; served as captain, and afterward as colonel of South Carolina troops in the Revolution; was aid to Washington in 1777; displayed great valor and skill in the Southern campaigns 1778–80; suffered much as a prisoner of war 1780–82; became a brigadier-general 1783, and later a major-general of the State, and still later of U. S. troops (1797); declined many important offices; assisted in framing the U. S. Constitution; was one of the special ministers to France 1796–97, when he was ordered to leave that country; was the author of the famous sentiment, "Millions for defense, but not one cent for tribute"; Federalist candidate for Vice-President 1800, and one of the ablest lawyers of his time. D. at Charleston, S. C., Aug. 16, 1825.

Pinckney, THOMAS: statesman; brother of C. C. Pinckney; b. at Charleston Oct. 23, 1750; graduated at Oxford, and was called to the bar at the Temple, London, 1770; entered the Revolutionary army, in which he served with much distinction, receiving a bad wound at Camden; Governor of South Carolina 1787–89; U. S. minister to London 1792–94, and to Madrid 1794–96, when he negotiated the important treaty of San Ildefonso; was in Congress 1799–1801; appointed major-general 1812, and served against the Creeks and Seminoles with success. D. at Charleston, Nov. 2, 1828.

Pindar (in Gr. Πίνδαρος): the greatest of Greek lyric poets; b. about 522 B. C. of an ancient family of Cynoscephalæ near Thebes; was carefully trained in musical arts by the best masters; began his career at an early age, and before the Persian war (490 B. C.) had gained a national reputation. During the Persian war, however, he did not and could not espouse the national cause, for Thebes was on the side of the invader, and being a Theban and an aristocrat, he went with his state and his caste. Still he showed that he was too good a Greek not to sympathize with the great achievements of the war of liberation, and his praise of Athens is said to have brought on him a fine from his "Mother Thebes" and a rich reward from the "violet-wreath'd city." Pindar traveled far and wide in the exercise of his profession as a lyric poet whose office it was to adorn the great occasions of life, and he was everywhere honored and reverenced by the princes of earth. His character was as lofty as his verse. He was a priest as well as a poet, a favored guest of the Delphic god, and the last prophet of the old Doric creed. The date of his death is uncertain, but he can not have lived much beyond 450 B. C. His poetry covered the whole field of Greek lyric, and the fragments that remain show his poetical faculty in various ranges of composition, in banquet songs and in choruses for virgins, in dithyrambs and in dirges, but the height of his art reveals itself in the only poems that we have entire, his *Hymns of Victory* (Ἐπινίκια), odes written in honor of victors in the four great national games of Greece, Olympian, Pythian, Nemean, and Isthmian. The opulence of these poems, their brilliancy of imagination and of diction, the swing of their movement, their elevation and their force, have been recognized by all critics and have excited the emulation of lyrists from the poet's day to this; but the springs of Pindar's art seem to have been hidden from critics and imitators alike for many generations. A "Pindaric ode" has been too often synonymous with rant and bombast, and it was not until the nineteenth century that a diligent study of Pindar showed that there is profound art in the plan, as well as in the details, and that everything works together to produce a total effect. The myths which constitute so important a part of these *epinicia* are not mere idle or incidental adornments, but grow up out of the theme and form an organic part of the structure; they serve to idealize victory and victor and to make what might have been a mere occasional poem into an eternal type. The meters are not lawless, as they were once thought to be, but obey the rule of a refined and exacting system, and it is through the symmetry of the meters that scholars learned first to divine and then to prove the symmetry of the thought. Much that would have aided in the appreciation of Pindar has been lost, but though music and dance have perished, the rhythm that regulated both survives in the language and has proved itself a key to the inner life of the Pindaric poems. Renewed study only confirms the judgment that Pindar combines, in almost unique perfection, largeness of manner and elaborateness of detail.

His poems were edited by Böckh (Berlin, 1811–21) in three parts, still the great edition; Dissen-Schneidewin (1847); Mommsen (1864); Bergk in his *Poetæ Lyrici Græci* (4 ed. 1878). Text edition by Christ in the Teubner Library (1879); with English notes by Fennell (1879–83, new ed. of *Olympians and Pythians*, 1893); by Gildersleeve, *Olympians and Pythians* (New York, 1885); by Bury, *Nemeans and Isthmians* (1890–92). Translated into English prose by Ernest Myers (2 ed. 1884). The best book on Pindar and his art is by Alfred Croiset, *Pindare et les lois du lyrisme grec* (2 ed. Paris, 1886). See also the chapter on Pindar, in Jebb's *Classical Greek Poetry* (1893), and Fracearoli's elaborate work, *Le Odi di Pindaro* (1894). B. L. GILDERSLEEVE.

Pindar, PETER: See WOLCOT, JOHN.

Pindemonte, IPPOLITO: poet; b. at Verona, Italy, Nov. 13, 1753. Of noble birth, he was entered by his family, as soon as he had completed his studies at Modena, among the Knights of the Order of Malta. After some years of service in Malta and Sicily his health gave out, and he was obliged to retire from active life. He settled at his country estate, Avesa, near Verona, and gave himself to letters. He tried his hand at tragedy, but with poor success. In 1785, however, he brought out *Poesie Campestri*, which had immediate recognition. These were delicate and tender praises of the country life, after the manner of the English poets of the eighteenth century. He had already begun to be intimate with the best Italian poets of his time, among them Monti and Foscolo, of whom the latter had dedicated to him his *Sepolcri*. In 1788 he went to Paris, where he remained for two years, becoming intimate with Alfieri, who deferred to his critical judgment. The French Revolution caused him to return to Italy in 1791. In 1795 he published a new edition of the *Poesie Campestri*, with the addition of *Prose Campestri*—essays of a contemplative and philosophic kind. In 1804 he published his tragedy *Arminio*—suitable for reading rather than for representation, and accompanied by three dissertations on the dramatic art. In 1805 appeared a volume of *Sermoni*—satires in the manner of Horace, and gay rather than angry castigations of the follies of his time. In 1809 he printed the first books of his delicate and graceful translation in blank verse of Homer's *Odyssey*, and in 1822 the remainder. His *Epistole in versi* (1819) are filled with sadness at the sufferings of Italy. His last work, a series of *Elogi di letterati* (1825–26), contains sympathetic notices of contemporary scholars and poets. D. at Verona, Italy, Nov. 18, 1828. See B. Montanari, *Della vita e delle opere d'Ippolito Pindemonte* (Venice, 1834) and *Le Poesie originali di Ipp. Pindemonte*, ed. by A. Torri, with *discorso* by P. Dal Ris (Florence, 1858).—His brother, Marquis GIOVANNI PINDEMONTE (b. at Verona in 1751; d. there Jan. 23, 1812) wrote a number of interesting plays, collected under the title *Componimenti teatrali* (4 vols., Milan, 1804).

A. R. MARSH.

Pine [O. Eng. *pīn*, from Lat. *pī'nus*, pine]: gymnospermous trees belonging to the genus *Pinus* of the family *Pinaceæ* and order *Coniferæ*. (See CONIFERS.) They are described as follows by Dr. George Engelmann:

"Their angular, two or three edged leaves (almost always serrulate or rough on the edges), in bunches of two to five, are inclosed in a sheath of membranaceous scales; one (Western American) species has a single rounded leaf in this sheath. Their sterile flowers develop abundantly at the base of the shoots of the same spring; the fertile clusters appear singly, or a few together higher up or near the top of such shoots. The young fruit remains almost sta-

tionary for a whole year, and only in the second summer the cone enlarges, maturing in the autumn. We distinguish two sections of true pines. The white pines have five mostly slender leaves in a bunch; scales of the cones rather thin; wood whiter, lighter, softer, and less resinous, and therefore highly prized for carpenter-work. Of these, the white pine of the Eastern and Northern U. S. (*P. strobus*) is the fairest representative, a tree of magnificent proportions and universal application, and highly prized as an ornamental tree. Similar, still more ornamental, but also more slender, is the Himalaya or Butan white pine. In the Western U. S. this group of pines is represented by the colossal sugar-pine (*P. lambertiana*), with its immense cones and large edible seeds, and by the mountain white pine (*P. monticola*) of the Pacific mountains; another species, with large squarrose cones (*P. ayacahuite*), is spread over the Mexican mountains. Similar to these, but distinguished by more rigid leaves, shorter, thicker cones, with thicker scales and large, edible, almost wingless seeds, is the small group of the Cembra pines, the principal species of which grows on the European and Siberian Alps, the similar *P. albicaulis* on the Pacific alps, and *P. flexilis* on the Rocky Mountains. *P. cembra* furnishes the red wood with the white sap from which particolored Swiss carvings are made.

"The second and by far the largest section of true pines comprises those with knobby scales, leaves from one to five in a bundle. The small group of the four Mexican and Western American nut-pines closely approaches to the last; they are small and scraggy trees that make excellent firewood, with globose cones, the scales thick with very prominent knobs, bearing large, edible, wingless seeds, like those of Cembra, and with leaves varying in the different species from a single one (*P. monophyllos*) to five in number.

"Next to these range the large-fruited nut-pines, with thick or hook-knobbed scales, and large short-winged seeds, of which *P. pinea* is the Mediterranean and *P. sabiniana*, *coulteri*, and *torreyana* the Western American representatives. Of the large number of pines remaining, some bear their cones just below the terminal bud of the same year's shoot; their scales are usually thinner, with less prominent prickles, and their wood whiter and less resinous. The Scotch and the Austrian pine of Europe, and the red pine of the Northern U. S., all of them with leaves in pairs, belong here, as also the long and five-leaved, large-coned, and variable Mexican pines of the alliance of *P. montezumæ*. Those pines that bear lateral cones have usually very knobby and prickly scales, and heavy, resinous, yellowish wood—the real *yellow* or *pitch pines*. Here range the seaside pine (*P. pinaster* of the Mediterranean regions), the Eastern pitch-pine, the Jersey pine, prickly pine, loblolly pine, the yellow pine, Elliott's pine, and, above all, that most important and magnificent of all pitch-pines in the U. S., the long-leaved pine of the South (*P. australis*), which furnishes a most highly prized naval timber and nearly all the resinous products of the country. To the yellow pines belong also a number of Western pines, the most important and widest spread of which is the heavy pine (*P. ponderosa*), *P. contorta*, the interesting but very local Monterey pine (*P. insignis*), and a few others."

In all, seventy species of pines are known, extending from the Arctic regions southward in both hemispheres to subtropical or tropical countries (Central America and the East Indies); and somewhat more than one-half of these occur in North America. CHARLES E. BESSEY.

Pin'eal Gland or **Body**: See PARIETAL EYE and BRAIN.

Pineapple: the compound conical fruit of a plant of the family *Bromeliaceæ* (*Ananassa sativa*); a native of tropical America, naturalized in many hot countries, and cultivated also in hothouses. It is one of the best of fruits. The Bahamas and South Florida are finely adapted to pineapple culture. From the fibers of the leaves of this and allied plants a beautiful fabric called pina muslin is made.

Pine Bluff: city (settled in 1819, plotted in 1836); capital of Jefferson co., Ark. (for location, see map of Arkansas, ref. 4–D); on the Arkansas river at the head of low-water navigation, and on the St. L., Iron Mount. and South., and the St. L. S. West. railways; 42 miles S. S. E. of Little Rock. It is built on a bluff 228 feet above sea-level; is in the cotton-producing region of the State; has a large cotton-compress, extensive railway-car factory, the general shops of the St. Louis S. Western Railroad, flour-mill and grain-elevator, cottonseed-oil mill, 2 planing-mills, and ice-factory, and contains a branch of the State Normal College, 3 State banks with combined capital of $350,000, and 2 daily and 4 weekly papers. A large amount of cotton and lumber is handled annually. Pop. (1880) 3,203; (1890) 9,952; (1900) 11,496. EDITOR OF "COMMERCIAL."

Pine, Cape: See CAPE PINE.

Pine-chafer: any one of various coleopterous insects whose larvæ commit great ravages in pine forests, eating away the new material between the bark and the wood. These insects are *Pissodes strobi*, *Tomicus pini*, *T. xylographus*, and several species of *Hylurgus*.

Pine Family: See CONIFERS.

Pine-finch, or **Goldfinch**: a bird of the family *Fringillidæ*, the *Spinus pinus* of recent authors. It is a near relative of the common goldfinch of the U. S. (*Spinus tristis*), and occurs more or less abundantly throughout North America. It attains a length of about 4¾ inches, is brownish olive above, and beneath whitish, streaked with dusky. It feeds chiefly on the seeds of hemlock and other trees, as well as those of grasses, etc. Revised by F. A. LUCAS.

Pine-grosbeak: a bird of the family *Fringillidæ*, the *Pinicola enucleator* (Linn.), Cab. It is found throughout the northern regions of the Old as well as New World. Its average length is about 8½ inches; the bill and legs are black; the male is rosy colored (tinged, except on the head, with brownish) above, ashy below; the female brownish above, ashy (tinged with greenish yellow) below. As indicated by the name, this bird frequents pine and other evergreen forests; it feeds on spruce-seeds, etc. It is rare in the U. S., except near the northern border, although occasionally abundant even so far S. as Philadelphia.
Revised by F. A. LUCAS.

Pinel', PHILIPPE, M. D.: alienist; b. at St.-Paul, Tarn, France, Apr. 20, 1745; studied medicine at Toulouse and Montpellier, graduating M. D. from the former in 1773; removed in 1778 to Paris; obtained a prize in 1791 for his *Traité médico-philosophique sur l'Aliénation mentale*, and was appointed physician of the Bicêtre in 1792, and in 1795 of the Salpêtrière. He substituted compassion, kindness, and justice for the chains and cells that confined the insane, and, recognizing insanity as a disease, he inaugurated its scientific study. He was Professor of Hygiene and subsequently of Pathology in the School of Medicine at Paris until 1822, when the faculty was reorganized, and, owing to jealousies, his name was omitted save as an honorary professor. He was author of *La Nosographie philosophique* (1798) and *La Médecine clinique* (1802). D. in Paris, Oct. 26, 1826.
Revised by S. T. ARMSTRONG.

Pine'lo, ANTONIO DE LEON: jurist and author; b. at Córdoba (now in the Argentine Republic) about 1590. He studied law at Lima, and subsequently went to Spain, where he was judge of the Casa de Contratación at Seville, and historical secretary of the Council of the Indies. He was employed to codify the laws relating to the Spanish colonies, laboring for many years and examining more than 500,000 *cédulas*. The work was published under the title *Recopilación general de las Leyes de las Indias*, in four volumes, in Madrid, 1680; it was made authoritative, was for over a century the organic law of the colonies, and is, besides, a mine of historical information. There are several revisions. Pinelo also published a life of Toribio, Archbishop of Lima, several valuable works on the American colonies and their laws, and the first bibliography of the Spanish colonies, entitled *Biblioteca oriental y occidental. náutica y geográfica* (Madrid, 1629; revised ed. by Gonzalez de Barcia, 3 vols., 1737–38). D. at Seville about 1675. HERBERT H. SMITH.

Pinero'lo (in Fr. *Pignerol*): town of Northern Italy, in the province of Turin, on a hill 1,200 feet above the sea; on the left bank of the torrent Chisone; 23 miles S. W. of the city of Turin (see map of Italy, ref. 3–A). The cathedral stands near an ancient tower, once a prison, but at present serving as a campanile or belfry. The old Piazza d'Armi is now shaded with American elms. From the early part of the eleventh century it was a strong fortress, held for the most part by the house of Savoy, though France frequently, and often successfully, disputed its possession. In 1696 the fortifications of Pinerolo were, in accordance with a treaty, mostly destroyed. Since 1748 it has been an episcopal see. It is a place of considerable industry; its manufactures are silks, woolens, cottons, liqueurs, etc. Pop. 12,000.

Pines, Isle of: an island of the West Indies; 35 miles S. of the western end of Cuba. The island is a dependency of

Cuba, contains 1,214 sq. miles of undulating or flat and marshy land, and has (1899) 3,199 inhabitants. Capital and prineipal village, Nueva Gerona. The island contains marble quarries, and is a favorite health resort for sufferers from lung diseases. H. H. S.

Pines, Isle of, or **Hunea**: an island in the southern Paeific Ocean, belonging to France; in lat. 22° 38′ S., lon. 167° 25′ E.; 30 miles from the southeastern extremity of New Caledonia. It was discovered in 1774 by Capt. Cook, and was selected in 1872 by the French Assembly for a penal station. The inhabitants belong to the same race as the population of New Caledonia. Exclusive of the convicts they number about 800.

Pine-snake: a large serpent (*Pituophis melanoleucus*), 6 feet long, 2 inches thick, of a shining white color with dark-brown spots. It receives its name from having its home in the pineries of Eastern North America, from New Jersey southward, though it is also sometimes called the "bull-snake," from the loud bellowing sound it produees. It emits a strong, disagreeable odor. It feeds on eggs and small birds and mammals, and is harmless to man.

Pingré, păn′grā′, Alexandre Gui: astronomer; b. in Paris, Franee, Sept. 4, 1711; studied theology, but adopted Jansenistic views, and devoted himself to astronomy; published 1754–57 a nautical almanac under the title of *État du Ciel*; greatly extended Lacaille's table of eclipses in the second edition of *L'Art de vérifier les Dates*; wrote in 1783 his *Cométographie, ou Traité historique des Comètes* (2 vols.), which is his principal work, and translated the poem by Manilius, *Astronomica* (1786). D. in Paris, May 1, 1796.

Pinguicula: See Butterwort.

Pini, pee′nĕe, Gaetano, M. D.: physician and hygienist; b. at Leghorn, Italy, Apr. 1, 1846; studied at the Universities of Pisa and Naples, graduating M. D. *summa cum laude* from the former in 1869. His medieal studies were interrupted in 1866 by service as a private in the war between Italy and Austria, and again in 1867 under Garibaldi. In 1870 he was on the staff of the *Enciclopedia Medica Italiana*. He originated and secured the funds for the erection of the hospital for rhachitic children in Milan in 1875. He originated and organized the Royal Italian Society of Hygiene in 1878. In 1876 he founded the Milan society for cremation, and was instrumental in originating a number of these soeieties in Italy. He was an earnest worker in philanthropy, originating the Brotherly Aid Society and the Night Asylums. He was a member of the Italian Pellagra commission. D. Sept. 25, 1886. S. T. Armstrong.

Pink [cf. *pink*, priek, make jagged]: the name of various plants of the genus *Dianthus*, all natives of Asia and Europe, for the wild pinks of the U. S. are of the genus *Silene*, and are properly called campions or catchflies; although *D. armeria*, *D. prolifer*, and one or two others are sparingly naturalized. The most eommon pinks are beautiful garden and window flowers, often delightfully fragrant. There are thousands of fine varieties—carnations (comprising flakes, bizarres, picotees), pheasant's-eyes, monthlies, Chinese pinks, maidens, Carthusian pinks, etc. (See Carnation.) They are somewhat doubtfully referred to some four or five original species (*D. plumarius*, *caryophyllus*, *chinensis*, *carthusianorum*, *superbus*, *deltoides*, etc.). The commonest pink of old gardens, once much used for borders, is *D. plumarius*. Revised by L. H. Bailey.

Pinkerton, Allan G.: founder of the Pinkerton detective agency; b. at Glasgow, Scotland, in 1819; took part in the Chartist outbreak in Birmingham, and to eseape imprisonment emigrated to the U. S. in 1842. He settled in Illinois, where he became a deputy-sheriff, and in 1850 founded his deteetive agency in Chicago. During the U. S. eivil war he was in eharge of the secret-serviee division of the army, and both at that time and later showed unusual skill and courage in detecting and bringing to justiee the authors of crime. He broke up several notorious gangs of thieves, recovered large amounts of stolen money, and did effective work against the Molly Maguires in Pennsylvania. Among his published writings are *The Molly Maguires and the Detective* (1877); *Criminal Reminiscences* (1878); *The Spy of the Rebellion* (1883); and *Thirty Years a Detective* (1884). D. in Chicago, 1884. F. M. Colby.

Pinkerton, John: author; b. at Edinburgh, Scotland, Feb. 13, 1758; passed an apprenticeship of five years to the law in his native city; settled in London 1780; devoted himself to literature under the patronage of Horace Walpole, and produced an immense number of works, chiefly historical, none of which, however, were marked by any great talent. The best known is his *General Collection of Voyages and Travels* (17 vols. 4to, 1808–14), with maps and engravings, which is still useful for reference. He wrote some poems of merit, but his *Ancient Scottish Poems* (2 vols., 1786), purporting to be from the MS. colleetions of Sir Richard Maitland, has been pronounced a literary forgery, probably executed by himself. In 1804 he settled in Paris, where he died Mar. 10, 1826. See his *Literary Correspondence*, edited by Dawson Turner, 1830.

Pinkeye, or **Influenza** (Epizoötic): an infectious disease of horses, charaeterized by high temperature, great prostration, redness, and swelling of the eyelids (whence its name), and other mucous membranes of the head, and swelling of the limbs. It is one of the oldest known diseases of horses, having been described by Rusius, an Italian writer, in 1301; sinee then numerous outbreaks have been recorded at varying intervals. In 1872 and 1873 the disease spread over all of North America, and so many horses were attacked that commeree was seriously interfered with. An outbreak oeeurred in Europe in 1882 and 1883, when large numbers of horses were affected.

This disease always results from direet or indirect exposure to diseased animals or to their exhalations. The infectious material is sometimes carried long distances by the wind or by fomites. In outbreaks it is noticed that the disease spreads most rapidly along channels of commerce, and requires a long time to reach remote and thinly settled districts. The cause of pinkeye has not been discovered, although it has been determined by Pfeiffer that a short bacillus is the etiological factor in a similar disease—influenza of man. The period of incubation is from four to seven days, at the end of which time the disease begins suddenly with high fever and great depression. The onslaught and progress are so rapid that the height of the disease may be reached in twenty-four hours. The temperature sometimes advanees from normal to 106° F. within a few hours. The pulse and respirations are quiekened. The animal evidenees depression by hanging the head, allowing the ears to droop, refusing food, refusing to move, but when forced to do so walking with an irregular, tottering gait. The eyelids are swollen, the legs and sheath become œdematous, and sometimes the substernal region as well. The visible mucous membranes of the digestive tract are injected and red, and there is some constipation. A diseharge from the nose and a cough indieate irritation of the respiratory mucous membrane. The eye is sometimes involved to the extent of an inflammation of the cornea and iris that may lead to blindness. Recovery usually takes plaee in from five to fourteen days, but complications, as exhaustion of the heart, eatarrhal pneumonia, diarrhœa, laminitis, or paralysis of the brain, may prolong the case or cause death. Mortality results in from 2 to 10 per cent., depending largely on the type and virulence of the special outbreak.

In treating pinkeye good care and properly selected foods are of the greatest importanee. The horse should be allowed a plentiful supply of pure air, an abundance of pure cold water, and soft laxative foods, as grass, green-corn fodder, roots, apples, bran mashes, steamed grain, etc. The skin should be kept brushed and the swollen parts moistened frequently with cooling, astringent washes. The eyes should be washed at short intervals with boraeie-acid solution, and, if painful, proteeted from the light. Constant stimulation of the heart is required. The bowels should be kept open with small doses of salts or with calomel. Clysters of cold water are useful to reduee the temperature. Antipyrine is frequently used with benefit, and nux vomiea and quinine are usually administered freely.

Leonard Pearson.

Pink Family, or **Pinkworts**: the *Caryophyllaceæ*, a group of (mostly) herbaceous dieotyledons, with opposite entire leaves, and stems with swollen joints; flowers usually dichlamydeous, the petals separate; ovary superior, compound, one- to five-celled, the ovules axial, or on a central column. There are about 1,100 known speeies, mostly natives of temperate and cold countries. Many species are cultivated for their beautiful flowers, as the pinks (species of *Dianthus*, especially *D. caryophyllus*, the carnation; *D. chinensis*, the Chinese pink; *D. barbatus*, the sweet-william; *D. superbus*, etc.), rose-campions (species of *Lychnis*), catchfly (*Silene*), soapwort (*Saponaria*), etc.

Charles E. Bessey.

Pinkney, Edward Coate: poet; son of William Pinkney, statesman: b. in London, England, Oct. 1, 1802; educated at St. Mary's College, Baltimore; was in the naval service 1816–24; practiced law at Baltimore with little success, but was appointed Professor of Rhetoric and Belles-Lettres in the University of Maryland; published *Rodolph and other Poems* (1825), and edited for a short time a political journal, *The Marylander* (1827). D. at Baltimore, Apr. 11, 1828. Some of his lyrics have much grace and spirit. The best known of them, *A Health*—"I fill this cup to one made up of loveliness alone," was enthusiastically praised by Edgar Allan Poe. Revised by H. A. Beers.

Pinkney, William, LL. D.: statesman; b. at Annapolis, Md., Mar. 17, 1764; was the son of an English loyalist; studied medicine and law; was admitted to the bar 1786, and rapidly rose to eminence. He was a member of the State convention that ratified the U. S. Constitution in 1788, and was elected in the same year to the State Legislature. He was a U. S. commissioner in England under the Jay Treaty 1796–1804; attorney-general of his native State 1805; minister extraordinary, with Monroe, to Great Britain 1806; minister resident there 1807–11; U. S. attorney-general 1811–14; served as a volunteer officer in the war of 1812, and was wounded at Bladensburg; was in Congress 1815–1816; was appointed minister to Russia, and special envoy to Naples in 1816, but resigned in 1818. He was U. S. Senator 1820–22. D. Feb. 25, 1822. See *Life*, by H. Wheaton (1826); by W. Pinkney, D. D. (1853).

Pinkroot: the root of a showy herb of the U. S. (*Spigelia marilandica*), found from New Jersey to Wisconsin and Texas. The infusion of this root is much used as an anthelmintic; it has also some narcotic qualities. In use it should be combined with a cathartic, such as senna. Four other species occur in the U. S. *S. anthelmia* is a similar plant of South America. They belong to the *Loganiaceæ*.

Pinkworts: See Pink Family.

Pin-money: in law, an annual sum of money, sometimes provided for in a marriage settlement, to be paid by the husband to the wife for the purpose of defraying her own personal expenses for dress and the like. When the wife dies, her representatives can not claim any arrears that may be unpaid at the time, nor can the husband ever be compelled to pay more than the arrears of a single year; for the allowance is intended to be fully expended in each current year, and is designed to keep up the family dignity and appearance, and not to furnish the wife a means of accumulation. Both the name and the provision for the wife which it designates are practically unknown in the U. S., being nearly confined to the English law and social customs, though the term sometimes occurs in Scotch marriage contracts. The origin of the term is uncertain; by some it is traced to an ancient tax in France for supplying the queen with pins. See Frazer on *Husband and Wife*.
Revised by F. Sturges Allen.

Pinnated Grouse: a name given to the prairie-hen (*Tympanuchus americanus*) on account of the pointed tufts of feathers on either side of the neck. See Prairie-hen.

Pin'nidæ [Mod. Lat., named from *Pin'na*, the typical genus, from Gr. πίννα, a kind of mussel]: a family of bivalve molluscs occurring in warm seas. They have an elongate triangular shell of delicate texture and moor themselves, like the mussels, by a silken "byssus." About fifty living species are known.

Pinnipedes [Lat. *pin'na*, feather, fin + *pes*, *pe'dis*, foot]: a sub-order of carnivorous mammals containing the seals, sea-lions, walruses, and their relatives; so called from the fact that the feet are so modified as to form paddles for swimming, the toes being united by a web or fold of skin. The group is differentiated into three well-defined families: (1) *Otariidæ*, or sea-lions and sea-bears; (2) *Phocidæ*, or typical seals, and (3) *Odobœnidæ*, or walruses, each of which is noticed under its own name. Revised by F. A. Lucas.

Pins [M. Eng. *pinne* < O. Eng. *pinn*, pin, peg, from Lat. *pin'na*, feather, fin, pen]: pieces of wire pointed at one end and provided with a head at the other, designed for fastening together various articles or for ornament. The pins which have been found in Egyptian, Etruscan, and old Scandinavian tombs, or in other ways have come down to us from antiquity, are mostly very elaborate and expensive instruments, made of iron, bronze, brass, silver, or gold, sometimes 12 inches long, with artistically executed heads of wood, bone, ivory, amber, metal, or precious stones; and it is evident that in many cases in which we now use pins the ancients used clasps, laces, and other contrivances. In England pins came into common use in the fifteenth century, but were at first imported from the Continent. Soon, however, the manufacture was introduced into England, and in the latter part of the seventeenth century Birmingham became the center of this branch of industry. In the U. S. it was attempted in 1820, and again in 1824, but not firmly established until the invention of the Howe machine in 1832. The original process of the manufacture by hand, from the straightening of the wire to the spinning and hammering of the head, was long and tedious, and required no less than fourteen distinctly different operations. At present, all these processes, from the cutting of the wire to the sticking of the pins into papers, are performed by machinery, which needs only to be fed by the proper materials at each stage of its operation. The manufacture of safety pins (in which the point rests in and is covered by a loop) has also reached large proportions both in Birmingham and the U. S.

Pinsk: town; in the government of Minsk, Russia; 172 miles S. W. of Minsk (see map of Russia, ref. 8–B). It has a considerable trade carried on by means of the navigable river Pina, which connects it with the fertile regions on the Dnieper. Pop. (1890) 32,480, mostly Jews.

Pint: a measure of capacity, the eighth part of a gallon. See Weights and Measures.

Pinto: See Mendez-Pinto.

Pinto: See Serpa Pinto.

Pinto, Francisco Antonio: soldier and politician; b. at Santiago, Chili, 1785. He studied law at Santiago; supported the patriot cause in 1810, and represented the first republic in Buenos Ayres and England; returned in 1817, entered the patriot army, and served with distinction in Charcas and Peru. In 1824 he was foreign minister; was elected vice-president of Chili at the beginning of 1827, and soon after, by the resignation of Freire, became president, holding the post until July, 1829, when he resigned. Two months later he was again made president by election, but the republic was on the eve of a revolution, and he was forced to resign Nov. 2, 1829. He was the liberal candidate for president in 1841. D. at Santiago, July 18, 1858. —His son, Aníbal Pinto, was b. at Santiago in 1825; was Minister of War and Marine 1871–76 and president Sept. 18, 1876–Sept. 18, 1881; he was a moderate liberal in politics, and was the first of his party elected to the presidency after 1830. The war with Bolivia and Peru began in 1879 and continued through President Pinto's term. D. at Valparaiso, 1884. Herbert H. Smith.

Pinturicchio, pin-too-ree'kĕe-ō, Bernardino di Betto: painter; b. at Perugia, Italy, in 1454. Fiorenzo di Lorenzo was his first master. He afterward entered into partnership with Pietro Perugino. He is considered the greatest decorative artist of his time. He painted some frescoes in the Sistine chapel and the Borgia apartments in the Vatican, some frescoes in Castel St. Angelo, which have entirely been effaced, the library of the Duomo of Siena, the vault of the choir of Santa Maria del Popolo in Rome, and the Buffalini chapel in the Church of Aracoeli in Rome. At Spello there is much of his work, but it is sadly decayed. His altar-pieces are numerous. Pinturicchio always painted in tempera. D. at Siena, 1513. W. J. Stillman.

Pin-worm: a name given to a parasitic nematode worm, *Oxyuris vermicularis*, in allusion to the pricking sensation it produces in the perianal region of infected persons. It is thread-like, rarely more than half an inch in length, and occurs, often in numbers, in the rectum of human beings, especially children. It comes to the exterior to lay its eggs in the region around the vent. The eggs or young must be again taken into the alimentary canal before going through their development, and infection takes place through the mouth. The trouble usually disappears in a short time spontaneously, but medical treatment, and, above all, cleanliness, will mitigate the attacks. J. S. Kingsley.

Pinzon': the name of three brothers, ship-builders and navigators, of Palos, Spain, who were connected with some of the first voyages to America. The eldest, Martin Alonso, aided Columbus in preparing for his first voyage in 1492. He sailed with the expedition, in command of the Pinta; parted company with Columbus on the coast of Cuba Nov., 1492; was the first to discover Haiti, where he rejoined the admiral Jan. 6, 1493; and during the return voyage was again sepa-

rated by a storm, Feb. 14, reaching Bayona, a port of Galicia. Thence he sent an account of the discovery to the Spanish sovereigns, but they paid little attention to it, giving all the honor to Columbus. Pinzon returned to Palos, where he died shortly after of chagrin, as was asserted. Columbus and his friends charged Pinzon with willful desertion on the coast of Cuba, and with attempting to appropriate the honor of the discovery. On the other hand, it was asserted later that Columbus had been incited to the voyage by information received from Pinzon, and there is a generally discredited story that Pinzon had already been on the coast of Brazil in a French ship.—Another brother, VICENTE YAÑEZ, commanded the Niña under Columbus in 1492, but he is better known for his voyage of 1500, when he crossed the equator, reached the coast of Brazil near Cape St. Augustine, coasted northwestward, discovered the mouth of the Amazon, passed between Trinidad and the mainland, and returned to Spain by way of Española. This was the first discovery of the Brazilian coast, but as the country was in the hemisphere assigned to Portugal by the convention of Tordesillas, Spain derived no benefit from it. Pinzon was associated with Juan Diaz de Solis in two voyages—an exploration of the Gulf of Honduras in 1506, and one of the eastern coast of South America, probably to lat. 40° S., in 1508. D. at Palos about 1524.—A third brother, FRANCISCO MARTIN, was pilot of the Pinta in 1492–93, but is not otherwise known. The family was ennobled by Charles V., and has had some distinguished modern representatives. HERBERT H. SMITH.

Piombo, pĕe-om'bō, Fra SEBASTIANO, del (his real name was Luciani, but he signed himself *Sebastiano Veneziano*, that is, the Venetian): painter; b. at Venice in 1485. He was a pupil of Giovanni Bellini at first, and afterward of Giorgione, whose style he adopted in his great altar-piece in the Church of San Giovanni Crisostomo. In 1512 he went to Rome to paint some frescoes in the Farnesina, at the invitation of Agostino Chigi. Michelangelo then became his friend, and employed him in some of his important work. He became second to none as a painter of altar-pieces, and was also very successful in portraiture. Clement VII. appointed him Frate del Piombo (that is, the monk, keeper of the seal) in 1531, and he held this office also under Paul III. till his death at Rome in 1547. The National Gallery in London possesses Sebastiano's masterpiece. *The Raising of Lazarus.* At Viterbo there is a *Pietà* of great beauty. The *Scourging of our Lord*, in San Pietro in Montorio, Rome, is also a great work. His portrait of Andrea Doria in the Doria Palace, Rome, and his portrait of a lady in the Uffizi Gallery, Florence, are excellent examples of his skill.

W. J. STILLMAN.

Piorry, pĕe'ō'ree', PIERRE ADOLPHE, M. D.: clinician; b. at Poitiers, France, Dec. 31, 1794; studied medicine; took his degree in 1816; became professor of pathology at Paris in 1840, changing this for the chair of clinical medicine in 1850, and retired into private life in 1866. He invented the pleximeter, described in his *Traité sur la Percussion médiate*, for which he received the Montyon prize in 1828. He also wrote *De l'Hérédité dans les Maladies* (1840); *Traité de Médecine pratique et de Pathologie iatrique ou médicale* (9 vols., 1841–51); *Traité de Plessimétrisme et d'Organographisme* (1866). D. in Paris, May 29, 1879.

Revised by S. T. ARMSTRONG.

Piozzi, pĕe-ot'sĕe, Mrs. HESTER LYNCH SALUSBURY: author; b. at Bodvel, Carnarvonshire, Wales, Jan. 16, 1740; married, in 1763, Henry Thrale, a wealthy brewer, subsequently a member of Parliament; made in 1764 the acquaintance of Dr. Samuel Johnson, who became in 1766 an inmate of her family at Southwark, and remained such until Mr. Thrale's death in 1781; contributed several poems to Mrs. Anna Williams's volume of *Miscellanies* (1766), among which was the celebrated *Three Warnings*, often supposed to be the composition of Dr. Johnson; married, in 1784, Gabriel Piozzi, a native of Florence, then a music-teacher at Bath; resided a year or two at Florence, where she edited a volume entitled *The Florence Miscellany* (1785) under the signature of "Anna Matilda," thereby attracting the relentless criticism of Gifford against the Della Crusca school; published *Anecdotes of Dr. Johnson* (1786); *Letters to and from Dr. Johnson* (1788); a book of travels on the Continent (1789); *British Synonymy* (1794); and *Retrospection* (1801). D. at Clifton, near Bristol, May 2, 1821. See her *Autobiography, Letters, and Literary Remains* (2 vols., 1861), edited by Abraham Hayward.

Pipefish: a name given to various fishes with a tubular or pipe-like snout, chiefly belonging to the order *Lophobranchiata* and family SYNGNATHIDÆ (*q. v.*).

Pipe-line: See PETROLEUM.

Piperaceæ: the pepper family; dicotyledonous herbs, shrubs, or rarely trees, with naked, usually small, and often imperfect flowers which are commonly spicate; stamens usually two to six; ovary superior, simple, or compound; ovules one or few in each carpel; seeds with small endosperm and large perisperm; embryo very small. There are 1,025 known species, nearly all tropical. Many possess acrid, astringent, or narcotic properties, which have given them economic value, as *Piper nigrum*, a climbing shrubby species of the East Indies, whose dried fruits constitute the well-known black pepper of commerce. Other products are cubebs, obtained from *P. cubeba* of the East Indies, and betel-leaves used from *P. betle*. Species of *Peperomia* are cultivated, and many are known as pepper-elders. CHARLES E. BESSEY.

Piper'no: town of Italy, province of Rome; about 50 miles S. E. of the city of Rome (see map of Italy, ref. 6–E). It stands on an elevation in the midst of an amphitheater of lofty hills near the site of the ancient Volscian town of *Privernum*, from which it takes its name. It is almost entirely surrounded by castellated walls with towers, and stones and inscriptions, taken from the ruined temples and palaces of the ancient city just below it, serve to adorn the more modern town. Here Thomas Aquinas died in 1272. Piperno is very unhealthful, owing to its nearness to the Pontine marshes. Pop. about 4,500.

Pipette [= Fr., dimin. of *pipe*, pipe]: a chemical laboratory instrument of glass which is used for sucking up quantities of liquids by the application of mouth-suction. The pipette has therefore a long stem with a contracted orifice for introduction into deep or narrow-mouthed vessels, with a bulbous or elongated expanded portion above to contain the liquid. Sometimes pipettes are graduated, so that known quantities of liquids may be taken up.

Pipit: See TITLARK.

Pippi: See GIULIO ROMANO.

Piqua: city; Miami co., O.; on the Miami river, the Miami and Erie Canal, and the Cin., Hamil. and Dayton, Pitts., Cin., Chi. and St. L., and the Miami Valley railways; 28 miles N. by W. of Dayton, 73 miles W. by N. of Columbus (for location, see map of Ohio, ref. 5–C). It is the second largest linseed-oil center in the U. S., and contains linseed-oil works, straw-board mills, bent-wood works, rolling-mills, tin-plate works, stove-foundry, corrugated iron-works, woolen-mills, hosiery and wagon works, and school-desk and furniture factories. There are 7 public-school buildings, public-school property valued at over $300,000, the Schmidlapp Free School, public library, 3 national banks with combined capital of $500,000, and 3 daily and 4 weekly newspapers. Pop. (1880) 6,031; (1890) 9,090; (1900) 12,172.

J. W. MORRIS, EDITOR OF "DAILY CALL."

Piquet [Fr.]: a game of cards in which the ace, king, queen, knave, ten, nine, eight, and seven of each suit are employed, ranking in the order given. After shuffling and dealing, two by two, to each of the two players, until each holds twelve cards, the rest are laid on the table, and constitute a talon of eight cards. Next, the non-dealer discards from one to five of his poorest cards, and draws as many more from the talon. The opponent next discards. The first player now reckons points, as follows: For *carte blanche* (twelve plain cards), 10 points; for *point* (the hand fullest of any one suit, or, if both hands are alike, the best hand of the two high suits, calling aces eleven, face-cards each ten, and counting pips on the plain cards) the highest hand scores the number of cards in his fullest suit; for *sequence* (the greatest number of consecutive cards in any suit, or, if both hands are alike in this respect, the one whose highest sequence begins with the higher card; but no two cards make a sequence) the better hand scores as follows: If the best sequence is three cards, count 3; for four cards, 4; for five, 15; for six, 16; for seven, 17, etc. Sometimes all sequences are scored. For the *quatorze*, of four equal honor-cards, the highest scores 14, or if there are no sets of four, the highest set of three equal honor-cards counts 3, etc. The first player now plays a card. The opponent now scores his *carte blanche* if he has any, adds what other points he has, and then follows suit. Each player counts 1 for each lead; and if the second player takes a trick, he counts 1 for that. The one who takes the larger number of

tricks counts 10 for *cards*; if he takes all, he counts 40 more for *capot*. If the first hand makes 29 by preliminary scores, and 1 by first lead, he counts 30 more by *pique*; but if his first score comes up to 30 before his lead, he scores 60 more by *repique*: 100 or 101 points make the game, but there are several ways of scoring besides the above.

Piracicaba, pĕe-raă-sĕe-kaa'baă, or **Constituição**, kŏnstĕe-twĕe-sowñ': a city of the state of São Paulo, Brazil; on a river of the same name, a branch of the Tieté; 97 miles N. W. of São Paulo, with which it is connected by rail. It is the center of a rich coffee and sugar district, and has a thriving trade; a water-fall on the river is utilized for several mills. Pop. (1894) about 15,000. H. H. S.

Piracy [from Gr. πειρατεία, deriv. of Gr. πειρατής, pirate, liter., one who makes attacks, deriv. of πεῖρα, trial, attempt, attack, deriv. of πειρᾶν, try]: robbery on the high seas; depredations committed by persons without the commission or authority of any state. In the law of nations the essential element of the crime is the intention of preying indiscriminately on the human race, rather than a desire to inflict damage upon some particular nationality. As the high seas are not under the jurisdiction of any state, piracy is justiciable in any court. A pirate is a sea-rover who preys on the vessels and goods of any nation that he falls in with, or makes descents on the land for a similar purpose of plunder. A privateer exceeding its commission might not be accounted as a piratical vessel, but one with a commission from *two opposite* belligerents would be piratical, since the only motive for such a double commission is plunder of both parties and of vessels bound to the ports of either. The vessel of a part of a state, organized for rebellion and independence, has been held to be piratical, because, although it may have received a commission from the rebel government, it carries a flag unknown to international law, and offers no guaranty of legal belligerent behavior; but the better opinion is that as such a vessel does not scour the sea for the purpose of plunder, and wages war with but one nation, it wants two important characteristics of piracy. Piracy, in the international sense of the word, is a crime against all nations, but each nation in its own criminal code may class other crimes under this head; thus the U. S. made the slave-trade to be piracy for all its citizens on any ship, and for persons not citizens on its vessels; yet, for all that, the slave-trade, though it might be made criminal by the laws of all civilized nations, is not piratical in an international sense. A slave-trading vessel from the U. S. could not be captured by the cruisers of any other country without special treaty to that effect; but an act of strict piracy could be tried everywhere, for a piratical ship, as being at war with the world, could be captured by the vessel of any nation. As a rule, the search of one vessel by a public ship of another state is a war right only, but search on suspicion of piracy exists in time of peace. The usual penalty for piracy is the confiscation of the piratical ship and hanging of its crew. This shows the wide difference between piracy and privateering, since the penalty for the latter is at most imprisonment. Revised by T. S. Woolsey.

Piræ'us [= Lat. = Gr. Πειραιεύς]: a town situated about the chief harbor of Athens (*q. v.*), and connected with Athens by the celebrated long walls (see map of Greece, ref. 17–L). It is a town of great commercial importance. Pop. (1896) 42,169.

Piranesi, pĕe-raă-naa'sĕe, Giambattista: etcher and line-engraver and architect: b. at Venice in 1720. He first studied drawing with his mother's brother, but perfected himself in this art in Rome under Giuseppe Vasi, who taught him engraving also. He became an excellent architect. Clement XIII. employed him to restore the Church of the Knights of Malta on the Aventine. He is best known for his engravings of the monuments of Rome, ancient and modern, a work in sixteen volumes.—His son Francesco, b. in 1748, was also an engraver, and continued this series after his father's death. Their works are scarcely distinguishable.

Pirbright, Henry de Worms: See the Appendix.

Piro: See Pueblo Indians and Tañoan Indians.

Piron, pĕe'rōñ', Alexis: author; b. at Dijon, France, July 9, 1689; studied law, but did not practice; left his native town chiefly on account of an improper ode he wrote; lived in Paris for a long time in obscurity; began to write for the minor theaters, and obtained admission to literary and elegant society by his brilliant sarcasm and ready wit; entered into rather ludicrous rivalry with Voltaire as a tragedian, but wrote an excellent comedy, *La Métromanie* (1738). When proposed as a member of the Academy he was rejected on account of his ode, not by the Academy, but by Louis XV. D. in Paris, Jan. 21, 1773. There is a collected edition of his works by Rigoley de Juvigny (7 vols., Paris, 1776).

Pisa, pee'zaă, or pee'saă: capital of the province of Pisa, Italy; on the Arno; 49 miles W. by rail of Florence (see map of Italy, ref. 4–C). It is still a walled town, and is entered by six gates. The bridges are very fine, especially the Ponte del Mezzo, which spans the center of the semicircle formed by the Arno within the town. An aqueduct 4 miles in length supplies the town with water. The Duomo (or cathedral), founded probably in 1063, on the site of a palace of Hadrian, has a fine dome, and possesses several paintings by Cimabue, Andrea del Sarto, and others. The Baptistery (1154) and the Leaning Tower (1174) are both circular structures, the former 180 feet in height and 160 in diameter; the latter, 179 feet in height and 50 in diameter, with an inclination of 13 ft. 8 in. (the cornices being included), from the perpendicular. This position, it seems probable, was not due to the design of the architects, but was assumed during the progress of the work. The Campo Santo is adorned with frescoes by Benozzo Gozzoli, Orcagna, and others. The University of Pisa (1338) counts Galileo among its former pupils and professors. It has a natural history museum, a library of 120,000 volumes, and (1891) 64 teachers and 728 students. The town possesses an academy of fine arts and a botanical garden. Pisa is of very remote and uncertain origin. Under the first Roman emperors it rose to great prosperity, which lasted till the middle of the fifth century, after which time it shared in the common calamities of barbarian invasion. In 1003 the pope invited Pisa, then an independent republic, to assist in expelling the Saracens from the Roman territory. After wresting Sardinia, Corsica, and other places from the infidels, Pisa gave herself to commerce and the arts of peace, but her rapidly increasing power and wealth excited the jealousy of Genoa and of the other neighboring republics. Several Guelphic cities, instigated by Ugolino Gherardesca, a traitor noble of Pisa, united in a league against this Ghibelline commonwealth. The Pisans finally suffered a great naval defeat at Meloria in 1284. Henceforth, rival families and rival parties disputed the government of the city, but the commonwealth sustained itself, both against France and its own sister republics, until 1509, when it was forced to submit to Florence. From this time the history of Pisa is one with that of Tuscany. It was formerly a seaport, but, owing to the accumulation of deposits at the mouth of the Arno, is now about 6 miles distant from the sea, and its once important commerce has been transferred to Leghorn. There are manufactures of cottons and silks and coral and alabaster ornaments. Pop. (1893), with the suburbs, 61,500. Revised by R. A. Roberts.

Pisa, Council of: a council called to heal the schism which had distracted the Church since 1378. It was considered œcumenical by Gallican theologians, but not by the Roman Catholic Church. Bellarmine says it was "neither clearly approved nor clearly rejected." It was summoned neither by pope nor emperor, but by fourteen cardinals (seven in each obedience) of the two rival popes. It met in the cathedral of Pisa, Mar. 25, 1409, and held its twenty-third and last session Aug. 7, 1409. It was composed of 24 cardinals, 4 patriarchs, 80 bishops in person and 102 by proxy, 87 abbots in person and 200 by proxy, the ambassadors of several governments, the representatives of 13 universities, and more than 300 professors and doctors of canon law. On June 5, 1409, the council deposed Gregory XII. of the Roman line and Benedict XIII. of the Avignon line, declaring them both to be schismatics, heretics, perjurers, and vow-breakers. On June 26, the 24 (some say only 22) cardinals elected Peter Philargi, who took the name of Alexander V. The reforms talked of were then adjourned for the consideration of a general council to meet in Apr., 1412. The Church now had three rival popes instead of two. F. M. Colby.

Pisa'gua: a town and port of the province of Tarapacá, Chili (formerly in Peru); 45 miles N. of Iquique; lat. 19° 36′ 30″ S. (see map of South America, ref. 6–C). A partial shelter is here afforded to ships by a projecting point. The town is built on a narrow space between the shore and a line of high cliffs; the whole surrounding country is a desert. Next to Iquique, it is the principal center of the

nitrate-trade; the product is brought down from the interior by rail. At the breaking out of the Chilian war this was a point of great importance; it was bombarded Apr. 18, 1879, and taken by the Chilians Nov. 2. During the civil war of 1891 it was the scene of severe fighting, changing hands several times. Pop. 8,000. H. H. S.

Pisan, Christine, de: poet; b. in Venice in 1364; d. about 1431. Her father, Thomas de Pisan (or Pezano), famous in his time for his knowledge of the speculative sciences and especially astrology, held a public position of influence. Hence he was drawn, soon after the daughter's birth, by a tempting offer of King Charles V. of France. Four years later, probably in 1368, he removed his family also to Paris, where they were received into the society of the court. In 1379 Christine was married to a Picard gentleman, by name Estienne du Castel, who died in 1389. Left with three children to a life of care and pecuniary difficulties, and tormented with lawsuits by unscrupulous persons, who had had business relations with her husband, she seems to have turned to writing almost of necessity. The example and care of her father had made her an excellent scholar, perhaps the best Latinist of her period in France. Her opinions were original, and she was able to estimate critically the ideas and tendencies she saw about her. Her acquaintance with great people enabled her to obtain an income from her works by dedications and similar means, and speedily her fame spread even beyond the borders of France. Her poetical manner seems to owe much to Guillaume de Machault and to Eustache Deschamps; but her prose, perhaps owing to her reading of classic models, has an amplitude and power all its own. In her earlier years she seems to have composed many of those light but gracious verses so popular at the time—ballades, lais, virelais, rondeaux, jeux à vendre, etc. Later she wrote a number of longer and more serious poems, including *Épître au Dieu d'Amours* (1399) and *Les sept Seaumes* (1410). Her prose works fall into several groups. The first deals with the dignity of woman, which had been maligned in the famous *Roman de la Rose* and other works. Here belong *La Cité des Dames* (1405?); *Le Livre des trois Vertus* (1406?); *Épîtres sur le Roman de la Rose* (1407). Another group contains works of a moral or didactic character designed primarily for men: *Épître d'Othéa à Hector* (1386?, in mingled verse and prose); *Le Corps de Policie* (1407?); *Faits d'armes et de Chevalerie* (1404–07?), based largely on Vegetius. Finally we have works of an historical or patriotic kind: *La Vie et les bonnes Meurs du sage Roy Charles V.* (1404); *Lamentations sur les maux de la guerre civile* (1410); *Le Livre de la Paix* (1412–13). Besides the above works, we have a quaint biographical piece, *La Vision de Christine* (1405), and two versions from the Latin, which show Christine's love of moralizing. These are the *Dits Moraux*, in verse, based on the distiches of the so-called Dionysius Cato, and the *Livre de Prudence et l'Enseignement de bien vivre*, in prose, based on the treatise *De quattuor virtutibus*, attributed to Martin of Braga. In 1418 the poet entered a convent, and her voice was stilled until 1429, when the appearance of Jeanne d'Arc as the savior of France elicited from her the last and most beautiful of her poems. She seems not to have been living when her heroine met her sad fate.

There is no complete edition of the works of Christine de Pisan. The earlier poems are edited by M. Roy, 2 vols., Paris, 1886–91 (Soc. des anciens textes franç.); *Le Chemin du long Estude*, by R. Püschel (Berlin and Paris, 1881); *Le Dit de la Rose*, by F. Heuchenkamp (Halle, 1891). See also R. Thomassy, *Essai sur les écrits politiques de Christine de Pisan* (Paris, 1838); and F. Koch, *Leben u. Werke der Christine de Pizan* (Goslar, 1885), and *Ueber die Werke der Christine de Pizan* (in *Zeitsch. f. neufranz. Sprache u. Litt.*, 1886). A. R. Marsh.

Pisan'der (in Gr. Πείσανδρος) of Rhodes: Greek epic poet who flourished, according to Suidas, about the middle of the seventh century B. C., but probably much later. Pisander is noteworthy for having first endowed Hercules with the club and the lion's skin, suggestive of sun-worship. It has been conjectured that he too fixed the number of labors at twelve, corresponding to the signs of the zodiac.

B. L. G.

Pisano, Andrea: See Andrea Pisano.

Pisano, Giovanni: See Giovanni da Pisa.

Pisano, Giunta: painter; b. at Pisa, Italy, 1190. He was the first who attempted to free himself from the Byzantine traditions. One of his earliest works is in the Cathedral of Pisa, a *Crucifixion*. Examples of his art exist in Santa Maria degli Angeli at Assisi, as also in the upper church of St. Francis there. He may be considered to have prepared the way for Cimabue. D. in 1236. W. J. S.

Pisano, Vittore, known also as **Pisanello**: Italian painter and medalist; b. at San Vigilio, in Veronese territory, in 1380. He studied painting under Altichieri da Zevio, and painted both in tempera and fresco. He worked in Venice in 1421–22 together with Gentile da Fabriano. Most of his works in fresco at Verona and elsewhere have disappeared. Of his easel-pictures only three exist, one of which, *St. Anthony and St. George*, is in the National Gallery, London. It is as a medalist that he is best known. D. in 1455 or 1456. W. J. S.

Piscary: See Hereditaments.

Piscary, Common of: See Fishery Laws.

Piscat'aqua River: a river which is for a few miles the boundary between Maine and New Hampshire; formed by the junction of Salmon Falls and Cocheco rivers, both of which furnish extensive and well-utilized water-power. Its lower course is tidal, and constitutes the harbor of Portsmouth, N. H. Drainage area, 550 sq. miles.

Piscataquis River: a stream which rises in Somerset co., Me., flows E., and reaches the Penobscot at Howland. Length, 71 miles. Drainage area, 1,276 sq. miles.

Pisces: the twelfth sign of the zodiac, which the sun enters Feb. 20. It formerly corresponded to the constellation of that name. Owing to the precession of the equinoxes, the constellation Pisces is now mostly in the sign Aries. It contains no prominent stars.

Pis'ciculture [Lat. *piscis*, fish + *cultura*, culture, care]: the artificial cultivation of aquatic animals, as described under the synonymous term Fish-culture (*q. v.*). Resting upon the basis of scientific study and associated with adequate protective legislation, it is capable of maintaining the sources of supply utilized by the fishery industries. Pisciculturai operations are extensively carried on by private individuals for profit and by governments for the public benefit.

European Fish-culture.—In Europe Dr. Nicolas Borodine reported 416 fish-hatcheries in 1891, all of which except 82 were private establishments occupied chiefly with trout and salmon culture. Governmental aid was extended in Norway, Switzerland, France, Italy, Great Britain, Austria, and Russia, named in the order of the number of hatcheries supported by them. Norway entered upon the work in 1850 and now takes first rank in the number of its establishments, the amount of its annual grant for fish-culture, and the results accomplished, having produced 200,000,000 cod in 1891 at its station at Flodevigen. Germany supports the once famous but now unimportant hatchery at Hüningen; France subsidizes a small private shad-hatchery at St.-Pierre-les-Elbeuf on the Seine, and contemplates the establishment of a piscicultural school at Gremaz, where M. Lugrin invented a method of artificially propagating live food for young fish; Italy has hatching stations at Brescia and Rome; the Netherlands appropriates a small sum for planting salmon fry in the Rhine; Russia has a station principally for whitefish-culture at Nicholsk; and Scotland sustains a small marine hatchery at Dunbar. The Governments of New Zealand, Australia, and Japan also aid in restocking their public waters, their operations relating almost exclusively to the acclimatization of exotic salmon and trout.

Fish and Fishery Commissions.—Public fish-culture in many countries is conducted through the agency of scientific bureaus and associations. Thus in Norway operations are carried on by the Society for the Development of Norwegian Fisheries; the Netherlands has its commission for the sea fisheries, to which the Government refers all matters relating to fishery interests; in Germany the Deutscher Fischerei Verein (German Fishery Union) and the Commission for the Investigation of the German Seas are partly supported by public funds in their piscicultural work and scientific investigations; Scotland has a fishery board, chiefly for the inquiry into the proper basis of fishery legislation, but partly engaged in marine fish-culture at its Dunbar station. For the extent to which the Government promotes pisciculture in the U. S. see Fish-culture. Newfoundland also maintains a superintendent of the fisheries, and is especially active in the propagation of the cod and the lobster.

Artificial Propagation.—Modern pisciculture includes

artificial as well as natural propagation and rearing of useful and ornamental water-animals, and the acclimatization of species in waters to which they are not native. The necessity of artificial propagation has become most manifest in interior waters where fishing operations and artificial obstructions have interfered with natural reproduction; also in shallow seas to which the shoals of gravid fish resort for spawning, just as the need of regulation has become evident to protect the seals on their shore breeding-grounds and the approaches thereto, the oyster on its flats, and the whale in its arctic nursery shallows.

Artificial propagation forms the basis of successful pisciculture, and has arrived at such a point of development that it affords many advantages over natural reproduction. Under natural conditions only a small percentage of the eggs cast by the female are impregnated. A. N. Cheney found by actual counting of eggs in a Canadian salmon river that only 2 per cent. had been fertilized. By the artificial method nearly all the eggs can be impregnated and hatched; it is common to hatch 97 per cent. of them. In a state of nature eggs are devoured by insects, fishes, birds, mammals, and other enemies; they are destroyed by freshets, crushed by logs, or smothered in mud and mill refuse. The young fish escaping these dangers are attacked incessantly by hosts of predatory animals as well as by larger individuals of their own kind. In a hatchery or pond station both eggs and young are protected almost entirely from all these destructive agencies, the growing fish are assorted according to size, and are regularly and properly fed.

Classification of Eggs.—The fish egg, like that of other animals, consists of the germ-cell, the yolk, and the yolk-membrane, and varies greatly in size according to the amount of its yolk element. After leaving the yolk-membrane, or shell, the young fish is nourished by the yolk for a period varying from a few days, as in the case of the pike-perch, shad, and bass, to several weeks, as in the case of salmon and trout. The eggs differ greatly not only in size and toughness of the shell, but also in their specific gravity, and they have been classified with reference to the latter property into: 1, heavy eggs, like those of salmon, trout, pike-perch, yellow perch, black bass, sea-herring, and smelt; 2, semi-buoyant eggs, as in the shad, whitefish, and sucker; 3, buoyant eggs, as found in the cod, haddock, mackerel, tautog, and cunner. Heavy eggs are again divided into adhesive and non-adhesive, according to the presence or absence of a glutinous covering on the yolk-membrane.

Hatching Apparatus.—Salmon and trout eggs were first hatched on gravel in perforated boxes placed in running water. Next in order came the Coste parallel glass tubes or grilles as a substitute for the gravel. In 1873 Holton invented a box intended to utilize an upward current of water passing through a number of egg-trays placed one above another, and escaping at the top. The Clark hatching-trough, also intended to economize space, is divided by watertight partitions into ten or twenty compartments, each containing a series of egg-trays. Water is introduced into the top of the first compartment, escapes at the bottom, passes over the top of the partition into the next compartment, and so on. The Williamson box resembles Clark's, but utilizes an upward current of water produced by a double partition. Livingston Stone substituted wire-trays or baskets for the egg-trays used in the Williamson box, placing in each basket numerous layers of salmon eggs. This form of apparatus was among those successfully employed by the U. S. Fish Commission at the Columbian Exposition at Chicago.

Heavy eggs are developed also in cylindrical glass jars, either open or closed at the top, the water being admitted near the bottom, directly or by means of a tube, and escaping at the top. Types of such devices are the Chase, the Wilmot, the Ferguson, and the McDonald jars. The upward current not only buoys up the eggs, but also facilitates the removal of dead eggs and other injurious substances. As the embryos developed from heavy eggs are unable to swim when first hatched, they must be removed to rearing troughs, where they are usually kept on gravel.

Adhesive eggs were formerly, and to some extent still are, collected on grass roots, twigs, panes of glass, or other surfaces to which they adhere during the incubation period. The apparatus was placed in running water or in an alternating upward and downward current, the water passing over one partition, under the next, and so on. The box used by Christian Lund in 1761, the smelt-hatching box of James Ricardo, employed in 1876, and the box devised at Gloucester, Mass., by F. N. Clark in 1878, are among the early types. At the present time glutinous eggs—those of the pike-perch for example—are freed from their adhesive envelope by manipulation in a solution of starch or muck, and are afterward hatched like free heavy eggs.

Among semi-buoyant eggs those of the shad were formerly hatched successfully, but inconveniently, in a rectangular box invented by Seth Green. The box had a wire-cloth bottom, and was caused to float at a small angle to the current by means of long wooden cleats on the sides. This arrangement was intended to intensify the action of the current in buoying up the eggs. The boxes were placed in a stream, and required constant supervision to prevent injury to their contents. Variations of the Green box were made by Brackett, of Massachusetts, and by Stilwell and Atkins, of Maine. Semi-buoyant eggs are now developed in the jars used for heavy eggs with greater comfort and safety and an increased percentage of fry.

Buoyant eggs were first successfully hatched in large numbers in the U. S. by Capt. H. C. Chester in 1885 by means of the McDonald cod-hatching box modified by substituting large glass jars for the inner box of McDonald. That box was supplied with water through the center of the bottom, and had an intermittent siphon at each end, so arranged as to give a rise and fall of 5 inches, imitating tidal motion. The improved cod-hatching box of Marshall McDonald resembles the original pattern devised in 1880, but the inner wooden box has a slightly oval bottom covered with cheese-cloth, and a small additional current of water is introduced from the water-chamber through an opening near the bottom of the box, and this gives the eggs a rotary motion which is highly advantageous. The flow of water is from below upward.

Lobsters.—The hatching period of lobster eggs in 1892 varied from two days to thirty-five days, according to temperature of the water. The eggs did not begin to hatch until the water reached 54° F. The largest lobster brought to the Wood's Hole, Mass., station that year measured 12½ inches and had 24,300 eggs. The average number obtained was 12,000. The eggs are readily hatched in the cod boxes above referred to and in the jars used for heavy fish eggs.

Transportation of Eggs.—Fish eggs are usually shipped after the eye-spots are present between layers of damp moss or cotton, or on flannel or zinc bottom-trays lined with moss, and sometimes with a covering of clean snow. The temperature of the inside of the shipping-box is kept low by means of ice. Eggs are frequently sent before they have reached the eyed stage, notably pike-perch and whitefish eggs. The method of shipping shad eggs in bulk on flannel trays, introduced by U. S. Fish Commissioner McDonald, revolutionized the movement of such eggs from the field stations to distant hatching establishments.

Care of the Young.—No attempt is made to feed the young of marine fishes or of the fresh-water shad and pike-perch, the fry being released soon after hatching. Shad, however, have been successfully reared on natural food in ponds to the age of six months, when they are allowed to migrate seaward. The yolk-sac of salmon and trout sustains the fry during a period of thirty to fifty days after leaving the egg, but feeding usually begins a week or ten days before the absorption of the sac is completed. Raw liver ground very fine and passed through a sieve is used. This is diluted with water to the consistence of cream, and the fry are fed just enough to satisfy their hunger several times a day, care being taken to remove all refuse remaining on the bottom after feeding. The larvæ of gnats, mosquitoes, flies, and various small crustaceans, are employed at different stages of the growth of the young, and the flesh of domestic animals constitutes the principal food of older fish.

A series of rearing ponds is one of the most important adjuncts to a fish-hatchery. These should have an adequate supply of brook or river water, which for trout or salmon work should not exceed 70° in temperature in midsummer. The shape, size, and depths of ponds vary with the purpose for which they are intended, but each should have an independent supply and drainage to provide for complete isolation from the remainder of the series. A prime requisite is a bountiful supply of pure water under perfect control.

LITERATURE.—Among the numerous works upon pisciculture methods are the following: *Fischzucht*, by Max von dem Borne and others (Berlin, 1881); Hubrecht, *Oyster-culture and Oyster-fisheries in the Netherlands* (London, 1883); Haxo, *De la fécondation artificielle des œufs des poissons* (Épinal, 1853); Coste, *Instructions sur la pisciculture* (Paris,

1856); Koltz, *Multiplication artificielle des poissons* (Brussels, 1858); Buckland, *Fish-hatching* (London. 1863); Francis, *Fish-culture* (London, 1863); Bertram, *Harvest of the Sea* (London, 1865; New York, 1866); Day, *Fish-culture* (London, 1883); Home, *Salmon and Salmon-fisheries* (London, 1883); Marston, *Coarse Fish-culture* (London, 1883); Maitland, *On the Culture of Salmonidæ and the Acclimatization of Fish* (London, 1883); Maitland, *The History of Howietoun*; Kent, *Artificial Culture of Lobsters* (London, 1883); Day, *British and Irish Salmonidæ* (London, 1887); Fry, *A Complete Treatise on Artificial Fish-breeding* (New York, 1854); Garlick, *A Treatise on the Artificial Propagation of Certain Kinds of Fish* (Cleveland, 1857); Marsh, *Artificial Propagation of Fish* (Burlington, Vt., 1857); Norris, *American Fish-culture* (Philadelphia, 1868); Green, *Trout-culture* (Caledonia, N. Y., 1870); Slack, *Practical Trout-culture* (New York, 1872); Klippart, *An Essay on Fish-culture* (Columbus, O., 1873); Stone, *Domesticated Trout* (Boston, 1873); Green and Roosevelt, *Fish-hatching and Fish-catching* (Rochester, N. Y., 1879); Hessel, *Carp-culture*, U. S. Fish Comm. *Report*, part iv.; Logan, *Carp-culture* (Youngstown, O., 1888); Mulertt, *The Gold-fish and its Culture* (Cincinnati). Much varied information can also be obtained from the annual reports and bulletins of the U. S. Fish Commission, the reports of State fish commissions and of the Department of Marine and Fisheries of Canada, the journals of the Society of Acclimatization and the Society of Agriculture of France, the Transactions of the American Fisheries Society, the publications of the Dentscher Fischerei Verein, and of the fisheries departments of Norway and Finland, *The Field*, *Land and Water*, and *The Fishing Gazette* (London). TARLETON H. BEAN.

Piscidia erythria: a leguminous tree growing in the West Indies, popularly known as Jamaica dogwood. The wood of this tree is largely sold in commerce, and the bark has been employed for catching fish, as when placed in the water it stupefies them. It is supposed to possess considerable narcotic power, and to be a useful substitute for opium in some cases of insomnia due to pain. H. A. HARE.

Pi'semskiĭ, ALEKSEĬ TEOFILAKTOVICH: author; b. in the village of Ramene, in the government of Kostroma, Russia, Mar. 20, 1820; d. Jan., 1881. During his youth he became familiar with the life of the people, and also saw something of the Freemasons, whom he afterward described in a poor novel, *The Freemasons* (1881). After studying mathematics four years in the University of Moscow, he entered the Government service (1844) in the town of Kostroma, but resigned (1853) and moved to St. Petersburg in order to devote himself exclusively to literature. After 1862 he lived in Moscow. His first novel, *Trufiak* (The Jester) appeared in 1850, his second, *A Love Match*, in 1853. The same year witnessed his best drama, *Gorkaĭa Sudbĭna* (A Bitter Lot), a powerful and painful piece that is still played. His greatest novel, *A Thousand Souls*, came out in 1858. Among his later books, which were especially attacks on the liberal tendencies of the time, *The Stormy Sea* (1863), *The Men of 1840* (1868), and *In the Whirlpool* (1871) are noteworthy. Some of his short stories, sueh as *Leshiĭ* (The Wood Demon) and *Piterstchik*, are masterpieces. Most of his dramas (*Veteran and Recruit*, *Baal*, *The Hypochondriac*, etc.) were less successful. He was an unsparing realist who painted with great force and fidelity low and repulsive charaeters, or the miseries of everyday life. His weakness lay in his utter absence of ideals. A complete edition of the novels and tales he had then written appeared in 1861–65; of his plays in 1874. Most of his best work has been translated into French and German. A. C. COOLIDGE.

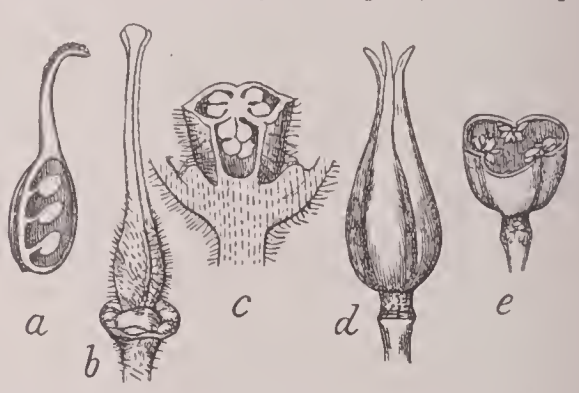
Pis'gah: a mountain of Palestine, E. of the Jordan, mentioned several times in the Pentatench. It was the summit from which Moses obtained his view of the Promised Land (Deut. xxxiv. 1). In 1873 it was identified by Prof. John A. Paine, of the American Palestine Exploration Society, with *Siâghah*, 2,360 feet above the sea. Though not the highest summit of the range, it reaches out toward the valley so as to command a very wide prospect.

Pisid'ia: an ancient territory of Asia Minor, with varying and ill-defined boundaries, situated between Phrygia, Isauria, Cilicia, Pamphylia, Lycia, and Caria. It was inhabited by wild and predatory tribes, ruled by petty chiefs. The Romans never wholly subdued Pisidia, though they held possession of its chief towns—Antioch, its capital, Salagassus, and Selge. It is now included in the Ottoman vilayet of Konieh. E. A. G.

Pisis'tratus [= Lat. = Gr. Πεισίστρατος]: a tyrant of Athens, a son of Hippocrates, and a kinsman of Solon. When in 571 B. C. Solon left Athens for ten years in order to test the working of his laws, Pisistratus entered politics as an advocate of the cause of the lower classes, whose confidence he won. By a ruse he persuaded the people to give him a body-guard, which he gradually increased, until in 560 B. C. he felt himself strong enough to assume the *rôle* of tyrant. Later he had to flee the country, and lived in exile for five years, when, with the help of Megacles, he was restored to power. A second time he was banished, and remained in exile eleven years. The dates of his exile are variously given by ehronologers. By the help of Thebans, Argives, and Naxians, he was again restored to power, and died on the throne in 527 B. C. Between 560 and 527 he was tyrant seventeen years and an exile sixteen years. As tyrant he was distinguished for his mildness and reverence for the laws of Solon, which in the main he left undisturbed. He was the patron of agriculture, the arts, and sciences. He built many public edifices, and caused the poems of Homer to be collected and edited. He was succeeded in the tyranny by his eldest son HIPPIAS (*q. v.*). J. R. S. S.

Pistachio-nut, or **Green Almond** [*pistachio* is from Span. *pistacho* < Lat. *pista'cium* = Gr. πιστάκιον, pistachio-nut, deriv. of πιστάκη, pistachio-tree, from Pers. *pistah*. Cf. Arab. *fistaq*]: the fruit of the pistachio-tree, *Pistacia vera* (family *Anacardiaceæ*), which is common in the S. of Europe and in Asia and Africa. The nut is delicious for dessert. The kernel is somewhat like that of the almond, but is green. The nut yields a good table oil. To the same genus belong the mastich, the terebinth, and other valuable trees. Lamb fattened upon pistachio-nuts is a famous delicacy.

Pistil [from Lat. *pistil'lum*, pestle, so called from its shape]: the part of a flower which produces ovules. It normally occupies the center of the flower, the stamens, petals, and sepals, when present, surrounding it. It is a leaf-structure (phyllome), and in its simplest form consists of a single phyllome (technically a "carpel"), folded upward so



Pistils: *a*, simple of *Isopyrum*; *b* and *c*, compound of *Staphylea*; *d* and *e*, compound of *Ascyrum*; enlarged.

that its edges meet (*a*). Here the ovules normally grow upon the infolded edges (placentæ). In many cases two or more pistils (carpels) grow more or less perfectly into a compound structure (*b c d e*). Here the ovules still grow upon the phyllome edges, but these may be the edges of the same or of different phyllomes, according as each phyllome is fully infolded (*b c*), or only partially so, its edges joining with those of other phyllomes (*d e*). In the pistils of many plants the placenta undergoes some displacement; thus the ovules may be on the surface or the midrib of the carpel.

In every pistil, whether simple or compound, the enlarged, ovule-bearing part is called the ovary, the more or less slender portion above it is the style, and this is terminated by the stigma. The style may be very long, as in Indian corn, where it is known as the "silk," or very short, or even wanting, as in the barberry. The stigma is composed of a soft, specialized tissue, commonly exuding a sticky substance, and designed for the reception of the pollen. It may be a cap on the summit of the style, a surface extending downward for some distance, or it may be more or less branched.

A flower may have many simple pistils, and this appears to have been the condition in primitive flowers, now illustrated by the crowfoots (*Ranunculaceæ*) and water-plantains (*Alismaceæ*); more commonly, however, the pistils have united into a single compound pistil, as in the great majority of flowering plants. Moreover, many compound

pistils have undergone such structural simplification that they often appear to be simple, as in the composites, where the bicarpellary pistil has but a single ovule, and appears at first sight to be monocarpellary.

Although the pistil normally occupies the inner and upper part of the flower (then said to be *superior* to the other organs), it may seem to be below the other parts by the growth of the latter above it (when it is said to be *inferior* to the other organs), as in the composites, irises, and orchids. As the seeds form, the pistil (now called the *pericarp*) undergoes certain modifications, sometimes becoming fleshy, sometimes wholly or in part hard and stony, while sometimes it simply dries into a brittle pod.

CHARLES E. BESSEY.

Pistoja, pĕĕs-tō′yăă (anc. *Pistoria*): town; in the province of Florence, Italy; 21 miles N. W. of the city of Florence (see map of Italy, ref. 4–D). It lies in a fertile valley between two spurs of the Apennines, one of which separates the valley of the lower Arno from that of the Ombrone, a torrent flowing a little to the E. of this town. A wall, rhomboidal in outline, surrounds the town, which is entered by four gates besides the railway barrier. The streets are wide and well paved, and the squares large. The cathedral, in form an ancient basilica, was built in the twelfth century, rebuilt by Niccolo da Pisa, and since modernized. It contains a famous silver altar and the cenotaph of Cino da Pistoja. San Bartolomeo, San Giovanni, and Sant' Andrea are all churches of very ancient dates; the last named contains a pulpit of white marble (1301) exquisitely wrought in alto-rilievo; also a marble group by Niccolo da Pisa. The bishop's palace is an imposing edifice. The façade of the hospital is decorated with remarkable terracottas by the younger members of the Della Robbia family, representing the seven works of mercy. In 62 B. C. Catiline was defeated here. Gregory the Great sent Pistoja its first bishop in 594. After a long period of prosperity the town fell under the dominion of Florence early in the fourteenth century. The manufactures of Pistoja consist chiefly of linens, glass, needles, and especially firearms. Pistols are said to have been first made here, a fact which is thought by many to explain their name. Pop. (1892) 20,190.

Pitaval, pĕĕ′tăă′vaal′, FRANÇOIS GAYOT, de: legal writer; b. at Lyons, France, in 1673; d. in Paris in 1743. After serving for a time in the army he studied law, and, being admitted as an advocate in 1713, practiced in Paris, and acquired a name by his publication of *Causes célèbres et intéressantes* (20 vols., Paris, 1734–43), which was a collection of celebrated law cases and their decisions. It was continued after the death of Pitaval by François Richer (22 vols., Amsterdam, 1772–88). In 1842 Hitzig and Häring began a similar collection at Leipzig, under the title of *Der neue Pitaval*, which was afterward continued by Vollert. He undertook a number of collections similar to *Causes célèbres*, some of which were of a more frivolous character. Among the most celebrated are the *Bibliothèque des Gens de Cour, ou Mélanges curieux des bons mots de Henri IV., de Louis XIV.*, etc. (2 vols., Paris, 1772, and 8 vols., 1746); *L'Art d'orner l'esprit en l'amusant* (2 vols., Paris, 1748); *Esprit des Conversations agréables* (3 vols., Paris, 1731); *Saillies d'esprit* (2 vols., 1732). Revised by F. STURGES ALLEN.

Pitcairn Island: island in the Pacific Ocean; in lat. 25° 3′ S., lon. 130° 6′ W. Area, 1¼ sq. miles. It is the only place on the route from South America to Otaheite in which fresh water can be procured. It was discovered in 1767 and colonized in 1790 by nine mutineers from H. M. S. Bounty and eighteen Tahitians—six men and twelve women. After successive murders there were left on the island in 1800 one Englishman who called himself John Adams, together with eight or nine women and several children. From these the present inhabitants, about 150, are descended. They came under British control in 1839. See NORFOLK ISLAND and T. B. Murray's *Pitcairn Island* (new ed. 1885).

Pitch: in music, the degree of acuteness or gravity of a sound, as distinguished from its other qualities, as loudness, harshness, or smoothness, etc. The fixing of some invariable standard of pitch, whereby any given note of the scale shall represent a sound of one and the same degree of acuteness in all written music, has been an object of interest and importance from the first rise of musical science. It is improbable that in early times, when music was in its rudest state, there was any standard corresponding to what we now call *concert-pitch*: for though the ancient Greeks had a certain familiarity with the relations and order of intervals, yet the very imperfect nature of their instruments seems to forbid the conclusion that the adjustment of such instruments to a strictly accurate pitch was an object of much practical importance. There is much room for conjecture in regard to the mode in which the pitch of the scale came to be settled by common consent as it stood, for instance, in the fifteenth or sixteenth century. It is probable that the organ-builders of that period contributed as much to the settlement of the question of pitch as those who found its solution in the doctrine of vibrations. The organ-builder knew that an open pipe about 2 feet long and of moderate diameter would give the sound which we now call "middle C"; and the theorist knew that the column of air in such a pipe would make 512 vibrations in a second of time; but in all such cases the practical issue would prove of more immediate consequence than the theoretical; and the fixing of any *one* sound by a pipe of a certain length would be, in fact, the fixing of the whole scale above and below, whether that sound were taken as tonic, dominant, or any other term in the octave. When by this or any other means a standard of pitch was once established, conformity to it would almost necessarily follow in vocal exercises and in the construction and tuning of instruments generally. This conformity, however, has never been strictly exact, either in time or place. From the seventeenth century down to the death of Beethoven evidence shows that the pitch was practically the same in various countries. From this date, however, the orchestral wind instruments began to be much improved in construction, and their manufacturers and players alike discovered that a slightly higher pitch much enhanced the quality and brilliancy of the instruments. As the strings were obliged to tune to the wind instruments, a gradual rise of pitch necessarily ensued, affecting voices as well whenever orchestral accompaniment was employed. In 1878 it was stated that the pitch at the Italian opera in London (not the pitch of Italy) was a semitone above that of Beethoven's day. All attempts to better this state of things in England have failed. The vocalist singing with orchestra must either have the piece transposed downward or tax his throat. Unfortunately this is not always a mere question of compass or endurance, but of a changed quality as compared with the composer's design.

In 1858 the French Government appointed a joint commission of distinguished musicians and physicists to examine and determine the question.  They reported in Feb., 1859, fixing the standard A at 435 double vibrations per second. This was confirmed by law, and has had a most beneficial musical influence in France and elsewhere. In the U. S. more or less discrepancy has existed, principally through the desire of piano-manufacturers to retain a high pitch for the sake of greater brilliancy. The orchestral pitch has not been so high as the English, although a trifle higher than the French. It was agreed, however, by the principal piano-manufacturers in convention at New York that the trade should adopt the French standard pitch (A = 435 double vibrations per second) for all musical instruments manufactured in the U. S., and that the change be accomplished on the part of all manufacturers by July 1, 1892. In view of the above the well-chosen title of "international pitch" was adopted as agreeing with that of France, Italy, and Germany. D. B.

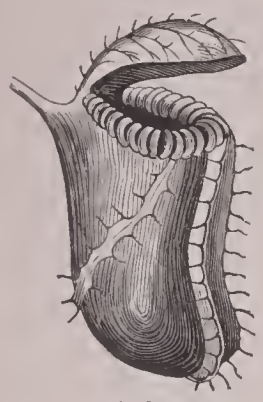
Pitch: See TAR.

Pitchblende: See URANINITE.

Pitcher, THOMAS GAMBLE: soldier; b. at Rockport, Ind., Oct. 23, 1824; graduated at the U. S. Military Academy, and entered the army as brevet second lieutenant of infantry July, 1845; served with his company in Texas throughout the Mexican war, receiving brevet of first lieutenant at Contreras and Churubusco; attained a captaincy 1858; served on the frontier till 1861; was severely wounded at the battle of Cedar Mountain, Aug. 9, 1862; was appointed brigadier-general of volunteers Nov., 1862, and on recovery from his wound served as assistant provost-marshal-general. He was appointed colonel Forty-fourth Infantry in 1866; transferred to First Infantry 1870; superintendent U. S. Military Academy 1866–70; governor of Soldiers' Home 1870–78; retired June, 1878; superintendent of New York State Soldiers' and Sailors' Home 1880–87. D. at Fort Bayard, N. M., Oct. 21, 1895. J. M.

Pitcher-plants: plants which have their leaves, or some considerable portion of the leaf, in the form of a pitcher,

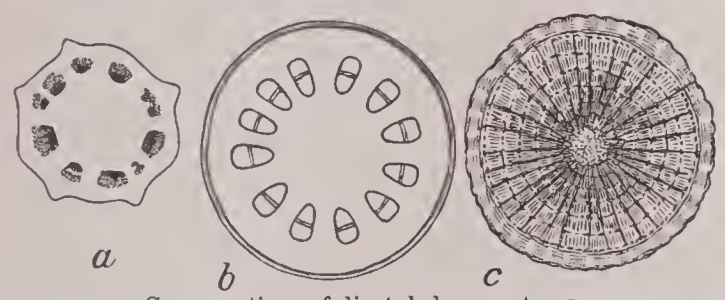
urn, trumpet-shaped tube, or other hollow vessel (technically called an *ascidium*) capable of holding water. The principal kinds belong to five different genera of plants in three families, which have no near relationship or resemblance except in the pitchers. All, or nearly all, are insectivorous. One, of a single species, peculiar to Southwestern Australia, is thought to belong to the Saxifrage family, where it stands alone. It is named *Cephalotus follicularis*. The leaves are all in a cluster next the ground; some are flat and of ordinary conformation; others are oval pitchers, hanging from a short stalk near the top on one side, and fitted with a lid, which neatly covers the mouth, resting at first upon a thickened and crested ring which surrounds and strengthens the orifice, but opening on its hinge as soon as the pitcher is full grown. It has long been observed that this pitcher secretes a watery fluid and entraps many insects. Little more is yet known as to its action, although the plant has long been in conservatories; but it is difficult of cultivation. The other pitcher-plants belong to two families, which so far as known contain only pitcher-bearing plants. One of them, *Nepenthaceæ*, consists of numerous species of one genus, chiefly inhabiting the Indian Archipelago; the other, *Sarraceniaceæ*, is wholly American, mainly North American, and consists of three genera—one, of a single species in the mountains of California; another, of one species, in the mountains of British Guiana; the third, of several species, confined to Atlantic North America. This is *Sarracenia*. The pitchers are all at the root, and appear to rise from the ground in a cluster. Instead of a lid, they have a sort of hood at the top, and a projecting wing runs down the inner or upper side from top to bottom. See Insectivorous Plants and Nepenthes. Revised by Charles E. Bessey.



Cephalotus.

Pitchstone: See Obsidian.

Pith: the central, usually soft, tissue in the stems of dicotyledonous plants. When the stem is young it consists throughout of uniform tissue, in which fibro-vascular bundles arise by a differentiation of the cells in certain columns equidistant from the center (*a*). The tissue inside of the



Cross-sections of dicotyledonous stems.

ring of bundles is the pith, and it is evident that that lying outside of the ring, the primary bark, is a part of the same tissue-mass. As the bundles become larger the pith and bark become more widely separated (*b*), and here the connecting radiating portions are known as "medullary rays." In woody stems the fibro-vascular bundles crowd so closely against one another that the connecting medullary rays are very thin, now known as the "silver grain" of wood (*c*).

The pith is continuous from the main stem into all its branches and branchlets. During the first year or two (rarely longer) the pith-cells are active, and are used for the storage of starch and other foodstuff; after this they die and are functionless. Charles E. Bessey.

Pithom [Egypt. *Pa-Tum*, dwelling of Tum or Atum; Copt. *Pethom*; Gr. Πάτουμος]: the Hebrew name of one of the "store-cities" of Egypt, built by the Israelites (Ex. i. 11) for Ramses II., at the east end of the Wadi Tumilat, just W. of the line of the Suez Canal, and at the present railway station, Ramses. The site was discovered by Naville in 1883 (*Store-city of Pithom*, 3d ed. 1888, first *Memoir* of the Egyptian Exploration Fund). The civil name of the place was Theku-t (Succoth), the second station mentioned in the Exodus itinerary. The discovery was particularly important, because it tended to fix both the date and the route of the Exodus. The general view is that the Exodus occurred under Meneptah, the follower of Ramses II. See also Heroöpolis. Charles R. Gillett.

Pitman, Sir Isaac: founder of the Pitman system of shorthand; b. at Trowbridge, Wiltshire, England, Jan. 4, 1813; was educated in the normal college of the British and Foreign School Society at London; was appointed master of the British School at Barton-on-Humber 1832; established a similar school at Wotton-under-Edge 1836; published *Stenographic Shorthand* (1837) and *Phonography, or Writing of Sound* (1840), giving the principles of his invention of a superior method of shorthand called phonography, since so widely diffused as almost to have extinguished the earlier systems; removed to Bath, where he conducted a school 1839–43; devoted himself to the perfection and propagation of phonography and its complement phonetics; founded in 1843 the Phonetic Society, and established the Phonetic Institute, a printing-office from which he has brought out for many years *The Phonetic Journal* (weekly, with a lithographed *Supplement*); issued several revised manuals of phonography and a considerable number of standard works in phonetic printing. His most complete professional work is the *Phonographic Reporter's Companion* (1853). His system was introduced into the U. S. by S. P. Andrews and A. F. Boyle in their *Complete Phonographic Class-book* (1847), soon followed by many similar works. He was knighted in 1894. D. Jan. 22, 1897. See Reed's *Biography of Isaac Pitman* (1890).—His brother, Benn Pitman, b. at Trowbridge, July 22, 1822, lectured on phonography in Great Britain 1843–52, and aided his brother in compiling text-books; removed to the U. S., settling at Cincinnati, where he devoted himself to phonography; published a *Manual of Phonography* (New York, 1855); reported the treason trials at Indianapolis (1865) and the trial of the assassins of President Lincoln (New York, 1865). In 1873 he abandoned reporting and became connected with the school of design, now the art academy of the University of Cincinnati, as lecturer and teacher. With Jerome B. Howard he published *The Phonographic Dictionary* (1883). His present system differs slightly from that of his brother.

Pito: See Chica.

Piton Bark: See Caribbee Bark.

Pitra, pē'traa', Jean Baptiste: ecclesiastic and author; b. at Champforgeuil, Saône-et-Loire, France, Aug. 31, 1812; took holy orders; became a member of the Benedictine congregation of Solesmes; published *Spicilegium Solesmense* (5 vols., Paris, 1852–60); was commissioned in 1858 by Pius IX. to write a history of Oriental rites and canon law, of which the first volume appeared in 1864, second in 1868, under the title of *Juris Ecclesiastici Græcorum Historia et Monumenta*. He became a cardinal Mar. 16, 1863; librarian of the Vatican in 1869, and cardinal-bishop of Frascati 1879. D. Feb. 3, 1889.

Pit River Indians: See Palaihnihan Indians.

Pitt, William: See Chatham, Earl of.

Pitt, William, generally called the Younger Pitt: statesman; second son of the Earl of Chatham; b. at Hayes, near Bromley, Kent, England, May 28, 1759; being of delicate constitution, he was educated by private tutor until he entered the University of Cambridge, in 1773; was called to the bar in 1780. He was elected M. P. for the pocket borough of Appleby in Jan., 1781, and allied himself to the opposition party under the leadership of Shelburne, and by brilliant speech at once won a position as a leader. Although he opposed the ministry on many occasions and denounced the war with the American colonies, he did not unreservedly ally himself to the opposition. He refused office under the Whig ministry of Rockingham, and at this time began the only partially successful advocacy of parliamentary reform which marked his political career. On the death of Rockingham he was given the great place of Chancellor of the Exchequer by Shelburne, who was made First Lord of the Treasury, in July, 1782. In 1783 Pitt resigned office with Shelburne, who was driven from power by the coalition of North (who had been leader of the Tories) with Rockingham and Fox, who had been Whig leaders. In the next session a cabinet was formed by North and Fox, who were made Secretaries of State with ostensibly equal power, and peace was made with the American colonies on terms practically the same as those of the treaty the negotiation of which had contributed to the downfall of the Shelburne ministry; but Fox's bill for transferring the government of India from the East Indian Company to seven commissioners was defeated, and the coalition cabinet compelled to retire. Pitt, in Dec., 1783, was called upon to form a new cabinet, be-

ing made First Lord of the Treasury and Chancellor of the Exchequer, and Henry Dundas (*q. v.*) became his chief counselor and adviser. Although Pitt had a good majority in the House of Lords, in the Commons he was opposed by practically all the great parliamentary debaters of his day, including Fox, Burke, North, and Sheridan. Although met with repeated adverse votes in the Commons he refused to resign or dissolve Parliament until, in 1784, he had succeeded in obtaining a majority, and then dissolved Parliament. At the general election he obtained a large majority and was established in the position of leader of the ministry, which he maintained for fourteen years. His administration was marked by parliamentary reforms, the establishment of the right of Parliament to provide for the exercise of supreme power during the incapacity of the king, the putting down of direct parliamentary corruption, and the abolition of many sinecures; reform in the system of collecting revenues and making loans, the reorganization of the Indian government upon the basis which continued until the abolition of the East Indian Company in 1858, the revision of the system of trade duties, and the making of an enlightened commercial treaty with France. He remained strictly neutral with regard to the opposing parties in the French Revolution, but in response to the pressure of public opinion he declared a war against the French Jacobins, which was weakly and unskillfully conducted, and marked by many disasters. His lack of success in this war, and the severity of his suppressive measures for putting down Jacobinism at home, weakened his position, and in Mar., 1801, on the failure to carry out his plan for uniting England and Ireland and removing the disabilities of the Roman Catholics, he resigned office. A new ministry was formed which concluded the Peace of Amiens in May, 1801, but in 1804 the ministry was defeated and Pitt was recalled. He formed a new ministry, made up, with the exception of Henry Dundas, of men of inferior talents, the king refusing to allow Fox to be summoned and Fox's friends refusing to accept positions without him. In 1805 he was driven from office and, embittered by England's reverses, he died at Putney, Jan. 23, 1806. F. Sturges Allen.

Pitta: a generic name, adopted as a common name for any bird of the family Pittidæ (*q. v.*).

Pit'tacus (in Gr. Πίττακος): one of the Seven Wise Men of Greece; b. at Mytilene in Lesbos 652 B. C.; as a leader of the democratic party participated very actively in all the feuds and embroilments of his native city, and in 589 B. C. was chosen *æsymnetes* (ruler with absolute power), which office he filled to 579 B. C. D. 569 B. C. Of his acts as a ruler nothing is known; of his elegiac poems Diogenes Laertius has preserved a few lines. Revised by J. R. S. Sterrett.

Pit'tidæ [Mod. Lat., named from *Pit'ta*, the typical genus, from Gr. πίττα, pitch]: a family of passerine birds popularly known under the name ant-thrushes. They are larger than the thrush, with a large head, plump body, short, even tail, and, for a passerine bird, remarkably long legs. They are strikingly or showily colored with black, white, red, and peculiar metallic blues. They are inhabitants of India and the contiguous regions, as well as Western Africa, Australia, and Madagascar, where alone the species of *Philopitta* are found. The family embraces only two genera—i. e. *Pitta* and *Philopitta*. F. A. Lucas.

Pitt-Lewis, George: See the Appendix.

Pittos'porum Family: the *Pittosporaceæ*; dicotyledonous shrubs and trees, with alternate leaves; flowers perfect, dichlamydeous; sepals and petals five each, free or coherent; stamens five, free; superior ovary, mostly bicarpellary, one-celled, many-ovuled. About ninety species are known, all natives of the region S. of the equator (exclusive of South America). The largest genus. *Pittosporum*, is represented by many shrubby species grown in conservatories, notably *P. tobira*, *P. viridiflorum*, *P. eugenioides*, etc. Species of *Sollya*, *Billardiera*, and *Marianthus*, all natives of Australia, are grown in conservatories. C. E. B.

Pittsburg: city; Crawford co., Kan.; on the Atch., Top. and S. Fé, the Kan. City, Ft. Scott and Mem., the Kan. City, Pitts. and Gulf, the Mo. Pac., and the St. L. and San Fran. railways; 10 miles S. E. of Girard, the county-seat (for location, see map of Kansas, ref. 7–K). It is in a coal-mining region, and contains zinc-works, a public high school, 3 national banks with combined capital of $250,000, a State bank with capital of $10,000, and 2 daily and 5 weekly newspapers. Pop. (1880) 624; (1890) 6,697; (1900) 10,112.

Pittsburg, or **Pittsburgh** (*Pittsburg* is the spelling adopted by the U. S. postal authorities; *Pittsburgh* is that of the municipal authorities): city; capital of Allegheny co., Pa.; at the confluence of the Allegheny and Monongahela rivers, which here form the Ohio river; on eight main and several branch lines of railway; 148 miles S. of Erie, 354 miles W. by N. of Philadelphia (for location, see map of Pennsylvania, ref. 5–A). It is 698 feet above tide-level at Philadelphia, is picturesque in its location and surroundings, has a length of 8 miles and an extreme width of 5 miles, and has an area of 28⅔ sq. miles. It is the second city in the State in population, manufactures, and wealth. The town originally occupied a very limited plateau between the Allegheny and Monongahela rivers, and was closely environed by lofty hills. As the city enlarged its borders these hills were at first either cut down or greatly reduced, but afterward they were left undisturbed as to size, and the city now spreads for miles over the hilltops, Herron Hill, 535 feet above the city datum line, being the highest, and Highland Avenue, 372 feet, being one of the most beautifully improved portions of the city. There are 450 miles of streets, of which 243 miles are paved and 275 miles sewered, and they are lighted by 2,570 arc-lights of 200-candle power, and by 3,150 gasoline lamps. The city is connected with Allegheny and other suburbs by seventeen bridges, twelve for general traffic and five for railways. The principal lines of railways centering in Pittsburg are the Pennsylvania system, the Baltimore and Ohio, and the Vanderbilt system. The Allegheny, Monongahela, and Ohio rivers form a waterway for an enormous freight and passenger traffic, extending 100 miles N. by the Allegheny, 100 miles S. into West Virginia by the Monongahela, and by way of the Ohio river S. to the Gulf of Mexico, W. to the foot of the Rocky Mountains, and N. to the Canadian border. During 1899 the river tonnage of freight originating in Pittsburg was 5,863,120 tons; railway tonnage, 49,475,211 tons—a total of 55,338,331 tons, which was larger than that of any other city in the U. S., and was claimed to be the largest in the world. Navigation on the three rivers has been greatly facilitated by the construction of dams principally on the movable plan. The greatest achievement in the way of river improvement is the Davis island dam, 5 miles below the city, on the Ohio river; this is the first of a series of movable dams for the permanent improvement of the river. The lock is 600 feet long and 110 feet wide: length of dam and width of lock, 1,333 feet. The dam creates a lake or pool of navigable water 8 miles long, throwing around Pittsburg a fine harbor unaffected by drought or low water in the rivers. Over seven years were spent in its construction. During periods of high water no dam or obstruction of any kind appears in the river, but as soon as the water begins to recede the wickets are raised and a uniform depth of water is preserved. The cost was about $1,000,000.

Pittsburg is the center of the greatest natural-gas field in the U. S. It is estimated that $40,000,000 are invested in the production and distribution of this smokeless fuel for domestic purposes and light manufacturing. The Pittsburg companies own 2,500 miles of pipe line, 1,200 wells, supply 500 mills and factories and 40,000 families. The daily consumption amounts to 110,000,000 cubic feet. The city is also the center of the petroleum-producing territory. In 1897 the total production in the Pittsburg district was 34,548,000 barrels, valued at $48,367,000.

The bituminous coal-field by which Pittsburg is surrounded is estimated at 14,000 sq. miles in extent; 140 mines are operated, all owned by two Pittsburg firms, employing 20,000 persons, whose wages reach about $8,500,000 per annum. The production in 1899 was 24,935,593 tons. The output of coke in the Pittsburg region in 1899 from 19,689 ovens aggregated 10,129,764 tons; value, $20,260,000. The region contains a total area of 87,776 acres, 11,219 of which have been mined and 683 reserved for buildings. All the plants are owned and operated by Pittsburg firms, and the output was 65 per cent. of all coke made in the U. S.

Pittsburg produced in 1898 one-third of the entire amount of iron and steel manufactured in the U. S. The 30 blast furnaces and 60 rolling-mills in the territory produced 3,022,901 tons of pig-iron, 52,352 tons of crucible steel ingots, 3,380,437 tons of all other kinds of steel, 2,091,503 tons of rails, bars, bolts, rods, shapes, and skelp-iron, and 444,850 tons of sheets and plates. More than half of the Bessemer steel, rolled iron and steel, rails, and plates and sheets made in the U. S. is manufactured here, making a total product of steel and iron of 8,992,043 tons. The Car-

negie Company (now of the United States Steel Corporation), owns many mills at Pittsburg, including the famous Homestead armor-plate mill, employs 30,000 workmen, and has an annual capacity of 3,250,000 gross tons of steel. The Westinghouse companies, which manufacture air-brakes, railway signals and electric machinery of all kinds, have a capitalization of $35,000,000, employ 9,000 workmen, and have an annual output valued at $30,000,000. Pittsburg is the leading plate-glass center of the world, having within a radius of 40 miles seven immense factories, with a yearly capacity of 24,500,000 sq. feet. These factories represent a direct investment of more than $12,000,000, and give employment to 5,000 people, and indirectly to many more in the immediate vicinity. Twenty-three firms are engaged in the manufacture of flint and lime glass. The annual production of tableware alone is about 63,000 tons; of bottles upward of 60,000,000; of lamp-chimneys upward of 40,000,000. The product of window glass in 1899 was 2,573,800 boxes, equal to 128,690,000 feet, or about 40 per cent. of the total product of the U. S.

Within or on the borders of the city are large mills for the manufacture of railway locomotives, stationary engines, steel bridges, steel tubing, and coal-drilling machinery. Other industries include the manufacture of artistic brass goods, fire-brick, salt, stoves, building-brick, chemicals, white lead, paper, corks, and pickles. There are 23 large wholesale grocery houses in the city whose operations exceed $25,000,000 a year; 6 houses engaged in the dry-goods and carpet trade whose yearly sales approximate $15,000,000; and 4 clothing houses whose annual sales exceed $4,600,000.

Conspicuous among the public buildings of the city are the county buildings, cost $2,500,000; Carnegie Library, at the entrance to Schenley Park, cost $1,100,000; U. S. custom-house and post-office, cost $1,500,000. In 1900 Andrew Carnegie pledged the erection and endowment of a great technical school. It is expected that $25,000,000 will be devoted by Mr. Carnegie to this institution. The fine main building of the Exposition Society was burned on March 17, 1901, but will soon be rebuilt. The city contains 258 churches, of which 197 are Protestant, 58 are Roman Catholic, and 3 Jewish. In 1900 there were 81 public-school buildings, which cost $3,500,000, including a new high-school building, which cost $250,000; 46,000 pupils, and 965 teachers. The high-school building is used exclusively for normal and commercial classes. Among the charitable institutions are seven hospitals: the Western Pennsylvania, the Homœopathic, the Mercy, the Pittsburg Infirmary, the Home for Incurables, and St. Francis's and St. Mary's hospitals. There are ten public parks: Schenley, the gift of Mrs. Schenley, of England, formerly of Pittsburg, a tract of 422 acres endowed by nature with rare beauty; Highland, a tract of 366 acres, which connects the East End with the Highland reservoir; and eight minor parks aggregating 122 acres. The city has recently constructed 2 boulevards, Grant, 3 miles long, and Beechwood, 7 miles long, extending from the business part of the city through Schenley Park to Highland Park, at a cost of $995,000. The city in January, 1901, contained 32 national banks with a combined capital and surplus of $27,850,000, 24 State banks with capital and surplus of $8,650,000, and seven trust companies with capital and surplus of $5,415,000. The exchanges of the Pittsburg clearing house during 1899 aggregated $1,528,478,652. There were 50 newspapers, of which 10 were dailies.

The territory occupied by the city of Pittsburg and Allegheny County was originally claimed by the French, on the grounds of discovery and explorations by La Salle in 1669. Traders and Indians followed soon after and made a lodgment in what promised to be a valuable acquisition of territory. The French resolved to expel the traders, and sent Capt. Celeron de Bienville with a company of soldiers and Indians in 1749 to take military possession of the land, claimed as far east as the Allegheny Mountains. In April, 1754, a company of militia arrived, under orders from Gov. Dinwiddie of Virginia, to establish a fort at the junction of the Allegheny and Monongahela rivers. While the erection of this work was in progress the French, led by Capt. Contrecœur with a large force of soldiers and Indians, fell upon the little band under command of Ensign Ward and compelled it to surrender. This was the beginning of the French war. The expulsion of the traders was followed by the erection of Fort Duquesne, named in honor of the governor of Canada. The English Government determined to regain the territory, and to this end sent Gen. Braddock with a large force of English and Virginian troops to drive out the French. The expedition met with a disastrous defeat in the famous battle of Braddock's Fields, July 9, 1755, at the hands of the French and Indians. Fort Duquesne was abandoned and burned Nov. 24, 1758. Gen. Forbes at once took possession, rebuilt the fort, and named it Fort Pitt in honor of the great English statesman. Pop. (1880) 156,389; (1890) 238,617; (1900) 321,616.

Revised by E. W. Hassler.

Pittsburg Landing: See Shiloh.

Pittsfield: city (site granted to Boston in 1735, known as Boston Plantation till its incorporation as a village under its present name in 1761, chartered as a city in 1890); county-seat of Berkshire co., Mass. (for location, see map of Massachusetts, ref. 2–C); between two branches of the Housatonic river; on the Boston and Albany, and the Berkshire division of the N. Y., N. H. and Hart. railways; 50 miles E. S. E. of Albany, N. Y., 53 miles W. N. W. of Springfield. It is on a plateau nearly 1,200 feet above sea-level, in a beautiful valley between the Hoosac Mountains on the E. and the Taconic Mountains on the W., through which flow the Hoosac and Housatonic rivers, and is partly surrounded by hills some 600 feet higher than the plateau. There are several lakes which discharge into the Housatonic river, from one of which, Ashley, is derived the supply of water for domestic purposes. The lakes and branches of the river afford fine power for manufacturing. The city has gas and electric light plants, 3 public parks, county court-house of white marble that cost nearly $400,000, Athenæum building that cost $100,000 and contains an art gallery, a museum, and a free library; Hospital of the House of Mercy, Old Woman's Home, Training-school for Nurses, 3 national banks with combined capital of $825,000, 2 savings-banks with deposits of $3,212,619; and 2 daily and 5 weekly periodicals. There are 11 churches, 24 public-school buildings, public-school property valued at over $215,000, and 15 cotton and woolen mills, 3 shoe factories, 2 machine-shops, a paper-mill, and other industrial works. The Berkshire Agricultural Society (1810) has large exhibition-grounds. Pop. (1880) 13,364; (1890) 17,281; (1900) 21,766. Editor of "Journal."

Pittston: city; Luzerne co., Pa.; on the Susquehanna river, near the mouth of the Lackawanna, and the Del., Lack. and West., the Del. and Hudson, the Lehigh Valley, the Cent. of N. J., the Erie and Wyo. Valley, and the Wilkesbarre and East. railways; 8 miles N. E. of Wilkesbarre, the county-seat, and 10 miles S. E. of Scranton (for location, see map of Pennsylvania, ref. 3–H). It is the geographical center of the Wyoming anthracite coal-field. The city is 1½ miles long, with an average width of half a mile. It is connected by a belt-line electric railway, running on both sides of the Susquehanna, with Wilkesbarre, Nanticoke, and Plymouth, and by four bridges across the river with the boroughs of West Pittston and Exeter, and, including the boroughs of West Pittston, Exeter, and Hughestown, and other contiguous territory, is the trade, postal, telegraph, and express center of a region which contains a population of more than 30,000 within a radius of 2 miles. Pittston is lighted by gas and electricity, and has a well-equipped volunteer fire department. There are English, German, Slavonian and Polish Roman Catholic, English and Welsh Baptist, Presbyterian, Methodist Episcopal, Methodist Protestant, Protestant Episcopal, Congregational, and Lutheran churches, a high school, 5 other public-schools, public-school property valued at over $80,000, a hospital erected in 1893, a national bank (First) with capital of $250,000, 2 savings-banks (Miners' and People's) with capital of $60,000 and $75,000 respectively, and a daily, a weekly, and a monthly periodical. Manufacturing is promoted by cheap fuel, superior railway facilities, and natural advantages. The establishments include 3 machine-shops, 3 planing-mills, 3 breweries, 2 knitting-mills, 2 pork-packing houses, stove-works, ladies' underwear factory, steam flour-mills, paper-mill, terra-cotta works, steel-range works, pressed-brick works, and dye-works. In 1894 the city had an assessed valuation of $750,000 and a debt of $32,000, and was about to increase the debt to the constitutional limit to aid local improvements. Pittston was named after William Pitt; was formerly a part of Pittston township, which was laid out in 1768; was settled about 1770; became a post-office station under the name of Pittston Ferry in 1811; was incorporated as a borough in 1853, and as a city of the third class in 1894. Pop. (1880) 7,472; (1890) 10,302; (1900) 12,556.—West Pittston, on the opposite side of the river, is largely a village of homes; has 5 Protestant churches and high school; in 1894 had an assessed valuation of $581,774, public-school

property valued at $63,000, and a debt of $16.000, about to be increased to constitutional limit for local improvements. The Luzerne County fair-grounds are immediately S. of the borough line. Pop. (1880) 2,544; (1890) 3,906; (1900) 5,846.

THEO. HART, EDITOR OF "EVENING GAZETTE."

Pitu'itary Body: See HYPOPHYSIS.

Piu'ra: a maritime department in the extreme northwestern part of Peru, bordering on Ecuador. Area, 27,201 sq. miles. The western or coast region consists mainly of deserts, which, however, afford a scanty pasturage at certain seasons; they are varied by rocky hills and headlands, and are divided by the fertile valley of the river Chira. The eastern part lies in the Cordillera, which here is of no great height, and is interspersed with valleys of tropical luxuriance. Grazing and cotton-growing are the principal rural industries; coal-beds exist; silver and to some extent gold are mined; a rich petroleum basin has been discovered, and several borings have been made. Pop., by census of 1876, 155,502; in 1894, nearly 200,000. Piura, the capital and largest town (pop. 1889, 8,000), lies on the river Piura in a fertile valley (see map of South America, ref. 4–B). It is connected by rail with its port of Paita. H. H. S.

Pi'us [Lat., liter., pious, religious, dutiful]: the name of nine popes. PIUS I., about the middle of the second century, of whom very little is accurately known.—PIUS II. (*Æneas Sylvio Piccolimini*), 1457–64; a native of Siena; humanist; secretary to the Council of Basel, friend and counselor of Frederick III.; brought about the Concordats "of the princes" (1446) and of Aschaffenburg (1448); made Bishop of Trent and afterward of Siena; proclaimed cardinal (1456) by Calixtus III., and succeeded the latter as pope (1457). The great object of his pontificate was a crusade against the Turks, but it proved abortive. As pope he rejected several principles and utterances of his earlier life, and labored hard to restore the Roman see to its ancient glory. As a writer he is known by his letters, his *History of Frederick III.*, his *Description of Germany*, and *Commentaries* on events of his own time.—PIUS III. (1503), a nephew of Pius II., reigned only twenty-six days.—PIUS IV. (*Giovanni Angelo de' Medici*), 1559–65; reopened the sessions of the Council of Trent, issued the profession of faith actually taken by all who hold any ecclesiastical office, either in the pastoral care or in seminaries and universities; conceded, by request of civil authorities, communion under both species to the laity of the German states; this was afterward withdrawn.—PIUS V. (*Michele Ghislieri*), 1566–72; published (1566) the *Roman Catechism*, and later on corrected editions of the Breviary and Missal; was very active against the spread of Protestantism; excommunicated Queen Elizabeth; and contributed much to the victory of Lepanto (1571). He died in the odor of sanctity, and was canonized by Clement XI. (1712).—PIUS VI. (*Giovanni Angelo de' Braschi*), 1775–99; improved the administration of the papal state; dried the Pontine marshes; built the Museo Clementino-Pio; visited Vienna 1782; condemned (1794) eighty-five propositions of the Synod of Pistoja (1786) as contrary to Catholic faith and discipline; rejected the principles and acts of the Congress of Ems in his *Reply to the Metropolituns* of Mayence, Treves, Cologne, and Salzburg, on the Apostolic Nunciatures (1789); refused to sanction the civil constitution of the French clergy; lost Avignon and the Venaissin to France (1790), and (1796–97) the northern part of the papal state to the new Cisalpine Republic, with a heavy indemnity in money, manuscripts, and art-works; signed the Treaty of Tolentino (1797), by which the dismemberment of his state was confirmed; and was carried off to France in Feb., 1798, by Gen. Berthier. He died, aged eighty-one, at Valence, Aug. 29, 1799, after suffering much cruelty and persecution from Napoleon.—PIUS VII. (*Gregorio Barnaba Chiaramonti*), 1800–23; a relative of Pius VI.; elected at Venice; signed the concordat of 1801 with Napoleon, by which the French Church was divided anew into ten metropolitan and fifty suffragan sees; the resignation of the actual bishops requested; the presentations of the new ones accorded to Napoleon; the Roman Catholic religion acknowledged as that of the state; and the salaries of the clergy paid by the latter, as a reparation for the confiscated estates. This concordat underwent various modifications. In 1821 a division into eighty dioceses was adopted, which has been further modified, until now there are in France eighty-four sees. The Roman Church has never recognized the Organic Articles which Napoleon added to the original concordat for political purposes. Pius visited Paris for the coronation of Napoleon (Dec. 2, 1804); refused to declare null the marriage of the emperor's brother, Jerome, with Miss Patterson; was seized by Napoleon's orders July 6, 1809, and imprisoned at Savona, while his cardinals were summoned to Paris, and the papal state abolished (Feb. 7, 1810); confirmed unwillingly the decrees of the National Council (1811); was brought (1812) from Savona to Fontainebleau, in order to terrify him into submission to the emperor's will; signed a new concordat (Jan. 25, 1813), which sacrificed many important rights of the pope; soon regretted his step, and by the advice of the black cardinals, notably Pietro and Pacca, recalled it in a document wherein he declared he would rather die than persevere in his sinful act. He was set free by Napoleon after the battle of Leipzig (Jan. 23, 1814), and saw Napoleon resign his throne in the very castle of Fontainebleau; returned to Rome (May 24, 1814); had several provinces of the papal state restored to him by the Congress of Vienna (1815); fled to Genoa on occasion of the escape of Napoleon from Elba; signed concordats with several European nations, and restored the Jesuits 1814. (See Wiseman, *The Last Four Popes*, London, 1859).—PIUS VIII. (*Francesco Xaverio Castiglione*), 1829–30; denounced indifferentism, Bible societies, and Freemasonry; obtained the erection of an Armenian archbishopric at Constantinople, and condemned the slave-trade.—PIUS IX. (*Giovanni Maria Mastai-Ferretti*), 1846–78; began his pontificate by an amnesty and liberal reforms; fled from Rome on an outbreak of revolution (1848); restored by France (1850); deprived of the legations (1860) by Victor Emmanuel, in spite of the spirited defense of the papal zouaves; maintained his independence against Garibaldi (1867), but was entirely dispossessed of the temporal power (Sept. 20, 1870) by the army of Victor Emmanuel; refused to accept the "guarantees" of May 15, 1871, as implying an indirect recognition of the "accomplished facts"; confined himself thenceforth to the precincts of the Vatican. The pontificate of Pius IX. is notable for many acts of importance. He declared the Immaculate Conception of the Blessed Virgin Mary to be a dogma, or ancient belief of the Church (Dec. 8, 1854); published the *Syllabus of* (80) *Errors*, extracted from previous documents of his pontificate (1864); convoked the Vatican Council (1868), in which the papal infallibility was declared by the constitution *Pastor Æternus* (July 18, 1870); restored the hierarchy in England (1850) and Holland (1853); canonized the Japanese martyrs (1867) on the occasion of the eighteenth century of the martyrdom of SS. Peter and Paul; established national colleges at Rome; encouraged the missions, protected learning, and elevated many distinguished scholars to places of influence. As a man, he was remarkable for his gentle and humane character, his geniality and affability, which never deserted him. He died Feb. 7, 1878, aged eighty-six, after a reign of over thirty-one years, the only one that surpasses the traditional twenty-five of St. Peter. He is buried at San Lorenzo fuori le Mura. See O'Reilly, *Life of Pius IX.*; the *Acta Pii IX.*; Cardinal Manning, *History of the Vatican Council.*

JOHN J. KEANE.

Piute or **Paiute Indians**: See SHOSHONEAN INDIANS.

Pizar'ro, FRANCISCO: conqueror of Peru; b. at Truxillo, Estremadura, Spain, about 1471. He was the illegitimate son of a Spanish officer; received no regular education, but served with his father in Italy; and ultimately drifted to America, where he first appears at Darien as a soldier under Ojeda (1509); the latter left the colony in his charge during its period of greatest suffering. (See DARIEN.) He was connected with various raids against the Indians, was with Balboa in the discovery of the Pacific 1513, and about 1519 settled at Panama. Rumors of a rich country to the S. had reached the isthmus, and in 1522 Pizarro joined with Diego de Almagro and a priest named Luque in a scheme for its discovery and conquest by way of the Pacific coast. The first attempt, in 1524, failed. In a second they were aided financially by Gaspar de Espinosa; great sufferings were endured, but Pizarro overcame them by his dogged pertinacity, and in 1528 saw and visited Tumbez and other towns of the Peruvian coast, where he was well received. With certain proof of the riches of the country he hastened to Spain, where he was empowered to conquer and settle Peru (at his own expense), and was appointed its governor, Almagro receiving the title of marshal. Espinosa continued to aid the enterprise, and Pizarro was able to leave Panama in Jan., 1531, with three vessels and 185 men; Hernando de Soto joined him in the Gulf of Guayaquil with re-enforcements; Almagro and others followed too late to share in

the first plunder. Pizarro landed at Tumbez; at Caxamarca, Nov. 15, 1532, he met the Inca Atahualpa, who had just conquered his brother Huascar, and was going to receive the crown at Cuzco. Atahualpa, while on a peaceful visit to Pizarro, was treacherously seized and his unarmed escort was massacred. To obtain his liberty he promised to fill a room with gold, and he actually collected, through his officers, a sum equal to 4,605,670 ducats, equivalent to $17,500,000 of modern money. Though this was appropriated by Pizarro and his band, the Inca was basely killed on a false charge of conspiracy. Pizarro now marched to Cuzco; he met with some resistance from Atahualpa's generals, but at Cuzco the legitimate Inca, Manco, swore fealty to the sovereign of Spain, and was allowed to reign as a puppet monarch under surveillance. Pizarro received the title of marquis, and founded Lima (Jan., 1535) as his capital. Manco escaped in Apr., 1536, and headed an Indian uprising, which, for a time, threatened to drive the Spaniards from the country; but aid flocked in from the other colonies, and the Indians were subdued. Almagro had frequently quarreled with Pizarro, whom he accused of appropriating all the benefits of the conquest, though the enterprise had been a joint one. He was quieted for a time by being made governor of Chili, but in 1537 he returned disappointed from that country and seized Cuzco, claiming that it lay within his domain. War with Pizarro followed; Almagro was defeated at Las Salinas Apr. 26, 1528, and was soon after captured and executed. Pizarro allowed many of Almagro's followers to live at Lima, where they conspired and murdered him in his palace June 26, 1541. He was an ignorant and often brutal soldier, though with a natural genius for command, and no worse than other leaders of the time.

HERBERT H. SMITH.

Pizarro, GONZALO: half-brother (also illegitimate) of Francisco Pizarro; b. at Truxillo about 1506. He followed his brother in the conquest of Peru 1531–34; took part in the defense of Cuzco against Manco Inca 1536; was captured by Almagro, but escaped and led the infantry against him at Las Salinas; and subsequently conquered Charcas or Bolivia, where he received a grant of the rich mining region around Potosí, and acquired great wealth. In 1540 he was made governor of Quito; thence, in 1541, he led an unsuccessful expedition over the mountains to the forests of the Napo, where ORELLANA (*q. v.*) deserted him and became the first explorer of the Amazon. In 1544 the viceroy Nuñez Vela arrived to enforce the "new laws" against Indian slavery. Pizarro headed a rebellion against him, seized Lima Oct., 1544, drove the viceroy into New Granada, and ultimately defeated and killed him at the battle of Añaquito, near Quito, Jan. 18, 1546. Pizarro's officers took possession of Panama, and for a year he ruled Peru undisturbed. Pedro de la Gasca, sent from Spain to subdue the rebellion, gained possession of the Isthmus by politic means and landed in Peru. Pizarro retreated southward, and near Lake Titicaca defeated the royalist force of Centeno, Oct. 26, 1547. Elated with his success, he returned and met Gasca's army near Cuzco, but his forces deserted him without fighting, he surrendered, and was executed at Cuzco Apr. 12 (?), 1548. Other brothers of the Pizarro family were JUAN, who was killed during the defense of Cuzco, July, 1536; and HERNANDO (legitimate), who was prominent in the conquest and commanded the army against Almagro 1538; he returned to Spain, where he was imprisoned for many years.—PEDRO PIZARRO, a cousin of the conqueror and his page, wrote an account of the conquest which has been published in modern times.—FERNANDO PIZARRO Y ORELLANA, grandson of Hernando and great-grandson of the conqueror, published, in 1639, *Varones ilustres del Nuevo Mundo*, which includes lives of the Pizarros and other conquerors of the New World. Descendants of the family have been prominent in Spanish America and in Brazil.

HERBERT H. SMITH.

Placenta [from Lat. *placen'ta*, flat cake, from Gr. πλακοῦς, πλακοῦντος, flat cake, deriv. of πλάξ, πλακός, anything flat and broad]: a special organ developed in the higher mammals (hence *Mammalia placentalia*) for the nourishment of the embryo while it remains in the uterus. Referring the reader to the articles FŒTUS and EMBRYOLOGY, where the human placenta is described, for a description of the parts concerned, we may here mention some of the modifications of this organ in the different orders of mammals. The chorion of the embryo may be regarded as the central structure in the formation of the placenta. Upon its surface are developed numerous small branching outgrowths (villi), into which ramifications of the embryonic blood-vessels extend. These villi enter into more or less intimate connection with the mucous uterine walls of the mother, and through them nourishment is brought to the young. Accordingly as the villi are arranged the character of the placenta varies. Thus in the pig, horse, etc., they are evenly distributed over the surface of the chorion, giving rise to a diffuse placenta. In most other forms they are restricted to certain regions, and the rest of the chorion is smooth and contains but few blood-vessels. Among the ruminants (cow, sheep, deer) the villi are aggregated in patches (cotyledons) varying from 5 to 100 or more (cotyledonary placenta). In the carnivores the villi are arranged in a ring (zonary placenta), while in the primates, bats, insectivores, and rodents they take the shape of a disk (*placenta discoidea*). The degree of union between the villi and the maternal tissues varies considerably. In those forms with diffuse and cotyledonary placentæ the villi extend into corresponding pits in the uterine walls, but the union is not intimate, and a little pulling is sufficient to effect a separation. In these forms at birth the embryonic placenta becomes separated from the maternal portion, and the latter remains behind (*placenta non deciduata*). In the other types the union is more intimate, the parts so growing together that separation is no longer possible without injury to the uterine mucosa. In these forms (*placenta decidua*) a portion of the uterine mucous membrane is cast as a part of the after-birth. Among the edentates almost every type of placenta is said to occur.

The attempt has been made to use placental characters as an aid in classification, but not with perfect success. The literature is large. Prominent works are Turner's *Anatomy of the Placenta* (Edinburgh, 1876); Minot, *Uterus and Embryo, Journal of Morphology* (ii., 1889; contains bibliography); and papers by Hubrecht (*Quarterly Journal of Micros. Science*, 1889–94).

J. S. KINGSLEY.

Placenta'lia [deriv. of *placenta*]: a name given by Owen to those mammals provided with a placenta. It is equivalent to the Monodelphia of recent authors. See MAMMALS.

Placentia: See PIACENZA.

Plac'idus, LUCTATIUS: a grammarian of the fifth century; author of a valuable glossary of obsolete and difficult words largely drawn from Plautus. He also composed scholia to the poet Statius. The best editions of the *Glossæ* are by A. Deuerling (Leipzig, 1875) and G. Goetz in *Corpus Glossariorum Latinorum*, vol. v., pp. 1–158 (Leipzig, 1894). M. W.

Placoph'ora [Mod. Lat., from Gr. πλάξ, plate + φέρειν, bear, in allusion to the several plate-like shells]: the order of MOLLUSCA (*q. v.*) which contains the chitons.

Plague [from Lat. *pla'ga*, stroke, blow, deriv. of *plan'gere*, strike (cf. Gr. πληγή, blow, deriv. of πλήσσειν, strike]: a malignant and fatal contagious fever, also called *bubonic plague*, from the frequency of suppurating lymphatic glands, so-called *buboes*. It is now little known, but was formerly endemic in Egypt and the Levant, and spread in devastating epidemics throughout Europe. By its mortality it was an obstacle to the growth of countries and the advance of civilization. It was termed "the pest," the "black death," and the "great mortality." Its first appearance in Europe was at Constantinople in A. D. 544. Since that time epidemics have occurred at variable intervals; there were forty-five in the seventeenth century. The Great Plague of London was in 1665, and was supposed to have been brought from Holland. It is estimated that in Europe 25,000,000 have died of plague. The disease has prevailed in brief and local epidemics during the eighteenth and first half of the nineteenth centuries—at Copenhagen in 1712, Marseilles 1720, Moscow 1771, Malta 1813, Silesia 1819, Bulgaria (in the Russian army) in 1828–29. Its last appearance in Egypt was in 1844. In 1857–58 it occurred among the Arabs of North Africa, in 1857 in Mesopotamia, and in 1871 in Persian Kurdistan. An epidemic in the provinces bordering the Volga in 1878 attracted considerable attention among scientific men. The plague is now regarded as a zymotic disease, dependent upon insalubrious and poisonous atmospheric or telluric conditions, a *materies morbi* gaining access to the blood, and rapidly multiplying in it and destroying its nutritive elements. In malignity and nature it resembles typhus fever. The propagation of the disease occurs by direct or indirect contagion. In Egypt the overflow of the Nile was considered its pestilential source. Overcrowding, bad ventilation, uncleanliness, deficient food, and

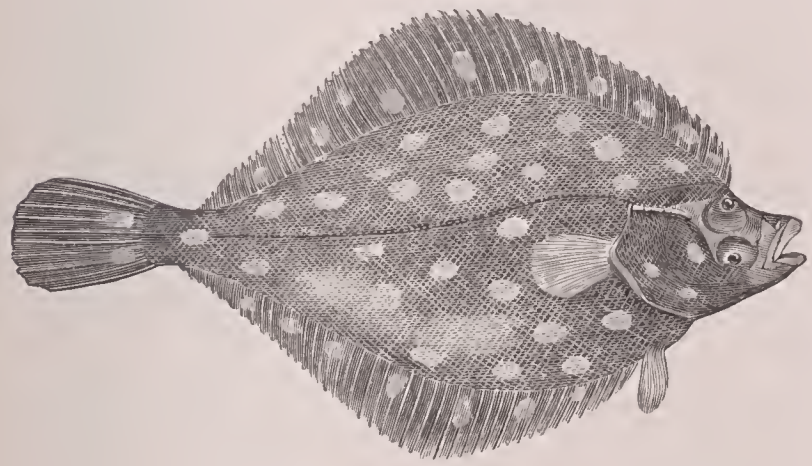
residence in damp, marshy soils have been considered the predisposing causes of local epidemics. After exposure there is a period of latency or incubation of from two to seven days. The disease has four stages, yet all may occur in rapid succession and brief time: (1) invasion, (2) fever, (3) local phlegmons, and (4) collapse or convalescence. It is preceded by lassitude and enfeeblement of mind and body; its definite onset is announced by shivering, headache, vertigo, vomiting, high fever-heat, great prostration, stupor or unconsciousness, blood in the urine or from the bowels, the appearance of buboes or suppurative enlargement of lymphatic glands, or of carbuncles; or, again, in fatal cases, of petechiæ or purple spots and mottling of the skin. Hæmorrhage into the lungs and from the lungs was a frequent symptom of the "black death" of the Middle Ages. Its duration is from two to ten days, and convalescence is slow. It is prevented by hygienic measures and public quarantine, but its treatment, beyond general measures of stimulation and nutritive support, avails little.

Revised by WILLIAM PEPPER.

Plagues of Egypt: a series of calamities, ten in number, which befel the Egyptians (Ex. vii. 14, ff.); due to the refusal of King Pharaoh to let the Israelites depart from his country. They have been explained upon a natural basis somewhat as follows. The red (blood) color of the Nile is alleged to have been witnessed in historic times, and is explained by the presence of infusoria from the swamps whose waters run into the Nile. During high Nile the frogs, the Egyptian symbol of "multitude," sought the higher ground and, dying when the water rapidly fell, were gathered into heaps, there to rot. The drying pools engendered multitudes of gnats and flies, whose part consisted in causing cutaneous irritation and in spreading the contagion of the murrain, which is regarded as anthrax, a disease due to the dead frogs. This disease principally attacks cattle, but may be communicated to men. Its outward manifestation would be in "boils," while inwardly it would prove fatal, particularly when re-enforced by the meat diet necessitated by the destruction of vegetable life after the plagues of the hail and locusts. Hail, thunder, and the east wind, the agents of other plagues, were usual phenomena except as to intensity. There are, nevertheless, other features of the plagues recorded in Exodus which are not capable of so easy an explanation, and even if the theory outlined above be granted there would remain the miracles of providence, if not of power.

CHARLES R. GILLETT.

Plaice: a flat-fish, *Pleuronectes platessa*, weighing from 6 to 12 lb. It feeds on mollusca, crustacea, and young fish,



The plaice.

and inhabits sandy banks and muddy grounds in the sea. It is highly esteemed for food, and is common on the European coasts. See PLEURONECTIDÆ.

Plain: a broad expanse of level or nearly level land. Plains are here considered with respect to the origin of their strata; to their altitude, whereby they are associated with plateaus; to the degree of development of valleys across their surface; and to their distribution, climate, fertility, and resources.

Marine Plains.—The largest plains of the world consist of horizontal strata, deposited when the region was the bed of a lake or the floor of the shallow ocean margin. For example, the COASTAL PLAIN (*q. v.*) of the Eastern U. S. is a surface of small relief, formerly part of the continental shelf. (See OCEAN.) When the land stood lower than now, it received sediments borne down by rivers or worn by waves; at present it is revealed in consequence of an even uplift, although a considerable extent of the shelf still remains under the sea. Its marine origin is indicated not only by its bedded structure, but also by its numerous fossils. Close study of this region demonstrates that it is geologically in a debatable state, oscillating up and down in the course of geological periods; at present exposing less surface as land than in a recently past period (see COAST), but more than in a still earlier period. The great plains of the U. S. are of a more complex history. Their sediments, as indicated by fossils, are in part marine, in part lacustrine. It is evident from their present slight incline that the region must have been uplifted and inclined since the strata were deposited.

Lacustrine Plains.—The plain of Hungary may be taken as the type of a lacustrine plain; its basin is inclosed by the Carpathian Mountains on the E., and the Danube has now cut a deep outlet-valley through them; but at an earlier time, before the outlet was cut so deep, a lake existed behind the mountains, and the present plain is composed chiefly of sediments brought into the lake from the inclosing slopes. The plain of the middle Rhine, between the Vosges and the Black Forest Mountains, and the Vale of Kashmir in Northwest India have a similar history; all these examples being more or less strewn over by river flood-plain deposits since their lakes disappeared. Plains, partly of lacustrine origin, partly of surface stream-wash, are well exhibited in the interior basins of Utah and Nevada (see BONNEVILLE LAKE and LAHONTAN LAKE), as well as in other basins of interior drainage, such as the inner plateau of Mexico, and presumably the great central depression of Asia. Basins of this kind are formed by the uneven uplift of mountain ranges and plateaus around their borders, while other ranges diversify their interior. The waste from the crests and shoulders of the mountains accumulates in the intermediate hollows, burying the mountains even up to their waists, and producing broad even plains. The process of degrading the mountains and filling the depressions proceeds in the dry climate of to-day, when streams spread out detritus as they wither after leaving the mountains, as well as in the former more humid climate of the region, when the wash from the mountains ran into lakes; but the most extensive plains of Utah and Nevada are old lake-bottoms revealed by desiccation, and not yet covered by the stream-wash of a dry climate. Sometimes the disappearance of former lakes leaves a broad central depression covered with a level sheet of salt, such as are known in Tibet, in Persia, and in the intermontane depression to which the southward discharge of Lake Titicaca flows in Bolivia. Broad saliferous marshes of this kind occur on the Argentine pampas, there called *salinas*. In regions of extreme dryness even the wind-borne dust from the uplands aids in filling up the depressions. Much importance has been attributed to this process in forming extended plains in inner China, their fine soil being generally given the German name *loess*. Peculiar examples of lacustrine plains are found in those regions where the retreating ice-sheet of the glacial period obstructed the flow of rivers whose basins sloped against it. Smooth sheets of fine silt were deposited in the lakes thus formed; but with the further retreat of the ice, the lakes were discharged and the lake-bottom plains laid bare. Many of the northern prairies of the U. S. are of this origin. See PRAIRIE and AGASSIZ, LAKE.

Fluviatile Plains.—Large rivers build broad flood-plains (see FLOOD-PLAIN) in their valleys, and delta plains (see DELTA) at their mouths. The Mississippi gives an example of a flood-plain with delta front, well inclosed between bluffs of the slightly higher marine coastal plain. Here must be included also various extensive areas over which wandering rivers have spread out their detritus. The plain of the "valley" of California, the plain of the "valley" of the Po, the Indo-Gangetic plain of Northern India, and the plain of Eastern China are all of this character, having received their materials from adjacent mountains. Along the margin of the sea, in shallow bays and lagoons protected by bars from the outer waves, tidal marshes are built up to high-tide level. These plains attain a considerable area along the coast of the U. S.

Lava-plains; *Ice-plains.*—Extensive outflows of lava have occurred in various parts of the world, flooding the lower lands and thus forming broad plains of remarkably level surface. These are exceptionally well illustrated in the basin of the Shoshone river in Southern Idaho. The river has transsected the plain in its canyon, revealing the

bedded structure of the lavas. The vast plains of ice and snow that cover Greenland, and that presumably exist inland from the Antarctic ice-wall, as seen by Ross, should not be forgotten. Nansen's journey across Greenland demonstrates that the interior of that land is a vast desert plain of ice and snow. The Malaspina glacier at the foot of Mt. St. Elias, in Canada, may be regarded as a glacial delta plain, being supplied by valley glaciers from the mountains, and spreading out over a surface of 15 by 40 miles on the coastal lowland. (See GLACIERS.) During the glacial period, ice-plains like those of Greenland had great extension in Northeastern America and Northwestern Europe. It was during the presence of these creeping ice-sheets that many of the smooth plains of unstratified glacial drift (till) were spread out in Ohio and the adjacent northern central States; for while glacial action has ordinarily been looked on as chiefly destructive, it was chiefly constructive in these regions, where the ice-sheet was relatively thin, its motion reduced, and the quantity of loose material beneath it excessive. Its action in Ohio may therefore be contrasted with its more destructive action in Canada, much in the same way that the constructive action of a river in its delta may be contrasted with the destructive action of its head-waters. Many fertile prairies in the northern central States are till-plains.

Dissection of Plains.—River flood-plains, being built at a slope suitable to the grade of their rivers, do not suffer dissection, unless the volume of the river is altered or the slope of the land is changed by tilting. The latter seems to have been the case with those former flood-plains, remnants of which are now seen in upper terrace-plains of many of the northern valleys of the U. S.

Marine plains, when rising above sea-level, may acquire a greater or less altitude, the loftier areas being called plateaus. (See PLATEAU.) They are then dissected by their streams and thus diversified in the course of geological periods of time. Many examples can be collected in various stages of development. Plains may thus acquire so strong and varied a relief as to be popularly called rolling or hilly country. The littoral portion of the gently inclined coastal plain from New Jersey to Texas is very little dissected, and only by shallow valleys; it presents broad stretches of almost dead-level surface. Further inland, where the ascending plain is higher and has been out of the sea longer, it is more diversified, giving a pleasing variety of gentle hills and valleys. It is not infrequently the case that the former inland extension of a coastal plain has been stripped off from its foundation rocks, and that the edges of the more resistant strata of the plain thus take the form of inland-facing slopes or escarpments. The lowland on the inner side of the escarpment is then chiefly drained by longitudinal streams, which escape by occasional transverse valleys through the outer and higher part of the plain. The belt of elevated ground from Navesink S. W. across New Jersey to Delaware Bay is of this origin; railways and canal between New York and Philadelphia follow the inner longitudinal lowland. If the coastal plain consists of several alternating harder and softer strata of considerable thickness and gentle seaward inclination, several higher and lower belts roughly parallel to the coast-line may be developed by denudation; the inner slope of the higher belts being relatively steep, while the outer slope is gentle and even. The coastal plain of Alabama has several of these belts, of which the Chunnenugga ridge is the strongest; it descends by a tame escarpment to an inner lowland belt. In Texas, similar features are well shown; one of the most distinct of the inward ascending plains being the Grand Prairie, which falls off westward by a well-marked ragged inland-facing escarpment to the central denuded region of the State. The Cotswold and the Chiltern hills, drained by the upper Thames in England, belong here; they descend gently to the S. E. and more abruptly in ragged escarpments to the N. W. The Niagara upland of Western New York terminates in an escarpment facing the ancient crystalline area of Canada. (See NIAGARA FALLS.) Wisconsin possesses a well-marked example of this kind; its central denuded plain being inclosed on the S. and W. by dissected uplands rising from the plain in very ragged escarpments and numerous detached outliers.

Plains of Denudation.—When plains have long been above the sea, the widening valleys consume the uplands, decreasing the variety of form that was for a time developed, and ultimately producing a broad lowland of denudation. A great part of the SAHARA (*q. v.*) is well advanced toward this consummation, its broadly denuded surface having a variety of open lowlands, retreating escarpments, and isolated outliers; but it is a mistake to regard it as an even lowland, and only a very small marginal part of its area is below sea-level. The great plains in the western part of the U. S. have also reached an advanced stage of denudation, as their numerous isolated mesas and outliers testify.

At any stage in the reduction of uplifted plains to lowlands of denudation the region may again be elevated and enter a new cycle of dissection and denudation. Large areas in Central Missouri, Southern Ohio, and Northern Kentucky have this composite history, their even uplands of to-day being old lowlands of denudation. Portions of the Great Plains, as in Eastern Montana, are similarly uplifted lowlands of advanced denudation, occasionally surmounted by unconsumed mesas and outliers, and now trenched across by young valleys that belong to the new cycle of dissection; many bad-land areas are found along the borders of these valleys of the second generation. Northwestern France possesses a well-marked old plain of denudation, now raised to an upland and beautifully dissected by the valleys of its rejuvenated streams.

Plains of quite another kind occur in regions of disordered structure that were once mountainous, but which are now reduced to lowlands of faint relief by long continued denudation. These lowlands are never so even as those formed beneath seas or lakes; nor have they commonly an extended surface; they most commonly occur as gently rolling lowlands, associated with low ridges that are not yet subdued to the lowland level. The open lowlands of the great Appalachian valley and the more irregular lowlands that run among the Appalachian ridges are of this kind. Mention of related features will be found under PLATEAU.

The climatic conditions of plains are in many cases closely associated with their conditions of origin. For example, the ice-plains are deserts of cold; the plains of interior basins, once lacustrine, are now prevailingly arid and desert, peopled only where streams descend from the inclosing mountains and afford water for natural or artificial irrigation. Salt-plains, the residual deposits of certain evaporated lakes, are absolutely barren. On the other hand, the flood-plains of rivers are ordinarily fertile, being of fine soil and plentiful water-supply; they may be productive even when bordered by deserts, as in the famous case of the Nile and in many less-known examples, such as those which descend from the Andes through the deserts on the westward slope. Delta plains of large rivers are fertile; but those of smaller rivers descending from mountains close to the sea are often stony. Lava-plains are deserts until a soil is formed by weathering their surface; then they may be fertile, as in the lava plateau of Southern India. Marine plains are of such vast extent that they embrace all conditions of climate and fertility. They include the frozen ground of Siberia and Northern Canada; the arid steppes of Western Asia, yielding grass under their summer rains; the broad Sahara, whose varied surface is parched by the drying trade-winds, refreshed by winter rains on its northern border, by summer rains on its southern border. In the New World there are the luxuriant selvas of the Amazon, partly marine, partly fluviatile in origin, well watered by the equatorial rains; the llanos of Venezuela and the campos of inner Brazil, well watered and grassed under a vertical sun, but dry and dusty in the opposite season. The Argentine pampas are prevailingly too dry, being like the Great Plains of the U. S. in the rain-shadow of the Cordilleras. (See DESERTS and RAIN.) South America, narrowing in the temperate zone, has no analogue to the broad plains and uplands of the eastern part of the U. S.

Resources of Plains.—Lacustrine plains and river flood-plains usually have a fine soil, admirable for agriculture if the climate is favorable; but they have no mineral resources except clays and sand, or salt in the case of certain lacustrine plains. Young marine plains, however well adapted to agriculture, are, as a rule, poor in mineral products, although they sometimes have, in addition to sand and clay, valuable deposits of marl and phosphates, useful as fertilizers, and sometimes diatomaceous earth, useful in various arts. In the absence of good road metal, and by reason of the flatness and poor drainage of the surface, the roads of all these plains are prevailingly poor, being least bad on gravels and worst on clays. Older dissected plains, whose rocks were deposited long ago, and whose surface may have been through successive cycles of denudation, may be as rich agriculturally as the younger forms; as, for example, in the famous Blue Grass region of Central Kentucky; and they

possess in addition a moderate variety of useful minerals and plentiful good road metal. Coal and iron ores are found in the dissected uplands of the Ohio valley; ores of lead and zinc occur in the uplands of Missouri, Iowa, and Wisconsin. Building-stones, limestone, and clay, as well as road materials of high value, are here well distributed. Those lowland plains which are produced by the denudation of former mountains have a great variety of mineral products. The forest products vary greatly with the climate.

W. M. Davis.

Plainfield: city (incorporated as a city in 1869); Union co., N. J.; on Green Brook, and the Central Railroad of N. J.; 11 miles N. of New Brunswick, 24 miles W. S. W. of New York city (for location, see map of New Jersey, ref. 3–D). It is a beautiful residential place, with Netherwood Heights on the E. and ranges of the Blue Mountains on the W. The city and cluster of suburban villages are lighted with gas and electricity, and are laid out with broad straight streets tastefully ornamented with lawns, parks, and shade trees. Plainfield contains 14 churches, 5 public-school buildings, public-school property valued at over $180,000, a seminary for young ladies, an academy for boys, public library and art gallery, public-school, seminary, and Y. M. C. A. libraries, 2 music-halls, Muhlenberg Hospital, 2 national banks with combined capital of $350,000, a savings-bank, and 3 daily, 2 weekly, and three monthly periodicals. The principal industries are the manufacture of printing-presses, oil-cloth, carpets, and machine tools. Pop. (1880) 8,125; (1890) 11,267; (1900) 15,369.

Plain Song, or **Plain Chant** (Lat. *can'tus fir'mus*, Ital. *canto fermo*): in music, the simple, grave, and unadorned chant in which the services of the Catholic Church have been rendered from a very early age. It consists largely of monotone, and its inflections seldom exceed the range of an octave. The ecclesiastical chant is supposed to be chiefly of Greek origin, with some modifications brought in from Hebrew sources by the converts from Judaism in the first centuries. Prior to the time of St. Ambrose (fourth century) the music of the Church was in a rude and unsettled condition, but by his skill and energy it assumed the more regular form known as the Ambrosian chant. At a later period Gregory the Great introduced many improvements, corrected certain abuses, and gave to the ritual chant that more systematic form which has since borne his name. Plain song is usually written in black note on a stave of four lines, with either a C or an F clef. See Gregorian Music.

Revised by Dudley Buck.

Plains, The, or **The Great Plains**: one of the great physiographic districts of North America. Through the entire breadth of the U. S. from Texas to the northern boundary and thence for a distance half as great in the Dominion of Canada, a sloping plateau descends eastward from the eastern base of the Rocky Mountains. Its breadth is from 300 to 600 miles, and the eastward descent in that distance ranges from 2,000 to 5,000 feet. The plain appears to have been more nearly level until a late geologic period, being partly occupied by lakes in early Neocene time. It then received its inclination through the uplifting of its western edge at a time when the plateau carrying the Rocky Mountains was also raised. Its surface is diversified by a few mountain districts, such as the Black Hills and Sun Dance Hills, by numerous streams which cross it from W. to E. and have excavated valleys to a depth of several hundred feet below the general surface, and by other districts, such as the Bad Lands of Dakota, where the surface has been intricately sculptured by rains and minor streams; but in general the surface is undulatory and monotonous. The characteristic feature of the climate is aridity, the amount of rainfall ranging from ten or fifteen degrees at the west to twenty or twenty-five degrees at the east. In the western portions agriculture can not be practiced without artificial irrigation of the land, and at the east it is somewhat precarious, as severe suffering is caused by occasional droughts. In general the stream-beds are of such character that the control of their waters for purposes of irrigation is difficult, but near the mountains the conditions are more favorable and an increasing acreage is irrigated. This, however, must always constitute but a small fraction of the entire surface, and grazing is likely to remain the prevailing industry of the region. In general the plains are treeless except in the immediate vicinity of permanent streams, but there are a few forest tracts in the northern portion and elsewhere near the eastern margin. See Plain.

G. K. Gilbert.

Plaintiff [from Anglo-Fr. = O. Fr. *plaintif*, complaining, deriv. of *plainte*, complaint. Cf. Eng. *plaintive*]: one who makes plaint; that is, one who states in a common-law court his cause of action against another. In equity courts, the moving party in a suit is called the complainant; and in admiralty and ecclesiastical tribunals, the libelant. Sometimes the legal title to the claim sued upon is in one person, while another holds the equitable title thereto. The former is known as the legal plaintiff, while the latter is the equitable plaintiff. Under the common-law procedure a claim which had been assigned was suable only in the name of the assigner, who was called the nominal plaintiff, while the one who brought and enforced the action was the real plaintiff. Modern codes generally require actions to be brought in the names of the real parties in interest. Plaintiff in error designates the one who sues out a writ of error.

Francis M. Burdick.

Plaisted, Harris Merrill: See the Appendix.

Planché, plaň'shā', James Robinson: playwright, archæologist, and herald; b. in London, Feb. 27, 1796; became early distinguished as a writer of plays and librettos; gave great attention to archæology and costumes, on which subjects he wrote; aided in founding the British Archæological Association, and was long its honorary secretary and editor of its *Journal*; author of some 200 dramatic pieces; published in 1852 *The Pursuivant of Arms* (3d ed. 1874), a treatise on heraldic subjects, which procured him the appointment of Rouge Croix Pursuivant in 1854. In 1866 he was promoted to be Somerset Herald. He wrote books of travel, songs, etc. D. May 29, 1880.

Plancy, plaň'see', Jacques Albin Simon Collin, de, generally called **Collin de Plancy**: author; b. at Plancy, department of Aube, France, Jan. 28, 1793; went to Paris in 1812; built up a business as a printer, publisher, editor, and author, and wrote *Dictionnaire infernal*, *Dictionnaire féodal*, *Mémoires d'un Vilain au 14e Siècle*, *Taxe des Parties casuelles de la Boutique du Pape*, *Biographie pittoresque des Jésuites*, *Le Diable peint par lui-même*, etc.—all in an anti-religious, revolutionary, and frivolous manner. In 1830 he fled from Paris on account of pecuniary difficulties, and settled at Brussels, where he wrote *Fastes militaires de la Belgique*, *Histoire des premières Années du Règne de Léopold*, and other things—all very flattering to the national vanity of the Belgians. In 1837 he was able to return to Paris, and he went back thoroughly converted. He then wrote *Légendes de la Sainte Vierge*, *Légendes des Origines*, *Légendes du Juif-Errant*, *Chronique de Godefroy de Bouillon*, *Légendes des Sept Péchés capitaux*, *Légendes des Esprits et des Démons qui circulent autour de nous*, *Le Chansonnier du Chrétien*, etc. The method which he generally applied in making a new book consisted in cutting up two old ones and rearranging their contents. The new book was then generally provided with a new pseudonym. Among the many names he employed as an author are Paul Béranger, Croquelardon, Hormisdas-Peath, Baron Nilense, Saint-Albin, and Johannes Videlbius. D. Jan. 13, 1881. Revised by A. G. Canfield.

Planer-tree [named from J. S. Planer (1743–89), a German botanist]: a rather small ulmaceous tree (*Planera aquatica*) of swampy lands in the southern parts of the U. S. It has the general appearance of the elms, but is quite distinct from them in flower and fruit. Its timber is hard, and suitable for many economic uses. The wood of *Planera abelicea*, of the Levant, is aromatic. It is the Cretan false sandal-wood of old writers. Another planer-tree is *P. richardi* of Persia and the Caucasus, partly naturalized in Europe, and sometimes called *zelkona*. It is a tall and handsome tree, producing excellent timber.

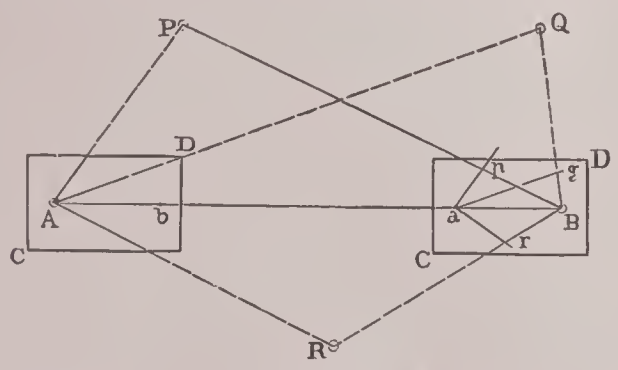
Revised by L. H. Bailey.

Planet [viâ O. Fr. from Lat. *plane'ta* = Gr. πλανήτης, planet, liter., wanderer, deriv. of πλάνη, a wandering, deriv. of πλανᾶσθαι, wander]: originally, any one of those heavenly bodies which seemed to change their positions on the celestial sphere. In the earliest days it was noticed that all the constellations and the thousands of stars which formed them preserved their relative positions from year to year and from generation to generation without any apparent change whatever, rising and setting as if they were fixed to the interior of a revolving sphere encompassing the whole earth. Seven celestial bodies were found to form an exception; these were the sun, the moon, and five bright stars, Mercury, Venus, Mars, Jupiter, and Saturn. From the changing positions of these bodies they derived their appellation of planets. See Ptolemaic System.

When the Copernican system was established a different classification became necessary. One of the planets, the sun, became the center of the solar system. The term planet could therefore no longer be applied to it. On the other hand, the earth itself became a heavenly body, revolving around the sun like the five known planets. The position of the moon alone remained unchanged. It was still a planet revolving around the earth. Thus by a natural use of words the term planet was applied to all the bodies which perform their revolutions around the sun. Those which, like the moon and the satellites of Jupiter, revolve around these planets are sometimes called secondary planets; but in the practical use of words the term planet is now applied only to those bodies of which the sun is the center of motion.

Among the common characters possessed by the planets are (1) they are globular bodies, rotating on their axes, and therefore slightly ellipsoidal in figure; (2) most of them are probably surrounded by atmospheres, more or less dense; (3) they shine by reflecting the light of the sun. Particulars of their relations to each other and of the elements of their orbits are given in the article SOLAR SYSTEM. A detailed description of each of the major planets is given under its name. S. NEWCOMB.

Plane-table: an instrument used in surveying for mapping in the field. It is particularly employed for making topographical maps in cases where a triangulation has first been executed. It is not used where great accuracy is required, but is particularly valuable on account of the rapidity with which it can be used in good weather. Although an ancient instrument, its use has been mainly confined to topographical mapping on a small scale. The plane-table consists essentially of a drawing-board mounted on a tripod in such manner that its upper surface may be made horizontal, and so that the entire table may be turned in azimuth through any angle whatever. The combination of parts by which these motions are effected is similar to that employed in leveling and orienting the horizontal limb of an engineer's transit. The instrument as described is accompanied by a ruler, usually of brass, and provided with a telescope so mounted that its line of collimation and the edge of the ruler shall always be in the same plane. The telescope is arranged with a vertical arc, by means of which small angles of elevation and of depression may be measured. The paper on which the map is to be made is stretched and held firmly in contact with the table by suitable clamps. One of the methods of using the plane-table is indicated in the diagram. Let it be required to determine the relative



position of the points P, Q, and R. Two stations, A and B, are selected as the extremities of a base-line, A B, and each is marked by a flag; the distance between them is measured; a line, A*b*, is drawn on the paper C D to any suitable scale to represent the line A B. The plane-table is then set up at A and leveled, so that the point A of the table shall be over the corresponding point A in the field; the edge of the ruler is then made to coincide with the line A*b*, and then the latter is turned in azimuth till the flag at B coincides with the intersection of the cross-hairs of the telescope, and in this position it is clamped. The telescope is then turned in succession upon the objects P, Q, and R, the edge of the ruler always touching the point A; and in each of these positions a pencil line is drawn along the edge of the ruler. The instrument is then taken to B and leveled, so that the point B of the table shall be over the point B in the field; the edge of the ruler is made to coincide with B*a*, and then the telescope is directed to the flag at A; and in this position the table is clamped. The telescope is then turned in succession to the points P, Q, and R, and in each position a line is drawn along the edge of the ruler intersecting the lines drawn to the same points at the other station; the points *p*, *q*, and *r*, in which the latter lines intersect the former, have the same relative positions on the plot that the given points have in the field. Another method is to determine the distances AP and AR by means of a stadia-rod, when they may be laid off to scale from A, thus locating *p* and *r*; by this method it will be unnecessary to transfer the table to B. Revised by MANSFIELD MERRIMAN.

Planetoid: See ASTEROID.

Plane-tree Family [*plane* is viâ O. Fr. from Lat. *pla'tanus* = Gr. πλάτανος, plane-tree, deriv. of πλατύς, broad]: the *Platanaceæ*; trees with alternate palmately veined leaves; flowers monœcious, much reduced, in globular heads; perianth of three to six sepal-like scales; stamens three to six; pistils two to eight, superior, each with a single ovule. The single genus, *Platanus*, contains six species, widely distributed in north temperate regions. *P. occidentalis* is the common plane-tree or buttonwood of the Eastern U. S., where it is often erroneously called sycamore. *P. orientalis*, the plane-tree of the Old World, which resembles the former species, is occasionally planted in America. In Cretaceous and Tertiary times there were many more species of *Platanus* than are now living. C. E. BESSEY.

Planquette, plăn'ket', ROBERT: opera-composer; b. in Paris, France, July 31, 1850; educated in the Paris Conservatory. His early operettas, *Valet de Cour*, *Le Serment de Mme. Gringoire*, and *Paille d'Avoine*, were successful. Next came his greatest success, *Les Cloches de Corneville*, well known in English as *The Chimes of Normandy*; first performed in Paris Apr. 19, 1877. He has since composed several operettas, including *Rip Van Winkle*, *Le Chevalier Gaston*, *Les Voltigeurs*, and *Nell Gwynne*. D. E. H.

Plant: See VEGETABLE KINGDOM, BOTANY, GEOGRAPHICAL BOTANY; PLANTS, FOSSIL; PHYSIOLOGY, VEGETABLE; MORPHOLOGY, VEGETABLE; CLIMATE, etc.

Plantag'enet: the surname of the Angevine dynasty of English monarchs, derived from the marriage of Matilda, daughter of Henry I., to Geoffrey Plantagenet, Count of Anjou. The Plantagenet monarchs reigned from 1154 to 1485, when the victory of Bosworth transferred the crown to the house of Tudor. They were usually ambitious and warlike princes. See ENGLAND, HISTORY OF.

Plantain [from O. Fr. *plantain*, plane-tree: Span. *plántano*, *plátano* < Lat. *pla'tanus*. See PLANE-TREE FAMILY]: the fruit of the coarser cultivated varieties of *Musa paradisiaca*, the finer and more delicate sorts being called bananas. The plantain is a native of the East Indies, but is now common in nearly all hot countries. It is of the family *Musaceæ*. The plantain furnishes a very large part of the food of the human race in some hot countries. The leaves yield a fiber which closely resembles MANILLA HEMP (*q. v.*). The name plantain is also applied to the species of the weedy genus *Plantago*, inhabitants of all yards and waste places in temperate climates. Revised by L. H. BAILEY.

Plantain Family: the *Plantaginaceæ*; a family of dicotyledonous herbs of doubtful affinity found in nearly every part of the world, but mostly in temperate regions. Most of the species, of which there are from 150 to 200, belong to the genus *Plantago*. The common plantain, *Plantago major*, is common in nearly every part of the world. Although nearly inert, it is employed in domestic medicine. Its seeds are fed to cage-birds, and its young leaves, boiled as pot-herbs, are palatable. In the U. S. the ribwort (*P. lanceolata*) is a common weed. The fleaworts (*P. psyllium* and *P. arenaria*) are raised in France for the seeds, which yield a valuable size for cotton goods and paper. CHARLES E. BESSEY.

Plant-cutter: a bird of the genus *Phytotoma*, so called from its habit of cutting off leaves and buds from trees and plants. The birds of this genus are characterized by tooth-like serrations along the edge of the mandible as well as inside the upper jaw. The few species are peculiar to South America, and are very destructive. They resemble sparrows in appearance, but are most nearly related to the tanagers.

Plantigrada, or **Plantigrades** [from Lat., pl. of *plantigradus*, plantigrade, from Lat. *planta*, sole + *gradi*, walk]: those animals in which the heel touches the ground in walking, as the bear, raccoon, etc. The term is the opposite of DIGITIGRADA (*q. v.*), and was employed by Illiger for a "family" of mammals, including species now placed in separate families. It is now used in a descriptive sense only. F. A. L.

Plant Jelly: See PECTIN.

Plant-louse: See APHIDES and GALL INSECTS.

Plants, Fossil: plants or vegetable impressions preserved in the earth by natural agencies, such as inhumation, petrifaction, carbonization, or incrustation.

History of the Science.—In view of the great abundance of vegetable remains now known to occur in nearly all the great systems of rocks throughout the world, it has been considered remarkable that no mention of their existence should have been found in the writings of the ancient Greeks and Romans nor in any extant work earlier than the thirteenth century. The first published allusion to fossil plants thus far discovered occurs in the treatise on minerals of Albertus Magnus, which appeared in the last half of that century. More than a hundred years later Martin Luther, in his commentaries on the books of Moses, brought forward the existence of petrified wood as evidence of the Noachian deluge, and during the sixteenth century considerable discussion was carried on by Agricola, Matthiolus, Gesner, and others relative to the nature and origin of vegetable petrifactions, embodying the vague speculations of these early times.

All this, however, had reference to petrified or lignitized blocks of wood or trunks of trees, and betrayed no acquaintance on the part of these writers with any of the definite organs of plants in the fossil state. It was not until toward the close of the seventeenth century that these latter at length attracted attention, and although Daniel Major of Jena, in 1664 included some such in his *Lithologia curiosa*, it remained for Edward Lhwyd, a Welshman, in 1699, in an important illustrated work, to furnish the basis for the future scientific study of fossil plants. From this time to the close of the eighteenth century the evidence rapidly accumulated, and discussion was rife and sometimes acrimonious.

The primitive notion of the formation of these objects in the rocks, through the action of a *virtus formativa* or *vis lapidifica*, gave way to the Lutheran doctrine that they represented plants that were washed up and stranded on the shores of Europe by the flood, of which Scheuchzer proved the most vigorous champion. The botanists who at last began to examine the abundant Carboniferous ferns taken from the coal-mines declared that they were not the same as those then inhabiting the country, but were of tropical aspect, and the theory was set on foot that by some great convulsion the vegetation of the torrid zone had once been torn from the soil by tidal waves of the sea and transported to more northern climes. Among those who leaned toward this view was Antoine Jussieu, the first of the great line of botanists of that name.

In this pregeologic age the idea that the fossil plants were extinct forms and belonged to a past age of the world had not yet dawned, but it was destined soon to do so, and the teachings of Leonardo da Vinci, Leibnitz, and Lehmann at last prepared the way for Blumenbach, who, before the end of the eighteenth century, laid the foundation for the true science, upon which Baron von Schlotheim, Count Sternberg, and especially Adolphe Brongniart, early in the nineteenth century, erected so noble a superstructure.

The succeeding half century brought forth an extensive literature of fossil plants, embracing among others the works of Göppert, Unger, Schimper, Williamson, Heer, Ettingshausen, Schenk, Saporta, and Carruthers in Europe, of Sir William Dawson in Canada, and of Lesquereux and Newberry in the U. S.

Progress in the knowledge of fossil plants naturally increased with the quantity and quality of the material brought to light. Scheuchzer in 1723 enumerated 445 species, and attempted to classify them according to the system of Tournefort, but his work was unscientific, and his species largely fanciful. Brongniart in 1828 described 501 species after a thorough revision of all the specimens known and careful exclusion of doubtful material. This formed a solid basis for future work, and the number of authenticated forms rapidly increased. Unger was able to catalogue 1,648 species in 1845, and three years later Göppert raised this to 2,055. Progress was unabated during the next twenty-five years, and Schimper's great work, published in 1874, describes about 6,000 species of fossil plants. At the present time (1895), though all care were exercised in eliminating synonyms, there would probably remain upward of 10,000 forms which, so far as can be known, are distinct.

When we consider that the present known flora of the globe comprises over 150,000 species of plants, the number of fossil plants, distributed as they are through so many geologic periods, seems small indeed, but it is still true that the representation from some horizons and particular localities occasionally approaches the numerical relations that subsist at the present time. But the botanist is interested in the number of these forms only as furnishing a basis for their classification, and thus throwing light upon the real character of the extinct vegetation of the earth.

Difficulties in the Way of the Study of Fossil Plants.—The study of fossil plants presents peculiar difficulties to the paleontologist from the fragmentary character of most plant-remains, and from the incomplete preservation of their perishable tissues. Of many extinct species of trees, in which the individuals may have been 100 feet in height, the only traces yet obtained are a few leaves of which the outlines and the nervation are imperfectly preserved. All botanists know how variable the leaves of trees are; and since they often find much difficulty in discriminating between genera and species when many entire individuals, complete in root, stem, leaf, flower, and fruit, are before them, it is not surprising that they have little faith in the deductions made from a few variable and incomplete organs. No doubt the inherent difficulties of the subject have favored hasty generalization—have, in fact, led to many errors—and should inspire a proper caution; yet many fossil plants have been discovered, and the preservation of some of them is so complete that they afford material for legitimate and important deductions in regard to the history of plant-life on the globe; indeed, it may be said that the generalities of this history are already well established.

Geological History of the Principal Types of Vegetation.—The plants now inhabiting the earth's surface, as well as those that have successively flourished during the several geologic ages of its history, may be divided into a few great groups which constitute so many different kinds or *types* of vegetation, varying greatly in form and general character as well as in their degree of structural advancement or perfection. The time and manner in which these several great types made their appearance on the globe are indicated, in so far as they can be known at all, by fossil plants. It therefore becomes a matter of the highest interest to endeavor to trace these types of vegetation back to their origin, and to note the manner of their subsequent development.

According to the most approved modern classification of plants the vegetable kingdom is primarily divided into the four co-ordinate groups or sub-kingdoms called respectively, 1, *Thallophytes*; 2, *Bryophytes*; 3, *Pteridophytes*; and 4, *Spermophytes*; the first of which embraces the lowest cryptogams, the second the mosses and liverworts (these two constituting the old division of cellular cryptogams), the third the vascular cryptogams, and the fourth all phanerogams. These divisions are, however, usually broader than the *types* which will be treated below, and in most cases embrace several such. It must also be remembered that in dealing with the extinct forms of the remote past one is looking back through the stages of plant-development. In fact, there is no longer any doubt that many of those ancient types really embodied the primal elements of several of those which in the slow course of ages were evolved out of them, and ultimately assumed more definite and distinct form. They are in such cases what have been called *comprehensive types*—i. e. types that comprehend in their structures the inchoate germs of later forms. Such types have also been happily termed *prophetic*, in that they contain the promise and prophecy of a life that is to flourish in subsequent ages.

The types of vegetation whose history the study of fossil plants serves best to elucidate are the following: Under the Thallophytes fall, in ascending order of development, 1, the *Protophytes*; 2, the *Algæ*; 3, the *Characeæ*; 4, the *Lichens*; and 5, the *Fungi*. The Bryophytes play so inconspicuous a *rôle* that their subdivision is unnecessary. Under the Pteridophytes are ranged, 1, the *Ferns*; 2, the *Rhizocarps*; 3, the *Equisetineæ*; and 4, the *Lycopodineæ*. The above ten types complete the cryptogamic series, which, though it fills a subordinate place in the present flora, assumes extraordinary prominence in the history of past plant-life. The great sub-kingdom of spermophytes or phanerogams has for its leading fossil types, 1, the *Gymnosperms*; 2, the *Monocotyledons*; and 3, the *Dicotyledons*; the last two constituting the *Angiosperms*, which crown the vegetable series. The geological history of these thirteen types of vegetation may be briefly sketched as follows:

The Protophytes.—From the supposed absence of the lowest forms of cellular cryptogams in the older rocks it has been argued that such forms are of comparatively modern origin. The greater part of these, however, are of such a

soft or gelatinous nature that they obviously could not be preserved under any ordinary conditions of sedimentation. The diatoms, which possess siliceous shields, are preserved in vast abundance in many parts of the world, heavy deposits of diatomaceous earth occurring along the Potomac and James rivers in Maryland and Virginia, at Monterey in California, in Bohemia, and many other parts of Europe, as well as in remoter regions. But all such beds are of Tertiary or more recent date, and it is fair to claim that this group at least is of modern origin.

The fact that plants alone can transform inorganic into organic matter has justly been brought forward in support of the claim that plant-life must have preceded animal life. But however conclusive this proposition may seem it would have little value for science if not confirmed by facts. There are, however, certain facts bearing upon this question which were confidently urged long before the discovery of any of the primitive forms of vegetable life in the older sedimentary rocks. Chief among these is the existence of vast deposits of plumbago or graphite, a pure form of carbon, in rocks too ancient to contain any definite forms of life either animal or vegetable—viz., in the Laurentian system of Canada and other ancient deposits. The doubts that existed in the minds of some as to the organic origin of graphite would seem now to be dispelled by the discovery of the fronds of ferns in the Devonian in the state of graphite.

The nature of the vegetation that produced the Laurentian graphite beds is of course conjectural, but within the last decade, due chiefly to the investigations of Reinsch, it has been made practically certain that the waters of the Paleozoic seas teemed with myriad forms of lowly cryptogamic life, forms related to the *Myxomycetes* and other protophytes. The metamorphic rocks have probably lost all traces of these structures, while those of the Cambrian and Silurian do not seem to be adapted to retaining them, but from the Devonian upward to the Cretaceous, and especially in the Carboniferous, impressed upon the coal itself and occupying the chinks and crevices in its seams and lumps, these strange microscopic organisms have left their traces in great profusion. Much light is thus thrown on the origin of coal, while the existence of a great abundance of primordial vegetable life as the food and sustenance of the early animals seems sufficiently demonstrated.

The Algæ.—There has been much animated discussion as to the nature of certain objects which have been held by some paleobotanists to be fossil algæ. These consist of markings and reliefs of somewhat definite form resembling living Algæ upon the rocks of Paleozoic or even earlier ages. The most important of these have been referred by these authors to the genera *Bilobites*, *Cruziana*, *Rhysophycus*, *Vexillum*, *Eophyton*, *Dendrophycus*, etc. In most cases they are so indefinite that even the most sanguine admit their doubtful character; in a few, however, the evidence of their vegetable origin is more distinct. But in nearly all it has been called in question, and the problem is one for which from its very nature a definite settlement can scarcely be hoped. The principal authors who have maintained that these markings represent real plants are the Marquis Saporta and Senhor Delgado, while of those who have most vigorously attacked this view Dr. A. G. Nathorst has taken the lead, and been followed by Dawson, Newberry, and many others. All, however, admit that there is no antecedent improbability that algæ inhabited the waters in which these rocks were laid down, and also that some of these forms really represent such organisms. Among the best authenticated of these fossil algæ may be mentioned forms of *Buthotrephis*, *Palæophycus*, *Licrophycus*, *Phytopsis*, *Sphenothallus*, *Harlania* (*Arthrophycus*), and *Palæochondrites* of the Silurian, and *Spirophyton*, *Fucoides*, and *Nematophyton* of the Devonian. The remarkable trunks from the Lower Devonian of Canada, described by Dawson and Penhallow under the name of *Nematophyton*, and claimed to represent veritable trees, have been subjected to the most rigid examination, and are pronounced to be Algæ allied to the *Laminariæ*. Similar trunks have also been found lower in the scale, even as low as the Denbighshire Grits at the base of the Lower Silurian. Amid all the diversity of opinion therefore it seems evident that the Paleozoic seas contained and probably abounded in marine algæ; while the occurrence of *Nematophyton*, above mentioned, which is held to have inhabited the land, tends to show that this type formed no exception to the law, so well exemplified by the higher ones, that the prevailing types of structure reached a higher expression in Paleozoic time than the same types exhibit at the present time.

In later geological formations the forms of algæ, though less robust, are more definite and better preserved, and from the Carboniferous to the Miocene, but especially in the Cretaceous and Eocene (Flysch), such genera as *Chondrites*, *Halymenites*, *Sphærococcites*, *Gyrophyllites*, *Münsteria*, *Cylindrites*, *Delesserites*, *Cystoseira*, etc., are of common occurrence.

The *Characeæ*, which mark a sort of transition from the algæ to the bryophytes, are represented in the fossil state by some sixty species of the genus *Chara*, which makes the "feather beds" at the bottom of ponds and rivers, all founded on the characteristic spirally twisted "fruits" of that genus. They range from the Oölite to the Pleistocene, but are most abundant in the Eocene. That the group may have had a much earlier origin is at least suggested by the discovery in the Lower Devonian (Corniferous Limestone) of Ohio of small bodies having a great general resemblance to *Chara* fruits, though differing in both the number and direction of the coils. The former reference of these forms, as well as of the nearly identical *Saccamina* of Dawson, to the *Foraminifera* is disputed by Brady, the highest authority on that group of animals.

The Lichens.—This group, which is classed with the fungi by many modern botanists, but forms a type very distinct in external appearance, though abundant at the present day is hardly known in the fossil state, some dozen species only, part of which are of doubtful character, having been described, all from the late Tertiary deposits. Those, however, that have been found imbedded in amber are very perfectly preserved, and belong in some instances to the same species with the lichens most common in Europe and America at the present time. From their nature the lichens are not likely to be preserved, but it is probable that certain of the hard and woody forms that grow on trees will be found attached to petrified trunks so abundant in some places. It seems quite certain that if these plants had been at all abundant in the forests of the coal period they would have been found in connection with the perfectly preserved impressions of the external surfaces of trees in our coal mines. It is probable that lichens, if they existed at all, were much less abundant in the Carboniferous period than they are at present.

The Fungi.—Quite a large number of fossil fungi have been described first and last by Unger, Göppert, Heer, and others, and Prof. Meschinelli has recently published, as a part of Saccardo's great work on the fungi of the globe, a complete list of all the known species, amounting to 329, and classed under forty-one genera. They are chiefly Tertiary, and found forming spots on dicotyledonous leaves. Such are the large genera *Sphærites*, *Xylomites*, etc., but the genera *Archagaricon*, *Peronosporites*, *Protomycites*, and *Excipulites* are Carboniferous, and there are a few Mesozoic forms.

The Bryophytes.—The plants of this group, which include the mosses and liverworts, and with the thallophytes constitute the cellular cryptogams, form a conspicuous feature in the present vegetation of the world. They were, however, prior to the year 1885, unknown with certainty in any formation older than the Tertiary. It is true that Debey and Ettingshausen in 1859 had figured an obscure form from the Upper Cretaceous of Limburg, in Belgium, which they regarded as an ancestral moss, and still earlier (1839) Roemer had made known another equally uncertain supposed museite from the Wealden of Hanover, neither of which, however, was accepted by Schimper, the great authority on both living and fossil mosses. The celebrated Swiss paleontologist Oswald Heer, having in 1865 detected certain beetles of the genus *Byrrhus* that now live exclusively among mosses as occurring in the Lias of Schambelen in Switzerland, remarked that the ground at that spot was then probably carpeted with mosses, and ventured the prediction that their fossil remains would yet be found. This prediction has not yet been verified for any part of the Mesozoic age, but its sagacity has been strongly vindicated by the identification in 1885 by Renault and Zeiller in the coal-measures of Commentry, department of Allier, France, of what these authors regard as a true moss allied to *Polytrichum*, to which they gave the name *Muscites polytrichaceus*. This accidental discovery of mosses in the Carboniferous is due to the extremely favorable conditions that existed at that period for the preservation of fossil plants, even those least adapted to it, and the absence of the

Bryophytes throughout the Mesozoic must in like manner be attributed to the less favorable conditions for the preservation of plant remains that characterize that prolonged period. That plants of this type will some time be found in considerable abundance in the Paleozoic and the history of the type be traced through the several systems of Mesozoic strata is a forecast which is justified by the history of science.

Both mosses and liverworts occur in considerable abundance in the Tertiary, especially in the amber and lignite or brown coal, to the latter of which they seem to have contributed largely, as they now do to the formation of peat. The species found in the amber are so perfectly preserved that their generic and specific characters may often be determined with accuracy, and it is an interesting fact that all the species so determined are closely allied to, and some are identical with, those now growing in Europe. The *Marchantia polymorpha*, a liverwort, is perhaps the most widely distributed of all living plants, and a fossil species, *M. sezannensis*, from the lowest Tertiary (Paleocene) strata of France, closely resembles it and may have been its progenitor. The *Hepaticæ*, or liverwort family, are somewhat less highly organized than the *Musci*, or moss family, and their future discovery much earlier in the series would not be a matter of surprise.

The Pteridophytes.—These embrace the great group more popularly known as the vascular cryptogams, and it is not an exaggeration to say that they have a greater interest for paleobotany than any other one of the primary subdivisions of the vegetable kingdom. Nearly all the living types are represented in the fossil state, but several of these, especially the ferns, *Equisetineæ* and *Lycopodineæ*, attained in Paleozoic time a development and luxuriance far exceeding those exhibited by the same types at the present day. They constituted the bulk of the great coal flora, assumed the stature of true trees, and formed veritable forests on the low marshy continents and islands of the Carboniferous epoch.

The Ferns.—Probably the most conspicuous type of ancient vegetation was that of the ferns. The ferns of temperate regions are now chiefly small herbaceous plants, but in the tropics tree-ferns still abound. In the Carboniferous there were doubtless some ferns of low stature, but there is evidence that the tree-ferns were a regular constituent of the forests everywhere, and that in many places they overshadowed all other vegetation. The classification of ferns is chiefly possible only by their fruiting organs, but the remains that have come down contain these only in extremely rare cases, so that it is still scarcely known to which of the living groups the great genera *Pecopteris*, *Neuropteris*, etc., are most closely related. Discoveries, however, point to the conclusion that these ancient forms were very unlike those of modern, or even of Mesozoic time, and that there was almost as great a change at the close of the Paleozoic in the character of the ferns as in that of the other types of pteridophytes.

The Rhizocarps.—The small family of rhizocarps includes the popularly little-known genera *Marsilea*, *Pilularia*, *Salvinia*, and *Azolla*. They differ in appearance from most ferns, but structurally they are the same except in bearing two kinds of spores, the one kind small, called microspores, and performing male functions, the other large, called macrospores, and performing female functions. The first named of these genera occurs in the fossil state, the four or five species of fossil *Marsilea* ranging from the Jurassic to the Miocene. *Salvinia* is even better represented, a dozen or more species occurring in the Upper Cretaceous and through the Tertiary. But the type is probably much older. Sir J. W. Dawson is disposed to refer his Devonian genus *Psilophyton* to the rhizocarps, and it certainly does closely resemble the modern *Pilularia* or pillworts. The Mesozoic *Sagenopteris* is now referred to the *Marsileaceæ*, and this may take with it the much older *Glossopteris* and its allies. But besides these indications of the antiquity of this type there have now been found at a number of places in the Devonian the characteristic spore-cases of the rhizocarps, most resembling those of *Salvinia*. These occur in Canada, Illinois, Ohio, and Brazil. Dawson has described a number of species founded on these objects under the name of *Protosalvinia*, and he cogently argues that they indicate the prevalence in those ages of an abundant rhizocarpean flora.

The Equisetineæ.—This type is only represented in the living flora by the genus *Equisetum*, the scouring-rushes, so called from the quantity of silex contained in their tissues. They are mostly low, rush-like, but leafless marsh-plants with jointed stems. In the early floras, however, the type embraced the great family *Calamariæ*, including the genera *Calamites*, *Calamodendron*, *Asterophyllites*, *Annularia*, and a host of other forms mostly of arborescent character and strange aspect. They abound in the coal-measures of all countries, and reach far back into the Devonian. They became extinct at the close of the Paleozoic and were succeeded by Triassic forms of *Equisetum*, much larger than those of the present day, and by the allied genus *Schizoneura*. Reduced forms of *Equisetum* continue through the Tertiary, at the close of which the type had dwindled to something like its present insignificance.

The Lycopodineæ.—If the ferns were the most universal and ubiquitous of the primordial types of vegetation, the lycopods excelled in their size, majesty, and strangeness. For to this type, now represented by the humble ground-pines or club-mosses, belonged the great Carboniferous genera *Lepidodendron* and *Sigillaria* with their numerous relatives, whose scaly trunks are so abundant in the roof-stones of all coal-mines. It was also one or several of these great trees whose subterranean parts are known as *Stigmaria*, and which form such conspicuous and grotesque objects in the coal-measures of nearly all countries. These plants were also true forest-trees, rising above the ferns and calamites and dominating the Carboniferous landscape. They probably had their origin in the Silurian, being abundant in the Devonian, where many species of *Lepidodendron* have been found, and where the anomalous *Berwynia* and *Arthrostigma* described by Dawson may have preceded and begotten them.

All these monarchs of the Paleozoic forests went down with the calamites before the Permian winter, to be but feebly succeeded by forms of *Lycopodites* connecting them with the modern *Lycopodium*. Of other lycopods the genus *Selaginella* is sparingly represented in the fossil state from the Cretaceous upward, while forms allied to *Isoëtes*, the quillworts, have been found in the Jurassic and also in the Miocene.

The Gymnosperms.—This group, now constituting a class in botany, and perhaps too comprehensive to be regarded as a single type, embraces the three natural orders *Cycadaceæ*, *Coniferæ*, and *Gnetaceæ*. The first two of these are among the most important families of fossil plants.

The *Cycadaceæ*, now a rare group, but familiar to all through the common *Cycas revoluta* of the greenhouses, and seeming, by its external appearance at least, to connect the tree-ferns with the palms, once formed the leading type of vegetation over the greater part of the earth. This was in Jurassic time, since which, like the great cryptogamic types of earlier ages, it has declined and nearly disappeared.

The *Coniferæ*, or cone-bearing family of plants, which embraces the pines, firs, spruces, cedars, etc., had a very early origin, being found in forms approaching some of the living ones at the close of the Carboniferous, when such genera as *Walchia*, *Ullmannia*, and *Voltzia* made their appearance. These, however, as well as the modified Mesozoic forms, *Brachyphyllum*, *Palissya*, *Araucarites*, etc., that succeeded them, were more closely allied to the present South American araucarian pines than to those that make up the evergreen forests of the northern hemisphere, while the predominant Cretaceous and Tertiary forms so closely approach the great redwoods of Western North America that most of them have been referred to the genus *Sequoia*. The true pines were of more modern origin.

The *Gnetaceæ* embrace the three genera *Gnetum*, *Ephedra*, and *Welwitschia*, all singular plants, the last two especially being among the most anomalous of all known forms of vegetable life. *Ephedra* is the only one of the three genera to which any fossil plants are believed to be related. One such was described by Heer from the Oölite of Siberia under the name of *Ephedrites antiquus*. Another has been found in the Upper Jurassic of France. Two others range through the Tertiary, and one, possibly a true *Ephedra*, is a celebrated amber-plant. The genus has also been found in the Pleistocene.

There exist in the flora of the globe certain forms which bear evidence of being the lingering representatives of great families that have flourished in the remote past, and are now approaching extinction. Such forms have been appropriately called *waning types*. To this class belong the genera *Equisetum* and *Lycopodium*. The modern cycads are a further illustration. Some of the most interesting of these waning types, however, belong to the *Coniferæ*, chief

among which are the well-known maidenhair-tree, *Ginkgo biloba*, and the redwood and mammoth trees of the Pacific coast. The maidenhair-tree is the sole survivor of a long line of ancestors which appear to have been abundant at different epochs. It can be traced back through all the ages of Cenozoic and Mesozoic time, with little change in the form of leaf until the Oölite is reached, when the blade becomes so divided that some of its extreme forms take the name of *Baiera*, a genus ranging through most of the Mesozoic. In the Permian it is replaced by the still more dissected forms *Ginkgophyllum* and *Trichopitys*, which are probably its ancestors, and these in turn were preceded, and perhaps begotten, by the whittleseyas, noeggerathias, and cordaïtes of the Carboniferous and Devonian measures.

That the sequoias are a waning type is proved by their extremely restricted range and number in the present flora, coupled with their great abundance and wide distribution in the floras of the past, the two Californian species being all that remain of more than fifty species known in the fossil state, ranging from the Jurassic to the Pliocene, and from Greenland and Spitzbergen to Chili and New Zealand.

These are by no means the only cases, and the class of gymnosperms bears evidence of having been very gradually ushered into existence. Toward the close of the Carboniferous there appeared a number of aberrant forms, such as *Dolerophyllum*, *Psygmophyllum*, *Cannophyllites*, *Dicranophyllum*, etc., which are probably ancestral Gymnosperms, and these, with the line of *Taxineæ* leading from *Cordaïtes* to the modern ginkgo and the yews, it has been proposed to erect into a group to be called *progymnosperms*. Indeed, the Marquis Saporta would take the *Cycadaceæ* out of the true gymnospermic column and unite them with this ancestral group.

The Monocotyledons.—Much interest attaches to this type of vegetation, which, though comparatively small, has the extraordinary merit of furnishing all the cereals for man's use. None of these, however, are found at any remote geologic epoch, and they seem, singularly enough, to have been developed at about the same time that man made his appearance on the earth. The ancestry of this type is enshrouded in obscurity, and some have maintained that its origin was not as remote as that of the dicotyledons. Certain it is that none of the now recognized forms of monocotyledonous plants have been recognized with certainty at an earlier period than the Cretaceous. There are, however, certain peculiar forms of extinct vegetation occurring in the Lower Trias and extending to the Upper Jurassic, that have been referred with confidence by some authors to the monocotyledons. Such are the *Yuccites* and *Æthophyllum* of the Buntersandstein of Alsatia, and the *Williamsonia* and *Weltrichia* of the Rhetic and Oölite. To these have been added the *Dichoneuron hookeri* of the Permian of Russia. Of these and some other forms usually referred to the *Cycadaceæ*, Saporta would establish an ancestral group, the *proangiosperms*, analogous to the progymnosperms abovementioned. This author, in conjunction with Dr. Marion, made an exceedingly praiseworthy effort to demonstrate from both paleontology and embryology the transition from the monocotyledon to the dicotyledon, and at least succeeded in showing that the distinction so obvious between the linear parallel-nerved monocotyledonous and the broad netted-veined dicotyledonous leaf is obliterated in many cases in the life-history of these plants.

With the exception of the palms the monocotyledons have played an unimportant *rôle* in the past history of vegetation. The date of their first appearance is imperfectly known on account of the problematical character of most of the early forms. All those that can with certainty be so classed occur as late as the Cretaceous, while the ancestors of our grasses and cereals, as well as of the now abundant rushes, club-rushes, and sedges do not appear earlier than the Tertiary. The chief interest centers in the palms, which began their career in the Upper Cretaceous and attained their maximum development in the early Tertiary. During all but the latter part (Pliocene) of Tertiary time, as well as during the Senonian and Laramie periods (Upper Cretaceous), the palms flourished in great luxuriance, and have left their gigantic leaves and peculiar fruits in the rocks of Europe and North America as far north as England and Vancouver island. Among the richest of these deposits of palms are those of Golden and Florissant, Colorado, representing the Laramie, Denver, and Green river formations, where *Sabal major* and *Flabellaria florissanti* exhibit leaves from 2 to 4 feet in width.

The Dicotyledons.—This great type, embracing most deciduous trees and foliage-plants and thousands of broad-leaved evergreen tropical and subtropical trees and shrubs, now constitutes the dominant vegetation of the globe. It had no existence in the earlier geologic ages and only came on the scene in late Mesozoic time. But it soon outstripped all its competitors, vying with the palms for the mastery during the late Cretaceous and gaining the complete ascendant during early Tertiary time. Its geologic history is chiefly known through leaves that have been dropped or blown by the winds into the waters of the seas, lakes, and rivers on whose shores these plants grew, and which, from the thin and broad nature of such organs, were quickly covered by the sediment and preserved in the rocks. Other organs, such as flowers and fruits, especially the latter, are, however, sometimes found, and by their aid the determinations based on leaves alone can then be verified or corrected. The necessity for identifying so large a mass of material from leaves alone has created a new department of botany previously neglected. The form of leaves was formerly alone relied upon in describing plants, but this furnishes little aid to the paleobotanist, who must determine not only the species but the genus and even the order from such data alone. This led to the study of nervation, which was found to have a much higher systematic value. It may be said that while form possesses only specific value, nervation possesses generic, and sometimes ordinal, value in the classification of plants, and a somewhat complete system of classification has been laboriously elaborated, based on the nature and arrangement of the veins and veinlets that distribute the fibro-vascular bundles to the blade of the leaf.

Throughout Cretaceous and all but late Tertiary time the evidence thus presented goes to prove that the dicotyledonous vegetation consisted chiefly of trees and shrubs with somewhat thick, tough, and leathery leaves, such as now characterize the flora of tropical and subtropical countries, and this is in harmony with the views of most geologists that the climate of the earth has undergone a gradual change by the slow lowering of its temperature, at least down to the beginning of the last series of glacial epochs, during and since which little is known of the fossil vegetation.

Many Cretaceous and early Tertiary forms have been referred to genera that now exist, such as *Populus*, *Salix*, *Sassafras*, *Platanus*, *Quercus*, *Ficus*, *Magnolia*, *Liriodendron*, *Viburnum*, etc., and doubtless such references possess a degree of correctness, but it is better to make the mental reservation in most cases that these ancient forms are probably the forerunners and ancestors of the living genera, and that could their flowers, fruits, and other organs be perfectly known it might be necessary to create new genera for their reception.

The Dicotyledons furnish numerous examples of waning types as defined above. Such is the genus *Sassafras*, with only one living representative of some dozen fossil species. The same is true of the tulip-tree, *Liriodendron tulipifera*, and the ancestors of both these species date back to the Lower Cretaceous. *Liquidambar* is a somewhat similar example, and seems to merge into *Platanus*, which is probably the most interesting genus from this point of view.

Geological Résumé.—The general character of the fossil vegetation of the globe has been depicted in the foregoing paragraphs, but in treating the great types, some of which range through a series of geologic ages, it has not been possible to convey as clear an idea as seems desirable of the flora of each of the successive periods of geologic time. A brief *résumé*, therefore, from this point of view, seems to be justified even at the risk of some slight repetition.

It should be premised, however, that the fundamental divisions of geologic time which are suggested by the history of plant-life differ slightly from those commonly adopted as based upon animal life. The Eophytic and Paleophytic ages correspond with sufficient exactness with the Eozoic (Archean and Algonkian) and Paleozoic (Cambrian, Silurian, Devonian, and Carboniferous) ages, but the Mesophytic age properly ends with the Jurassic instead of the Cretaceous, because it is here that the greatest break in the entire series occurs by the introduction and rapid rise of the great dicotyledonous flora which ever afterward maintained such an undisputed supremacy. Again, the Cenophytic age begins with the Cretaceous instead of the Tertiary, which is the point of origin of the Cenozoic, and is more completely broken in the plant than in the animal series by the approach of the glacial epoch, while this break occurs some-

what earlier in the former than in the latter, or at a point in the Neocene period corresponding approximately to the line drawn by Lyell between the Miocene and the Pliocene. Below this line there is everywhere evidence of a warm tropical or subtropical climate, and the introduction of forms indicative of a temperate or more or less arctic climate is here somewhat sudden and abrupt.

So far as plants are concerned, therefore, the geological series may be divided into five great ages: the Eophytic, Paleophytic, Mesophytic, Cenophytic, and Neophytic ages. The Eophytic and Paleophytic constitute the Primary, the Mesophytic the Secondary, the Cenophytic the Tertiary, and the Neophytic the Quaternary division of time. In the following enumeration of the successive floras, however, the lesser periods in more common use by geologists will be employed:

The Precambrian Flora.—Little as is known of what the real nature of the Eophytic flora was, there is still sufficient evidence, as was set forth when treating of the Protophytes, to make it tolerably safe to assume that this primitive vegetation consisted mainly or exclusively of the lowest forms of cryptogamic life—those unorganized plasmata, cytodes, or unicellular bodies which formed the initial life of the planet, and sprang by some unknown archegonic process from the womb of the great "mother of life," the sea. To such forms, and many still exist, the term Protophytes has been applied. The Eophytic period may therefore be appropriately called the age of Protophytes.

The Cambrian Flora.—The Cambrian, which is now recognized as including the Potsdam Sandstone, the Taconic system, and all below the Ordovician of some authors, contains many of the problematical organisms discussed under *Algæ*, some of which are undoubtedly plants belonging to that type, Among these are probably some of the species of *Fucoides*, *Buthotrephis*, and *Palæophycus* that have been described from rocks of this age in New York, Vermont, Wisconsin, and the Black Hills of South Dakota, as well as from England, Wales, Sweden, and other countries of Europe.

The Silurian Flora.—Scarcely more can be said for the Lower Silurian than for the Cambrian, and the same forms recur only in greater number and distinctness. But here is encountered in the Trenton Limestone the genus *Phytopsis*, and in the Hudson River Group the genera *Sphenothallus* and *Licrophycus*, as well as all the various forms from Southern Ohio, some of which are doubtless of vegetable nature. The *Sphenophyllum primævum* and *Protostigma sigillarioides*, as well as the supposed species of *Sigillaria*, described by Lesquereux from this deposit have been called in question and are still in doubt, and the same is true of *Eopteris morierei*, a supposed Lower Silurian fern from Southern France. It is therefore still uncertain whether any positive evidence exists of the occurrence of Pteridophytes or any form of land-vegetation in the Lower Silurian.

In the Upper Silurian, however, such forms have been found under conditions that seem to leave no doubt of their existence at that epoch. Besides the recurrence of the fucoidal remains with increasing abundance and definiteness of structure, there is not only the land-thallophyte *Nematophyton*, but the supposed rhizocarpean genus *Psilophyton*, and the probably pteridophytic *Protannularia*, *Arthrostigma*, *Berwynia*, and *Glyptodendron*, constituting a firm Silurian basis for the future land-vegetation of the globe.

The Devonian Flora.—The change in passing from the Silurian to the Devonian flora is so abrupt that it must be attributed in great part to the imperfection of the geological record. Still it strongly suggests that there may have been about the close of Silurian time a great lowering of temperature analogous to that which is now generally believed to have occurred at the close of the Carboniferous. Scarcely any of the fucoidal forms persisted, though some peculiar to that age, such as the *Spirophyton*, or cockstail fucoid, are found. But the places of these are supplied many times over by far higher types of land-plants, clearly impressed upon the rocks or petrified in place with their internal structure preserved, so as to leave no doubt as to their vegetable nature, and to enable us to determine their botanical relations. Not only were all the great types of Pteridophytes represented—the ferns by *Archæopteris*, *Cyclopteris*, *Sphenopteris*, *Rhachiopteris*, *Megalopteris*, etc.; the rhizocarps by *Psilophyton* and *Protosalvinia*; the *Calamariæ* by *Bornia*, *Calamites*, *Asterophyllites*, and *Annularia*; and the lycopods by *Lepidodendron*, *Sigillaria*, *Knorria*, and *Stigmaria*—but a large number of gymnospermous or progymnospermous forms were introduced, such as *Noeggerathia*, *Cordaïtes*, *Dadoxylon*, and *Syringoxylon*. The Devonian flora was therefore the beginning of the Carboniferous flora, which is next to be considered.

The Carboniferous Flora.—This flora is too well and popularly known to require a detailed examination. It was the climax in the development of all the great types of Pteridophytes above described. It flourished during a period of the earth's history marked by a warm, tropical climate, yet not too hot for the growth of land-vegetation; by a great preponderance of ocean over land; by a mostly low, flat, marshy condition of the land-surface, which was probably largely insular or peninsular, the islands, tongues, and necks of land, as well as the marshy and lake-strewn continental expanses bathed in the moisture of their almost steaming waters, and perhaps nearly always overhung with a nimbus cloud-envelope and drenched by ceaseless mists or rains. Under such conditions the luxuriant forests of tree-ferns, lepidophytes, calamites, and cordaïtes, flourished unmolested, and were able to attain that extraordinary development which constitutes one of the greatest wonders that science has revealed to man.

Toward the close of the period, during the phase which is commonly marked off as the Permian, a change began to take place in the character of the flora; the earlier forms were reduced in size and importance, and new ones, such as *Walchia* and *Ullmannia*, appeared, more nearly approaching the later forms of the *Coniferæ*. Among these the genus *Voltzia* is sparingly found, a form which was to reappear in the early Trias. The rapid and ultimately complete extinction during this epoch of the great Paleozoic Pteridophytes that reigned so absolutely over the preceding ages marks one of the most abrupt transitions in the geological history of the earth.

The Triassic Flora.—To pass from the Paleozoic to the Mesozoic age is to enter a new world. The calamites of the Carboniferous had disappeared, but these had given place to forms of true *Equisetum*, some of which, such as *E. rogersi* of the Richmond coal-field in Virginia, still attained a great size. The great lycopods of the coal-period had all perished, as no traces of them are found in the Triassic. The most noticeable trees of the Lower Trias are the peculiar conifers *Albertia* and *Voltzia*. They are both araucarians, but quite different from those which preceded and followed them. The most conspicuous and characteristic feature in the Triassic flora is the great development it exhibits of the family of cycads. These were so numerous, varied, and showy that they have caused the Triassic and Jurassic ages to be called by some the reign of cycads.

The flora of the Trias has now been somewhat thoroughly studied in North America from large collections made in the coal-basins of Richmond, Va., and of the Deep and Dan rivers, North Carolina, as well as from the Connecticut valley, from the Newark beds of New Jersey, and in the West from the copper region near Abiquiu, New Mexico. These investigations have revealed a flora most like that of the Upper Trias in the Old World, being composed of the same genera and in part of the same species. The ferns and cycads form the largest groups, and are about equally predominant. After these come the conifers and next the equiseta. More than one hundred species of these four types are now known from the American deposits. Careful comparisons have been made of this flora with those of other countries, and the conclusion has been reached that it represents the extreme upper member of that system, corresponding to the Upper Keuper or Rhetic of Europe.

This Upper Triassic flora is of the greatest interest, as it bears evidence of having migrated from the southern hemisphere. It abounds in Australia and India, and has been found in South Africa and the Argentine Republic. From these regions it seems to have spread in the Old World to Asia Minor, Cochin China, China proper, Japan, Siberia, and Europe, and in the New World to Honduras, Mexico, and the regions of the U. S. enumerated above. It appears in India and Australia at an earlier period, and is a modification of the Carboniferous types that existed there. These survived the ordeal that laid low the pteridophytic coal flora of the north, and reappeared in altered forms as the widespread Mesozoic flora of the globe.

The Jurassic Flora.—No fossil plants have yet been found in America which come from strata that have been identified with certainty as Jurassic, although the Triassic flora above described belongs, as stated, to the extreme top of

that system, and was long supposed to represent the Oölite, which in Europe is rich in plant-remains. On the Yorkshire coast of England and in many parts of France, Italy, and Germany, as well as in India and Siberia, there are extensive deposits of that age that contain fossil plants, of which some five or six hundred species have been described. Several hundred more are known from the Lias below, and the Coral, Portland, Purbeck, and Kimmeridge beds above the Oölite. These constitute simply a gradual modification of the Keuper and Rhetic flora already described, and their differences are too much matters of detail to require enumeration here.

The Cretaceous Flora.—As already remarked, the Cretaceous gave a new dispensation to the plant-life of the globe in the first appearance here of the great type of Dicotyledons. These are now known to occur at the very base of the system, but of peculiar form and character, indicative of an embryonic state, and mingled with other types—ferns, cycads, conifers, etc.—of Jurassic aspect. The Potomac formation of Virginia, first made known in its botanical relations by Prof. Fontaine in 1889, is the earliest in the world at which this type of vegetation is known to have existed. Saporta, however, has discovered dicotyledonous plants in collections from Portugal at a horizon only slightly higher. A single plant of this sub-class had been found by Heer during his study of the arctic floras in the Kome beds of Greenland, which were referred to the Lower Cretaceous, but not to its extreme base, prior to which none were known older than the Cenomanian or Middle Cretaceous of Europe. At that horizon they had long been known, and have been described from many parts of the Continent—Saxony, Bohemia, Moravia, etc.—also from the Atane beds of Greenland. The Dakota formation of Kansas and Nebraska is placed at about the same age, and has yielded a very large flora in which Dicotyledons greatly predominate. Until very recently it was believed that the Raritan and Amboy clays of New Jersey, which have also furnished plants of this type, were nearly of the same age, but researches now in progress point to an earlier date for these deposits, while the same flora has been found to extend southward to the Chesapeake Bay and Potomac river, where it blends with that of the Potomac formation. It likewise recurs in Alabama and Mississippi, where large collections have already been made, and it will probably be traced much farther.

The forms other than dicotyledons that characterize the Potomac formation—ferns, equiseta, cycads, and conifers—have been found in the Kootanie formation of the British Northwest Territories and at Great Falls, Montana; and during the summer of 1891 a flora was brought to light in the Trinity division of the great Comanche series of Texas which embodies the same types and is probably of the same age.

The Upper Cretaceous flora, which is also very rich and has been made known in many parts of Europe, in Greenland, and in British America, shows some advance toward that of the Tertiary, especially in the presence of palms, but also in the more modern character of both its dicotyledons and its less advanced types. Distinct from this and occupying the extreme Upper Cretaceous, perhaps extending into the Eocene, is the great Laramie formation of the Rocky Mountain region. Its flora is remarkable both in its character and its abundance. Notwithstanding its modern aspect, containing as it does several now living species, it still embraces a great number of wholly peculiar forms, some of which seem to be of South American type. This interesting flora is as yet only partially known to the world, and is still the object of active research.

The Tertiary Flora.—In the geological history of the earth there have been two great periods during which the deposition of vegetable matter has played a leading *rôle*—great shoaling periods, they may be called—resulting in extensive coal-beds, and in and about these, immense deposits of fossil plants. These periods were the Carboniferous and the Tertiary, or, in a more restricted sense, the coal-measures and the Eo-Miocene. No other periods can be compared with these from this point of view, and they seem to mark the completion of a great cycle in the ages.

The dicotyledons predominate in the Tertiary flora, and the generalities of its features have been already given in what has been said of the geological history of that type. The flora of the Tertiary is also so great and so varied that any detailed description of it would carry this article far beyond its prescribed limits. Probably half of all known species of fossil plants occur in the Tertiary, and these not only represent every one of the great types of vegetation that have been passed in review, but they also represent a great number of the orders and genera of the present flora of the earth. A few general conclusions drawn from the facts are therefore all that can, with propriety, be added:

1. Everything indicates that the flora of the Tertiary was directly derived from that of the Cretaceous, and has in turn given birth to the flora of the present day.

2. In the Eocene Tertiary a luxuriant vegetation covered the northern portion of the North American continent, Northern Asia, and the arctic lands as far north as Grinnel Land, lat. 81° 46′ N., and some 400 species of chiefly arborescent plants are represented in this arctic flora.

3. The number of arctic American Tertiary species found in European deposits of the same age is so large as to warrant the inference that there was a land connection between the two continents during this age. This community of character has also been considered indicative of the colonization of Europe by the American flora in the Miocene age, and the plane-tree of the Old World has been shown to have had an American origin. Moreover the similarity of the flora of Japan to that of Eastern North America indicates that there was a land-connection between North America and Asia during Tertiary time.

The Neophytic Flora.—The properly geological record of plant-life practically closes with the Miocene. The Plio-Pleistocene flora is very small, and most of the forms occurring in it are still living. The remainder are found upon comparison to resemble living ones more or less closely, which lessens the interest usually felt in them. The Auriferous Gravels of California and Australia contain, however, a good number of apparently extinct species represented chiefly in the former case by leaf-impressions and in the latter by fruits and seeds. Pleistocene plant-bearing deposits occur in many parts of Europe, notably at Utznach and Dürnten in Switzerland, at Cannstatt in France, and on the Norfolk, Suffolk, and Sussex coasts of England. They are also known in North America, as at Green's creek on the Ottawa river in Canada, near Columbus, Ky., on the Mississippi river, and at Boaz in Graves County of the same State. Dr. Nathorst has long been studying the glacial-drift deposits of Northern Europe to find remains of glacial vegetation, and has discovered many species. Some of the localities are as far south as Switzerland, Würtemberg, Bavaria, and Hungary. Prolonged study of the geographical distribution of living plants, in connection with the above-mentioned facts, has led to the following general conclusion: With the approach of the glacial period the flora of the Tertiary, where it could retreat, was driven southward; where it could not, it was destroyed, and even the lowlands were occupied by an arctic vegetation. When at length, however, the climate moderated after the ice period, these boreal plants moved northward or climbed the mountains, where they found a permanent arctic temperature. The more ancient flora that had been driven southward then gradually resumed its northward march, and, greatly modified by its long exile and wanderings, slowly reclaimed the less elevated territory, forming ultimately the present flora of the temperate zone.

Dominant Types of Geologic Ages.—A retrospective glance over the successive ages of geologic time, as stamped each by its peculiar flora, will make it possible to select in each case some type of plants which may be said to characterize that age, to dominate it, as it were, and reign for the time being over all other types. Thus the Eophytic age may be called the reign of protophytes; the Cambrian and Silurian taken together, the reign of algæ; the Devonian and Carboniferous taken together, the reign of pteridophytes; the Triassic and Jurassic taken together, the reign of gymnosperms; and the Cretaceous and Tertiary taken together, the reign of dicotyledons. The algæ culminated in the Upper Silurian; the ferns, lepidophytes, and calamites in the coal-measures; the cycads in the Oölite; the conifers in the Cretaceous; the palms in the Eocene; and the apetalous and polypetalous dicotyledons in the Miocene. The present may be regarded as the age of liliaceous and glumaceous monocotyledons and gamopetalous dicotyledons.

Relation of Fossil Plants to Biology in General.—The discovery and careful study of such large numbers of plant-forms occurring in the different geological formations have greatly enlarged the fund of knowledge relative to the history and development of plants, and led to extensive modifications in the prevailing system of classification.

Only a few of the more important of these results can be presented here.

It was formerly supposed that the structure of the stem constituted the most fundamental character in the classification of phanerogams, and that sub-kingdom was accordingly subdivided primarily into those possessing the endogenous and exogenous structures respectively. This classification naturally grouped the gymnosperms with the dicotyledonous angiosperms, leaving the monocotyledons to constitute a distinct class supposed to be lower in organization than any of these. But the order of appearance of these several types in the past history of the earth, as set forth above, showed that the gymnosperms antedated the monocotyledons by a vast period, and almost demonstrated their direct development out of the early cryptogams. At first it was sought to take advantage of this to disprove the true course of evolution of plant-life from the lower to the higher types; but, on the one hand, closer study of the internal structure of the gymnosperms soon showed that this was widely unlike that of the dicotyledons, while on the other, the investigations of German botanists established the real genetic relationship between the reproductive apparatus and function in gymnosperms and the higher cryptogams. Both these results may now be regarded as established in their general aspects, and discussion is narrowed down to the minor details. This affiliates the *Cycadaceæ* and *Coniferæ* with the cryptogams and separates the gymnosperms from the dicotyledons as forming a far earlier and less developed type of vegetation. The monocotyledons, possessing the closed ovary in common with the dicotyledons, can now be appropriately united with the latter to form the true angiosperms, giving to their endogenous structure its proper subordinate rank in the classification. To add to the force of these modifications it has more recently been discovered that a number of the more highly developed cryptogams of Paleozoic time acquired the exogenous structure. Such is the case with *Sigillaria*, *Stigmaria*, *Calamites*, *Calamodendron*, and other less prominent types. The truth seems to be that in the process of development in plants the exogenous structure has been attained in varying degrees along several ascending lines, and that there is a different kind of exogeny in the calamite, the lepidophyte, the cycad, the conifer, and the dicotyledonous angiosperm, while something resembling exogeny has been shown to exist in certain fossil ferns and in certain living monocotyledons.

Fossil plants also clearly illustrate the much wider truth that progress in organic development takes place by means of an irregular succession of new departures or fresh ramifications from the older or lower parts of the generally advancing trunk by a process which has been called *sympodial dichotomy*, and is not in any sense a continuous chain or linear series. The ancient types that reached so high a degree of development became extinct, while lower and less perfect types underwent advantageous modification and were perpetuated. In other words, evolution takes place through the extinction of trunk lines of descent and the persistence of unspecialized types—through the origination out of the lower, less differentiated forms of potentially higher types of structure, i. e. types of structure better adapted to their environment, while the forms that have become specialized and attained the maximum development possible for that type of structure, unable to change, succumb to the changing environment. Thus broadly viewed the law of evolution holds strictly throughout the geological history of the vegetable kingdom; that is to say, progress from the lower to the higher types went on with the advance of geologic time, and there was a general upward tendency in structural development through the great periods of geology. Although the highest forms of all the most ancient types have become extinct they have always been succeeded by higher types, and although the lower forms of these earliest types have sometimes persisted, they have always remained subordinate to the great ruling types that have distanced them in the race for life.

Bibliography.—The following are a few of the most important modern works that treat the subject of fossil plants either in a general or a popular way: W. Ph. Schimper, *Traité de Paléontologie Végétale* (Paris, 1869–74; text in 3 vols. 8vo, Atlas 4to); G. Saporta, *Le Monde des Plantes avant l'apparition de l'homme* (1 vol., Paris, 1879); A. Schenk, *Die fossilen Pflanzenreste* (1 vol., Breslau, 1888); Lester F. Ward, *Sketch of Paleobotany* (in Fifth Annual Report U. S. Geological Survey for 1883–84, pp. 363–452, Washington, 1885); J. W. Dawson, *The Geological History of Plants* (International Scientific Series, vol. lxi., 1 vol., New York, 1888); Schimper and Schenk, *Paläophytologie*, being Part II. of Zittel's *Handbuch der Paläontologie* (Munich and Leipzig, 1890); H. Solms-Laubach, *Fossil Botany* (translated from the German, 1 vol., Oxford, 1891).

Lester F. Ward.

Planula [Lat., liter., little plane]: a stage in the development of Cœlenterates, etc., in which a solid, two-layered embryo is developed, not by typical gastrulation (see Embryology), but by a cutting off of the inner ends of the cells of an earlier stage.

Plaquemine, plăăk'meen': town; capital of Iberville parish, La.; on the Mississippi river, and the Texas and Pacific Railway; 20 miles S. of Baton Rouge, 85 miles W. by N. of New Orleans (for location, see map of Louisiana, ref. 10–E). It is a shipping-point for cotton and sugar, and has sawmills and shingle-mills, barrel-factory, a State bank, the Academy of St. Basil, and a daily and two weekly newspapers. Pop. (1880) 2,061; (1890) 3,222; (1900) 3,590.

Plasma: See Blood; also Chalcedony.

Plassey, Battle of: See Clive.

Plaster [O. Eng. *plaster*, from Lat. **plas'trum*, *emplastrum* = Gr. ἔμπλαστρον, plaster, deriv. of ἐμπλάσσειν, daub on, stuff in; ἐν, in + πλάσσειν, to mould]: in pharmacy, an adhesive mixture of lead oxide and a fatty acid, or a resinous and fatty compound, often medicated, designed to be spread upon leather, linen, or even paper, and then applied to some portion of the human body. Plasters have a considerable use in medicine, and especially in surgery, where strips of adhesive plaster are employed for many purposes.

Plastering: See Stucco.

Plaster-of-Paris: See Gypsum.

Platæ'æ (in Gr. Πλαταιαί, or Πλάταια): ancient city of Greece, in Bœotia; on the northern slope of Mt. Cithæron; famous as the place where in 479 B.C. the Greeks under Pausanias totally routed the Persians under Mardonius. The city was destroyed by the Thebans, in 427 and in 374 B.C., but was both times rebuilt, and existed in the sixth century A.D. Remains of it are still visible near the village of Kokhla. The site was excavated by the American School of Classical Studies at Athens in 1889. See *American Journal of Archæology* (1889), pp. 428–439, and 1890, pp. 108–111.

Revised by J. R. S. Sterrett.

Plata, La: See Argentine Republic.

Plata, La (city): See La Plata.

Platanis'tidæ [Mod. Lat., named from *Platanis'ta*, the typical genus, from Lat. *platanis'ta* = Gr. πλατανιστής, an animal of the Ganges, perhaps the susu]: a family of the toothed cetaceans, allied to the dolphins and represented by the singular susus of the Indian rivers. The form is dolphin-like except as to the head, which is distinguished by its upraised forehead and its small eyes; the blow-hole is longitudinal; the beak is elongated; the cervical vertebræ are all separate; the costal cartilages remain unossified; the maxillary bones are remarkable for their large bony, incurved crests; the teeth are simple and destitute of cingulum or tubercle. The family is represented by a single known genus, with two species—(1) *Platanista gangetica*, inhabiting the Ganges and Brahmaputra and their tributaries; and (2) *P. indi*, found in the river Indus. They rarely exceed the length of 7 feet. Although the body appears to be adapted for swiftness, they are said to be rather sluggish animals; they prey upon fish, like their salt-water relatives.

Revised by F. A. Lucas.

Plata, Rio de la (in English often called *River Plate*): an inlet in the southeastern coast of South America; properly the estuary of the river Paraná (*q. v.*), but also receiving the Uruguay. It separates Uruguay on the N. from the Argentine Republic on the S. W. It is about 190 miles long and 143 miles wide at the mouth; the depth varies from 2½ to 10 fathoms; and the strong currents make navigation difficult. During storms, especially the *pamperos* of the winter months (May to October), the Plata is more dangerous than the open sea. The best harbor is that of Montevideo; there are no good natural ones on the Argentine side, landing being obstructed by wide shallows; a partial remedy has been formed in the artificial port of La Plata. The Rio de la Plata drains, by the Paraná, Paraguay and Uruguay, an area of about 1,100,000 sq. miles. H. H. S.

Plateau: a term introduced by the French geographer Buache in the eighteenth century, to designate elevated regions of somewhat even surface. Like plains, the greater number of plateaus are built of essentially horizontal strata, either sedimentary beds or lava-sheets. The effort to distinguish between plains and plateaus at some definite limit of altitude is not successful, because it introduces an arbitrary division where nature exhibits many gradations. The Great Plains of the U. S. are known as plains, although only their eastern border is below the altitude that is usually adopted as separating the two classes of forms. On the other hand, the term plateau is often justly applied to an upland having a moderate altitude above sea-level, but rising over a lower plain by a well-marked escarpment, as in the case of the Niagara limestone plateau of Western New York. Plateau is not an appropriate name for elevated basins, like the parks of the Rocky Mountains in Colorado or the Vale of Kashmir in the Himalaya Mountains, which are closely walled in on all sides by higher land; nor is the word well used to refer to the unseen foundation-mass of land above which mountains rise and into which valleys are not yet cut, although it is employed in this sense by some geographers.

Lofty plateaus are seldom so level as lowland plains; for example, the plateaus of Arizona are great blocks of country, 6,000 to 10,000 feet in altitude, separated from one another by profound divisional planes or "faults," each block having a slight inclination and a slightly different altitude from that of its neighbor; yet the *llano estacado* or stockaded plain of Western Texas, with an altitude of 3,000 or 4,000 feet, is remarkably smooth over great areas, being compared to the surface of the sea; its margin, however, is eroded into deep valleys and isolated outliers.

Owing to their height, plateaus may attain a great diversity and intensity of relief under the action of denuding forces, as in the high plateaus of Utah, whose marginal cliffs or escarpments are profoundly gashed by colossal ravines, or the plateaus of Arizona, which are trenched across by the cañon of the Colorado River (*q. v.*). Like lofty mountains, the uplands of lofty plateaus are cooler and generally better watered than the surrounding lowlands; thus one of the plateaus of Utah is named the Aquarius, from bearing streams and forests while overlooking arid and desert lower lands; but when, in spite of being high, plateaus are sheltered on the side toward the sea by yet more lofty mountains, they are dry, and instead of suffering dissection by outflowing streams, they may gather the waste from the adjacent higher slopes and build up their surface. Thus the broad interior plateau of Tibet, with an altitude of 12,000 or 14,000 feet, bordered on the S. by the towering Himalaya and broken by various mountain ranges, is an arid region, with glaring sun and strong dusty winds by day, and cold, relatively calm nights.

When plateaus are well dissected little of the even surface of the original upland may remain, the region being thoroughly invaded by irregularly branching valleys. The greater part of the Alleghany plateau is in this stage of development. In the northeastern part its inequality of form is so great as to give it the name of Catskill Mountains. In West Virginia it is deeply trenched by many valleys, notably by the canyon of New river, over 1,000 feet deep beneath the remaining portion of the upland, all of which is diversified by ramifying river branches. In Northern Alabama relatively large blocks of even upland remain between wide open valleys. Plateaus in this stage of varied form and strong relief are less easily occupied than in earlier or later stages. The people dwelling in strongly dissected plateaus have a difficult life; they can not move about easily, and their advance in civilization is slow.

In later stages of denudation the valleys within the plateaus widen and consume the greater part of the uplands, leaving only isolated masses, such as occur on a moderate scale in Saxon Switzerland, or with much greater magnitude in the interior of British Guiana, where great table-mountains—Roraima and its fellows—rise to commanding altitudes, descending on all sides by steep cliffs of 1,000 or more feet to the surrounding lower lands. Similar dissected plateaus and table-mountains of sandstone and lava beds are found in the plateau region of Abyssinia.

Denudation of Plateaus.—In the progress of denudation of a great plateau-mass the weaker strata are selected for faster consumption by the atmospheric forces, while the interbedded harder strata stand out in bold escarpments or cliffs. Thus in Eastern Utah, when standing on the margin of one of the higher plateaus at an altitude of 11,000 feet or more, the eye ranges over a vast expanse of nearly level terraces, descending from one to the next by cliffs of strange aspect, which, as described by Dutton, "are truly marvelous, whether considered with respect to their magnitude, their seemingly interminable length, their great number, or their singular sculpture." Each terrace slopes gently back from its cliff-edge to the foot of the next cliff behind it. Each cliff, 1,000 to 1,500 feet in height, marks the occurrence of a relatively resistant stratum in the plateau-mass, the total thickness of strata being 10,000 feet. Although for the most part barren of vegetation, the color of the region is greatly varied through reds, yellows, grays, and whites. The features thus described are the result of extensive denudation, while the whole region stood at a much less elevation above sea-level; since then it has been broadly uplifted, and the revived rivers and streams have trenched deep and narrow cañons across the terraced surface. It is a marvelous region, not only from its gigantic illustration of plateau-topography, but from its emphatic teaching of the principles of land-sculpture on a huge scale. A good example of a plateau, of gently ascending surface, terminating in a bold escarpment, is found in the Rauhe Alp and the associated uplands of Würtemberg. A series of similar forms of moderate altitude occurs on either side of Rheims in Northeastern France. These forms are of interest in their influence on products and occupations in populations of closely adjacent areas, above and below the escarpment.

Plateaus of another class possess an even surface in spite of being composed of disordered rocks, being in fact old mountain regions reduced to lowlands by long-continued denudation (see Plain), and then broadly elevated to greater altitude. The plateaus thus formed are never so smooth as the younger plains of the first class; when elevated they are again attacked by streams, and thus diversified in the manner already described for the other class of plateaus; but the valleys are still generally arranged in the prevailing trend of the former mountains, and the intervening plateau uplands therefore present a linear grouping quite unlike the remnants of plateaus of horizontal structure, in which the disposition of the interstream uplands and spurs is excessively irregular. Plateaus of the first class frequently possess well-marked cliffs that rim around their remnant masses, continuous for many miles; plateaus of the second class never possess these forms, but, on account of the tilted and disordered structure of their rocks, are worn into a ridge-like topography. While plateaus of the first class are built of unaltered sedimentary rocks or lava-sheets, those of the second class are often built of greatly disturbed metamorphic sedimentary rocks, or of foliated or massive crystalline rocks, such as prevailed deep within the original mountain mass, now laid bare by denudation. The mineral products of the two classes of plateaus are therefore quite unlike, the second class being much the richer in rarer minerals and in metallic ores.

The broad plateau-like uplands of the Ardennes, along the Franco-Belgian boundary and extending northeastward into Germany, are examples of the second class of plateaus: they are not yet much dissected, but are here and there deeply trenched, as by the Rhine, the Moselle, and the Meuse. The Black Forest is a highland of the same nature, but it was never so well worn down when a lowland, and it is now more dissected since its elevation. The Scotch highlands repeat the same features, but rise to a greater height, and are much interrupted by the opening of their deep glens. Much of the interior of the Scandinavian peninsula seems to belong in this class of forms; but it is still overlooked by so many bold eminences that were not consumed before its elevation to its present altitude that it is commonly classed with mountains; it is, moreover, traversed by deep valleys whose lower courses are submerged, producing the renowned fiords of the Norwegian coast. In the U. S. the highlands of Southeastern New York constitute a dissected plateau, although the relatively even uplands are not to be recognized by the traveler through the deep gorge of the Hudson. As a whole, the uplands slope gently to the S. E., but they may be traced with even altitude southwestward into the highlands of New Jersey, and northeastward into the western plateau (Berkshire Hills) of Massachusetts and beyond. Occasional eminences, unconsumed when the region was a lowland, rise here and there above the plateau uplands, and of these Mt. Monadnock in Southwestern New Hampshire may be taken as the type. The middle part of the Sierra Nevada is an inclined plateau of the same kind,

falling abruptly into the interior basin of Nevada, descending gently to the valley of California, and deeply trenched by cañons. See PHYSIOGRAPHY. W. M. DAVIS.

Plateau, plăă'tō', JOSEPH ANTOINE FERDINAND: physicist; b. in Brussels, Oct. 14, 1801. He was an authority in physiological optics and capillarity, but his writings extend over nearly the entire range of experimental physics. He was Professor of Physics in the University of Ghent from 1835 till his death, Sept. 15, 1883, in spite of the fact that in middle life he had sacrificed his eyesight to his studies of subjective vision. Notwithstanding that misfortune, he continued his investigations in physiological optics, observing through the eyes of members of his family. Thus in his paper on *Persistence of Vision* (1876) his son Felix and his son-in-law Van der Mensbrugghe were his visual assistants. Plateau's researches upon the surface tension of liquids were collected in book-form under the title *Statique expérimentale et théorique des Liquides soumis aux seules Forces moléculaires* (2 vols., 1873). His latest work was a very complete bibliography of works on physiologieal optics.

E. L. NICHOLS.

Plated Ware: See ELECTRO-PLATING.

Platen-Hallermünde, plaa'ten-haa'ler-mün-de, Graf von: poet; b. at Ansbach, Bavaria, Oct. 24, 1796; was educated in the military academy of Munich; served for a short time as an officer in the Bavarian army, but soon tired of military life and studied philology and philosophy at Würzburg and Erlangen. A pension which the King of Bavaria granted him in 1826 enabled him to devote himself entirely to literary pursuits. He went to Italy, where he lived during the rest of his life. D. at Syracuse, Sicily, Dec. 5, 1835. Though Platen in his excellent dramatic satires *Die verhängnissvolle Gabel* (1826) and *Der romantische Oedipus* (1829) is one of the strongest assailants of the romantic school, his earliest literary productions, the dramas *Der gläserne Pantoffel* (1823) and *Der Schatz des Rhampsinit* (1824), distinctly show the influence of romanticism. Of this, however, he gradually freed himself by the study of the classic ancient poets as well as by the development of his innate feeling for perfect artistic form. His mastership in regard to the latter is especially evinced in his poems, which by the purity of their rhymes and the easy handling of the most difficult and complicated rhythms became the models for the younger generations of German poets. While the true poetic value of his lyric productions must be questioned, Platen's claims as a reformer of the technics of poetry remain undisputed. See Platen's *Sämmtliche Werke* (1876); Schack, *Pandora* (1890); B. L. Gildersleeve, *Essays and Studies* (1890). JULIUS GOEBEL.

Plathelminthes [Gr. πλατύς, flat + ἕλμινς (plur. ἕλμινθες), a parasitic worm]: one of the divisions of the animal kingdom, embracing worm-like forms with unjointed bodies, in which no cœlom is recognizable, and in which the alimentary canal has but a single opening (mouth). Some live freely, and others as parasites. The free forms occur some on the land, some in fresh water, and some in the sea. The parasitic forms, which are usually provided with one or more suckers for adhering to the host, affect almost every group of animals, fastening themselves to the exterior, or occurring in the alimentary tract or penetrating into the various tissues of the body. Three classes are recognized: Turbellaria, Trematoda, and Cestoidea. The Nemertines, formerly regarded as members of this group, are now assigned a different position. J. S. KINGSLEY.

Platin-iridium: See IRIDIUM.

Platinum, or **Plat'ina** [*platinum* is Mod. Lat., from Span. *platina*, platinum, dimin. of *plata*, silver]: a whitish, steel-gray metal, malleable, very ductile, and as unalterable by ordinary agencies as gold. It occurs in the native state, and in this form its specific gravity ranges from 16 to 19, and its hardness upon the mineralogical scale from 4 to 4·5, being harder than either gold or silver, and a little softer than iron. When fused and refined, however, it is as soft as copper, and the gravity is increased to 21·5. The conductivity for heat at 12° C. is 8·4; for electricity of the annealed metal at 0° C. is 16·4; silver = 100. This metal was first discovered in Choco, South America, and was taken thence to Spain in 1735 by the traveler Ulloa. Its chemical and physical properties were studied by European chemists as early as 1750. The native mixture of metals from Siberia, called "polyxene," was analyzed in 1828 by Berzelius, who found it to contain iron, rhodium, iridium, palladium, copper, and osmium, the amount of platinum ranging from 73 to 86·5 per cent.

Platinum is found, like gold, chiefly in alluvial deposits, in rounded grains, *pépites* or nuggets, or in flattened scales worn smooth by attrition in the gravel of river-beds. It is there associated with gold and the other heavy metals, as iridium and iridosmine. Having nearly the same specific gravity as gold, it can not be separated from it by washing in the ordinary way, so that quicksilver, which will amalgamate with the gold and leave the platinum untouched, is used to effect the separation.

Daubrée has shown that a part, at least, of the metal from the Urals was originally imbedded with chromic iron in a serpentine rock derived from olivine. This view has been sustained by the discovery of platinum in place upon Mt. Soloncff, in an inclusion of chromite and serpentine in alternate bands with dolomite, in a country rock of olivine, or peridot, of the variety known as dunite. It has not been found, however, in regular veins in quartz, and its precise mode of occurrence is still obscure. A nugget of platinum weighing 104 grammes, associated with chromite, was found near Plattsburg, N. Y., and is believed to have been derived from serpentine rock. It has been discovered in the form of an arsenide in the Sudbury region, Ontario, Canada. This mineral, containing 52·57 per cent. of platinum, has been described under the name of sperrylite. It has the peculiar property of not being easily wetted by water, and the fine particles float on the surface. British Columbia has supplied a small amount of platinum annually since 1887. It is found in the beach-sands at Port Orford, Or., in small thin scales with osmiridium and other metals of the group. (See *Geol. Rec. Cal.*, p. 300.) The production, however, is only nominal, being incidental to gold-washing, the amount for the whole of the U. S. for 1890 being officially stated as 600 oz., and in 1898 225 oz., valued at $3,375. The metal is reported to have been found in New South Wales, but there is no notable production, and while the old localities of Columbia, Brazil, and Borneo may contribute somewhat to the total of the world's supply, the great bulk of the metal is produced in Russia from gravel deposits upon the western slope of the Ural Mountains in the government of Perm, where it is found on various private properties and state lands. In the mining district of Goroblagodat there are seventy allotments, or claims. The product of platinum is subject to a tax of 3 per cent. for leasehold claims and 4 per cent. for the freehold. There are two establishments in St. Petersburg for refining crude platinum ore, polyxene, but the greater portion of the product is exported in its crude state. Although the deposits were discovered in 1819, actual working for production of the metal did not begin until 1824, when rich deposits were found in the Nijnii-Tagilsk district.

From 1828 to 1845 platinum was coined and used as money in Russia in pieces of 3, 6, and 12 roubles; the total value of the platinum coinage was 4,250,000 roubles. During this period the production of platinum was much stimulated. When the coinage was stopped the production almost ceased for some years, but it revived in 1859. From that time the production has been variable according to the demand and price. From 1886 to 1890 the average yearly product was 206 pouds, equivalent to about 3,375 kilog., or 7,425 lb. avoir. The total production of crude platinum in Russia from 1824 to 1890, inclusive, was 6,373 pouds.

At present the most productive deposits are those at Nijnii-Tagilsk, belonging to Prince Donato, and those belonging to Count Shuvalov. In 1890 there were 5,853 men engaged in the production of platinum.

Nearly all the native platinum from the Urals is magnetic. Some masses have true polarity and hold iron filings like magnetic iron ore. There were several specimens of this kind in the collection sent to the Paris Exposition in 1867 by Prince Demidoff. One specimen at Paris was 6 inches in its greatest diameter, and weighed 13 lb. troy. A mass weighing 21 lb. is preserved in the Demidoff cabinet. Masses weighing from 9 to 12 lb. were shown by the Russian Government at Philadelphia 1876. A specimen weighing 4,728 grammes, and perfect in form, was shown at Vienna in 1873.

Platinum is infusible in any ordinary furnace, but melts freely in the flame of the oxyhydrogen or Hare furnace, and in the electric arc. Its melting-point is given as 1,779° C. When heated beyond fusion it begins to volatilize. The fused metal absorbs oxygen and "spits" on cooling. At a red heat it occludes hydrogen, which it retains on cooling. It has the property of condensing oxygen upon its surface,

and the gas so condensed has a high degree of chemical activity shown particularly in spongy platinum and Platinum Black (*q. v.*). At a red heat platinum permits hydrogen to pass through it, but is not permeable to oxygen, nitrogen, or carbonic acid. At a white heat it is easily welded, which permits of large masses being made from scraps and from platinum sponge.

Achard as early as 1784 worked the metal by alloying it with arsenic, shaping it as desired, and then expelling the arsenic by heat. The process of working platinum sponge into compact metal by compression, usually credited to Wollaston, is said to have originated with Thomas Cock, of England, about the year 1800. Since the production of large homogeneous masses by fusion before the oxyhydrogen flame, these processes have been abandoned. Dr. Hare, of Philadelphia, originated the modern method of fusion. As early as the year 1837 he melted 28 oz. into one homogeneous malleable mass. Deville and Debray, of Paris, perfected this method, and now ingots weighing 200 lb. or more are readily cast. An ingot of this weight was exhibited by Johnson & Matthey at the London Exhibition of 1862. A regulus of platin-iridium which weighed a quarter of a ton was made in 1874 for the metric commission in Paris.

The chief solvent of the metal is aqua regia, and the chloride is the most important salt. Platinum forms alloys with gold and silver and with many of the more fusible metals. These alloys are more fusible than pure platinum. When combined with iridium it forms an alloy of great hardness, especially well adapted for gun-vents and for standard weights and measures. The alloy known as platin-iridium is used for the manufacture of standard meters, and is melted in lime-crucibles upon Deville's method. For details of the process for the purification of platinum and its fusion in large quantities reference should be made to the memoirs of Deville and Debray upon platinum and the associated metals. Gold is used as the solder for platinum, but the best joints are made by the autogenic method. Molten platinum is regarded as the best standard of light.

The invention of the incandescent electrical lamp caused a great demand for platinum wire. It is estimated that the quantity required increased from nothing in 1880 to 55,000 oz. in 1892. Large quantities are consumed yearly for dental purposes, probably 35,000 oz. in the U. S. and 25,000 oz. in England. About 80,000 oz. are required yearly for sulphuric-acid stills. Chemists and jewelers require some 20,000 oz., making the entire consumption about 215,000 oz. yearly, of which probably 30 to 40 per cent. is old scrap (see *Eng. and Min. Jour.*, lv., 194). The U. S. importations of platinum for 1900 were 7,767 lb.

The price of platinum varies greatly: In Dec., 1891, it commanded $12 per oz. in New York; in Jan., 1892, $10.50; in Mar., 1892, it fell to $9. For the results of researches on the platinum metals and compounds, reference is made to a series of articles by Prof. Wolcott Gibbs in *The American Journal of Science*, xxix., 1860; xxxi., p. 63; xxxiv., p. 342; xxxvii., p. 57.

W. P. Blake.

Platinum Black: a finely divided form of platinum, resembling soot; discovered by Liebig. It has the property of condensing gases upon its surface in a remarkable degree. It absorbs many times its bulk of oxygen gas, and gives it off in contact with alcohol or ether, forming new compounds. It is capable of taking up 800 times its own volume of oxygen, and is a most active catalytic agent. Platinum sponge is another form of the metal, porous and slightly coherent, obtained by heating to redness the double chloride of platinum and ammonium. It also condenses gases upon its surface, and becomes red-hot in a current of hydrogen gas and inflames the gas. The hydrogen lamp of Döbereiner, a scientific toy used to a limited extent for producing a light before the discovery of friction matches, was based upon this property of platinum sponge.

W. P. Blake.

Pla'to [= Lat. = Gr. πλάτων, Plato, a nickname given him from his broad shoulders, deriv. of πλατύς, broad, his true name being *Aristocles* (Ἀριστοκλῆς)]: a Greek philosopher, who was born 429 B. C., and died at the age of eighty-one years. Solon and Codrus were both reckoned among his ancestors. With the opinions of all previous philosophers he seems to have been familiar. There are stories of his travels in Egypt and the East, but they rest on little or no foundation in his own writings. Aristotle shows an intimate acquaintance with his doctrines, but tells us hardly anything about him personally. The accounts given first by writers who lived many centuries after him, such as Proclus and Iamblichus, are of no value; and yet there is no philosopher of antiquity with whom we have the means of so close an acquaintance. There was one teacher whom he has made most familiar to us, and from whom, in turn, we become most familiar with the pupil: Plato and Socrates are inseparable names. They are one power in the world's movement. This view can be held without diminishing the value or the position of either. Plato is not the mere reporter, neither is Socrates the merely ideal sketch. The identity of the two minds appears especially in the *doctrine of ideas*. It is this, more than anything else, that gives character to the Platonic philosophy. It is, too, the doctrine which shows how far from the truth is the prevailing notion of this philosophy, as mystical, transcendental, imaginative, far removed from what is called "common sense" or "positive knowledge." "Nothing so clear," says the young man Simmias in the *Phædo*, "as this doctrine of reminiscence, and the ideas of the fair and the good thus awakened in the soul." The word *idea* is used in two different yet closely related aspects. An idea is, in the first place, what the mind adds to a sensation, so as to make it rational. Without it the sense is ἄλογος, as Plato supposed the animal to be (a view, in fact, held by Aristotle as well as Plato), mere sense, and of itself incapable of becoming anything more. His illustrations are drawn mainly from the mathematical ideas. In attempting to follow him here the utmost brevity must be consulted. Let us image to ourselves a confused mass of spots or points, such as the spatterings of a paint-brush thrown at hazard upon a canvas. There is visible, at first, no order, no idea —nothing for the mind, all for the sense. As far as the soul is concerned, there seems *nothing* there—or rather *no thing* since it is *form* of some kind that makes a *thing*; that is, a thing thinkable, a *res* or *reality* for the mind. The animal and the man see at first the same, neither more nor less. So far as sense is concerned, the former may even have the keener vision. The human subject at last beholds the dawning of something supersensual, though the light has come from himself. Even in a single point he sees something more than the point. It is the idea of unity. The spatterings begin to assume form, or the soul is waking up to give its own forms to the formless. He is rising above sense. He begins to see *continuity*, or the rudiments of line-extension. He looks more steadily; there is something more than mere lineality; rectilineality, or *straightness*, is coming into view. It may be a mere approach to it; for the cognition of defect, or deviation, or *non-straightness*, is just as positive an evidence of some supersensual measuring-rule or idea as the most perfect agreement. In all this he not only *cognizes*, but *re-cognizes*. This supersensual thing has an interest for him beyond anything of sense. There is beauty in it. He seems to *know* it, although it never may have crossed his sense before. Has he imagined it? What, then, called out that supersensual power? A closer gaze sees not only a series of points forming one straight line (or evenness, τὸ ἴσον), but another seeming to hold to it a peculiar relation. There is the equality, or the approach to equality, of angular spaces. Here is a new beauty, a new interest, which could not have come from lines, perfect or imperfect, inclining to each other in any manner however irregular. There is no name as yet, but the soul sees perpendicularity, and delights in it as satisfying its idea. In the same way it sees parallelism. It is another aspect of the τὸ ἴσον. It sees relation; it sees ratio, multiple, proportion. In this way one might go through the infinite range of the mathematical ideas. Their teaching is really ἀνάμνησις, recollection, but not merely the recollection of one object of sense by another, as of Simmias by Cebes, but the true calling up of something *in the soul* at the sight of some outward object serving as its perfect or imperfect diagram. It is that which gives intelligibility to the object, making it a real thing for the mind—its own creation, in fact, instead of the *tohu* and *bohu*, the utter formlessness of sense.

In an analogous way are seen the ideas of the *fair* and the *good*. The emotional mingles with them all. In the sight of a straight line even there is beauty, interest, emotion, something of the soul's own; and this is because, like all beauty, it is in some way soul seeing soul, and rejoicing at the sight. If such an appearance were made by nature, it only shows that ideas are older still, fashioning the laws and *powers* of nature in harmony with their forms and equalities. Or it is like the emotion of the boys in the *Meno* and the *Theætetus*, as Socrates, in his obstetric way,

delivers them of their mental births: it is something which they felt they had ever *known*, but did not *know* that they *knew* it. Even experience, here, teaches an *a priori* truth, strange as that may seem. A man need only carefully examine the difference in his own feelings between the learning of an inductive truth wholly from without, and the soul's recognition of an idea in geometry, in morals, or in æsthetics.

Now, this is not mystical or transcendental or a mere play upon words, as the followers of Mill would call it. It is clear as the light itself. It is, as has been said, the true doctrine of "common sense," of the κοινῶν ἐννοιῶν, and Plato is the most lucid of all writers in bringing it out. When a young man sees it, his mode of thinking, his philosophical and, in some respects, his theological, temperament is changed for ever.

Another Platonic doctrine, somewhat different from this, though often confounded with it, is that of *universals* as real existences. Nothing is more certain than that names for them are in language before the names of individuals; and that is one reason why Plato insists so much on dialectics as a mode of discovering universal truths. It is not generalization alone, but that within us, which makes us generalize, instead of being content with individual sense-objects. Without it we should be like the animal, who has no language, not from defect of vocal organs (for some are here superior to man), but because he has no inner or ideal world for which language is needed. We can not seek, says Plutarch, without some idea of that for which we are seeking. We must have some notion of universals before we can even think of classifying. *Humanity* is as real as the individual man, who becomes *man*—that is, who becomes *real*—by partaking of this divine creation. It was for this doctrine of universals that Plato was ever a favorite with the best of the Christian Fathers, the Schoolmen, and the Reformers. In the old Nominalism of Epicurus, especially as revived by Abelard, they saw the dissolution of all faith, even as the best thinkers now regard it as threatening the interest of all true science. If individuals are the only realities, it can not stop short of individual atoms. All forms are but accidental phenomena; there are no species; all are reduced to arbitrary classifications, having no standard but the ever-varying assimilations of sense.

Connected with *ideas* is Plato's doctrine of pre-existence. Did he mean an individual pre-existence? He sometimes seems to accommodate his language to such a conception. In the highly imaginative *Phædrus*, Socrates has something to say of unborn souls "riding on the supercelestial sphere." On the other hand, it is easy to see that to maintain such a pre-existence of *individual* souls in a former sense-world, like the present, would destroy the argument in the *Phædo*. The true ideal reminiscence is gone. It would only be a sense-notice in this life, recalling a preceding sense-notice in another. The whole of that immortal argument is based upon the fact of a sense-experience here, calling up an idea belonging to the very constitution of the soul regarded as lying back of all sense. It is the pre-existence, then, of something belonging to all rational souls, and by partaking of which they become rational as they are born into this life. "In the image of God made He man."

The doctrine of Plato, that evil dwells in matter, whether as an eternal or an acquired principle, might be regarded as a mere speculation, and in that sense comparatively harmless. It may be called, however, the great defect of the Platonic philosophy; not by making two eternals, but from the great practical mischief it works in its ethical teaching. It may be said to have given it ascetic features not derived from Pythagoras. It introduces a purgatorial idea into its otherwise most impressive system of future retribution; but worse than all is the view it gives of *sin* as mainly, if not wholly, belonging to the *flesh*. It is the φρόνημα σαρκός, taking the latter word literally for the very body itself, instead of using it, as Paul does, for all that is wrong in our perverted human nature. In consequence of this laying all evil upon the poor body, it ignores the sins of the spirit, or "lusts of the mind," as Paul calls them—the dire soul-sins, such as ambition, malice, revenge—that have little if anything to do with any corporeal constitution—or envy, that pure spiritual devilism, hatred of another's excellence, which a disembodied demon may be conceived as possessing in even a higher degree than the most fleshly man. These *soul-sins* are hardly mentioned by Plato at all. He stands in striking contrast with the Greek poets here, as his doctrine is equally opposed to a sound ethical psychology. The body would soon be all right, a σῶμα πνευματικόν, in fact, if the soul, the original corrupter, were perfectly pure; and yet to get away from this body, as the seat of evil, is represented, even in the *Phædon*, as the most morally deserving of human efforts.

To compensate for this great defect there is the noble argument, presented in so many places, that *virtue*, the good, the ἀγαθόν, inseparable from the καλόν, the fair, is the end of the rational life, instead of happiness, the ἡδύ, the pleasant, the agreeable, evermore resolving itself, in its more refined as well as its grosser forms, into pleasurable sensations as its ultimate analysis. If *happiness* be the *end*, whether of the individual or of the universe, then *virtue* is a *means*, a subordinate thing; and that is a position which Plato could not bear. It was not a compromise between Hedonism and Cyreneacism, that is, an identifying virtue with happiness, and making the latter, in the end, the unfailing accompaniment of the former, or, as it is commonly expressed, virtue its own reward. Any such thought of compensation would have destroyed the Platonic idea: "Men must serve God, or serve the good, for naught." See the picture of "the superlatively righteous man" (ὁ δικαιότατος ἀνήρ, in the second book of the *Republic*, 360, 361). He has the ring of Gyges that gives invisibility; he can do all evil with impunity and without reproach; yet is he righteous still. He may be the very opposite of this, having the reputation of unrighteousness, and no means of ever reversing the unjust decision; yet is he righteous still. The picture, even thus far, tries our Christian faith, but it does not stop here. He may be made to endure the severest pains, with no prospect of deliverance either now or at any other time; yet he is righteous still. The hope of compensation must have no place on the canvas. Finally, says this strange painter, what may a man thus conditioned expect from his fellow men? Wonderful is the answer: Ὁ δίκαιος, οὕτω διακείμενος, μαστιγώσεται, στρεβλώσεται, δεδήσεται, καὶ, τελευτῶν, πάντα κακὰ παθὼν, ἀνασχινδυλευθήσεται (The righteous man in this state will be scourged; he will suffer dislocating tortures; he shall be bound with cords, and, finally, after suffering all evils, he shall be impaled or crucified.) It is not at all strange that some of the Christian Fathers were almost inclined to regard this as a prophecy of Him, "the Prince and Perfecter of Faith," who, "instead of the joy set before him (ἀντὶ χαρᾶς), endured the cross, despising shame," that we might be "partakers of his righteousness." In another place (*Gorg.*, 494, 495) the same exhausting process is pursued in respect to *pleasure*. The ἡδύ, or happiness, if it is the end of being, becomes simply a question of *quantity*. It is the amount that is to be considered, whether it be the glut of some exquisite moment, or a thinner pleasure hoarded for its rarity and spread over a longer period. The cultivated Cyrenean has no right to talk of his refined happiness and to condemn that of others as gross and low. If the ἡδύ is the ἀγαθόν, then it constitutes the ἀγαθὸς ἀνήρ, and the man who gets the most of it is "the better man." Then, too, if the world were one huge ζῷον, so made as to be quivering forever with the maximum of ecstatic sensational delight, that would be the best of all possible worlds. Discard the ἀγαθόν as the end of life, and the maxim *De gustibus non est disputandum* becomes the highest ethical rule. Happiness in that case is only to be judged by its degree or its intensity. If there are real differences in pleasures, so that some may be called *good* and others *bad*, then there must be some more ultimate principle, not resolving itself into happiness or into "self-rewarding virtues," according to which their respective ranks and moral values are to be determined. The argument is unanswerable, and this gives rise to a like extreme statement in the opposite direction. Some of the lowest pleasures, as they are called, excel all others in the fullness of their pleasing sensations. Let the man who chooses this have it for his portion to all eternity—no palling, no abatement; one everlasting succession of never-paining, never-cloying, pleasurable, and even ecstatic, emotion. The Almighty might have made it so. He has, indeed, most mercifully put Nature in the way, making her his executioner, instead of the lawgiver, as a certain kind of modern ethics are inclined to regard it. Plato, however, presents it as an ethical and æsthetical supposition. What should we think of one who had chosen, and to whom there was permitted, for ever, such an uncloyed existence? The answer is most dramatically brought out of the moral feeling, even of the sensualist. Socrates but gives back to him his own rising thoughts: "Such an existence, would it not be δεινὸς καὶ αἰσχρός—awful and shame-

ful?" "Would he not be ἄθλιος, a very *wretch* indeed, not in the sense of pain, but as denoting the extreme of degradation and perdition, abhorrent to the rational mind?"

What is called Plato's hedonic view is carried even into the state. As he says, in the beginning of the fourth book and in other parts of the *Republic*, the object of government is not so much to make men happier or richer as to secure a healthy civic organism—ὅπως ὅτι μάλιστα ὅλη ἡ πόλις —"for in such a commonwealth may we best hope to find righteousness." There is the same idea in the *Gorgias*, that the true statesman is he who aims not to *please*, but to leave the people morally better, "healthier in their souls," than he found them.

There is one feature in the Platonic *Dialogues* which has not received the attention it deserves. Allusion is made to what are called the Platonic myths. For the more extensive and gorgeous of them the reader is referred to the close of the *Republic*, the *Phædon*, and the *Gorgias*; the first two setting forth the retributions of the unseen world, and the third the appalling scenes of the spiritual judgment "*for sins done in the body.*" Nowhere out of the writings of Paul does this expression assume a more terrific significance. The "sins done in the body," all appearing as marks in the soul, not one, the least, having failed in stamping itself upon the tablet of the eternal spiritual memory. There is the myth of *Prometheus* in the *Protagoras*, the fanciful myth of the *Phædrus*; the wholly original and splendid myth of the *Politicus*, setting forth the alternating cosmical periods, the one of the divine order, the other of Nature left to herself, when (in direct opposition to the latest scientific holdings) she inevitably begins to degenerate, as having in herself no principle of progression, or even of permanence, though even in her abandonment she may preserve some portions of the spermatic reasons that were sown during her diviner circuit.

Some dialogues, even quite long ones, seem to come to no result. These have been called *tentative*, sometimes skeptical. Socrates himself is made to style them the *kathartic*, sometimes the *kunegetic*. Their object is to evacuate the soul of error before the attempt to fill it with truth—to chase away the idols of the cavern in order to admit the sunlight with its realities; or, to use another figure, to test whether the idea so long sought proves to be, on its birth, a true offspring of the soul or nothing more than an ὠὸν ἀνεμιαῖον, an abortion, or *wind-egg*, to be cast away.

There have been various translations of Plato, such as those of Taylor, Sydenham, Victor Cousin, and others. The one, however, which for the English reader must supersede all others is that of Jowett. He has transferred this most spiritual and colloquial Greek into the most vivacious and, at the same time, idiomatic English. See Socrates, Idea, and Idealism, Philosophy, Plotinus, Immortality, Realism, and Soul. Revised by W. T. Harris.

Platt, Charles Adams: See the Appendix.

Platt, Thomas Collier: politician; b. in Owego, N. Y., July 15, 1833; was educated at Yale College, but early gave up the idea of a professional career; entered into business, was president of the Tioga National Bank, afterward of the United States Express Company; took an active part in politics, and was elected a member of Congress in 1873 and 1875. On Jan. 18, 1881, he was chosen U. S. Senator, but, on account of a disagreement between him and the executive with respect to the appointment of the collector of the port of New York, he resigned his seat on May 14, 1881. He was again elected to the U. S. Senate Jan., 1897.

Platt, William Henry: See the Appendix.

Plattdeutsch, or **Low Saxon**: the eastern branch of Low German. The term "Plattdeutsch" occurs first in the middle of the seventeenth century. Low Saxon is spoken in Northern Germany, its area covering about one-third of that of the German empire. It passes beyond the German boundary only toward the W., where it is found in the eastern provinces of the Netherlands. (See Dutch Language.) The boundary between Low Saxon and Low Frankish—and further on between Low Saxon and Midland German—lies E. of the Rhine, and may be roughly indicated by a line running from the southeast corner of the Zuyder Zee to a point a few miles beyond Elberfeld in the direction of Siegen. There it turns northeastward, running in an almost straight line to the Elbe, N. of Wittenberg. From Wittenberg the boundary-line takes its course eastward until it crosses the Spree near Lübben. There it again turns to the N. E., crosses the Oder at Fürstenberg, and finally reaches the Slavonic frontier in the Prussian province of Posen, near Birnbaum on the Warthe. In the east and north the boundary of the Low Saxon dialect coincides with that of the German language, which is, however, not exactly identical with that of the German empire.

There are, according to time and locality, several varieties of Low Saxon, viz.:

(1) *Old Saxon*, from the earliest times until about the end of the eleventh century. The earliest monument is a baptismal vow, composed for the mission among the heathen Saxons in 772 or soon afterward. The year 830 is generally assumed as the date of the most important work in Old Saxon, viz., the so-called *Heliand* (i. e. Saviour), a poem of about 6,000 lines in alliterative verse, narrating the life and death of the Saviour according to the four Gospels. Its author seems to have been a monk of the monastery Werden on the Ruhr. It is certain that the poem originated in the neighborhood of the Low Frankish dialect. For a long time the text of the *Heliand* was known from two fairly complete manuscripts (the *Cottonianus*, *C*, and the *Monacensis*, *M*) and a short fragment found in 1880 at Prague (and accordingly marked *P*). Another fragment (*V*) was discovered in Apr., 1894, by Prof. Zangemeister, of Heidelberg, in the Vatican Library at Rome. The same MS. in which this was found also contains several fragments (amounting altogether to 337 lines) of an Old Saxon *Genesis*, written like the *Heliand* in alliterative verse, and probably also the work of the author of the *Heliand*. This discovery is important in several respects, since it throws additional light on the question of the origin of the *Heliand*, and, among others, confirms the theory advanced in 1875 by Prof. Sievers that part (viz., about 600 lines) of the Anglo-Saxon *Genesis* was translated from an Old Saxon poem.

To the ninth and the beginning of the tenth century belong, furthermore, a formula of confession (apparently older than the *Heliand*), two charms, a fragment of a translation of one of Beda's homilies, two leaves (badly conserved) from a commentary to the Psalms, lists from two monasteries of taxes which they were entitled to collect, and finally several collections of glosses. Old Saxon dialect forms are recognizable, too, in one of the earliest and most important Old High German poems, the *Hildebrandslied*, which was transcribed into High Frankish from an Old Saxon original. Most of the remnants of Old Saxon literature come from the western part of the Saxon territory, especially from Westphalia and the districts near the area of the Low Frankish dialect. There existed at that time no common literary language in Low German, each scribe using, as a rule (i. e. unless he copied, more or less closely, the dialect of another manuscript), his own dialect. Toward the end of the tenth century literary production in Old Saxon apparently came to a stop; at least there is in tradition at that time a break which extends beyond the next 200 years.

(2) *Middle Low Saxon*, from the twelfth to the end of the sixteenth century. This period is distinguished from Old Saxon by differences similar to those that separate Middle Dutch from Old Dutch, or Middle High German from Old High German, the most noticeable among which is the transition of the earlier various vowels of inflectional endings into the one vowel *e*. There is every reason to believe that these changes took place gradually. The year 1100 is an approximative limit between the two periods, although, as far as literary tradition is concerned, the former ceases during the tenth century and the latter does not commence before the beginning of the thirteenth. The earliest poetical work in Middle Saxon appears to be the rhymed chronicle of Gandersheim (a convent in Brunswick, near the Hartz Mountains), written in 1216 by the priest Eberhard. Among the earliest prose works is the *Sachsenspiegel*, a description of the Saxon common and feudal law, made by the knight Eyke von Repechowe (or Repgau, in the duchy of Anhalt), probably between 1220 and 1230. This is one of the most important works in Low German and one of the chief sources of Germanic law. It was soon adopted as a legal code in Northern Germany and was imitated in Southern Germany by similar works, the best known of which is the *Schwabenspiegel*. To a cleric, who, like the author of the *Sachsenspiegel*, belonged to the family von Repgau in Anhalt, is due the first attempt in Middle Saxon historical prose, viz., the so-called *Saxon* or *Repgowish Chronicle*, written in or soon after the year 1237. It is noteworthy that most of the earlier Middle Low Saxon literature belongs to the region N. and E. of the Hartz Mountains, in the vicinity of Goslar, Blankenburg, Bernburg, and near the frontier of

those districts in which formerly Slavonic was spoken. Later on the center of literature is shifted northward, and a predominant position is occupied by the Hanse towns, Bremen, Hamburg, Lübeck, Lüneburg, Brunswick, Stralsund, Riga, and others. The culmination of Middle Low Saxon or, as it is generally termed, Middle Low German literature (from about 1350 to 1500) almost entirely coincides with that of the Hanseatic League. There is from the fourteenth century downward a remarkable uniformity in the literary language, which finds its explanation by the fact that the official language of the Hanseatic League (sometimes called *de ostersche Sprake*, the eastern language), or, in other words, the dialect of its metropolis, Lübeck, furnished the basis for a fixed literary language. The differences between the local dialects of Lübeck, Hamburg, Bremen, Lüneburg, Stralsund, and other towns of Northern Germany were from the outset very slight. Using in script the same dialect as Lübeck did not for these towns mean adopting a new but simply writing their own dialect. After this dialect had gained the rank of an official and literary language among the Northern German towns it was gradually adopted in literary usage in the southern and western parts of the Low Saxon territory, where it differed considerably from the local dialects. Traces, indeed, of local peculiarities are found in works written, e. g., in Brunswick or in Westphalia, but not to such an extent as we should find them if the scribes had really intended to write in their own dialect. Even in charters and private deeds the usage of local dialects is more and more superseded by that of the literary language. It is for this reason impossible to gain from our sources a correct idea of the condition of the Low German dialects at the Middle Saxon time. There is in Middle Low German after 1350 an extensive literature, both in poetry and in prose. Most of the poetical works lack in originality, and do not, with the exception of the beast-epic and of several ecclesiastical dramas, reach the standard of Middle High German literature. The best-known poem is the beast-epic *Reineke der Vos*, published at Lübeck in 1498. The work is a mere translation of the Dutch *Reinaert*. It follows closely that edition of *Reinaert's Historie* which about 1487 had been published by the Dutch schoolmaster Heinric van Alkmaer; but the unknown Low German author has translated so skillfully that his work reads like an original poem. It at once met with general favor and before 1662 there were 14 Low German editions, 7 Latin, 3 Danish, and 1 Swedish. As regards prose works, Middle Low German is in every respect superior to Middle High German. The prose style had been cultivated in Middle Saxon at an early date in legal, historical, and ecclesiastic writings. The authors even of those early works show a perfect command of the language, and we must admire, in translations as well as in works written originally in Low German, on the one hand a natural gift for narrating in a simple and entertaining manner, on the other hand a remarkable ability in expressing abstract thoughts and in easily handling difficult syntactical relations. Specimens of Low German prose of the best time are Detmar's *Chronic of Lübeck* (written between 1386 and 1400), the *Seelentrost* (a dogmatic work, preserved in several MSS., the earliest of which is from 1407), and the *Passional* (printed at Lübeck in 1488 and later, also found in earlier MSS.). After the beginning of the sixteenth century, when the Hanseatic League was losing its influence and High German began to occupy a predominant position in the Church and in literature, Low German entered upon a period of decline. The transition of the sixteenth to the seventeenth century marks the limit between Middle Saxon and Modern Saxon, since by that time High German had in Northern Germany become the recognized literary language.

(3) *Modern Low Saxon*, from about 1600 to the present time. While the present Low Saxon dialects differ considerably from Middle Low Saxon, there is but little difference between the language of the sixteenth and that of the early seventeenth century. Not a few Middle Low German books intended for the use of the people appeared in new editions in the first half of the seventeenth century, and in exceptional cases even later. The last Low German Bible was printed in 1621. With the exception of these posthumous works of Middle Low German literature, Low Saxon in the seventeenth and eighteenth centuries takes the position of a popular dialect, which is admitted into regular literature only occasionally and for special purposes—e. g. in rustic poems or in poems that ridicule current fashions and follies (especially those of the upper classes), or contrast Low German with High German. Here belong the *Veer Schertz Gedichte* (Four Humorous Poems), published in 1652 by Prof. Lauremberg (see Lauremberg, Johann), and in the eighteenth century several original poems (e. g. *Die hülflose Sassinne*) and translations of Vergil's *Eclogues* and of some of Horace's *Epistles and Satires* (partly published in 1729 and 1732, partly extant in a MS. volume of 1738), by the rector Caspar Abel. Low Saxon scenes occur in melodramas and comic operas of the sixteenth and the seventeenth centuries, the Low German peasant being a traditional favorite in the jester's part. Among the *Idyllen*, written in hexameters by the well-known poet Joh. Heinr. Voss, there are two in Low Saxon, viz., *De Winterawend* (1775) and *De Geldhapers* (1777). His example caused Joh. P. Hebel to publish in his native South German dialect his *Allemannische Gedichte*, which soon became popular, and in return encouraged Low Saxons to avail themselves more frequently of their dialect in poetry. There is at present an ample literature in Low Saxon, both in poetry and in prose, representing many local varieties of the dialect. The best-known modern authors in Plattdeutsch are Fritz Reuter (1810–74) and Klaus Groth (b. 1819). The former gained a prominent place among the German humorists by his *Ut mine Stromtid* (i. e. In my Farming Time), *Dörchläuchting* (i. e. His Highness), and other tales from Low German country life, written in the Mecklenburg dialect and collected under the name of *Olle Kamellen* (i. e. Old Stories). Groth's chief work is the *Quickborn* (i. e.—Spring of Life), a collection of poems written in the dialect of Ditmarschen (in Holstein), which were first published in 1852 and have gone through many editions since. While Reuter is an eminently realistic author, Groth's purpose was to write poems in which the Low German people might recognize themselves in an idealized form. Notwithstanding these and many other attempts to secure for the Plattdeutsch a place in literature, High German is at present in Northern Germany the language of literature, and also that of the school and the Church, of the Government, and of the educated classes. Low Saxon, as a spoken language, is losing ground from day to day. Even where the people still adhere to the Plattdeutsch, which as a rule is the case in the country districts, the genuine dialect is becoming adulterated by words and constructions borrowed from High German. On the other hand, the value of Low Saxon, both in its literary monuments and in its living dialects, as a means for investigating the development of German mental life and the history of the German language, is more and more appreciated. The center of the efforts that are made to this end is the Low German Dialect Society (*Verein für niederdeutsche Sprachforschung*), founded in 1875, whose publications consist of an annual volume (*Jahrbuch*), a monthly periodical (*Korrespondenzblatt*), a series of Low German texts (mostly reprints of earlier works), and a collection of dictionaries and grammatical studies. Among the works undertaken by individual scholars, the most important is the *Sprachatlas von Nord- und Mitteldeutschland*, which is being compiled, with the support of the German Government, by Dr. G. Wenker at Marburg. This author sent to every schoolteacher in Germany a sheet containing forty simple sentences in Modern German, and asked for a translation into the local dialects. These sentences were selected so as to contain certain words in which the peculiarities of the various dialects should appear. The 44,251 answers furnished him with the material for his maps. The first number of the *Sprachatlas*, containing six maps, appeared in 1881. Publication, however, was subsequently abandoned, and the author now gives his autograph maps to the Royal Library at Berlin for preservation. They are open to the inspection of scholars. The Modern Low Saxon dialects fall into two groups, viz., (1) Northeast Saxon, in Oldenburg, Bremen, Hanover, Brunswick, Hamburg, Holstein, Mecklenburg, Brandenburg, Pommern, East Prussia; (2) Westphalian, in the Prussian province of Westphalia and in the principality of Waldeck. The former are better known, since the writings of Reuter and Groth belong to that group. They are closely related to the Hanse dialect of Middle Low German literature. The Westphalian dialects are especially noteworthy on account of their vowel system, which to this day preserves many original features that were lost in the northeastern group more than 600 years ago. There are numerous local varieties in both groups.

References.* (*a*) *Old Saxon.*—Old Saxon literature is treated by R. Kögel in his *Geschichte der deutschen Litteratur*, vol. i., pt. 1 (Strassburg, 1894), p. 276, *seq.*, and in Paul's

* Works on Low German dialects in general are given under (*c*).

Grundriss der german. Philologie, vol. ii., pt. 1 (Strassburg, 1893), p. 198, *seq.* The best critical edition of the *Heliand* is the one by Sievers (Halle, 1878), which gives the MSS. *C* and *M*. The Prague fragment, *P*, was published by Lambel (Vienna, 1881), the Vatican fragment, *V* (with the Vatican fragments of the *Genesis*, by Zangemeister and Braune), in *Neue Heidelberger Jahrbücher*, iv., nr. 2 (Heidelberg, 1894). There are smaller editions, with vocabulary, by Rückert (Leipzig, 1876, with notes), Heyne (3d ed. Paderborn, 1883), and Behaghel (Halle, 1882). The best dictionary is Schmeller's *Glossarium Saxonicum* (Munich, 1840). The smaller Old Saxon texts are found in Heyne's *Kleinere altniederdeutsche Denkmäler* (2d ed. Paderborn, 1877). A new edition by J. H. Gallée is to appear at Leyden. For Old Saxon grammar, see Gallée's *Altsächsische Grammatik*, i. (Halle and Leyden, 1891), and W. Sehlüter, *Untersuchungen zur Geschichte d. altsächs. Sprache*, i. (Göttingen, 1892).

(*b*) *Middle Low Saxon.*—A brief sketch of Middle Low Saxon literature by H. Jellinghaus is found in Paul's *Grundriss*, ii., 1, p. 419, *seq.*; a fuller account of the poetry in Goedeke's *Deutsche Literaturgeschichte*, i., pp. 457–484. The Gandersheim chronicle was published by Weiland in *Deutsche Chroniken*, vol. ii., p. 397, *seq.* There is a critical edition of the *Sachsenspiegel*, by Homeyer, in 3 vols. (1835–44; vol. i. in 3d ed. 1861), and smaller editions by Weiske (6th ed. 1882) and by Lübben (1879). An edition of the *Saxon* or *Repgowish Chronicle*, by Weiland, appeared at Hanover in 1877. Recent editions (with vocabulary) of the Low Saxon *Reineke der Vos* are those by Lübben (Oldenburg, 1867), by K. Schröder (Leipzig, 1872), and by Prien (Halle, 1887). Many Middle Low Saxon texts are still unpublished. The elements of Middle Low Saxon grammar and specimens of various literary works are given in Lübben's *Mittelniederdeutsche Grammatik mit Chrestomathie und Glossar* (Leipzig, 1882). A comprehensive dictionary, in six volumes, was begun by Schiller in 1872 and finished by Lübben in 1881. There is a handy dictionary, in one volume, by Lübben and Walther (Norden, 1888).

Herrmann, *Bibliotheca Germanica* (Halle, 1878), p. 67, *seq.*; von Bahder, *Die deutsche Philologie* (Paderborn, 1883), p. 160, *seq.*; Kauffmann, in Paul's *Grundriss*, i. (1891), p. 968, *seq.*; Mentz, *Bibliographie der deutschen Mundartenforschung* (Leipzig, 1892); also the *Jahresbericht über germanische Philologie*, vol. i., *seq.* (Berlin, 1879, *seq.*). Important periodicals are *Die deutschen Mundarten* (vols. i.–vi., 1854–58; vol. vii., 1877); *Jahrbuch des Vereins für niederd. Sprachforschung* (vol. i., *seq.*, 1875, *seq.*); *Korrespondenzblatt des Vereins für niederd. Sprachforschung* (vol. i., *seq.*, 1874, *seq.*). There are several dialect maps, e. g. Bernhardi, *Sprachkarte von Deutschland* (2d ed. Cassel, 1849); Piper, *Die Verbreitung der deutschen Dialekte bis um das Jahr 1300* (Lahr, 1880). Laurenberg's *Veer Schertz Gedichte* have been reprinted by Braune (Halle, 1879). Selections from Abel's poems are given by Hofmeister in the *Jahrbuch* of the Low German Dialect Society, vol. viii., p. 115, *seq.* (collected by Gaedertz). There is a small *Plattdeutsches Wörterbuch zu Fritz Reuters Werken*, by Frehse (Wismar, 1867). Groth's *Quickborn* contains a brief but valuable glossary by K. Müllenhoff. A comprehensive collection of specimens of the various dialects is Firmenich's *Germaniens Völkerstimmen* (3 vols., Berlin, 1843–68). Grammars and dictionaries are: (1) Northeast Saxon: Nerger, *Grammatik des mecklenburgischen Dialekts* (Leipzig, 1869); *Versuch eines Bremisch-Niedersächsischen Wörterbuches* (6 vols., Bremen, 1767–1869); Ten Doornkaat-Koolmann, *Wörterbuch der ostfries. Sprache* (3 vols., Norden, 1879–84); Schambach, *Göttingisch-Grubenhagensches Idiotikon* (Hanover, 1858); Schütz, *Holsteinisches Idiotikon* (4 vols., Hamburg, 1800–06), etc. (2) Westphalian: Holthausen, *Die Soester Mundart* (Norden, 1886); Woeste, *Wörterbuch der Westfälischen Mundart* (Norden, 1882). On classification of modern dialects and differences between Northeast Saxon and Westphalian, see Jellinghaus, *Zur Einteilung der niederdeutschen Mundarten* (Kiel, 1884); Wenker, *Das rheinische Platt* (Düsseldorf, 1877); reports on Wenker's *Sprachatlas* in *Anzeiger f. dt. Alterthum* (Berlin, 1892, *seq.*); Jostes, *Schriftsprache und Volksdialekte* (in *Jahrbuch* of Low German Dialect Society, xi., p. 85, *seq.*); Collitz, *Ueber das vergleichende Studium der niederdeutschen Mundarten* (in *Korrespondenzblatt* of Low German Dialect Society, xi., p. 23, *seq.*) HERMANN COLLITZ.

Platter (or **Plater**), THOMAS: See the Appendix.

Platte River: a stream formed in Lincoln co., Neb., by the union of the North and South Forks. The former rises in the North Park, Col., receiving the Sweetwater, the Laramie, and other streams. The South Platte flows from the South Park of Colorado, and in its upper course is extensively utilized in irrigation and as a source of water-power. The united stream flows E., and reaches the Missouri at Plattsmouth. It is the widest affluent of the Missouri, but neither the largest in volume nor the longest. Its mouth is over 1,000 yards wide, but it is so shallow that it can nowhere be navigated with much success. Its valley is generally very fertile. The drainage area is estimated at 7,500 sq. miles. The Loup Fork and Elkhorn are the chief tributaries. Length of the main stream, 900 miles.

Platteville: city; Grant co., Wis.; on the Little Platte river, and the Chi. and N. W. and the Chi., Mil. and St. P. railways; 18 miles N. N. E. of Dubuque, Ia. (for location, see map of Wisconsin, ref. 7–C). It is in an agricultural and lead-mining region, contains a State normal school, a national bank with capital of $50,000, and two weekly newspapers, and has several flour- and planing-mills, foundries, etc. Pop. (1880) 2,687; (1890) 2,740; (1900) 3,340.

Plattsburg: village; capital of Clinton co., N. Y.; on the Saranac river at its entrance into Cumberland Bay, a part of Lake Champlain, and on the Chateaugay and the Del. and Hudson railways; 20 miles N. W. of Burlington, Vt., 155 miles N. of Albany (for location, see map of New York, ref. 1–J). It has an excellent harbor, good water-power from the lake, and a large lake commerce and lumber-trade. There are 4 national banks with combined capital of $400,000, a daily, 2 monthly, and 2 weekly periodicals, U. S. Government building, the finest U. S. army barracks in the Union, a State normal school, academy, 2 libraries, and woolen-, flour-, and saw-mills, several large pulp-mills, and 3 foundries, sewing-machine factory, and machine-shops. Plattsburg is becoming noted as a summer resort. It is the home of the Roman Catholic Summer School of America, an institution on the plan of Chautauqua. In Sept., 1814, Commodore McDonough gained a victory over a British fleet in Cumberland Bay, and Gen. Macomb repulsed a superior British force on land. Pop. (1880) 5,245: (1890) 7,010: (1900) 8,434. W. H. FERRELL, EDITOR OF "THE PRESS."

Plattsmouth: city (site acquired by the U. S. Government by treaty with the Indians in 1854, incorporated as a town in 1855); capital of Cass co., Neb. (for location, see map of Nebraska, ref. 10–H); at the confluence of the Platte and Missouri rivers; on the Burlington Route and the Mo. Pac. railways; 22 miles S. of Omaha. It is engaged in the grain-, cattle-, and lumber-trade, and has 4 cigar-factories, brick- and terra-cotta works, carriage- and wagon-factories, and the principal shops of the Burlington Route Railway. There are 11 churches, 8 public-school buildings, including a high school that cost $25,000; court-house that cost $80,000; opera-house that cost $50,000; gas and electric light plants; improved water-works; new sewerage system; a national bank with capital of $50,000, and 2 State banks with capital of $100,000; and 3 daily and 3 weekly newspapers. Pop. (1880) 4,175; (1890) 8,392; (1900) 4,964. EDITOR OF "HERALD."

Platyp'tera [Mod. Lat., from Gr. πλατύς, broad + πτερόν, wing]: the order of insects which includes the white ants and which is also known as Isoptera. See ENTOMOLOGY and TERMITES.

Plat'ypus: See DUCKBILL and ORNITHORHYNCHIDÆ.

Plauen, plow'en: town; in the kingdom of Saxony, Germany; on the Elster; 78 miles by rail S. of Leipzig (see map of Germany, ref. 5–F). It has many good educational institutions, and large manufactures of paper, leather, muslin, cambric, jaconet, and other woolen and linen goods. Pop. (1890) 47,007.

Plau'tus, TITUS MACCIUS: play-writer; b. about 254 B. C. at Sarsina, in Umbria; went early to Rome, where he found employment with the actors; saved some money and started a business of his own, but failed; worked afterward at a hand-mill at Rome, and wrote, while thus employed, three comedies, which he succeeded in selling to the managers of the public festivals. They were well received, and from this time till his death, 184 B. C., he lived as a play-writer. The plots, and also generally the characters, of his plays he took from the Greek comedians, as Menander, Diphilus, Demophilus, and Philemon, but both underwent a very free treatment and a thorough Latinization, which may be in-

ferred from the general character of his dialogue; it is not only fluent and witty, but racy and taken fresh from the lips of the people. In his handling of the meters he shows great skill and versatility. While Terence, who was much more elegant, but also a much closer imitator of the Greeks, complains that the audience ran away from his plays to look at some rope-dancer, Plautus remained a favorite with the Romans down to the time of Diocletian, and was appreciated not only by the masses, but also by the most fastidious people—e. g. Cicero. According to Gellius, there existed 130 plays which bore his name, but the number of those unquestionably genuine Varro limited to twenty-one, which are doubtless those extant, namely, *Amphitruo*, *Asinaria*, *Aulularia*, *Bacchides*, *Captivi*, *Casina*, *Cistellaria*, *Curculio*, *Epidicus*, *Menæchmi*, *Mercator*, *Miles gloriosus*, *Mostellaria*, *Pœnulus*, *Persa*, *Pseudolus*, *Rudens*, *Stichus*, *Trinummus*, *Truculentus*, and *Vidularia*. Of the last of these, only fragments remain in the Ambrosian palimpsest. The great progress made in Plautine criticism in the nineteenth century is due largely to Ritschl and his school. The great critical edition begun by him was completed by Loewe, Goetz, and Schoell (Leipzig, 1871–94). A notable contribution also is Studemund's *Plauti fabularum reliquiæ Ambrosianæ* (Berlin, 1889). See also Ussing's complete edition with Latin notes (5 vols., Copenhagen, 1875–86). The Plautine literature is very extensive. Of annotated editions of separate plays may be mentioned *Captivi*, *Trinummus*, *Miles*, and *Menæchmi*, by Brix (Leipzig); *Miles*, *Mostellaria*, and *Pseudolus*, by Lorenz (Berlin); *Captivi*, by Hallidie; *Miles*, by Tyrrell; *Amphitruo*, by Palmer; *Rudens* and *Mostellaria*, by Sonnenschein; *Pseudolus*, by E. P. Morris. There is an English translation by Thornton and Warner (5 vols., 1767–74); another by Riley (2 vols., 1852).

Revised by M. Warren.

Playa: a name adopted from the Spanish (meaning, literally, shore or strand), for barren mud-plains, left by the evaporation of temporary lakes in arid regions. Typical examples occur in many of the desert valleys of the Great Basin, between the Rocky Mountains and Sierra Nevada. The winter is there the rainy season, and water collects in the valleys, forming shallow lakes, or "sinks," which are sometimes 200 or 300 sq. miles in area, but do not overflow. These lakes usually evaporate to dryness during the succeeding summer, but in other instances exist for a series of years, and are desiccated only during seasons of exceptional dryness. These "playa-lakes" are always alkaline, and of a yellowish color, owing to the exceedingly fine silt held in suspension. The deposits they leave on evaporating become so hard that the wheels of a heavy wagon leave but a slight impression on them. Their surfaces shrink and crack so as to resemble a tessellated pavement of cream-colored marble. In some instances the playas become coated with efflorescent salts during the summer, and then appear as if covered with drifting snow. Excavations made in the playa-earth fail to reveal a stratification of the deposit. In some instances land- and fresh-water shells are washed into the playa-lakes, and bones of land-animals and other stream-borne *débris* may be contributed by the streams which feed them. The valleys of the Great Basin are filled to the depth of many hundreds of feet with playa-deposits, and in some instances, judging from the character of the nearly buried mountain-peaks in the centers of broad deserts, the depth of filling must be measured by thousands of feet. Playa deposits bear a striking similarity to the loess of Asia, and seem to indicate the mode in which that deposit was formed. (See Loess.) Consult *Lake Lahontan*, *Monograph No. 11, United States Geological Survey*, and *Subaërial Deposits of the Arid Region of North America*, in *Geological Magazine*, vol. vi. (London, 1889).

Israel C. Russell.

Playfair, John: scientist; b. at Benvie, Forfarshire, Scotland, Mar. 10, 1748; educated at the University of St. Andrews, where he was distinguished for his attainments in natural history; became a minister of the Scotch Church 1772; held the living of Benvie 1773–82, when he resigned, removed to Edinburgh, and became a private tutor; was appointed assistant Professor of Mathematics in the University of Edinburgh 1785, Professor of Natural Philosophy 1805, and became in the same year general secretary of the Edinburgh Royal Society. He was a frequent contributor to the *Transactions* of that body, as well as to *The Edinburgh Review*; published *Illustrations of the Huttonian Theory of the Earth* (1802) and *Outlines of Natural Philosophy* (2 vols., 1812–16), containing the substance of his university lectures. Prof. Playfair was one of the precursors of the geological discoverers of the nineteenth century, and traveled in search of geological data in France, Switzerland, and Italy; left incomplete at his death an interesting *Dissertation on the Progress of Mathematical and Physical Science*, prepared for the supplement to the *Encyclopædia Britannica*. D. in Edinburgh July 19, 1819. A collected edition of his works was issued at Edinburgh (4 vols., 1822).

Revised by G. K. Gilbert.

Playfair, Lyon, Baron, K. C. B., F. R. S., LL. D.: scientist and statesman; b. at Meerut, in Bengal, May 21, 1819; educated at St. Andrews, Scotland, and the Andersonian University, Glasgow; studied chemistry under Graham and Liebig; engaged in industrial chemistry; became in 1843 Professor of Chemistry in the Royal Institution, and was in 1844 appointed on the commission constituted to examine into the sanitary condition of the large towns and populous districts of Great Britain; was appointed special commissioner in charge of the department of juries at the London exhibition of 1851, and in 1858 took the chair of Chemistry in the University of Edinburgh; became in 1868 a Liberal member of Parliament for the Universities of Edinburgh and Aberdeen; postmaster-general 1873–74; and held many other public positions of importance. He was made a K. C. B. in 1883 and raised to the peerage as Baron Playfair of St. Andrews in 1892. Together with W. Gregory he edited Liebig's *Chemistry in its Application to Agriculture and Physiology*, and is the author of numerous scientific memoirs—*Science in its Relation to Labor* (1853); *On the Food of Man in Relation to his Useful Work* (1865); *On Primary and Technical Education* (1870); *On Teaching, Universities, and Examining Boards* (1872); *Universities in their Relation to Professional Education* (1873); *Science in Relation to the Public Weal* (1885), and a variety of minor papers. D. in London, May 29, 1898.

Playing-cards: a kind of cards used for playing games. In modern times, and for the most common games, a pack of cards numbers fifty-two, and consists of four suits, two red (hearts and diamonds) and two black (clubs and spades), each suit comprising thirteen cards—three picture-cards, the king, queen, and knave; and ten pip-cards numbered from one, the ace, to ten. Chinese packs have only thirty cards—three suits of nine cards each, and three single cards, which rank higher than the others. In India and other countries there are various other kinds of playing-cards, and in Europe and America innumerable games require cards made especially for them.

The traditional history of European playing-cards derived them, like chess, from Asiatic sources. In one account it is asserted that the Saracens first introduced them into Spain and Italy, and that thence they spread to the rest of Europe, while other authorities attribute their origin to China and to India; but later investigations have thrown much doubt on all previous theories, and it is claimed that playing-cards originated in Europe itself, probably in the fourteenth century. Prior to their invention, cards with emblematic pictures were used in fortune-telling. The first packs for playing-purposes varied in the number of picture cards, but pip-cards were from the first divided into four suits. The modern hearts, diamonds, clubs, and spades were designated in Italy and Spain by cups, money, clubs, and swords, and in Germany by hearts, bells, acorns, and leaves. All symbolic meanings attached to these devices are fanciful.

The fifty-two card pack has existed substantially as at present since the fifteenth century. Indicators, or small indexes placed at the corners of the cards, were introduced in 1860. The modern production of playing-cards is enormous; the number of packs made annually runs up to the tens of millions. Their manufacture is a Government monopoly in Russia, and in Great Britain and the U. S. forms a subject of special taxation. The first games played were chiefly of chance, but the tendency has generally been toward those that require greater skill. See E. S. Taylor's *History of Playing-cards* (1865); Willshire, *Descriptive Catalogue of Cards in the British Museum* (1877); Van Rensselaer, *The Devil's Picture-books* (New York, 1890). For a description of the most common games, see Whist, Cassino, Euchre, Seven-up, etc.

S. A. Torrance.

Plea [M. Eng. *plee*, *plai*, *plait*, from O. Fr. *plait*, *plaid* < Lat. *pla'citum*, judgment, opinion, decision, liter., that which is pleasing to one, deriv. of *place're*, please]: in the common-law system of pleading, strictly, the first defense

or statement of fact interposed by the defendant in an action at law. (See PLEADING.) The term plea is also used as a name for an action or suit, as in the expression *court of common pleas* (see COURTS); also in the expression *pleas of the crown*, used to designate the criminal cases in England, in which the crown is the nominal PROSECUTOR (*q. v.*), although in fact the prosecutor is usually a private person.

F. STURGES ALLEN.

Pleading [deriv. of *plead* < M. Eng. *pleden*, *plaiden*, from O. Fr. *plaidier*, deriv. of *plaid*, plea. See PLEA]: in law, the making of the written allegations of the parties to an action, by which they state their respective claims and defenses and finally arrive at an issue of fact or of law, the decision of which will determine the judicial controversy between them; also (in the pl.) the allegations themselves. The pleadings of an action are a part of the steps comprehended under the general term PROCEDURE (*q. v.*), and, like the other parts of procedure, they are marked in the early stage by a rigid and excessive formality which is unsuited to the needs of our modern civilization. This early excessive formality and the subsequent modifications to meet the needs of changing circumstances can be noted here only as it has taken place in the law of England and the U. S. Only pleading in civil actions will be here treated of, since, although the terminologies in civil and criminal pleading differ, the principles are the same; thus, an *indictment* in a criminal action corresponds to the *declaration* or *complaint* of a civil action. Prior to the comprehensive reforms effected by statute there had long existed in England and the U. S. three different types or species of pleading—*common-law* pleading, *equity* pleading, and pleading by *allegation* (in the admiralty and ecclesiastical courts).

Common-law Pleading.—The common-law method prevailed exclusively in the courts of law. At a very early period the parties to a suit appeared in open court and made oral statements of their claims and defenses in the actual presence of the judges, which were at once written down by an officer of court; and this official transcript constituted the record of the proceedings. This oral mode seems to have continued until about the middle of the reign of Edward III. The common-law system, as it was subsequently perfected, arose from the substitution of written allegations in the place of these oral ones; and such writings, instead of being presented to the judges themselves sitting in court, were filed by the attorneys in the offices of the proper clerks.

The first pleading by the plaintiff was the *declaration*, which contained a statement of the cause of action made in a highly artificial, formal, and technical manner, and in language which differed widely from the English of ordinary narrative, and also indicated the particular form of action which the plaintiff had adopted.

If the defendant admitted the truth of the facts set forth by the plaintiff, but denied that in law they constituted the cause of action against him, his pleading was termed a *demurrer*. If, however, he desired to present an issue of fact, his pleading was styled the *plea*. The pleas by the defendant, and all subsequent pleadings in the suit by either of the parties, were separated into two classes—those by way of *traverse*, which directly denied all of the essential statements of fact contained in the preceding pleadings of the adverse party; and those by way of *confession and avoidance*, which admitted such statements to be true, but alleged other and new facts obviating and destroying their legal effect. If the defendant's plea was a traverse, an issue of fact was formed at once; if it was in confession and avoidance, the plaintiff must interpose a *replication* or a demurrer. In this manner the alternate allegations were conducted until either an issue of law was presented by a demurrer or an issue of fact by a direct affirmation on the one side and a denial thereof on the other; in actual practice, however, the series seldom was extended beyond the replication.

The rules which governed the common-law system and regulated the manner of making the averments were exceedingly refined, precise, and formal, and litigations were often decided upon the most technical questions, without reference to the merits of the controversy.

Equity Pleading.—In a case in equity the complainant's case was stated in a *bill of complaint* and the defendant's in an *answer*, and these ordinarily constituted the only pleadings, although a few particular defenses were set out in a form known as the *plea*. The parties were not subjected to the technical rules of the common law, but used a more natural mode of statement. The pleader averred not only the principal facts constituting the ground for relief or the defense, but also the evidence by which these facts were substantiated, so that the cause could often be decided upon these averments alone.

Pleading by Allegation.—The mode of pleading in the court of admiralty and the ecclesiastical courts was substantially identical, in respect to the matters required to be stated, with the equity method, and differed from that simply in the external form of the averments. Each important fact, together with the detail of evidence concerning it, was contained in a separate paragraph, technically termed an *allegation*, so that the LIBEL (*q. v.*) of the complaining party, which corresponded to the declaration and the bill of other courts, was separated into a number of distinct paragraphs or allegations, each relating to a single fact or occurrence.

Code Pleading.—The injustice and delay occasioned by these formal and cumbersome methods of pleading led to the series of reforms which have created the systems of code pleading. In the U. S. the Legislature of New York began the reform in 1848 by effecting for that State a radical change in these modes of pleading by the adoption of the Code of Civil Procedure; the reform thus inaugurated has extended into most of the States and Territories of the U. S. In England the first decisive step in this direction was made by the Common-law Procedure Act of 1854; but the system of code pleading was not fully adopted there until the Judicature Acts of 1873 and 1875 consolidated all the common-law and equity courts, and abolished the distinction between legal and equitable suits and the rules which governed the common-law pleading. The parties in all actions are required to state the facts constituting the ground of relief or the defense as they actually existed, in ordinary language, without any technical formality, and without any averments of evidence or of legal conclusions. In some of the States the first pleading by the plaintiff is denominated the *complaint*, in others the *petition*, while in England it is called the *statement of claim*. The only pleading of fact by the defendant is styled the *answer* in all of the several States, but in the English practice the *statement of defense*. Under certain circumstances the plaintiff must put in a *reply*, but the pleadings of fact can seldom extend beyond this point. The defendant may demur to the plaintiff's complaint, petition, or statement of claim, and to his reply; and the plaintiff may demur to the defendant's answer or statement of defense. The underlying principle of this reformed system is natural, correct, and at the same time truly scientific, but in its practical application there is yet much to be learned. See the works of Stephen, Chitty, Story, and Gould on *Pleading*; Odgers's *Principles of Pleading* (in England); Bishop's *Code Practice in Personal Actions* (in New York); and the *Reports of the Royal Commissioners on Practice and Pleading* (1829–34 and 1851–60); also the *American and English Encyclopædia of Law*.

JOHN NORTON POMEROY.
Revised by F. STURGES ALLEN.

Pleas of the Crown: See PLEA.

Pleasonton, ALFRED: soldier; b. in the District of Columbia, Dec., 1823; graduated at the U. S. Military Academy 1844; assigned to First Dragoons; captain Second Dragoons Mar., 1855; major Second Cavalry Feb., 1862. He took part in the war against Mexico, and served on frontier duty as acting assistant adjutant-general. In the civil war he served throughout the Virginia Peninsular campaign of 1862; appointed brigadier-general of volunteers July 16, 1862, he commanded in September the division of cavalry following Lee's army. He was engaged at Boonsboro, South Mountain, Antietam, and Fredericksburg; at Chancellorsville his action was most effective in checking the further advance of Stonewall Jackson's corps, which threatened to carry all before it. Promoted to be major-general in June, 1863, he was engaged in the actions preceding Gettysburg, where he also commanded in chief the cavalry; transferred to Missouri in 1864, he drove Gen. Price from the State. He received the brevets of lieutenant-colonel, colonel, brigadier- and major-general for gallantry in the field. Mustered out of the volunteer service Jan., 1866, he in 1868 resigned his commission in the regular army, and became U. S. collector of internal revenue. He was appointed major U. S. army Oct. 19, 1888; retired 1888. D. in Washington, D. C., Feb. 17, 1897.

Pleasure: See PAIN.

Plébiscite, plā'bi-seet' [Lat. *plebiscitum*]: in modern France, a decree of the whole nation obtained by universal suffrage, a proceeding which both Napoleon I. and Napoleon III. used in order to legitimize their *coups d'élat*. After the dissolution of the Directory, Nov. 9, 1799, Napoleon I. appealed to the nation in this way, and Napoleon III. did the same after the dissolution of the National Assembly, Dec. 2, 1851, the first *plébiscite*, in May, 1804, giving a majority of 3,572,399 votes; the second, in Nov., 1852, giving a majority of 8,157,752 votes. In the Roman republic a *plebiscilum* was a law passed at the *comitia tribula* by the *plebs* or commons on the rogation of a tribune, and was different from a *lex*, which was passed at the *comitia centuriata* by the *populus* or patricians on the rogation of a consul or other senatorian magistrate.

Plebs and Plebeians: See PATRICIAN.

Plecop'tera [Mod. Lat., from Gr. πλέκειν, twist + πτερόν, wing]: that order of insects which contains the so-called stone-flies (*Perlidæ*), and which receives its name from the fact that the broader hinder wing is folded, when at rest, beneath the other, much as in the grasshoppers. The larvæ are very abundant in fresh-water streams, where they crawl about beneath stones, etc., and furnish a considerable element in the food-supply of many fishes. In Europe several species are used for bait in fishing, one being called "yellow Sally" and another "willow-fly." See ENTOMOLOGY.

J. S. KINGSLEY.

Pledge: See PAWNBROKING and MORTGAGE.

Pleiade: name assumed by a group of seven Greek poets of the third century B. C., and in imitation of them by seven French poets of the sixteenth century, who, inspired by the revival of the study of classical letters, strove to renew French language and literature in their image. They were Pierre Ronsard, who came to be the leader of the movement, Joachim du Bellay, Remi Bellau, Jean Daurat, Pontus de Thyard, Antoine de Baif, and Étienne Jodelle. A. G. C.

Ple'iades, or **Plei'ades** [= Lat. = Gr. Πληιάδες and Πλειάδες; cf. πλεῖν, to sail, their rising indicating the beginning of the time of safe navigation]: in astronomy, a group of stars in the shoulder of Taurus, called "the seven stars," though to most eyes only six are visible, while keen eyes can see eleven. There are, however, hundreds of telescopic stars in the group, and Herschel has shown that they are, physically, closely related to each other. In Grecian mythology the seven stars were seven daughters of Atlas and Pleïone, one of whom (Sterope) became invisible from shame, because she had been embraced by a mortal. S. NEWCOMB.

Pleistocene Period [*pleistocene* is from Gr. πλεῖστος, most + καινός, new]: the latest division of geologic time, or the division succeeding the Neocene period and preceding historic time. The terms Quaternary era, Post-tertiary period, Glacial period, and Ice-age are synonyms. Most of the geologic periods are distinguished one from another by means of their faunas and floras, but the Pleistocene is primarily distinguished by peculiarities of its climatic history. The climate of the earth, or of a large part of it, was then colder than it had previously been for several geologic periods, and colder than it is at present.

Extent of Glaciation.—The most striking feature connected with this lowered temperature was the growth of mountain glaciers and the creation of immense ice-fields where none had existed before. The evidence of these changes is found not only in certain deposits of peculiar composition, but in equally peculiar types of topographic form. In unglaciated regions streams descend over successively gentler slopes from head to mouth. Lakes are of rare occurrence, being confined for the most part to deltas and to interior basins. In glaciated regions there is relatively little continuity of slope, lakes are abundant, and the courses of streams are irregular. In unglaciated regions the soil results from the disintegration and decomposition of the rock beneath, except that the alluvium along streams consists of gravel and finer particles brought down by the streams. In glaciated regions the soil is never derived directly from the rock beneath, but consists of material transported from a greater or less distance. This material, known as DRIFT (*q. v.*), differs from alluvium in that some of its bowlders are of great size, in that its transportation has not been simply down the slope, in that its materials are not generally rounded and sorted, and in other ways. Beneath the drift the bed-rock lies undecomposed, and its surface is usually polished or covered with parallel scratches and grooves. Deposits made by water are in general smooth of surface, and slope in the direction of the depositing current. Deposits from ice are of uneven surface, abounding in knolls and undrained hollows. By the aid of such data as these the following general facts have been learned with reference to the distribution of the Pleistocene ice. In North America the small glaciers of the Rocky Mountains and the Sierra Nevada, and the greater glaciers of Alaska, were all expanded, descending the mountain slopes to greater distances. Glaciers were also formed on many mountains where they no longer exist. The glaciers of the Alaskan mountains and the western mountains of British America extended so as to coalesce and fill the intervening valleys, producing an ice-field comparable with that of Greenland. At the same time a much larger field was formed in Northeastern America. Its northern limits are not yet determined, but it extended eastward to the Atlantic Ocean, westward nearly to the northwestern field just mentioned, and southward over the Great Lakes into the U. S. (See GEOLOGY, map No. 2.) New England was completely buried, nearly the whole of New York, and parts of New Jersey and Pennsylvania. The Ohio river was reached near Cincinnati, and the Missouri at many points. Indeed, the present courses of the Ohio and Missouri were largely determined by the position of the ice-front. In Europe the glaciers of the Pyrenees, Alps, and Caucasus were greatly extended. Those of Scandinavia not merely coalesced, but spread to immense distances eastward, southward, and southwestward, making an ice-field several times greater than that of Greenland. A large part of Russia, Poland, Denmark, and Holland, and parts of Germany and Belgium were covered, as also were the North Sea, the whole of Scotland and Ireland, and all but the southern extremity of England. In the Himalayas, Tian Shan, and other high mountains of Asia the local glaciers were increased. The combined ice-fields of Europe and North America were then equal to the present great ice-field of the Antarctic continent.

In the southern hemisphere the changes were equally significant, although less in areal extent by reason of the smaller ratio of land to water. It is believed that the Antarctic ice-field was extended. The mountain-glaciers of Patagonia were expanded, becoming confluent and overrunning the greater part of the peninsula, so as to produce a field little inferior to that of Greenland. The southern island of New Zealand was largely overrun by ice, and a few glaciers were created in Australia and South Africa.

Associated Phenomena.—Where the glaciers reached the ocean they broke up into icebergs, which distributed the detrital matter widely over the bottom of the sea, and some portions of this sea-bottom have since been lifted into land. Elsewhere ice-tongues served as dams, obstructing the free drainage of valleys and creating temporary lakes, by means of which iceberg drift was transported. Some of the most important of these occupied the basins of Lake Winnipeg and the Laurentian lakes, but instead of discharging to Hudson Bay and the Gulf of St. Lawrence, found outlet southward to the Mississippi and Ohio, and eastward to the Hudson. (See AGASSIZ, LAKE.) In regions of interior drainage the cooler climate, by diminishing evaporation and possibly by increasing rainfall, caused the creation or expansion of lakes which left permanent record in the form of beach-lines and sediments. Great Salt Lake, Utah, Pyramid Lake, Nevada, and the Caspian and Dead Seas of Asia were all greatly enlarged. (See BONNEVILLE, LAKE, and LAHONTAN, LAKE.) Coincident with the greatest expansion of glaciers were local changes in the relative altitude of land and sea, and to some extent the connection of these has been definitely established. Thus certain gravels, sands, and terraces on the plains bordering the Atlantic and Gulf coasts of the U. S. have been determined to be of Pleistocene age.

As the temperature fell, animals and plants of polar and temperate zones gradually worked toward the tropics, and as the temperature again rose they slowly migrated poleward. At each locality, therefore, there was a series of life-changes corresponding to the climatic changes, and to some extent these are recorded by fossils in contemporaneous deposits. They are recorded also by a peculiar isolation of various species upon mountain tops. During the period of rising temperature the plants and animals favored by low temperature were able to adjust themselves to changing conditions not only by migrating poleward, but also by ascending mountain slopes; and thus many mountain tracts in temperate regions came to be inhabited by colonies of plants and animals belonging to distant latitudes and separated

from cognate floras and faunas by wide intervals whose present climate is a complete barrier to intercommunication.

Cause of Climatic Changes.—One of the vexed questions of geology is the cause of the Pleistocene cold. One theory ascribes it to variations in the quantity of heat radiated by the sun. This theory is adequate, and, as regards the earth, simple; but it has not been widely entertained, because no satisfactory explanation has been offered of the postulated variation in solar radiation. A second theory is based on secular variations in the relation of the earth to the sun. The eccentricity of the earth's orbit varies slowly and irregularly, and it is computed that two important maxima of eccentricity have occurred at late geologic dates. The theoretic effect of high eccentricity is to produce a glacial climate in one hemisphere and a mild climate in the other, the difference depending on the relation of the solstices to perihelion. When these relations are reversed through precession, the climates of the two hemispheres would be interchanged, and such interchange should theoretically occur many times during each period of maximum eccentricity. This theory has received more attention and is more widely entertained than any other. A third theory assumes that the axis of rotation has changed its position with reference to the earth's surface, or, in other words, that the pole has wandered, carrying with it glacial conditions. This theory seems adequate, but there is no independent evidence that the pole has thus wandered, and a competent cause for any permanent or large change of position has not been discovered. A fourth theory appeals to geographic changes, especially changes in the distribution of land and water. As large aqueous precipitation is necessary to the formation of glaciers, their present distribution is greatly influenced by the relation of bodies of warm water to bodies of cold land. Thus ocean currents are important factors. The directions of ocean currents are determined by the distribution of land and water. It can readily be imagined that the land and water of the globe might be so distributed as to prevent, on the one hand, or greatly increase, on the other, the polar accumulations of ice, and the theory appeals to this possibility; but it has not yet been ascertained that the actual arrangement of land and water in Pleistocene time was such as to produce the climates which then existed. A fifth theory ascribes Pleistocene glaciation to a general and great uplifting of the regions in which it occurred. This cause is probably competent, but it has not been shown that the glaciated districts actually had great elevation at the time when their glaciers were formed. In the presence of so large a number of theories deserving serious consideration, it is needless to enumerate less plausible explanations, of which a considerable number have been suggested. The body of known facts is of such importance, and the body of pertinent and obtainable knowledge is so vast, that we may feel assured a satisfactory explanation will eventually be found.

Complexity of Pleistocene History.—In many places glacial deposits are overlain by peat or other deposits which could not have been formed beneath the ice, and these in turn are overlain by other glacial deposits. In this way it is shown that mountain glaciers and lowland ice-sheets advanced and retreated more than once. In the opinion of some students, such advances and retreats were numerous and of great amount, so that there were in effect a considerable number of glacial epochs. In the opinion of others, there were two principal glacial epochs, separated by an interglacial epoch, when the climate did not differ greatly from that of the present time. A third opinion recognizes but one great climatic revolution, this being characterized by minor oscillations, causing the ice margin to advance and retreat over narrow areas. When this question has been settled, an important contribution will have been made to the question of cause, for the current theory, founded on the astronomic history of eccentricity and precession, implies a long alternation of glacial and mild climates in each hemisphere, while the theories of varying solar energy and geographic change can most plausibly be appealed to in explanation of a single great climatic event.

Closely related to the question of complexity is the question of synchrony. While there is much evidence to show that the ancient glaciation of different continents and different hemispheres occurred in the same general portion of geologic time, it is as yet impossible to say whether the great climatic changes of widely separated regions occurred at the same time.

Literature.—Although the Pleistocene is the shortest of all the geologic periods, its literature is by far the most abundant. This is due largely to the fact that the Pleistocene deposits, being last formed, overlie all others, and are exceptionally prominent and accessible. From these abundant data it is possible to derive some comprehension of the complexity of the physical history of the period, and the field for discussion thus opened has proved fertile and attractive. It may fairly be assumed that the histories of other geologic periods are equally complex, and appear simple only from the paucity of data for their determination.

Additional information in regard to glacial sculpture may be found in the articles Glaciers and Mountain. (See also Drift and Geology.) The question of the unity or diversity of the period is discussed by Wright and Chamberlin in *The American Journal of Science* for 1892 and 1893. The following books and papers discuss the causes of the glacial climate, and describe the more important of the American Pleistocene phenomena: Chamberlin's *Hypotheses as to the Cause of the Glacial Period* (*American Geologist*, vol. viii., 1891); *Terminal Moraine of the Second Glacial Epoch* (*Third Annual Report, United States Geological Survey*, 1883); *Rock Scorings of the Great Ice Invasions* (*Seventh Annual Report, United States Geological Survey*, 1888); Croll's *Climate and Time* (1875), *Climate and Cosmology* (1885); Dawson's *Later Physiographical Geology of the Rocky Mountain Region of Canada* (*Transactions of the Royal Society of Canada*, vol. viii., 1890); Geikie's *Great Ice Age* (1873), *Fragments of Earth Lore* (1893); Gilbert's *Lake Bonneville* (*Monograph I., United States Geological Survey*, 1890); Wright's *Ice Age in America* (1887).

G. K. Gilbert.

Pleonasm [from Gr. πλεονασμός, superabundance, deriv. of πλεονάζειν, to be more than enough]: the use of more words than are strictly necessary for the bare expression of an idea. It involves the use of words whose idea is already contained in some other part of the statement, generally in some part which is syntactically different. It represents, though logically inaccurate, a natural linguistic method of enhancing and enforcing an idea, or of giving it clearer definition, and appears in the greatest variety of usages; thus, *like as if*, *from henceforth*, *most unkindest*, φεύγειν φυγῇ, to flee in flight, *the reason why he did this is because*, etc.

Benj. Ide Wheeler.

Plesiop'idæ [Mod. Lat., named from *Ple'siops*, the typical genus; Gr. πλησίος, near + ὤψ, ὠπός, eye, face]: a family of fishes of the order *Teleocephali*. In external appearance they have some resemblance to the American sunfishes, the body being oblong, compressed, and covered with moderate scales; the lateral line is interrupted; the head rounded anteriorly; the opercula unarmed; the mouth has a lateral cleft, and the upper jaw is moderately protractile; teeth small, on the jaws as well as palate; branchial apertures continuous below; branchiostegal rays six; dorsal elongated, with the spinous portion longer than the soft; anal with its soft part opposite that of the dorsal, and armed with three spines; pectorals with branched rays; ventrals each with a spine and four soft rays. These fishes are especially recognizable by the development of only four soft rays in the ventral fins. They inhabit the salt water, and extend from the Red Sea to the Pacific Ocean. The scientific name alludes to the approximation of the eyes, resulting from the narrow frontal bones.

Plesiosau'rus [Mod. Lat.; Gr. πλησίος, near + σαῦρος, lizard]: a genus of large extinct marine reptiles, which were abundant in Mesozoic time, but had no representatives in the Tertiary. The skull was small, and the teeth were in distinct sockets. The neck was much elongated, and the tail comparatively short. The limbs were in the form of paddles, resembling those of the turtles, and were nearly of the same size before and behind. Some members of the group were of enormous size, and others quite small. The genus *Plesiosaurus* is not rare in European formations, but has not been found in America, its chief representatives there being *Pantosaurus* in the Jurassic, and *Cimoliosaurus* in the Cretaceous.

O. C. Marsh.

Pleskov: See Pskov.

Pleth'ora [Mod. Lat., from Gr. πληθώρη, fullness, plethora, deriv. of πλῆθος, multitude; cf. πλήρης, full]: among older medical authorities, the condition now commonly called full-bloodedness. This excessive richness in the quantity or quality of the blood was thought to be indicated by the redness of the skin and mucous membranes, the full, bounding

pulses, the tendency to hæmorrhages and palpitations, and other symptoms. Modern investigation, however, has shown that these symptoms are the result of peculiarly vigorous circulation and not of excess of blood.

Plethysmograph: See RECORDING APPARATUS, PSYCHOLOGICAL, in the Appendix.

Pleu'ra [Mod. Lat., from Gr. πλευρά, rib, side]: a thin membrane that lines the cavities of the chest, extending over the external surface of the lungs. It consists of two closed sacs. The portion lining the chest is distinguished as the costal pleura, and is a sheet of elastic cellular tissue loosely attached to the ribs, muscles, and adjacent parts. That lining the lungs, known as the pulmonary pleura, is composed of a superficial layer of fine cellular tissue and a second elastic layer of coarser fibrous tissue, which materially assists in expiration. Both portions of the pleura are covered inside with a delicate layer of endothelium, and the narrow spaces inclosed in each sac are known as the pleural cavities, and are kept constantly supplied with a serous fluid which enables the opposite layers to glide easily upon each other in the movements of respiration.

In *entomology* the pleura is the side of the stethidium between the thorax and pectus. Revised by W. PEPPER.

Pleurisy, or **Pleuritis** [*pleurisy* is from Fr. *pleurésie* < Lat. *pleu'risis*, for earlier *pleuri'tis* = Gr. πλευρῖτις, pleurisy, deriv. of πλευρά, rib, side]: inflammation of the PLEURA (*q. v.*), acute or chronic. It may be what is called dry, with little or no effusion, or it may be accompanied by effusion. Pleurisy may be caused by exposure to cold, injuries to the membrane itself (traumatism), or the communication of inflammation from adjacent structures. This latter head includes many causes, such as inflammation of the lung, of the chest-wall, of the diaphragm, and of the organs contiguous to the wall of the chest and the diaphragm. Besides these, a very common cause of pleurisy is tuberculosis; and in patients who have repeated attacks of pleurisy this is probably almost always the cause. Rheumatism is also a cause of pleurisy, and it may occur in the course of fevers, especially in smallpox and scarlet fever. Blood-poisoning (septicæmia) is quite a common cause of pleurisy, and so is disease of the kidneys.

In the dry form of pleurisy the first change visible is a clouding of the cells on the surface of the pleura, so that it loses its beautiful transparent luster and looks opaque, reddened, slightly roughened, and is marked by minute congested blood-vessels. This congestion sometimes causes a rupture of small vessels and the pouring out (extravasation) of small quantities of blood beneath the surface layer of the pleura. After this there often form on the surface of the pleura patches of organized lymph (plastic exudate) like adherent flakes. At this stage of pleurisy the exudate may be reabsorbed and the patient may recover perfectly, or it may remain as an organized deposit on either the lung pleura (visceral pleura) or the pleura covering the chest-wall (parietal pleura), or that of the diaphragm or mediastinum. This form of pleurisy may also result in adhesions between the opposite pleural surface and the formation of patches of adhesion or of bands, narrow but of appreciable length, limiting the movement of the lung in the thoracic cavity.

In pleurisy with effusion (hydrothorax) there is poured out more or less excess of the fluid which ordinarily merely lubricates the pleural surfaces. When this effusion is small it may cause no appreciable trouble, and indeed entirely escape detection; when it is extensive, it may press the lung into a very small space, and so seriously interfere with respiration and circulation as to cause death. A pleuritic effusion may become purulent by the multiplication in it of pus cells. This constitutes empyema, a condition which endangers life, not only by mechanical pressure on the lung, but also by the impairment of the constitution incident to the presence in the body of what is practically a huge abscess. An empyema may remain for some time without communication with the outer air, or it may burrow its way out through the walls of the chest or the diaphragm, or into a bronchial tube. In the latter case the pus is discharged by coughing.

The symptoms of pleurisy are fever, pain in the side, difficulty in breathing, and often a dry, unproductive cough. A patient often finds it easier to lie upon the affected side, because the motion of the side is thereby restricted. There are general symptoms of illness, by which the disease may be distinguished from neuralgia or rheumatism of the chest-wall. The physical signs of dry pleurisy are very slight, consisting chiefly in the sound of rubbing (friction sound) between the two roughened pleural surfaces. In the stage of effusion the sounds are those to be expected from the displacement of the air vesicles of the lungs by a fluid. Percussion over the former discloses resonance, while there is dullness or flatness on percussion over the area occupied by fluid, whether this be serous or purulent. In pleurisy there is always some impairment of the motion of the side of the chest affected, and evidences of interference with the function of respiration, such as shortness of breath and imperfect aëration of the blood, are often plainly discernible by the eye. Where there is much effusion there is bulging of the affected side, and obliteration of the lines of depression which normally exist between each pair of ribs. With such effusions there is sometimes displacement of the heart and even encroachment upon the opposite side of the chest. After the fluid of pleuritic effusion has been absorbed, or that of empyema has been carried off or discharged, the crowded lung sometimes fails to expand again and to occupy the full lung space of its side of the chest. This may be due to permanent contraction of the lung, or to the formation, when it is contracted, of adhesions to the chest-wall, which prevent the lung from resuming its former dimensions. In either case the thorax becomes distorted by depression of the chest-wall under the pressure of the atmosphere, especially in young subjects.

The treatment of pleurisy without effusion is usually simple, consisting in measures to promote excretion from the bowels, from the kidneys, and from the skin, with rest in bed and judicious diet. No medicines are needed except such as contribute to these ends or as are used to allay pain. Pleurisy with effusion requires more treatment and often surgical measures to rid the chest of its accumulated fluid. When the effusion is serous it may be removed easily and simply by the operation of tapping the chest. The most perfect form of tapping is that by means of an instrument called "the aspirator," invented by a French physician, Dieulafoy. In this, a suction pump, attached to a tube and a hollow needle, is used to withdraw fluid from the chest. When the effusion of pleurisy is purulent, the accumulation must be treated on the same principles as those that govern the treatment of abscesses elsewhere in the cavities of the body. So long ago as the time of Hippocrates such cases were treated wisely and skillfully by surgical operation—that is, by making an incision through the chest-wall and allowing the fluid to come away. In modern times such abscess cavities are treated by opening, emptying, washing out—especially with medicated fluids—and prolonged drainage by means of the insertion of tubes, or even by the removal of a portion of a rib or ribs.

In itself pleurisy is not a very dangerous disease, but if it be caused by constitutional disease like tuberculosis, or if it occur in a patient with a poor constitution, or if it be unwisely managed, it may end in death or permanent disability. CHARLES W. DULLES.

Pleurisy-root: See ASCLEPIAS and BUTTERFLY-WEED.

Pleurodel'idæ [Mod. Lat., named from *Pleuro'deles*, the typical genus; Gr. πλευρά, side, ribs + δῆλος, visible]: a family of salamanders chiefly inhabiting the Old World. The palatines bear teeth on the inner margins; prefrontals as well as pterygoids are present; the frontals are broad, and not embraced by the parietals; the occipital condyles are sessile; the parasphenoid has no dentigerous plates; the vertebræ are only concave behind; the carpus and tarsus are ossified. The typical species has the ribs protruding through the sides of the body, in allusion to which the name *Pleurodeles* has been given. J. S. KINGSLEY.

Pleurodi'ra [Mod. Lat.; Gr. πλευρά, side + δειρή (dial. for δέρη), neck]: according to some authors, a sub-order of the order *Testudinata*, or tortoises; distinguished by the neck bending sideways and the incapability of retraction of the head completely under the carapace, and thus contrasting with those tortoises in which the neck bends in a vertical plane. The pelvis is fixed to the carapace and plastron. The group embraces families peculiar to the southern hemisphere and related forms found in the early epochs of the northern. The generally recognized families are *Podocnemididæ*, *Chelydidæ*, *Hydraspididæ*, *Pelomedusidæ*, and *Sternothæridæ*. Revised by D. S. JORDAN.

Pleuronec'tidæ [Mod. Lat., named from *Pleuronec'tes*, the typical genus; Gr. πλευρά, side + νήκτης, swimmer]: a family of fishes including the ordinary flat-fishes, such as flounders, turbots, halibuts, plaice, etc. It belongs to the

order *Heterosomata*. The body is always much compressed, with one of its sides (which is upward when the animal is reclining on its side) dark-colored, and the other (which is downward) generally white; the scales are variously developed (sometimes ctenoid, sometimes cycloid, and sometimes wanting); the head compressed; both eyes are on the same side, one being on or near the forehead, the other comparatively low down; opercula normal, unarmed; mouth terminal, and with an oblique lateral cleft and of various extent; branchial apertures continuous below; branchiostegal rays five to eight; dorsal elongated, extending generally from about the rostral region to near the caudal fin; anal fin also elongated, and extending about as far back as the dorsal; both are composed almost solely of articulated rays; caudal fin distinct from the dorsal and anal; pectorals on both sides; ventrals jugular. The skeleton has numerous vertebræ; pyloric cæca are generally developed, but in small number. The species of the family thus defined are distinguishable into three sub-families—(1) *Pleuronectinæ*, in which the mouth is small, and the supramaxillary ends before or under the front of the eye; (2) *Hippoglossinæ*, in which the mouth is large, and the supermaxillaries extend more or less under the eye, and the ventrals are lateral; and (3) *Rhombinæ*, in which the mouth is large, and the ventral fin on the dark side inserted on the ridge of the abdomen. The species are numerous, and are found distributed in every sea, and some of them ascend rivers. They live chiefly on sandy bottoms, and rest with their white side below and the dark one upturned. Although almost all have the eyeless side white or colorless, a few have dull spots on that side, and in some species it is colored like the eyed side. The very young have the body vertical in the water and the eyes symmetrical. In the process of development the body becomes horizontal, and the head is twisted or modified so that the eye of the lower side is transferred around or through the head to the opposite side. In the U. S. the most common species in the markets of the Eastern States are the small-mouthed flounder (*Pseudopleuronectes americanus*), a large-mouthed flounder (*Paralichthys dentatus*), and the halibut (*Hippoglossus hippoglossus*). The American species are mostly different from those of Europe, and the true turbot, like the true sole, has never been taken in American waters. Revised by D. S. Jordan.

Pleuro-pneumonia: one of the names by which the ordinary type of pneumonia (croupous pneumonia) has been designated. It signifies that the pleura or covering of the lung is inflamed at the same time as the lung itself. This is always the case in croupous pneumonia; but exceptionally the pleural involvement is of such prominence that the term pleuro-pneumonia seems specially applicable. W. P.

Pleuro-pneumonia (of cattle), or **Lung Plague**: a contagious febrile disease of cattle, characterized by a progressive interstitial pneumonia, in which the inflammatory process usually extends to the pleura.

It has been known from the time of the first written records of the diseases of animals. It has often followed in the wake of European armies, having been spread by the cattle carried along for food. This disease has existed in all countries of Europe, with the exception of Norway and Sweden, and has been carried by cattle from these infected countries to Great Britain, Africa, Australia, and North America. Lung plague usually spreads rapidly among the cattle of a country into which it is introduced, unless restrictive measures are adopted to prevent traffic in diseased and possibly diseased animals. In 1839 cattle from The Hague carried this malady to Cork, Ireland, and from this point the British Isles became infected. A British ship landed a cow suffering with pleuro-pneumonia at Brooklyn in 1843. Many cattle in the adjacent districts became infected from this source, and the disease gradually spread until herds were infected in several of the Eastern States. Subsequently shipments of diseased cattle carried pleuro-pneumonia to Kentucky, Indiana, Illinois, and Missouri. The disease has, however, been completely stamped out in the U. S. by the bureau of animal industry. The symptoms of lung plague are fever, dry muzzle, accelerated pulse and respiration, depression, cough, and the altered sounds upon auscultation and percussion that indicate pneumonia and pleurisy. In about one-half of the cases death occurs in from two to four weeks after the beginning of an attack. Of the remaining cases about equal numbers become chronic and recover. After death the lungs have a peculiar "marbled" appearance, due to the exudation of yellowish serum into the thick layers of connective tissue which separate the dark colored and hepatized areas of lung tissue. In advanced cases the lung becomes broken down and caseous in spots that range in size from that of a walnut to that of a child's head. These areas are encapsulated in a fibrous membrane. It sometimes happens that cattle that have apparently recovered convey the disease to others after several months or years have passed, and this is explained by the fact that these capsules may break, allowing their semi-fluid contents to escape.

No therapeusis that has been tried is of any value, so efforts to cure have been abandoned, and governments have made regulations providing for the quarantine of diseased and suspected animals and for the slaughter of all that are regarded as dangerous to healthy cattle. It was by the enforcement of these measures that the U. S. freed itself from pleuro-pneumonia, and the same measures are (1894) being employed in England with good prospects.

It is estimated that for a long series of years the annual loss to Great Britain from lung plague amounted to £2,000,000. It is impossible to estimate accurately the amount of loss caused by this disease in the U. S., but it is known to amount to several million dollars. Leonard Pearson.

Plevna (Bulgarian, *Pleven*): town of Bulgaria; on the Vid; 26 miles S. of the Danube (see map of Turkey, ref. 3-C). Here the Ottoman army under Osman Pasha was besieged by the Russians from July 18 to Dec. 10, 1877, and, after a desperate resistance, was forced to surrender, 43,000 men being taken prisoners. This was the critical event of the Russo-Turkish war. Pop. (1888) 14,307.

Plin'y (full Latin name *Gaius Plinius Secundus*), generally called **Pliny the Elder**: author; b. at *Novum Comum*, 23 A. D., of a noble and wealthy family; served in the army under Domitius Corbulo and Pomponius Secundus in Germany, where he composed *De Jaculatione Equestri* and began a history of the wars in Germany (*Bellorum Germaniæ libri xx.*); was in Rome again in 52; studied jurisprudence and began to practice. During Nero's reign he composed his *Studiosus*, in 3 books, and *Dubius Sermo*, in 8 books. According to a Greek inscription found in Arados, which Mommsen refers to Pliny, he served in the Jewish war in Syria in 70 and was afterward *procurator Syriæ*. We know also that he was procurator in Spain under Vespasian, and that he must have been in Gaul and Africa, but it is impossible to date his journeys. In Rome he lived in great intimacy with the Emperors Vespasian and Titus, and was suffocated by the eruption of Vesuvius in 79. There is a detailed and very interesting account of his death by his nephew, Pliny the Younger, in a letter to Tacitus (*Epist.*, vi. 16). He was a very prolific writer, but of his works only the *Historia Naturalis*, in 37 books, is extant, edited in 20 vols. by Panckoucke, with commentaries and notes (Paris, 1829–33), by Sillig (8 vols., Gotha, 1851–58), and by Detlefsen (6 vols., Berlin, 1866–73); translated into English by Philemon Holland (London, 1601), and in Bohn's Classical Library (6 vols., 1855).—His nephew, Gaius Plinius Cæcilius Secundus, generally called Pliny the Younger, b. 61 or 62 A. D. in Novum Comum, was adopted and educated by his uncle; served in the army in Syria; held several high offices (consul 100), but devoted most of his time to literary studies and the practice of law. He was an intimate friend of Tacitus and Trajan. According to Mommsen, he was legate proprætor of Bithynia, with consular power in 111 and 112 or 112 and 113, persecuting the Christians there in 112. There is no trace of him after this time. His *Panegyricus* and his *Epistolæ*, 10 books, were edited, with notes, by G. H. Schäfer (Leipzig, 1805) and G. E. Gierig (Leipzig, 1806); best critical ed. by Keil (Leipzig, 1870); *Epistolæ*, translated into English by Melmoth (1746), Lord Orrery (1759); summary in *Ancient Classics* (1872). See also Mommsen in *Hermes* (vol. iii., pp. 31–139). Revised by M. Warren.

Pliocene Period [*pliocene* is from Gr. πλείων, more + καινός, new]: the division of geologic time following the Miocene Period and preceding the Pleistocene. In the chronological system adopted by the U. S. Geological Survey for the geologic atlas of the U. S., the Miocene and Pliocene periods of earlier classifications are included in the Neocene Period (*q. v.*).

Pliohippus: See Horse, Fossil.

Ploce'idæ [Mod. Lat., named from *Plo'ceus*, the typical genus, from Gr. πλοκεύς, weaver, braider, deriv. of πλέκειν, twist, braid, weave]: a family of small finch-like birds, com-

prising the weaver-birds which in the tropical regions of the Old World hold the place of the finches of the temperate zone. The bill is strong and conical, the culmen advancing backward on the forehead and arched to the tip, which is entire; the wings are somewhat rounded, with the first quill remarkably short; the tarsi with long scutellæ in front. The family contains about 250 species. See WEAVER-BIRD. F. A. LUCAS.

Plombières, plōn'bi-ār': a small town in the department of Vosges, France; 14 miles S. of Épinal (see map of France, ref. 4–H). It is beautifully situated in the valley of the Angronne, a tributary of the Saone, and is noted for its thermal springs, much recommended for diseases of the liver, the digestive organs, and the skin. The springs have been used for medicinal purposes since the times of the Romans, but the present elegant bathing establishments were founded by Napoleon III. Pop. (1891) 1,869.

Plot'idæ [Mod. Lat., named from *Plo'tus*, the typical genus, from Gr. πλωτός, floating, sailing]: a family of water birds belonging to the order *Steganopodes*, and containing the darters. See DARTER.

Ploti'nus: philosopher; b. at Lycopolis, Egypt, about 205 A. D.; went to Alexandria in 232, and spent there ten years under the tutelage and instruction of Ammonius Saccas. In 242 he accompanied the Emperor Gordianus on his expedition against the Persians, in order to make himself acquainted with the philosophy of Persia and India; but the emperor was murdered in Mesopotamia in 243, and Plotinus repaired by Antiochia to Rome. Here he applied himself to the teaching of philosophy, attracted immense audiences, gained numerous disciples, and enjoyed great respect and confidence. In 269 he retired into solitude. D. at Puteoli, in Campania, the following year. The most famous of his disciples, Porphyrius, collected his works and wrote a biography of him. The collection comprises a great number of treatises on different subjects—on beauty, the immortality of the soul, the supreme good, the genesis of ideas, against the Gnostics, etc.—arranged in six divisions, each consisting of nine books, for which reason they are called *Enneads*. Parts have been translated into German and English (by Thomas Taylor into English, namely, six books of the first *Ennead*, two of the second, four of the third, four of the fourth, five of the fifth, and three of the sixth), the whole into French by Bouillet in 3 vols., with full commentary (Paris, 1857).

The philosophy of Plotinus is a vision rather than a system. The center of all that exists is the One, which is above intellect, if not above the good; in short, a God that does not create in any proper sense; the intellect "emanates" from it, not as its creation. The intellect in turn is of a divine nature, though secondary, and it alone is the creator of lower orders of being. From God emanates the soul of the world; from the soul of the world emanates the soul of man; and in this way the divine descends from sphere to sphere, forming itself into time and space and building up its own body, until at last it arrives at matter. The divine can form matter, but not penetrate it so as to prevent it from collapsing and returning into chaos. Matter is the seat of imperfection and evil; and the aim of life is to return from the polluting contact with it into the One. The connection between the soul and God is much deeper and more intimate than that between the soul and the body. In the third *Ennead*, book viii., chapters iii. and iv., is found the original of those fine poetic sayings attributed to Schelling and Oken, that reason dreams in the plant, feels in the animal, and thinks in man. Although the soul, with its power of vegetative, sensitive, intellectual, and rational life, actuates the body even in the most minute details of life, still it does not form one with it. Otherwise with respect to its union with God. "We move round him like a choral dance; even when we look from him we revolve about him; we do not always look at him, but when we do we have satisfaction and rest and the harmony which belongs to that divine movement. In this movement the mind beholds the fountain of life, the fountain of mind, the origin of being, the cause of good, the root of the soul. There will be a time when this vision shall be continual, the mind being no more interrupted nor suffering any perturbation from the body." For it is the body which disturbs that contemplation of God in which our soul unites with the universal soul, a union which can not be effected by the reason, as the reason is incapable of grappling immediately with things divine, but which must be effected by an immediate intuition, by an ecstasy, in which "the soul sinks into a deep silence and all around her the tumult of the senses and the agitations of the body grow still." It is this doctrine of a unity transcending the intellect that constitutes the weakness of the Neoplatonistic philosophy. It professes to derive this doctrine from Plato, but it is Plato's merit to have identified God with absolute reason. It is a lapse out of Hellenistic philosophy proper into Orientalism which holds the Absolute to be empty being or unity.

Revised by W. T. HARRIS.

Ploug, plowg, PARMO CARL: poet; b. in Kolding, Denmark, Oct. 29, 1813. Like Hostrup, he began as a students' poet, but later developed into one of the warmest and most effective champions of Scandinavianism and the Danish spirit in Southern Jutland. His influence for these causes was exerted both through his poems and his work as editor of the patriotic paper *Fædrelandet* (1841–87). He was also for many years a member of the Rigsdag, and played an important part in the drafting of the constitution (1848). His first collection of poems, *Poul Rytters Viser og Vers* (Paul Rytter's Ballads and Verses, 1847), appeared anonymously, and was followed by *Samlede Digte* (Collected Poems, 1861), containing a number of patriotic poems, and *Nyere Sange og Digte* (Later Songs and Poems, 1869). D. Oct. 27, 1894, D. K. DODGE.

Plough, or **Plow** [O. Eng. *plōh*: Germ. *pflug*: Dutch *ploeg*]: an implement for breaking up the soil; used, though in a primitive form, as far back in ancient time as history reaches. The Old Testament speaks of ploughs with shares shod with socks of iron or bronze. The Greeks knew the wheel-plough. The modern plough, with its mould-board to turn over the broken-up soil, was invented in the Netherlands in the seventeenth century, but has since been much improved. The first steam-plough was worked in England in 1832.

Plover [from O. Fr. *plovier*, liter., rain-bird; cf. Lat. *pluvia*, rain; so called, perhaps, because it makes its appearance in wet weather, or because its piping cry was thought to portend rain]: a common name for any member of the family *Charadriidæ*, a group of wading birds of the order *Limicolæ*. Plovers have a bill much like that of a pigeon, hard at the tip, covered with soft skin toward the base, reticulate tarsi, long pointed wings, tail of moderate length and usually twelve feathers, toes slightly webbed, the hindermost lacking or very small. The head is rather large and full, neck short, body plump. There are nearly a hundred species distributed pretty much over the world

The golden plover.

The golden plover (*Charadrius dominicus*), a typical and well-known species, is named from its plumage, which in summer is black above, spotted with golden yellow and white; beneath, as well as the sides of the head, about the base of the bill and eyes, black. In winter it is much grayer, for, in common with many other species, there is a considerable difference in the plumage at different seasons. This bird is remarkable for the extent of its migrations, breeding in Arctic North America and moving S. in winter nearly or quite to Patagonia. The European golden plover is *Charadrius pluvialis*. The gray plover (*Charadrius*—or *Squatarola—helvetica*) is another wide-ranging species, for it breeds in the northern parts of America, Asia, and

Eastern Europe, and occurs at other times as far S. as Tasmania. The thick-knees (*Œdicnemus*) are the largest members of the group, measuring about 14 inches in length. Their plumage of reddish or brownish gray harmonizes well with the barren tracts which they seem to prefer, and the young, when surprised, often escape detection by crouching flat among the pebbles. The killdeer (*Ægialitis vocifera*), so named from its note, is the type of a small group of pretty plovers distinguished by black breast-bands. The killdeer is brown above, but the piping plovers belonging to the same genus are light gray, their plumage blending in with the sand and pebbles of the sea beaches. The crook-billed plover (*Anarhynchus frontalis*) of New Zealand is a small species noteworthy from the fact that it is the only bird whose bill is decidedly bent sideways. Some of the large plovers of the genus *Lobivanellus* and allied genera have a well-developed sharp spur on the bend of the wing which forms a rather formidable weapon. The plovers have been made the subject of a monograph by Seebohm (London, 1887). The CROCODILE-BIRD, DOTTEREL, and LAPWING (*qq. v.*) are also plovers. F. A. LUCAS.

Plowden, EDMUND: law reporter; b. in 1519 at Plowden, in Shropshire; began the study of law in the Middle Temple in 1539, then studied in Cambridge and Oxford, in which latter place he was admitted (1552) to practice surgery and physic; in 1557 again studied in the Middle Temple, and was made sergeant-at-law Oct. 27, 1558. He was a strict Roman Catholic, and this alone is said to have prevented him from promotion to high office. He was treasurer of the Middle Temple during the rebuilding of the Great Hall, in one of the windows of which his arms, with the date 1576, still remain. D. Feb. 6, 1584, and was buried in the Temple church. His *Commentaries or Reports* of law cases, which were originally in law French, cover the period from 3 Edward VI. to 22 Elizabeth (1550–80), and rank among the best reports of any age. Plowden's grandson was made "Earl Palatine, Governor, and Captain of the province of New Albion in North America." See Wallace, *The Reporters* (Boston, 1882). F. STURGES ALLEN.

Plum [O. Eng. *plūme*, from Lat. *prūnum*, later *prūna* (whence Eng. *prune*, viâ Fr.) = Gr. *προῦνον*, earlier *προῦμνον*, plum]: any tree of the genus *Prunus*, family *Rosaceæ*; characterized by a smooth, usually glaucous fruit (also called plum), with a more or less elongated stem and a flat or flattish stone. The botany of the plums is more complex than that of any other fruit of the northern part of the U. S. The origin of the common plum is itself a matter of dispute, but the fruit was probably originally native to Persia and Anatolia. It is known to most botanists as *Prunus domestica*, but some writers hold that two or more species are concerned in its origin. The only other European or Western Asian species of plum in common cultivation in the U. S. is the myrobalan, or cherry plum, *P. cerasifera* (or *P. myrobalana*). This is used mostly as a stock upon which to bud other plums, although there are two or three fruit-bearing varieties of it. This plum is distinguished from *P. domestica* by a somewhat slower growth, smaller and thinner leaves, very early small flowers, and small, round, cherry-like fruits which have a soft, watery, sweet flesh. It is possible that this myrobalan plum is really of the same species as *P. domestica*, and that it represents a nearer approach to the aboriginal type. The varieties of plums (*Prunus domestica*) are numerous, and several classifications of them, by form or color, have been suggested. It is customary to divide them into plums proper and prunes, although there are no constant differences between these two groups. (See PRUNE.) The damsons are sometimes held to be a distinct type, or even species, but they are simply very small firm-meated plums. In North America these common or European plums (*P. domestica*) thrive best in the States and provinces from Pennsylvania north and east, and westward to Lake Michigan, and upon the Pacific coast.

Another type of plum which is now attracting much attention is the Japanese group, the offspring of *Prunus triflora*, which is supposed to be native to China. This species first reached the U. S. in 1870, when Mr. Hough, of Vacaville, Cal., procured several trees from Japan. A variety was generally introduced or distributed about 1883, under the name of Kelsey, in memory of John Kelsey, of Berkeley, Cal., who first recognized the merits of the fruit, and who first obtained ripe specimens. This variety is adapted only to the warmer portions of the U. S.; but other varieties of this type thrive as well in the North—at least ten are hardy and productive in New York. The Japanese plums differ from those of the *Prunus domestica* type in a more robust growth, longer, thinner, and glabrous obovate, or broadly oblanceolate leaves, flower buds usually in threes, fruit heart-shaped and often unequilateral, with a very firm flesh and often a thick, tough skin. Most of the Japanese plums are very handsome, and keep long after being picked. They are very valuable for commercial cultivation in the U. S., and appear to thrive equally well where any of the common orchard fruits can endure the climate, and in this respect they are greatly superior to the varieties of *P. domestica*. Their nomenclature is much confused.

A third important group of plums comprises the native types, the offshoots of several indigenous species. The first of these plums to attract wide attention was the Wild Goose, which was introduced from Tennessee about 1850. About 200 varieties have been described, the greater number being chance varieties found in woods and copses. These native plums belong chiefly to three species: *Prunus americana*, characterized by dark, rough growth, large obovate, and more or less jagged dull leaves, and red or red-marked, mostly flattened fruits, with a very heavy bloom, tough skin, and sweet, firm flesh; *Prunus hortulana* (Wild Goose type), with a smoother and more peach-like growth, narrowly ovate or lance-ovate, smooth, shining, finely toothed leaves, and very bright, slightly speckled slender-stemmed red or yellow fruits with a soft, juicy flesh and a very thin bloom; and *Prunus angustifolia*, the Chickasaw plums, with a slender, zigzag growth and narrower conduplicate leaves, and fruit much like that of the Wild Goose type. As a whole, these native plums are adapted to almost every climate in the U. S. The varieties of *P. americana* thrive in all the Northern States, even in the Dakotas, and also as far S. as Delaware, and some varieties are recommended even for Texas. The Wild Goose, or *P. hortulana* type, is adapted to the Southern and Middle States, and some forms thrive in New York and Illinois. The true Chickasaws are not adapted to cultivation much N. of Mason and Dixon's line. Other native plums in cultivation are the beach-plum (*P. maritima*), the sand-plum of the plains (*P. watsoni*), and the Pacific coast plum (*P. subcordata*). The native plums are inferior to the *P. domestica* and *P. triflora* types, but their great hardiness and adaptability strongly recommend them.

The Simon or Apricot plum (*Prunus simonii*) is a distinct Chinese species, which was introduced into the U. S. by way of France about 1880 or a little earlier. It is peach-like in botanical characters, the fruit being closely sessile and the leaves long. The fruit is maroon red and very handsome, flattened endwise, with a strong suture. The habit of the tree is very strict, and the leaves are strongly conduplicate. In the eastern parts of the U. S. the tree is unproductive, and the fruit usually has an unpleasant, bitter-almond flavor; but upon the Pacific slope the species has distinct commercial value.

Plums thrive best, as a rule, upon rather heavy soils, particularly upon those containing clay. All varieties can be budded upon the peach, although this method of propagation is not common in the northern parts of the U. S., except perhaps for the Japanese type. The commonest stock is the myrobalan, but because of its slow growth it tends to dwarf the tree, and it suckers badly from the root. The ideal stock for the common plum is undoubtedly its own seedlings, particularly the seedlings of the half-wild and consequently little variable forms. The buds are usually set in the second summer following the sowing of the seed, and the trees are ready for sale when the tops are two or three years old.

The chief insect depredator of the plum is the curculio, the same insect which infests the peach, apricot, and cherry. The beetle lays its eggs under flaps or crescents, which it raises on the surface of the young fruits, and the larvæ are the "worms" of the stone fruits. The only accepted method of fighting the insect is to jar the beetles on to sheets in early morning, before they begin to fly.

Plums are attacked by many kinds of fungi. One of the most serious is the shot-hole fungus or leaf-blight, which perforates the leaves and causes them to fall. This disease is held in check by spraying with Bordeaux mixture. (See FUNGICIDE.) Another fungus causes PLUM POCKETS (*q. v.*). The fruit-rot, which causes the death and decay of the fruit while it still hangs on the tree, and which may also kill the fruit-spurs, is kept in check by the use of Bordeaux mixture aided by the destruction of diseased fruits. The black-knot,

or pluin-wart, is a fungous disease affecting the branches or even the trunk. (See PLUM KNOT). In some of the U. S. laws for the suppression of this disease have been passed.

Some of the leading varieties of plums are the following:

Prunus domestica.—Lombard, Bavay Green Gage, Bradshaw or Niagara, Coe's Golden Drop or Silver Prune, French and Shropshire Damsons, German Prune, Fellenberg, Gueii, Moore's Arctic, Green Gage, Prune d'Agen, Hungarian Prune, Copper, Jefferson, Imperial Gage, Quackenbos, Yellow Egg, Washington, French Prune.

P. triflora.—Kelsey, Burbank, Abundance, Satsuma, Chabot, Maru, Ogon, Red Nagate.

P. americana.—Weaver, Wolf, Quaker, De Soto, Rollingstone, Purple Yosemite, Forest Garden, Deep Creek, Chency.

P. hortulana.—Wild Goose, Golden Beauty, Missouri Apricot, Morcman, Reed, Roulette, Wayland, Miner.

P. angustifolia.—Newman, Arkansas Lombard, Caddo Chief, Lone Star, Jennie Lucas, Pottawattamie, Robinson.

L. H. BAILEY.

Plumbago: See GRAPHITE.

Plumbing [deriv. of *plumb*, liter., seal or repair with lead, from Lat. *plum'bum*, lead]: the art of casting and working in lead or other metals and applying them to various purposes connected with buildings, especially to purposes of water-supply and drainage. In the earlier ages lead was the material most used for these purposes, on account of the facility with which it can be worked by simple means. The progress of the arts has taught the ready manipulation of iron, and it has to a great extent supplanted the softer metals in works of this nature. Lead pipes were used by all the celebrated nations of old. In the ancient cities of Asia, Egypt, Greece, Syria, etc., they were used for conveying water under pressures too great for pipes of earthenware. In the earlier ages lead pipes were made from sheets of lead rolled into the form of cylinders and soldered at the edges. They were rarely subjected to pressure. Ancient cities were usually supplied with water by aqueducts, and the distributing pipes seldom rose above the ground floor. The Romans, however, used lead pipes in their aqueducts in some cases in crossing deep valleys where bridging was difficult. Several pipes were generally put in, of small size, so that they could be more easily made to withstand the pressure, and in such a way that a break in one of them would not entirely cut off the supply. Corfield cites a case where there were ten of these leaden siphons in one aqueduct. He cites cases where the pressure was about 200 lb. per square inch.

The perfection of pumping-machinery, and especially of that class of pumping-machinery designed to pump against heavy pressures, modern high buildings, and the modern system of fire-protection, unite to modify the ancient methods of plumbing. Distributing-pipes are now often subjected to a pressure of 100 to 200 lb. per square inch. In a majority of cases distributing-pipes are continuously under a pressure, and no reservoir is needed. In some districts the pressure is periodically raised so as to fill the pipes, and tanks are necessary to maintain a constant supply. In some cases where the street-mains are under a high pressure, pressure-reducing valves are inserted in the service-pipes to modify the pressure on the pipes within the houses.

Street-mains are now usually constructed of cast iron with leaded joints: into these cast-iron pipes are screwed brass stopcocks to which the service-pipes supplying buildings are attached. Service-pipes are usually made of lead or wrought iron. The capacities of different sizes of service-pipes in gallons per minute are given in the following table, compiled by J. N. Tubbs:

DIAMETER IN INCHES.	HEAD IN FEET.									
	10.	20.	30.	40.	50.	60.	70.	80.	90.	100.
⅜	0·92	1·30	1·59	1·84	2·06	2·26	2·44	2·61	2·76	2·91
½	1·89	2·68	3·27	3·78	4·23	4·63	5·00	5·34	5·67	5·98
⅝	3·30	4·68	5·72	6·61	7·39	8·09	8·74	9·34	9·91	10·44
¾	5·21	7·37	9·03	10·42	11·65	12·77	13·79	14·74	15·64	16·48
⅞	7·66	10·84	13·27	15·32	17·13	18·77	20·27	21·67	22·97	24·23
1	10·70	15·13	18·53	21·40	23·92	26·20	28·30	30·26	32·10	33·83
1¼	14·36	20·31	24·87	28·72	32·11	35·18	38·00	40·62	43·08	45·31

1¾	23·72	33·54	41·08	47·43	53·03	58·09	62·75	67·08	71·15	75·00
2	29·48	41·65	51·06	58 96	65·92	72·22	78·00	83·38	88·44	93·23

The average amount of water supplied to each consumer per day in cities of the U. S. is about 100 gal., this excessive use being due to wastefulness. In European cities the supply is usually less than 50 gal. The practice in Germany is to allow 40 gal. per day per person. In Great Britain it is customary to allow 34 gal. The waste of water can be best checked by meters set in the supply-pipe of each consumer.

The purposes for which water is used in buildings are constantly increasing, and as a consequence the plumbing is constantly becoming more intricate. An ordinary modern dwelling is usually supplied with water-closets, urinals, bathtubs, laundry-tubs, slop-sinks, washstands, hot-water boiler, etc.

The distributing-pipes within buildings should be arranged so that by means of a stop and waste cock they can be completely emptied. To accomplish this it is necessary that the main pipe and each branch pipe taken off from it shall be continuously ascending. If there are pockets or depressions in the system they will retain water, and when the building is unoccupied the pipes will be liable to injury from freezing.

Whenever the water-supply is used for flushing water-closets, urinals, etc., or for any purpose where a back flow of water might contaminate the supply used for drinking and culinary purposes, the water should first be received into a special tank or the pipes otherwise disconnected, so that a back flow will not be possible.

House-drainage.—In the arrangement of pipes and appliances for house-drainage or the removal of water which has been fouled (sewage), more care and ingenuity are required on the part of the plumber than in the pipes and fixtures pertaining to water-supply; for sewage is a constant menace to health.

In the system of pipes intended for the removal of sewage from buildings a complete barrier should be interposed against the passage of air currents into the building. To maintain a proper barrier at all times and under all conditions of use and disuse is a somewhat difficult matter. The method in use, and about the only practical one, is by traps or depressions in the pipe, whereby the passage of air is opposed by a head of water. The head is necessarily slight, however, and it is necessary to protect the traps from pressure and from siphonage by ample vents which maintain the pressure within the pipes at the normal atmospheric pressure. The fouled water should be immediately and completely removed from the vicinity of the building. Any system which contemplates the retention of any portion of it for any length of time is imperfect. The main drain for buildings should be from 4 to 6 inches in diameter, except in extreme cases, and laid with as much descent as possible. The inclination should not be less than one in fifty. The method of connecting the main drain with the soil-pipe depends on the method of ventilation. The simplest method is to extend the main drain upward and out through the roof, unbroken by a trap in any portion. In this case it serves the double purpose of soil- and ventilating-pipe, and the air which passes into the street sewers at manholes supplies the draft upward along the street sewers and out through the house ventilating-pipes and their upward extensions. In this case the isolation of the interior of buildings from sewer air depends solely upon the trap under each fixture. When the street sewers are properly constructed on the "separate" system (see SEWERAGE) and properly cared for, this method has proved entirely satisfactory. It has advantages in simplicity and facility of arrangement. Where the sewers are built on the combined plan a trap on the house sewer combined with a fresh-air inlet is to be preferred. This diverts the foul-air currents from the interior pipe and provides a supply of fresh air for the upward current through the soil and ventilating pipe. If the street sewers are not properly ventilated at frequent intervals, either by the upward extension of exterior or interior unobstructed pipes or otherwise, there may be reason to believe that an isolated one may draw from too wide a territory and prove offensive. In this case it is advisable to dispense with any vent-pipe communicating directly with the sewer.

The main drain within or under the house and for a few feet outside of it should be of iron, with lead-calked joints. It is better to fasten it along the wall by iron brackets or hangers above the cellar bottom, giving it as great an inclination as is possible. Fixtures in the basement should be avoided. Removable hand-holes or brass cleaning-screws should be provided at intervals through which obstructions can be removed. All iron pipes and fittings should be thoroughly coated outside and inside with coal-pitch varnish applied hot.

It is customary to make waste-pipes, particularly short ones, of lead, for the reason that it is much more easily

manipulated than iron. The proper method of connecting lead pipes to iron is by means of a brass thimble soldered to the lead pipe and calked into a hub on the iron pipe.

It is best to have soil-, waste-, and ventilating-pipes exposed as much as possible. When inclosed within partitions they are not readily accessible for inspection or repair. Plumbing fixtures should be confined to the bath-room, where special means of ventilation can be employed, and to the kitchen, laundry, and similar rooms. A fixture rarely used is a greater source of danger than one used frequently.

Particular care should be used in arranging the ventilation of a building so that the air currents tend to pass outward from the group of rooms containing plumbing fixtures, fresh air being admitted to other portions of the building. The facility with which this can be accomplished, and also the proper grouping of the fixtures and the simplicity of the system of pipes, will depend largely upon the architect. Ample means should be provided for flushing all portions of the soil- and waste-pipes and all fixtures. This is most effective when special flushing cisterns are supplied. Every fixture should be provided with a trap, and since the object of the trap is to isolate the fouled interior surface of the waste-pipe from the air of the room, it is evident that the trap should be as close to the fixture as possible. Notwithstanding many efforts to introduce a trap whose seal can not be broken by siphonage, and which will be self-cleansing, the plain running trap of uniform bore is still in general use. This trap is liable to have its seal broken by siphonage, and to prevent this it is necessary to resort to a back air-pipe which is connected with the crown of the trap on the downward side and passes to the roof independently of the ventilating-pipe proper, or is connected with it above the highest fixture. This back air-pipe should be of ample capacity to preserve the normal air-pressure when considerable quantities of water are flowing down the soil-pipe. The system of back air-vents is open to the following objections: It considerably complicates the system of piping, especially when fixtures are not closely grouped. There is a possibility of the pipes being fouled at their junction with the crown of the trap. It adds to the expense. Back air-vents tend to increase the interior circulation of air considerably. This is beneficial so far as the purity of the interior of the pipes is concerned, but it also increases the evaporation from traps. This will do no harm if the fixtures are in constant use. On the other hand, if special anti-siphoning traps are used there will be little circulation of the outer purifying air through the waste-pipes.

When the soil-, waste-, and ventilating-pipes are all in position, and before the fixtures are put in place, a test of the thoroughness of the work should be made. This can be done as follows: Close up the main drain where the iron pipe terminates outside the house wall, also the exposed ends of all pipes where fixtures are to be connected, and the fresh-air inlet if there is any. The ends of lead pipes should be left somewhat longer than necessary, so that this can be conveniently done by flattening them and closing with solder. When all openings in the entire system of pipes are tightly closed below, fill the system of pipes with water nearly to the top and mark the height at which the water stands. The entire work should be inspected while under pressure, and joints recalked where necessary.

If roof water is admitted to the sewers the rain-water leader should connect with the main soil-pipe directly above the main trap. No waste- or soil-pipe should be connected with the rain-water leader. The following table gives the requisite size of house drains for roof areas of the dimensions given (calculated by Robert Moore):

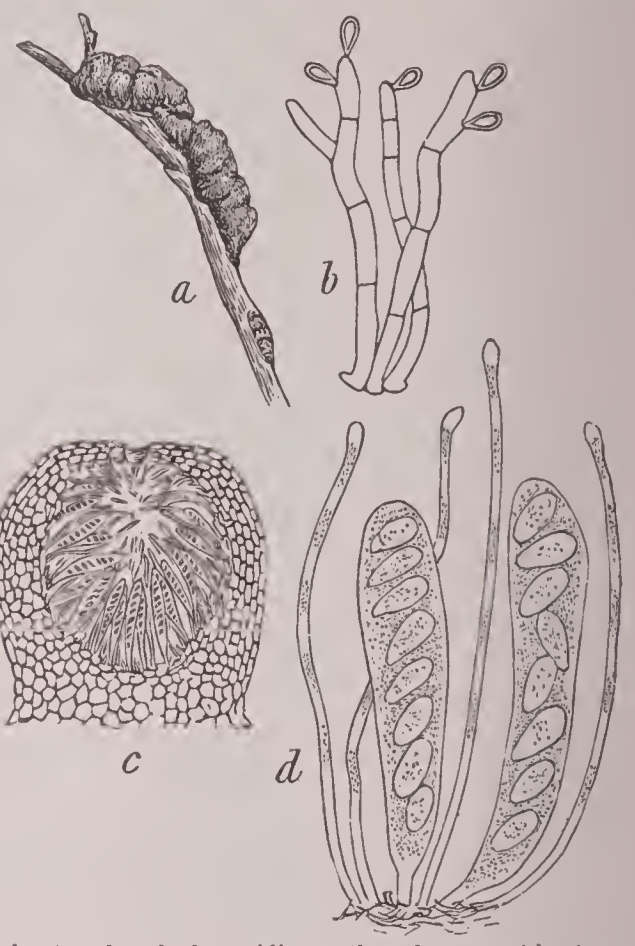
SIZE OF LOT IN FEET.	FALL PER HUNDRED.				
	1·0.	1·5.	2·0.	2·5.	3·0.
	Diameter in Inches.	Diameter in inches.	Diameter in inches.	Diameter in Inches.	Diameter in inches.
20 × 150.....	3·5	3·12	3·0	2·87	2·75
25 × 150.....	3·74	3·5	3·25	3·12	3·0
30 × 150.....	4·0	3·75	3·5	3·37	3·25
35 × 150.....	4·25	4·0	3·75	3·62	3·5
40 × 150.....	4·5	4·25	3·87	3·75	3·62
45 × 150.....	4·75	4·37	4·12	4·0	3·87
50 × 150.....	5·0	4·5	4·2	4·12	4·0
60 × 150.....	5·37	4·87	4·62	4·37	4·25
70 × 150.....	5·62	5·25	4·87	4·75	4·5
80 × 150.....	6·0	5·5	5·25	5·0	4·87
90 × 150.....	6·25	5·75	5·5	5·25	5·0
100 × 150.....	6·5	6·0	5·75	5·5	5·25

In nearly all cities plumbing is governed by rules and regulations defining specifically the class of work to be done, sizes of pipes of various kinds for particular purposes, class of fixtures, etc. The work is permitted to be done by licensed plumbers only, and in the larger cities they are under the surveillance of expert inspectors in the employ of the city.

GEORGE S. PIERSON.

Plumes: See FEATHERS.

Plum Knot: the *Plowrightia morbosa*, a parasitic fungus of the order *Pyrenomyceteæ* and family *Dothidiaceæ*, which lives upon twigs of plums and cherries, producing black, knot-like masses, 2 to 4 inches long and ½ to ¾ inch in diameter (*a*, reduced). The threads of the parasite penetrate the living tissues of the host in spring and early summer, producing a considerable swelling of the tissues. The surface of the young knot now becomes covered with a velvety coating of dark-colored vertical threads, which produce minute spores (conidia, *b*). As winter approaches other reproductive



a, plum knot, reduced; *b*, conidia on threads; *c*, perithecium, with spore-sacs; *d*, spore-sacs and spores (*b*, *c*, *d*, much enlarged).

structures develop: the surface becomes covered with minute hollow, wart-like bodies (perithecia) within which are produced a number of spore-sacs, each with eight ascospores (*c*, *d*). Plum knot may be reproduced from the conidia or the ascospores, but it is often perennial, the parasitic threads growing down each year from the old knot into previously unaffected tissues.

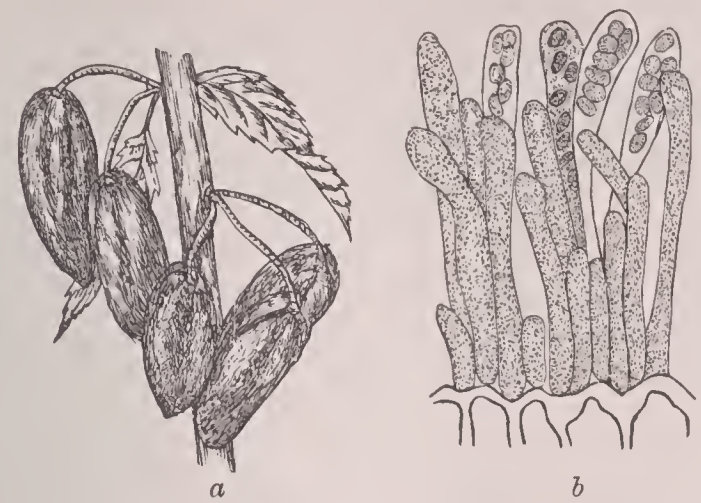
This disease is sometimes quite harmful. All knots should be cut off and burned as soon as they appear. The thorough washing of the tree in early spring with poisonous solutions, as of copper or iron sulphate, will doubtless destroy many spores and tend to prevent the spread of the disease.

CHARLES E. BESSEY.

Plum Pockets: a disease of plums in which they are swollen, hollow, and distorted (*a*). It is caused by a parasitic fungus, *Exoascus pruni* (family *Gymnoasceæ*), which penetrates the tissues of the young plum and finally produces spore-sacs upon the surface. Each spore-sac at maturity contains about eight ascospores (*b*).

"The pockets make their appearance soon after the flowers have fallen, attain full size, and drop from the tree toward the middle or last of June. At first they are more or less globular in shape, but as they grow older they become oblong or oval, and frequently more or less curved. They vary in size, but as a rule are from 1 to 2 inches in length and from ½ to 1 inch in diameter. When young they are nearly smooth, and can be distinguished from the healthy fruit by their pale-yellow or reddish color. As they grow older the color changes to gray, the surface appearing

as though it had been sprinkled with fine powder, and at the same time the pockets become wrinkled. Finally they turn black or dark brown, and rattle like bladders when brought in contact with any hard substance. They remain



a *b*

a, plum pockets ; *b*, a mass of spore-sacs, highly magnified.

on the tree in this condition for two or three days, then fall to the ground and perish."—*Galloway*. This disease may be considerably reduced by the early removal and destruction of all the diseased plums. For an exhaustive account of plum pockets and the fungus producing the disease, consult B. T. Galloway's paper in the *Annual Report of the Department of Agriculture* for 1888. Charles E. Bessey.

Plump'tre, Edward Hayes, D. D.: clergyman and author; b. in London, Aug. 6, 1821; was educated at University College, Oxford; became fellow of Brasenose College 1844; chaplain at King's College, London, 1847; Professor of Pastoral Theology in that institution 1853; prebendary of St. Paul's 1863; professor of exegesis of the New Testament 1864; rector of Pluckley 1869; vicar of Bickley 1873, and Dean of Wells 1881. He was preacher at Lincoln's Inn and Boyle lecturer (1866–67), and was one of the Old Testament company of revisers. Author of several volumes of sermons, addresses, and classical translations—*King's College Sermons* (1859); *Lazarus, and other Poems* (1864); *Sermons on Theology and Life* (1866); *Christ and Christendom* (1867); *Biblical Studies* (1870); *Respice, Aspice, Prospice, and the Law of Progress in Theology* (1876); *St. Paul in Asia Minor and at the Syrian Antioch* (1877); *A Popular Exposition of the Epistles to the Seven Churches of Asia* (1877); translations of Sophocles and Æschylus; *The Spirits in Prison, and other Studies on the Life after Death* (1885), etc.—of many articles in Dr. Smith's *Dictionary of the Bible*, of *Biblical Studies* (1870), and editor of the *New Bible Expositor* (1875). His latest work was a *Life of Bishop Kerr* (1886). D. at Tunbridge Wells, Feb. 1, 1891.

Revised by W. S. Perry.

Plunket, William Conyngham, Baron: orator and statesman; b. at Enniskillen, Ireland, in July, 1765; graduated at the University of Dublin; studied law at Lincoln's Inn; was called to the Irish bar 1787. He became king's counsel 1798; was elected to the Irish Parliament in the same year; was in 1803, as solicitor-general, prosecuting attorney in the trial of Emmet; was attorney-general for Ireland 1805–07. He sat in Parliament 1807–22, where he favored Catholic emancipation; became again attorney-general for Ireland 1822; chief justice and baron 1827, and was lord chancellor of Ireland 1830–41. D. in County Wicklow, Jan. 4, 1854.

Pluralism [from Lat. *plus*, *plu'ris*, more]: in canon law, the possession of more than one ecclesiastical benefice by the same person at the same time. In the earlier times of the Christian Church pluralism was considered unlawful, and it was forbidden by many councils, as, for instance, by those of Chalcedon (451) and Nicæa (787). Later, however, it became one of the most common and most vicious practices in the Roman Catholic Church, and in order to screen its unlawfulness very subtle distinctions were made by the canonists. Benefices were divided into compatible and incompatible—that is, such as could be held together and such as could not. Incompatibility might arise, for instance, from the duty of residence; thus it would be impossible for the same man to be Bishop of Palermo and Trondhjem at the same time, because it was a bishop's duty to reside in his diocese; but then the pope could grant a dispensation from the duty of residence, and thereby the two benefices became at once compatible. At one time it was very common to find Italian clergymen living at the court of Rome and enjoying the revenues of different benefices in Spain, France, Germany, and Scandinavia. In modern times this evil has disappeared almost entirely in the Roman Catholic Church.

The English law before the Reformation in the main coincided with the canon law, and the legislation of Henry VIII. generally preserved the same spirit, only substituting the dispensing power of the crown for that of the pope. By 13 and 14 Victoria, c. 98, it is provided that no incumbent of a benefice shall take and hold together with it another benefice—the word "benefice" in this sense comprising any perpetual curacy, endowed public chapel, parochial chapelry, or district chapelry—unless the churches are within 3 miles of one another by the nearest road and the annual value of one of them does not exceed £100; nor can two benefices be held together if the population of one exceeds 3,000 and that of the other 500. A dispensation or license can be obtained from the archbishop, however, so as to allow two benefices to be held together; and if the archbishop should refuse his license, the party may appeal to the privy council. A special provision prohibits the head ruler of any college or hall in the Universities of Oxford and Cambridge from taking any cathedral preferment or any other benefice. If any person holding a benefice accepts another benefice contrary to the statute, the first benefice becomes *ipso facto* void. Pluralism has almost died out in the Church of England. It does not obtain in the other branches of the Anglican communion. In Ireland no dispensation to hold two benefices can be granted. In Scotland no minister of the Established Church can hold two or more charges, but it is possible for a minister also to hold a chair as professor in a university provided that his charge is in the same city as the university. If a country minister accepts a chair as professor, he must resign one of the offices within a certain time after the appointment.

Revised by W. S. Perry.

Plush [from Fr. *pluche*, *peluche* : Ital. *peluzzo* < Late Lat. **pilu'ceus*, hairy, shaggy, deriv. of Lat. *pi'lus*, hair]: a fabric which differs from velvet in not being shorn, and in having a long pile or shag. It is sometimes all worsted, sometimes worsted with a mohair pile, and most frequently of cotton with a silk pile. This kind last mentioned is used for hat-making. The loops of the pile are cut with a long needle-like knife.

Plutarch (in Gr. Πλούταρχος): Greek biographer and essayist; b. at Chæronea in Bœotia, 46 A. D. He belonged to a wealthy and distinguished family, and lived a long life of study and of honorable employment both in the service of the empire and in the service of Bœotia. A model husband and father, he practiced the noble doctrines that he preached. There was no more amiable character in the history of his times, no more sympathetic and generous soul. D. about 120 A. D. His works, which are many, fall into two classes, historical and ethical, the latter dealing with philosophical, moral, and miscellaneous subjects and commonly referred to roughly as *Moralia*. Of his historical works the most famous is the collection of *Parallel Lives* (Βίοι παράλληλοι), forty-six lives in twenty-three pairs, a Greek life being set over against a Roman. Nineteen of the pairs are followed each by a comparison. Besides these *Parallel Lives* four isolated lives have been preserved. Plutarch is not an historian, he is a moralist, and thinks more of the lesson conveyed by the facts than of the facts themselves. Everything is welcome to him that will illuminate the character he is drawing, that will point to the moral he is teaching. Anecdote, jest, quotation, nothing comes amiss; and while the free and easy handling of his material gives many problems to historical critics, Plutarch has been the delight of all succeeding generations, and is still to be reckoned among the greatest of biographers. His treatises called *Moralia* have not been so popular as they deserve to be, especially of recent years, but they are full of interesting anecdotes, happy quotations, fine reflections, odd bits of recondite learning, a perfect treasure-house of wisdom and knowledge. Plutarch is not a philosopher of the first order any more than he is an historian of the first order; he is not a consecutive thinker; he is not a vigorous writer, nor a soaring genius, but he is a man of sweet and pure nature, whose vast reading is lighted up by true humanity.

Editions.—The text with Latin translation most conven-

iently accessible is in the Didot collection (5 vols., Paris, 1846–55); Reiske (Leipzig, 1774–82). The *Lives* were edited by Koraës (6 vols., Paris, 1809–14); *Morals*, by Wyttenbach (8 vols., Leipzig, 1796–1834). There is a critical edition of the *Lives*, by Sintenis (Leipzig, 1852–55), in the Teubner collection, and of the *Morals* in the same by Bernadakis. Dr. Holden's editions of Plutarch's *Demosthenes* and of the *Gracchi*, of *Nicias*, *Sulla*, and *Timoleon* are very serviceable. A famous old English translation after the French of Amyot is by North (1579). There is a later rendering by the Langhornes (1770), revised by Clough (1859). An old English translation of the *Morals* by several hands has been revised and corrected by W. W. Goodwin (5 vols., Boston, 1870). See *A Popular Introduction to Plutarch*, by Archbishop R. C. Trench (London, 1873), and R. Volkmann, *Plutarch* (Berlin, 1869). B. L. Gildersleeve.

Pluto (in Gr. Πλούτων): the name used among the Romans for Hades (*q. v.*), though it originated with the Greeks, who called him by that name because, as the god of the lower world, he was lord over all wealth, both vegetable and mineral, that is concealed by the earth from which all wealth springs. J. R. S. S.

Plutus [= Lat. = Gr. Πλοῦτος, liter., wealth]: in ancient mythology, the personification of riches, much used by the poets and often represented by art, but never worshiped. Zeus is said to have blinded him in order that he might not bestow his favors on righteous men only, but that he might distribute his gifts blindly and without any regard to merit. At Thebes there was a statue of Fortune, at Athens one of Peace, and at Thespiæ one of Athene the Worker, and in each of these cases Plutus was represented as the child of those divinities, symbolically expressing the sources of wealth. He seems to have commonly been represented as a boy with a cornucopia. Revised by J. R. S. Sterrett.

Plymouth: town; in the county of Devonshire, England; on the northern shore of the sound of the same name; at the mouth of the Plym; 246 miles W. S. W. by rail of London, and 128 S. W. of Bristol (see map of England, ref. 15–D). Taken in its largest sense, it comprises what are called the "three towns"—Plymouth proper on the E., Stonehouse in the middle, and Devonport on the W. Beside the citadel, an obsolete fortification built by Charles II. at the eastern end of the bold headland called the Hoe, there is a chain of forts of great strength mounted with guns of heavy caliber, which form a complete line of defense by land and sea. The town is irregularly built, but great improvements have been made. Among the principal buildings are the new Guildhall, in the Gothic style, opened in 1874; the Proprietary Library, in which there is the Cottonian collection of pictures; and the Athenæum, which contains a library, lecture-hall, museum, and art gallery. The parish church of St. Andrew, in the Perpendicular style, dates originally from 1430, but was completely restored in 1875 by Sir Gilbert Scott. In 1888 the Marine Biological Laboratory was opened.

As a great naval station Plymouth owes its pre-eminence to the spaciousness and extent of Plymouth Sound, within which the whole British navy might anchor with safety. To protect the interior of this estuary the Plymouth breakwater was constructed. (See Breakwater.) The eastern harbor, Sutton Pool, is an anchorage for the shipping employed in the fisheries and general trade. The Great Western Docks include a floating basin of over 13 acres, a tidal harbor of 35 acres, and a graving-dock. The port has a considerable trade, and is used by lines of passenger steamers to South Africa, the East, and Australasia. There is also a large coasting trade. There are some manufactures of chemical compounds, biscuits, soap, manures, etc.

Plymouth was used as a port by the Black Prince, and in the reign of Elizabeth it was the principal port of England. In the wars with Napoleon it was the rival of Portsmouth in naval activity. Plymouth returns two members to Parliament. Pop. of Plymouth proper (1901) 107,509; with Stonehouse and Devonport (1891) 154,417. R. A. Roberts.

Plymouth: town; capital of Plymouth co., Mass. (for location, see map of Massachusetts, ref. 4–J); on Massachusetts Bay and the Old Colony division of the N. Y., N. H. and Hart. Railroad; 37 miles S. E. of Boston. It occupies a strip of 18 miles along the coast varying from 5 to 9 miles in width, is the oldest town in New England, and has a healthful climate, the heat of summer seldom being oppressive or the cold of winter intense. It has public waterworks and sewer system, gas, electric plant for light and power, electric street-railway, 2 national banks with combined capital of $410,000, 2 savings-banks with aggregate deposits of $3,276,892, a co-operative bank, 9 churches, public library, and 2 weekly newspapers. The industries comprise the manufacture of woolen cloth, cotton sail-duck, insulated wire, patent bedstead joints, boots and shoes, cordage, tacks, rivets, wire nails, stoves, hollow-ware, steel shanks, zinc and copper electrical supplies, and other articles. Plymouth is celebrated as the landing-place of the Pilgrim Fathers on Dec. 11 (Dec. 21, N. S.), 1620. The rock on which they first stepped is in Water Street, and is now covered with a fine granite canopy. Pilgrim Hall contains numerous relics of the Pilgrims, and many interesting antiquities. Cole's Hill and Burial Hill are points of much interest, because of the burial there of many of the Pilgrims. The corner-stone of a national monument to the Pilgrims was laid Aug. 1, 1859, and the structure was dedicated Aug. 1, 1889. It is 81 ft. high, cost about $150,000, and is surmounted by a statue of Faith, in granite, 36 ft. high, the largest granite statue in the world. Four immense monolithic statues, weighing about 16 tons each, and representing Morality, Law, Education, and Freedom, with beautiful marble bas-reliefs beneath each, are seated on the buttresses of this monument. Pop. (1880) 7,093; (1890) 7,314; (1900) 9,592.

C. C. Doten, editor of "Old Colony Memorial."

Plymouth: town; one of the capitals of Grafton co., N. H.; at the junction of the Pemigewasset and Baker's rivers, and on the Concord and Montreal Railroad; 50 miles N. by W. of Concord, the State capital (for location, see map of New Hampshire, ref. 6–E). It is in a region much frequented by tourists and widely known for its beautiful scenery, and contains the State Normal School (opened in 1871), the Holderness School for Boys (Protestant Episcopal), a national bank with capital of $75,000, a weekly newspaper, and manufactories of gloves, shoes, and leather. Pop. (1880) 1,719; (1890) 1,852; (1900) 1,972.

Plymouth: town, seaport, and capital of Washington co., N. C.; on Albemarle Sound; about 100 miles E. of Raleigh (for location, see map of North Carolina, ref. 3–J). It is in an agricultural region, ships large quantities of cotton, lumber, and vegetables, and contains a State normal school (opened in 1886), lumber and cotton mills, and a weekly newspaper, Pop. (1880) 836; (1890) 1,212; (1900) 1,011.

Plymouth: borough; Luzerne co., Pa.; on the Susquehanna river, and the Del., Lack. and West. Railroad; 4 miles S. W. of Wilkesbarre, the county-seat, 20 miles S. W. of Scranton (for location, see map of Pennsylvania, ref. 3–H). It is in a coal-mining region, and contains a high school, 4 public-school buildings, public-school property valued at over $50,000, a national bank with capital of $100,000, and 3 weekly newspapers. Pop. (1890) 9,344; (1900) 13,649.

Plymouth Brethren: a Christian body holding in the main Calvinistic views, but peculiar in that it rejects all ecclesiastical organization and insists on the complete parity of all believers. Hence it has no presiding officers in its public meetings, nor any clergy. It was started in Dublin in 1827, mainly through the exertions of John Nelson Darby, from whom the sect gets its best-known name, *Darbyites*; in 1831 it took a fresh hold at Plymouth, England, whence its name, *Plymouth Brethren*, again under Darby, and largely by his writings and personal service spread over the British Isles, the Continent, Canada, and the U. S. Darby was born in London, Nov. 18, 1800; graduated at Trinity College, Dublin, 1819; was first a lawyer, then a clergyman, 1825, but in 1827 he left the Established Church. He died at Bournemouth, England, Apr. 29, 1882. His writings were collected and edited by W. Kelly (32 vols., London, 1867–83). The brethren are now divided into several parties, but all agree in rejecting creeds, an ordained ministry, and a separate organization, and in meeting in halls or private houses instead of having churches. According to the census of 1890 there were in the U. S. four such parties, with an aggregate of 6,661 communicants. S. M. Jackson.

Plymouth Sound: an inlet of the English Channel on the southern coast of England, between the counties of Devon and Cornwall. It is 3 miles long, 4 miles broad, and forms, with the estuaries of the Plym and the Tamar, the harbors of Plymouth and Devonport, well known as one of the principal naval stations of Great Britain. See Devonport and Plymouth.

Plympton, George Washington: scientist; b. at Waltham, Mass., Nov. 18, 1827; graduated at the Rensselaer

Polytechnic Institute at Troy, N. Y., 1847; was Professor of Engineering and Architecture at Cleveland University 1852–53; of mathematics in the State Normal School, Albany, N. Y., 1853–55, and again 1858–60, and in the State Normal School, Trenton, N. J., 1860–63; became Professor of Physical Science at the Brooklyn Polytechnic Institute 1863, and of Chemistry and Toxicology in the Long Island College Hospital in 1864, and of Physics at Cooper Institute, N. Y., 1869. He was appointed director of the night schools of the Cooper Union in 1879. In the practice of engineering he was chief engineer of water-supply and drainage of Bergen, N. J., from 1867 to 1869; commissioner of electrical subways for the city of Brooklyn 1885 to 1889; and member of the board of experts to improve transportation over the East River bridge. He has been a member of the American Society of Civil Engineers since 1868. He is the author of *The Blowpipe* (1859), *The Starfinder* (1878), *The Aneroid* (1880), and translator of Jannetaz's *Determination of Rocks* (1877). He was editor of Van Nostrand's *Eclectic Engineering Magazine* 1870–86.

Pneumatic Dynamite Gun: See ORDNANCE.

Pneumatics [from Gr. *πνευματικός*, relating to wind or air, deriv. of *πνεῦμα*, *πνεύματος*, wind, air, breath, spirit, deriv. of *πνεῖν*, blow, breath]: that department of physics which deals with the properties of gases.

In this article the influence of pressure is particularly considered, together with the means of producing changes of pressure and of measuring the same.

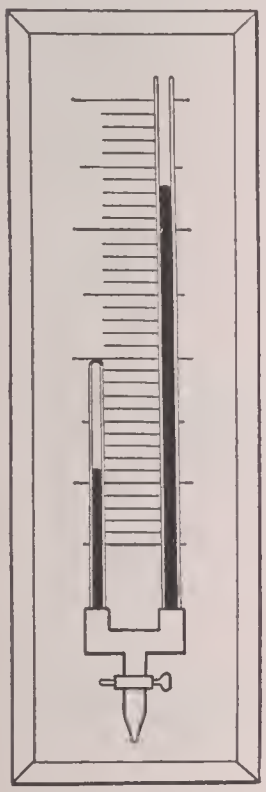


FIG. 1.

The principal phenomena of pneumatics depend upon what is known as the *law of Mariotte (or Boyle)*, a law which expresses the relation between the pressure of a gas and its volume. This law, which applies rigorously only to what is known as a "perfect gas," is given in the simple formula

$$v_o p_o = vp,$$

which states the fact that pressures p_o, p and volumes v_o, v are inversely proportional to one another.

For the verification of Mariotte's law the two pieces of apparatus, shown in Figs. 1 and 2 respectively, are commonly used.

Fig. 1, which gives the essential features of the apparatus for moderate pressures greater than one atmosphere, shows a glass tube with two arms, one of which, the shorter, is closed above, while the other is open.

When the open arm of the apparatus is partly filled with mercury, a certain amount of air is entrapped in the closed portion of the tube, and the volume of this air depends upon the pressure to which it is subjected. The pressure is measured by the difference in the height of the columns of mercury in the two arms, plus the barometric pressure. A stop-cock at the bottom of the tube facilitates the withdrawing of mercury.

The contents of the closed arm, per unit of length, having been carefully determined, pressure is applied by the introduction of mercury until the volume reaches a desired value. By further adjustment of the mercury and determination of the corresponding volumes, the law of Mariotte may be verified through a considerable range of pressures.

Below one atmosphere the apparatus is given the form shown in Fig. 2, in which C is a deep cistern of mercury into which an inverted tube of glass, t, previously nearly filled with the same liquid, is inverted. As the inverted tube is raised and lowered the column of air therein expands and contracts in accordance with the law under discussion. The volumes are determined by calibration of the tube; the pressures from the barometric pressure, minus the elevation of the mercury in the inner tube above the level of that within the cistern. The figure shows the apparatus with the inverted tube in three positions (Fig. 2).

Marked divergence from Mariotte's law occurs in the case of all known gases, as we approach a certain temperature (the so-called critical temperature) which is fixed for each particular gas. Hydrogen, nitrogen, oxygen, air, methane, and carbon monoxide have critical temperatures so low that they can only be reached by processes of artificial refrigeration. (See LIQUIDS.) They are known as the permanent gases, an appellation which is justified under all usual conditions, since they obey Mariotte's law approximately under whatever pressures may be brought to bear.

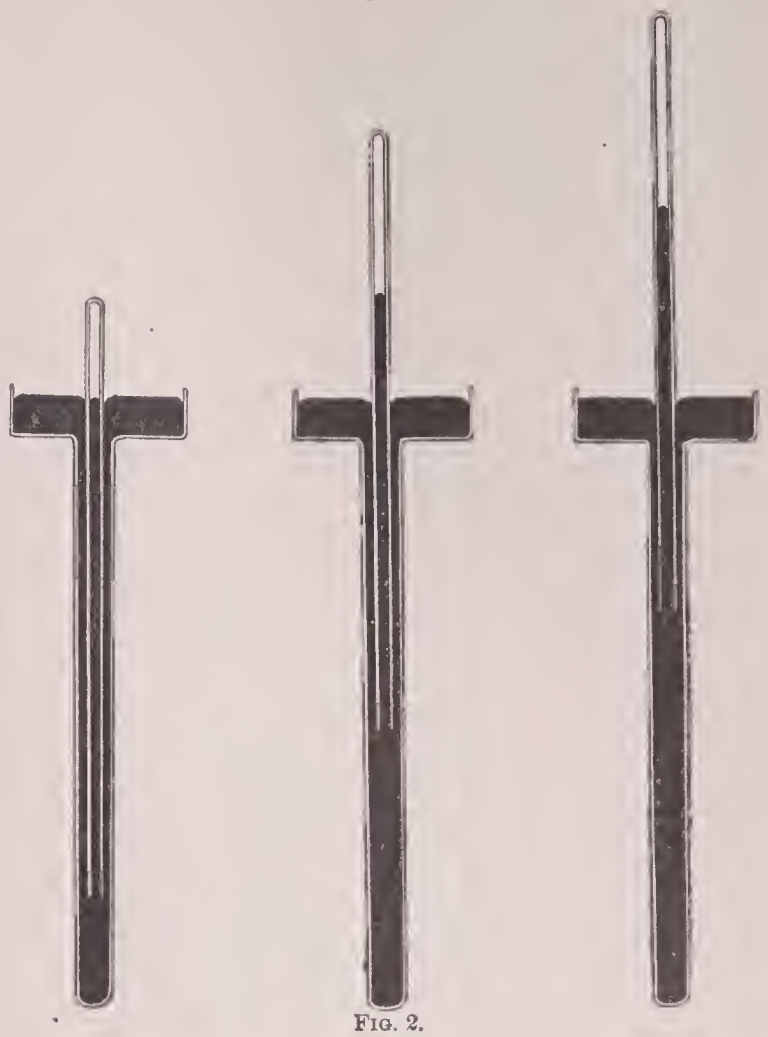

FIG. 2.

Gases, as sulphur dioxide, which have a critical temperature higher than the temperature of experimentation are capable of being liquefied by pressure alone. Such gases show a divergence from Mariotte's law which is always in the direction of too great compressibility. The presence of such vapors in admixture with a permanent gas will also cause appreciable deviation from the law on the part of the mixture.

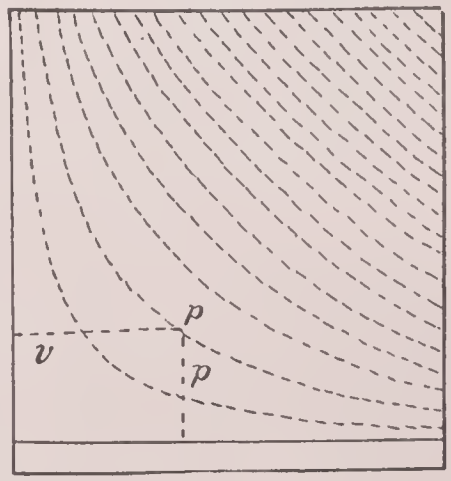

FIG. 3.

The behavior of a gas remote from its boiling-point, and consequently obedient to Mariotte's law, and that of a gas near the point of liquefaction, and therefore exhibiting deviations from the law, are shown graphically in the diagrams of Figs. 3 and 4, in which ordinates are pressures and abscissas are volumes.

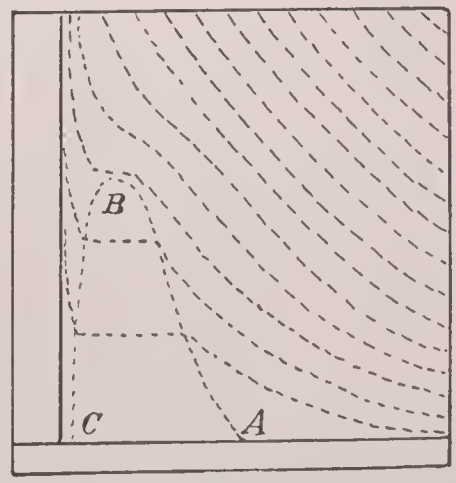

FIG. 4.

The peculiarity of the lines in the former diagram, which are hyperbolic, is that upon any line the product of the or-

dinates (vp) is a constant. Each line describes the changes of volume corresponding to the variations of pressure for a given temperature. The temperatures rise with increase in the ordinates. Fig. 4 gives the corresponding lines in the case of a vapor. At the highest temperature shown, those for the lines in the upper right-hand corner, the divergence from Mariotte's law is inconsiderable. For lower temperatures a tendency is developed which shows itself in double curvature of the lines. Finally, certain lines, those, namely, which cross the dotted area A B C, suffer discontinuity of curvature. Temperatures corresponding to these lines are below the critical temperature. The breaks in them indicate the points at which liquefaction begins and is completed.

Researches by Regnault, Amagat, Natterer, Cailletet seem to show that even the permanent gases do not fulfill the definition of a perfect gas mentioned above. The divergence from the law of Mariotte does not, however, consist simply in the exhibition of greater and greater compressibility with increasing pressure, as is the case with vapors. It is more complicated in character. Amagat, using a modification of the method of Cailletet, found for nitrogen the product pv, which for perfect gases should be constant, the following values all of which are referred to the value of that product at a pressure of one atmosphere.

TABLE I.

Pressures.	pv.	Pressures.	pv.
27·29 atm	0·9894	168·81 atm	1·0255
46·50 "	0·9876	208·64 "	1·0520
62·03 "	0·9858	251·13 "	1·0815
73·00 "	0·9868	290·93 "	1·1218
80·58 "	0·9875	332·04 "	1·1625
90·98 "	0·9893	373·30 "	1·2070
109·17 "	0·9940	430·77 "	1·2696
126·90 "	1·0015		

The values for this and for the other gases tested, with the exception of hydrogen, show a too great compressibility up to a maximum in the neighborhood of sixty atmospheres (corresponding to the minimum value of pv in the foregoing table). The compressibility then diminishes again, so that at the pressure of about 100 atmospheres the value of pv becomes unity and at higher pressures takes increasingly large values. Hydrogen alone shows for all pressure a degree of compressibility smaller than those demanded by Mariotte's law.

Of importance, likewise, are the densities of gases and their behavior when subjected to changes of temperature. The densities of some of the more important gases and vapors are given in Table II.

TABLE II.—DENSITY OF GASES AND VAPORS.

GAS.	Density (compared with air).	Weight of one liter, grammes.
Ammonia (NH_3)	0·589	0·761
Chlorine (Cl_2)	2·449	3·167
Hydrochloric acid (HCl)	1·259	1·628
Methane (CH_4)	0·553	0·715
Carbon monoxide (CO)	0·967	1·251
Carbon dioxide (CO_2)	1·51968	1·96503
Oxygen (O_2)	1·10521	1·42908
Sulphur dioxide (SO_2)	2·213	2·861
Nitrogen (N_2)	0·9701	1·2544
Hydrogen (H_2)	0·069234	0·089523
Steam (H_2O)	0·62182	0·80405
Air	1·0000	1·293052

Influence of Temperature.—This is expressed by the law explained in HEAT (*q. v.*), which may be written

$$pv = p_0 v_0 \left(1 + \frac{t}{273}\right).$$

Taking into consideration the deviations from Mariotte's law and analogous deviations from the law of Gay-Lussac, numerous attempts have been made to find an equation which will express completely the behavior of an actual gas. Van der Waals (1873) gave as the complete formula of condition,

$$\left(p + \frac{a}{v^2}\right)(v - b) = \frac{p_0 v_0}{273} T,$$

in which a and b are small constants and T is the absolute temperature.

The usual instrument for producing changes of pressure is the air-pump (invented by Otto von Guericke about 1650). The term is usually applied alike to pumps used for the production of a vacuum and to compression-pumps.

Vacuum-pumps, in their earlier forms, were modifications of water-pumps, and the forms still in use in the production of ordinary vacua are constructed with valves.

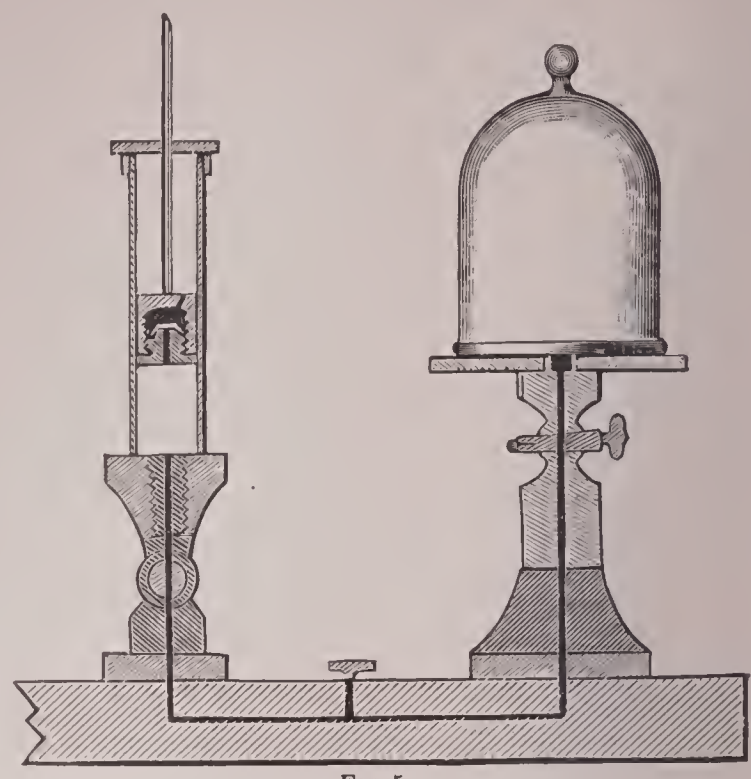

FIG. 5.

One of the simplest and best-known types of vacuum-pump is shown in Fig. 5. This pump contains only one

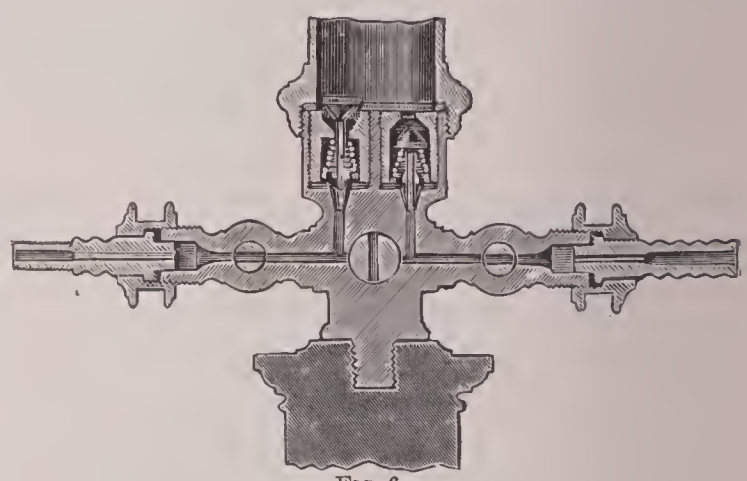

FIG. 6.

valve which is placed within the piston. Another form (that of Silbermann), Fig. 6, contains two valves, one working upward and the other downward, situated in the base of the cylinder. The piston is solid.

Many other varieties of the mechanical vacuum-pump have been devised. The general principles, applicable to all forms, are given here: (1) Since gases are of small density the volumes displaced should be relatively much larger than in the case of water-pumps. (2) The valves should be capable of action under the smallest possible differences of pressure. This point is of great importance where the production of high vacua is desired. (3) Joints must be as nearly perfect as regards the matter of gas-leakage as it is possible to make them.

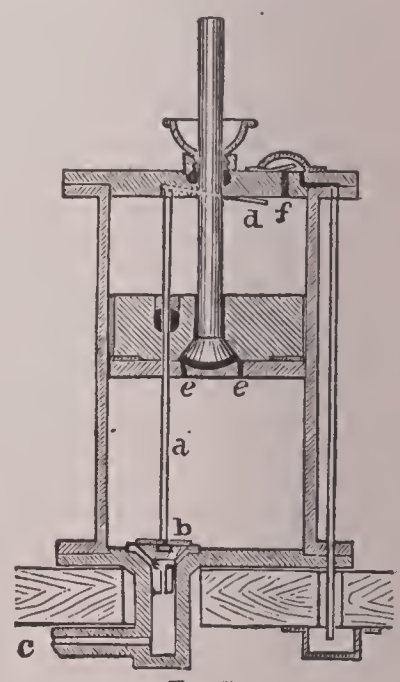

FIG. 7.

These two last factors limit the usefulness of air-pumps with valves, since the highest degree of exhaustion which can be obtained with such a pump is either that at which the valves cease to work or at which the rate of leakage equals the rate of exhaustion.

The latter is the more important, since the failure of valve-action may be remedied by supplanting the movements due to differences of pressure with movements which follow positively and at the proper instant those of the piston.

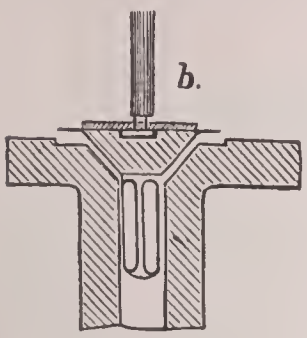

FIG. 8.

Fig. 7 shows such a device, by E. S. Ritchie. In these instruments the valve at the bottom of the cylinder is opened and closed by means of a rod (*a*) which is fitted to a stuffing-box in the plunger. The valve in the piston is also operated directly from the stroke, for which purpose the piston-rod is given the form shown in the figure. Thus *b* is opened and *e e* is closed at the beginning of the stroke without reference to the differences of pressure.

The arrangement of the lower valve in Ritchie's pump is shown in more detail in Fig. 8. It consists of a conical plug which is carefully fitted to the tapering end of the tube which leads from the exhausted receiver to the lower end of the pump-cylinder. This plug is attached to the end of a rod carried by the piston, as above described. A disk of oiled silk completes the closure.

Mercury Vacuum-pumps. — An important class of air-pumps are those used in the production of very high vacua, such as it is necessary to obtain in many scientific investigations, and commercially, in the manufacture of all forms of the electric glow-lamp, where an inert atmosphere is not used. Mechanical pumps of the forms just described can rarely be made to produce an exhaustion amounting to $\frac{1}{1000}$th of an atmosphere, whereas the pressure within the bulb of a properly constructed glow-lamp does not exceed $\frac{1}{20000}$th of an atmosphere. In physical research it is frequently necessary to obtain still higher vacua, amounting sometimes to $\frac{1}{1000000}$th or even to $\frac{1}{100000000}$th of an atmosphere. For such purposes one of the following forms of mercury-pumps is used:

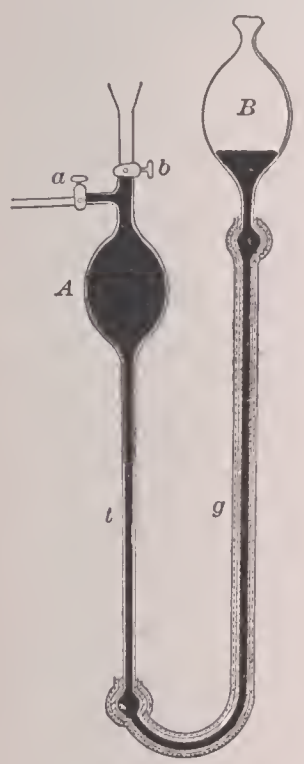

FIG. 9.

(*a*) *The Geissler Pump.* — This instrument, which has found extended application in the manufacture of electric lamps, is shown in one of its very simplest forms in Fig. 9. The essential parts are the two bulbs of heavy glass, each of which is capable of holding about two liters. These are connected by means of the long vertical glass tube *t*, which must somewhat exceed the barometric column in height, and the strong flexible tube *g* attached to the lower end of *t* and to the movable bulb B. There must be, further, two tubes connecting the fixed bulb A respectively with the outer air and with the vessel which is to be exhausted. These must be provided with stop-cocks.

The process of pumping with apparatus of this type consists (1) in closing the stop-cock *a*, which leads to the receiver and opening *b*, which gives egress to the outer air, the movable bulb B being raised to a height such as to cause the mercury to flow over into A, completely filling it, and driving the previously contained air out through the egress-tube. (2) This operation being completed the stop-cock *b* is closed; the bulb B is lowered to a position at least 760 mm. below the bottom of the bulb A and the stop-cock *a* is opened. The result of the second operation is an influx of air from the receiver to the bulb A, which is then expelled by a repetition of operation (1). By continued alternations of the two operations the pressure may be reduced to any desired point within a limit lying much below that attainable with valve-pumps.

In practice, there are attached to the Geissler pump various accessory parts not shown in the figure, such as drying-tubes between the vessel to be exhausted and the bulb A, and mercury-traps between the latter and the outer air.

The operation of the Geissler pump is a laborious one, since it involves the repeated lifting of a large mass of mercury through a vertical distance of about a meter. Where such pumps are in continual use, as in the pump-rooms of incandescent-lamp factories, it is usual to drive the mercury into and out of the bulb A by pneumatic pressure, leaving to the manipulator only the task of turning the stop-cocks.

In these cases the apparatus consists of a mechanical pump driven by power, and capable of maintaining a reduc-

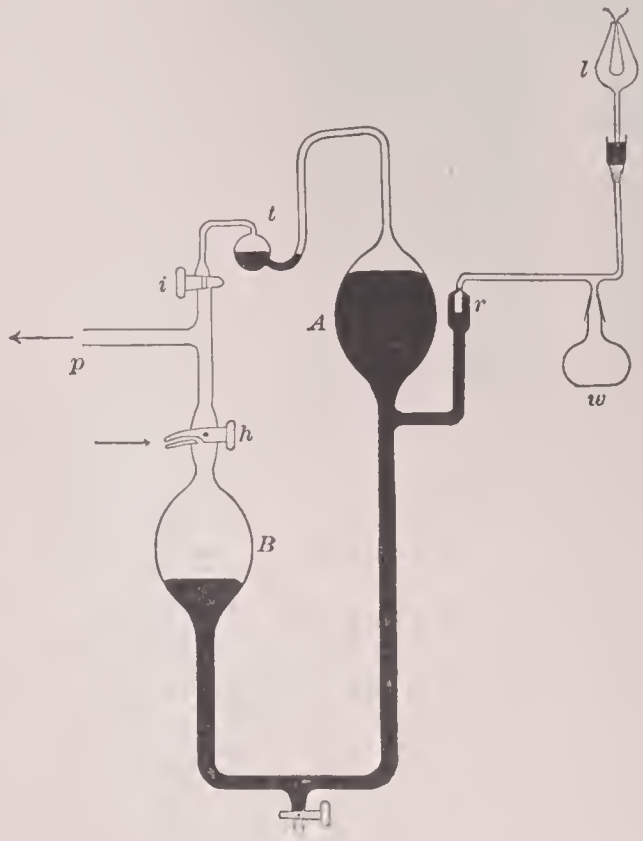

FIG. 10.

tion of pressure of 700 mm. The Geissler pump, also, is modified to suit the conditions of working. The bulb B is fixed, its position with reference to A being that shown in Fig. 10, which gives the arrangement of one of the simplest of this type of pumps.

In the use of such a pump the tube *p* is connected with the mechanical pump, and the stop-cocks *h* and *i* are turned so as to bring the atmosphere within B A, the connected vessel *w* (drying-flask), and *l* to the low pressure produced by the action of the latter. The two-way stop-cock *h* is then turned so as to admit air from without to B, whereby the mercury rises into A, driving the air before it through the mercury-trap *t*. A glass valve, *r*, rises upon the surface of the mercury during this operation until it closes the contraction in the tube, which it has been ground to fit. The restoration of the stop-cock *h* to its first position empties the bulb A, and produces further exhaustion of *l* in proportion to the additional space thus provided.

FIG. 11.

(*b*) *The Sprengel pump* is a mercury-pump based upon a different principle from that of Geissler. The principle was really due to Bunsen, who, in 1868, described a water-jet pump for hastening the filtration processes of the analytical chemist. Sprengel made use of a mercury column flowing downward through a vertical tube of small bore. Fig. 11 shows a simple form of the Sprengel pump, designed by Weinhold. The long vertical tube *a*, enlarged at *c*, is fed with mercury from the tube *b*, which is given the form shown in the figure to prevent loss of vacuum in case the supply of that liquid is not continuously maintained. The mercury flowing from the narrow tube, at a rate which is regulated by the height of the reservoir, R, forms drops in the wider upper portion of the pump-tube *a*. Each of these, as it falls into the contracted part, entraps a bubble of air and carries it down into the lower reservoir *r*, whence it escapes to the

outer atmosphere. This process is a continuous one, and when the apparatus is properly proportioned and clean, and when clean mercury is used, the pump will frequently continue in action until a pressure of less than the millionth of an atmosphere is attained. For vacua of a still higher order many special precautions must be taken.

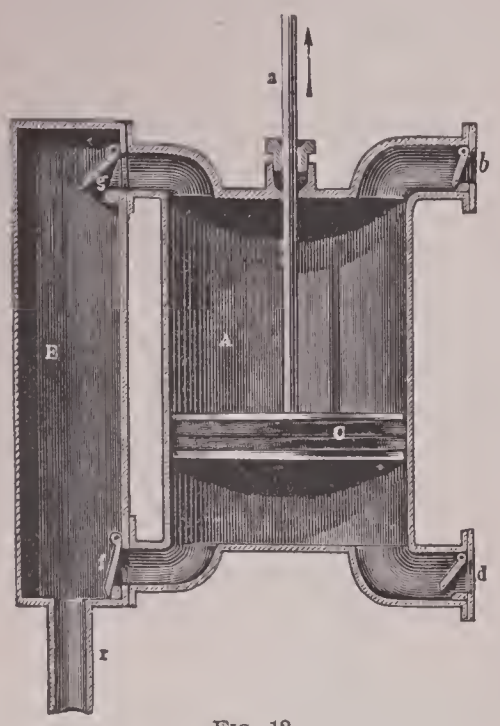

Fig. 12.

Compression-pumps.—This class of air-pumps is much easier to construct than are vacuum-pumps, since it is not necessary, generally speaking, to overcome all leakage, nor do the valves need to be brought to the same degree of delicacy. The characteristic features of compression-pumps, when used as blowers, are the large size of the cylinder and of the valves. There are, as a rule, two sets of valves, so that both the up and the down stroke are effective. When pumps are to be used for the production of high pressures, rather than for the supply of large quantities of air, they are made, as a matter of necessity, with thick walls and small apertures. Figs. 12 and 13 show typical pumps for the production of a blast; Fig. 14 a fan in which the rapid rotation of floats within a cylindrical compartment takes the place of the piston-motion, and, by centrifugal action, produces a continuous and powerful draught.

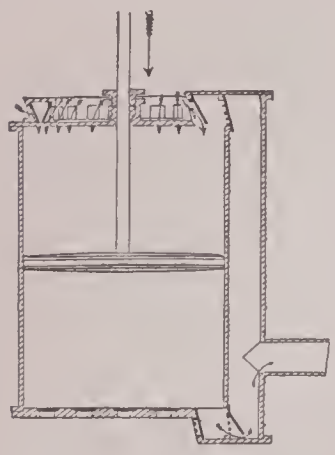

Fig. 13.

Measurements of gas-pressure are made by means of *manometers.* These instruments depend upon the balancing of the elastic forces of the gas by means of a column of liquid, usually mercury (open-tube manometers), upon the compression of a gas within a closed receiver (closed-tube manometers), or upon the direct mechanical action of the gas in distorting a flexible closed box or tube (pressure-gauges). The last-named class corresponds to the aneroid barometer, of which indeed it is only a suitable modification.

Fig. 15 shows the essential parts of an "open-tube" manometer for moderate pressures; Fig. 16 of a "closed-tube" manometer with cylindrical bore; and Fig. 17 an instrument of the same class in which the tube is conical. The object of this modification in which the scale will remain open is for high pressures. Fig. 18 presents the essential features of a well-known type of pressure-gauges.

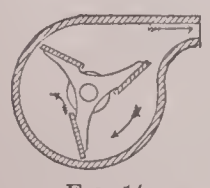

Fig. 14.

For the measurement of high vacua a special form of "closed-tube" manometer is used. This instrument, which is known from its inventor as the McLeod gauge, is shown in its essential features in Fig. 19. It consists of a bulb of glass mounted upon a glass tube somewhat longer than a barometer tube. Into the top of this bulb is inserted, by the glass-blower's process, a capillary tube, closed above, the contents of which, for each centimeter of its length, is known in terms of the contents of the bulb. A side-tube inserted below the mouth of the bulb connects the apparatus hermetically with the receiver the vacuum of which is to be measured. To the bottom of the long vertical tube an open reservoir of mercury is attached by means of a strong flexible tube similar to that used in the Geissler pump.

The process of measuring a vacuum with the McLeod gauge is as follows: During the exhaustion the reservoir of mercury is kept in a position so far below the bulb of the gauge that the manometric column formed by the atmos-

Fig. 15.

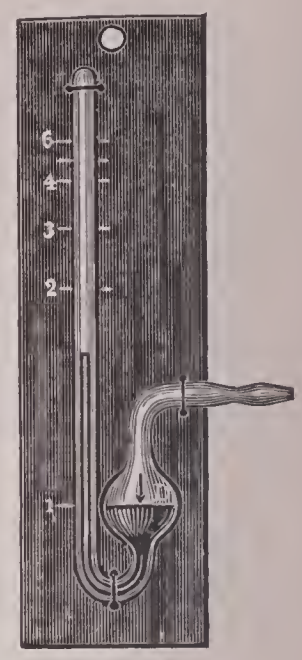

Fig. 16.

pheric pressure without will not reach the side tube. (See Fig. 19.) When it is desired to measure the vacuum, the reservoir is raised until the mercury reaches the side-tube,

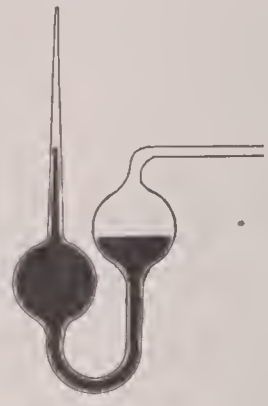

Fig. 17.

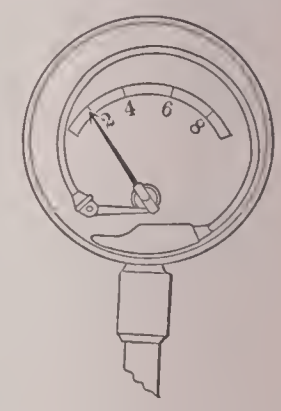

Fig. 18.

thus isolating the body of extenuated gas within the bulb. The reservoir is then raised still farther, and the air within the bulb thus caused to contract under the increasing pressure until, if the vacuum be one sufficiently high to be measured in this way, the mercury has entirely filled the bulb and has driven the air into the capillary tube. The final operations consist in adjusting the mercury within and without to the same height, and in observing the volume of the compressed air. A comparison of its volume with that at which it existed at the beginning of the experiment affords data for computation of the initial pressure.

Fig. 19.

Appliances based upon the behavior of gases under pressure are numerous. Within the limits of this article it is possible to refer very briefly only to a few familiar examples.

The properties of compressed gases afford a means of storage of energy. Sometimes this is for short intervals, as between the strokes of a force-pump, where the air compressed in the receiver maintains the velocity of efflux during the periods when there is no direct impulse. In other cases the storage is on a much

larger scale, as in the case of compressed-air motors. In the city of Berne, for instance, a street-railway is operated by means of the energy stored at a pumping-station at one end of the line, where a cylinder upon the car is filled with air at high pressure. One such filling serves to drive the car to the other end of the road and back again. On account of the thermal losses involved, such systems are never of high economical efficiency. They can be used to advantage only where power which would otherwise go to waste can be utilized, as in the case of abundant water-power.

Compressed air is extensively used in the building of bridge piers, of tunnels, and of foundations, where water or quicksand is to be excluded. It is also used for the transmission of small parcels, etc., through tubes, at high speed. (See PNEUMATIC TRANSMISSION.) The fact that pressure is transmitted through gases at a velocity equivalent to that of a sound-wave has led to the use of pneumatic systems of signaling, in which change of pressure at one point in a system of closed tubes is made to operate some signaling device at a distance. E. L. NICHOLS.

Pneumatic Transmission: a method of transmitting written messages and packages of goods through tubes by the pressure of the atmosphere or the action of compressed air. The operation of the apparatus may be illustrated by inserting one end of a small tube of glass or metal, containing a pellet of moistened paper, in the mouth. Upon forcing air into the tube the pellet will move from the experimenter, but if the air is drawn out of the tube the pellet will move toward the experimenter. These methods are used in all apparatus for pneumatic transmission, a compression or exhausting air-pump being used for controlling the air and a hollow piston of leather or other suitable material for containing and carrying the messages; but there is a variety of special apparatus for regulating the speed and for inserting and removing the piston with its freight of messages from the tube.

In 1687 Denys Papin first suggested the idea of apparatus for pneumatic transmission, but there is no evidence that his plan was tried. In 1792 *Le Dictionnaire Encyclopédique des Amusements des Sciences*, published in Paris, gave a graphic account of an experiment in pneumatic transmission, a round wooden box containing a paper being propelled by a powerful blast of air through an underground pipe for a distance of three-quarters of a mile. This, however, was only for amusement. The industrial aspect of pneumatic transmission was investigated in 1810 by Medhurst, a Danish engineer, who issued a pamphlet entitled *A New Method for Transporting Parcels and Letters by Air*. He followed this by another in 1812 entitled *Some Calculations and Remarks Tending to Prove the Possibility of the New Method for Transporting Letters and Parcels by Air*. Nothing practical was developed from the proposal of Medhurst. In 1824 Valloric proposed a wooden tube 6 ft. 6 in. in diameter for carrying passengers between London and Brighton; carriages were to be blown through the tube, but the suggestion was never carried out. In 1827 Medhurst again proposed a method of pneumatic transmission by means of a piston propelled in a tube by air-pressure, the piston being connected with a carriage exterior to the tube by means of a rod passing through a slot covered by a valve which the rod opened and closed as the piston moved forward. As the air-pressure was obtained from the atmosphere (the air being exhausted in front of the traveling piston and allowed to enter the tube behind it), this system was called the atmospheric railway.

Although Medhurst's proposals were not carried out practically, the idea of pneumatic transmission, by which the movement of the load transmitted was accomplished in carriages outside of the tube in which the piston moved, originated with him, and was in reality the first system which was commercially employed. Medhurst's invention has been made the foundation of upward of fifty British patents (ranging in date from 1827 to 1850), most of which relate to modifications of the valve covering the slit in the top of the tube, or to mechanism for opening and closing it. This system was first tried in 1842 on a half mile of line at Wormwood Scrubs, near London, and a speed of 30 miles an hour was obtained. This experiment led to the employment of the system on the Kingstown and Dalkey Railway, a line of 1¾ miles near Kingstown, Ireland, on which trains were run at the rate of 45 miles per hour. Several short lines were constructed in England, and in 1847 the line from Paris to St.-Germain was built. This road was worked on the pneumatic plan for over twenty years, and outlived all its pneumatic predecessors. At present there is no pneumatic transmission system using a slit tube and an exterior carriage.

In the system of pneumatic transmission employed in all the large cities of Europe and in many places in the U. S. the articles to be conveyed are always within the tube, which extends from one station to another. This method of pneumatic transmission was first carried out on a commercial scale by Latimer Clark in 1853 between the Central and Stock Exchange stations of the Electric and International Telegraph Company in London. The tube connecting the stations was 1½ inches in diameter and 660 feet long. Carriers containing a number of messages were sucked through (in one direction only) by creating a partial vacuum at the delivery end of the tube. C. F. Varley, in 1858, improved the system by using compressed air to force the carriers in one direction, a partial vacuum being used to draw them in the opposite; this is known as the radial system of pneumatic transmission, for the reason that a large number of tubes can radiate in all directions from a single station. This system has been brought to great perfection in connection with the telegraph department of the British post-office, with thirty-six tubes in London alone. Another method of working, used in Paris and other large continental cities, is called the circuit system. In this stations are grouped on circular or looped lines, around which carriers travel in one direction only. The pressure used in the tubes of the British post-office is 10 lb. per square inch of compression, or 7 lb. of vacuum, and the time of transit through a tube 2½ inches in diameter is 1 minute for a distance of 3,000 feet and 5½ minutes for 9,000 feet.

The first application of pneumatic transmission to the conveying of mails and parcels was made in 1863 by the Pneumatic Dispatch Company of London, which constructed a line of D-shaped tube (the convex side uppermost) beneath the surface of the ground from the terminus of the Northwestern Railway at Euston to the district post-office in Eversholt Street, a distance of about 1,800 feet. The dimensions of the tube were 2 ft. 8 in. wide and the same in height. The carriages were cradle-like boxes made to conform to the shape of the tube (although not touching it) and mounted upon four wheels. These carriages were made to travel in the tube at the rate of 17 miles per hour, and regularly transmitted fifteen mails per day each way. The result of the working of this line was so satisfactory that in 1872 a line with a pair of D-shaped tubes, 4 feet wide and 4 ft. 6 in. high, was laid from Euston station to the General Post-office, a distance of 14,214 feet. The time usually occupied in transit is 12 minutes, and 10 or 12 tons are drawn up grades of 1 in 14 without difficulty.

With a view of demonstrating the applicability of the principles of pneumatic transmission to passenger traffic, the Pneumatic Dispatch Company had constructed at the Crystal Palace, Sydenham, a brick tunnel about 10 feet high by 9 feet wide, capable of admitting the largest carriages used on the Northwestern Railway. This tunnel was 1,800 feet in length. The gradients were 1 in 15 (352 feet per mile) and the transit was made in 50 seconds with a pressure of but 2½ oz. per square inch. The motion was said to be smooth and agreeable, and stoppages were made gently and without jerk. In 1869 Alfred Beach began the construction of a pneumatic railway under Broadway, New York. The internal diameter of the tunnel was 8 feet, and the portion of the line completed extended from Warren to Barclay Streets. Some experimental work was done on this line, but the enterprise was abandoned owing to a variety of reasons not at all connected with the principle of pneumatic transmission.

Notwithstanding the success of pneumatic transmission in connection with the postal service of European nations, it was not until 1892 that the U. S. Government decided to give the system a trial, and a plant was laid down in Philadelphia, extending from the General Post-office at Ninth and Chestnut Streets to the sub-station on Chestnut Street between Third and Fourth Streets, a distance of 2,928 feet. There are two tubes of iron, bored to an internal diameter of 6⅛ inches and made in sections of 12 feet in length. This plant was put in operation on Feb. 17, 1893, and has been so successful that it is proposed to establish an extended system of pneumatic transmission covering the whole city. Pneumatic tubes have been used for many years by the Western Union Telegraph Company to convey messages from sub-stations in New York to the general office, and they have also been largely employed in commercial establishments to convey change from a central office to the

several sales-counters; but pneumatic transmission has not reached a development in the U. S. equal to that in Europe.
W. F. Durfee.

Pneumogastric Nerve [*pneumogastric* is from Gr. *πνεύμων*, lung + *γαστήρ*, stomach; so called from its distribution to the lungs and stomach]: the tenth cerebral nerve, though largely a spinal nerve. Its nucleus of origin is a mass of ganglion-cells lying deep in the posterior part of the medulla oblongata, in the floor of the fourth ventricle, and its fibers escape from the side of the medulla. It issues from the skull by the jugular foramen, at which point there is a ganglionic enlargement of the nerve. It then descends with the carotid artery to the chest, and after entering the thorax lies upon the œsophagus. Upon the lower part of the œsophagus the two nerves conjoin, pass through the diaphragm, and are distributed to the stomach and solar plexus. At the level of the jugular foramen the pneumogastric is joined by branches from motor nerves—the facial, hypoglossal, spinal accessory, etc. The branches of the pneumogastric are sent to the pharynx, to the larynx (superior laryngeal nerve, which is sensory, inferior laryngeal, which is motor), to the heart, lungs, œsophagus, and stomach. From its origin to its ganglion (analogous to posterior root of spinal nerves) the pneumogastric nerve is purely sensory, and its most important function—viz., the regulation of breathing by the transmission of sensations through its pulmonary branches to the medulla—is performed by that property. Below the ganglion it is a mixed nerve. The motor properties of the inferior laryngeal are derived chiefly from the branch of the spinal accessory nerve, and the pharyngeal branch derives its motor power from the nerves which join the pneumogastric below the ganglion. The action of the pneumogastric on the heart is checking or inhibitory, paralysis of the pneumogastric producing excessive rapidity of the heart's action (and slow respiration), while irritation of the nerve slows or stops the cardiac movements. The movements of the œsophagus and stomach are under the control of the motor fibers of the pneumogastric. Revised by William Pepper.

Pneumograph: See Recording Apparatus, Psychological, in the Appendix.

Pneumonia [= Mod. Lat. = Gr., deriv. of *πνεύμων*, lung]: inflammation of the lung, of the lining of the air-sacs, and of the interstitial framework of the lung. Pneumonia has been classified into (1) catarrhal pneumonia, when only the air-sacs are involved, filled with products of catarrhal inflammation, extending from the bronchial tubes; (2) croupous pneumonia, when the air-sacs are filled with solid lymph exuded from their inflamed walls; (3) interstitial pneumonia, a slow and chronic inflammatory infiltration and consolidation of the fibrous structures which surround the air-sacs and minute bronchial tubes. As commonly used, however, in Great Britain and the U. S., the term pneumonia means the croupous form only, an inflammation of the air-sacs, which are the functional elements of the lung for the oxygenation of the blood and the liberation of carbonic acid gas. This form, popularly known by the name of "lung fever," is usually confined to one lung and often to one lobe, though it sometimes attacks the lobes successively. Accordingly, it is further designated as "lobar pneumonia." Primary pneumonia in healthy persons occurs more often in the right lung, beginning, as a rule, at the base of the lung and progressing upward toward the apex. In old and feeble persons it may begin at the apex, but pneumonia when local or beginning at the apex is usually tuberculous in nature and the beginning of a chronic phthisis. Pneumonia is a disease chiefly of adults, and more often of males. It results from infection by a specific microorganism, the *Pneumococcus* or *Diplococcus pneumoniæ*, when the system is rendered susceptible by chilling, exposure, fatigue, and similar causes. Pneumonia is therefore an infectious disease, and to a degree it is also contagious. House and institution epidemics have frequently been observed. The disease is announced by a heavy chill, high fever, rapid respiration, frequent pulse, flushed cheek—on the side of the affected lung; in severe cases by delirium and symptoms of a typhoid nature. There is acute pain in the side, due to congestion of the pleura, and a duller, heavier pain or soreness of the side, with sense of weight, due to excess of blood and the solid products of inflammation in the lung. There is cough, with expectoration of mucus tinged with blood or rust-colored, and in grave cases brownish or dark sputa, resembling tobacco-juice or prune-juice, and indicative of a decomposed state of the blood, and the exuded elements filling the vesicles. The contents of the vesicles are gradually softened and expectorated, and the lung restored to its normal state. Acute pneumonia of adults, although grave in its symptoms, is usually curable, and, contrary to popular apprehension, seldom leads to subsequent consumption.

Pneumonia in children is usually acute catarrhal inflammation of the minute bronchial tubes and air-sacs, occurring in one or many lobules of both lungs. It is liable to leave portions of lung-substance inactive, collapsed, or consolidated, and develop the catarrhal form of phthisis; but many of the cases in which it is supposed that phthisis has followed catarrhal pneumonia are really *tuberculous catarrhal pneumonia* from the first.

Pneumonia is variously treated. Locally, cold water and ice-bags may abort or limit the inflammation at its beginning. When established, warm applications, as poultices, warm anodyne fomentations, cotton-batting, and oil-silk afford the greatest comfort and favor resolution and removal of the exudation from the air-sacs. Carbonate and muriate of ammonia are used as diffusive stimulants and to liquefy the exuded lymph; calisaya bark or quinine, alcoholic stimulation, and rich liquid diet to sustain strength are also employed. At the very onset bleeding is at times a useful measure of treatment. Revised by W. Pepper.

Po [Lat. *Padus*, or, poetically, *Eridanus*; Gr. *Ἠριδανός*]: the largest river of Italy. Rising on the east flank of Monte Viso, at a height of 6,560 feet above the sea, it flows N. E., receiving many affluents in its course, till its junction with the Dora Baltea near Chivasso, thence a little S. of E. to the Adriatic, into which it discharges by several mouths; length, 360 miles; drainage area, 27,000 sq. miles. In the first 20 miles of its course it descends 5,300 feet to a point near Revello, and though here a large stream its bed is sometimes left dry for a considerable distance. At Valenza, about one-third of the whole distance from its source to its outlet, it reaches the level of some 600 feet above the sea, and from this point it flows chiefly through its own alluvion to the Adriatic, and is navigable for vessels of 130 tons.

The Po is diked continuously from near Cremona to the marshes at its outlet. The levees do not follow the smaller windings of the river, but in many places leave a space of even miles between them. An embankment running along the margin of the channel is called *argine a froldo*, or simply *froldo*. When it recedes sensibly from the river it is called *argine a golena*. The *golene*, or spaces between the levee and the channel, are frequently protected by low dikes and cultivated, but in every considerable rise of the river the natural banks are overflowed and the *golene* submerged.

The river receives fully four-tenths of its volume from a chain of lakes lying at the foot of the Alps, extending E. and W. about 150 miles, and with a total area of more than 300 sq. miles. The mean discharge into the Adriatic is 60,745 cubic feet to the second, which appears to differ little from the delivery of the Rhône and of the Rhine, and equals about one-eleventh of that of the Mississippi. Its waters are usually at their lowest stage twice in the year, about the summer and winter solstices, and at their highest in May and October.

Besides its vast discharge proportionally to the extent of its basin, the enormous amount of mineral matter ground down to fine silt deposited by its waters at and near its outlet—a consequence of the fact that most of its tributaries are mountain-torrents—is a noteworthy feature in the physical character of the Po. In floods this is calculated to equal $\frac{1}{300}$th part of the total delivery in *volume*, or almost ten times the mean proportion of solid matter borne down by the Mississippi. The deposit extends the delta of the Po into the Adriatic at a rate of advance not greatly inferior to that of the Mississippi, or more than 200 feet per year, though the lateral spread of the sediment is less than at the mouth of the American river.
George P. Marsh.
Abridged by M. W. Harrington.

Pocahontas: daughter of Powhatan, a powerful Indian chief of Virginia; b. about 1595. According to the *True Relation* of Capt. John Smith, she in 1607 rescued the latter from death when he was taken prisoner by the Indians. The rescue, according to Smith's narrative, took place at Werowocomoco (now Shelly), Gloucester co., Va., near the junction of Carter's creek and York river. In 1609 she visited Smith with news of an intended Indian attack, and she several times supplied the hungry colonists of Jamestown with corn. In 1612 the chief Japazaws sold her to Argall, and her

father offered a ransom for her release, but could not agree with her captor on the terms. In 1613 she married Thomas Rolfe, afterward secretary and recorder-general of Virginia. She was baptized as Rebeeca, went to London, and was presented at court. D. at Gravesend, England, Mar., 1617, leaving a son, Thomas Rolfe, from whom the Randolphs, Guys, Hemmings, and other leading families of Virginia trace their descent. See Doyle's *English Colonies in America* (1882).

Pocock, Edward, D. D.: Orientalist; b. at Oxford, England, Nov. 8, 1604; graduated there in 1622; was fellow of Corpus Christi College in 1628, and devoted himself to the study of Eastern learning. He was chaplain to the English factory at Aleppo, Syria, from 1630 to 1636, when he returned to Oxford to take the professorship of Arabic, then just founded by Arehbishop Laud. After giving one course of lectures he went back to the Orient, and was in Constantinople from 1637 to 1640, collecting manuscripts and coins and ardently pursuing his favorite studies. He returned to England in 1640, and in 1643 his college gave him the living of Childrey in Berkshire, near Oxford. In 1648 he was appointed to the chair of Hebrew, and became canon of Christ Church the same year. A staneh though not intemperate royalist, he would have lost his professorships in the time of Cromwell but for the remonstrances of John Owen and John Selden. The restoration of Charles II. in 1660 multiplied and secured his honors. D. in Oxford, Sept. 10, 1691. He published, besides other works, *Version from the Syriac and Notes on the Epistles of 2 Peter, 2 and 3 John, and Jude*, omitted in the Peshito (1630); *Specimen Historiæ Arabum* (1648); *Porta Mosis* (1655); *Annals of Eutychius* (1658); *Arabic Version of Grotius de Veritate* (1660); *Abulfaragii Historia Dynastiarum* (1663); and English *Commentaries* on Micah (1677), Malaehi (1677), Hosea (1685), and Joel (1691). See his *Works and Life*, in 2 vols., by Leonard Twells (London, 1740).

Revised by S. M. Jackson.

Pococke, Richard, LL. D.: traveler; b. at Southampton, England, in 1704; graduated at Oxford in 1731; took the degree of LL. D. in 1733; traveled in the East 1737–42; published his *Description of the East and some other Countries* (2 vols. fol., with 178 plates: vol. i., *Observations on Egypt*; vol. ii., part i., *Palestine, Syria, Mesopotamia, Cyprus, and Candia*—part ii., *Islands of the Archipelago, Asia Minor, Thrace, Greece, etc.*) in 1743–45; a German translation appeared (Erlangen, 1754–55, 3 parts), and a Freneh one (Neuchâtel, 1772–73, 7 vols.). He was made Arehdeaeon of Dublin in 1745, Bishop of Ossory in 1756, and in 1765 Bishop of Meath, and died at Charleville, near Tullamore, on Sept. 15 of that year. He wrote his *Travels in Scotland* (edited from original MS., with memoir by D. W. Kemp, Edinburgh, Seottish Historieal Society, 1887), in *Ireland* (edited by G. T. Stokes, Dublin, 1891), and in *England* (2 vols., London, Camden Soe., 1888–89). He was the author of some papers in the *Philosophical Transactions* and in the *Archæologia*, but his fame rests upon his work on Palestine, whieh Robinson pronounces "one of the most important," although he knew but little Arabic and his seholarship was more classieal than biblieal.

Revised by S. M. Jackson.

Po'comoke River: a river whieh rises in the Cypress Swamp of Sussex co., Del., and flows 60 miles S. and S. W., mostly in Maryland, to Chesapeake Bay. The tide ascends 22 miles, and it is navigable 20 miles, to Snow Hill, Md.

Podes'ta [Lat. *potestas*, power]: a municipal magistrate in Italian eities. The name was formerly applied to the chief magistrates of Italian towns, appointed in troubled times with full dictatorial powers. He was usually a stranger to all the loeal factions, and during his term of offiee was prohibited by law from forming any intimate eonneetion with the citizens over whom he ruled. He was appointed for a term of years, but he sometimes beeame a permanent despotie ruler. The name was probably first given to the German magistrates whom Frederick Barbarossa appointed over the Lombard eities.

Podgoritza (eity under the hill): town; situated on the Moratcha in territory ceded to Montenegro by the Treaty of Berlin (1878); strategieally important as commanding Northern Albania. It was founded in the fifteenth century by Mohammed II., and built from the neighboring ruins of Dioclea, where Diocletian was born. Every Sunday a great bazar or market is held, thronged by Albanian and Montenegrin mountaineers when not engaged in war. It carries on a large trade in honey, skins, wax, and wool. Pop. 6,000.

E. A. Grosvenor.

Podiciped'idæ [Mod. Lat., named from *Podiceps*, the typical genus; Lat. *po'dex, po'dicis*, rump + *pes, pe'dis*, foot]: a family of swimming birds, including the grebes, distinguished by their rudimentary tail, flattened tarsi, broadly lobed toes, of which the outermost is the longest, and flattened nails. The body is short, plumage close and silky, legs placed far backward. The name is sometimes written *Podicipidæ*. See Grebe.

F. A. L.

Podiebrad, pōd-yā'brăd, George: King of Bohemia; b. in Apr., 1420, of a noble and wealthy Bohemian family belonging to the moderate section of the Hussite party; joined the Utraquists after the election of Albert of Austria to the Bohemian throne in 1438, and distinguished himself greatly by compelling Albert to raise the siege of Tabor. As leader of the whole Hussite party he became governor of Bohemia in 1444, during the minority of Albert's son, Ladislaus the Posthumous, and on the death of Ladislaus he was elected king himself, and crowned at Prague Mar. 2, 1458. It was his great aim to reconcile the Hussites and the Roman Catholics among his subjects, and he acted with wisdom, and with some success; but the pope excommunicated him as a heretic, preached a crusade against him in Germany, incited his son-in-law, Matthias Corvinus, King of Hungary, to attack him, and even instigated his own Roman Catholic subjects to revolt against him. Podiebrad suppressed the insurrection, routed the German crusaders, defeated the Hungarians several times, and, in order to strengthen the anti-papal and anti-Hungarian party in Bohemia, he induced his countrymen to elect Ladislaus, heir of the Polish crown, as his successor, while his two sons retired into the ranks of the nobility. D. Mar. 22, 1471. See Richter, *Georg von Podiebrad's Bestrebungen* (1863); Jordan, *Das Königthum Georgs von Podiebrad* (1869); and Baehmann, *Ein Jahr böhmischer Geschichte* (1876).

Revised by F. M. Colby.

Podo'lia: government of European Russia; bounded W. by Galicia (Austria) and S. by the Dniester. Area, 16,224 sq. miles. The surface is mostly level, the soil fertile, and the climate mild. Grain, hemp, flax, hops, and tobacco are grown, and the vine and the mulberry are extensively cultivated. Large herds of cattle and sheep are reared, and there are important manufactories of beetroot sugar, distilleries, and sugar-refineries. Pop. (1897) 3,031,040.

Podophyllum and **Podophyllin**: See May-apple.

Podu'ra [Mod. Lat.; Gr. *πούς, ποδός*, foot + *οὐρά*, tail]: a genus of insects of the order *Thysanura*, interesting from the fact that the scales with which the body is covered are sometimes used as test-objects for the microscope.

Poe, Edgar Allan: author; b. in Boston, Mass., Jan. 19, 1809; son of David Poe and Elizabeth Arnold, an English actress. His parents, who pursued the vocation of actors, having died in his early childhood, Edgar was adopted by a wealthy citizen of Richmond, Va. (John Allan), by whom he was sent to school at Stoke Newington, near London, England, from 1815 to 1820; entered the University of Virginia, at Charlottesville, in 1826, but was removed within a year, probably on account of addiction to the gaming-table. In 1827 he went to Boston, and issued there his first volume, *Tamerlane and other Poems*; enlisted in the U. S. army as a private under an assumed name, and was admitted a cadet at West Point 1830, but was dismissed Mar. 6, 1831. In 1833, while living at Baltimore, Md., he took a $100 prize by his story *A Manuscript found in a Bottle*, and this led to his appointment as editor of *The Southern Literary Messenger*, Richmond, Va. While occupying that position Poe married his cousin, Virginia Clemm, and led for two or three years a life of considerable regularity, devoting himself to study and writing many tales, reviews, essays, and brief poems. Having at length quarreled with his publisher, Poe removed to New York Jan., 1837; earned a precarious living for a year by writing occasional articles in several papers; published in 1838 his first prose volume, *The Narrative of Arthur Gordon Pym*; went to Philadelphia; was editor of Burton's *Gentleman's Magazine* from May, 1839, to June, 1840, and of *Graham's Magazine* from Apr., 1841, for about a year; published *Tales of the Grotesque and Arabesque* (2 vols., Philadelphia, 1840); gained a prize of $100 offered by *The Dollar Newspaper*, in 1843, with his tale *The Gold Bug*; removed to New York in the autumn of 1844, where the appearance of his best-known production,

The Raven, in Colton's *Whig Review* for Feb., 1845, gained him a wide reputation, and procured him the post of sub-editor on Willis's and Morris's *Home Journal*; was associated with C. F. Briggs in the management of *The Broadway Journal* 1845–46; contributed to *Godey's Lady's Book* May to July, 1846, the biographical and critical sketches entitled *The Literati of New York City*; resided about this time in a cottage at Fordham, Westchester County, and fell into such poverty that an appeal to public charity in his behalf was made by N. P. Willis in *The Home Journal*; lost his wife, who had clung to him with fond devotion, in Jan., 1847; delivered at the Society Library, Feb., 1848, a lecture, published soon after under the title *Eureka, a Prose Poem*. D. in Baltimore, Oct. 7, 1849. A monument to his memory was erected in the Westminster churchyard, Baltimore, Oct., 1875, by a subscription raised by the school-teachers of that city. The works of Poe have been repeatedly republished since his death, both in the U. S. and in England, and have attained an immense popularity in a French translation. They were first edited in New York (4 vols., 1850) by Poe's "literary executor," Rufus Wilmot Griswold, who prefixed a defamatory *Memoir*, many of the allegations of which have been successfully refuted by later biographers, such as Mrs. Sarah Helen Whitman in her *Edgar A. Poe and his Critics* (1860), John H. Ingram in a *Memoir* prefixed to Poe's *Works* (Edinburgh, 1874), and Richard Henry Stoddard in a memoir accompanying a new edition of the *Poems* (New York and London, 1875). The best biography of him is that written by George E. Woodberry and published in the American Men of Letters Series (1885). Revised by H. A. Beers.

Poe, Orlando Metcalfe: soldier; b. in Ohio, Mar., 1832; graduated at the U. S. Military Academy, and entered the topographical engineers July, 1856: captain of engineers 1863; colonel July, 1888. He was engaged upon lake-survey duty until the outbreak of civil war in 1861, when, after serving as chief engineer in the department of the Ohio and on the staff of Gen. McClellan, he was (Sept., 1861) appointed colonel of the Second Michigan Volunteers, and served with the Army of the Potomac until Dec., 1862, having been appointed brigadier-general Nov. 29, 1862; subsequently served as chief engineer of the Twenty-third Corps of the Army of the Ohio, and of Gen. Sherman's army in the invasion of Georgia and march to the sea, gaining the successive brevets from major to brigadier-general for gallant and meritorious services. Returning to duty with the Corps of Engineers at the close of the war, he was (1865–70) engineer secretary of the U. S. lighthouse board; in 1870–73 constructed the lighthouse on Spectacle Reef, Lake Huron. He was aide-de-camp on the staff of the general of the army 1873–84, member of the lighthouse board 1874–84, and had been since 1883 member of various engineer boards charged with the construction of river and harbor works on the northern and northwestern lakes, including the new lock at the Ste. Marie's Falls Canal. D. in Detroit, Mich., Oct. 2, 1895.

Pœcilop'oda [Mod. Lat., from Gr. *ποικίλος*, many-colored, manifold + *πούς*, *ποδός*, foot]: a term sometimes used as equivalent to Merostomata (*q. v.*).

Poetics: See Poetry.

Poet-laureate [*laureate* is from Lat. *laurea'tus*, crowned with laurel, deriv. of *lau'rea*, laurel (in both ancient and modern times a symbol of triumph)]: a title bestowed at universities and by sovereigns at various courts. The Greeks and Romans, in their public ceremonies, sometimes crowned their poets with symbolical chaplets of the bay-tree sacred to Apollo. It was in imitation of this ceremony that Petrarch was laureated on the Capitol in Rome, on Easter Day, 1341. The title, during the Middle Ages, was commonly an academic and not a courtly distinction; it was conferred by the universities for skill in Latin verse, and was of the nature of a degree. It was in that scholastic sense of the term that John Skelton was made *poeta laureatus* at Oxford in 1489.

The fact that the king united with the university in the bestowal of the honor indicates the way in which the laureateship finally became a regular court appointment. In Germany the custom of crowning poets with laurel was an imperial prerogative, but was sometimes delegated by the emperor to the counts palatine and the universities. In Spain the custom was established at the University of Seville. France was seemingly the only country of mediæval Europe in which the title was not known.

During the reigns of the Norman kings of England there had frequently been attached to the royal household an officer called the *versificator*, or king's poet, who celebrated his lord's achievements in Latin verse, and received an annual stipend. The circumstances under which the title of poet-laureate was transferred to these court poets are somewhat obscure. Robert Whittington, who received the laurel at Oxford in 1512, is described as the last of the university laureates. The first king's laureate of whom any mention is made was John Kay, who was poet to Edward IV. The second was Andrew Bernard, who held the title under Henry VII. and Henry VIII. He had a salary of ten marks. His *Epithalamia*, New Year's verses, and other official performances are in Latin, thus continuing the tradition of the university laureates. Then follow a number of poets who have been termed volunteer laureates. These were Richard Edwards, Edmund Spenser, and Samuel Daniel. They all held court appointments of one kind or another, and received grants of money or of land, but they were not officially styled poets-laureate.

Ben Jonson was the first in the line of officially appointed poets-laureate. He was appointed by James I. in 1616, at an annual salary of 100 marks (£67), which was raised by Charles I. to £100, with a tierce of canary wine. The written instrument granting this increase of pension is dated Mar., 1630, and is the first regularly issued patent for the office of poet-laureate.

After his death in 1637 the laureateship was conferred upon Sir William Davenant (Dec. 13, 1638). From the outbreak of the civil war and during the Commonwealth (1642–60) the office was in abeyance. Davenant was a royalist, was active in the king's cause, and was several times imprisoned by the Parliament. After his death in 1668 John Dryden succeeded to the laurel (1670), and was also made historiographer royal. The salary of the two offices amounted to £200, with the annual tierce of canary. His salary was shortly increased to £300, with a further annual pension of £100 to be dependent on the king's pleasure. He wrote no laureate odes, but composed an elegy, *Threnodia Augustalis*, on the death of Charles II. in 1685. James II. continued to Dryden the title and emoluments of the office, but omitted the butt of canary from his perquisites. In 1686 he was granted an additional pension of £100 a year. At the revolution of 1688 Dryden was deposed from his office, which was given to his old enemy, the "true blue" Protestant and Whig poet Thomas Shadwell, whom he had lampooned unmercifully in his satire *Mac Flecknoe*.

From the time of Dryden to the time of Southey the English laurel was worn by a succession of poetasters. Poets like Pope, Prior, Goldsmith, and Cowper were passed over, and the honor bestowed upon Tate, Eusden, and Pye. "The bays" became a sure badge of mediocrity and a target for universal scorn in lampoon, epigram, caricature, and parody. The names of these laureates and the dates of their incumbency are as follows: Thomas Shadwell, 1688–92; Nahum Tate, 1692–1715; Nicholas Rowe, 1715–18; Lawrence Eusden, 1718–30; Colley Cibber, 1730–57; William Whitehead, 1757–85; Thomas Warton, 1785–90; Henry James Pye, 1790–1813. Shadwell began the fashion, which was continued by his successors down to the time of Southey, of composing anniversary odes on the king's birthday and on New Year's Day. These were set to music by the court composer, and sung in the royal chapel or the state drawing-rooms. During the reign of Queen Anne the appointment of the poet-laureate was vested in the lord chamberlain; and Tate, who had served under William and Mary, was formally reappointed in 1714 by that functionary, in whose hands the bestowal of the office has remained ever since.

Of the eighteenth-century laureates, Tate is remembered chiefly by his (and Brady's) versions of the Psalms in meter, and Rowe by his edition of Shakspeare. Cibber, the manager of Drury Lane theater, was a man of wit and a successful playwright, but a small poet. Thomas Warton was a respectable appointment. He was an antiquary and critic, a scholar of elegant tastes, and a genuine though by no means a great poet. In Eusden and Pye the laureateship touched the lowest point in the history of the institution. On Cibber's death the laurel had been offered to Gray, who declined it. During Pye's tenure of office the annual tierce of canary was commuted for a money payment of £27.

In 1813 the laureateship, which had been offered Sir Walter Scott and by him declined, was given to Robert Southey, who made it a condition of his acceptance that he should be expected to write official odes only upon occasions

of his own choosing. A number of such performances, composed at irregular intervals, are among his writings. Southey's poems on public events are not of his happiest, and his unfortunate *Vision of Judgment*, composed on the death of George III., brought upon him a terrible punishment in the shape of Byron's wicked and brilliant satire of the same title. Southey was by no means the best poet in England, but his worth and abilities rescued the office of poet-laureate from the general contempt in which it was held.

After his death in 1843 the laureateship was most fittingly bestowed upon William Wordsworth, the first great poet who had received it since Dryden. It was expressly stipulated that nothing should be required from him in the way of official verses, and nothing of the kind came from his pen during the seven years of his incumbency.

On Wordsworth's death in 1850 the honor was conferred upon Alfred Tennyson, the foremost living English poet, who inherited, in his own words,

> This laurel, greener from the brows
> Of him who uttered nothing base.

As in the case of his two immediate predecessors, Tennyson's official verses were strictly voluntary. Among them may be mentioned the dedication of his *Idyls of the King* to the memory of Prince Albert, the dedication to the Queen of his 1851 volume of poems, and the *Welcome to Alexandra* (1863). The present poet-laureate is Alfred Austin. See *The Lives of the Poets Laureate*, by W. S. Austin and J. Ralph, London, 1853; *The Poets Laureate of England*, by Walter Hamilton, London, 1879. H. A. Beers.

Poetry [from O. Fr. *poëterie*, deriv. of *poëte* < Lat. *poe'ta* = Gr. *ποιητής*, maker, the creator of a poem]: according to Aristotle (*Poetics*, i., 1), the imitation, by means of rhythm, words, and melody, of the actions of men. To the modern inquirer, however, this definition seems somewhat far-fetched and decidedly inadequate. In trying to frame a better one there is an inevitable confusion, owing to the fact that the mind, as it strives to define, oscillates between realization of the process of poetic creation, or making, and recollection of what has in fact been created by poets. The creative arts are really closely akin, and the term "making" fits one almost as well as another; but we do not call painting and sculpture poetry, and although the prose novel is imitation of the actions of men, and often implies the act of making or creating, yet we do not denominate even this poetry. We are, in fact, even in the field of literature, forced back upon a purely empirical definition, and we can probably do no better than to adopt the test which is popularly employed for determining whether a literary work is or is not poetry. This is, and perhaps always has been, the presence of rhythm or meter.

It seems to be certain that this addition of rhythmical or metrical effect is what in the first place made any form of literature possible. Language first gained distinction and became something with an existence apart from the speaker through the imposition upon it of a form unused in ordinary intercourse between men. There were several ways in which this imposition could occur. One of the most primitive of human impulses is that to rhythmic motions of the body—i. e. to the dance; and it is inevitable that words uttered in accompaniment to the dance should partake of its rhythmic character. Then, modulated utterance, or song, may fairly be called instinctive in the human race, and this necessarily brings with it rhythm in the words sung. The extension of music to instruments, even the most barbarous, carries the same result. The very memory, with its demand for regularity in the form of what is remembered, tends in the same direction. Thus many forces must have co-operated to give to language at certain times and on certain occasions a quality which ordinarily it has not. Here was the beginning of poetry; and it was inevitable that in time all the sentiments and emotions, all the memories, traditions, and intellectual interests of mankind that are at all removed from the gross needs of daily life, should find utterance in poetical form.

The varieties of poetry are numerous and not rigidly distinguishable from one another. At the same time each has in a sense an organic life of its own, and corresponds with some accuracy to a human interest or function. The reader will find the character and history of the chief poetic forms discussed in the following articles: Ballad Poetry, Didactic, Drama, Epic Poetry, Epigram, Geste, Gnomic Poets, Hymnology, Lyric Poetry, Ode, Pastoral Poetry, Romances, Satire, Sonnet, and Theater. See also Fine Arts.

Of inquiries into the nature and function of poetry, Aristotle's *Poetics* is, despite its incompleteness, still the best. The *Ars Poetica* of Horace has a practical rather than theoretic purpose, and this is true of the numerous treatises that Horace has inspired—e. g. the *Ars poetica* of Vida, Boileau's *Art Poétique*, and Pope's *Essay on Criticism*. As a rule, however, poetry has been systematically discussed chiefly by writers engaged with some theory of æsthetics. These have rarely taken the trouble to base their conclusions on a careful investigation of the history of poetry in its several kinds. Two brief treatises in English in defense of poetry contain interesting hints upon the inner nature of the art. These are Sir Philip Sidney's *Defense of Poesy* and Shelley's essay with the same title. Wilhelm Scherer's *Poetik* (Berlin, 1888) and F. B. Gummere's *Handbook of Poetics for Students of English Verse* (Boston, 1885) are also helpful and suggestive.
A. R. Marsh.

Poge, Cape: See Cape Poge.

Pog'gendorff, Johann Christian: physicist; b. in Hamburg, Germany, Dec. 29, 1796; was educated at the University of Berlin, where he became Professor of Physics in 1834; attained great distinction as an observer of magnetic and electrical phenomena; published a *Treatise on Voltaic Electricity* (1821), and in 1824 became editor of the renowned *Annalen der Physik und Chemie*, and with Liebig edited the *Wörterbuch der Chemie*; wrote important works on biography and on the literature of the physical and mathematical sciences. D. Jan. 24, 1877.

Poggio, Bracciolini, pod'jō-braăt-chō-lee'nĕe, Giovanni Francesco: humanist: b. at Terranuovo, near Arezzo, Italy, in 1380; apostolic secretary 1403–53, in which year he was elected chancellor of Florence. D. in 1459. On his diplomatic missions he employed his leisure in looking for MSS., and his search was rewarded by the discovery of a complete Quintilian, seven speeches of Cicero, twelve hitherto unknown comedies of Plautus, Ammianus Marcellinus, Aratea, Silius Italicus, Manilius, Petronius, Columella, Frontinus, Nonius, Probus, parts of Lucretius, Valerius Flaccus, Priscian, Vitruvius, Statius's *Silvæ*, and it is due to his unflagging enthusiasm and perseverance that the *Dialogus* and *Germania* of Tacitus and the fragment of Suetonius, *De grammaticis et rhetoribus*, were rescued from destruction in a German monastery. Poggio also did good service in preserving the ruins of ancient Rome, and his collection of inscriptions, only rivaled in extent by those of his contemporary Kyriacus, prove him to have been fully alive to the paramount historical importance which attaches to epigraphic documents. See Voigt, *Wiederbelebung des class. Atterthums* (i., pp. 237–262, ii., 254, ff., 329–342); I. A. Symonds, *Renaissance in Italy* (ii., pp. 134, ff., 230–246); Henzen, in the *Corpus Inscript. Latin.* (vi., 1); W. Shepard, *The Life of Poggio* (2d ed. London, 1807). A. Gudeman.

Pogo'din, Mikhail Petrovich: writer and archæologist; b. in Moscow, Russia, Nov. 23, 1800. Even before graduating from the university he had begun to establish a reputation by his articles on *The Chronicle of Nestor* and by translations of German works. In 1823 he published his dissertation on *The Origin of the Russians*. In 1825 he was made instructor and in 1830 professor at the Moscow University, where he remained until 1844, when he resigned in order to devote himself entirely to his other tasks. During this time he attempted various kinds of literature, including translations from the German, an historical tragedy, *Marfa the Possadnitsa* (1831), stories (3 vols., 1833), and a dramatized *History of the False Demetrius* (1835), besides editing works of various kinds. He was one of the editors of the *Moscowskiĭ Vestnik* (Moscow Messenger, 1827–30) and the *Russian Observer*. His chief interest, however, was the early history of his country. He was an ardent Slavophil, though he defended the memory of Peter the Great, and he was one of the founders of the Moscow Slav Committee, which labored to prepare the way for Panslavism. Although he never completed his great history of Russia (1846–54, 7 vols., fragmentary disquisitions rather than a connected account), he wrote much of value. In 1841 he founded *Moskvitianin* (The Muscovite), an historical magazine that came out for fifteen years. D. in Moscow, Dec. 8, 1875. Among the best-known of his works are *The Character of Ivan the Terrible* (1828); *The Complicity of Godunov in the Murder of Demetrius* (1829); *The Historical Basis of Serfdom* (1858); and *The First Seventeen Years of the Reign of Peter the Great* (1875).
A. C. Coolidge.

Poinsett, Joel Roberts, LL. D.: statesman; b. at Charleston, S. C., Mar. 2, 1779, of a Huguenot family; spent his early childhood in England; educated at Greenfield Hill, Conn., under Timothy Dwight 1793–94; went again to England 1796; studied medicine at Edinburgh, and entered the military academy at Woolwich; returned to Charleston and studied law 1800; went again to Europe 1801; traveled in Asia Minor and in Russia; returned home in 1809; was sent to Chili by President Madison to report on the revolution in that country, and there acquired great popularity; was in Congress from South Carolina 1821–25; U. S. minister to Mexico 1822 and 1825–29, filling a position then very difficult and important; U. S. Secretary of War 1837–41; founded the Academy of Fine Arts, Charleston, S. C., and liberally endowed the National Institution; author of *Notes on Mexico* (Philadelphia, 1824) and of various published essays and discourses, and was a strong opponent of the extreme States-rights view. D. at Statesburg, S. C., Dec. 12, 1851.

Point Alphabet: See Blind, Education of the.

Point de Galle: a town of Ceylon. See Galle.

Pointe-à-Pitre, La: largest town and principal port of Guadeloupe, French West Indies; at the southwestern corner of the island of Grande Terre, near the narrow channel which separates it from Basse Terre (see map of West Indies, ref. 7–M). The harbor, sheltered by the two islands, is one of the best in the West Indies. The town is well laid out. There is a fine shaded promenade, and many of the dwellings are surrounded by beautiful gardens. The most important export is sugar. Pointe-à-Pitre was destroyed by an earthquake in 1843, and has suffered severely from fires. Pop. about 20,000. Herbert H. Smith.

Point Edward: See Sarnia.

Pointer: one of a breed of dogs much used by sportsmen; so called because they stop and *point* toward the game which they scent. This habit has been so developed by training and breeding as to have almost become an instinct. Pointers are short-haired dogs, and should have a wide head, with very apparent occipital crest; ears thin, soft, and long, hanging flat at the side of the head; deep chest, strong loins, and tapering tail, thick at the root. The pointer is one of the hound group, and it is believed the breed originated in Spain. See Dogs. F. A. Lucas.

Point Levi: See Levis.

Poison: See Toxicology, Jurisprudence, Medical; and Lead-poisoning.

Poison-ivy: See Rhus.

Poison of Serpents: a poison with which certain serpents are provided, and which is formed by a pair of glands which lie back of and below the eye on each side. Each gland discharges its secretion through a duct which leads to a reservoir and finally to the base of a hollow fang. When the mouth is closed the fangs lie in a horizontal position against the upper jaw, but when open and the serpent is about to strike, muscular fibers connected with the roots of the fangs contract and throw the latter almost at right angles to the jaw. When the prey is seized the fangs are driven into the flesh of the victim, and muscular fibers connected with the venom-reservoirs are simultaneously rendered active, so that the poison is forced through the gland-ducts and hollow fangs into the wound. The quantity discharged varies from a part of a drop to over a teaspoonful, depending chiefly upon the size and activity of the serpent, the climate and season of the year, and the lapse of time intervening since the last discharge.

The venom of all serpents is a thin yellowish (occasionally colorless) fluid which is composed chiefly of albuminous matters in solution, and bears certain general resemblances to the saliva of higher vertebrates. It contains about 25 per cent. of water, and when dried breaks up into bright translucent pieces which closely resemble crystals. Many attempts have been made to isolate its poisonous principles, which for a long time were believed to be of the nature of alkaloids, especially ptomaines, but Mitchell and Reichert, who were the first to isolate them, have shown that they are represented in the albuminous substances above referred to. These they have found may be divided into two classes, which they have termed *venom-globulins* and *venom-peptones*. Their researches render it probable that all venoms contain one or more representatives of each of these classes. In some as many as four venom-globulins and one venom-peptone have been isolated, thus proving the existence of as many as five distinct poisons in a single specimen. Venom belongs to the group of virulent poisons, a quarter of a drop being sufficient to kill a pigeon, and a few drops to kill a dog.

The effects are divisible into local and general, immediate and remote. The venom having been injected under the skin by the fang, the first effect is a general feebleness, in which the heart shares, and which is sometimes accompanied by nausea and vomiting. If the amount be large, the animal or man dies within a time which varies from a few minutes to hours; if the early depression passes over, recovery is often sudden, or else the creature poisoned enters the second stage of the poisoning. This is characterized by blood-changes, and by a general degradation in the nutrition of every tissue, so that all suffer in some degree. The series of changes begins with lessened or lost power of the blood to clot; at the same time the texture of the smaller vessels is so altered as to allow the escape of the incoagulable blood, which, if the animal survive long, finds its way into the tissue of nearly every organ, thus causing symptoms which vary according as the organ most affected is the brain, spinal cord, liver, lungs, or kidneys. These changes result, therefore, in bleeding from the mucous surfaces of the breathing and digestive organs, and in oppressed respiration, bloody stools, or bloody urine, and finally in coma or convulsions and death. The local symptoms vary with the snake, but vary in degree only. First, there is thrown out about the fang-track a vast amount of blood, which, as it can not clot, soaks through the tissues, and even stains the bones. The adjacent muscles soften, and at last inflammation comes on, with great swelling and pain, and finally local death of the part.

There is no antidote that is efficient when administered internally. A solution of permanganate of potassium and the liquor chloride of iron are powerful local antidotes; that is, when they are brought in contact with the venom in the wound they chemically destroy the poison and thus render it inert. The permanganate is for all venoms the better, since it destroys both globulins and peptones, while the chloride of iron is destructive only to the globulins, and but slightly impairs the toxicity of the peptone. The proper treatment of snake-bite is at once to tie a ligature above the part bitten (or, better, put an elastic bandage around the whole limb), immediately lay open the wound in the line of the fang-mark, and thoroughly wash out the part with a solution of permanganate of potassium, encouraging bleeding by pressure toward the incision. In case no antidote such as permanganate of potassium or chloride of iron is at hand, it is useless to apply any local dressing save to put the part in hot water, wash it, and provoke bleeding. Next, alcohol should be given until the heart is excited, when the ligature may be loosened a little, so as to admit to the general circulation some of the poison, which soon or late must reach it unless destroyed by some local antidote or removed by bleeding, etc. Should the heart begin to fail the ligature should be tightened again and more stimulant given, so that any poison that might remain may be fought in detail. Alcohol is an antidote of uncertain value. It is but a stimulant to carry a suddenly enfeebled system over a time of weakness. For the second stage there is little to do but to ease pain.

Rattlesnake-bite is rarely fatal; cobra-bite is often fatal, as is attested by the fearful death-rate in India from this cause. Cobra-bite is more deadly partly on account of the venom being a stronger poison, and partly because of the generally larger size of the snakes and of the speed with which in hot climates the serpents accumulate venom, the severity of the symptoms being, in a large measure, directly as the dose of the poison. Sewall has shown that animals subjected to repeated small doses of venom gradually acquire immunity from what would be under ordinary circumstances fatal doses. Snake-venom does not affect plants, but to all life above these it is fatal when inoculated in sufficient amount, although it does not seem to have much power to injure when swallowed, so that pigeons have even been fed on it to the extent of twenty or thirty drops a day for a week without harming them. Mixture with gastric juice alone does not destroy its power, but it is altered below the stomach, and seems unable to enter the blood in a virulent form by this channel. Warm-blooded animals die easily from venom—cold-blooded creatures slowly, unless kept very warm.

The authorities on serpent-venom are Fontana's *Poisons*;

Weir Mitchell, *Venom of the Rattlesnake*; Fayrer, *The Poisonous Serpents of India*; Weir Mitchell and Edward T. Reichert, *Venoms of Poisonous Serpents*; and Wall, *Indian Snake-poisons*. Revised by EDWARD T. REICHERT.

Pois'son, SIMÉON DENIS: physicist; b. at Pithiviers, department of Loiret, France, June 21, 1781; was educated at the École Polytechnique, and became professor in that school in 1802; member of the bureau of longitudes in 1808; counselor of the university in 1820; peer of France in 1837. D. Apr. 25, 1840. His principal works are *Traité de Mécanique* (2 vols., 1811); *Théorie nouvelle de l'action capillaire* (1831); *Théorie Mathématique de la chaleur* (2 vols., 1835–37); *Sur l'invariabilité des moyen mouvements des grands axes planétaires*, besides about 300 memoirs in scientific journals, mostly on mathematical physics.

Poitiers, Fr. pron. pwăă'ti-ā': chief town of the department of Vienne, France; on the Clain, at its junction with the Boivre (see map of France, ref. 5–D). It is old and irregularly built, but it has a celebrated lyceum, a theological seminary, a public library with 30,000 volumes and 400 MSS., and other educational institutions. The Cathedral of St. Peter was begun by Eleanor of Guienne in 1162, on the ruins of a Roman basilica, and completed in the fifteenth century. The Church of St. John, originally a baptistery (about 700), is the oldest Christian building in France. In 1882 the remains of an entire Gallo-Roman town were discovered here; they comprise a temple, baths, and streets, spread over 14 acres. Breweries, distilleries, spinning-mills, glass-works, and tanneries are in operation, and an active trade is carried on in grain, wine, hemp, wool, wax, honey, and leather. Called Limonum at the time of the Roman conquest, it took the name Poitiers, from the Pictones or Pictavi. Christianity was introduced in the third century, and St. HILARY (*q. v.*) was the first bishop. Near here Edward the Black Prince defeated and captured King John of France in 1356. Pop. (1896) 38,518.

Poitiers, Diana of: See DIANE DE POITIERS.

Poitou': an old province of Western France, now divided into the departments of Deux-Sèvres, Vendée, and Vienne. It became an English possession in 1152, on the marriage of Eleanor, the Countess of Poitou, and Henry of Anjou, afterward Henry II. of England. In 1204 Philip Augustus took it from England, and although it once more reverted to that country in 1360 by the Peace of Brétigny, it was soon after reconquered, and finally incorporated with the possessions of the French crown. It contains some of the most fertile tracts of French soil, and is remarkably well cultivated.

Poke: See GARGET-ROOT and POKEWEED FAMILY.

Poker: a game at cards, played with a full pack by from two to six persons. Five cards are dealt each player, one at a time. The eldest hand (*age*) deposits a certain number of chips (tokens which represent money, unless the game is played merely for amusement), called the *ante*; the others in turn either deposit twice this amount (i. e. *go in*), or withdraw from the hand (*pass*). If they all pass, the eldest hand takes back the ante and deals a new hand; otherwise he either doubles his original stake or withdraws, forfeiting his ante. (Another, more common, method is for all the players to go in each hand by contributing the ante.) The players who have gone in then in turn discard as many cards as they wish, and receive the same number of new cards from the pack. The player at the left of the eldest hand then bets any amount not exceeding a limit previously agreed upon, or passes out and forfeits the stake already in the pool. The next player either *sees* him (bets a like amount), *goes better* (bets in addition to this a sum not exceeding the limit), or passes out. This continues till one player forces the others out and takes the pool, or until all the other players in see the last raise (none going better), and *call*. They then show their hands and the strongest hand wins the pool.

Hands rank in strength as follows, beginning with the highest: 1, *straight flush* (sequence of five cards in the same suit); 2, *four of a kind* (accompanied, of course, by a card of different denomination); 3, *full*, or *full house* (a triplet and a pair); 4, *flush* (five cards of the same suit); 5, *straight* (five cards in sequence); 6, *triplet*, or *three of a kind*; 7, *two pairs*; 8, *one pair* (two cards of the same denomination, the other three being of different ones). The denominations of cards rank in value as in whist (except that in the straight and straight flush the ace may rank either above the king or below the deuce); as between two or more straights or straight flushes, the one beginning with the highest card wins. Four aces form the highest four of a kind, four deuces the lowest; and so for triplets and pairs. In deciding between two fulls, only the triplets are considered; between two hands each containing two pairs, only the higher pair in each, unless these are alike. As between flushes, that containing the highest card wins; if cards of the same denomination lead each, the cards second highest are considered, and so on. Sometimes it is necessary to decide between two hands, each containing (1) two pairs, pair and pair alike, (2) one pair of the same denomination, or (3) not even a pair. In this case the highest single card wins; of hands remaining tied in this respect also, each counts its next highest card (the highest winning), and so on.

The game above described is the simplest form of draw-poker. Variations from it, especially in the manner of forming the hand and of betting, are innumerable. In *straight poker* no discard is made, and all the players must stake the ante. In *whisky-poker* an extra hand is dealt, and the players strive to improve their hands by exchanging cards with it in turn.

Pokeweed Family: the *Phytolaccaceæ*; dicotyledonous herbs or shrubs, rarely trees, with alternate leaves; flowers mostly perfect; perianth regular, usually single; pistil one, simple or compound; ovules usually solitary; seeds with copious endosperm, and a large peripheral curved embryo. The species number about fifty-five, and are very widely distributed throughout sub-tropical and temperate regions. In the U. S. there are four species of *Phytolacca*, *Petiveria*, and *Rivina*. The common pokeweed or GARGET-ROOT (*q. v.*), *Phytolacca decandra*, is grown for ornamental purposes in Europe, as are also the other species indigenous to the U. S.
CHARLES E. BESSEY.

Po'la: town; near the southern extremity of the Peninsula of Istria, Austria; 54 miles S. of Trieste (see map of Austria-Hungary, ref. 9–C). It is the most important naval station of Austria-Hungary; it has a deep and spacious harbor, almost completely landlocked, an arsenal, docks, artillery stores, etc. The hills surrounding the harbor are crowned with forts and batteries. Pola has also a considerable shipping-trade, exporting fish, timber, and the sand used in making Venetian glass, and importing coal and provisions. Besides the citadel, which overlooks the town and the bay, the chief buildings are the cathedral (fifteenth century), the Franciscan convent (thirteenth century), and the infantry barracks. There is a naval observatory, founded in 1871, where twenty-eight planetoids were discovered (1874–80) by I. Palisa. In the suburb of San Policarpo there is a fine park with a monument to the Emperor Maximilian of Mexico. Pola occupies the site of the ancient *Pietas Julia*, of which it contains several interesting remains, a well-preserved amphitheater, which could accommodate 20,000 spectators, a triumphal arch, etc. Pop. (1890) 39,273. R. A. ROBERTS.

Po'land [*Pole*, Polack + *land*]: a former kingdom of Europe, the Polish *Polsko*. About the middle of the seventeenth century it extended from the Baltic to the Carpathian Mountains; was bounded on the W. by the Prussian provinces of Pomerania, Brandenburg, and Silesia, and on the N. and E. by the Russian governments of Livonia, Pskoff, Smolensk, Chernigoff, Poltava, and Kherson. Its area was about 282,000 sq. miles (a little larger than Texas). This territory belongs to the central plain of Europe, and is crossed by only one range of hills, which form a watershed between the rivers flowing into the Baltic and the Black Sea. Large tracts are covered with swamps, sand and forests, but generally the soil is a light loam, well suited for agriculture and pasturage. For many centuries large herds of cattle, horses, and swine have been reared here; and cereals, hemp, timber, honey, and wax have been produced. There are extensive mines of salt, and a few of iron, copper, and silver. The bulk of the present inhabitants consists of Poles, but there are several other races, including Germans, Lithuanians, and Jews, each of which numbers over 2,000,000. The Poles are chiefly Roman Catholics. The members of the Greek Church come next in numbers, and the Germans are mostly Protestants.

The Poles belong ethnologically to the Slavic family. They appeared first in history in the fifth century under the name of Poliani; they occupied the plain between the Oder and the Vistula along with other Slavic tribes, which in the course of time they partly subdued and absorbed. Their

history does not cease to be fabulous, however, until the time of Mieczyslas (962–992). He was converted to Christianity, and so brought his country in contact with the south and west of Europe. His son, Boleslas I. (992–1025), extended his frontiers to the Saale, the Dnieper, and the Danube, and received the royal crown from the pope. These rulers belonged to the Piast dynasty, which became extinct with Casimir III. in 1370. On the death of his successor, Louis of Hungary, the latter's daughter married Jagiello, Grand Duke of Lithuania, who united that country with Poland. In 1572 the dynasty of the Jagellons (*q. v.*) became extinct with Sigismund II., and Poland became an elective monarchy. This principle was one of the chief causes of the national downfall. The people saw in the elective monarchy a guarantee of their liberty, but overlooked the fact that it threatened their existence as a nation. There were other defects in their political organization, as, for instance, the *liberum veto*. By this principle the decision of the Polish Diet did not depend upon the majority but the unanimity of the votes, so that any one member, by his veto, had it in his power to render the diet's proceedings ineffective. Further, there were grave defects in the social organization. Trade and commerce were almost entirely in the hands of the Jews, who were avaricious and the objects of popular contempt; they never ranked as an important branch of the business of the people. Literature and art were the only serious occupations of the nobility. The nation consisted of two classes only—the nobles, who owned the soil and strove to gain an illusory freedom from the crown; and the serfs, who cultivated the soil to which they were tied. There was no third estate. In several cases the peasants sided with the oppressors of the Polish nation, and fell on their countrymen who were fighting for the freedom of their fatherland. In 1573 25,000 Polish noblemen assembled on the field of Wola to elect their new king. Henry of Valois, the most worthless of the candidates, was chosen, but shortly afterward fled from the country. Stephen Bathori (1575–86), voivode of Transylvania, one of Poland's best kings, followed. He organized the Cossacks into regiments, and fought successfully against the Russians. Then came three princes of the Swedish Vasa dynasty (1587–1668), Sigismund III., Ladislas IV., and Casimir John II. (*qq. v.*). Then followed Michael Wisniowiecki (1669–73) and John III., Sobieski (1674–96), and next two electors of Saxony, Augustus II. and Augustus III. (*qq. v.*). Every new ruler caused new wars with new enemies, and internal dissensions split the nation into as many parties as there were claimants to the throne, while bribery, intrigue, treachery, and violence flourished. On the death of Augustus III. in 1763 a party called monarchists or reformers, and headed by the Czartoryski family, desired to abolish the *liberum veto* and establish an hereditary constitutional monarchy, and with this object they secured the support of Catharine II. of Russia. With her aid they placed Stanislaus Augustus Poniatowski (*q. v.*) on the throne (1764). The work of reform began, but Catharine, seeing that in this way Poland would fall out of her grasp, changed her policy. There was another party, headed by the family of Potocki, who maintained the old oligarchical institutions. They had adopted the Polish principle of religious toleration, while the Czartoryskis were fanatical Roman Catholics. Catharine elected to support religious toleration, and, opposing her former favorite Poniatowski, had a number of his adherents exiled to Siberia. The Confederation of Bar (in Podolia) was now formed; an army was assembled, and an alliance made with the Turks. Catharine already had a large army in the country, and in 1772 Prussian and Austrian armies also entered Poland, when the first partition was effected. Russia took an area of 42,000 sq. miles, Prussia took Posen (*q. v.*) with an area of 13,000 sq. miles, and Austria took Galicia (*q. v.*) with an area of 27,000 sq. miles. The whole country was now aroused to a sense of danger. The *liberum veto* was formally suppressed and many reforms were made; but some of the nobles were discontented at the loss of their privileges, and formed the Confederation of Targovitza (1792). At their instigation Russian troops entered Poland again. Prussia now joined the Russians, and a fruitless resistance, headed by Joseph Poniatowski (*q. v.*) and Kosciusko (*q. v.*), resulted in a second partition. Russia took 96,000 sq. miles and Prussia 22,000 sq. miles. A general rising in all the Polish provinces was the consequence, and the Russians and Prussians were compelled to retreat; but at the critical moment Austria came upon the scene and turned the balance. Kosciusko was taken prisoner at the battle of Maciejowice, Warsaw capitulated to Suwarow, the king resigned his crown, and the third partition (1795) put an end to the political existence of Poland. Russia took 43,000 sq. miles, Prussia 21,000 sq. miles, including the capital, Warsaw, and Anstria 18,000 sq. miles. The subsequent wars of the French with the enemies of Poland and the promises of Napoleon rallied the Poles around him; but all that Napoleon accomplished was the formation of the duchy of Warsaw by the Treaty of Tilsit (1807), with a liberal constitution and the King of Saxony at its head. It was chiefly composed of the greater part of the Prussian and Austrian portions of the later partitions. By the Congress of Vienna in 1815 the division of Poland was re-arranged. The share of Austria was diminished, and Prussia received less than it had after the second partition. The greater part of the duchy of Warsaw was united, as the kingdom of Poland, to the Russian empire, but only by the bond of a common monarch. Thus finally Russia obtained 220,500 sq. miles, viz., the kingdom of Poland and the governments of Courland, Vitebsk, Grodno, Minsk, Moghilev, Volhynia, Kieff, and Podolia. Of these, however, Kieff had been conquered and held by Russia since 1669, while Courland had had no close connection with Poland since 1710. (See Biren.) The population of this territory, excluding the two latter provinces, in 1890 was about 19,000,000. Prussia obtained 26,000 sq. miles, viz., Posen and about half of East and West Prussia, with a population (1890) of over 3,000,000; and Austria obtained 35,500 sq. miles, viz., Galicia, Bukowina, and some small districts (see Cracow), with a population (1890) of over 7,000,000.

The so-called kingdom of Poland received from Alexander I. a constitution with a responsible ministry and a separate army; but there was still a spirit of discontent which developed into an insurrection in 1830. After several sanguinary engagements this was suppressed the following year, and in 1832 Poland was declared an integral part of Russia. After another unsuccessful insurrection (1863–64) Poland was deprived of its last remnant of independence. Finally, by a ukase of the emperor, dated Feb. 23, 1868, the government of Poland was incorporated with that of Russia, and since then its ten governments—Kalisz, Kielce, Lomja, Lublin, Piotrkow, Ploek, Radom, Siedlce, Suwalki, and Warsaw—have been grouped with those of Russia. Their area is 49,159 sq. miles, and their population, exclusive of the military, was, in 1897, 9,442,590. R. A. Roberts.

Poland, John Scroggs: See the Appendix.

Polar Circles: See Antarctic and Arctic.

Polar Clock: an instrument invented by Wheatstone, which, when accurately adjusted, indicates the apparent solar time within a very few minutes. It will operate even when the sky is overcast with clouds, provided there be an unobscured spot at the pole through which the blue sky may be seen. It applies the fact that the plane of polarization of sky light is always 90° from the sun.

Polarization [deriv. of *polarize*, deriv. of *polar*]: a term applied in optics to certain modifications in the character of the wave-motions to which light is due. These modifications arise under certain conditions from reflection, refraction, etc. They are the source of some of the most beautiful and interesting phenomena in the domain of light.

Polarization is a question, primarily, of the plane of vibration of light-waves. (See Light.) Light-waves possess a period of vibration so brief (509,000,000,000 vibrations per second for yellow light) that the shortest period of time which can be isolated and dealt with experimentally will contain millions of oscillations. Even the wave-length lies almost beyond the range of direct observation. Our knowledge of the motions which constitute light is therefore almost entirely indirect. There is an abundance of indirect evidence that the wave-motion is transverse, but in the case of ordinary light, as it comes to us from the sun or from artificial sources, there appears to be no plane of vibration which remains fixed long enough to enable us to determine its position. On the contrary, the ray behaves as though composed of components vibrating in every plane. This is an effect which might be produced, as was long since suggested by Fresnel, by a plane transverse wave, the plane of vibration of which revolves with a rotational period small in comparison with appreciable time-intervals. Such a ray is said to be *unpolarized*. Any process which will serve to give a ray a fixed plane of vibration is termed a *polarizing* process; the apparatus is called a *polarizer*.

Polarization by Double Refraction.—An important example of the production of polarized light occurs when a

ray is made to pass through any substance the elasticity of which is not in all directions the same. In such media the velocity of waves vibrating in a single plane depends upon the position of that plane. Many crystals possess the above property, and when a ray of light is transmitted by them it is resolved into two plane waves, which travel, in general, with different velocities. See MINERALOGY (*Optical Properties*).

The simplest method of attacking the problem is that adopted by Huyghens 200 years ago. This consists in finding the form of the wave-surfaces in the case of a wave emanating from a point within the crystal.

From the optical point of view, doubly refracting crystals may be grouped as follows:

(1) *Uniaxial negative* crystals (calcite, tourmaline, sodium nitrate, etc.).

(2) *Uniaxial positive* crystals (quartz, zircon, ice, etc.).

(3) *Biaxial* crystals (aragonite, selenite, potassium nitrate, sugar, and all crystals which do not belong to the cubic or the hexagonal systems).

In uniaxial crystals a ray from without, in the direction of the optical axis, suffers no double refraction, and therefore all waves due to vibrations at right angles to the axis travel with the same velocity.

If *o*, Figs. 1 and 2, be a center of radiation within a uniaxial crystal, two waves will be propagated. The first of these is due to vibrations always perpendicular to the axis, and its surface is a sphere. It is called the ordinary wave. The other wave is due to vibrations at various angles with the axis. Its surface is an ellipsoid of revolution. In negative crystals the directions of greatest velocity are those for which the vibrations are parallel to the axis. The ellipsoid of the wave-surface therefore has its major axis (*c d*, Fig. 1) perpendicular to the axis *a b*. The wave-surfaces of negative uniaxial crystals are the surfaces of revolution produced by the rotation of the sphere and ellipse in Fig. 1 upon the axis *a b*. The ellipsoid which forms the surface of the extraordinary wave incloses the sphere.

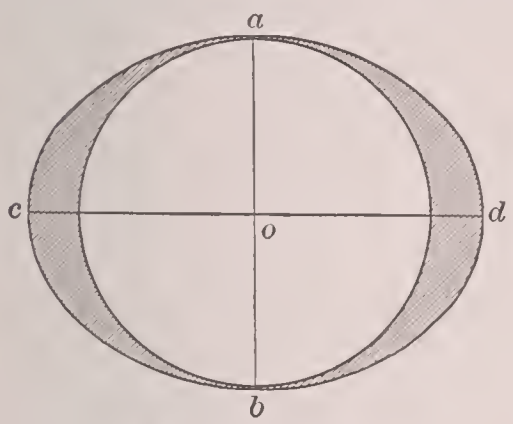

FIG. 1.—Wave-propagation in a negative uniaxial crystal.

In positive uniaxial crystals waves produced by vibrations parallel to the axis possess a minimum velocity. The ellipsoidal surface of the extraordinary ray has its major axis coincident with the optical axis of the crystal, and the two wave-surfaces are those generated by the revolution of the circle and the inscribed ellipse of Fig. 2. It will be seen that the extraordinary ray in negative crystals possesses the higher velocity, except in the direction of the axis, where it attains the velocity of the ordinary ray as a minimum limiting value. In positive crystals the velocity of the extraordinary ray, however, is always less than that of the ordinary, excepting in the axial direction, where it reaches its maximum value.

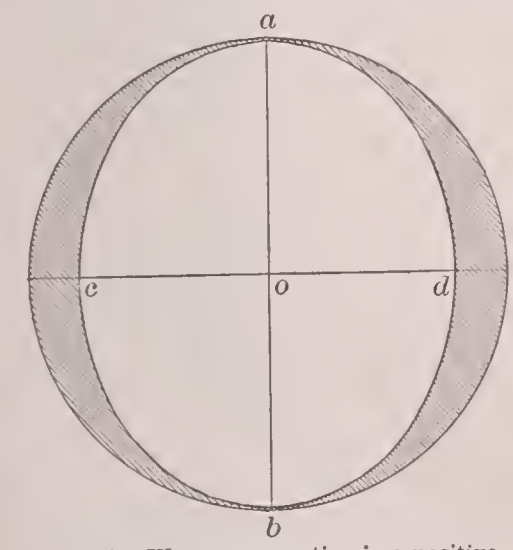

FIG. 2.—Wave-propagation in a positive uniaxial crystal.

The application of the above-described properties of anisotropic media to the case of a ray entering a uniaxial negative crystal, such as calcite, obliquely from without, is as follows:

A bundle of rays is represented by *a b*, *c d*, Fig. 3, of which the wave-surface is plane and normal to the direction-lines. Such a wave-surface, *b e*, impinges obliquely

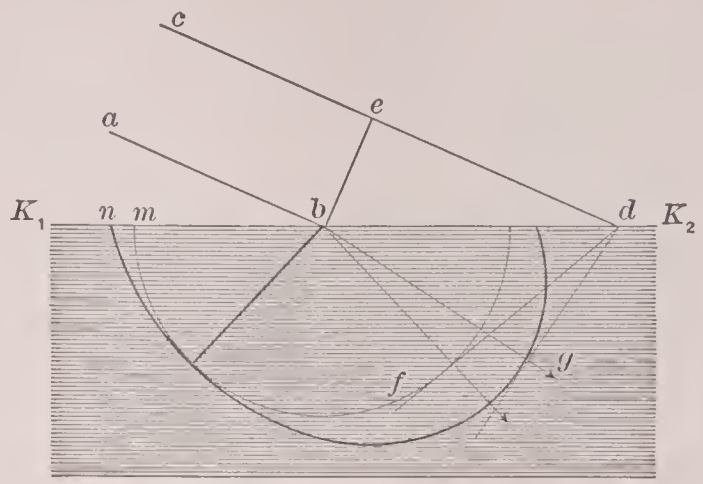

FIG. 3.

upon the surface of the crystal ($K_1 K_2$) at *b*. During the time in which the wave in air passes over a distance, *e d*, two waves within the crystal are being propagated. Of these, we need to consider only the elements which may be regarded as arising from the point *b*. The two wave-surfaces within the crystal having *b* as their origin will be a sphere and an ellipsoid, represented in the figure by the circle (*m*) and the ellipse (*n*), respectively. At the instant when the wave in air reaches *d* the position of the two waves within the crystal will be defined by the radius *b f* and radius vector *b g*, respectively. These have lengths determined by the relations of the velocities of the ordinary ray *b f* and the extraordinary ray *b g* to the velocity in air. The direction of the two rays is determined by drawing tangents to the circle and ellipse from the point *d*. The ordinary ray, being most retarded, is most bent from its course. The law of its refraction is that of Snell. See REFRACTION.

The passage of a ray through a rhombic piece of calcite is shown in Fig. 4, in which *i* is the incident ray and *o* and

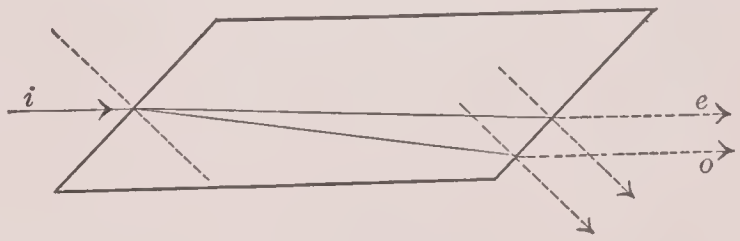

FIG. 4.

e are the emergent ordinary and extraordinary rays. It is evident, since these are completely polarized, that any device which would suppress one of them would afford a single ray of polarized light. Such a device is the Nicol prism, the best-known and most useful of polarizers.

The Nicol prism, described in 1841 by William Nicol, consists of a block of calcite (Fig. 5), cut through at right angles to its end-faces and cemented in the section by means of Canada balsam. The angles of the rhomb are such that the ordinary ray meets the cemented layer at an angle greater than the critical angle of total reflection, and is therefore entirely diverted to the side wall of the prism. To the ordinary ray, therefore, the Nicol prism is opaque. The extraordinary ray reaches the cemented interfaces at an

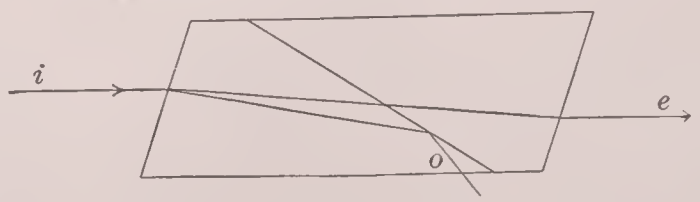

FIG. 5.

angle less than that at which total reflection begins. It, therefore, is transmitted. When we throw a beam of unpolarized light through the prism, we obtain after transmission a completely polarized ray, the intensity of which is equal to one-half that of the incident ray, less the sum of the losses by reflection and absorption.

The Foucault Prism.—Various modifications of the Nicol prism have been made, all of which, however, make use of the essential principle of the original form—the suppres-

sion of one component by total reflection. The best known of these modifications is that devised by Foucault, in which the layer of Canada balsam is supplanted by an air-space between the halves of the divided rhomb. See Figure 6.

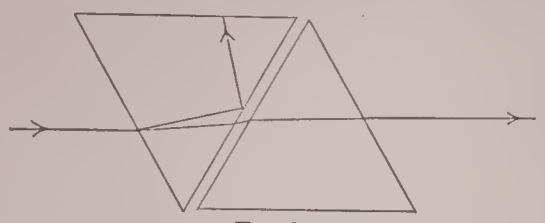

FIG. 6.

Polarization by Reflection.—The nature of the phenomena of polarization would lead one to expect that polarization of a ray might be obtained by causing the same to be reflected. If we consider an ordinary ray to be resolved into two components, vibrating at right angles to one another, and suppose the ray obliquely incident to a plane mirror so placed that one of the components will vibrate parallel to its face, it is evident that the two components will meet the mirror under different conditions. In point of fact the mirror does not reflect both components equally well, save when the incidence is normal, under which condition both rays are vibrating parallel to its surface. As the angle of incidence increases, the components whose vibrations make an angle with the mirror are less and less strongly reflected, whereby the resultant becomes *partially polarized*. At a certain angle, known as the *angle of complete polarization*, the above-mentioned component ceases to be reflected, and the reflected ray consists of completely polarized light, vibrating at right angles to the plane of incidence and reflection.

Brewster's Law.—The angle of complete polarization, as was pointed out by Malus, who discovered the phenomenon of polarization by reflection in 1810, depends upon the refractive index of the material of which the mirror is made. Brewster gave definite expression to the relation (1815), as follows:

The angle of complete polarization is the angle of incidence for which the reflected ray is perpendicular to the refracted ray.

In Fig. 7 we have from Snell's law $\frac{\sin i}{\sin r} = n$, which at the angle of complete polarization, when $i + r = 90°$, becomes $\frac{\sin i}{\sin r} = \frac{\sin i}{\sin (90° - i)} = \frac{\sin i}{\cos i} = \tan i = n$.

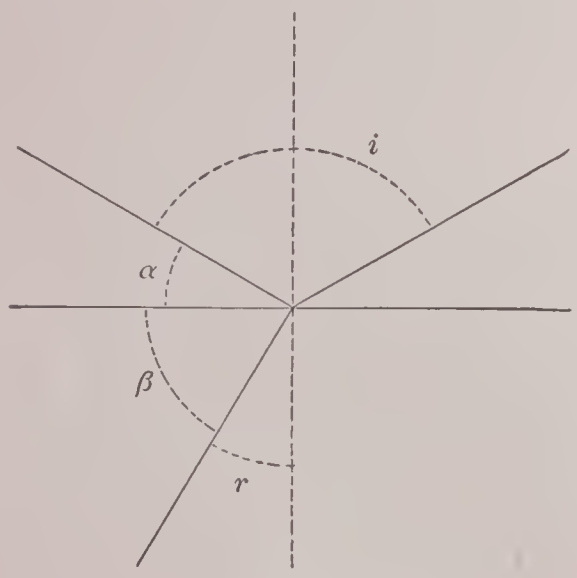

FIG. 7.

This affords another statement of Brewster's law, viz.:

The angle of complete polarization is that angle of incidence the tangent of which is equal to the index of refraction of the mirror.

The above statements refer to the reflection from the first surface, and not to internal reflection. They apply to non-metallic surfaces only. To obtain plane polarized light therefore by a single reflection we must use a non-metallic mirror, and must suppress all those rays which, entering the substance of the mirror, might be reflected from its second surface. The material commonly used is an opaque black glass.

Polarization by Ordinary Refraction.—An inquiry which follows directly upon the statement of polarization by reflection is that concerning the condition of the refracted ray. That component of the incident ray which ceases to be reflected at the angle of complete polarization we should expect to find transmitted by the medium as a refracted ray, unless the vibrations were destroyed at the surface with transformation of energy. Experiment shows that this polarized component always forms a part of the refracted ray, but never the whole of it, since the other component is partly refracted and partly reflected at every angle of incidence. By ordinary refraction, then, partial polarization in a plane perpendicular to that obtained by reflection is produced, the degree of polarization reaching a maximum at the angle of incidence for which $\tan i = n$. By passing this partially polarized ray at the proper angle through a series of parallel glass plates the unpolarized portion can be reduced indefinitely, so that by successive transmission an almost completely polarized ray can be obtained.

Polarization by means of Tourmaline.—The crystalline mineral tourmaline possesses a molecular structure which adapts it peculiarly to the production of polarization by transmission. A plate of this mineral, cut in such a manner that the principal axis of the crystal is parallel to the surface, will transmit only those vibrations which are perpendicular to the direction of the axis. To waves vibrating parallel to the axis such a plate is opaque. The objection to this method of obtaining polarized light is the strong selective absorption to which rays passing through tourmaline are subjected. The best specimens are far from colorless or transparent.

FIG. 8.

Polariscopes.—In the study of polarized light it is necessary, in addition to the production of a polarized ray, to be able to test the character of radiation as to the plane of its vibrations. To these ends two polarizing devices, such as the black glass mirror, the Nicol prism, or the plate of tourmaline, must be used together. Such a combination is called a *polariscope*.

The essential parts of a reflecting polariscope are two mirrors, M_1 M_2, Fig. 8, affording reflection from their first surfaces only. These are so mounted that the incident ray i will always strike M_1 at the polarizing angle, and the reflected ray r will strike M_2 at the same angle. The latter mirror (M_2) is called the *analyzer*, in contradistinction to the *polarizer* (M_1). The same terms are used to designate the corresponding parts of any polariscope.

The reflecting polariscope is frequently given the form shown in Fig. 9, an arrangement due to Nörremberg, in which the lower mirror is a plate of clear unsilvered glass. Rays of light reaching the mirror from the direction a are polarized by reflection, and thrown downward upon the mirror c, whence they are returned vertically upward through A B to the analyzer S, which is a mirror of black glass. The analyzer revolves within a graduated circle by means of which its position can be determined. An adjustable platform between the two mirrors supports objects the behavior of which when subjected to polarized light is to be studied.

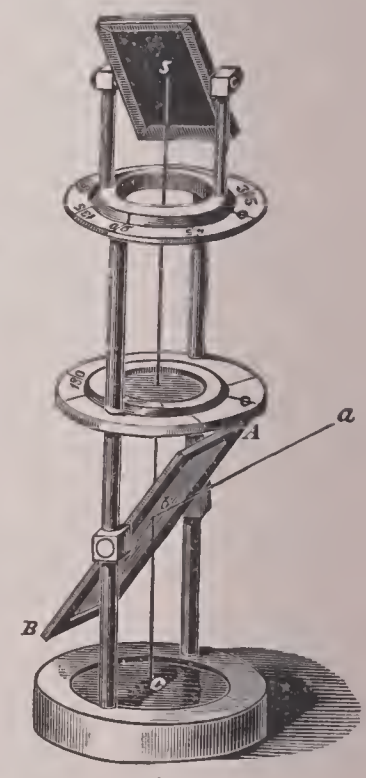

FIG. 9.

Since the angle of complete polarization depends upon the index of refraction, and since the latter is a function of the wave-length, it follows that no reflecting polariscope can give complete polarization excepting in monochromatic light. On that account and for other reasons polariscopes making use of double refraction are to be preferred. Such instruments consist of two Nicol prisms, or equivalent devices, mounted one behind the other in the path of the ray which is to be polarized and analyzed. The analyzer (A, Fig. 10), and sometimes the polarizer (P, Fig. 10) also, is free to revolve in the axis of the ray. Divided circles enable the observer to

ascertain the angle which their polarizing planes make with one another.

The performance of two Nicol prisms mounted as above follows directly from what has already been stated with reference to this method of producing polarized light.

Rays transmitted by P in the direction of the axis of the instrument will be completely polarized in the principal

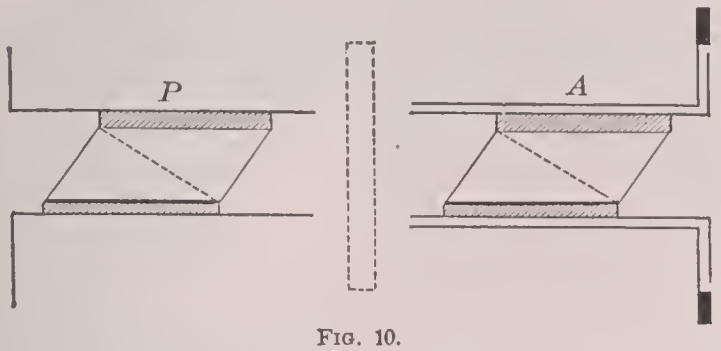

FIG. 10.

plane of the prism, with loss of something more than half of the initial intensity. The polarized ray upon entering the prism A will be resolved into two components vibrating at right angles to and in the principal plane of A. The former of these components, which is the ordinary ray, is suppressed by total reflection, while the extraordinary ray is transmitted.

The relative intensity of the two components depends upon the angle α between the principal planes of the prisms P and A, a relationship which may be expressed as follows:

$$I_o = I \sin^2 \alpha.$$
$$I_e = I \cos^2 \alpha \; . \; .$$
$$I_o + I_e = I(\sin^2 \alpha + \cos^2 \alpha) = I.$$

I is the ray incident upon A, I_o and I_e the ordinary and extraordinary components of the same. Losses by common reflection and absorption are neglected. It will be seen that the intensity of the transmitted ray, I_e, is proportional to $\cos^2 \alpha$. When the prisms are crossed ($\alpha = 90°$) no light is transmitted; when they are parallel ($\alpha = 0°$) A is transparent to the polarized ray, transmitting it without any losses other than those due to reflection and absorption.

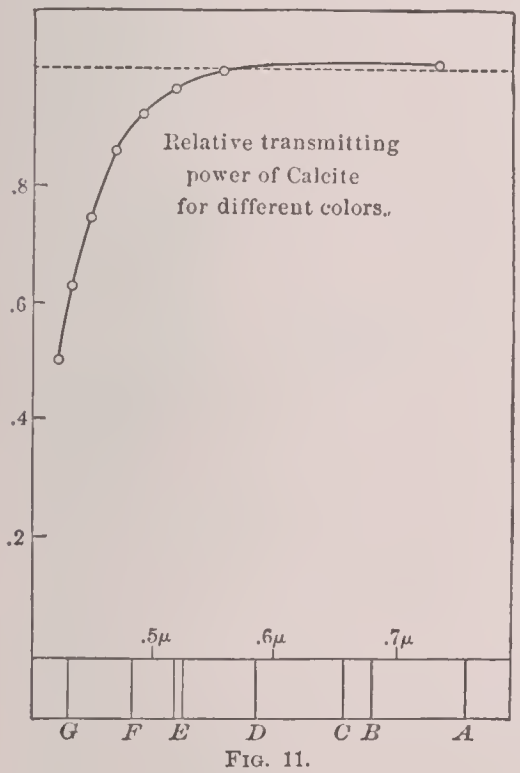

FIG. 11.

Polariscopes with Nicol prisms possess the advantage of affording complete polarization of all wave-lengths alike. They are indeed for most purposes the best of all types. The chief disadvantages are costliness of the material, calcite, of which the prisms are made, and the smallness of the apertures of the instrument. Small dimensions are a matter of necessity in Nicol prisms on account of the giving out of the supply of large crystals of transparent calcite. Prisms, like those exhibited by Spottiswoode at an exhibition of scientific apparatus in London, which had a clear aperture of 9 cm., are no longer to be obtained.

Another disadvantage in the use of calcite lies in its failure to transmit all wave-lengths of the visible spectrum with equal freedom. Measurements of the losses experienced by a ray of white light in traversing a pair of Nicol prisms were made by the writer and Prof. B. W. Snow in 1891 (*Philosophical Magazine* (5), vol. xxxiii., p. 379). The results, which are given graphically in Fig. 11, show diminishing transparency throughout the green and blue of the spectrum, until at wave-length 0·4 μ relatively less than half as much light is transmitted as at wave-length 0·6 μ.

Tourmaline Polariscopes.—The property which tourmaline possesses of absorbing one of the polarized components of rays traversing it at right angles to the principal axis makes it practicable to construct a simple form of polariscope out of two plates of that material. Two tourmaline plates (A B and C D, Fig. 12) placed one over the other with axes parallel will transmit light with losses due only to reflection and ordinary absorption; the latter source of loss is unfortunately an important one, greatly diminishing in optical work the usefulness of tourmaline. When placed with axes crossed as in Fig. 13 the plates A B, C D are completely opaque. The usual form of the tourmaline polariscope is that of Fig. 14. The two plates are mounted in a tongs-shaped clamp, with freedom of rotation upon a common axis. Specimens to be examined in polarized light are placed between them. Tourmaline plates also serve as eye-pieces in many forms of polarizing apparatus.

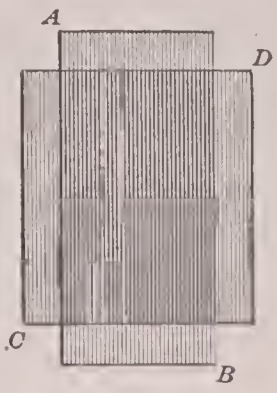

FIG. 12.

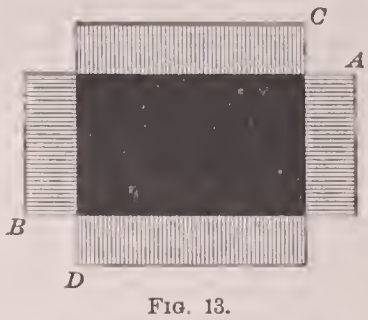

FIG. 13.

Polarization in Biaxial Crystals.—In the discussion of the passage of light through anisotropic bodies we have considered, thus far, crystals in which only a single direction could be found for which double refraction did not exist. All crystals of the *rhombic*, *monoclinic*, and *triclinic* systems, however, possess two such directions, from which fact they are called biaxial crystals. Polarization-phenomena in such crystals are necessarily more complicated than in crystals with one axis. They can be discussed only very briefly here. In biaxial crystals there is no ordinary ray. Neither of the two components into which rays traversing such crystals are divided follows the law of refraction for isotropic media. The two rays are polarized at right angles, and they travel at velocities depending upon the elastic structure of the crystal.

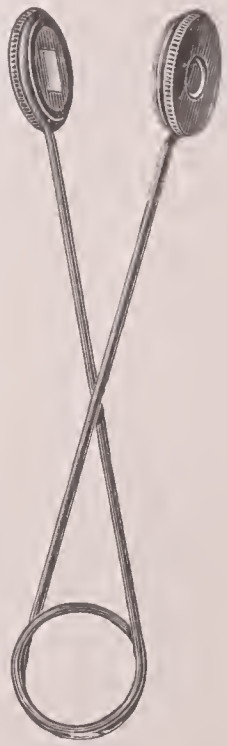

FIG. 14.

Fresnel's method of finding the wave-surface in a biaxial crystal, stated in a few words, consisted in establishing three axes (Fig. 15): one (a b) in the direction of greatest elasticity, one (c d) in the direction of least elasticity, and a third perpendicular to these. Upon these axes an ellipsoid is to be imagined, taking the length of each axis proportional to the elastic quality for light-vibrations in the direction in question. The velocity of the two light-waves propagated in any desired direction from a source at the center of the ellipsoid can be found by taking a plane section of the ellipsoid through the center of the same and at right angles to the line along which the velocities are required. The major and minor axes of the ellipse which forms the section of the ellipsoid, as mentioned above, give the velocities of the two waves. By means of this procedure the surface can be fully determined. This surface can be represented only by means of a three-dimensional model. Cross-sections of it in the planes a b, c d; a b, e f; and c d, e f, are shown in Figs. 16, 17, and 18.

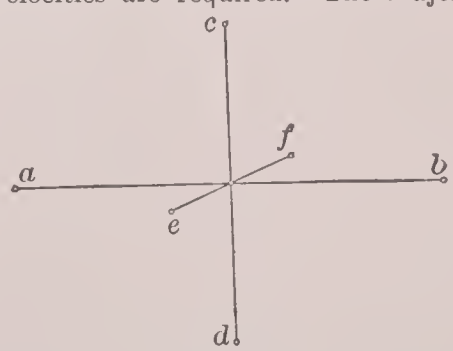

FIG. 15.

Applications of polarized light are made in the study of crystalline forms, in which field many very beautiful phenomena occur; in the microscopic detection of various cel-

lular structures, as, for example, in distinguishing between the various forms of starch; and, what is very important

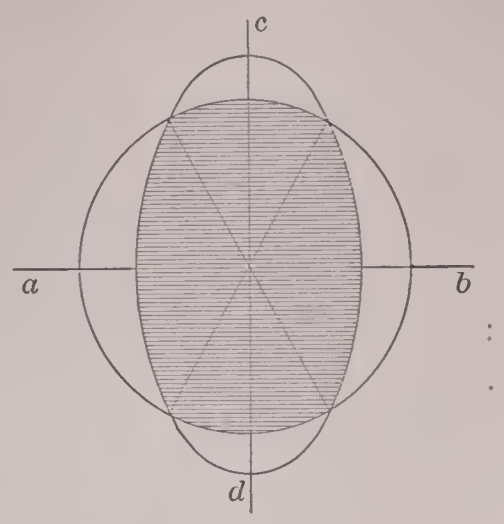

Fig. 16.

from an industrial point of view, in the determination of the strength of sugar-solutions. The last-named application has led to the development of a special class of apparatus and of special methods of work. See Saccharimetry.

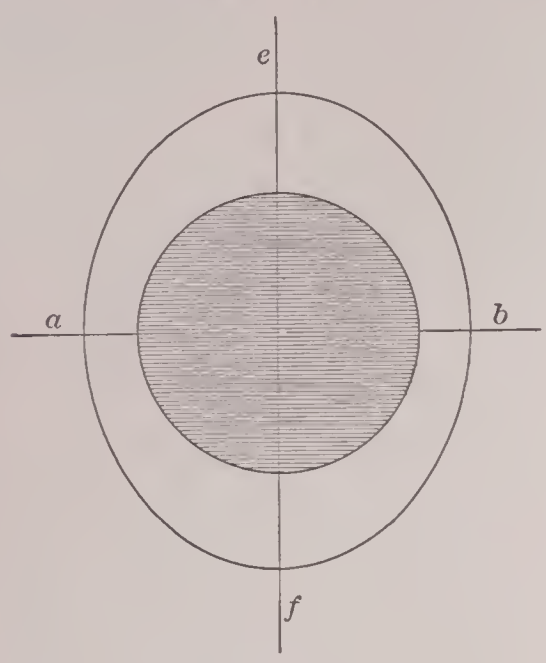

Fig. 17.

In the study of crystals under the polariscope the specimen is placed between crossed nicols, and is viewed by transmitted light. If double refraction takes place the result is the restoration of light to the hitherto dark field of

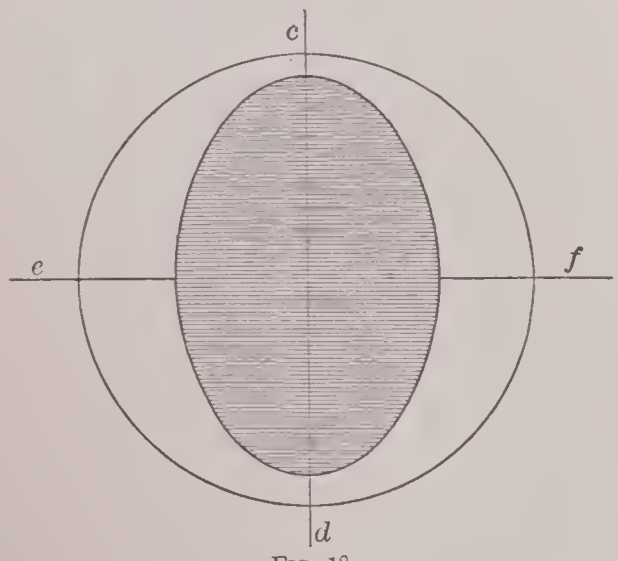

Fig. 18.

view and the production of color effects, the nature of which depends upon the character of the specimen and the kind of illumination to which it is subjected. The most important of these color effects may be classified as follows:

(1) *Thin plates of uniaxial or biaxial crystals* cut parallel to the axis or axes. When viewed by parallel rays between crossed nicols they show in general a brilliant color, which depends upon the thickness of the plate and the positions of polarizer, analyzer, and specimen with reference to each other.

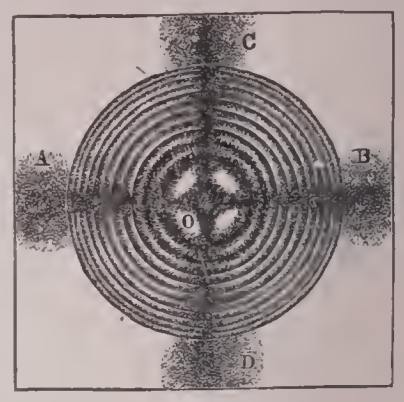

Fig. 19.

This phenomenon, which is the simplest with which we have to do in chromatic polarization, is due to the same causes as the more complicated cases to be mentioned later. The plane polarized ray from the first prism is, in general, resolved into two components within the specimen. These vibrate at right angles with one another, and, traveling at different velocities within the crystal, issue with difference of phase. In the second nicol each of these components is again resolved, and those components of each which move in the polarizing plane are transmitted. After passage of the second nicol we have then all the conditions necessary for the production of color by interference (see Interference and Thin Plates, Colors of), viz., two rays traveling along the same path, with difference of phase but with the same plane of vibration. A tint will therefore be produced, of which the intensity depends upon the relative amplitudes of the transmitted components, and the color upon the difference of phase. If the plate be of uniform thickness, the tint will be uniform over its surface; if wedge-shaped, it will be crossed by interference-bands, etc.

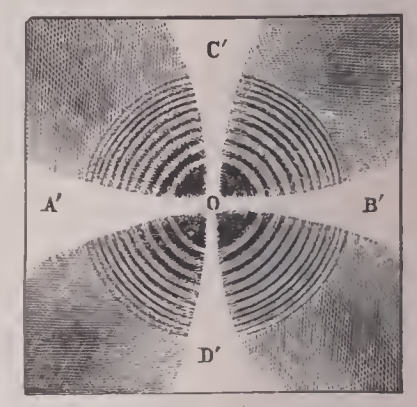

Fig. 20.

(2) *Uniaxial crystals cut perpendicularly to the axis, and viewed by convergent light between crossed nicols.* In this case, which can be tested in a simple manner by placing a properly cut piece between the plates of the tourmaline tongs and holding the same close to the eye, one sees a beautiful set of colored rings, either with a bright center and cut by a dark rectangular cross (Fig. 19), or with a dark center and bright cross (Fig. 20), according to the relative positions of the part of the apparatus.

Fig. 21.

(3) *Biaxial crystals cut at right angles to the median line and viewed by convergent light between crossed nicols.* The system of rings and brushes is that shown in Fig. 21, when the planes of the optical axes are at 45° with the polarizing planes of the nicols. This goes over into the pattern of Fig. 22 when the planes of the optical axes coincide with that of one of the prisms.

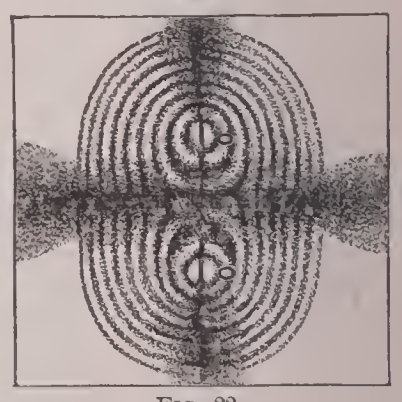

Fig. 22.

The above are among the most important of the numerous cases which the crystallographer has occasion to observe and to analyze. The color effects in all are due to the same cause, the interference of the polarized rays after emergence from the second Nicol prism.

Temporary and Artificial Double Refraction.—Isotropic media can be rendered doubly refracting by any process which produces internal strains. A rectangular block of glass, for instance, when placed between crossed nicols does not restore light to the field of view, but when pressure is

applied by means of a clamp, like that shown in Fig. 23, temporary double refraction is produced and color-effects

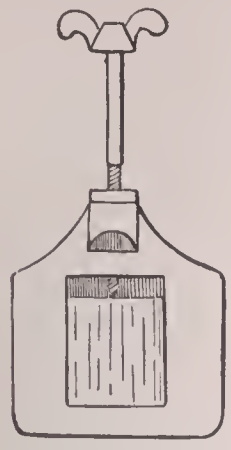

Fig. 23.

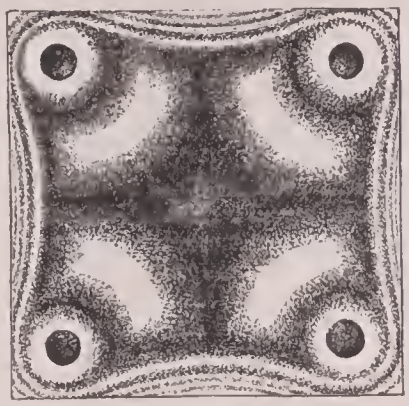

Fig. 24.

analogous to those in crystals occur. The sudden cooling of heated glass produces permanent strains, the presence of which gives figures of great symmetry and beauty. Fig. 24 shows such a pattern produced by polarized light in a rectangular plate of chilled glass.

In the foregoing account many phenomena have been altogether neglected. Such are those connected with the passage of light through quartz, the rotation of the plane of polarization in that substance and in various liquids, the rotation of the plane of polarization in the magnetic field, and the question of circular and elliptical polarization. For a discussion of these the reader is referred to the larger treatises on experimental optics and to the proper chapters in the manuals of physics. Among the best known of such books are Fresnel's *Œuvres*; Verdet, *Traité d'Optique*; Mascart, *Traité d'Optique*; Wüllner, *Lehrbuch der Physik*; Müller-Pouillet, *Lehrbuch der Physik*; Violle, *Cours de Physique*; Winkelmann, *Handbuch der Physik*; Preston, *Light*; Spottiswoode, *Polarization of Light*, a popular treatise.

E. L. Nichols.

Polar Research [*polar* is from Lat. *pola'ris*, pertaining to the poles, deriv. of *po'lus*, pole = Gr. πόλος, pivot, hinge, axis, pole, deriv. of πέλειν, move, go]: exploration of the regions about the poles of the earth, and investigation of the various questions concerned therewith. This is the greatest unsolved problem in geography, and on its solution turn many theories of terrestrial physics and even some of those of astronomy. The older attempts at its solution were only partial in design, being devoted to finding a northeast or northwest passage, or to reaching the geographic or magnetic pole. They were unsuccessful, except in finding the magnetic pole, and they did not add greatly to knowledge, although full of hardship and disaster. The later idea of residence in the polar region and gradual advance has proved so much more successful and less perilous that we may now safely reckon on eventual and complete success in the solution of all questions depending on polar research.

History of Arctic Exploration.—The different relations of the two poles to the distribution of land and water and to the zone of maritime and geographic enterprise have caused the exploration of the Arctic and Antarctic regions to follow quite different courses.

The earliest recorded attempt at Arctic research was one to find a commercial maritime route to China and India by the north of Europe and Asia. The first expedition was that of Sir Hugh Willoughby, who left the Thames with three ships in 1553. Two of the ships appear to have reached Kalguev island, but were never heard from afterward. The third reached the mouth of the Dwina, and its company crossed over by land to Moscow. As a result the White Sea was opened to British commerce. A later expedition under Stephen Burroughs reached Vaygach island, and in 1580 Pet and Jackman penetrated the Kara Sea. The expeditions so far were British; the work was now taken up by the Dutch. Under Barents an expedition reached Nova Zembla in 1594 and the Kara Sea in 1595. In 1596 Barents discovered Spitzbergen and reached a latitude of at least 80° N. In the seventeenth century Franz Joseph Land was apparently reached by a whaler named Roule. In the succeeding centuries many attempts, mostly by Russians and Norwegians, were made to penetrate along the northeast passage farther E. than Nova Zembla and the Kara Sea, but all were unsuccessful until in 1878–79, when the passage was successfully made by Nordenskjöld on the Vega.

Spitzbergen had probably long been known to hardy Russian and Norwegian fishermen, but, brought once to the attention of geographers by Barents, it became a point of departure for farther polar exploration, and in these explorations all the nations of Northern Europe have taken part. Departing from this archipelago in 1607 Hudson discovered Jan Mayen. It was soon found that the sea to the N. of Spitzbergen was usually blocked by ice, and numerous expeditions were undertaken on sledges. They have all been relatively unsuccessful, and the highest latitude reached in this way was 82° 45′ N. by Parry in 1827.

An easy access to the pole seems to be afforded by the great expanse of ocean between Greenland and Spitzbergen, but efforts in this direction have been especially barren of useful results. This part of the Arctic Ocean is encumbered by ice apparently brought down by a current from the N. The east coast of Greenland is more inhospitable than the west coast.

The greatest activity in Arctic exploration has been to the N. of the American continent in the Arctic Archipelago, and especially along the west coast of Greenland. This coast had long been known to the Northmen, and was apparently visited by Nicolas and Antonio Zeno, two Venetian noblemen, in the fourteenth century. It also offered the problem of the northwest passage, corresponding to that of the northeast, already described. Sebastian Cabot unsuccessfully searched for this passage in 1498, and was followed in 1576 by Frobisher. The search was actively continued by Davis, Hudson, Ross, Parry, Richardson, Franklin, and others until, on his return in 1833, Ross announced that a practicable northwest passage could not exist. Nevertheless in 1845 Franklin was sent out with two ships and 168 men under instructions to find this passage at all hazards. As time passed and nothing further was heard from this expedition, intense interest in its fate was aroused throughout the civilized world, and expedition after expedition was sent under the auspices of Great Britain and the U. S. in its search. Among the leaders of these were Ross, Collinson and MacClure, Belcher, Kennedy, McClintock, Rae, and Kane. The search continued for more than thirty years before the fate of the Franklin expedition was finally determined, and this was done by a young U. S. lieutenant named Schwatka, who, following the indications of McClintock and the reports of natives, found the graves of the last remnant of the force and other mementoes in the desert expanse between Great Fish river and Hudson Bay. The geographic results of the search for Franklin were very rich. The great complicated and ice-covered Arctic Archipelago was explored, adding from 4,000 to 5,000 sq. miles to the area capable of being mapped with fair accuracy.

Hayes, who had accompanied Kane, was convinced that an open sea exists about the geographic pole. He returned in 1860, and reached the latitude of 81° 35′ N. by way of Smith Sound, but did not find the open sea. Hall repeated the expedition in 1871, and reached lat. 82° 16′ N. Hall died the following winter, and the remnants of the expedition were rescued from a field of ice on which they had been floating 186 days and on which they had traveled 1,700 miles. In 1875 Nares took the same course, and in 1876 a party of his men under Markham traversed the frozen surface of the polar sea to the N. of Grinnell Land and reached the latitude of 83° 20′ N. For the winter 1882–83, by international co-operation, stations were established at many points near or within the Arctic and Antarctic Circles, chiefly to carry on meteorological and magnetic observations. The most northerly of these was that established at Lady Franklin Bay, on the eastern coast of Grinnell Land, in lat. 81° 44′ N., under the charge of Greely. The party was established in Aug., 1881. It retreated S. to Camp Clay in Aug., 1883, and was rescued in June, 1884, having only seven survivors out of thirty-two men. The northernmost point reached was on the north coast of Greenland, in lat. 83° 24′, and was gained by a small party under Lieut. Lockwood. This is the northernmost point reached by civilized man up to Dec., 1894. The idea of residence in polar latitudes has since been carried out by Lieut. Peary, who has spent two winters with his family, and without serious hardship, on the west coast of Greenland above lat. 75°.

The New Siberian islands were discovered in 1770 by a Russian merchant named Liakhof. The abundance of fossil ivory on Kotelnyi (one of these islands) attracted commercial attention to the southern members of this group, and they were often visited. Bennett island was discovered by De Long in his perilous escape from the Jeannette in

1881, as well as two small islands farther W. but belonging to the same group.

There have been but few expeditions by way of Bering Straits, and they have been unsuccessful. A modification of the plans heretofore employed is that of NANSEN (*q. v.*), who believed that a general ocean current sweeps over the polar region from the vicinity of the New Siberian islands to the eastern and western coasts of Greenland. To this hypothetical current, and in a ship made for the purpose of being fastened in the ice and drifting with it, he intrusted himself in the summer of 1893. In Aug., 1896, he returned without mishap, and reported that he had reached 86° 14′ N. lat. before turning southward. See *Furthest North* (London and New York, 1897).

History of Antarctic Exploration.—The lands of the Antarctic region were unknown and unsuspected until 1773–75, when they were discovered by Cook. Previous searches for a *terra australis* seem to have related only to Australasia and isolated islands far N. of the Antarctic Circle. On a second cruise Cook circumnavigated the globe in the vicinity of the Antarctic Circle, and showed that the southern continent was isolated and almost entirely within that circle. In 1819 an English whaler, William Smith, was driven S. of the Falkland islands to South Shetland, and in 1819–21 the Russian navigator Bellingshausen passed westward from South Shetland within the Antarctic Circle and discovered two small islands which he named Alexander I. and Peter I. In 1823 the whaler Weddell penetrated to the parallel 74° 15′ S. in the longitude of Cape St. Roque, and reported little serious obstacle to navigation. In the early part of the nineteenth century the Messrs. Enderby, of London, interested in whaling, instructed their captains to explore as far southward and as thoroughly as possible. Their Capt. Briscoe in 1831 discovered Enderby Land, about one-third of a circle eastward from South Shetland and forming the second angle of the triangular southern continent. In 1832 he discovered and landed on Adelaide island, which lies S. W. of South Shetland and near Graham Land. He was apparently the first man to set foot on the southern continent. In 1833 Capt. Kemp discovered the eastern extremity of Enderby Land. In 1838 their Capt. Balleny discovered the third angle of this continent in what is now known as Wilkes Land. In 1839–43 the Antarctic region was visited by a U. S. expedition under Wilkes, a French one under d'Urville, and a British one under Ross. Many discoveries were made by each, but the most successful was the last named. Ross penetrated to 78° S. in the latitude of New Zealand and discovered the mountainous district of Victoria Land, terminating to the southward in the active volcano Mt. Erebus, 12,000 feet high. Since this date only occasional sealers or whalers have penetrated to the southern continent, the most notable of these cruises being that of three Dundee whalers (Donald, Bruce, and Murdoch) in 1893–94. No noteworthy additions to the knowledge of Antarctic lands have been made since the expeditions of 1839–43.

Results.—Each terrestrial pole is covered by a cap of continuous ice, which remains unbroken on the land-areas and apparently over the smaller inclosed water-areas of extreme high latitudes, and these caps vary in size with the season and with the year. Greenland is covered with an unbroken ice-sheet, and so probably is also the southern continent. Around the margin of these caps is an area of variable width covered with floating ice, either derived from the frozen surface of the ocean when it forms the pack, the ice-fields or the floebergs, or derived from the sheet of land-ice when it forms icebergs. This area is more or less open, and at its outer margin is very open, irregular, and variable. Floating ice extends farther toward the equator in the Atlantic Ocean than elsewhere. In the North Atlantic it may float as far S. as lat. 42° N. and in the South Atlantic to lat. 39° S.

In general the surface-currents of the ocean flow away from the ice-caps. An exception is found in the Antarctic field, where S. of New Zealand a current sets in toward the great bay in this field which was found by Ross. Another is in the Arctic field, where the Gulf Stream extended enters the Arctic Ocean to the N. of Scandinavia.

Of the climate of the Antarctic regions little is known, but a fairly accurate picture of the succession of seasons can be made for the Arctic. The entire Arctic area (extending far S. in Siberia and North America) has a mean annual temperature of 32° or lower, except the northeast coast of Norway and a coastal strip of small size on Eastern Greenland. The region of lowest mean annual temperatures appears to extend over a strip reaching from Grinnell Land across the New Siberian islands to the basin of the Yana river in Siberia. This area passes slightly to the American side of the pole, is apparently mostly covered by water, and has a mean annual temperature of 0° F. or lower. The seasons are reduced to two, summer and winter, and the diurnal changes are relatively slight. The greatest cold in winter is in the Yana basin, where the mean temperature for January descends to — 50° F. or lower. In Grinnell Land for this month it is about — 35° F. The July mean temperatures run from 36° F. in the vicinity of the pole to about 50° F. near the Arctic Circle. In the Yana basin it is about 30°. The precipitation about the pole is small, varying from 8 to 25 inches, and is somewhat more likely to fall in late summer than at other seasons. The accumulations of ice and snow are due not to heavy precipitation, but to the conservation of what does fall. It is largely in the form of snow, and evaporation is very small because of the low temperatures. Fog and high winds are common.

The north magnetic pole was found by Ross to be on Boothia Felix in 1832. It has since traveled a few degrees E. and is now probably near the southeast angle of this peninsula. The south magnetic pole is in an unexplored area S. of Australia and 17° 25′ from the geographic pole. In Arctic regions the compass-needle is subject to so great variations and uncertainties that its usefulness is much impaired. These variations are due in part to the vicinity of the magnetic pole and in part to sudden and severe, yet unexplained, magnetic storms. Other anomalies, not explained as above, are thought to be due to the existence of masses of iron ore in the rocks. Arctic researches have also given opportunity for many studies of the aurora. The center of greatest frequency is in Northeastern America.

The geology of the Arctic region is apparently as diversified as elsewhere. Certain Cretaceous and Tertiary strata in Spitzbergen, Northern Greenland, and the Arctic Archipelago show that in Cretaceous times this area had a subtropical climate with a luxuriant flora, something like that now found in Southern Japan. By Tertiary times the climate, as shown by the fossil flora, had become cooler and was like that of Western Oregon. Volcanic action is seen only about the south pole. The Erebus volcano already mentioned was active when seen, and a small isolated peak 500 feet high among the South Shetland islands emits smoke continuously. Several volcanic peaks and craters have been recognized and much volcanic scoria seen.

The flora of Arctic regions is scanty. Willows, dwarf birches, and a few other shrubs extend to Southern Greenland and a dwarf willow extends far north. The flowering herbs of high latitudes are few in number, and include several rushes and grasses, the dandelion, a poppy, the crowberry, and several saxifrages. The most common and most Arctic flowering plant is the *Saxifraga oppositifolia*. Beyond these are found only flowerless plants—mosses, algæ, and lichens. The Antarctic flora is much more scanty than the Arctic. The species are identical or very similar in all longitudes in each polar region.

Animal life is relatively more abundant, but there is the same resemblance of species. The Lady Franklin Bay party recorded N. of lat. 81° the polar bear, the Arctic fox, the blue fox, the wolf, the ermine, a lemming, the polar hare, the reindeer, and the musk-ox. The two last named have been abundant in Northern Greenland and the reindeer is abundant on Spitzbergen. The party also recorded three species of seal, two species of whale, the swordfish, and the narwhal. Thirty-two species of birds have been observed N. of 81° 30′ N., and the most of these have also been seen at Point Barrow and on Nova Zembla and Spitzbergen. The rock-ptarmigan is the only winter resident, the others being migratory. The list includes the gray eagle, gyrfalcon, snowy owl, raven, snow-bunting, two geese, three ducks, and a dozen gulls, terns, auks, divers, and similar birds. The migratory birds arrive usually in June and depart in September. There are also many fish and lower marine forms and insects.

The Antarctic region has generally been represented as swarming with animal life, especially the marine forms. The Dundee whalers before referred to in the summer of 1893–94 found five species of whale (not, however, right whales or sperm-whales), four species of seals, and twenty species of birds, among them seven petrels, two gulls, two terns, the common hooded crow, and a black-and-white duck. Enormous numbers of penguins were seen.

The Antarctic area is uninhabited by man, as also are Nova Zembla, the New Siberian islands, Franz Joseph Land, Spitzbergen, Jan Mayen, and the Aretic Arehipelago, but on the eoasts of the last named are many evidenees of a former oeeupation by the Eskimo. The Lapps oeeupy the Aretic eoasts of Europe W. of the White Sea, and the Samoyeds eastward to the Yalmal Peninsula. From the mouth of the Obi to that of the Kolyma the eoast is now uninhabited, though probably onee oeeupied. From the Kolyma mouth to Bering Straits the coast is oeeupied by the Chukchees, who also extend southward about the Anadyr Gulf. The Aretic eoast of America, both sides of Baffin Bay, and Davis Strait, and the southeast coast of Greenland are oecupied by Eskimo. The most northern of these are the Arctic Highlanders, who occupy the western shore of Greenland to the N. of Melville Bay. They are simple in life, kindly in charaeter, and not less intelleetual than their brethren farther S. They now reach in their migrations no higher N. than lat. 79°, but traces of their former oeeupation can be found farther N. and on Grinnell Land. Though they endure the rigors of their climate with equanimity and fair eomfort, they are thought to be deereasing in numbers. See GREENLAND, SIBERIA, NOVA ZEMBLA, SPITZBERGEN; COOK, JAMES; FRANKLIN, JOHN, etc. See also POLAR RESEARCH in the Appendix.

REFERENCES.—The literature of polar research is very extensive. The best modern books are the series of reports of the international polar expeditions of 1882–83. These are all government reports, and are as follows: U. S., *Point Barrow* (1885) and *Lady Franklin Bay* (1888); English, *Fort Rae* (1886); Freneh, *Cape Horn* (5 vols., 1884–88); Danish, *Godthaab* (1889); Norwegian, *Bossekop* (1888); Swedish, *Spitzbergen* (1887); German, *Kingua Fiord* (1886) and *South Georgia* (1886); Austrian, *Jan Mayen* (1886); Finnish, *Sodenkyla* (1886); Russian, *Lena* (1886) and *Nova Zembla* (1886). A list of the literature to 1890 is given in Saint-Martin and Rousselet—*Nouveau Dictionnaire de Géographie universelle*, articles *Région Antarctique* and *Région Arctique* (1892). MARK W. HARRINGTON.

Polar Seas: See ANTARCTIC OCEAN and ARCTIC OCEAN.

Pol'der [Dutch]: the technieal term in Holland for a onee submerged area of land surrounded by dikes and reclaimed by artifieial drainage, usually in the smaller polders by wheels driven by windmills, in the great polders by powerful pumping-engines moved by steam. The polders vary in area from 100 aeres and less to 12,000 or 15,000 aeres; their surfaee is usually depressed from 1 to 15 or 20 feet below the surrounding eountry, and these lowest, as those of Schieland near Rotterdam, the Haarlemermeer polder, etc., are below the sea-level. South Holland alone contains more than 1,000 polders. The most important are those which have been created by artificial drainage of what were permanently-submerged areas, such as that of the Haarlemermeer. (See HAARLEM LAKE.) In connection with the formation of the NORTH SEA CANAL (*q. v.*), all the areas once eovered by the waters of the Y and Wijkermeer are converted into polders.

Pole, REGINALD: prelate; b. at Stourton Castle, Staffordshire, England, in Mar., 1500; son of Sir Riehard Pole, Lord Montacute, and of Margaret Plantagenet, Countess of Salisbury; graduated at Oxford, 1515, and afterward studied at the University of Padua, Italy, 1520–23. Returning to England in 1525, he was favorably reeeived by his cousin, Henry VIII., by whom he was sent in 1529 to negotiate for the approval by the University of Paris of the projected divorce of Queen Catharine of Aragon, but soon came himself to an opinion adverse to that measure, and though the king sought to win his support by making him Arehbishop of York, Pole refused the offer and left the kingdom. He resided successively at Avignon, Padua, and Venice; sent to Henry his book, *Pro Ecclesiasticæ Unitatis Defensione* (1536), for writing which he was summoned to return to England, and, refusing to obey, was deprived of his ecclesiastical preferments and attainted by Parliament, but in compensation was in the same year invited to Rome by Pope Paul III. and created cardinal Dec. 3. In his hostility to the Protestant eause he tried to induee the Roman Catholic powers to undertake the invasion of England, but was unsuecessful. He was legate at Viterbo 1539–42; presided as papal legate at the opening of the Counеil of Trent, Dec. 13, 1545; was exeepted by name from the amnesty decreed by Edward VI. on his aecession to the throne 1547: was a prominent eandidate for the papaey in the eleetion of 1549; was appointed legate to England on the accession of Queen Mary, and reeeived by her with great pomp Nov. 24, 1554; successfully invited Parliament to a reeoneiliation with the papacy, and freed the realm from spiritual censures; was appointed by the pope Arehbishop of Canterbury Dec. 11, 1555; was consecrated Mar. 22, 1556; elected chancellor of the Universities of Oxford and Cambridge 1556; made a visitation of the universities Feb., 1557, and exereised a great influence upon the government of Mary. D. at Lambeth Palaee Nov. 18, 1558, the day following the death of Mary. Author of *Liber de Concilio* (1562), the first work printed at Rome by Paulus Manutius; *De Summo Pontifice Christi in Terræ Vicario* (1569), and *A Treatise of Justification* (1569), besides his principal work, previously mentioned. Revised by F. M. COLBY.

Pole-axe: See BATTLE-AXE.

Polecat: a name often, in the U. S., applied to the skunk, *Mephitis mephitica*, but properly belonging to one of the weasels—*Putorius fœtidus*—a European speeies (also ealled fiteh), about 16 inches long. The fur, whieh is brown, blackish on the tail and feet, and harsh, is used in making paintbrushes, but the name fiteh, originally given to brushes made from the fur of this animal, has been extended to others. The ferret is a semi-domesticated, more or less albinistic, variety of this speeies. F. A. L.

Polem'ics [from Gr. πολεμικός, warlike, deriv. of πόλεμος, war]: the side of the department of dogmaties especially eoncerned with eeclesiastieal controversy, particularly of an aggressive eharaeter. It reeognizes and emphasizes eonfessional differences and maintains the distinetive denominational tenets. It may be justly said that polemics is as old as the Chureh. For many eenturies it was a somewhat prominent feature of all theological writing. As was inevitable, at times there was more disposition to win a victory over an opponent than to establish the truth, and the literary battle between the Latin and Greek Churehes, between Protestants and Roman Catholies, and between different braneh es of the Protestant Chureh have been too frequently eharaeterized by unholy passion and unfair methods; but there is a growing indifferenee to theological distinetions, and the ehurches are eoming nearer together; so there is less polemies in the systems of theology. Irenies, or the harmonizing of differenees, is the end to be sought by polemies. The formation of religious and philanthropie societies by members of different denominations, the bringing of the Old Catholie, the orthodox Oriental, and the Anglican Churehes together, in conferences and sueh gatherings as the World's Parliament of Religions in Chieago in 1893—these are signs that polemies is yielding to irenies. The early Christian apologies, while defenses against, were also attaeks upon Paganism. They are translated in the Ante-Nieene Christian Library. The Latin theologians of the ninth eentury busied themselves with attaeks upon the Greek theologians. The most elaborate work upon this controversy is by Joseph Cardinal Hergenröther, *Photius, Patriarch von Constantinopel* (Regensburg, 3 vols., 1867–69). Of the eonfliet between Romanism and Protestantism the best works are by J. A. Moehler (R. C.), Eng. trans. *Symbolism* (2 vols., London, 1847), and by K. Hase, *Handbuch der protestantischen Polemik gegen die römisch-katholische Kirche* (Leipzig, 5th ed. 1890). The systematie theologies of the various Protestant denominations, e. g. C. Hodge (Presbyterian, 3 vols., New York, 1872), W. G. T. Shedd (Presbyterian, 3 vols., 1884–94), H. B. Smith (Presbyterian 1884), A. H. Strong (Baptist, 1889), H. Sehmid (Lutheran, Eng. trans., Philadelphia, 1876), S. Buel (Anglican, New York, 1890), J. Miley (Methodist, 2 vols., 1892–94), contain discussions of points in eontroversy betweeu the different denominations, sueh as predestination, regeneration, and the divine unity. The Chureh creeds are to a eertain extent polemieal. See the most eomplete collection, by P. Sehaff, *The Creeds of Christendom* (5th ed., New York, 1890). See APOLOGETICS.

SAMUEL MACAULEY JACKSON.

Polemon (in Gr. Πολέμων) THE PERIEGETE: the first to develop the preparation of "guide-books," with especial referenee to works of art, inseriptions, and the like; flourished about 150 B. C., and is supposed to have been the souree of mueh of the wisdom of PAUSANIAS (*q. v.*). See Müller, *Frag. Histor. Græcorum*, vol. iii., pp. 108–148. B. L. G.

Polemoniaceæ: See PHLOX FAMILY.

Polevoï, NIKOLAÏ ALEKSEÏEVICH: author; b. in Irkutsk, Siberia, June 22, 1796. Self-taught and originally a merchant, he gave himself up to literature, and founded the

Moscow *Telegraph* (1825), which became one of the chief Russian journals of the day. He attacked with passion and skill the writers of the pseudo-classical school, in opposition to whom he defended Pushkin, Byron, and other romantic authors. His own talent was remarkably many-sided, for he was at the same time critic, story-teller, dramatist, historian, and translator with varying success. Some of his plays (*Ugolino*, *Parasha*, *The Grandfather of the Russian Fleet*, *Death and Honor*, etc.) are still played, in spite of absurd exaggerations in them, which are also to be found in his stories (*Abaddonna*, *The Bliss of Madness*, *Emma*, etc.). His *Outlines of Russian Literature* had value for his time, but his unfinished attempt to write Russian history (6 vols., 1824–33) in the style of Guizot and Niebuhr, and in rivalry to the great work of KARAMZIN (*q. v.*), was a failure. His later years were unfortunate. His paper was suppressed by the Government (1835). As by changing his opinions he had lost his former adherents, in order to support his numerous family he was obliged to do literary hack-work as one of the editors of the *Son of the Fatherland*, in support of the party he had formerly opposed. D. Feb. 22, 1846.—His son, PETR NIKOLAÏEVICH POLEVOÏ, has written a *Life* of Shakspeare (prefatory to the edition of translations from Shakspeare of Gerbel and Nekrasov, 4 vols., 1866–67); a well-known *History of Russia in Sketches and Biographies* (4th ed. 1881), and other works. A. C. COOLIDGE.

Polianthes Tuberosa: See TUBEROSE.

Police [= Fr. < Lat. *politi'a* = Gr. πολιτεία, condition of a city or state, government, administration, from πόλις, city, state]: the means instituted by the government to maintain public order, liberty, property, and individual or personal security. In the accomplishment of this function it is sometimes the auxiliary of the administrative department, sometimes of the judicial department. In the former case the measures which it employs are chiefly preventive, and to a certain extent discretionary.

The real court of first instance is the policeman. The policeman on his daily post is the universal referee, as well as the universal guide-board; he has knowledge of more disputes and quarrels and he decides more cases than all the courts in the land. Of course, these are to the last degree trivial when looked at individually, but in the aggregate they are of vast importance. If the policeman be a man of good common sense he so decides these cases as not only to put an end to animosity between neighbors, but to prevent an infinite number of petty lawsuits which would otherwise occupy the courts. In doing this he merely carries out the object of his vocation—to keep the peace.

It is a narrow view of a policeman's functions which pictures him solely as arresting criminals. The discovery and apprehension of those who have broken the law is a most important part of his work, but in addition he has many petty duties, such as seeing that outside doors are locked, watching the street traffic and untangling blocks of vehicles, looking after the safety of women and children, enforcing corporation ordinances, and finding lost children. The organization of the police in a city enables cognate branches of that city's government to bring laws to the knowledge of the people as no other machinery can. In time of threatened epidemic, for example, the health authorities would be practically helpless without the police. As contrasted with the aggregate of these functions, in their value to the community, the sterner duties of the police, such as suppressing riot, are of comparatively little worth.

The need of discipline, of centralized power, has imparted to the police in every large city a semi-military organization. Everywhere the same general system is to be found. The people are represented by the police commission, which appoints men to serve on the force, makes the rules which are to govern them, sometimes fixes salaries, etc. It is in the commission, when there is more than one member, that all debate on police matters takes place, and it is here that debate ends. Immediately after the commission, and subject to the rules made by it, comes the police force. A marked difference is seen at once, because membership in this is always for life or good behavior, and there is always a pension for those worn out in the service. In some cases the police force is complete within itself; that is, the administration of the rules made by the commission is carried on by the officials of the force without interference. In other words, the force is autonomous.

At the head of the force is an official known by various titles in the different localities, but often called superintendent. It is his business to see the orders of the commission carried out, to see that the members of the force, each in his degree, perform the multifarious duties exacted of them. He is the executive head of the force, and while he may, if he sees fit, consult with the higher officers on matters of moment, he issues orders to the force which all must obey. He is, from his position, not only the central authority, but the very mainspring of the force. In practice it has been found that the more uncontrolled the authority of this officer, the better the force; the more it is interfered with, the more disorganized and inefficient the force becomes. In some organizations of police, all promotions rest on the recommendation of the official who is the immediate superior of the person to be promoted and on the approval of the superintendent. This system has given the best results among the members of the force. No other has so completely secured promotion for merit, simply because all other systems have introduced causes for promotion which are not connected with the direct efficiency of the force.

Immediately under the superintendent there are officials called inspectors in the U. S. Each inspector has assigned to him five or more precincts over which he has executive control. As the superintendent carries out the orders of the commission, so the inspectors carry out the orders of the superintendent, and see that they are obeyed.

With reference to the population, a city is divided into sections called precincts, or in some countries, districts, and at the head of each is a captain of police. He rules the men attached to his precinct or station house—a building fitted up for the police and containing cells for prisoners—sees that the laws are obeyed, and the rules of the force carried out.

Below the captains in rank come the sergeants, or in some cities lieutenants and then sergeants. One of these is on duty in the precinct-house day and night. In many respects his duties are those of the captain. He is, however, more in contact with the people. He has many decisions to make, and must have a fair knowledge of the simpler rules of criminal law.

The "roundsmen," as they are called in the U. S., are the officers to whom is intrusted the inspection of the patrolmen. It is their duty to see that the latter are walking their posts, that they do not break any of the rules made for them, and that they are at all times carefully watching for the welfare of the people.

There is a separate branch of the force which contributes in no small degree to the suppression and punishment of criminals. This is the detective bureau. It consists of a number of men who have been selected for their shrewdness, courage, and common sense, and for their acquaintance with the faces and careers of criminals. It is the special duty of the detectives to investigate crime, but a far more important part of their work is the prevention of crime by a ceaseless watch kept on the dangerous elements of society. Under their scrutiny come the anarchist and the pickpocket, the burglar and the confidence operator, and though the greater part of their work is never known to the public, they are a powerful agency in the maintenance of order in the community.

In many countries there is a branch of the police which is practically unknown in the U. S. These are the political detectives, the men who watch those who are or who are supposed to be inimical to the existing government. During the civil war, and for a short time afterward, the members of the secret service of the U. S. Government did work of this kind, but since then the only avowed enemies of the Government in the U. S., the anarchists, are looked after by the local police.

The police force of the city of New York is governed by a commission, having four members, appointed for a period by the mayor. The force consists (1894) of a superintendent, 4 inspectors, 38 captains, 163 sergeants, 40 detective sergeants, 174 roundsmen, and 3,380 patrolmen—in all, 3,800 men, besides 15 surgeons, 79 doormen or janitors of station-houses, and 21 matrons who attend female prisoners. The city is divided into 38 precincts and 3 inspection districts. The posts patrolled in the day are twice as long as those during the night, so that during the latter twice as many men are on duty. In addition, a reserve of men is kept in each precinct-house ready to be sent to any point at which they are required. In the upper part of the city, where the posts are very long, many of the men are mounted. In time of danger, or when there is any great popular festival, the whole force is on duty night and day. There is a special

detail, known as the harbor police, which watches the shipping from launches and boats.

In Chicago the police force consists of a superintendent, an assistant superintendent, 3 inspectors, a chief of detectives, a superintendent of the bureau of identification, 15 captains, 59 lieutenants, 267 sergeants, and 2,493 patrolmen —in all 2,841 men.

In London the commission consists of a chief commissioner and two assistants, who are appointed for life by the Queen on the recommendation of the Home Secretary. The metropolitan police force consists of (1891) 5 chief constables, 31 superintendents, 787 inspectors—equivalent to captains in New York—1,637 sergeants, and 12,583 constables—in all, 15,043 men. There are 180 police districts (precincts) in London. This is exclusive of the city police, which consists of 905 men.

The metropolitan district of Dublin has its own police, created under parliamentary act of 1836. The force consisted on Dec. 31, 1892, of 1 chief commissioner, 8 superintendents, 24 inspectors, 176 sergeants, and 940 constables.

The Scotch police were organized under parliamentary acts of 1857 and 1862, auxiliary to and amendatory of acts passed during the early part of the nineteenth century. The force is subdivided into county districts, the authority governing each county force being vested in a commission consisting of seven county chancellors, and the sheriff of the county being an *ex officio* member of the commission. In Scotland, which has an area of 29,785 sq. miles and a population of 4,025,647, the total number of police in all the different counties is 4,700, or 1 for every 852 of the population.

In Paris the organization of the police is distinctly military. Under the Minister of the Interior, who is in the cabinet, there is the prefect of police and his subordinate, the director of public safety. The prefect occupies almost a cabinet position, in that he is expected to resign if the force fail in any great emergency. For example, the prefect, M. Lozé, resigned after the students' riots in 1892, and his successor, M. Lepin, after the assassination of President Carnot. There are 80 commissionnaires, 2 division inspectors, 25 clerks, 38 officers, 25 principal inspectors, 100 brigadiers (equivalent to sergeants in New York), 700 under-brigadiers (roundsmen), and 6,800 guards of the public peace —in all, 7,770 men. "Indicators," as they are called, are men outside the force who watch everybody. They are, in fact, spies, and the majority are reformed criminals.

In Berlin the police are divided into the county police, the industrial, the building, the criminal, the public safety, the stranger, and the community police. The fire department is also a part of the same general bureau. The Minister of the Interior is the head of the police force, and the system is purely military. Under him is the general with a staff of twelve brigade-generals who rank as colonels in the army, forty-nine district-officers who rank as majors or captains, and so on. The men carry swords and firearms.

In Russia the police form the executive administrators of the whole empire, and their number is not published. In St. Petersburg there are about 10,000 police—officials of the public safety—who maintain order. They are not armed in any way, but carry whistles. The number of those employed as detectives in the famous "Third Section" is unknown. It is the duty of these men to keep a constant watch on everybody, especially foreigners in the country, and to make their reports to the head of the section personally. For many years this was the Minister of the Interior, but of late it has been some man, generally selected from the army, who has been especially appointed.

The police in cities in Spain, Belgium, and Italy are organized under the military system so generally approved of on the Continent. In Turkey the police are more like watchmen who look out for fires than guardians of the peace.

Police organizations of a military character are maintained in several portions of the British empire. In Ireland the Royal Irish Constabulary, organized in 1836, have done good service, and it is this force which put into effect the various coercion acts passed by Parliament. In Canada a system of mounted police was formed on the model of the Royal Irish Constabulary, and in the Northwest territories have managed the Indians and maintained laws with thoroughness. In Australia and Africa similar organizations have been started, and the police branch of the East Indian Government is much like them. The organization is purely military in form: there is generally a lieutenant-colonel or major at the head, responsible to the Minister of the Interior or the official who answers to him. Under the commanding officer there are captains, lieutenants, sergeants, and privates. These bodies of men have done splendid service and have kept the peace over large territories at a minimum of cost. In Australia the police have ruled the gold-fields and the blacks, and in South Africa a similar force has (1894) been organized to maintain order among the miners in the gold regions and to hold in check the Matabeles and other tribes. In India the force is recruited from the natives, but the officers are British. There is life-tenure of position and a pension for old age or disability. With the mixed population of India, governed by an alien race, the supervision exercised by the police is of enormous value.

Returning to the police in cities, a comparison of the number of men with the population is of interest. The figures are as follows:

CITIES.	Population.	No. of police.	No. of men, women, and children guarded by one policeman.
New York	1,975,646 *	3,800	519
Paris	2,344,550	7,836	299
London, metropolitan and city police districts (1891)	5,633,806	15,948	353
St. Petersburg	978,309	10,000	97
Glasgow	670,000	1,303	514

* Population estimated by Registrar of Vital Statistics, New York Health Department, October 12, 1894.

It must be remembered that in the Paris police the "indicators" and the Government political detectives are not included, and that in London the extremely puzzling streets make a large number of human sign-boards imperatively necessary, and the dense traffic requires to be regulated by a large number of men. The police in European cities, not excepting those of Great Britain, are aided to a great extent in their duties, so far as those duties relate to suppressing organized lawlessness, by the regular troops, large garrisons of which are quartered in every town of any considerable size.

THOMAS BYRNES.

Police Power: See the Appendix.

Policy: a name applied to various forms of lottery. In one form the "policy shops" give out each afternoon slips containing two columns of twelve numbers each, and each evening slips containing two columns of thirteen each. The numbers in each column are drawn by lot from those between 1 and 78 inclusive. Before the drawing a person may make bets in various ways; in a "straight gig" the player selects three numbers and receives odds of 100 to 1 for the afternoon slips, or 87½ to 1 for the evening slips, that they will not all three appear in the same column of the slip. In this the real chances against the player are nearly 173 to 1 for the afternoon, and exactly 133 to 1 for the evening, even when the drawing is fairly conducted. Policy-playing is much in vogue among certain classes, in spite of laws against it.

Polignac, pō'lĕĕn'yaăk': the name of a French family which played a conspicuous and fatal part in the later history of the Bourbons.—JULES, COUNT DE POLIGNAC, and his wife, YOLANDE MARTINE GABRIELLE DE POLASTRON, were the most intimate friends of Marie Antoinette and the most prominent members of that faction of the court which intrigued against the reforms of Louis XVI. and his ministers. The count was made a duke in 1780, postmaster-general in 1782, and the family received immense dotations of land and money. As the prodigality of the queen and the political mistakes she made were generally ascribed to the influence of the Duchess of Polignac, she and her husband were the special objects of the French people's hatred and contempt. They left the country, together with the Count of Artois, July 16, 1789, as the first *émigrés*. The duchess died at Vienna in Dec., 1793. The duke went afterward to Russia, where he was well received by Catherine II.; she gave him an estate in Ukraine, where he died Sept. 21, 1817. His three sons tried first to form an intrigue for the re-establishment of the Bourbons by the First Consul, through his wife, Josephine; afterward they participated in the conspiracy of Cadoudal, and were imprisoned at Paris when the allied army approached the city. The second of them, JULES AUGUSTUS ARMAND MARIE, b. May 14, 1780, was made a Roman prince by the pope in 1820, and became president of the cabinet Aug. 8, 1829. As such he signed the famous *ordonnances* of July 25, 1830, which caused the immediate downfall of the Bourbon dynasty. He fled, but was arrest-

ed, and sentenced by the Chamber of Peers to imprisonment for life and forfeiture of his titles and rights as a citizen. Restored to liberty by the amnesty of Nov. 29, 1836, he went to England. D. at St.-Germain, Mar. 29, 1847.

Revised by F. M. COLBY.

Polish Language: See SLAVIC LANGUAGES.

Polish Literature: the literary monuments of the Polish language both before and since the final partition of Poland. This literature, like the nation itself, has passed through many vicissitudes. Seven distinct periods of its development are generally recognized.

I. *Poland under the Piasts* (down to 1386 A. D.).—The ancient (heathen) Poles were not acquainted with the art of writing, and what little of their literature has been preserved by tradition is found in folk-song and fairy-tale. Christianity introduced Bohemian, German, and Latin culture into Poland, and the native language entered on a struggle against the German and Latin cultivated by the priests in their schools. The earliest specimens of Polish literature are a translation of Psalm l. (about 1290), the hymn *Bogarodzica* (Mother of God), ascribed to St. Adalbert (d. 997), and the psalter of Queen Margareth (d. 1349). The historians of this period, Martin Gallus, Mateusz Cholewa, Wincenty Kadlubek (d. 1223), and others, wrote in Latin.

II. *Poland under the Jagellons* (1386–1548).—The invention of printing (first press in Cracow, 1465) and the foundation of the Academy of Cracow (re-established, 1397) exercised a powerful influence on the development of native Polish literature. The Bible of Saros Patak dates from 1455. Important collections of judicial decisions were made. Some poets still wrote in Latin, but Stanislaw Ciolek, Jedrzey Galka, and others, wrote in Polish. In this period were made the first attempts at dramatic composition (mysteries, with biblical subjects). Theological controversies created considerable polemical literature. The chief works of the period are the legal tracts of Jan Ostroróg and the historical writings (in Latin) of Jan Dlugosz (d. 1480), who is justly considered the father of Polish history. *Kronika Polska*, by Chwalczewski, and a few other works were written in Polish.

III. *The Golden Age* (1548–1606).—The Reformation and the generous policy of Sigismund August combined to raise the standard of native literature to a level hitherto unknown. Poland was the common refuge of western "heretics," the Bohemian Hussites, and others, whose Polish adherents championed their tenets in Polish and thus compelled the Catholic majority to employ that language, though Latin did not yet wholly disappear; but the large number of polemical tracts, postillas, religious songs, and translations of the Scriptures possessed but an ephemeral value. Talented literary men received encouragement and generous support from the king and many high-minded nobles and ecclesiastics; native poetry found a number of gifted interpreters, and this period is pre-eminent in both quality and quantity of literary works. It is also marked by the decline of the Cracow Academy and the rise of Jesuit influence in Poland (first Jesuit college established 1564).

The most prominent names of the golden age are those of Mikolaj Rej z Naglowic (d. 1569), Jan Kochanowski (d. 1584), his brother Peter, Sebastian Klonowicz, Mikolaj Sep Szarzyński (d. 1581), Kaspar Miaskowski, Piotr Skarga (d. 1575), and Stanislaw Grochowski (d. 1612). Rej was not a great poet, but his prose work *Zwierciadlo* (The Mirror), in which he presents the portrait of an ideal Polish nobleman, patriot, and Christian, is very valuable. Jan Kochanowski is the first great poet. Having no domestic models he had to invent a poetical language. He is best known by his excellent translation of the Psalms, his touching elegies *Treny* (Tears), his songs and satires, and, above all, the *Fraszky*. His drama *Odprawa poslów greckich* (The Expedition of the Grecian Envoys) is one of the earliest Slavonic dramas. Piotr Skarga, a champion of Catholicism, was the greatest preacher of his country. Szarzyński and Klonowicz followed Jan Kochanowski; Miaskowski and Grochowski cultivated religious poetry; Szymon Szymonowicz and Szymon Zimorowicz wrote five idyls. Mikolaj, Piotr and Jedrzej Kochanowski translated Greek, Latin, and Italian classics. Some of the poets still wrote in Latin. Valuable historical material is contained in the *Acta Tomiciana*.

IV. *The Panegyrists* (1606–1764).—The corruption of taste prevailing throughout Europe soon invaded Poland, and the golden age of her literature was followed by a period of decline. Panegyric verses, full of bombast, generally written for a pecuniary consideration, became the fashion. Every wedding, funeral, and baptism was celebrated by long-winded speeches and poems, and the custom of mingling Latin and other foreign words with those of the native language in macaronic verse became universal. The best poets of the time were survivors of the preceding era. At their head stands Waclaw Potocki (d. about 1696), whose fame rests on his great epic, *Wojna Chocimska* (The Campaign of Chocim). Krysztóf Opaliński (d. 1656) is the only satirist of note. A complete transition to Frenchified poetry was effected in the works of the Morsztyns: Hieronym, Jedrzej, Stanislaw, and Zbihniev. During this period historians confined their attention to memoirs. The first Polish newspaper made its appearance under Sigismund III.

V. *The Era of Stanislaw Augustus* (1764–1821).—This was an era of French classicism, a period of frivolous self-conceit. French customs, ideas, and forms dominated in literature as well as in society. At first the amount of literary work was comparatively small, notwithstanding the efforts of individual talent. Between 1764 and 1778 only 416 works were published in Poland, of which 84 were religious, 37 ethical, 32 political, 13 philosophical, 24 mathematical, 14 geographical, 56 historical, 13 oratorical, 56 poetical, 23 fiction, 27 grammatical, 13 medical, 2 architectural, and 22 agricultural. With a change of political conditions, however, came a change in literature; in the four years of the famous parliament (1788–91) the nation did more thinking and printing than it had done before in a century, and the functions of public newspapers became highly important.

Poetry followed French models for the most part, though there are some notable exceptions. Ignacy Krasicki (d. 1801) was an original genius, particularly in his satires, as was also Adam Stanislaw Naruszewicz. Krasicki's works *Myszeis* (The War of Mice) and *Monomachia* (War of Monks) are famous. Stanislaw Trembecki (d. 1812) was a master of form, but not a true poet. Kajetan Wegierski (d. 1787) was a clever rhymester, but his poetry is too sensual and voluptuous. Franciszek Karpiński (d. 1828) and Kniažnin (d. 1807) were authors of popular songs. Midway between the national and the French schools stood three notable poets of the Warsaw principality—Jan Pawel Woronicz (d. 1829), Julian Ursyn Niemcewicz (d. 1841), a patriotic satirist, theorist, historian, dramatist, and novelist, and Wojciech Boguslawski, the true founder of Polish drama, whose *Cud mniemany* won great popularity. French tragedy at this time found many translators and imitators, who were loudly applauded, though lacking talent.

In history the greatest name was that of the archæologist Adam Naruszewicz. Of his later followers Lelewel was the best. Politics gave rise to a considerable number of pamphlets, history of literature began to receive attention, and philology made rapid progress. Onufryj Kopczyński was the first great grammarian, and Samuel Bogumil Linde wrote the first standard dictionary of the Polish language.

VI. *The Era of Mickiewicz* (1821–63).—French pseudo-classicism could not dominate Poland for any considerable length of time; national poetry inspired the poets of the new generation. In Boguslawski's idyllic drama *Krakowiacy i górale* (The Cracowians and the Mountaineers) the national note is first sounded. The influence of Byron, Walter Scott, Goethe, Schiller, and Victor Hugo is manifest. Adam Mickiewicz (d. 1855), the leader of the romanticists, is the greatest poet not only of Poland, but of the entire Slavonic race. His great epic poems *Grażyna*, *Konrad Wallenrod*, and *Pan Tadeusz* marked him at once as a modern Homer. In his footsteps followed Antoni Eduard Odyniec, Julian Korsak, Alexander Chodzko, Antoni Gorecki, Józef Massalski, and others. The life of the people of Ukraina found its poets in Bogdan Zaleski (d. 1887), Severyn Goszczyński, and Michael Grabowski. The unfortunate Antoni Malczewski, too, wrote *Marya*, a story of Ukraina. The romanticists were sharply criticised by Osiński, Dmochowski, and others, but the attacks were ably repelled by Mickiewicz himself, and pseudo-classicism was finally doomed in Maurice Mochnacki's critical work *O literaturze polskiéj w wieku XIX*.

In Galicia reform was preached by the *Haliczanin*. The new movement soon invaded the field of novel-writing, Walter Scott being the principal model for Polish authors. Niemcewicz's *Jan z Teczyna* created a sensation. Then followed K. Gaszyński, F. Wężyk, F. Skarbek, the historical novelist Felix Bernatowicz, Mme. Jaraczewska, Alex. Bromikowski, and others.

The revolution of 1830 stopped the peaceable evolution of Polish letters. It brought stagnation to domestic production. Polish talent was to be found in exile, and Polish books then began to appear at Paris, Avignon, Strassburg, Brussels, London, Berlin, Vienna, and especially Leipzig. Poland revived slowly. The review *Wizerunki* appeared first, followed at Warsaw by the *Ateneum* of Józef Ignacy Kraszewski (d. 1887), Poland's greatest novelist. In the forties St. Petersburg became an important literary center. A decided turn for the better was announced in 1851 by the appearance of the *Dziennik Warszawski*. Some of the old poets were heard again. Mickiewicz published *Pan Tadeusz*; Bogdan Zaleski, S. Goszczyński, and S. Witwicki were still active. Among the younger generation appeared three great lights of the romantic school—Zygmunt Krasiński, Wincenty Pol, and the proud and daring Juljusz Slowacki, a rival of Mickiewicz himself. The greatest poets to come to prominence at the end of this period were Kornel Ujejski (lyric) and Wladyslaw Syrokomla (d. 1862), and the greatest novelists Jan Zacharjasewicz and Eliza Orzeszkowa.

Waclaw A. Maciejowski was at first the only historian of note, and kindred branches of literature were much neglected; but an increased activity dates from 1841. Karol Szajnocha and Alex. Batowski, editors of ancient historical documents, deserve special notice. Philosophy found its first exponents in Karol Libelt and Bronislaw Trentowski. Among the linguists Antoni Malecki is foremost.

VII. *The Present* (since 1863).—The present literature is noted for its riches, though it possesses but few names of international fame. The modern Polish novel deals chiefly with social questions—the relation of the nobility to the peasantry, the position of woman, that of the Jew, etc. The best-known author is Henryk Sienkiewicz, a number of whose novels have been translated into English by Jeremiah Curtin (*With Fire and Sword*, *Without Dogma*, etc.). Other well-known novelists are Boleslaw Prus, W. Los, T. T. Jež, Eliza Orzeszkowa, Marya Konopnicka (poet as well as novelist), Jan Zacharjasiewicz (writer of character novels), Ostoja, and Lewer. Among the poets should be mentioned Marya Konopnicka, W. Wysocki, Felicyan, K. Lewandowski, and Miriam (Zenon Przesmycki). The foremost dramatist of the nineteenth century is Alexander, the Count Fredro, whose comedies are still popular, though French in style and color. Others whose works are meritorious are Antoni Malecki (*List zelazny*, *Grochowy wieniec*), Józef Szujski (*Halszka z Ostroga*), Apollo Karzeniowski, Romanowski (*Popiel i Piast*), and, above all, Edward Lubowski (*Przesądy*, *Sąd honorowy*, etc.). The prominent historians are Antoni Malecki, the veteran, A. Szczepanski, K. Waliszewski, W. Boguslawski, and W. Spasowicz. Owing to the division of Poland the kingdom has three literary centers—Warsaw, Posen, and Cracow.

Bibliography.—A number of histories of Polish literature have been written in the native tongue, among them those of Bentkowski (1814) and Wiesniewski (10 vols., Cracow, 1845–57), besides many works on special portions of it. There are also several good works in German.

Political Economy [*political* is from Gr. *πολιτικός*, pertaining to citizens or to government or a state, deriv. of *πολίτης*, citizen, deriv. of *πόλις*, city, state; *economy* is from Gr. *οἰκονομία*, economy, management, liter., household management; *οἶκος*, house + *νέμειν*, distribute]: the science of wealth, or the body of knowledge which relates to the production, distribution, and exchange of wealth. It is only within the concluding years of the nineteenth century that this view of the scope of political economy has been generally accepted. Down to the end of the eighteenth century it was regarded as an art rather than a science. It meant the art of conducting the business of a nation, just as domestic economy meant the art of conducting the business of a household, while it was a broader term than finance, which applied to the business of the government alone. The writers of the seventeenth and eighteenth centuries made the analogy between national and domestic economy far too close. They thought that it was the object of a nation to get rich in the same sense that it was the object of an individual to get rich. As an individual may grow prosperous by producing more than he consumes, and thus selling more than he buys, so the earlier writers on political economy conceived that a nation would grow rich by selling more to other nations than it bought from them, and that this was the only way by which the nation could be thoroughly prosperous. This view was at the basis of the *mercantile system* of political economy, so called, because it treated the business of a nation like that of a single merchant. Perhaps the leading British mercantilists were Thomas Mun in the seventeenth century and Sir James Steuart in the eighteenth. Steuart's *Inquiry into the Principles of Political Economy* (1767) was the most comprehensive English treatise previous to that of Adam Smith. To the eighteenth century belongs the work of Galiani in Italy, Justi in Germany, and Sonnenfels in Austria. Practical applications of the mercantile principle were seen in the commercial policy of nearly all European states down to the French Revolution, and still survive in many of the protective tariff systems. It was exemplified in the English navigation acts, and by the financial policy of Colbert in France in the seventeenth century.

It is easy to see that the mercantilists applied to national policy the principles of a miser rather than of a farsighted merchant, and that a wise business man becomes rich, not by the money that he accumulates, but by that which he spends farsightedly as a reinvestment. This line of criticism did not escape the notice of the mercantilists themselves. It was vigorously urged by Sir Dudley North (1691), and by his contemporary Sir William Petty. In the eighteenth century these criticisms were carried still further by the French school of economists known as *physiocrats*. This name was intended to emphasize their belief that legislative policy was subordinate in its effects to the action of the *powers of nature*. Whereas the mercantilists had attached too much importance to money as a measure of wealth and laid undue stress on forms of commerce, the physiocrats considered that national wealth was represented by the raw materials available, and laid chief stress on the productiveness of agriculture. The leaders of this school were Quesnay (1694–1774) and de Gournay (1712–59). The most eminent representative of the school in practical life was the great French minister Turgot (1727–81). It was a severe misfortune to France that this farsighted statesman was thwarted in the carrying out of his proposed reforms, which might have done much to mitigate the violence of the Revolution. Contemporary with the French physiocrats we find the work of Beccaria (1738–94) in Italy, and Adam Smith (1723–90) in England.

The work of Smith, whose *Wealth of Nations* was published in 1776, forms the starting-point of modern thought on political economy. He criticised the mercantilists as unsparingly as did his French and Italian contemporaries; but he took a broader view than the physiocrats in seeing that labor, as well as natural resources, was a decisive element in wealth and national prosperity. He also developed far more clearly than the physiocrats some operations of individual freedom and enterprise in their effect upon prices, and in so doing laid the foundation for the modern conception of economics as a science rather than an art. To Smith, more than any one else, is due the clear presentation of the truth that under free competition prices will ordinarily adjust themselves to cost of production; and the analysis—imperfect, it is true—of cost of production into its various component parts. The scientific method of Smith was carried much further by Malthus (1766–1834) and Ricardo (1772–1823). Malthus devoted special attention to social economy, the principles of consumption, and the effect of increasing numbers upon national or individual well-being. Ricardo started at the opposite extreme, with the investigation of money, banking, and finance. Applying the methods of finance to the analysis of cost of production, he developed the theory of rent which is associated with his name, as the theory of population is connected with that of Malthus. The popular movement for the repeal of the corn-laws gave these writers and their successors, of whom McCulloch and Senior were the most prominent, an opportunity to make their influence felt. To this group of writers the name of the English classical school is habitually applied. The work of this school is summed up and systematized in John Stuart Mill's *Principles of Political Economy* (1848), which is the leading treatise on the science. Its views are set forth in a more popular, but less philosophic, form in Fawcett's *Manual of Political Economy*. The continental writers at the beginning of the nineteenth century followed closely in the lines of the English. Among the French were J. B. Say (1767–1832), Sismondi (1773–1842), and Bastiat (1801–50), the last named being the most brilliant, but least scientific. The classical doctrines of political economy are gen-

erally held by French economists of the present day, among whom Leroy-Beaulieu is perhaps the most prominent. In Germany during the same period the leading names are those of Rau (1792–1870) and von Thünen (1783–1850), the latter of whom perhaps anticipated modern developments more than any contemporary writer in France or England.

It was a general characteristic of the classical school to believe in the let-alone or *laissez-faire* policy. With few exceptions these writers held that, under the action of individual liberty, the maximum of efficiency, as well as of justice, would be secured, and that all interference with liberty of contract was at least *prima facie* bad. Not content with criticising the mercantile system, they opposed the factory acts as such. Not content with pointing out the error of most legislation, they indulged in the most optimistic views as to the results of non-interference—views which the facts did not always justify. They thus exposed themselves to severe criticism from the socialist school, of whom Marx (1818–83) and Lassalle (1825–64) were the recognized leaders. Marx showed that, in point of fact, free competition did not produce the results which the political economists expected, and he therefore drew the conclusion that the social system which formed the basis of their assumptions was radically bad, while Lassalle, whose reasonings were historical rather than economic, endeavored to trace the direction which social changes must take in order to give the workman what he considered a just share of the product of industry. The protectionist writers also criticised the English classical school, but on lines wholly different from those of the socialists. Instead of accepting the deductions and attacking the system on which they were based, they may be said to have accepted the system and attacked certain deductions from it. The leading writers of the protectionist school during the first half of the nineteenth century were List in Germany (1789–1846) and Carey in the U. S. (1793–1879). They agree with Adam Smith and his followers in condemning the extreme errors of the mercantile system and in regarding labor and capital as the essential forms of wealth, but they believe that the greatest efficiency of labor and wisest expenditure of capital can be obtained, not by individual self-interest, but by certain restrictions on the part of government. Much of their argument is historical, rather than deductive. That is, they trace changes in the economic policy of nations as a whole, rather than methods of individual action under given conditions. In this way the protectionist school shades almost indistinguishably into the modern German historical school, of which Knies is regarded as the founder, and which numbers among its most prominent members the names of Hildebrand, Brentano, Schäffle, Wagner, Cohn, and Schmoller.

The criticisms of the German historical school have found an echo in England, to a greater or less extent, in Cliffe Leslie and Thorold Rogers and W. J. Ashley.

On the whole, it may be said that the work of the historical school has been very ineffective in proportion to its volume. The modifications in economic doctrines since 1870 have largely come through the detailed criticisms of those writers who profess to apply the deductive or individual method. The beginnings of this criticism may be seen in the writings of Cairnes (1823–75) and Bagehot (1826–77). Of greater importance were the criticisms of Longe and Thornton on the traditional doctrine of wages. Mill himself was converted to Thornton's views, although he died too early to incorporate the results in his *Principles of Political Economy*. Similar lines of criticism were carried on by F. A. Walker in America and Marshall in England.

Side by side with this critical progress we have a constructive movement on the part of the mathematical school of economists. As early as 1838 Cournot had made some important applications of mathematics to the economic analysis, and the almost unnoticed work of Gossen in 1857 had carried the same method still further; but it was reserved for Stanley Jevons in 1871, in his *Theory of Political Economy*, to call general attention to the advantages of this method. Coming at the time he did, he was able to lay the foundation for certain positive theories of political economy which could take the place of some of the untenable principles of the classical school. Contemporary with Jevons we have the work of Walras in Switzerland, and subsequently of Pantaleoni in Italy and Edgeworth in England, while Marshall in England, Clark and Patten in America, Menger, Wieser, Sax, and Böhm-Bawerk in Austria have done much to present the results of similar methods of analysis, divested of their algebraic form. So important have been the contributions of the Austrians in this field that the name "Austrian school" is now habitually applied to this whole group of writers.

Political economy in the U. S. was somewhat slow in its development. With the exception of Henry C. Carey, there was for a long time no economist of originality and eminence. The first teachers of political economy, like Amasa Walker, A. L. Chapin, or A. L. Perry, both in their thought and in their writings followed closely in the lines of the English classical school. Much more important work was done in the years following the war by a group of practical men working in special lines of study. First in this group should be named David A. Wells, for some years U. S. revenue commissioner, whose works on taxation and trade have a world-wide reputation. His last, and in some respects most comprehensive, book is entitled *Recent Economic Changes*. Edward Atkinson has done work of equal importance with reference to questions of production, distribution, and internal commerce. Charles Francis Adams, as Massachusetts railway commissioner, laid the foundation for a scientific study of railway problems. Carroll D. Wright, as labor commissioner, first of Massachusetts and then of the U. S., has attained a world-wide reputation for his investigations on wages and other matters connected with the factory system. In connection with this group should be mentioned the names of John Jay Knox and Horace White, leading authorities on questions of banking and finance. Chief among theoretical writers should be named F. A. Walker, superintendent of the census of 1870 and 1880, professor at Yale, and afterward president of the Massachusetts Institute of Technology, who is probably the leading economist of the present day, in the English-speaking world, at any rate; W. G. Sumner, of Yale, who has published books on American financial history and on certain sociological questions; and Simon Newcomb, of Washington, a political economist as well as astronomer.

A special place in the history of economics in the U. S. must be assigned to Henry George, a writer standing midway between the classical economists and the socialists, agreeing with the former in their advocacy of freedom from interference, with the latter in their projects of nationalization of the land. His *Progress and Poverty* was first published in 1879, and has had an unprecedented popular influence. Another important writer, springing like Henry George from the ranks of the laborers, but more conservative in his conclusions and more careful in his methods of analysis, is George Gunton.

Until about 1880 most of the study of political economy in the U. S. had been under English influence. At that time a group of younger men who had studied in Germany came into prominence, and began to mould economic thought in the direction of the historical method. Among those who were prominent in this direction were Prof. R. T. Ely, of Johns Hopkins University and subsequently of the University of Wisconsin, Prof. E. J. James, of the University of Pennsylvania, and Prof. Henry C. Adams, now of the University of Michigan. Under their influence the American Economic Association, whose publications have done much to increase the interest in economic study, was founded in 1885. Among its most important members are Prof. J. B. Clark, of Amherst College, Prof. F. H. Giddings, of Bryn Mawr, and Prof. J. W. Jenks, of Cornell. In the most recent years the economic courses in all the leading colleges of the U. S. have been strengthened, and most of them maintain publications specially devoted to economics and political science. Among scientific publications largely devoted to political economy, besides those of the American Economic Association, may be mentioned *The Quarterly Journal of Economics* (Harvard), *Political Science Quarterly* (Columbia), *The Economic Journal* (Chicago), *The Yale Review*, and the *Annals of the American Academy of Political and Social Science*.

Scope of the Science.—Political economy or economics is the science which undertakes to explain prices and price-movements. Any such explanation involves two processes. We may assume a given set of laws and customs, and see how the operation of individual motives will affect the price of different goods or services; or we may go one step farther back and investigate the reasons which have caused those laws and customs to be established, and which make modifications desirable or probable. Those who chiefly occupy themselves with the former class of problems are said to employ the deductive method, those who chiefly study the latter class employ the historical method; but it is begin-

ning to be understood that any good economist must employ both methods, and that the distinction between the so-called deductive and historical schools is much less fundamental than was once supposed.

Political economy, as thus defined, is a science and not an art. It is occupied primarily with explanations rather than precepts. It bears the same relation to the arts of finance and legislation that the science of physiology bears to the arts of medicine and hygiene, or the science of mechanics to the art of building.

Price and Value.—A price is the quantity of one article or service which is exchanged for another. If a ton of coal is exchanged for 5 bush. of wheat, either may be said to be the price of the other; but usually prices are expressed in some one article—money—which is adopted as a common measure or standard.

Many economists make a distinction between price and value by restricting the term price to those cases where it is measured in money, and applying the word value to all other standards of exchange; but this does not correspond to common usage, and is almost always misleading. In common usage, a price is a *fact*, the amount of something which we must pay for something else; while value is an *estimate*, either by the community or by some individual, of what a price ought to be. Under ordinary circumstances value means the average probable price. If we say, for example, that certain railway stock is selling below its true value, we mean that, in our opinion, this stock will, on an average, sell for a higher price than it now commands. Value is also sometimes used to mean what, in the opinion of the speaker, is regarded as a just price. If we say that a combination is able to keep the price of oil above its true value, we mean above that price which would constitute a fair return for the labor and capital invested. Many of the fallacies in economic reasoning arise from treating the term value as an estimate at one point of the reasoning, and as a fact at another point. It is better to confine it entirely to the former use and to employ the word price for the latter.

How Value is Determined. Competition.—The value or proper price of an article may be determined by the community in two ways, either by custom or by competition. The former was almost universal in mediæval times.

It was believed by the mediæval writers, as it is believed by the modern socialists, that value depends on cost of production, that there is a constant effort on the part of the producers to sell their articles for more than the value or just price, and that public sentiment, or even legislative enactment, should fix a price of this kind and compel the producers to maintain it. The objections to this view are, first, that such a way of determining prices is possible only where the processes of industry are simple and uniform. In the absence of such uniformity, the public can not readily determine what is the cost of production of an article or its just price on this basis. Second, even when the price has been fixed with substantial correctness, it is difficult to insure the production of the right quantity. If more is produced than the public will take at the price in question, it goes to waste. If less is produced than the public wants at such a price, there will be scarcity and distress. Only in the case of production for orders or for a perfectly uniform market could this matter be regulated under the mediæval system, and even under such circumstances it was necessary to determine by the most tyrannical rules what trade each man should be allowed to pursue.

The modern method of determining value by competition avoids these difficulties. Suppose wheat has been selling in the New York market at $1 a bushel. The dealers find that the quantities supplied by the producers at this price are less than the quantities demanded by the consumers, that the stocks on hand are diminishing, that if this process continues there will be a scarcity. They put the price up to $1.05 a bushel. At this price there will obviously be somewhat fewer persons who wish to buy and somewhat more who are willing to sell. The quantity supplied becomes equal to the quantity demanded; if this process goes far enough, it becomes even greater. Then comes a reaction. The dealers are afraid that unsold stock will accumulate on their hands. They will put the price down to $1, or even to 95 cents, in order to adjust the quantity which the public is willing to buy, to that which the producers stand ready to sell. The essence of this method is that the producers are allowed to fix the price at the point which the public is prepared to pay. The advantages of this system over the system of customary prices are, first, that it prevents waste. If wheat remained at $1 a bushel until the whole supply was used up, people would not economize in their consumption, and would find themselves unexpectedly face to face with a season of famine. On the other hand, if the price were kept at $1 a bushel when the supply was so great that it could not all be used at that price, the accumulated stocks would deteriorate and not be used to advantage. By adjusting the prices to the quantities on hand, excessive use on the part of consumers or excessive accumulation on the part of producers is avoided. Second, the system of competition directs production automatically. If there is going to be a scarcity of wheat, any custom or law which prevents an increase of price takes away from producers the motive to meet the public need. If the price of wheat be allowed to rise to $1.05, new supplies of wheat are attracted to the market and prevent famine or scarcity. If, on the other hand, such increase be prohibited, it is merely an attempt to check the distress by repressing the symptom. In fixing prices by custom, a deficiency in production is perpetuated; but if free competition be allowed, that deficiency is permitted to correct itself. Third, and most important of all, competition makes price conform to cost of production more closely than is possible by any system of legal enactments; for if the price of any article continues for any length of time in excess of the cost of production, new capital and new laborers will be attracted in the business of supplying it. The quantity offered will increase, and the price will go down. If, on the other hand, the price of an article for any considerable time fails to cover the cost of production, capital and labor will go out of the business, the quantity supplied will be diminished, and prices will rise until they reach a fair and just level. This automatic adjustment of price to cost makes the modern system fairer, as well as more elastic, than the mediæval one.

Relation of Value to Utility and Cost of Production.—Under this system the value of an article does not depend primarily on its cost of production, but on its utility; not upon the utility of the article as a whole, be it observed, but upon the utility of additional supplies of that article. It may be laid down as a general rule that the utility of additional supplies of any article in a given market tends to decrease as the quantity of that article supplied from day to day increases. This utility of additional supplies is the primary cause of the value. Competition among different sellers insures that the price of one part of the supply will not be much greater than that of another; in other words, that the value of the article as a whole will be fixed by the utility of the last increments or additions to the supply. The increase of supply will go on so long as this value more than covers the cost of production. When it ceases to cover the cost of production there is at once a reaction; the utility of the additional supplies is less than the sacrifices involved in producing them, the price received no longer covers the expenses of production, and the quantity offered will diminish until the utility becomes substantially equal to the cost.

Functions of the Speculator.—The adjustment is not universal or immediate. In some lines of business, where considerable stocks of goods must be kept on hand, and where large amounts of fixed capital are required before additional supplies can be put on the market, such an adjustment may take months, or even years, during which competition of sellers may be very ineffective, and prices remain much higher than cost of production. Such a state of things is not practically remedied by the socialistic schemes that have hitherto been tried, for the government is quite as likely as the individual producer to take advantage of any such temporary monopoly. It is the function of the speculator in modern society to avoid such fluctuations. A man is allowed to buy cheap and to sell dear because, on the whole, such a process does the community more good than harm. If the speculator makes money for himself by simply anticipating the needs of the market instead of manipulating it, he does an inestimable service to the community at the same time. By buying when prices are low he prevents waste. By selling when prices are high he makes available those supplies which he has saved in times of plenty. Nor is speculation confined to mercantile transactions. Under the modern system, every manufacturer and almost every producer is, to a greater or less extent, a speculator. If by his skill and foresight he is able to sell goods for more than they cost him, he serves the public by directing labor in lines where its products are needed. If, on the other hand,

he fails to cover his expenses, he has injured the public as well as himself, for he has directed labor in lines where its products were much less needed. What holds true of the control of labor is still more conspicuously true of the control of capital. The man who directs capital into profitable lines is making profitable use not merely of the labor of the present, but of that of the past. He is utilizing not merely the community's present work, but its system of past accumulations.

It must not be assumed that this speculative system always selects the best employers or the best methods of business management, but it is true that it develops better employers and better methods than any other system which has hitherto been devised. It was because of its superior efficiency that it supplanted by degrees the old mediæval system which has been already described, and which was closely analogous to that proposed by the socialists. From the fifteenth century down to the nineteenth greater powers have been constantly put in the hands of those who could control capital. In the fifteenth century the right to pursue a trade and to hire laborers was in large measure hereditary. To-day any one who will take the risks of advancing the capital is allowed to assume the direction of industry. This constitutes the wages system. He is even allowed to borrow the capital of others, and, within wide limits, to make what terms he pleases for borrowing it. This constitutes the system of interest. To encourage the speculative investment of capital for remote ends, there has developed a system of land-tenure and land-transfer, which gives control of agriculture and building to the capitalist instead of the government. To facilitate the investment of capital in new methods of manufacture whose return is somewhat doubtful, a system of patents and patent-rights has come into existence. To make possible the association of the capital of different individuals in industries requiring concentrated management, governments have not merely promoted the establishment of joint-stock companies or corporations, but have allowed their power to increase almost to the danger limit. Each step in this development has been taken somewhat reluctantly, because the speculative management of industry proved more efficient than its regulation by tradition or by government.

Attacks on the Existing System.—It is claimed by the socialists that the price determined under the existing system tends to the advantage of the capitalists and the disadvantage of the laborers—that the rich are growing richer and the poor poorer as a direct consequence of this system. They hold that of the enormous increase in efficiency of labor during the nineteenth century the laborer himself has received but a slight benefit, and that the rest has therefore accrued to the speculator or capitalist, as a class. Most of the reasoning of writers of this school rests upon the assumption that capital is monopolized, while laborers are competing with one another. If there were but one capitalist in the world, the reasoning of the socialists might possibly hold true. In those industries where capital is so concentrated as to form a practical monopoly, what they say may be partly true; but, taking the world as a whole, their charges are not well founded in fact or in theory. The investigations of Col. Wright and Edward Atkinson show conclusively that the poor are not growing poorer, either in their absolute condition or in their share of the national income, and that if the difference in accumulations between the richest and the poorest is greater now than it was a hundred years ago, it is because the accumulated wealth itself is so much greater that the difference between the richest and the poorest must necessarily be larger. There is reason to believe that the laborers individually have a higher average standard of comfort under the operation of the speculative system than ever before, and that, as a class, their share in the national income is increasing rather than diminishing.

The Distribution of Wealth.—The distribution of returns between laborers and capitalists is one of the most perplexing subjects in political economy. The old or "classical" theory was that the owners of capital, as a class, set aside certain funds for the payment of wages, that the amount of this fund depended on the amount of capital available for employment, and furnished the total real wages of the community, while the average rate of wages of each individual was to be found by dividing this fund by the number of laborers. Under this view, known as the wage-fund theory, the aggregate wages could be increased only by an increase in accumulations. The rate of wages in any given amount of accumulation could be increased only by diminishing the number of laborers among whom this product was to be divided. This theory is incomplete because it fails to take account of the fact that, with a given amount of accumulation, a greater or less activity in the use of capital may cause the amount offered to the laborer to rise at the expense of the amount wasted or imperfectly utilized. It will often happen that years when the past accumulations are small are the very ones when wages are high, because the expectation of renewed business activity causes business men to utilize the existing product to the utmost. This is sometimes seen after a war. It is often seen in a time of recovery from a commercial crisis. It is almost always seen in the early development of a new country. In all these cases accumulations are small, but the spirit of enterprise is so large that wages become really, as well as nominally, high. It is evident that the speculator will advance money so long as he expects the product to be decidedly in excess of the cost of wages and materials. Each extension of his enterprise constitutes at once a demand for labor in the present and a supply of products in the future. His operations and those of other persons in the same business tend to push wages up now and to push prices down six months or a year hence. This will continue until the difference becomes very small. The limit of this difference between what the employer will pay for wages and materials (and this expenditure for materials is, for the most part, but a repayment of wages already advanced) and the expected price of the product is to be found in the interest which he must pay on his advances during the period of production. Price tends to conform to the amount of wages and interest under ordinary conditions. If the price is inadequate to pay wages and interest, the employer will find that he has made a speculative mistake and will go out of business. If the price more than covers wages and interest, the employer will feel that he has done well and will strive to extend his operations in the next period of production.

Differential Gains. Theory of Rent.—Some business, however, is not done under ordinary conditions. A part of the supply may be produced under exceptional advantages of location. If the New York market must have a certain amount of Dakota wheat, the people in Minnesota, who are supplying the same market, have an advantage due to the fact that they do not have to ship their wheat so far. The price can not fall below the cost of production for Dakota wheat, else the quantity supplied would be too small. The difference in location gives rise to a gain which is known as rent. If certain of the persons supplying the New York market have the benefit of some processes and methods of industry which are not open to all, we again have a special gain closely analogous to the rent of land, due to patents or monopolies of a process of production. Finally, if under a given set of conditions one producer is possessed of exceptional organizing power, so that he can produce part of the supply at less than the general cost of the whole, he obtains a gain known as profits in the narrower sense, due to his monopoly of brains. Price, under the existing system, is not determined by the average cost of production of the commodity as a whole, but tends to approach the cost of production of that part of the supply which is produced without exceptional advantages of any kind. Rent and profits form part of the returns of industry, but are not elements in the cost of production in the same sense that wages and interest are elements. They are known to the economist by the name of differential gains, and the laws to which they are subject are much clearer than those which regulate wages and interest.

Theory of Population and Wages.—Wages form, without any question, the largest element in cost of production. Under the competitive system they are determined by an adjustment between the supply of and demand for labor. The supply of labor under certain conditions tends to increase so rapidly that some persons have supposed that wages for unskilled labor must perpetually remain at the starvation-point, and that no progress for the mass of laborers was possible except by rigid limitation of their numbers. This view has been associated with the name of Malthus, who first developed certain important facts relating to population. He showed the existence of a tendency of population to increase faster than the means of subsistence, and pointed out that if this tendency went on unchecked there must soon come a time when the increased numbers of the laborers would prevent any gain from improved processes; a time, in short, when wages would be so low that starvation must

ensue, and continue until the number of laborers was again brought within the limit of the food-supply. He saw no escape from this difficulty except by a policy of conscious restriction of population on the part of the laborers themselves. In its main features the theory of Malthus has withstood the attacks of the critics. It is not true, as urged by Henry George, that increased population will take care of itself. It is, however, a mistake to assume that there is any such general pressure of population upon subsistence as Malthus supposes. The institutions of private property and of the family have localized this pressure of population upon subsistence, and have confined the destructive effects of overpopulation within narrow limits. If a confirmation of these views were needed, it would be found in the experience of England and other countries with regard to poor relief. Wherever it has been assumed that groups or classes of men would be supported by the community, there has been a tendency to multiply their numbers. Wherever, on the contrary, relief has been strictly limited and a spirit of independence cultivated, the number of paupers has diminished in a most unexpected manner. What Malthus says about population as a whole would probably be true in the case of a society organized on the more extreme forms of socialism, but it does not hold true of society today. On the contrary, the institution of the family has established certain standards of comfort and certain habits of providence which prevent the multiplication of numbers up to the limit of the food-supply, and which causes the increase of wages to be largely spent, not in supporting greater numbers under the old conditions, but in supporting the old numbers under better conditions. Of this generalization, the statistics of America and Western Europe furnish sufficient proof. The rate of wages for any given grade of industry is primarily determined by the standard of comfort set by the mass of laborers themselves. The extent to which labor can be employed in any given direction depends upon the amount of product which the public will consume at rates sufficient to insure to the laborers wages which will conform to this standard. The employer, under the existing system, makes a speculative judgment of what this amount will be. The demand for labor is not determined by accumulations, as was falsely stated by the "classical" theory already referred to, but by the expected value of the product as estimated by those who control the capital of the community.

Theory of Interest.—If no time elapsed between the expenditure of labor and the return of the product, or if there were no such thing as interest, the probability is that the price would adjust itself accurately to the labor cost; but as it is, interest enters into the prices of nearly all products. The rate of interest is determined by a bargain or series of bargains between the borrowers and the lenders. Whoever has accumulated disposable property or capital, of which money is but the symbol, has the right to the control of industry, and the speculative employer is paying a greater or less rate of interest to secure the chance of using that right himself. (Even if he is working with his own capital the case is not essentially altered, for he could sell the right to the use of that capital to some one else, and he will therefore not employ it himself unless he can obtain a profit corresponding to that which he would receive by disposing of these rights to others.) The conditions which enter into this bargain are an estimate of risk on the part of the lender and an expectation of profit on the part of the borrower. The expected profit on a loan creates a demand for such loans, just as utility creates a demand for commodities. The estimated risk tends to limit the supply of such loans, just as cost of production and many other considerations tend to limit the supply of commodities; but, just as in the purchase of ordinary commodities some persons are able to buy them for less than their utility to them as individuals, and some are able to sell those commodities for less than the cost to them as individuals, so, in the case of interest, some can borrow at rates which leave them a large margin of expected profit, and some can lend at rates decidedly above those which they would take in case of necessity. The rate for any given class of loans adjusts itself to the point which will bring into the market an amount of such capital equal to the amount business men demand at the rate in question. Risk enters into interest in precisely the same way that cost of production enters into value.

Depreciation of Capital.—It is, to say the least, an open question whether in the U. S. and Great Britain to-day the losses of investors on their principal do not more than counterbalance the receipts in the form of interest or dividends. That the borrowers of capital as a class make money by the aggregate of transactions there can be little doubt, but that the lenders of money more than indemnify themselves for their losses is by no means certain. The socialist assumption of an enormous sum earned by capital in the form of interest is unquestionably false, and so long as this is so any scheme based upon the assumption of such a surplus must be regarded as utopian. The causes which fix the rate or the amount of interest must be carefully distinguished from those which establish the system of interest. The system of interest has grown up because, on the whole, it brought the use of capital into efficient hands. Society maintains this system as a means of securing efficiency. Whether the judgment of individual investors with regard to the rate they are receiving be true or false is a secondary question, and one with which society has not hitherto concerned itself.

Effect of Improvements in Production.—A controversy has arisen as to what class in society receives the "residual share" of the product of industry. To whom, it is asked, does the benefit of improvements in production ultimately go? The socialist, as a rule, holds that it goes to the capitalist. Henry George thinks that it goes to the landowner. Gen. Walker, with the majority of economists, believes that it goes to the laborer. The last view appears to be nearest the truth. To be sure, in an individual transaction under the existing system it is the speculator who receives the gain. If he has introduced an improved process which is covered by a patent, he is, for the time being, enabled to sell his goods at the old prices, while his cost of production has been much reduced and his profits correspondingly increased. When, however, the use of the new process becomes general and all the less economical producers have gradually dropped out of the business, a fall in prices or an increase in wages, or both, must ultimately follow. There *may* be a considerable gain to the landowner in the form of rent, as urged by George; but it does not seem likely that this is nearly so important an element as George assumes. The action of different business men narrows down the margin between wages at one extreme and prices at the other. True, there always remains a certain amount of margin represented by the rate of interest, and it might be supposed that with the increased accumulations of capital the amount paid in interest would be covered; but the investigations of Edward Atkinson go to show that the increase in capital under the old system of industry, where each man worked by himself or in small factories, though less in each individual case, was even greater in the aggregate than exists at the present day, and that the ultimate benefit of the improvement shows itself in a larger demand for labor and a lower price of product. By the former the laborer benefits directly. By the latter he benefits with the rest of the community, as a consumer. Though it doubtless is true that the gain to consumers from new processes has been more conspicuous than the increase in wages, it is also true that the result of new processes and new methods has been to promote an increased popular use of commodities which were formerly confined to a few. It is the staples, rather than the luxuries, that have cheapened. So far as this is true, the gain from the new processes goes to the laborers rather than to the landowners or capitalists. This will appear in another way if the conditions under the present system of manufacture be compared with those under the system of hand labor. Under the system of hand labor there was a small quantity of each kind of manufactured article sold at high prices, and the laborer made his money not by the quantity of his output, but by the high price for each unit of work. He resisted labor-saving machinery because it seemed likely to throw him out of employment; but the cheapening of the product created an increased demand which more than counterbalanced the increase in supply. When railways were first introduced they were opposed by large classes of the community because it was thought that the increased efficiency of transportation would throw teamsters and innkeepers out of employment; but the increase of travel and shipment proved to be many times more than the increase of efficiency, so that to-day the reduction of cost from a dollar a ton-mile to a cent a ton-mile has increased the amount of transportation more than a hundredfold, and has increased the demand for labor instead of diminishing it.

Government Interference with Industry.—These general principles form the basis of what is known as the system of

laissez faire, or the scientific justification of the let-alone policy. The majority of economists have held that it was best for the community that the interference of government with industry should be reduced to a minimum, and that in this way a higher degree of industrial efficiency and a more equitable distribution of wealth could be secured than in any other; but there has been some disposition to modify these views, especially with regard to equity of distribution. The principle that government should not interfere with industry is no longer treated as an axiom, but as a general result of experience. That most cases of government interference with industry have done harm instead of good is pretty clearly proved by history; but it is far from true that all such interference has been bad, or that proposed measures of restriction should be condemned unheard.

Usury laws furnish an example of the kind of government interference which seems right, but really is wrong. Those who advocate the restriction of the rate of interest say that the capitalists are few in number, intelligent, and well organized, while the borrowers are many, needy, and short-sighted. In these circumstances it has been urged that the government should step in and fix a maximum rate as a necessary means of preventing extortion. Yet the amount of good which has been done by such interference has been very much less than the amount of harm. In the great majority of cases the high rate of interest is not an indication of extortion so much as of exceptional opportunities for the investment of capital. If we refuse to permit the high rate one of two things happens. Either the law will be evaded, which is always bad, or the supply of capital will be restricted, the development of the country checked, and the rich opportunities which made the high rate of interest possible will remain unused. The high rate of interest is a symptom of scarcity of capital. The attempt to lower the rate by law makes that scarcity continue, and deprives the community of the natural means of remedying it.

The Labor Contract.—A somewhat similar case is furnished by the relations between labor and capital. Here again the relations between workmen and employers are somewhat like those between borrowers and lenders, and it has been proposed that the government should remedy the disadvantage under which laborers act by direct interference with the wages contract. A few extremists think that government ought to fix the rate of wages, a great many more believe in regulation of the hours of labor, while a still larger number hold that the work of women and children should be subjected to special oversight and special regulations. It is hardly necessary to say that attempts to fix the rate of wages have proved a failure wherever tried. Attempts to regulate the hours of labor have been successful in a limited degree, yet even here it may be questioned whether much good has been done in connection with the labor of adult men. The work of women and children furnishes much better ground for regulation. This is one of the cases where the self-interest of the individuals does not promote the best interests of the community. As men are constituted each is likely to strive for the maximum enjoyment in the present, even though the labor power and the intelligence of the community in the future be jeopardized by keeping married women and children in factories. The experience of England and of many parts of the U. S. with restrictive acts concerning such labor has been distinctly good. See FACTORIES AND FACTORY SYSTEM.

Monopolies, Railway Regulation.—Special regulation is also proposed in those cases where an individual or group of individuals has a monopoly in a particular line of business, whether that monopoly be due to special legislation, or, as is now more commonly the case, to the necessities of business organization. With the progress of invention large establishments have become more economical than small ones. It is no longer possible for the independent workman to compete with the large monopoly. It is scarcely possible for the small establishment to compete with the great one. In railway business first, and afterward in all other lines of industry requiring much capital, monopolies have grown up in the hands of enormous joint-stock companies. It is held, with a great deal of plausibility, that such industries form a necessary subject for special regulation by the government, if not for direct government ownership, and that in the absence of such special regulation the public has no protection whatever. Most of the arrangements of modern society are based upon the assumption that individuals will act as individuals, and where such individual action does not in fact take place many of the traditions of modern industrial law cease to apply. Yet even in those cases the dangers of interference are greater and those of non-interference less than superficial observers suppose. See MONOPOLIES.

Throughout this article the purchasing power of money has been assumed to be constant, and little has been said about variations in the operation of the credit system. On the way in which supply and demand regulates the value of money comment will be found under CURRENCY. The operations of the credit system and their effect on speculation are treated under the head of COMMERCIAL CRISES, while certain details respecting the relation of labor and capital are treated more at length under WAGES. See also RENT.

BIBLIOGRAPHY.—The best account of the literature of the science is Luigi Cossa's *Introduction to the Study of Political Economy* (translated from Italian by Louis Dyer, London, 1893). Among the most important of the many books on the subject accessible to English readers are Adam Smith, *An Inquiry into the Nature and Causes of the Wealth of Nations* (edited by J. E. Thorold Rogers, Oxford, 1880); John Stuart Mill, *Principles of Political Economy* (London, 1848); Henry C. Carey, *Principles of Social Science* (Philadelphia, 1858, a classical work of the protectionist school); W. Stanley Jevons, *Theory of Political Economy* (London, 1871, the first important work of the mathematical school); Henry George, *Progress and Poverty* (San Francisco, 1879); Francis A. Walker, *Political Economy* (2d ed. New York, 1887); Alfred Marshall, *Principles of Economics* (London, 1890).

A. T. HADLEY.

Political Parties: free social organizations founded and kept together for the purpose of accomplishing certain political results.

POLITICAL PARTIES IN GENERAL.—*Essential Principles.*—Political parties can not exist and flourish where government is not of a nature to be influenced greatly by public opinion; but where public opinion is recognized and encouraged they grow up spontaneously out of certain psychological characteristics of human nature. In regard to all important political questions there will not only be differing opinions, but such opinions, when free to act, will almost invariably range themselves ultimately into two opposing parties. When not influenced by authority or considerations of personal gain or loss, such party alliances are determined by certain fundamental conceptions or principles. Those persons in whom the importance of stability and order predominates range themselves on the one side, while on the opposite side are to be found those who give emphasis to the importance of action and progress. Frederick Rohmer, in his *Doctrine of Parties*, compares these two principles with the peculiarities of the different periods of human life. The boy and the youth, he says, represent the impulse in behalf of action and progress. This impulse corresponds with the radical element in political life. At the other extreme the old man represents the most conservative element. He is inclined to oppose every departure from the ways of the past; he distrusts all innovations; he forms at once an obstacle to progress and a security against precipitancy. Between these two elements represented by age and youth there are elements represented by the developing stages of manhood. Conservatism may be found in the boy and radicalism may be found in the old man, but whatever the views of the individuals at the two extremes, there is an intermediate period during which less extreme views are commonly held. While, therefore, youth and old age are the personifications of radicalism and absolutism, manhood is the personification on the one hand of liberalism, and of conservatism on the other. Hence wherever political parties are organized these four elements, corresponding to the terms absolutist, conservative, liberal, and radical, will be found in a greater or less state of activity. The doctrines in relation to which political parties take their characteristic positions are determined by the dominant political issues of the day; but whatever the question at issue, the matter of personal temperament will generally exercise a controlling influence in determining party affiliations. This, however, must not be understood as applying to all classes of persons. On the contrary, there are two classes to whom these considerations do not apply: First, those who unselfishly devote their lives to the work of reforming what they consider abuses, and, secondly, those whose political actions are selfishly determined by considerations of personal advantage. These two classes either refuse to acknowledge allegiance to any party or are bound by such feeble party ties that they can readily pass from

one party to another. It is in consequence of such feebleness of tenure that these two classes constitute the uncertain element in every popular election. Notwithstanding the tendencies of political parties to group themselves into a dual system under the general character of conservatives and liberals, it frequently happens that minor interests of various kinds express themselves, as shown below, by means of separate organizations.

Party Declarations and Methods of Action.—The doctrines of political parties are nowhere very clearly or authoritatively expressed. This statement would seem to be at variance with the custom in the U. S. of adopting "party platforms"; but a very slight familiarity with the political history of that country must reveal the fact that such declarations have no very authoritative significance. The importance of such a manifesto of course depends upon the deliberateness and the discretion with which it is framed. The Tamworth manifesto of Sir Robert Peel in 1837 outlined the policy by which the Conservative party in Great Britain was guided for many years, and the Nottingham address by W. E. Gladstone in 1890 performed a similar service for the Liberals; but in the U. S. the platforms are either the joint product of conflicting opinions, or the utterances of single individuals acting in an irresponsible capacity. They are ordinarily designed quite as much to show the weaknesses of the opposing party as to set forth the principles of the party making the declaration. Moreover, new exigencies may arise, and if the declarations are too definite there may be no room for that flexibility necessary to party efficiency. If a party declares itself unequivocally in favor of an immediate policy of a certain kind, it may be found a little later that only a partial fulfillment of its promises are for the present within the range of possibility. Hence it is that the various party platforms are generally somewhat vague in their utterances, and that parties consider themselves bound to such utterances by very slender ties.

The management of political parties differs greatly in different countries. In Great Britain each party has its official leader, who, acting under such advice as he may seek, controls and directs all party action. By parliamentary law all candidates are required under oath to make a public statement in detail of expenditures of every kind, such expenditures being strictly defined and limited by statute. Contested elections are tried, not by Parliament, but by the courts, and in case the law in regard to expenditures is shown to have been violated the seat of the defendant goes to his opponent. Nominations are made by personal announcement, not by the choice of a CAUCUS (*q. v.*). As the legitimate expenses of a parliamentary election for printing and for speakers are necessarily very considerable, the number of candidates presenting themselves is limited by the probabilities of success or failure. In the U. S., on the other hand, there is practically very much less individual liberty on the part of candidates, and very much more party supervision. The candidate does not nominate himself, but is nominated by a caucus or a convention. Each political party has its national committee, its committee in each State, and its local committees. These committees determine the general plan of canvass or "campaign," providing, for the most part, by voluntary subscriptions for the necessary expenses. Toward these expenses the candidates are expected to make large contributions; and in many instances holders of minor offices have been made to feel that the permanency of their tenure depended upon the liberality of their contributions. The freedom with which money is expended depends upon the supposed importance of the election. In case of a hotly contested election, especially when a U. S. Senator is to be chosen by the Legislature or when there is a presidential election, the efforts of the various political committees are extended down to a personal canvass of the voters in every voting precinct. It not infrequently happens that even in the largest States the issue is determined by a very small majority. In the presidential election of 1884 the entire electoral vote of the State of New York was determined by a majority of only a few hundred, and the electoral vote of the State determined the presidential election, on which depended the tenure of more than 100,000 subordinate officials. Either human nature must be reformed or so momentous an issue must be the parent of widespread corruption. With human nature as it is, the more thorough the organization of political parties, the more intense will be the political feeling, and the more dangerous will be the political menace.

POLITICAL PARTIES IN PARTICULAR STATES.—*In Great Britain.*—The four principal parties represented in the British Parliament are the Conservatives, Liberals, Home-rulers, and Liberal-Unionists. Of these, the first two can be traced back to the early times of the monarchy, in that the earliest records reveal the existence of contests between a party of progress and a party that clung with tenacity to the established order. A clearer dividing-line appears in the reign of Elizabeth, but party designations corresponding in any respect to the present party terms were not employed till the time of the great civil war, in which Cavaliers and Roundheads may be regarded as the prototypes of the two modern groups. The latter, however, correspond more nearly to the later distinction between Petitioners and Abhorrers—terms employed in the reign of Charles II. to designate respectively those who favored the petition for the summoning of a Parliament hostile to the succession of the Duke of York, and those who, in their hatred of the Exclusion Bill, declared their "abhorrence" of the attempt to induce the king to call Parliament. These terms soon gave way to the more familiar Whigs and Tories, as the enemies and friends of the royal prerogative were respectively called; and these names continued to designate the party of progress and the party that held to established rights till, in the nineteenth century, they were replaced by the terms Liberals and Conservatives. It is not to be supposed that the party issues which divide modern Liberals and Conservatives can be found in the older distinctions between Whigs and Tories or their respective predecessors, but the same attitude toward measures of change and reform is discernible throughout all the vicissitudes of party history. The Home Rule party came into existence as a distinct political organization through the efforts of Butt and Parnell. (See HOME RULE.) By an alliance with the Liberals under Gladstone's leadership, in 1886, it made Home Rule the chief issue between the Liberals and Conservatives, and in the House of Commons of 1892 secured a majority favorable to that measure. This action of the Liberals caused the defection of an important group of members who, under the name of LIBERAL-UNIONISTS (*q. v.*), have strenuously opposed Home Rule for Ireland. A less important party than any of these is the Labor party, which is socialistic in some features. See GREAT BRITAIN (*History*) and PARLIAMENT.

In France.—While progressive and conservative elements are discernible throughout French political history, it was not till the era of the Revolution that definite party issues and party names made their appearance. Radical and moderate opposition to the old *régime* were the respective characteristics of the JACOBINS and the GIRONDISTS (*qq. v.*) during this period, while the Feuillants tried to maintain the Bourbon monarchy, but with constitutional limitations. Since that time political parties in France have passed through many changes both of name and principle. After the restoration of the Bourbons on the final overthrow of Napoleon I., there were, in addition to the Constitutional Monarchists who supported Louis XVIII., the Ultra-Royalists, or adherents of the Count of Artois, afterward Charles X., the Bonapartists, the DOCTRINAIRES (*q. v.*), and the Republicans. When the Bourbon monarchy was finally overthrown, Louis Philippe, the representative of constitutional monarchy, encountered an opposition from Bonapartists, Republicans, and Legitimists. The first of these triumphed with the elevation of Napoleon III. to the imperial throne in 1852, and the second, the Republicans, with the establishment of the republic in 1871. The death of the Comte de Chambord in 1886 made the Count of Paris of the Orleans branch the heir to the Legitimist claims, and his death in 1894 has brought the young Duke of Orleans forward as the representative of the Royalist party. This group, however, has lost much of its importance as an element of opposition to the French republic, and the Bonapartists and Radicals have shown themselves more dangerous enemies to the Government. The reactionary elements of the opposition, including both Bonapartists and Monarchists, sit together in the Chamber, and are known as the Right. The Republicans may be divided into the Opportunists, who believe in adapting their political action to circumstances rather than forcing it into conformity with certain pre-established principles, the Moderates, and the Radicals. The last of these constitute the Extreme Left, while the more moderate groups make up the Center. See FRANCE, HISTORY OF.

In the German Empire.—The leading parliamentary groups in the Reichstag after the formation of the empire were the National Liberals, who, though not in sympathy

with Bismarck's general policy, supported his efforts for unification and reform; the remnant of the Progressists (*Fortschrittspartei*), who opposed all compromise with Bismarck; the Old Conservatives, hostile even to the measure of reform that Bismarck was willing to concede; and the Free Conservatives (*Reichspartei*), who were his thoroughgoing supporters. To these were added the Ultramontane party, or Center, composed of Roman Catholics who opposed the Government's policy during the KULTURKAMPF (*q. v.*), the Social Democrats, with a socialistic programme, the Jewish members held together by racial interests; and the protesting delegates from Alsace-Lorraine. Since 1871 the representation of the Social Democrats in the Reichstag has increased from two in that year to forty-three after the election of 1893; but none of the numerous parties has increased sufficiently to secure a majority in the Reichstag. After the election of 1893 the principal parties represented in that body were, in the order of numerical strength, the Center, called also the Ultramontane or Clerical party, German Conservatives, National Liberals, Social Democrats, Radicals (*Freisinnige*), Free Conservatives, and Anti-Semites.

In Italy.—The distinction between conservatism and liberalism can not be clearly discerned in the division of Italian parties, since both the majority and the greater portion of the minority profess liberal principles. They are divided, however, on minor issues, the supporters of the ministry being known as the Ministerial Left, and the others as the Opposition Left, or the Pentarchists. The Irredentists are those who demand the annexation of "unredeemed" Italy—i. e. of the provinces inhabited by an Italian-speaking population but subject to a foreign government.

In other European countries the names and principles of the leading political parties may be briefly summarized as follows: In Austria racial and religious differences constitute the chief political issues. Thus the party of the Young Czechs desire national emancipation, to which the Germans, the most numerous element, are opposed. The chief parties in the lower house of the Reichsrath may be described as the German Liberals, the Poles, and the German Conservatives and Clericals. In Belgium the two leading parties are the Catholics, or Clericals, and the Liberals. In the Danish Rigsdag the Right, or Conservatives, hold that the lower house, or Folkething, has not the supremacy in matters of taxation and finance and in the choice of the ministers, while the Left contend that these rights are vested in that body. In the Spanish Cortes there are, in addition to the usual division into Liberals and Conservatives, the extreme Republicans and the moderate Republicans, or Possibilists. A few Carlists were returned in the elections of 1893.

In the United States.—The principal political parties in the U. S. are discussed in the articles DEMOCRATIC PARTY, REPUBLICAN PARTY, PEOPLE'S PARTY, and PROHIBITION PARTY (*qq. v.*). For an account of older political groups, see FEDERALIST, ANTI-FEDERALISTS, FREE-SOIL PARTY, and KNOW-NOTHINGS; and for the general facts of party history and the discussion of party programmes, see UNITED STATES (*History*), SLAVERY, FREE TRADE, PROTECTION, NATIONALISM, etc. On the subject of the methods of political parties in the U. S., see the articles CIVIL SERVICE AND CIVIL SERVICE REFORM and PRIMARY ELECTIONS. On the general subject of political parties, consult Wachsmuth, *Geschichte der politischen Parteiungen* (3 vols., 1856): Cooke, *History of Party in England* (3 vols., 1836); Rohmer, *Doctrine of Parties* (1844); Sidgwick, *Elements of Politics* (1891, chap. xxix.); Woolsey, *Political Science* (1878, pt. iii., chap. xiv.); Bryce, *American Commonwealth* (vol. i.).

C. K. ADAMS.

Political Science: the science which treats of the nature of the state, and of the principles underlying society organized for the purpose of governing itself. In accomplishing its objects political society employs force. This is what especially distinguishes it from industrial society, whose moving power is simply the desires of its individual members, and from religious society, whose motive power is likewise individualistic, acting through the consciences of its members. Of course, religious bodies have often employed force to carry out their plans, but in that case they have become political, interfering in the government of the state.

NATURE.—*The origin of the state* has been explained usually in accordance with one of three theories: First, the theological. By this God is declared to have directly instructed man how to organize government, and to have upheld government by divine intervention. Second, the contract theory. This presumes that men first lived in a state of nature, each independent of others, and with unlimited rights to all things. To keep peace and to secure the benefits of co-operation, they entered into a contract by which each gave up many of his individual rights and agreed to submit to government. Hobbes, Locke, and Rousseau, the chief exponents of this doctrine, advocate entirely different forms of government, as will be seen in the historical portion of this article, and the theory is now abandoned by scientific writers, though it still has some vogue. Third, the natural or development theory. As Aristotle says, man is a political being, formed for society. From the family, organized unconsciously under the father, grows the tribe, thence the state, assuming gradually the form of government best adapted to its needs. Man can not develop normally outside the state.

The purpose of the state may be considered either from the standpoint of its members or from that of the state as an organized unit. From the standpoint of the individual, Aristotle has well said that the state exists to enable man not merely to live, but to live well, or better, as Pollock puts it, the purpose is "complete life in the associated state." From the other point of view, Burgess, following Holtzendorff, gives three ends: the immediate purpose of securing orderly government and liberty within the state; the next end of developing the national spirit and strength; the ultimate purpose, the perfection of humanity, to be secured finally, after æons of separate national governments, in one all-inclusive world-state.

Relation of Political Science to Politics.—Ordinarily by the word politics used alone one understands the art corresponding to political science. The practice of politics, naturally, arises in governments of a low grade long before the science, and experience eventually furnishes the material from which the general principles of the science are drawn. The politician, however, or the statesman—for a statesman is simply a practical politician of the highest class—in an advanced stage of civilization has much to learn from the teacher of the science of politics, the political philosopher. The latter, from his studies, is the better equipped of the two in the knowledge of the experience of the past and in the fundamental principles of true statecraft, though it is doubtless true that he less often knows the temper of the people and the special form into which a law must be put to be adapted to their needs. The two classes of men need to work hand in hand. Neither can do his best work without the aid of the other. It has been a common fault of political philosophers to limit their studies too much to the letter of constitutions and laws. By so doing, and by thus failing to study the actual working of the laws, they have often been led into false judgments. They have failed to catch the spirit of the law. Even great writers like Montesquieu have at times failed in this regard. The chief intellectual characteristic of the political philosopher should be an unprejudiced judgment; but he needs a wide and accurate knowledge of facts as well. The business of the statesman is action—the accomplishment of some specific purpose for the good of his people. He needs chiefly knowledge of men, their motives and passions, and firmness and skill in handling the means at his disposal to bring about the desired results.

The relation of politics to morals is as difficult a topic as the political philosopher has to consider; it is one that the practical politician meets daily, and no one who is conversant with the actual working of politics doubts that many politicians treat the subject of morals differently when considering it from the standpoint of their duties as statesmen than when looking at it from their private standpoint. Few men will plant themselves openly on the side of Machiavelli, and say that when the advantage of the state is concerned the end justifies the means, however corrupt or wicked in themselves the means may be; and yet politicians—honest men—condone many corrupt practices in public life. The following is practically the view of Bluntschli on this subject: Many of the aims of statesmen may be morally indifferent, as when they favor the extension of a railway system, but they ought never to be immoral. It must be borne in mind, however, that the statesman deals with men as they are—weak, and often wicked—and that his business is to do something for the good of his people. He is a man of action. He can not, therefore, if he is to succeed, lift himself far above the level of the best average thought of his people. He ought to have high ideals; he can not hope to attain them soon. These ideals are doubtless rising among the

people, and it is the duty of the statesman to lead the people; but he can not push forward very rapidly. One would not justify the cruel acts of earlier times against prisoners of war; but we justify war itself, one of the greatest of evils and wrongs, and justifiable only on the ground that it prevents a greater evil. In modern society one of the chief purposes of the state is to effect the moral advancement of its citizens. This suggests the question whether the man whose political sagacity and skill are likely to serve the interests of the state, but whose private life is known to be immoral, is entitled to the support of conscientious citizens. The evil of an individual may possibly further the good of the whole, and in certain circumstances the statesman seems to be justified in making use of corrupt agents and evil passions to secure good results. This doctrine, however, may readily be abused.

Closely connected with this topic is the one concerning what has been called the *right of revolution.* Society develops and changes; laws once suitable become so no longer. Often to avoid an injustice they must be broken or evaded before they are changed. To suit the law to specific cases is the duty of the courts; and in its interpretation the law itself is slowly changed to meet the needs of the times. When, however, need is felt for a great change it must come, or suffering will ensue. It is one of the chief advantages of modern governments that the laws can be changed directly by the act of the people, usually without violence. In this way peaceful revolutions arise. When, however, the executors of the law have a personal interest in upholding the law, and the law, as executed, has become very oppressive, the question arises, Shall the people endure the wrong or commit the crime of overthrowing the law? Here, as before, one has but a choice of evils, and all agree nowadays that circumstances may be so onerous as to justify a bloody revolution. The law exists for the state; it must be shaped to meet the needs of the state.

The relation of political science to economics appears most clearly in the fact that the individualistic economic motive often determines the political action of the citizens. In times of war or other national crisis the patriotic impulses are apt to dominate, but in times of peace each person and each class is inclined to keep personal welfare in the foreground and to think little of the good of the state. Hence arise class legislation, political corruption, and the rule of the wealthy or of demagogues. The clashing economic interests of different classes lead to struggles for political supremacy, and by these struggles constitutions are subverted and new ones made. Contrariwise, political action is often the dominant cause in bringing about a change in economic conditions. See REPRESENTATION.

The best form of government for the state is a topic that has engaged the thoughts of philosophers in all ages. Comparative studies have led to the belief that there is no absolutely best form. Each people must have a form adapted to its special stage of civilization, character, and needs. No one doubts that the nineteenth century shows a strong tendency toward democracy, under various forms, in all civilized nations. There is also an evident tendency for the state to increase its functions and to become more active in regulating business and private life. The limit of this activity can not yet be seen.

HISTORY.—*Ancient Times.*—Aristotle may be said to be the founder of political science, and, indeed, since his day no other writer has appeared who has surpassed him in philosophical penetration and power of analysis, or even probably in extent and thoroughness of research. Before his time in the East—in India and China—there had been writings that touched the subject, especially in connection with religious teachings, but no one had formulated it. The laws of Manu in India give in detail many duties of the different castes in society, and even those of the king and courts are considered at some length, while Confucius and Mencius in China, among many other wise sayings, especially on morals and religion, give some also on the relations and duties of governments and people. Mencius even goes so far in liberal views as to declare that a people may rid itself of a king with whom it is dissatisfied. Again, he divides citizens into two classes, the head-workers and the hand-workers, but he has not treated the subject at all fully or scientifically. In early Greece Homer and Solon give wise advice on specific points; Aristophanes, in satirizing the wickedness of demagogues and the folly of the people, shows much political wisdom. Socrates rendered important service to the science by his discussions on ethics as applied in political life. Plato, in his *Republic*, and especially in the *Laws*, treats the subject at considerable length, though not systematically. In the *Republic* he gives us an ideal state. He does not pretend to consider the state as it is, or even to consider men as they are; rather he writes a romance showing a state and men as he might wish them to be. In the *Laws* he discusses the subject of government with much more regard for actual affairs, and, in fact, in both works there are wise suggestions for statesmen and many good ideas that might bear fruit in experience. For example, though the mental and physical education of the young can not wisely be directed in all respects as Plato advises, the importance of the proper training of the young, if one would have a successful state, can not be overlooked. It would not be well, perhaps, to have philosophers the sole governing class, with the other classes under their control, as he suggests; it would be well to have rulers, by whatever means selected, wise. The family can not be abolished, as Plato wishes. He is right in thinking that, in great part, at least, justice is the true end of the state, and that the true strength of the state lies in virtue.

In Aristotle we find thorough preparation for his work, the proper method, wonderful insight, and completeness in his treatment. He had collected, arranged, and digested, it is said, 360 different constitutions; and with this mass of facts at hand he formulated his general principles. He analyzes into their elements the state and government. He traces the influence of the various factors of which the state is composed, and their relations to one another. His idea regarding the origin and nature of the state is summed up in the words, man is a political being. This contains what is true regarding the divine origin of the state; it implies all that is true regarding the theory of the social contract. Man was created to live in society, and with a nature that develops only there. Society begins without special intent of man. As he develops his acts become more and more conscious, and politics becomes an art as well as a science; civilized government is based in great part upon contract. Aristotle classified governments into monarchies, aristocracies, and democracies, a division followed since his day, though the mixed forms of the present day render it now of doubtful utility for modern use, the names often not conforming to the reality. He rightly, too, saw that the chief danger to each form of government was in the abuse of its principle, the carrying of its principle so far that it would become unbearable. The chief danger of a democracy, for instance, is that democracy will be carried to the extent of anarchy, when the people will demand a strong hand to restore tranquillity. The monarchy, too, is in danger of becoming a tyranny, as he said, that in its turn must be overthrown. In France, since the days of Mazarin, this principle of Aristotle's has been exemplified more than once. From the nature of Greek civilization Aristotle was unable to see the evil of slavery. Instead of that, he seems to consider it a necessity and even a blessing. His doctrine of natural slavery—that some men are born to command, while others, from their natures, are incapable of self-direction—has in it much truth, and is an advanced criticism on the practice of his time. In the philosophical schools established after Aristotle's time there are hints of some of the later doctrines. The Cynics protested rightfully against the too great exaltation of the state by Plato and Aristotle. The Epicurean doctrine, by leading men away from public life, had a like tendency. Epicurus, too, may be fairly considered the precursor of Hobbes in the enunciation of the doctrine of the social compact. The Stoics laid down and emphasized the principle of natural justice that played so great a *rôle* in later times. Cicero, Marcus Aurelius, Epictetus, and others, in their writings on ethical subjects, exposed the weakness of the slave system, while Cicero, Polybius, and the jurisconsults of the empire, discussed with effect the forms of the state, the nature of law, etc., though generally with little advance on the doctrines of Aristotle.

Christianity and the Renaissance.—Although Christianity may be said to have revolutionized the politics of the world, the purpose of Christianity was not political. Christ stated that his "kingdom was not of this world," and the disciples taught men to "be subject unto the higher powers." The doctrine of absolute submission to the will of God and the founding of a spiritual "kingdom" with Christ as its supreme head show nothing different in purpose from the old Jewish political theories. Practically, however, when the "kingdom" is made a spiritual kingdom solely, and when the decision as to the duty of every individual regard-

ing this kingdom is left to himself to make, and he is held individually responsible for his beliefs and his acts, we have an entirely new principle. Individual responsibility and the equality of all are democratic principles that, if carried out in the religious world, will certainly make themselves felt ultimately in the political world. The manifestation, however, of the force of this principle did not make itself felt until about the beginning of modern history, and not until recent times has it been of prime consequence in the political world. The early Christians contented themselves with keeping Church and state apart, and with looking after the moral and religious life. When at length the state became Christian, however, the question of supremacy arose; and the struggle between Church and state lasted throughout the Middle Ages. Thomas Aquinas was the most illustrious writer on one side, as was Dante on the other.

With the Renaissance came a new spirit into all fields of learning, and in Machiavelli political science found an admirably equipped exponent of the political doctrines of his day and a writer whose teachings have had a great influence. He was a man of wide experience in political matters and of keen insight into human nature and the real character of political problems. He did for political science the great service of separating in thought the field of politics from that of morals. In political practice the statesman can not afford to neglect the moral sentiment of his people nor to favor immoral practices. It is, nevertheless, very important for the student of political science to distinguish the two fields, and to be able to look at political problems from the standpoint of only the advantage of the state. This Machiavelli did more completely, probably, than any other writer. He sets out in the *Prince* the way in which a ruler, under various circumstances, should act in order to hold and to strengthen his government, and in giving these counsels he halts at nothing, however bad. If they can strengthen the ruler, as he thinks they can under certain circumstances, he advises hypocrisy, treachery, oppression, and murder. See MACHIAVELLI, NICCOLO DI BERNARDO.

Modern Times.—The Reformation emphasized the principle of individual responsibility as it had never before been emphasized, and this brought about a freer discussion of religious and, naturally, also of political principles. Protestants first, and then Catholics, questioned the rights of kings and peoples, and then first the question of sovereignty and where it rests was propounded, the question that since then has been the central one in political philosophy. There were many writers on all sides—Luther, Melanchthon, Reuchlin, Colet, More, Erasmus, Politian, Suarez, Calvin, Bacon. The most illustrious was Bodin, whose great work *Les Livres de la République* in method and extent may be compared with those of Aristotle and Montesquieu, for he, too, studies historically, and attempts to base his opinions on a wide knowledge of facts. He criticises Aristotle on many points, sometimes effectively, sometimes not. He exposes well the weakness of slavery, and his denunciation comes with more force from the fact that slavery was then rapidly on the increase, owing to the discovery of America nearly a century before. His discussion of sovereignty is able, and though in attempting to discover the best form of government he takes sides in favor of monarchy, he yet recognizes so well the weaknesses as well as the strong points of each form that he can not be considered partisan or narrow-minded. In his opinion every form of government should be subject to divine law. He is a vigorous opponent of Machiavelli, declaring that justice is the strongest support of all governments, and that the governor is bound at any rate to do justice. He has also rendered a valuable service to the science by his careful distinction between public and private law.

The English revolutions were indirectly the cause of the two greatest works on political science of the seventeenth century. When the doctrine of the divine right of kings had been pushed to an extreme in practical politics by the house of Stuart, its weakness was shown by the decapitation of Charles I. and the forced abdication of James II. Naturally the violent controversies of the day led the thinkers of both schools to formulate their doctrines and to defend the actions of their parties by an appeal to reason. Hobbes, in his *Leviathan*, defends absolutism. In a state of nature, which seems to him to be a state of natural warfare, each man has a right to defend himself. To secure peace and protection each one surrenders this right to a common ruler. This surrender is complete and irrevocable; the ruler therefore is absolute, subject only to the law of God. See HOBBES, THOMAS.

Many others wrote on the side of Hobbes, notably Filmer, and many wrote refutations of his opinions. The best work of the latter kind, though it was directed especially against Filmer, and the one that had by far the most influence, was the *Essay on Civil Government*, by John Locke. Locke starts, as does Hobbes, from the state of nature; but the state of nature in his judgment exists between men whenever there is no superior power to determine their possible disputes. This state is not necessarily a state of warfare, for there are rights which exist among men even without government—natural rights which have their corresponding obligations recognized by all even where civil law does not exist. Among these natural rights are the right of property, the right of liberty, the right to labor. Society is formed by contract, to be sure, to protect and carry out these rights, but it is not formed by the renunciation of these rights to a ruler. Rather the ruler is the instrument in the hands of the people to enforce these natural, but still retained, rights. One readily sees the conclusions that are drawn from such premises. He founds the right of property upon labor, a new doctrine then, and one tending most strongly toward upholding the control of the House of Commons over the royal purse. He, of course, attacks slavery as subversive of one of the natural rights. Most pointed of all at the time, and most closely applicable to the situation, is his doctrine of the right of revolution—if the king fails in his duty to the people, they may depose him.

Montesquieu, in his *Esprit des Lois*, furnished one of the most learned works on the subject of political science. "History explained by laws and laws by customs; the secrets of the customs sought for in the hidden instincts of human nature, in the mode of development of each society, in the influence of climate, and in the particular needs created for each nation by its geographical position; all the differences of race, genius, and legislation ranged in harmonious order; the science of government, which embraces morals, religion, commerce, and industry, and withal, order, method, and perspicuity, joined to an ever-present consciousness of the grandeur of man, of the responsibility of the powerful, of the rights of the oppressed, and a vigorous love of justice and right"—these are some of the merits claimed for the work by its admirers. In it are found some wrong interpretations of facts, but it is filled with valuable information, with profound reflections, and has been probably the most influential work in modern practical politics. Montesquieu's interpretation of the English Constitution, with his strong advocacy of the doctrine of the separation of the legislative, judicial, and executive powers, has been generally followed until within a few years, and it doubtless had direct influence in shaping the Constitution of the U. S. American thinkers are inclined to believe in the desirability of this separation of powers, as did he; but the experience of Great Britain has led many to question its wisdom, and it is doubtful if now a majority of writers on political science will be found in agreement with him. His theory as to the principles of governments, in which he makes monarchy rest upon honor and democracy upon virtue, i. e. patriotism and love of equality, is very suggestive and contains much truth. His views as to corruption in governments and as to the dangers from corruption that surround democracies can not be kept too closely in mind. His view of popular liberty is that of to-day, and to him is due the credit of having established it as a principle. His method was right. His thoughts, that one must carefully study the human passions that underlie political forms; that the forms of government were relative to climate, stage of civilization, surrounding people, etc.; the theory of the division of powers and of checks and balances in government, were important services rendered to the science.

Jean Jacques Rousseau, in his *Contrat Social*, elaborated the doctrine of the social contract that had been propounded by Hobbes and developed in another direction by Locke. Before examining the act by which a people choose a king, he thinks it wise to examine the process by which people become a people. "To find a form of association which shall defend and protect with the public force the person and property of each associate, and by means of which each, uniting with all, shall obey, however, only himself, and remain as free as before" is his problem. Each citizen in his state loses natural liberty, but gains civil liberty. The general will controls all. The contract is among the people. The relation between people and king is not a

contract, but a business method that the people can change at will. Any form of government may do, so long as people really keep control. Indeed, unless the people are good and intelligent, a republic is perhaps not suited to them. He thinks that all the people should come together periodically to vote (*a*) whether they wish to keep the present form of government, and (*b*) whether they wish to leave the government in the hands of the present rulers.

To his teachings regarding the omnipotence of the people, set before the people in attractive form and widely read, is ascribed by many a great influence in forming a theory for the French Revolution.

The economists of the close of the eighteenth century and of the first half of the nineteenth, by their doctrine of free trade, which resulted in extreme *laissez-faire* doctrines, exercised a great influence over political thought and theories, which has not yet ceased. This doctrine tended toward individualism, springing from the theory that the interests of the state coincide with those of individuals, without sufficient consideration of the frequent hostility of private interests to one another. Later in the century the rise of the socialistic school gave a new turn to political as well as to economic thought, and as a consequence the great question of political science of to-day is to fix the limits of the activity of the state. On the one hand, the individualists think that the state should exert only what may be called its police power, securing to each safety of property and liberty to work as he will, but taking no initiative in industrial enterprises. On the other hand, the socialists or nationalists wish to put all industrial control, and even all capital, into the hands of the state for management. Both seek equally the good of the greatest number, or, perhaps, more accurately stated the greatest good of all; both claim to base their theories on justice.

Among other modern writers who have contributed to the advancement a few require especial mention. Bentham and Austin, in England, did much in expounding the theory of sovereignty and law, and in effecting legislation along criminal and economic lines. De Tocqueville, in his *Democracy in America*, attempted to show by an examination of the real working of democracy in the great republic the fundamental principles of that form of government. The work is of great value from the standpoint of information as well as of philosophical criticism, though it may now be said to be superseded in great part by the work of James Bryce, *The American Commonwealth*. Bluntschli in Germany, Lieber in the U. S., and Laveleye in Belgium rendered distinguished service in expounding political principles. Herbert Spencer, in his *Political Institutions* and in his great collection of facts regarding various societies, better than any other writer of the day, perhaps, may be said to have formulated a general theory, and to have thrown light upon the origin of political institutions, though on this last point some of the writers on anthropology have done as good work. Space will not permit the enumeration of the long list of names that might be cited as those of living writers in this field, for the present day is one of active investigation, and many works of great value have been produced. The tendency seems to be toward study of special problems and separate states rather than toward general philosophical works, though two or three of the later writers, especially in connection with sociology, seem to be preparing to formulate again with ability the general principles of politics.

Authorities.—The best authorities are, of course, the works of the great writers, the best of whom have been mentioned. The best general commentary covering the whole field is Paul Janet's *Histoire de ta science potitique dans ses rapports avec la morate*. Besides may be mentioned Burgess, *Political Science and Comparative Constitutionat Law*; Pollock, *History of the Science of Potitics*; Bluntschli, *Lehre vom Modernen Staat* (the first volume has been translated into English under the title, *The Theory of the State*); Woolsey, *Potitical Science*; Lieber, *Civil Liberty and Self-government and Political Ethics*. Lalor's *Cyclopædia of Political Science* contains many excellent articles on the various branches of the subject.

Jeremiah W. Jenks.

Polity, Ecclesiastical: the form, system, and method of Church government. There are three general plans of such government, each of which has been advocated on the ground that it is the plan laid down in the New Testament for the perpetual conduct of the Church. There is, however, a growing agreement among Protestant scholars to concede that the New Testament can not be quoted for any one plan exclusively. The three plans named are in their historic order: 1. The *Presbyterian*, or government by presbyters, or elders, also styled bishops, all the clergy being on a level, these officers coming directly from the synagogue, and historically from the earliest constitution of the Hebrew people. (See Presbyter and Presbyterian Church.) 2. The *Congregational*, according to which each congregation regulates its affairs and settles its belief independent of control by other congregations, although such are called in for consultative purposes and joint action. (See Congregationalism.) 3. The *Episcopalian*, or government by bishops who constitute an order superior to the presbyters and deacons. (See Bishop.) Originally it would seem that the bishop was merely the presiding elder over the board of elders which governed the local church; then he was the permanent president, then raised above the other elders. In the Ignatian Epistles (A. D. 107–18) this distinction between presbyter and bishop is first made. The next step is the development of the diocese, or the union of several congregations under one bishop. This phenomenon comes out in Irenæus (d. about 200), Tertullian (d. 240), and especially in Cyprian (d. 258). Then came the metropolitan and patriarchal system, when the union of Church and state had been effected under Constantine (d. 337). The metropolitans were styled archbishops in the West. They were the bishops of the chief cities and presided over the bishops of the adjacent province. The patriarchs were the Bishops of Alexandria, Antioch, Rome, Jerusalem, and Constantinople, and had the oversight of two or more provinces. They ordained the metropolitans. The Greek Church has five patriarchs, but substituted the Patriarchate of Moscow for that of Rome. The Bishop of Rome protested against the action of the Fourth Œcumenical Council (Chaleedon 451, *Can.* 28, cf. Hefele ii., 527, *seq.*) in putting the Bishop of New Rome (Constantinople) on a level with him of Old Rome, and the conflict of the East and West Churches may be said to have thus begun. So came about the final development and the highest of the episcopal idea. The Bishop of Rome became the pope, and since 1870 the infallible pope, superior to patriarchs, metropolitans, and bishops, the successor of St. Peter, and the head of the Universal Church.

The Church of England is episcopal in government, and claims apostolic succession. It is governed by two archbishops—Canterbury and York—under the supremacy of the sovereign. The Church in the U. S., as the Episcopal denomination prefers to be called, and the branches of the Church of England are also episcopal. The bishops of the Swedish and Danish Lutheran Churches, of the Moravians, Methodist Episcopal, United Brethren in Christ, Evangelical Association, and other denominations are properly superintendents, and no divine right is predicated of them.

The Presbyterian plan is adopted by Reformed bodies which do not call themselves Presbyterian. It is usually linked with Calvinistic theology. The Congregational plan in like manner is adopted by those who are not styled Congregationalists, as the Baptists, Disciples of Christ, Unitarians, and Universalists.

Literature.—For the New Testament polity, see G. A. Jacob, *The Ecclesiastical Polity of the New Testament* (London and New York, 1871; 3d. ed. 1894); E. Hatch, *The Organization of the Earty Christian Churches* (1881; 2d ed. 1888) [advocates the Greek origin of the Church polity]; for Presbyterian view, see Charles Hodge, *Discussions in Church Polity* (New York, 1878); A. T. McGill, *Church Government* (Philadelphia, 1890); for the Congregational, H. M. Dexter, *Congregationatism* (Boston, 1865; 5th ed. 1879); G. T. Ladd, *The Principles of Church Polity* (New York, 1882); and for the Episcopalian, see Francis Vinton, *Manual Commentary on the General Canon Law and Constitution of the Protestant Episcopal Church in the United States* (1870). Samuel Macauley Jackson.

Poliziano (Lat. *Politianus*; Eng. *Potitian*), Angelo: humanist and poet; b. at Montepulciano (whence his own name), July 14, 1454; d. at Florence, Sept. 24, 1494. In 1469 he was sent to Florence to study, and had as his masters several of the most renowned scholars of the time; attracting the attention of Pietro de' Medici, he was made the school-companion of the latter's son Lorenzo. Here began the lifelong intimacy of the scholar with the great Florentine family. At eighteen years of age he began a Latin version of the *Iliad*, which, so far as it was finished (5 books, of

which, however, the first was by Marsuppini), showed marvelous facility. Even earlier he had tried his hand at both Greek and Latin verses—epigrams, elegies, odes—and these he wrote with great ease and brilliancy all his life. He was the first modern whose command of both classic tongues was so great that he could freely clothe his thought in either. Not less remarkable was his passion for exact scholarship. He toiled unremittingly on the text of the ancients, employing as aids inscriptions and coins, as well as manuscripts. Particularly important were his labors on the text of the famous manuscript of the *Pandects*, which Florence had taken from Pisa, as Pisa from Amalfi. He translated from Greek into Latin Epictetus, Herodian, Hippocrates, Galen, Plutarch's *Eroticus*, Plato's *Charmides*, and portions of other authors. At the age of twenty-six he was made Professor of Greek and Latin Eloquence in the studio, or university, at Florence; and his lecture-room was frequented even by his own former masters. To these audiences were read his introductions to his courses (*prælectiones*), several of them in verse, in which he discussed and praised that form of literature represented by the author about to be expounded. This success aroused the jealousies of other scholars; and when in 1489 Poliziano printed a collection of critical notes to classical authors (*Miscellanea*), he was speedily assailed by Giorgio Merula, Bartolommeo Scala, Michele Marullo, and other humanists. The strife lasted till his death. Poliziano was also one of the most important Italian poets of the fifteenth century. He was a spirit eager for beauty, delighting in nature, gifted with imaginative sympathy for the loveliness to be found even in simple things, and, though he was essentially a court poet, it was not as subservient or adulatory that he praised his friends as well as masters, the Medici. His first important work in Italian, *L'Orfeo*, which was recited in Mantua in July, 1471, is the earliest Italian secular drama extant. Later this was remodeled, probably by one Antonio Tebaldeo, into a regular tragedy in five acts. Probably in 1475, in honor of a splendid tournament held in Florence, Poliziano began his *Stanze per la giostra del magnifico Giuliano di Piero de' Medici*—left unfinished, however, perhaps because of the death of Simonetta Cattaneo, whom Giuliano loved and the poet sang. Still more gracious and lovely than these longer works are the *rispetti* and *ballate* which the poet wrote under the inspiration of the naïve popular songs of Tuscany —*strambotti*, *rispetti*, etc. Like many scholars of his time, Poliziano, though not a priest, enjoyed benefices and emoluments of the Church. He became secular prior of the Church of San Paolo in Florence, and in 1486 was made canon. Only his premature death prevented his becoming a cardinal. The *Opera Angeli Politiani* were published at Lyons (3 vols., 1536–46). G. Carducci edited, with excellent introduction, *Le Stanze, l'Orfeo e le Rime* (Florence, 1863); and I. del Lungo, the *Prose Volgari e Poesie Latine e Greche* (Florence, 1867). The best *Life* is the Latin one of F. O. Menckenius (Leipzig, 1736). See also A. Gaspary, *Geschichte der italienischen Literatur*, vol. ii., p. 213, *seq.* (Berlin, 1888); and J. A. Symonds, *The Renaissance in Italy*.

A. R. Marsh.

Polk, James Knox: eleventh President of the U. S.; b. in Mecklenburg co., N. C., Nov. 2, 1795, of Scotch-Irish stock originally named Pollock; was a grand-nephew of Col. Thomas Polk, celebrated in connection with the Mecklenburg Declaration (*q. v.*); removed to Tennessee with his father, Samuel Polk, 1806; graduated at the University of North Carolina 1818; studied law in Nashville with Felix Grundy (*q. v.*); was admitted to the bar 1820; was a member of the State Legislature 1823–25; acquired prominence as a lawyer; was elected to Congress 1824, and continuously re-elected until 1839; was an able speaker and debater; conspicuous as an opponent of the administration of Adams, of all Federal appropriations for internal improvements, of protective tariffs, and of the national bank; was an early and influential supporter of Jackson, whose conduct in the removal of the deposits he vindicated in the session of 1833–34, being then chairman of the committee of ways and means; was defeated as a Democratic candidate for Speaker 1834, but elected 1835, and re-elected 1837, presiding over the House with dignity and ability; was Governor of Tennessee 1839–40; was proposed by the Legislatures of Tennessee and of other States 1840 as a suitable candidate for Vice-President of the U. S., but received only one electoral vote. He was defeated in 1841 as a candidate for re-election as Governor; was nominated by the Democratic national convention at Baltimore (May 27, 1844) for the presidency in opposition to Henry Clay, and elected by 170 electoral votes against 105, the chief issue being the annexation of Texas, which was accomplished by the expiring administration of Tyler the day before Polk's inauguration, Mar. 4, 1845. President Polk formed an able cabinet, consisting of James Buchanan, Robert J. Walker, William L. Marcy, George Bancroft, Cave Johnson, and John Y. Mason; settled the Oregon boundary question; created the Department of the Interior; succeeded in carrying the low tariff of 1846: reorganized the financial system of the Government; and conducted the Mexican war, which resulted in the acquisition of California and New Mexico and had far-reaching consequences upon the later fortunes of the republic. The annexation of Texas caused, as had been predicted, an immediate rupture between the U. S. and Mexico. On June 4, 1845, President Herrera of Mexico issued a proclamation declaring the right of Mexico to the Texan territory, and his determination to defend it by arms if necessary. Fully aware of the hostile feelings of the Mexicans, President Polk ordered Gen. Zachary Taylor, then in command of the U. S. troops in the Southwest, to go to Texas and take up a position as near the Rio Grande as prudence would allow, that river being regarded by the U. S. as the boundary between Mexico and Texas, while the Mexican Government claimed jurisdiction to the Nueces. In September Gen. Taylor formed a camp at Corpus Christi, and there he remained during the autumn and winter; but in Jan., 1846, he was ordered to move his camp to the Rio Grande, opposite the city of Matamoras. There he was attacked by the Mexicans, but defeated them; and on May 11, 1846, Congress declared that "by the act of the republic of Mexico a state of war exists between that Government and the U. S.," authorized the President to raise 50,000 volunteers, and appropriated $10,000,000 for carrying on the war. It was prosecuted with great energy, and lasted two years. Declining to seek a renomination, Polk retired from the presidency Mar. 4, 1849, when he was succeeded by Gen. Zachary Taylor; retired to Nashville, and died there June 15, 1849. Without being possessed of extraordinary talents, he was a capable administrator of public affairs and irreproachable in private life. Revised by F. M. Colby.

Polk, Leonidas: bishop and soldier; b. at Raleigh, N. C., Apr. 10, 1806; graduated at the U. S. Military Academy, and entered the artillery July, 1827; resigned Dec. 1, 1827; in 1831 was ordained in the Protestant Episcopal Church; was missionary bishop of Arkansas and the Indian Territory S. of 36° 30′, with provisional charge of the diocese of Alabama, Mississippi, and Louisiana, and missions in the republic of Texas 1838–41; bishop of Louisiana 1841–61. In 1861 he accepted the appointment of major-general in the Confederate army—without, however, resigning his bishopric—and was placed in command of the districts along the Mississippi from the mouth of the Arkansas to Paducah, on the Ohio; Fort Donelson and Fort Henry were constructed under his direction. He subsequently commanded a division in the West; at Murfreesboro', Chattanooga, Chickamauga, and in the Georgia campaign of 1864 commanded a corps, ranking then as lieutenant-general. He was killed by a cannon-shot at Pine Mountain, Ga., June 14, 1864. See *Leonidas Polk, Bishop and General*, by W. M. Polk, LL. D. (2 vols., New York, 1893). Revised by James Mercur.

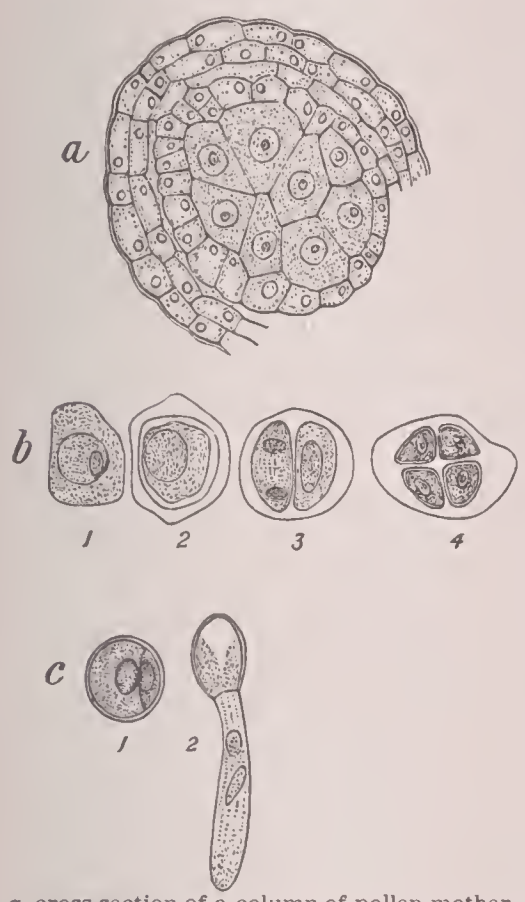
Polko, Elise: story-writer; b. at Leipzig, Jan. 31, 1823; a sister of the African traveler Edward Vogel; was trained under Garcia as an opera-singer, and appeared on the stage in Frankfort; after her marriage left the stage and devoted herself to literature, living at Minden and subsequently at Deutz, on the Rhine; made her *début* by her *Musikalische Märchen* (1852), which afterward grew into a whole series, comprising many volumes. Among her other works are *Neue Novellen; Ein Frauenleben* (1854); *Aus der Künstlerwelt; Erinnerungen an Felix Mendelssohn-Bartholdy* (1868; translated into English by Lady Wallace, 1869); a *Life* of her brother; *Plaudereien* (1872–73); *Aus dem Jahre 1870; Neues Märchenbuch* (1884); and several books for children. D. in Munich, May 29, 1899.

Pollaiuolo, pol-lăă-yoo-ō′lō, Antonio: painter, sculptor, goldsmith, and engraver; b. at Florence, Italy, in 1429. He studied under Bartoluccio, the stepfather of Lorenzo Ghiberti, who employed him in modeling the ornaments of the architrave of the central gates of the baptistery of Florence. After this he worked on his own account as a goldsmith. Vasari asserts that he was the first artist who dissected the

dead body for art instruction. He devoted himself to painting after he had attained much success as a sculptor, and was one of the earliest Florentine artists who used the oil medium. D. at Rome, Feb. 14, 1498. W. J. Stillman.

Pollaiuolo, Piero: painter; b. at Florence, Italy, 1443; brother of Antonio Pollaiuolo. Vasari says that the younger Pollaiuolo was a pupil of Andrea del Castagno, but this is doubtful. The two brothers generally worked conjointly, Antonio furnishing the design and Piero carrying it out in color in many instances. D. in 1496. *The Martyrdom of St. Sebastian* in the London National Gallery is supposed to have been the work of both brothers. It was painted for the Pucci chapel in Florence, and finished in 1475. Piero designed the Belvedere Palace built by Innocent VIII. He was a medalist also, and an engraver; his works in this branch surpassed all others of his time. W. J. Stillman.

Pollen [from Lat. *pollen*, fine flour or dust]: the dust-like cells produced in the anthers of flowers. They are developed as follows: When the anther is still young the cells in (usually four) longitudinal columns undergo internal division, each into four daughter-cells (see Figures, *a*, *b*) and these cover themselves with a coat of cellulose, at first thin, but later thick and separable into an outer and an inner wall. In the meantime the wall of the mother-cell usually deliquesces, and the pollen-cells are set free within the anther. Later the anther opens (usually by splitting longitudinally) and the pollen falls out as a yellowish, sometimes whitish powder. In some cases the pollen-cells adhere more or less to one another by a sticky substance in masses of considerable size, as is seen in milkweeds and orchids.



a, cross-section of a column of pollen mother-cells; *b*, development of pollen-cells from a mother-cell; *c*, the two nuclei in pollen-cells, one cell germinating. All highly magnified.

In the study of the comparative anatomy of plants it is seen that the pollen-cell is the homologue of the microspore of the higher fernworts, and some botanists now use this term in preference to the old one of pollen-cell. Before germination the pollen-cell has two nuclei—namely, the "vegetative" and the "generative" nuclei, the former the sole representative of the prothallium (*c*). In gymnosperms there are usually two or more fully formed vegetative cells. See, further, the articles Botany, Flower, and Physiology, Vegetable.

Charles E. Bessey.

Pol'lio, Gaius Asinius: orator and author; b. at Rome in 76 B. C.; began his career as an orator; sided in the war between Cæsar and Pompey with the former, whom he accompanied from the Rubicon to Rome, and again on the march to Pharsalia; commanded in Spain against Sextus Pompeius; was consul in 40 B. C., during the first triumvirate; made a successful campaign in Illyria in 39; retired from public life, and devoted himself to literary pursuits; was a friend of Vergil, Horace, and Catullus; founded the first public library in Rome, and wrote a history of the civil war in seventeen books, which is lost. He was also a poet and literary critic. D. 5 A. D. Three letters from him to Cicero have been preserved, and a few fragments of his orations. As an orator he enjoyed a very great reputation; his contemporaries ranked him next to Cicero and on the same line as Cæsar and Brutus. He was very young when he attracted great attention by his accusation of C. Cato, who as tribune, in 56 B. C., had committed numerous illegal acts in favor of Pompey and Crassus. Afterward he defended the rhetors Moschus and Apollodorus, who were accused of poisoning their relatives for the sake of the inheritance, and he continued to plead to the last. His speeches were always very carefully prepared. He was especially anxious to eliminate anything vague or superfluous, avoiding the redundancy of Cicero, whom he sharply criticised; but his austere taste sometimes made him dry, a quality which became still more visible among his pupils and imitators. He was fond of archaic and poetic expressions, and Landgraf and Wölfflin attribute to him the *Bellum Africum*, but this is still a disputed question. He introduced the custom, afterward so common, of reciting his writings to an audience of friends. See J. H. Schmalz, *Ueber den Sprachgebrauch des Asinius Pollio* (Munich, 1890); also Wölfflin, *Archiv für Lat. Lexikographie* (vi., 84–106); Landgraf, *Untersuchungen zu Cæsar und seinen Fortsetzern* (Erlangen, 1888); and Wölfflin and Miadoński, *Polionis de Bello Africo Commentarius* (Leipzig, 1889). Revised by M. Warren.

Pollock: See Coalfish.

Pollock, Sir Charles Edward: lawyer and author of legal works; b. Oct. 21, 1823; son of Sir Frederick Pollock; studied law under Justice Willes and was called to the bar in 1847; made queen's counsel in 1866; appointed baron of the exchequer in 1873, and knighted in the same year. Besides other writings he published a *Compendium on the Law of Merchant Shipping* (jointly with Frederick P. Maude; 4th ed. London, 1884) and a *Treatise on the Power of the Courts of Common Law to Compel the Production of Documents for Inspection*. D. in London, Nov. 21, 1897. F. S. A.

Pollock, Sir Frederick: lawyer; b. in London, England, Sept. 23, 1783: graduated at Cambridge 1806; studied law at the Middle Temple, and was called to the bar Nov., 1807; had great success in his profession; became king's counsel 1827; sat in Parliament for Huntingdon 1831–44; was knighted Dec., 1834; was attorney-general during the first and second administrations of Sir Robert Peel; chief baron of the court of exchequer and privy councilor from Apr., 1844, to 1866, when he retired with a baronetcy. D. at Hatton, near London, Aug. 23, 1870.

Revised by F. Sturges Allen.

Pollock, Sir Frederick: jurist; b. Dec. 10, 1845; grandson of Sir Frederick Pollock. He was educated at Cambridge University, and was called to the bar at Lincoln's Inn in 1871; has been several times examiner in law at Cambridge University and in other universities; Professor of Jurisprudence at University College, London, 1882–83; Professor of Law in the Inns of Court 1884–91; Corpus Professor of Jurisprudence at Oxford University since 1883; lecturer in the University of Calcutta 1893–94. He has been editor of *The Law Quarterly Review* since 1885, and of the revised reports since 1891. He has written much for periodicals upon jurisprudence and legal ethics, and is a leader in the modern school of historical and analytical law writers. His most important works are *Principles of Contract* (6th ed. 1894); *The Law of Torts* (4th ed. 1894); *A Digest of the Law of Partnership* (5th ed. 1890); *The Land Laws* (2d ed. 1887); *Spinoza, his Life and Philosophy* (1880); *The Law of Fraud, Misrepresentation, and Mistake in British India* (1894); *Leading Cases done into English, and Other Diversions* (1892); *Essays on Jurisprudence and Ethics* (1882). F. Sturges Allen.

Pollock, Walter Herries: journalist; b. in London in 1850; brother of Sir Frederick Pollock, jurist. He graduated at Cambridge, in 1871, and was called to the bar in 1874. In 1884 he became editor of *The Saturday Review*. Author of *Lectures on French Poets* (1879); *Songs and Rhymes* (1882); *The Picture's Secret* (1883); *Verses of Two Tongues* (1884): and (with Lady Pollock, his mother) *Amateur Theatricals* (1880). H. A. Beers.

Pol'lok, Robert: poet; b. at Muirhouse, Renfrewshire, Scotland, in 1799; graduated at the University of Glasgow; studied theology, and was licensed as a preacher of the United Secession Church 1827. D. at Southampton, Hants, Sept. 17, 1827. Author of *Tales of the Covenanters* (1823) and of *The Course of Time* (1827), a poem in blank verse which gave great promise of future excellence. It became extremely popular in Great Britain and in the U. S., where for many years it was used in schools as a parsing-book.

Poll-tax: See Finance.

Pollux: See Castor and Pollux.

Pol'lux (in Gr. Πολυδεύκης), Julius: scholar; b. at Naucratis, Egypt, about 130 A. D.; lived in Athens as teacher of rhetoric and philosophy. His *Onomasticon*, edited by Dindorf (Leipzig, 1824) and Bekker (Berlin, 1846), is a kind of dictionary in which the principal words relating to certain subjects are collected into groups, defined, and illustrated by quotations. The work is of manifold interest to the student of the Greek language, literature, and art.

Po'lo: a modern adaptation of the Persian game of *chaugán*, the origin of which is unknown. It was introduced into Great Britain in 1869, from India, by officers of the Tenth Hussars; into the U. S. in 1876 by James Gordon Bennett; and in 1883 a flourishing club was started in Mexico city. It has earnest supporters in Africa and Australia, while in Great Britain it has long been a recognized sport. The game is an old one in Tibet, and the Japanese have a very similar form of recreation in *daiku*.

Briefly, polo is simply playing the game of "hockey" or "shinny," on horseback. The game consists in knocking a ball, with a stick having a crook or "mallet" at its end, from one goal to another, these goals being some 8 yards wide and about 250 yards apart at opposite sides of a level rectangular field. The players, four upon each side, are mounted on ponies. By the rules of the New York club the height of the ponies is limited to 14 hands, and the "mallets" to be used must be 4 ft. 4 in. in length. The ponies used are "hogmaned," and have their tails cut short. The game is extremely rough, and accidents upon the field are numerous. Because of the expense attached to securing and keeping "mounts" the game is confined to the wealthier classes.

Roller-polo came in with roller-skating rinks, with rules adapting it to skaters and indoor playing.

Water-polo seems to have no logical connection with polo proper, it being a game played by swimmers. Sides are chosen, and the attempt made while swimming to force a football through the opponents' goal. This game has generally been confined to the baths in the larger gymnasiums.

E. Hitchcock, Jr.

Polo: city; Ogle co., Ill.; on the Burl. Route and the Ill. Cent. railways; 12 miles N. of Dixon, 23 miles S. of Freeport (for location, see map of Illinois, ref. 2–E). It is in an agricultural region; contains a high school, the Buffalo Public Library (founded in 1871), a national bank with capital of $65,000, a private bank, a semi-weekly and a weekly newspaper, and manufactories of agricultural implements and buggies; and ships large quantities of cattle and hogs. Pop. (1880) 1,819; (1890) 1,728; (1900) 1,869.

Polo, Gaspar Gil: romancer; b. at Valencia, Spain, probably about 1540; little is known of his life. Most likely he is the same Gaspar Gil Polo who held the second professorship of Greek in the University of Valencia from 1566 to 1574. He seems also to have had legal training, for he appears in Valencian documents of 1571 to 1573 with the title of "Notario." He died probably before 1591. His fame is due to the fact that he published at Valencia, in 1564, a continuation of the *Diana Enamorada* of Montemayor (*q. v.*). This passed through many editions in Spain, and was translated into several other languages—e. g. English, by Bartholomew Yong (with Montemayor's *Diana*, 1598); Latin, by Caspar Barth (under the title *Eroto-didascalus sive Nemoralium libri V.*, Hanover, 1625). Cervantes esteemed Polo's work more highly than Montemayor's (cf. *Don Quijote*, i., 6). The best edition of Gil Polo's *Diana* is that with *Life* by Francisco Cerda y Rico (Madrid, 1778). A good modern edition of the text is printed with that of Montemayor's *Diana*, in the *Biblioteca clásica española* (Barcelona, 1886). A. R. Marsh.

Polo de Medina, Salvador Jacinto: poet; b. in Murcia, Spain, about 1607; d. about 1660. After studying and amusing himself with poetry in his native place he went, about 1630, to Madrid to continue his studies. He became a priest, and in 1638 was secretary to the Bishop of Lugo. In his earlier work he showed himself gifted with considerable satiric power. His chief model was Cervantes, but he was influenced also by Góngora and Saavedra. In 1630 he published at Madrid his *Academias del Jardín*, his *Buen humor de las musas*, and his fables *Apolo y Dafne* and *Pan y Siringa*. In 1636 appeared his *Hospital de incurables, viaje de este mundo al otro*—a vision, in which the poet visits the infernal world. His moral treatise *Gobierno moral á Lelio* (1657) was much admired, and frequently imitated during the remainder of the seventeenth century. The first complete edition of his works, *Obras en prosa y verso*, appeared at Saragossa in 1664. The works in verse are printed in vol. xlii. of Rivadeneyra's *Biblioteca de Autores Españoles* (Madrid, 1875). A. R. Marsh.

Polo, Marco: traveler; b. in Venice in 1254; son of Nicolo Polo, one of three brothers, who seem to have been jointly engaged in extensive mercantile ventures in the East. In the year 1260 Nicolo, who had left a family at Venice, and his brother Maffeo went on a mercantile venture to the Tartar court at Sarai on the Volga. Thence circumstances carried them to Bokhara, and a party of Mongol envoys, passing that way, invited their company to the court of the Great Khan in the far East. Kublai, the ablest descendant and successor of Chinghiz, was then reigning. Never before having seen European gentlemen, he took the Polos into great favor, and after a time sent them back, in the character of envoys, to the papal court, to ask, among other things, for a great body of priests to instruct his people. The two brothers reached Acre in Apr., 1269, and, hearing that the papal see was vacant, went home. Nicolo found that his wife was dead, but that his son Marco, the subject of this article, was then a fine lad of fifteen. After waiting two years vainly for a new pope, the brothers started again for the East, taking young Marco. They were yet on the Gulf of Scanderoon when they heard at last of a pope's election in the person of Tedaldo Visconti, a Church dignitary of Acre, who had shown great interest in their mission, and who afterward reigned creditably as Gregory X. He recalled them to Acre to receive his letters, but in lieu of the hundred teachers asked by Kublai he could give but two, and the hearts of these failed at the outset. The long journey to Cathay occupied three years and a half. It lay through Southern Armenia, Persia, the valley of the Oxus, and Badakhshan, thence over the high plateau of Pamir. From Pamir they descended upon Kashgar, and thence by Khotan and across the Gobi desert to *Tangut*, as the country at the western end of the Great Wall was then called. Here they were met as the Great Khan's guests, and conducted to his summer-seat at Shangtu on the plateau of Mongolia, nearly 200 miles N. of Peking. Kublai received the party cordially, and showed especial favor to Marco. The young man applied himself to acquire some languages current at the Mongol court (though Chinese was certainly not one of his acquisitions), and soon got employment in the khan's service. His first important commission carried him through Western China and the wild Tibetan frontier to Yunnan, called by the Mongols Karajang (*Carajan*), and thence to the borders of Burma (*Mien*). A mission to India was one of his charges, and the government of the great city of Yangchow, on the Grand Canal, with its district, was another. The khan grew old, and the Polos began to fear what might follow his death; they desired to depart, but he heard them with displeasure; and it was not till 1292 that an opportunity offered. Kublai's kinsman, Arghûn, Khan of Persia in 1286, having lost his favorite wife, Bulugân, envoys were sent to Cambaluc to request that a Mongol lady of Bulugân's own family be selected to succeed her, as she had requested on her deathbed. Kukâchin, a beautiful maiden of seventeen, was selected. The envoys desired to return by sea, and sought the company of the experienced Venetians. Kublai was reluctant, but consented, and fitted the party out nobly for the voyage, charging the Polos with friendly messages for the Kings of France, England, and Spain. Their fleet of fourteen vessels sailed from Fuh-kien in the beginning of 1292; the voyage was long and disastrous, but the Polos after two years landed in Persia. After a time the Polos proceeded to Europe, and late in 1295 reached Venice, where they were received coldly by their relatives, who had long considered them dead. Venice and Genoa were then in hot and often sanguinary rivalry. In 1298 Marco joined the Venetian fleet under Andrea Dandolo as gentleman-commander (*sopra comito*) of a galley, and in an action off Curzola was taken prisoner with 7,000 others and carried to Genoa. At Genoa he fell in with a certain Rusticiano or Rustichello of Pisa, an inmate also of the prison there. To him is due the preservation of Polo's travels and memory, for he probably suggested the record of his experiences, and certainly he wrote them down from Polo's dictation. In the summer of 1299 peace was made and the prisoners were liberated. Marco Polo survived to Jan., 1324, the date of his will still extant, but died soon after—certainly before June, 1325. He had married, and left three daughters; two of them married before his death.

The *Book of Marco Polo* consists of two unequal sections. The first, called *Prologue*, is a personal narrative of great interest, but too great brevity. The second consists of a long series of chapters, extremely various in length and interest, descriptive of the regions of Asia visited by the Polos in their different journeys, but especially of the Emperor Kublai, his court and dominions. It is a curious fact that the original work, dictated by Marco, a Venetian, to Rustichello, a Pisan, was written in French, and very bad French too. The greatest number of MSS. are, however, in Latin, a version by Friar Pipino, executed in Polo's lifetime, having been much diffused. Italian versions are also numerous, the French less so, but far more valuable. The whole number of MSS. known is under eighty. Polo's recognition as prince of mediæval travelers is due to his romantic story and to the vast compass of his travels, anticipating so many supposed discoveries of the sixteenth century, rather than to transcendent character or capacity. He was the first traveler to trace a route across the whole longitude of Asia from the shores of Cilicia to the Yellow Sea—the first traveler to reveal China in all its wealth and vastness, the first to tell of the nations on its borders; of Tibet, of Burma, of Laos, of Siam, of Cochin-China, of Japan; the first to speak of that museum of beauty and wonder, the Indian Archipelago; of Java, the pearl of islands; of Sumatra (*Java Minor*); of Ceylon, with its Mountain of Adam; of India, not as a mythical region, but as a country seen and partially explored; of the secluded Christian kingdom of Abyssinia; of Zanzibar, Madagascar, and Socotra; and of remotely opposite quarters of the high plateaus of Pamir, with their wild sheep; of Siberia and the Arctic Ocean; of white bears, sledge-dogs, and reindeer-riding Tunguses. His book has presented many difficulties, but progress in exploration and in the translation of Oriental literature has made most of them now clear. Marsden's (London, 1818) was the first edition of value; Pauthier's (Paris, 1865) brought a vast amount of interesting Chinese learning to bear upon the subject. The most important is Yule's *Book of Ser Marco Polo* (2 vols., London, 1871; 2d ed. 1875).

Polonium: See the Appendix.

Polo y Bernabe, Luis: See the Appendix.

Poltava, pōl-taa′vă: government of European Russia; bordering S. and W. on the Dnieper. Area, 19,265 sq. miles. The surface is level, the soil fertile, and the climate mild. Agriculture and rearing of cattle are almost the only branches of industry pursued. Grain, hemp, tobacco, the sunflower, and fruits are raised; bees and silkworms are extensively reared. Pop. (1897) 2,794,756.

Poltava, or **Pultowa**: town; capital of the government of Poltava, Russia; on the Vorskla, a tributary of the Dnieper; 88 miles S. W. of Kharkoff (see map of Russia, ref. 9–D). It has manufactures of tobacco and leather and four annual fairs, at which horses, cattle, leather, wool, hides, etc., are sold to the value of about $12,000,000 annually. It is the seat of a bishopric. June 27, 1709, Peter the Great won here a decisive victory over Charles XII., in commemoration of which a large monument has been raised in the principal square. Pop. (1897) 53,060.

Polyæ′nus (Gr. Πολύαινος): sophist; flourished under Marcus Aurelius, and composed in rhetorical style and with an utter lack of critical spirit eight books of *Stratagems* (Στρατηγήματα), which are extant with the exception of gaps in the sixth and seventh. There are editions by Casaubon (1589) and by Wölfflin Melber. B. L. Gildersleeve.

Polyandry [Gr. πολύς, much, many + ἀνήρ, ἀνδρός, man]: See Marriage and Married Women.

Polyan′thus [Mod. Lat., from Gr. πολύανθος, many-flowered; πολύς, much, many + ἄνθος, flower]: any one of a large class of primroses, probably belonging to *Primula grandiflora*, and closely allied to the auriculas, cowslips, oxlips, etc. The polyanthus is a hardy perennial, and the flowers are often beautiful and profuse.

Polyatomic Alcohols: See Alcohols.

Polybasic Acids: See Acid.

Polyb′ius: Greek historian (b. 205, d. about 123 B. C.); a native of Megalopolis, in Arcadia; son of Lycortas, general of the Achæan League. His birth and his ability brought him early to the front, and he was employed in important diplomatic and military affairs. After the defeat of Perseus at Pydna, in 167, he was one of the 1,000 prominent Achæans who were deported to Italy by the Romans as hostages for the future good conduct of the Achæan League. In his seventeen years of exile he learned to appreciate the mission of Rome; and his study of the Roman state and his familiar intercourse with the leading men of Rome filled him with admiration of the new favorites of fortune (Τύχη). He was an intimate in the house of Æmilius Paulus, and accompanied Scipio the younger on his campaigns. In 150 his exile was at an end, but he returned to Rome twice and was in the suite of Scipio at the fall of Carthage (146) and at the siege of Numantia. Polybius was of great service to his countrymen in their subsequent complications with Rome, and was highly honored for his patriotic intervention. He preserved his mental and physical vigor to the age of eighty-two years, when he died in consequence of a fall from his horse. His great work was his *Histories* in forty books, five of which have come down to us entire; of the remainder we have fragments of considerable compass, part of them preserved in the excerpts of Constantinus Porphyrogenitus.

Polybius is the expounder and exemplar of the "pragmatic" method in history. The facts (πράγματα) once ascertained must be made to yield their causes, the causes ascertained must be made to yield lessons for the future. Pragmatic and practical are the same thing from different points of view. For the ascertainment of the facts he was rarely equipped by practical knowledge of the art of war and the life of politics. Not only did he bring a critical spirit to bear on the traditions of the past and on the work of his predecessors in the domain of history, but he was personally cognizant of many of the events which he describes. He "thinks straight and sees clear," and his love of truth is manifest; but there is far too much "exposure" of his fellow-workers, far too much sermonizing about right methods and correct results; although no one can deny that in the study of the causes of events Polybius showed in some directions wider and deeper vision than any of his predecessors, and with him begins a new era of historiography. He studied what was in man, he studied what was in nature, in order to find the springs of action; and it was he who taught historians to take into calculation the effect of political institutions, and the influence of soil, of climate, of geographical situation. True, his practical soul was not open to the influence of religion, which was to him an engine to work on the masses withal, not a spirit to animate a nation. To him the central force of history which dominated all the causes he had so laboriously evolved was a mysterious Τύχη (Fortune), the unknown, unaccountable power that took the place of the old gods. He does not seem to have been susceptible to the charm of poetry or alive to the influences of philosophy, but, Romanized though he was, Polybius was still too much a Greek not to admit with Aristotle the potency of music. As a stylist, Polybius has the merit of clearness, but lacks grace and charm, and his mechanical scrupulousness in the avoidance of the hiatus stands in amusing contrast with his neglect of the weightier matters of stylistic law. With Polybius begins the period of the so-called common dialect in contradistinction to Attic; he lets in new words with a flood, multiplies periphrases, and inspissates his style with abstracts and articular infinitives. The student of classical Greek finds himself in a new world of language just as the student of Greek history finds himself in a new world of thought.

Editions.—Schweighäuser (Leipzig, 1789–95); 8 vols., I. Bekker (Berlin, 1844); L. Dindorf, re-edited by Büttner-Wobst (Leipzig, 1882; Hultsch, 2d ed. Leipzig, 1888. Translated into English by Shuckburgh, 2 vols., London, 1889). See also W. W. Capes, *The History of the Achæan League as contained in the Remains of Polybius* (London, 1888); J. L. Strachan-Davidson, *Selections from Polybius* (Oxford, 1888); and Rudolf von Scala, *Die Studien des Polybius* (2 vols., 1890). B. L. Gildersleeve.

Pol′ycarp [from Lat. *Polycarpus* = Gr. Πολύκαρπος, liter., bearing much fruit]: one of the Apostolic Fathers, b. about 70 A. D., apparently of Christian parentage: a disciple of St. John and Bishop of Smyrna, where he suffered martyrdom, probably, according to modern scholars, in 155 or 156. The old date was 166 or 167 A. D. Most of what is known of him comes from his pupil Irenæus, who was Bishop of Lyons 177–202 A. D. In his letter to Florinus (preserved by Eusebius, *Hist.*, v., 20) Irenæus gives a graphic account of Polycarp as remembered by him. Another extract (*Adv. Hær.*, iii., 3, 4) emphasizes Polycarp's hostility to heretics, and there is still another extract from a letter of Irenæus to Victor, Bishop of Rome (preserved by Eusebius, *Hist.*, v.,

24), in relation to the Passover dispute, describing a visit of Polycarp to Anicetus, Bishop of Rome from 154 A. D. An epistle from the Church in Smyrna to a neighboring Church in Philomelium, describing the martyrdom of Polycarp, is probably in its main contents genuine, but in its present form has two closing sections which are not. Some features of the narrative are above suspicion and in keeping with the best traditions of the age. When entreated to save his life by reviling Christ the answer of the martyr was: "Eighty and six years have I served him, and he has done me no ill. How, then, can I blaspheme my King who has saved me?" The spot now pointed out as the site of this martyrdom is marked by a tall cypress on the face of Mt. Pagus, overlooking the city of Smyrna. Polycarp's Epistle to the Philippians appears to have been written shortly after the martyrdom of Ignatius, 115 A. D. Its genuineness is now generally conceded. Its tone is hortatory; its most important characteristic, great profuseness of quotation from the apostolic writings. The best recent editions of Polycarp are by Jacobson (1838; 4th ed. 1863); by Hefele (1839; 5th ed. by Funk, 1878); by Dressel (1857; 3d ed. by Zahn, 1876); but especially by Lightfoot (*Ignatius and Polycarp*, 1885). See also Lightfoot's *Apostolic Fathers* (1893). Revised by S. M. Jackson.

Polycen'tridæ [Mod. Lat.; named from *Polycen'trus*, the typical genus; Gr. πολύς, much, many + κέντρον, goad, spine]: a family of spiny-rayed fishes peculiar to the fresh waters of tropical South America. It is composed of two genera—(1) *Polycentrus*, without a barbel, and (2) *Monocirrus*, with a barbel. Two species of the former and one of the latter are known.

Polychætæ [Mod. Lat., from Gr. πολύς, many + χαίτη, bristle]: an order of annelids (jointed worms) belonging to the class Chætopoda (*q. v.*). In these forms each segment of the body bears numerous bristles, which either project from the general surface or from fleshy outgrowths (parapodia) on the sides of the body. The head is distinct and usually provided with feeler-like appendages, some of which may be modified into gills; the parapodia are usually complicated in shape, and besides the bristles they may bear tentacular processes (cirri) and in some instances respiratory organs. The internal organs are upon the general annelid plan, but usually the circulatory organs are highly developed. Reproduction is largely by means of eggs, although some species have the power of spontaneously dividing into two individuals. The young escape from the egg as a spherical embryo (trochophore), which gradually elongates into the adult condition. With the exception of the single genus *Manyunkia* from the Schuylkill river, Pennsylvania, all are marine. Among them are many forms beautiful alike in shape and color, which go far toward contradicting the common impression that a worm is a loathsome creature. The *Polychætæ* are usually subdivided into two groups. In one, *Errantia*, the animal lives a free life, either burrowing in the mud or swimming through the water. These animals are predaceous and are provided with strong jaws for capturing their prey. In the second group, *Tubicola* or *Sedentaria*, the parapodia are less developed, the animals live in tubes of their own construction, and, since jaws are lacking, they have to depend for food upon the minute particles brought them in the currents of water produced by the appendages of the head. There are many hundreds of species of *Polychætæ*. The most valuable papers upon the group are Ehlers, *Die Borstenwürmer* (Leipzig, 1864–68); Claparède, *Annelides du Golfe du Naples* (Geneva, 1868–70); and various articles by Grube, Malmgren, etc. The American species have largely been described by Verrill (*Invertebrata of Vineyard Sound*), Webster, and Andrews. For the development, reference should be made to Hatschek (*Arbeiten Zool. Inst.*, Vienna, i., 1878), Wilson (*Johns Hopkins Studies*, ii., 1882; *Journal of Morphology*, vi., 1892), A. Agassiz, and Fewkes. For structure, Claparède (1862), Meyer (*Mittheil. d. Zool. Station*, Naples, vii., 1887), Andrews, and others.

J. S. Kingsley.

Polychrome: synonymous with Æsculin (*q. v.*).

Polychromy: the application of varied and generally bright colors to buildings, statuary, and other objects; also the study or theory of this art. Most ancient peoples decorated their buildings inside and out with painting in vivid colors. When this was not done it was because the materials of the building or of its facing were naturally varied in color: Thus the frieze of the Erechtheion at Athens was in black marble, with white-marble figures in relief upon it, and the interiors of Roman temples, basilicas, and palaces were lined with variegated natural marbles. Oriental nations, both those of the far East and the Mohammedan peoples of the Levant, show great skill in polychromy. The differences between these nations in their use of color in this way are considerable: Thus the Japanese excel in the combination of browns and grays, gold of different tints, bronze, and other alloys, and generally in all the effects of subdued and delicate color, while the Chinese surpass them and all other peoples of modern times in handling dark and light blue, pure green, vivid yellow, orange, and white. The surprisingly refined combinations which they make of these strong and pure colors help us to understand how a Greek temple may have looked with patterns and even broad surfaces of pure red and deep blue, with white and gold. The modern peoples of European extraction show little power in making designs in color, and are generally content to copy those of antiquity or of the East. Russell Sturgis.

Polycle'tus (in Gr. Πολύκλειτος): statuary of the fifth century B. C.; b. at Sicyon, Achæa; was made a citizen of Argos; received instruction, together with Phidias and Myron, from Ageladas, and made the celebrated chryselephantine statue of Hera in the Heræum of Argos, and the still more celebrated statue of the *Spear-bearer*, which was afterward studied by other artists as containing the *canon* with respect to the proportions of the human body. He was also famous as an architect, and built the theater of Epidaurus. See Murray, *History of Greek Sculpture* (London, 1880), i., p. 257 ff.; Mitchell, *History of Ancient Sculpture* (New York, 1888), i., p. 384 ff.; Overbeck, *Geschichte der Griechischen Plastik* (Leipzig, 1893), i., p. 507 ff.; Collignon, *Histoire de la Sculpture Grecque* (Paris, 1892), i., p. 485 ff.; see also the article *Polykleitos* in Baumeister's *Denkmäler*.

Revised by J. R. S. Sterrett.

Polyc'rates (in Gr. Πολυκράτης): tyrant of Samos; one of the most daring and most successful of the many sea-kings who in ancient times swarmed over the Ægean Sea. When seeking the alliance of Egypt, he was warned by Amasis that he should sacrifice whatever he valued most highly in order to ward off the envy of the gods. He consequently threw his ring, a jewel of immense value, into the sea, but the next day the ring was found in the stomach of a fish that was served up on his table. Thereupon Amasis abandoned the alliance on the ground that his destruction was decreed by the gods. His life, which was one long series of brilliant victories, ended, nevertheless, in a pitiful manner. One Orœtes, satrap of Sardis, lured him into Magnesia, and seized and crucified him for some unknown reason about 522 B. C. Revised by J. R. S. Sterrett.

Polydæmonism: See Animism.

Polyg'amy [from Gr. πολυγαμία, deriv. of πολύγαμος, polygamous, having many marriages: πολύς, many + γάμος, marriage]: the state of a man having two or more wives at the same time. The state of a woman having two or more husbands at the same time is generally called *polyandry*. In ancient times polygamy was practiced by all the Eastern nations, and was sanctioned, or at least tolerated, by their religions. In the Homeric age it seems to have existed to some extent among the Greeks, but during the later development of Greek civilization it entirely disappeared. To the Romans and the Gotho-Germanic races it was unknown. With the Jews it was common among the patriarchs and tolerated by the law of Moses, but toward the beginning of our era the custom appears to have died out. The Koran sanctions it, but among the Arabs it does not prevail as a general rule. Among Christians, although the New Testament contains no positive injunction against it, it was never tolerated except among the Mormons. (See Mormons.) In modern times polygamy is common only among the savage African and Malayo-Polynesian races, and among the degraded nations of Asia. See Bigamy.

Polyglot [from the Gr. πολύς, many, and γλῶττα, tongue]: a book with versions of its texts in several languages, but generally used only of such editions of the Bible. Of Origen's *Biblia Hexapla* (see Origen), only a few fragments are extant. The first great polyglot printed was the *Complutensian* (printed under the care and at the cost of Cardinal Ximenes at Alcalá de Henares, Spain, named in Latin *Complutum*, 1502–17, 6 vols. fol., but not published till 1520); it was followed by the Antwerp (edited by Benedict Arias Montanus, 8 vols. fol., 1569–72), the Parisian (ed-

ited by Gabriel Sionita, 1628–45, 10 vols. fol.), but all these are far surpassed by the London (edited by Walton, 6 vols. fol., 1654–57).

Polygno'tus: painter; b. in the beginning of the fifth century B. C. in the island of Thasos; was an intimate friend of Cimon, and lived mostly in Athens, where he decorated the temple of Theseus, the Anaceum or temple of Castor and Pollux, and the Pœcile or painted portico; afterward, also, the inner halls of the Propylæa. He painted also some important pictures at Delphi. His pictures were celebrated in antiquity, and the art of painting appears to have been raised from early formality and elevated to a high standard by his genius. Revised by R. STURGIS.

Polygon [from Gr. *πολύγωνος*, polygonal, many-cornered; *πολύς*, many + *γωνία*, corner, angle]: a plane figure bounded on all sides by straight lines. The bounding lines are called *sides* of the polygon, and the points at which they meet are called *vertices* of the polygon; the entire bounding line is called the *perimeter*. Polygons are divided into classes according to the number of their sides or angles. Polygons of three sides are called *triangles*; those of four sides are called *quadrilaterals*; those of five sides, *pentagons*; those of six sides, *hexagons*; and so on. If the sides of a polygon are equal, the polygon is said to be *equilateral*; if its angles are equal, it is called *equiangular*. A *regular* polygon is both equilateral and equiangular. A closed broken line, all of whose sides are not in a single plane, is often called a *twisted polygon*. Revised by R. A. ROBERTS.

Polyg'onal Numbers: See NUMBERS.

Polygor'dius [Mod. Lat., from Gr. *πολύς*, many + *Γόρδιος*, Gordius, in allusion to the Gordian knot]: a genus of annelid worms. It is usually, with a few others, assigned to a special group, *Archiannelida*. Species are found in the seas of Europe and America.

Polygraph: See RECORDING APPARATUS, PSYCHOLOGICAL, in the Appendix.

Polyhedral Angle: a solid angle formed by three or more planes passing through a common point. If there are but three planes the angle is called *trihedral*. The intersections of the bounding planes are called *edges* of the polyhedral angle, and their common point is called the *vertex* of an angle. If a sphere be described about the vertex as a center with a radius equal to 1, the part of its surface included within the bounding planes is taken as the measure of the angle. Revised by S. NEWCOMB.

Polyhedron [Mod. Lat., from Gr. *πολύεδρος*, having many bases or sides; *πολύς*, many + *ἕδρα*, seat, side]: a solid bounded on all sides by polygons. The polygons are called *faces*, and the lines in which they meet are called *edges* of the polyhedron. The points in which two or more edges meet are called *vertices* of the polyhedron. The simplest polyhedron is bounded by four triangles, and is the pyramid known as a tetrahedron.

Polyhym'nia [= Lat. = Gr. *Πολυμνία*, liter., abounding in songs; *πολύς*, many + *ὕμνος*, song]: one of the Muses, the inventor of the lyre and the genius of lyric poetry; generally represented by ancient artists in a pensive attitude.

Polymer'ism: See ISOMORPHISM.

Polymorphism [from Gr. *πολύμορφος*, multiform; *πολύς*, many + *μορφή*, form]: in biology, that condition in which different kinds of individuals appear in the same species. In the animal kingdom it has its greatest exemplification in the group of SIPHONOPHORÆ (*q. v.*), where the whole colony is made up of members, all reducible to a common type, which are specialized for the functions of floating, swimming, reproduction, eating, and touch. Among the free forms it is not so common, but still is not rare. Thus among insects we find butterflies in which not only the males and females are different in their markings, but among the females different patterns may easily be recognized; in fact, so different may they be that did we not know their life-history we should not regard them as belonging to the same species. Where but two forms are known, the phenomenon is spoken of as DIMORPHISM (*q. v.*). J. S. K.

Polynem'idæ [Mod. Lat., named from *Polyne'mus*, the typical genus; Gr. *πολύς*, many + *νῆμα*, thread]: a family of spiny-rayed fishes peculiar for the free filiform rays below the pectoral fins. The family is represented by about twenty-five species, distributed in almost all tropical regions, and one (*Polydactylus octonemus*) occasionally wanders northward as far as New York.

Polyne'sia [Gr. *πολύς*, many + *νῆσος*, island]: a geographical designation somewhat loosely applied. It is now generally used for that part of Oceanica which lies S. of the equator and E. of the 170th meridian of E. lon.—a division based on ethnographic grounds.

Polyni'ces (in Gr. *Πολυνείκης*): in Grecian mythology, the first-born son of ŒDIPUS (*q. v.*), by his own mother Jocasta. He was banished from Thebes by his younger brother, Eteocles, and fled to Argos, where he married Argeia, a daughter of Adrastus, the King of Argos. Adrastus undertook to reinstate Polynices, but the seer Amphiaraus knew that the expedition (see SEVEN AGAINST THEBES) was doomed to failure, and he urged Adrastus not to undertake it. Polynices gave the necklace of Harmonia to Eriphyle, and she persuaded her husband to sanction the expedition, which meant death to himself. All the chieftains except Adrastus were slain at Thebes, Polynices falling at the hands of Eteocles, whom he slew. J. R. S. STERRETT.

Polyp [Mod. Lat. *po'lypus*; Gr. *πολύς*, many + *πούς*, foot]: one of the individuals of any of the fixed CŒLENTERATA (*q. v.*), and in earlier times of the *Polyzoa* and Tunicates. At one time there was recognized a "class" of polyps or *Anthozoa*, but the term is obsolete. See SCYPHOZOA.

Polyphe'mus (in Gr. *Πολύφημος*): in Grecian mythology, the famous Cyclops, a son of Poseidon; a gigantic monster with one eye in the center of the forehead; lived in the island of Thrinacia, where he captured Odysseus on his return from Troy. Odysseus escaped by making Polyphemus drunk and burning out his eye. See GALATEA.

Polyphony [Gr. *πολυφωνία*, variety of tones; *πολύς*, many + *φωνή*, tone]: in music, composition in several parts, vocal or instrumental, each part having an independent melodic flow of its own, but all uniting to express one musical thought or idea. This is in contrast to *homophony*, so called, which may be popularly explained as a simple succession of chords supporting a given melody, but without independent progression among the various accompanying parts or voices themselves. A well-written fugue exhibits, through the independent movement of its parts, a good example of practical polyphony. There is no essential distinction between polyphonic and contrapuntal writing.
DUDLEY BUCK.

Polyplacoph'ora [Mod. Lat.; Gr. *πολύς*, many + *πλάξ*, *πλακός*, tablet, plate + *φέρειν*, bear]: an order of molluscs containing the chitons, and better called *Placophora*. See CHITON and MOLLUSCA.

Pol'ypod, or **Pol'ypody** [*polypod* is from Gr. *πολύς*, many + *πούς*, *ποδός*, foot; *polypody* is from Gr. *πολύς* + *ποδίον*, dimin. of *πούς*, foot]: popular names given to many ferns, but properly belonging to those of the genus *Polypodium*, of which the U. S. has eleven species, growing on rocks, tree-trunks, etc. See FERNWORTS. C. E. B.

Polyp'terus [Mod. Lat., from Gr. *πολύς*, many + *πτερόν*, feather, wing]: a genus of ganoid fishes of considerable interest to the naturalist from its affinities to the lower sharks, the siluroid fishes, and the urodele batrachians, as well as from the fact that it and another African genus (*Calamoichthys*) are the only living representatives of a group of fishes which were predominant in Palæozoic times. *Polypterus bichir*, the only species, occurs in the rivers of West Africa and in the upper Nile. It reaches a length of 4 feet, the body is covered with lozenge-shaped scales, and the dorsal fin is represented by from eight to eighteen spines, each bearing an articulated finlet. For details of structure, see Leydig, *Zeitschrift für wiss. Zoologie*, v. (1854); van Wihje, *Niederland. Archiv für Zool.*, v. (1882); Pollard, *Zoolog. Jahrbücher*, v. (1892); and Traquair, *Jour. of Anat. and Physiol.*, v. (1871). J. S. KINGSLEY.

Polytechnic Schools: See SCHOOLS.

Polytheism: See ANIMISM and GOD.

Polyu'ria [Gr. *πολύς*, much + *οὖρον*, urine]: excessive urination. The term is applied to occasional increase in the flow of urine, due to transient causes, but also to a permanent condition or disease characterized by excessive excretion of urine, consisting chiefly of water, but not dangerous and seldom met with. See DIABETES. W. P.

Polyzo'a [Gr. *πολύς*, many + *ζῷον*, animal]: a group of animals formerly associated with the hydroids, later among the molluscs, and recently placed among the worms, together with the brachiopods and sipunculids, in a class, *Prosopygii*. The name *Polyzoa* alludes to the fact that these forms are

colonial, many individuals being associated together, while the term *Bryozoa* used mostly by the Germans has reference to the mossy appearance due to the small size of the numerous individuals. The separate animals are situated in chambers or "cells" in a horny or calcareous exoskeleton, and each can retract entirely into the hard case. When extended, each polyp presents a circle of tentacles (sometimes folded into a horseshoe shape) borne on a disk or lophophore, in the center of which is the mouth, the alimentary canal (consisting of œsophagus, stomach, and intestine), folded on itself, the vent being either inside the circle of tentacles, or, more usually, just outside the lophophore. The nervous system consists of a ganglion between mouth and vent. Nephridia (but a single pair) are occasionally present, and open near the mouth. The stomach is usually tied to the body-wall by a cord, or funiculus, in which may be situated either the testes or both testes and ovaries. In some the sexes are separate, in others united in the same individual. The *Polyzoa* reproduce both by eggs and by budding. The eggs in their development pass through a metamorphosis, with free-swimming embryos entirely different from the adult. When the adult condition is reached, the sessile individual forms the beginning of a colony which increases in size by the outgrowth of new persons from the older members of the colony. In the *Entoprocta* the buds become detached, forming free individuals,

The *Polyzoa* are divided into *Entoprocta* and *Ectoprocta*, accordingly as the vent is within or outside the circle of tentacles. The *Entoprocta* are few in number, and are all marine. The numerous *Ectoprocta* are subdivided into the *Gymnolæmata*, in which the tentacles are in a true circle, and the *Phylactolæmata*, in which the circle of tentacles is folded in horseshoe shape. These latter are exclusively fresh-water forms, and frequently occur in large gelatinous masses in lakes and streams. To carry the species through the winter cold, they form peculiar reproductive buds or statoblasts, inclosed in hard shells, which, with the return of warm weather, re-form the colony. Except one or two genera, all of the *Gymnolæmata* are marine. The genera *Rhabdopleura* and *Cephalodiscus*, formerly regarded as polyzoans (*Pterobranchia*), are thought to be related to Balanoglossus (*q. v.*). Polyzoans occur in all geological ages since the Silurian. See Hincks's *British Marine Polyzoa* (1880); Hyatt, *Proceed. Essex Institute*, v.; and papers by Barrois, Schmidt, Smitt, etc. J. S. Kingsley.

Pombal', Sebastian Joseph de Carvalho e Mello, Marquis of: statesman; b. near Coimbra, Portugal, May 13, 1699; studied law at the University of Coimbra: spent some years in the army; afterward entered the civil service and obtained the favor of the court; was sent in 1739 as minister to London, and in 1745 to Vienna, where he married the wealthy Countess of Daun, and succeeded as mediator in averting the threatened rupture between the court of Austria and Pope Benedict XIV.; became Minister of Foreign Affairs of Portugal 1750; acquired a great influence over his sovereign, King Joseph; displayed great vigor and judgment as a political reformer, curtailing the powers of the Inquisition and improving the finances of the kingdom; exercised a kind of beneficent dictatorship during the days of panic following the great earthquake of Nov., 1755; superintended the rebuilding of the city with greater magnificence; became first minister 1756, and caused the banishment from Portugal of all the members of the Society of Jesus by royal decree of Sept. 3, 1759, they having been suspected of connection with the attempted assassination of the king in the previous year; created Count of Oeiras in 1759, he was made Marquis of Pombal in 1770, and retained nearly supreme power until Joseph's death in 1777. On the accession of Pedro III. he was superseded in favor at court, and retired to his estates. D. at Pombal, May 5, 1782. He is known in Portugal as the "great marquis." See Smith, *Memoirs of Pombal* (London, 1843); Oppermann, *Pombal und die Jesuiten* (Hanover, 1845); and Canota, *Marquis Pombal* (London, 1871). Revised by F. M. Colby.

Pomegranate, pŭm-grăn'it [from O. Fr. *pome grenate* < Late Lat. *po'mum* (earlier *ma'lum*) *grana'tum*, lit., apple with many seeds; *po'mum*, fruit, apple + *grana'tus*, seeded; deriv. of *gra'num*, grain, seed]: a shrub, *Punica granatum*, of the Old World (of the family *Granataceæ*), now naturalized in most warm countries. It grows finely in those parts of the U. S. bordering the Gulf of Mexico. Its fruit, also called pomegranate, is of fine appearance. Some of the varieties are sub-acid and others sweet; most of them abound in small seeds, but some are seedless. The fruit is very grateful in hot climates. The plant is sometimes used for hedges. The flowers are very fine, and sometimes are double. The bark is used in tanning. The rind of pomegranates is a good astringent for medicinal use. Its active principle (pelletierine) and the bark of the root are good anthelmintics against the tapeworm. H. A. H.

Pomelo, or Pumelo: See Shaddock.

Pomerania (Germ. *Pommern*): province of Prussia; bordering N. on the Baltic, and bounded W. by Mecklenburg and S. and E. by the provinces of Brandenburg and West Prussia. Area, 11,628 sq. miles. The ground is low and the surface level. Along the Oder and the Baltic the soil is marshy, and produces good pasture; in other places it is sandy and little productive. Rye, wheat, potatoes, and hemp are cultivated; cattle and poultry are reared; the fisheries are important; smoked geese and pickled eels form two considerable items of exportation. There is an extensive commerce in the coast towns, where also ship-building and manufactures of sugar, chemicals, machines, paper, tobacco, etc., are carried on. The former inhabitants of Pomerania were of Wendish origin, and formed an independent Wendish dukedom during the Middle Ages. The present Pomeranians belong principally to the old Saxon stock. From the fourteenth century the portions E. and W. of the Oder, called Hither and Farther Pomerania, were separate duchies until 1625, when they were united under Boleslaus XIV. On his death, in 1637, the ruling dynasty became extinct, and the country was divided between Prussia and Sweden, which during the Thirty Years' war had made large conquests in Germany. After the death of Charles XII., Sweden was compelled in 1720 to cede a part of Pomerania to Prussia, but it was not until the downfall of Napoleon that the entire province became part of Prussia. Pop. (1895) 1,574,147. R. A. R.

Pomeranian Dog: a name frequently given to the Spitz Dog (*q. v.*).

Pomeranus: See Bugenhagen.

Pomeroy: city; capital of Meigs co., O.; on the Ohio river, and the Columbus, Hock. Val. and Toledo Railway; 18 miles N. by E. of Gallipolis, about midway between Cincinnati and Pittsburg, Pa. (for location, see map of Ohio, ref. 7–G). It is situated on a narrow strip of land between the river and a range of precipitous hills, and has daily steamboat connection with the principal river towns; is in a region underlaid with bituminous and cannel coal and deposits of salt, and is engaged principally in coal-mining. Salt in large quantities is obtained by simply boring into the earth. There are rolling- and nail-mills, steam-engine and machine shops, flour-, saw-, planing-, and woolen-mills, a national bank with capital of $50,000, a private bank, and 2 daily, a semi-weekly, and 2 weekly newspapers. Pop. (1880) 5,560; (1890) 4,726; (1900) 4,639.

Pomeroy, John Norton, LL. D.: lawyer; b. at Rochester, N. Y., Apr. 12, 1828; graduated at Hamilton College 1847; studied law, and was admitted to the bar 1851; Professor of Law and dean of the law faculty in the University of New York 1864–69; returned to Rochester to practice his profession; removed in 1878 to San Francisco to take the chair of municipal law in the law department in the University of California. He was a man of wide and accurate learning, and wrote numerous articles for magazines upon topics connected with constitutional and international law, general jurisprudence, and the science of politics; edited editions of Sedgwick's *Statutory and Constitutional Law* (1874) and *Archbold's Criminal Pleading and Evidence* (1877), and, besides other minor works, wrote *An Introduction to Municipal Law* (2d ed. 1883); *An Introduction to the Constitutional Law of the United States* (9th ed. 1886); *Treatises on Jurisprudence as Administered in the United States* (3 vols., 1881–83); *Remedies and Remedial Rights, according to the Reformed American Procedure* (2d ed. 1883); *Civil Code in California* (1885); *Treatises on the Law of Riparian Rights* (posthumous, 1887). D. in San Francisco, Cal., Feb. 15, 1885. F. Sturges Allen.

Pomeroy, Seth: soldier; b. at Northampton, Mass., May 20, 1706; was major in the Massachusetts forces at the capture of Louisburg 1745; lieutenant-colonel of the regiment commanded by Col. Ephraim Williams, at whose death, in the battle of Lake George, Sept. 8, 1755, he took command and gained a complete victory over Baron Dieskau. By occupation a mechanic, he was skilled in the manufacture of

arms. He was a delegate to the Massachusetts provincial Congress 1774–75, by which he was elected a general officer Oct., 1774, and a brigadier-general Feb., 1775; fought at Bunker Hill as a private soldier, and was soon afterward appointed senior brigadier by the Continental Congress, but declined the honor in consequence of disputes which arose about military rank, and retired to his farm. In the autumn of 1776 he raised a considerable military force for the relief of the army under Washington, and marched to the Hudson river. D. at Peekskill, N. Y., in Feb., 1777.

Pomfret: See PONTEFRACT.

Pomology [Lat. *po'mum*, fruit + Gr. λόγος, discourse, reason]: the science of fruit-culture. Pomology may be divided into four heads, especially as concerns its application to the U. S.: *Viticulture*, or grape-growing; *orcharding* (which is again divided into the cultivation of pomaceous fruits, or the pear and apple-like tribes; drupaceous or stone fruits; citrous fruits, as oranges and lemons; nut-fruits, nuciculture; and palmaceous fruits); *small-fruit culture*; and *cranberry-culture*. Pomological interests are greater in the U. S. than in any other country.

Statistics of the viticultural interests in the U. S. are given under GRAPE. (See also NURSERY, and the articles on the various fruits; also HORTICULTURE.) The total investment in commercial fruit-growing in 1890 was estimated to exceed $1,000,000,000. The area devoted to peaches was 507,736 acres; valuation of produce, $76,160,400. Upward of $90,000,000 were invested in peach-growing. Of almonds, California had 1,450,224 trees, nearly half of which had arrived at bearing age. Of cocoanuts, Florida had 123,227 bearing trees and 1,199,549 young trees. There were 666,007 lemon-trees, of which 386,636 were in Florida, the remainder in California. California had 607,377 olive-trees. Pine-apples were represented in Florida by 21,605,000 plants. The number of orange-trees was as follows:

	Bearing.	Not bearing.	
Florida	2,725,272	7,408,543	
California	1,553,801	2,223,710	
	4,279,073	9,632,253	13,911,326
Other States, about			600,000
Total number of trees			14,511,326

The literature of American pomology, aside from viticulture, is not extensive. The first distinct pomological work was William Coxe's *View of the Cultivation of Fruit Trees* (Philadelphia, 1817). This was followed by works by James Thacher, *The American Orchardist* (1822, 2d ed. 1825); William Prince, *Pomological Manual* (2d ed. 1832); William Kenrick, *The New American Orchardist* (1833); Robert Manning, *Book of Fruits* (1838: 2d ed. by John M. Ives, 1844); E. Sayers, *The American Fruit Garden Companion* (1839); A. J. Downing, *The Fruits and Fruit Trees of America* (1845, with subsequent editions); John J. Thomas, *The Fruit Culturist* (1846, with subsequent editions); Thomas Bridgeman, *The Fruit Cultivator's Manual* (1845); George Jaques, *A Practical Treatise on the Management of Fruit Trees* (1849); Chauncey Goodrich, *The Northern Fruit Culturist* (1849). A few others of less note, as well as American editions of English works, appeared before 1850. Since that date the chief writers of books have been Hooper, Warder, Barry, Thomas, Downing, Fuller, Strong, Baker, Roe, and Wickson. L. H. BAILEY.

Pomo'na: the Roman goddess of gardens and fruit, of whose wooing by Vertumnus, the god of the revolving year, Ovid has made a pretty story (*Metamorphoses*, xiv., 623 ff.). Her worship was presided over by a special priest, the flamen Pomonalis, and in the country between Ardea and Ostia there was a grove, called the Pomonal, sacred to her.

Pomona: the largest of the Orkney islands.

Pomona: city; Los Angeles co., Cal.; on the S. Pac. Railroad; 33 miles E. of Los Angeles, the county-seat (for location, see map of California, ref. 12–F). It is in an agricultural, mining, and fruit-growing region, contains several manufactories, and has 3 banks with combined capital of $200,000, and 3 weekly newspapers. Pop. (1890) 3,634; (1900) 5,526.

Pompadour, pōn'pȧ'door', JEANNE ANTOINETTE POISSON, Marquise de: b. in Paris, France, Dec. 29, 1721; was supposed to be the natural daughter of Le Normant de Tournehem, a farmer-general of the revenues, who provided for her education; was noted for her dignity, beauty, intelligence, and wit; was married in 1741 to Le Normant d'Étoiles, a nephew of her guardian; became the mistress of Louis XV. in 1745; was presented at court as Marchioness of Pompadour, and splendidly established in the royal residences at Paris, Versailles, and Fontainebleau; received several magnificent estates and an annual income of 1,500,000 francs, and exercised a decided influence on the Government of France for nearly twenty years, in all its branches—its finances, foreign alliances, military operations, etc.—bringing loss and disgrace over the kingdom. On the other hand, she deserves praise for her patronage of literary men and artists. Her efforts to retain her influence over the king were unceasing, and she accomplished her ends largely by encouraging him in his excesses. D. at Versailles, Apr. 15, 1764, detested by the whole French people. See the study by Campardon (1867); E. and J. de Goncourt, *Les Maîtresses de Louis XV.* (vol. ii., 1860); Beaujoint, *Secret Memoirs of La Marquise de Pompadour* (1885); and the volumes of her *Correspondance*, edited by Malassis (1878) and by Bonhomme (1880).

Pompano [adapted from Spanish *pámpano*, a kind of fish (*Stromateus fiatola*) found in European waters]: a name applied to several food-fishes, particularly to *Trachynotus carolinus*, a species found in the Gulf of Mexico and highly valued. It is rather deep in form, bluish above, silvery on the sides, and attains a length of about 18 inches. In California the name is given to a smaller fish of somewhat similar shape (*Stromateus simillimus*). F. A. L.

Pompeii, pom-pā'yĕĕ: an ancient city of Campania, on the bay of Naples, at the foot of Mt. Vesuvius. The date of its founding is unknown. Its oldest architectural remains reveal the Doric style of the sixth century B. C. The Oscans seem to have occupied the city down to the end of the fifth century B. C., when it was wrested from them by the Samnites. At this early period, through contact with the Greek colonies of Southern Italy, the city had arrived at a degree of culture far surpassing the contemporary civilization of Rome. The Samnite wars (342–290 B. C.) brought Pompeii, along with the rest of Campania, into partial subjection to Rome, through an alliance in which Rome's position was supreme; but in all domestic affairs of government it still enjoyed autonomy. Not until the Social war (90–88 B. C.) was this semi-independence replaced by regular subjection to Rome as a Roman colony. Pompeii was a well-to-do commercial city, with a harbor on the Sarno, somewhat nearer to the sea than at present. For a century before its destruction it was also a favorite site for the villas of wealthy Romans, attracted hither by the beauty of its location and the healthfulness of its climate. Its population at the time of its destruction is conjecturally placed (by Mau) at 30,000. Up to the year 63 A. D. Vesuvius had never, since the settlement of the region, given any indication of its volcanic character, but at that time Pompeii and the surrounding country were violently shaken by earthquakes, which wrought much destruction, evidences of which are still distinguishable among the later ruins. While the inhabitants were still occupied in rebuilding the city, the sudden eruption of Aug. 24, 79 A. D., overwhelmed them. (For details of this event, see the famous descriptions in the correspondence of the younger Pliny, vi., 16 and 20). This eruption was attended by earthquake, which did much damage that could not have been caused by the shower of small stones and ashes beneath which the city was buried. The depth of the covering of volcanic matter is 14 or 15 feet, the lower layer consisting of small pumice-stones, the upper layer of ashes, each of about equal thickness. It is not likely that the volcanic matter set fire to the city, but the carbonized condition of all woodwork found is due rather to chemical change under the influence of moisture. After the eruption the upper portions of the larger buildings still projected above the surface, and were not only thus themselves more quickly destroyed, but they served also to guide excavations which were doubtless made soon afterward for valuables of all sorts, including the marble which must have adorned public buildings. Most of the inhabitants escaped unharmed, but, from the skeletons discovered, Mau estimates that not less than 2,000 perished. During the Middle Ages the existence of Pompeii was forgotten and its site was unknown. Excavations were begun in 1748, and continued irregularly for more than a century. The present systematic work of unearthing the city was begun in 1861 by Giuseppe Fiorelli. About half of the city has been disclosed, and the course of the wall has been determined.

The outline of the boundaries of Pompeii is of oval form, fitting in general the hill of lava formation on which it is built. The town was laid out regularly, with the principal

streets running N. and S. and E. and W., although some deviation from parallel lines was occasioned in places by irregularities of the surface. The streets vary in width, averaging, however, about 20 feet, and are paved with irregular blocks of lava. Narrow sidewalks are found on both sides of the street, beneath which the conduits of a very complete sewer system are carried. The public buildings were clustered about two centers, the Forum and the Stabian gate. The Forum, situated near the western edge of the city, was a rectangular space, completely surrounded by temples and other structures—such as the basilica, the tribunals, the macellum (or market-hall)—serving various public ends. The area of the Forum itself was adorned on the north side by the temple of Jupiter, and surrounded on the remaining three sides by long porticoes. None of the buildings about the Forum are perfectly preserved, but the foundations and the columns still standing have generally made it possible to ascertain their design. The second group of buildings about the Stabian gate extended along one side of the so-called triangular Forum, a three-sided space almost surrounded by an admirable Doric portico. Within this space is situated the most ancient edifice of Pompeii, commonly (but erroneously) called the temple of Hercules, a structure in the Doric style of the sixth century B. C., which had already fallen into ruins at the time of the city's destruction. The open space of the Forum triangulare served doubtless as the entrance to the large theater, an adjacent structure on the east side. This theater had a seating capacity of about 5,000. The stage is raised above the orchestra, and accessible from the latter by a flight of stairs. Adjoining the larger theater and nearer the Stabian gate is the smaller theater, used, it would seem, for less formal occasions. Further toward the center of the city from the Stabian gate are found the Stabian baths, the most completely preserved example of that institution so characteristic of Roman civilization. Two other establishments of similar character are found in different parts of the city. No buildings, however, possess a greater interest than the private houses, of which those here found are the only well-preserved examples now existing. The Pompeian private residence is identical with the Roman house as described by Vitruvius, and consists of a central room or atrium with smaller apartments clustered about it. Most commonly, however, this simple arrangement is amplified by the addition of an open court or garden behind the atrium surrounded by columns, and hence called the peristylium. The houses afforded no outlook upon the street, and indeed very frequently the apartments on either side of the entrance had no communication with the house itself, but were rented as shops.

The works of art in marble and bronze which have been discovered at Pompeii are for the most part preserved in the museum at Naples. They are of very great interest, although for the most part inferior to the works of similar character discovered at HERCULANEUM (*q. v.*). Among the most attractive and unique decorations discovered at Pompeii are the paintings which adorned the walls of public buildings and of the more sumptuous private residences. There is discernible in them considerable diversity of style, showing a development from the imitation of purely architectural effects to the treatment of landscape, mythological figures, and scenes from daily life and from history. The last and most characteristic period is represented by designs which combine, in curious and often grotesque fashion, fantastic architectural motives with figures and ornamental treatment of foliage. Another interesting form of decoration is the mosaic work which adorns the floors of many of the houses. Usually it consists of merely ornamental designs in black and white, but there are a few examples of more elaborate work, such as the famous representation of the battle of Alexander in the Casa del Fauno. No manuscripts or important literary monuments, aside from inscriptions, have been found at Pompeii. Of the latter there are many very interesting specimens, ranging in subject-matter from announcements of the merits of candidates for public office or proclamations of gladiatorial games to personal effusions of the most diversified character.

LITERATURE.—General works: G. Fiorelli, *Pompeianarum antiquitatum historia*, with plates (3 vols., Naples, 1860–64); T. B. Dyer, *Pompeii, its History, its Buildings, and its Antiquities* (2d ed. 2 vols., London, 1875); J. Overbeck, *Pompeii in seinen Gebäuden, Alterthümern und Kunstwerken dargestellt* (the principal work, 4th ed. revised by A. Mau, Leipzig, 1884); A. Mau, *Führer durch Pompeii* (Naples, 1893). On the mural paintings: A. Mau, *Geschichte der decorativen Wandmalerei in Pompeii* (Berlin, 1882). For the inscriptions, see vol. iv. of the *Corpus Inscriptionum Latinarum*, ed. C. Zangemeister (Berlin, 1871). For detailed bibliography, consult *Bibliografia di Pompei, Ercolano e Stabia*, compiled by F. Furchheim (Naples, 1891). G. L. HENDRICKSON.

Pompe'ius Trogus: See TROGUS.

Pompey (Lat. *Gnæus Pompeius*, called MAGNUS, the Great): a Roman general; b. in 106 B. C. of a plebeian family which had only recently emerged from obscurity. From childhood Pompey enjoyed a military training, fighting with his father in the Social War (90–88 B. C.), and taking sides with Sulla and the aristocratic party in the contest with Marius. In 81 B. C., contrary to all precedent and rule, he was granted a triumph, and was greeted by Sulla with the cognomen MAGNUS, which he continued to bear through life, and even passed on to his son. After Sulla's death he was recognized as the leader of the aristocratic party. His successes in the war against Sertorius in Spain, and in the suppression of the rebellion of the slaves, were not indicative of great military talent, but they stood out by contrast to the failures of the leaders who had preceded him with sufficient brilliancy to make him a successful candidate for the consulship before he had passed through the usual preliminary grades of office. However, it was only by accepting the programme of the democratic party that he could secure the coveted prize, thus alienating himself from the senatorial party with which he had hitherto been identified. Although as consul (70 B. C.) he carried out the popular measures in abolition of the constitution of Sulla, he did not make himself a leader of the democratic party. For several years after his consulship he took no active part in public affairs, but his military skill was too great and too much needed to be long unused. A popular measure proposed that he be intrusted with extraordinary and absolute powers for the purpose of clearing the Mediterranean of the pirates who infested it, and who had so harassed the carrying trade that the price of grain was intolerably high. The bill was passed against the united opposition of the aristocracy, which saw in the proposition nothing less than the abolition of the constitution and the inauguration of an absolute one-man rule. The pirates were speedily driven from the sea, and in less than a year the supreme command of the operations against Mithridates was intrusted to him (66 B. C.). In this mission he was also successful, and had attained a political and military influence which seemed to the aristocracy a menace to the constitution, and which would have been so in the case of a bolder and more discerning man; but on his return in 61 B. C. Pompey found himself in a position of complete isolation. He had disbanded his army, losing thereby his power of intimidation, and, feared by the democrats and disliked by the aristocracy, he ventured on no escape from his embarrassment in individual action, and was therefore forced into the coalition with Cæsar and Crassus (the first triumvirate), for the sake of having his wishes in regard to the reward of his army and himself carried out. Although Pompey enjoyed with Cæsar a position almost supreme in Roman politics, it became more and more apparent that Cæsar was the heir to the opportunity which Pompey had let slip. In the distribution of political prizes among the members of the coalition Pompey secured largesses of land with which to reward his army, and a formal approval of his settlement of affairs in the East. Again, after the renewal of the triumvirate in 56, Pompey and Crassus were made consuls for the following year, and the provinces of Spain were intrusted to Pompey for a period of five years. He, however, governed them only through his representatives. The course of events from the year 53 on, by which Pompey once more became the leader of the senatorial party against Cæsar, the advance of Cæsar on Rome (early part of 49 B. C.), and the retreat of Pompey through Italy into Epirus, belong equally to the history of CÆSAR (*q. v.*). The final contest took place at Pharsalus in Thessaly, and Pompey was completely routed. He fled to Egypt, and there, as he was disembarking, he was treacherously murdered. G. L. HENDRICKSON.

Pompey's Pillar (so called): a stone pillar erected, according to an inscription on its base, by one Publius, prefect of Egypt, in honor of Diocletian, about 296 A. D. It stands on an eminence just S. of Alexandria. The shaft, 73 feet long, is of beautiful highly polished red granite. The total height of the column is 98 ft. 9 in.

Pompelmoose: See SHADDOCK.

Pompo'nius, Lucius: a Latin poet from Bologna (Bononia), who flourished about 90 B. C.; famous as a writer of *Fabulæ Atellanæ*. Some seventy titles and nearly 200 verses have been preserved in the citations of grammarians. See Ribbeck, *Comicorum Romanorum Fragmenta*. M. W.

Pomponius Mela: See Mela.

Ponape Island: See the Appendix.

Ponca Indians: See Siouan Indians.

Ponce, pōn'thā: the second city in size and one of the most important ports of Puerto Rico; on a plain a mile back from a bay of the southern coast (see map of West Indies, ref. 6–J). A tramway connects it with its port on the bay, which forms a somewhat imperfectly sheltered harbor. Near the town are the celebrated mineral springs of Quintana, much frequented by invalids. Ponce has a thriving trade, principally in coffee. Population of the district (1887) 42,388; of the city proper probably 25,000.

Pon'ce de Leon', Juan: conqueror and discoverer; b. in Aragon, Spain, about 1460. He was of noble family, served in the conquest of Granada, and in 1493 went with Columbus to Española; later he was governor, under Ovando, of the eastern part of that island, whence he passed over to Puerto Rico in 1508 and began its conquest; in 1510 he was appointed its governor. From the Indians he heard of an "island" called Bimini, to the N. W., and it was reported that this contained a miraculous spring which would restore the aged to youth; probably the supposed island was Florida. Ponce de Leon received in 1512 a grant to discover and settle Bimini; he sailed from Puerto Rico in Mar., 1513, discovered some of the Bahamas, coasted along the Atlantic side of the mainland to lat. 30° 8′ N., and on Easter Sunday, Apr. 8, landed and took possession, calling the country Florida, from Pascua Florida, the Spanish name for Palm Sunday. He also explored the Gulf coast to lat. 27° 30′ N., and returned to Puerto Rico in September. His grants were renewed, but owing to Indian wars in Puerto Rico he could not again sail for Florida until 1521. He then attempted to plant a colony, but was driven off by the Indians and was himself so badly wounded that he died shortly after reaching the coast of Cuba. Herbert H. Smith.

Ponce de Leon, Luis: See Leon, de.

Ponchielli, pon-kĕe-el'lĕe, Amilcare: opera-composer; b. at Paderno Fasolaro, Cremona, Italy, Aug. 31, 1834; educated at the Milan Conservatory; produced his first opera, *I Promessi Sposi*, in Cremona, in 1856. He wrote *La Savojarda* (1861); *Roderico* (1864); *La Stella det Monte* (1867); *Le Due Gemelle* (ballet, 1873); *Ctarina* (ballet, 1873); *I Lituani* (1874); *Gioconda* (1876); *Il Figlio Prodigo* (1880); *Marion Delorme* (1885); together with several other operas, some cantatas, and smaller works. D. Jan. 16, 1886.

Pond, Frederick Eugene: See the Appendix.

Pond, John, F. R. S.: astronomer; b. in London in 1767; educated at Trinity College, Cambridge; studied astronomy under Wales, the companion of Capt. Cook; succeeded Dr. N. Maskelyne as astronomer-royal 1811; devoted himself to cataloguing and determining the exact places of the fixed stars; translated Laplace's *System of the Wortd* (2 vols., 1809); and published numerous papers in the *Transactions* of the learned societies. D. in Blackheath, Sept. 7, 1836.

Pondicherry, pōn-di-sher'ri: a French possession in India; on the Coromandel coast, 83 miles S. W. of Madras, in lat. 11° 55′ N. (see map of South India, ref. 6–F). It comprises an area of 107 sq. miles, with 172,941 inhabitants. It consists of a low, flat plain, with a sandy, not very productive soil, and is only partly watered by the river Gingee. The town of Pondicherry, which is the capital of all the French possessions in India, is regularly laid out and well built, with fine promenades and plantations. Its manufactures of fine cotton cloth and cotton thread are important; it has no harbor, vessels are compelled to anchor in an open roadstead, and landing is difficult on account of the surf. Pop. (1889) 41,253. Revised by M. W. Harrington.

Pondoland: a district of Cape Colony, Africa; inhabited by the Ama-Pondo, a branch of the Kaffir family. Pop., estimated, 200,000. It is the most eastern coast-region of Cape Colony, and is chiefly watered by the St. John's or Umzimvubu river. It was the last of independent Kaffraria to fall (1878) into the hands of the British, by whom a military post is maintained on the St. John's river, where the resident commissioner appointed by the Cape is stationed. See Kaffraria. C. C. Adams.

Pond-scums: small fresh-water algæ of the order *Conjugatæ* and the family *Zygnemaceæ*. See Vegetable Kingdom.

Pondweed Family: the *Naiadaceæ*; aquatic monocotyledonous herbs, with alternate or opposite submerged or floating leaves; flowers perfect or diclinous; perianth usually wanting, sometimes of six or more segments; pistils one to six, simple, superior, with two to many ovules. The species, which are found in all regions, number about 120. They occur in most ponds and ditches, especially in still, shallow waters. They are to be regarded as modified from the *Alisma* type by a suppression of the perianth and a reduction in the stamens and pistils. The species (sixty-four) indigenous to the U. S. are described and figured by Dr. Thomas Morong in his *Revision of the North American Naiadaceæ* (1893). Charles E. Bessey.

Poniatow'ski: the name of a celebrated princely family of Poland directly descended from the Italian family of the Torelli, which settled in Poland in the middle of the seventeenth century, and closely allied to the Leszczynskis and Czartoryskis. The most prominent members of the family were (1) Stanislas Augustus, the last King of Poland, b. in Lithuania, Jan. 17, 1732; ascended the throne in 1764 by the influence of Catherine II. of Russia; resigned in 1795, and died at St. Petersburg, Feb. 12, 1798. He was weak, irresolute, and utterly incapable of grappling with the party fury of his subjects and the treachery of his allies. The principal events of his unhappy reign are told in the history of Poland (*q. v.*).—(2) Joseph Antony, b. at Warsaw, May 7, 1762, a nephew of the king; received a military education; served in the Austrian army in the Turkish war; entered the Polish army in 1789 as a major-general; commanded against the Russians in 1792, but retired from service when the king joined the confederation of Targovitza; fought again in 1794 against Russia under Kosciusko; repaired to Vienna in 1795, but returned to Warsaw in 1798, and lived on his estates, at that time under Prussian dominion. In 1807 he commanded the Polish army which aided Napoleon against Russia, and when the duchy of Warsaw was established by the Peace of Tilsit he was appointed minister of war. In 1812 he commanded the Polish contingent of the grand army during the Russian campaign, and distinguished himself by his valor and tactical talent. Shortly before the battle of Leipzig he was made a marshal of France, and after the battle he was charged with covering the retreat of the army, but was drowned (Oct. 19, 1813) in crossing the river Elster.—(3) Joseph, b. at Rome in Feb., 1816; became known as a composer of several operas and masses. *Don Desiderio* was performed at Paris in 1868 with considerable success. D. in London, July 3, 1873.
Revised by F. M. Colby.

Ponka Indians: See Siouan Indians.

Ponsard, pōn'saar', Francis: dramatist; b. at Vienne, Isère, France, June 1, 1814; studied law in Paris, and began to practice at Vienne, but removed to Paris and gave up law for literature. He was first an admirer of Hugo, and in 1837 translated Byron's *Manfred*. He did not follow the romantic progress of Hugo, and profited by the new favor won for classical plays by the brilliant interpretations of Rachel and the recoil from the extremes of Hugo to bring out *Lucrèce*, an attempt to reconcile the old classical tragedy with a modest romanticism. His success was immense, and he was hailed as the founder of the school of "good sense." After the further tragedies, *Agnès de Méranie* (1846), *Charlotte Corday* (1850), and *Ulysse* (1852), he renewed his success with the comedies *L'Honneur et l'Argent* (1853), *La Bourse* (1856), *Le Lion Amoureux* (1866), and *Gatilée* (1867). D. in Paris, July 13, 1867. His *Œuvres complètes* (3 vols.) were published in 1876. A. G. C.

Ponson du Terrail, pōn'sōn'dü-tā'raal', Pierre Alexis de Ponson, Vicomte de: novelist; b. at Montmaur, Isère, France, July 8, 1829; intended for the navy, his weakness in mathematics unfitted him for it, and he turned to writing. He began in 1850 with *feuilletons* in *La Mode* and *L'Opinion pubtique*. *Les Coulisses du Monde* (1853) founded his celebrity and gained him a special public. He supplied the cheaper papers with a vast number of novels of sensational adventure and incident, which were very popular. D. at Bordeaux, Jan. 20, 1871. A. G. Canfield.

Pons Varolii: See Brain.

Ponta Delgada, pōn'tăa-del-gaa'dăă: town of the Azores islands, situated on the southern coast of St. Michael. Its

harbor is shallow and the roadstead outside the harbor unsafe, yet it has a large trade, especially in oranges to Great Britain, grain to Portugal, and earthenware to Brazil. Pop. about 17,500.

Pontchartrain, pon-char-trān′, **Lake** [named after Jérome Phélypeaux, Comte de Pontchartrain, Minister of Marine under Louis XIV.]: a lake of Louisiana, about 40 miles in its longest dimension E. and W. and 25 miles N. and S., the southern shore of which is but about 5 miles distant from and nearly parallel to the Mississippi river in its local easterly course in this region. It is separated on the W. by a peninsula of cypress-swamp from Lake Maurepas (named after Count Maurépas, son and successor of Pontchartrain), a much smaller lake, with which it is connected by the Pass Manchac. New Orleans communicates with the lake by a branch of the Louisville and Nashville Railroad, and by two canals navigable by schooners and smaller craft, one of which (see BORGNE) enters the head of the bayou St. John, by which the navigation is continued to the lake; the other is wholly artificial. These canals have their heads in "basins" in the rear of the city; they do not communicate with the Mississippi. The lake communicates with Lake Borgne and Mississippi Sound by the passes of the Rigolets and Chef Menteur, through which there is a tidal flow of the sea-water. Fort Pike and Fort Macomb defend these passes. An important commerce in lumber, firewood, bricks, etc., is carried on through the lake and the Rigolets. The northern shore of the lakes, a continuation westerly of the "pine-woods" region, is elevated and healthful. There are many places of resort on the shores of the lake.

Pont du Gard, pōn′dü-gaar′: the remains of one of the most magnificent Roman structures in France, consisting of three tiers of arches, on which the aqueduct which brought the water of the Aure to Nîmes crossed the Gard 10 miles N. E. of that city. See AQUEDUCTS.

Pontecorvo, pōn′tā-kōr′vō: town; in the province of Caserta, Italy; on the Garigliano, about 28 miles S. of Sora and 37 miles N. W. of Capua (see map of Italy, ref. 6–E). The old walls and towers, once very strong, are now in a ruinous condition. A bridge of Pelasgian construction connected the city with its suburbs. This bridge was broken down to check the march of Hannibal, and afterward restored. In 1860 it was blown up by the Bourbon troops, but was rebuilt soon after. In and near the town there are some fine churches, containing frescoes, and among the archives of the cathedral are Lombard, Gothic, and mediæval Latin MSS. The ruins of the ancient *Fregellæ* are distinctly traceable, and among them are found mosaics of great beauty. Bonaparte created Bernadotte Prince of Pontecorvo in 1806. Macaroni and works in plaster constitute the chief industries. Pop. 5,172.

Ponte, da: See BASSANO.

Pontefract, pom′fret, or **Pomfret**: town of Yorkshire, England; on the Aire; 13 miles S. E. of Leeds (see map of England, ref. 7–I). It has two churches, a grammar-school (founded in 1549), a town-hall, a market-hall; trades chiefly in grain, cattle, malt, and garden-produce. Pop. (1891) 9,702; of the parliamentary borough (which returns one member), 16,407.

Pontevedra, -vā′drăă: town; in the province of Pontevedra, Spain; at the head of the Bay of Pontevedra; on the Lerez, which is crossed by a noble bridge (*pons vetus*) built in Roman times (see map of Spain, ref. 13–A). The city is substantially built, and the surroundings are among the most fertile regions of Spain. There are sardine-fisheries and manufactures of hats and cloth. Pop. (1887) 19,996. The province of Pontevedra lies on the Atlantic Ocean, between the Minho and Ulla rivers. Area, 1,739 sq. miles. Pop. (1887) 443,385.

Pontiac: Indian chief; b. near the river Ottawa about 1720; son of an Ojibway woman; through the alliance of the Ojibways and Pottawattamies with the Ottawas became chief of the three tribes; became an ally of the French in Northern Michigan, and in 1746 defended Detroit against Indian attacks. He was present, it is believed, at Braddock's defeat in 1755. After the British in 1760 had displaced the French in the Northwest, Pontiac organized a conspiracy among the Indian tribes between the Ottawa and the lower Mississippi with the purpose of murdering the British garrisons at all points. In May, 1763, eight garrisons (ranging from Western Pennsylvania to Mackinaw) were destroyed or dispersed on the same day, and the whole frontier was ravaged. The attack on Detroit, led by Pontiac himself, was anticipated by the British, but the chieftain besieged the town May 12–Oct. 12, 1763, maintaining his force by food received from the Canadian settlers, who received in return promissory notes written on birch-bark, all of which Pontiac subsequently redeemed. Deserted by his followers, he still endeavored to arouse his people to the dangers in store for them, but in 1766 he was obliged to submit to the British rule. He was murdered at Cahokia, Ill., in 1769, by an Illinois Indian. See Parkman's *Conspiracy of Pontiac* (1867).

Pontiac: city; capital of Livingston co., Ill.; on the Vermilion river, and the Chi. and Alton, the Ill. Cent., and the Wabash railways; 33 miles N. N. E. of Bloomington, 93 miles S. S. W. of Chicago (for location, see map of Illinois, ref. 4–F). It is in an agricultural, coal-mining, and stock-raising region, and contains several mills, iron-foundry, shoe-factories, straw-paper factory, the Illinois State Reformatory, 2 national banks with combined capital of $100,000, and 3 weekly newspapers. Pop. (1880) 2,242; (1890) 2,784; (1900) 4,266.

Pontiac: city; capital of Oakland co., Mich. (for location, see map of Michigan, ref. 7–K); on the Clinton river, and the Detroit, Gr. Haven and Mil. and the Pontiac, Oxford and N. railways; 26 miles N. W. of Detroit. Within the county and a few miles from the city are over 400 lakes, with a total area of about 30,000 sq. miles, teeming with choice fish, and having on their shores the Michigan Military Academy and many club-houses, hotels, and summer residences. The city has a large trade in wool and agricultural productions, and contains the Eastern Michigan Asylum for the Insane, gas and electric lights, a national bank (capital $100,000), 2 State banks (combined capital $150,000), and 5 weekly newspapers. Pop. (1880) 4,509; (1890) 6,200; (1900) 9,769. EDITOR OF "GAZETTE."

Pontianak′: town of Borneo; on the west coast of the island, at the confluence of the Landak and the Kapuas, which from here to its mouth is called the Pontianak, and lined on both sides with impenetrable forests (see map of East Indies, ref. 7–D). Pontianak is the capital of the Dutch dominions of Western Borneo, the residence of the governor, and is defended by Fort du Bus. Its trade in diamonds, gold-dust, sugar, rice, cotton, and coffee is important. Pop., estimated, 15,000, most of whom are Chinese, and very few Europeans. Revised by M. W. HARRINGTON.

Pon′tifex [= Lat. *pons, pon′tis*, bridge (perhaps originally a path, road) + *fa′cere*, make]: a priest of the college of the pontifices, the foundation of which tradition carried back to Numa. Before the banishment of the kings the king himself was at the head of this college, but after that time it was presided over by a member of the college called the pontifex maximus, or chief priest, whose official residence was the old royal palace, the regia. The pontifices did not, like the flamens, have charge of the worship of particular divinities, but they exercised a general supervision over the public religion, interpreted and declared the pontifical law, managed the complex machinery of the Roman calendar, and acted as official advisers to the senate and magistrates in all religious matters requiring their attention. The college originally consisted of five members, including the pontifex maximus, but by the end of the republic it had been increased to fifteen, while under the empire new members were added to it without reference to a fixed number. At first vacancies were filled by the choice of the college itself (*coöptio*), later the pontifex maximus, and finally all of the pontifices were elected by the people. In imperial times the emperor was always the pontifex maximus. G. L. H.

Pontifical States: See PAPAL STATES.

Pontine Marshes [*Pontine* is from Lat. *Ponti′nus, Pompti′nus* for **Pometi′nus*, Pometian, deriv. of *Pome′tia*, ancient name of the place near which these marshes are situated]: a tract of marshy ground in the province of Rome in Italy. The marshes extend from the vicinity of Cisterna S. W. to the sea at Terracina, a distance of about 28 miles, with a mean width of little more than 5 miles. The level near Cisterna is about 30 feet above the sea, while at Terracina it dips below the sea-level. Both the marshes and the boggy and tangled forest on the low sands which bound them on the S. W. are very unhealthful during the warm season, and the miasma they exhale is borne by the south winds even to Rome. The ancient Romans made many par-

tially successful attempts to drain and reclaim this territory, built the Appian Way through the center of it, and constructed a navigable canal not far from the line of the road, quite down to Terracina. Pliny states that this district was once thickly inhabited and contained twenty or thirty large towns, besides numerous villages and hamlets. Several drainage schemes were promoted by the popes, especially by Pius VI., in the last quarter of the eighteenth century. See Prony, *Description hydrographique et statistique des Marais Pontins* (1813); Giordani, *Gita alle Paludi Pontine* (1872). Revised by M. W. Harrington.

Pontois, pōn'twăă', Jean Félix Honoré: lawyer and writer; b. at Thouars, France, July 26, 1837. After he came of age he took up legal work (1859) as a digester, and was made a judge of the tribunal of Annecy; was transferred to the tribunal of Algiers 1874; made judge of the appellate court of Algiers 1879; and successively judge of the court of Bourges, president of the tribunal of Tunis 1883, and president of the division of the court of appeals at Nîmes 1886; resigned in 1889, and entered into active and successful political work in opposition to the Boulangerists, with whose administration of affairs in Tunis he had been dissatisfied while there. He is a member of the Legion of Honor. He has published *Les Petits-fils de Tartuffe* (1864); *Réforme du Code d'Instruction criminelle et du Code pénal* (1871); *La Conspiration du Général Berton* (1877); and other political and judicial studies, as well as some theatrical plays, as *Les Hannetons*, *Dix Minutes d'Arrêt*, *La Robe de Chambre de Diderot*, etc. F. Sturges Allen.

Pontoon: See Bridges, Military.

Pontop'pidan, Erik Ludvigsen: historian and theologian; b. at Aarhuus, Jutland, Denmark, Aug. 24, 1698; studied theology at the University of Copenhagen; became professor in 1738; Bishop of Bergen, Norway, in 1747; chancellor of the University of Copenhagen in 1755. D. at Copenhagen Dec. 20, 1764. As a theologian he was a disciple of Spener; as an historical writer he was careful, generally accurate, and possessed of immense learning. His principal works, written in German, Danish, and Latin, are *Everriculum fermenti veteris* (1736); *Psalmebog* (1740); *Gesta et Vestigia Danorum extra Daniam* vols., 1740); *Menoza* (3 vols., 1742), a theological romance; *Glossariam Norvagicum* (1749); *Annales ecclesiæ Danicæ diplomatici* (1741–52); *Norges naturlige Historie* (1752; translated into English, London, 1755); *Den Danske Atlas* (7 vols., 1763–81), a topographical account of Denmark. D. K. Dodge.

Pontor'mo, Jacopo, di: painter; b. at Pontormo, near Empoli, Italy, in May, 1494; family name Carucci or Carrucci. He studied painting with his father, and afterward with Leonardo da Vinci, Albertinelli, and Piero di Cosimo successively, until in 1512 he became a follower of Andrea del Sarto, whose manner he finally adopted. His finest work is the fresco-painting of the *Visitation* in the court of the Annunziata in Florence. The fresco paintings of the *Deluge* and the *Last Judgment* for the Church of San Lorenzo in Florence have disappeared. He was the master of Bronzino, who painted under him in many of his works. Pontormo died at Florence, and was buried in the Church of the Annunziata, Jan. 2, 1557. A *Holy Family* and a portrait of Giovanni delle Corniole, in the Louvre, are good examples of his art; also the portrait of a boy in the London National Gallery. W. J. Stillman.

Pontus: an ancient territory of Asia Minor, lying S. of the Black Sea, between the Phasis and Halys. The name was first applied by Xenophon. Afterward it became an independent kingdom, and included the territory between Colchis, Armenia, Cappadocia, Galatia, and Paphlagonia. Its historic celebrity is mainly due to Mithridates VI. the Great (120–63 B. C.), who made it a great power, but who was conquered by Pompey 65 B. C. It became a Roman province 63 B. C. It is now comprised in the Ottoman vilayets of Sivas and Trebizond. E. A. Grosvenor.

Pontus Euxinus: See Black Sea.

Pontzen, Ernest: civil engineer; b. at Budapest, Hungary, Jan. 20, 1838; studied in the Polytechnic School of Vienna, and in the École de Ponts et Chaussées of France, graduating in 1860 at the head of his class; he was for four years in the service of the Austrian Railway Company; in 1864 was engaged by the Southern Railway of Austria, first as inspector of operation, and afterward placed in charge of the railways in Venice, upon completion of which he was for three years in charge of the works of the port of Trieste. In 1869–70 he was head of the main office of Kleim Brothers, where he worked out the complete plans of the Arlberg Railway and built a railway in Transylvania; in 1870–75 he was consulting engineer to the Anglo-Austrian Bank. In 1873 he visited the U. S. for study; in 1876 was member of the juries on railways and on industries of the Centennial Exposition. On his return he took up his permanent residence in Paris. He was a delegate of the French Government to the railway conference at Berne in 1886, and to that of St. Petersburg in 1892. He was sent to Russia by the French Government in 1890 to study the transportation of grain. His plans for the sewerage of Havre and of Cairo received first prizes. He is general manager of the Southern Railway of Spain and consulting engineer of the Peloponnesian railway in Greece. He has published many pamphlets, papers, etc., upon engineering subjects, has written many papers for the Society of Civil Engineers of France, and has published a treatise on *Methods of Construction*. His most important work, in which he was associated with E. Larvinne, is upon the railways of America. W. R. Hutton.

Pony [probably of Celtic origin; cf. Gaelic *ponaidh*]: a small form of the horse. The most famous European ponies are the Shetland, Iceland, Welsh, Dartmoor, Corsican, and Greek. In North America there are the Canadian, Sable Island, Gay Head, Sea Island, and mustang. These little animals are tough and spirited, but often vicious. The smallness and unusual growth of the hair, mane, and tail of many are due to exposure and scanty food for many generations.

Poodle [loan-word from Germ. *pudel*, small dog]: a dog distinguished by the extremely long and curly hair. This may vary from the wiry texture found in the Russian poodle to the woolly curls of the French breed, but should in all be thick and elastic. The color may be brown, white, or black, but not mottled, and the weight may vary from 5 to 40 lb. The head should be broad and carried high, ears long and well-clad, tail carried with an upward curve. Poodles are very intelligent and usually play an important part in exhibitions of trained dogs. F. A. Lucas.

Pool: in the U. S. and elsewhere, a game played on a table similar to that used in billiards, except that at each corner and midway of the two sides "pockets" are inserted. (See Billiards.) One cue-ball and object-balls numbered consecutively from one to fifteen are employed. In the beginning of a game the latter are usually arranged in the form of a pyramid, with the apex on what corresponds to the red-ball spot of a billiard-table. The cue-ball is placed anywhere behind the string-line, and is played at the numbered balls, the object being to drive them into the pockets; a player's turn ends with the first shot in which he fails fairly to pocket one, and the next player plays the cue-ball from where he finds it, or, if pocketed, from behind the string-line. There are many varieties of the game, each with elaborate rules. In *pyramid pool* each ball pocketed counts one, and (when only two play) the first to secure eight wins. Failing to hit any object-ball, or driving the cue-ball off the table or into a pocket, involves the forfeiture of one ball (together with any balls pocketed in the shot itself), and this is placed on the spot or as near as may be directly behind it. In *fifteen-ball pool* the forfeit is three points, and each ball secured counts its number. *Continuous pool* is played in tournaments; it is like pyramid pool, except that the game consists of any number of balls or points agreed on, and forfeitures are deducted from the player's score, instead of a ball being replaced on the table.

In Great Britain games like the above are called *pyramids*, the term pool being applied to a game played for a stake on a pool-table, each player having one ball. The object of this game is to drive the balls of opponents into the pockets; for each ball so pocketed the player receives from its owner a stipulated sum; when one's ball has thrice been so pocketed the player withdraws from the game and his share of the stake, but he may on certain conditions secure another "life" by adding a further sum to the stake. The player whose ball last remains on the table wins the game.

Poole: town; in Dorsetshire, England; on the estuary of the Frome (see map of England, ref. 14–C). It has some ship-building and manufactures of sail-cloth and cordage, and exports pipeclay and potter's clay. Pop. (1891) 15,405.

Poole, John: humorist; b. in England in 1792; author of a large number of successful dramas and farces, of which the best known were *Paul Pry* (1825), *Deaf as a Post*, *Turn-*

ing the Tables, and an adaptation of Shirley's *Wife's Stratagem*. He also wrote novels, essays, and character sketches, among which *Little Pedlington and the Pedlingtonians* (2 vols., 1839) took high rank for originality and racy humor. In his last years Poole enjoyed a pension from the civil list. D. in London, Feb. 5, 1879.

Poole, Matthew: author; b. at York in 1624; educated at Emmanuel College, Cambridge; took orders in the Church of England, and became rector of St. Michael-le-Querne, London, but was ejected for nonconformity in 1662; wrote much against Roman Catholicism; is said to have narrowly escaped being murdered at the time of the "Popish plot," and removed to Amsterdam, where he died Oct., 1679. Author, among other works, of a famous compendium of the critical views of 150 biblical commentators, entitled *Synopsis Criticorum* (5 vols. fol., London, 1669–76), and of *Annotations upon the Holy Bible* (2 vols. fol., 1683–85), left unfinished, but completed from Isaiah lviii. by eminent Nonconformists (reprinted 1842, 3 vols.).

Poole, William Frederick, LL. D.: bibliographer; b. at Salem, Mass., Dec. 24, 1821; graduated at Yale College 1849; published while there an *Index to Subjects in Reviews and Periodicals* (1848), subsequently expanded into the valuable *Index to Periodical Literature* (1853, and 3d ed. 1882). He was librarian of the Boston Mercantile Library 1852–56, of the Boston Athenæum 1856–69, of the Cincinnati Public Library 1869–73, of the Chicago Public Library 1873–87, when he became librarian of the Newberry Library, Chicago. Author of *The Battle of the Dictionaries* (1856); *Websterian Orthography* (1857); and *Cotton Mather and Salem Witchcraft* (1869). D. at Evanston, Ill., Mar. 1, 1894. H. A. Beers.

Poo'na: town of British India; capital of the district of Poona, in the Presidency of Bombay; on the Muta, near its influx in the Mula; on a dry and treeless plain, 2,000 feet above the sea (see map of South India, ref. 3–C). Although the climate is hot and dry, and water is scarce, the place is considered healthful, and has been made the station of the army of Bombay. The city is well built, and contains the palace of the former Mahratta rulers, many fine barracks, a college, and several other educational institutions. It is connected with Bombay by railway. Pop. (1891) 160,460.

Poore, Benjamin Perley: journalist; b. at Newbury, Mass., Nov. 2, 1820; learned the printing business; edited *The Southern Whig* at Atlanta, Ga., 1838–40; became an *attaché* of the U. S. legation in Belgium 1841; made a valuable collection of historical MSS. from the French archives for the State of Massachusetts 1844–48; traveled in Egypt, Palestine, and other Eastern countries as correspondent of the Boston *Atlas* 1843–48; published *The Rise and Fall of Louis Philippe* (1848); *Campaign Life of Gen. Taylor* (1848); *The Early Life of Napoleon* (1851); editor and proprietor of *The American Sentinel* (1851); editor of *Congressional Directory* in 1867; compiled *A Descriptive Catalogue of the Government Publications of the United States 1774–81* (1885); *Reminiscences of Sixty Years in the National Metropolis* (1886). D. at Washington, D. C., May 30, 1887.

Poore, George Vivian: See the Appendix.

Poor Laws: See Pauperism.

Poorten-schwartz, J. M. van der: novelist, whose pen-name is *Maarten Maartens*; b. in Holland in 1857; lived when a child in England, but was educated in Germany and at Utrecht University; became a barrister, and was destined by his parents for a political career, but devotes himself entirely to literature and the life of a country gentleman. His works which are written in English include *The Sin of Joost Avelingh* (1890); *An Old Maid's Love* (1891); *God's Fool* and *A Question of Taste* (1892); *The Greater Glory* (1894); and *My Lady Nobody* (1895).

Popayan': capital of the department of Cauca, Colombia; 3 miles from the left bank of the Cauca, near the source of that river; on the inland route from Bogotá to Quito, and 200 miles S. W. of the former (see map of South America, ref. 2–B). It is built on a beautiful plain near the foot of the Puracé volcano, 5,712 feet above sea-level. It was founded by Benalcazar in 1536, on the site of the Indian village which had been ruled by the chief Payan; for a time the district formed the province or "kingdom" of Popayan. The city was important for its commerce, for gold-mines, and for a mint established in 1749; but it suffered greatly during the revolution and in subsequent civil wars, and is now much decayed. It is a bishop's see, and has a university and college. Pop. about 8,000. Herbert H. Smith.

Pope [O. Eng. *pāpa*, from Lat. *pa'pa*, papa, father, bishop, (later) pope]: the ordinary name of the Bishop of Rome.

Origin of the Name.—The name was originally given to all bishops as signifying among other things the spiritual generation in baptism and their supreme responsibility. From the beginning of the sixth century there was a growing tendency in the West to restrict its use to the Bishop of Rome. Since Gregory VII. (1073–85) it has been formally reserved to the Bishop of Rome, as the usual title signifying his primacy of honor and jurisdiction within the Roman Catholic Church.

Beginnings of the Papacy.—The papal idea can be traced from primitive times. No other see ever claimed the supreme ecclesiastical primacy as the Roman see has from the most remote antiquity, and there are strong arguments to show that this claim was allowed. The magisterial letter of St. Clement to the Corinthians (about A. D. 96); the visit of St. Polycarp to Rome (Euseb., H. E. V., 24); the testimony of St. Irenæus (*Adv. hæreses*, iii., 3); St. Victor's display of world-wide authority and his power to exclude from the "common unity"; the claim to the "power of the keys," and the citation of Matt. xvi. 19, made by some pre-Constantinian pope, whom Harnack thinks to be Victor (see opp. S. Cypriani, ed. Hartel., vol. iii., p. 92, *seq.*); St. Stephen's judicial action in hearing appeals, and his vindication of the true tradition on baptism (*ibid.*, vol. ii.); St. Dionysius of Alexandria writing to his namesake of Rome for guidance, "so that he might not err" (St. Athanasius, *De Sententia Dionysii*); the conduct of the Emperors Decius and Aurelian; the ambition of early arch-heretics to obtain the favor of the Roman Church—all these indications, and several others previous to the peace of the Church (A. D. 312), show that Christian public opinion recognized at Rome the chief authority of the new religion. That this authority has been exercised since then in every age, both East and West, needs no proof, nor need the revolts against it, the disuse of it, the minimizing of its range, blind us to the fact of its existence or tempt us to modify its essential outlines. Of the latest definitions of the papal authority the highest and most authentic are those of the general councils of Florence (1439), Trent (1563), and the Vatican (1870). These great assemblies of Catholic bishops and doctors added nothing new to the ancient concept of the papal authority, but asserted in detail and in more definite phraseology what had been the rule in the Catholic Church from the remotest times. For a compendious collection of the earliest references to the papal authority, see Allnatt, *Cathedra Petri* (London, 1883). Among the best works on the early history of the Roman Church are Doellinger, *Hippolytus und Callistus*; Hagemann, *Die römische Kirche* (Freiburg, 1864); and Schroedl, *Geschichte der Päpste und der römischen Kirche in der Urzeit des Christenthums* (Mentz, 1888). The prefaces of Duchesne in his edition of the *Liber Pontificalis* are henceforth indispensable. See Rivington, *The Primitive Church and the See of Peter* (London, 1894).

Authority of the Pope.—The pope enjoys a primacy or supremacy of honor and jurisdiction over the whole Church, individually and collectively. He is the supreme teacher or doctor, and in this capacity is infallible when speaking as such—i. e. *ex cathedra*—or defining a doctrine of faith or morals to be held by the whole Church. He is the supreme legislator in the Church, and can interpret, modify, and dispense in all matters of ecclesiastical law. He is the supreme judge of the faithful, whether members of the hierarchy or laymen, and can hear and decide all major causes and appeals from lower tribunals. He is the supreme administrator, and as such has power to watch over the divine service, and to appoint, remove, or transfer bishops. He is the supreme supervisor, and in this quality receives regularly relations from bishops and other chief ecclesiastical authorities of the state of religion within the limits of their jurisdiction. This is supplemented by stated personal visits paid by the bishops, and known as the Visitation to the Tombs of the Apostles (SS. Peter and Paul). The universal ecclesiastical jurisdiction of the pope is immediate, ordinary, and truly episcopal, and includes the right to send agents who may represent his person and authority before the churches, or even before the temporal authorities. The authority described is vested in the pope by divine right, because he is the legitimate successor of St. Peter, and as such truly the Vicar of Christ, the chief bishop of the Catholic world, the visible and ministerial head of the whole Church, whose invisible and eternal head is Jesus Christ. The honorary distinctions of the pope in title,

dress, and functions are many. For an account of them see Laemmer, *Institutionen des Katholischen Kirchenrechts* (Freiburg, 1892). Cf. also Smith, *Elements of Ecclesiastical Law* (vol. i., New York, 1887).

The election of the pope, originally performed by the clergy of Rome and the suburban bishops, with participation of the faithful, has undergone many vicissitudes, as may be seen in Lucius Lector, *Le Conclave* (Paris, 1893). It was Nicholas II. who definitely placed it (1059) in the hands of the cardinals, and, with some modifications, this is the present method of the election. The cardinals meet on the eleventh day after the pope's decease in a series of double cells (conclave), one for each cardinal, his secretary and chamberlain, and on the twelfth day the election begins. They are not bound to elect a cardinal—only hereties and simoniacal persons are excluded—and the closing act of the election takes place in a chapel specially reserved for that purpose. Certain Catholic courts have been wont to exercise the right to exclude objectionable candidates, but there exists no juridical acknowledgment of this so-called "right of exclusion." When the pope-elect accepts the result of the conclave he changes his baptismal name (as a rule) and chooses another. If he be not a bishop, he is always consecrated by the Cardinal-bishop of Ostia. The reception of the pallium, the solemn coronation, and the "possession" of the Lateran Church take place after this, but the entire papal jurisdiction passes into his hands when he accepts the election.

Temporal Power of the Pope.—The origins of the temporal power are visible in the last deeades of the sixth century, especially under Gregory the Great. National and religious feeling contributed to its growth in the first half of the eighth century, and in the latter half of the same the papacy entered the list of European states by the formal donations of Pepin and Charlemagne. The spurious *Donatio Constantini* has been greatly overrated in the discussion of the evolution of the temporal power (*English Historical Review*, July, 1894). Under various forms and with varying boundaries the papal state existed through the Middle Ages as a spontaneous, legitimate growth, and its long, pacific possession through twelve centuries was no despicable element in the propagation of Christian faith and culture. The violent usurpation of Napoleon I. was undone by the Congress of Vienna (1815). Beginning with 1860 the Piedmontese government encroached on the states of the Church, and in 1870 they were incorporated into the kingdom of Italy. The popes have never recognized the fact, nor accepted the law of guarantees by which the Italian kingdom undertook to regulate its internal relations with the papacy.

The Papal Government.—The ordinary administration of the papal authority is carried on through the *Curia Romana* —i. e. the body of officials and agents whom the pope employs in his government, whether in the character of supreme head of the Church, as chief metropolitan of Italy, as Bishop of Rome, or as a temporal authority. The curial jurisdiction, though not distinct from the papal, is ordinary, i. e. legally fixed and attached to the office. The curia consists in general of cardinals, prelates, and *curiales*, or minor officials. The cardinals form the papal senate, and are the ordinary advisers of the pope. The solemn assembly of all the cardinals in the latter capacity is known as the *consistory*, whieh in turn may be either private or public; the latter kind usually takes place twice a year, and is only a formal ratification of acts already accomplished.

Since Sixtus V. (1585–90) the supreme jurisdiction of the pope is regularly exercised through a number of congregations, over which, as a rule, some cardinal presides in the quality of prefect, aided by assessors, consultors, secretaries, advocates, etc. Questions of law and finance, petitions of the faithful, the expedition of bulls, briefs, apostolic letters, etc., have each their special tribunal or agency, some of them very ancient, like the *Sacra Rota* and the *Cancellaria apostolica*. The cardinal-secretary of state is the official representative of the pope before foreign courts or states, and is the ordinary head of the body of legates, nuncios, ablegates, etc., through whom the pope keeps in touch with the temporal and spiritual affairs of Christendom.

Authorities and Literature.—The oldest lives of the popes are found in the *Liber Pontificalis* (ed. Duchesne, Paris, 1886–92), and in Watterich, *Vitæ Romanorum Pontificum* (Leipzig, 1862). There is a *catalogue raisonné* of their letters for the first twelve centuries in Jaffé, *Regesta Romanorum Pontificum* (2d ed.). The papal correspondence since the beginning of the thirteenth century is (1894) being published from the Vatican archives through a number of investigators, individual and collective. The *Bullarium Romanum* (ed. Coquelines, 19 vols., Rome, 1739–44, with later continuations, Turin, 1857–72) contains the text of a great many public papal documents in later centuries. Platina, Onofrio, Panvinio, Ciacconio, and Oldreinus are the post-Renaissance continuators of the "old lives of the popes." It is difficult to recommend any one work as absolutely reliable for the lives of all the popes. A multitude of monographs on individual popes, fixed epochs, and problems appear yearly. Their spirit differs according to the education and prepossessions of the writer, but there is a growing tendency toward a more calm and objective view of the papal history. A model of this new method is Pastor's *History of the Popes in the Period of the Renaissance* (Freiburg, 1886). Similar monographs of Creighton and Ranke on the popes since the Renaissance, of Gregory VII., by Voigt, and Innocent III., by Hurter, are valuable. An excellent means to obtain accurate information concerning a given pope is to consult U. Chevalier's *Répertoire des sources historiques du Moyen Âge* (Paris, 1877–88), where the sources and the relative literature up to date are given. Artaud de Montor's *History of the Popes*, and Groene's *Geschichte der Päpste* (Regensburg, 1875), are popular and useful books. The books of De Maistre, *Du Pape*, Doellinger, *Kirche und Kirchen, Papstthum und Kirchenstaat*, and Murphy, *The Chair of Peter*, are also to be read. Several foolish fables once current are exploded in Doellinger's *Papstfabeln* (Stuttgart, 1890).

List of the Popes.—The following list is taken from the chronological work of Father Gams, O. S. B., *Series Episcoporum Ecclesiæ Catholicæ* (Regensburg, 1873). The dates of accession of the popes up to the first part of the third century are approximative, but rest on sound calculations, as may be seen from the writings of Duchesne, De Rossi, Lightfoot, and others, as against the theory of Lipsius. Toward the end of the tenth century the custom arose of taking a new name on the occasion of election to the papacy. The usual mode of cessation of the papal office is by death, but it can be resigned, as was done by Celestine V. and Gregory XII. SS. Liberius, Silverius, and Martin were exiled for a time or forever, but they remained juridically popes to their death. There are some knotty problems in the long chronology, but they are not unsolvable, as may be seen from the prefaces and notes of Duchesne in his edition of the *Liber Pontificalis*. For a charming account of the tombs of the popes see Ampère's translation of Gregorovius's *Die Grabdenkmäler der Päpste*.

JOHN J. KEANE.

Pope, ALEXANDER: poet; b. in London, May 21, 1688; d. at Twickenham, May 30, 1744. His father was a retired linen-draper and a Roman Catholic, and shortly after the poet's birth the family took up their residence at Binfield, in Windsor Forest. Pope was sickly and deformed, and was educated at home by the family priest and at two small schools. He was very precocious, and at the age of fifteen translated into verse the first book of the *Thebais* and wrote an epic poem, *Alcander*, which was never published. His first publication was a series of *Pastorals* (1709), musically versified, but, like all Pope's poetry of natural description, tame and artificial. These were followed by the *Essay on Criticism* (1711), a didactic poem on the rules of taste; *The Rape of the Lock* (1712, and much enlarged in 1714), a brilliant mock-heroic, occasioned by a quarrel between Lord Petre and Miss Arabella Fermor; the *Messiah* (1712), a sacred pastoral modeled upon Vergil's *Pollio*; *Windsor Forest* (1713), a descriptive piece; *The Temple of Fame* (1715), a paraphrase of Chaucer's *House of Fame*; and a collection of his poetical works in 1717, which included his only experiments in the poetry of pathos and passion, the *Elegy to the Memory of an Unfortunate Lady* and *Eloisa to Abelard*. Meanwhile he had undertaken a verse-translation of Homer. The first volume of the *Iliad* appeared in 1715, and the last in 1720; the *Odyssey*, in which he had the help of Fenton and Broome, in 1725. Pope's *Homer* was published by subscription and brought him about £9,000. After his father's death in 1717 he bought a little villa, with five acres of ground, at Twickenham on the Thames. This was his home for the remainder of his life, where he amused himself with landscape-gardening and received his friends, among whom were Swift, Gay, Arbuthnot, and Henry St. John, Lord Bolingbroke. Pope was sensitive and spiteful. He had literary or personal quarrels with Addison, Colley Cibber, Curll the bookseller, John Dennis the critic, Lady Mary Wortley Montagu—for whom he had formerly professed warm admiration—Theobald the Shakspeare editor, and many others. He paid off his grudges in his clever and malicious satires. Stung by the incessant lampoons of the small Grub Street hacks and penny-a-liners, he crucified them all in his *Dunciad*, an epic of the dunces, the first edition of which was published in 1728, and a final edition, with *The New Dunciad*, or fourth book, added in 1743. In 1732–34 was published the *Essay on Man*, a moral didactic poem in four books. This poem abounds in pithy sayings and sententious maxims which have become universally current. As a philosophical poem it is neither coherent nor consecutive. It expresses in popular shape and with great verbal cunning ideas taken from the Leibnitzian optimism which Pope had caught from the conversations of his friend Bolingbroke, but which he himself imperfectly understood. From 1731 to 1738 he wrote and published the satires and verse-epistles which, under the titles *Moral Essays* and *Imitations of Horace*, form, perhaps, his most characteristic and most enduring work. Pope was not a great poet; he seldom touches the heart or stimulates the imagination. His translation of Homer is brilliant but false. His much-admired *Eloisa to Abelard*, though splendid in expression, is rhetoric rather than poetry; but he was a great verbal artist, and excelled especially in the art of putting things. He is more frequently quoted than any English poet with the exception of Shakspeare. He brought the mock epic of artificial society, the Horatian verse-essay, and the formal satire to the highest perfection, and he gave the heroic couplet the greatest possible smoothness, variety, and point. His influence in English poetry was supreme throughout nearly the whole of the eighteenth century. H. A. BEERS.

Pope, FRANKLIN LEONARD: See the Appendix.

Pope, JOHN: soldier; b. at Louisville, Ky., Mar. 16, 1822; graduated at the U. S. Military Academy, and commissioned brevet second lieutenant of topographical engineers July 1, 1842, captain 1856. Appointed brigadier-general of volunteers May 17, 1861, he held important commands in Missouri, and in Dec., 1861, surprised a Confederate camp at Milford, which he captured with large supplies, thus forcing the Confederate general Price to Southeastern Missouri; following up his success, now in command of the Army of the Mississippi, in co-operation with Admiral Foote New Madrid was taken (Mar. 14, 1862). He was made major-general Mar. 21, 1862, and on Apr. 8 captured Island No. 10 in Mississippi river, with upward of 6,500 prisoners and about 125 cannon and 7,000 small-arms. Uniting with the combined armies under Gen. Halleck, he participated in the advance upon Corinth, and upon the evacuation of that place (May 30) pursued the Confederate army as far as Baldwin. He was made a brigadier-general in the regular army (July 14, 1862) and placed in command of the Army of Virginia, to which was added the Army of the Potomac. The unsuccessful battle of Manassas, or Second Bull Run, was fought Aug. 29–30, and the next day (Sept. 1) that of Chantilly; a few days later Pope resigned his command, and resumed command of the department of the Northwest. He charged the failure of his operations in Virginia to the misconduct of Gen. Fitz John Porter at the battle of Manassas. (See PORTER, FITZ JOHN.) Subsequently he commanded the departments of the Missouri, the Lakes, and the Mississippi. He became major-general Oct. 26, 1882; retired Mar. 16, 1886. D. at Sandusky, O., Sept. 23, 1892. He published *Campaign of Virginia of July and August, 1862* (Washington, 1865).

Pope, John Henry: statesman; b. in the Eastern Townships, Province of Quebec, Canada, in 1824; educated at the High School in Compton; was a farmer in early life. He represented Compton in the Canadian Assembly 1857–67, and in the Dominion Parliament 1867–89; was Minister of Agriculture 1871–73 and 1878–85, and Minister of Railways and Canals 1885–89. In 1880 he visited London with Sir John A. Macdonald and Sir Charles Tupper, and took active part in the negotiations which led to the Pacific Railway contract. D. Apr. 1, 1889. N. M.

Popham, Sir John: b. at Wellington, Somersetshire, England, in 1531; entered Baliol College, Oxford, then the Middle Temple, and in 1571 became sergeant-at-law; afterward was appointed solicitor-general and gave up his sergeantship; Speaker of the House of Commons 1581; attorney-general 1585, in which office he conducted the trials of those implicated in the Babbington conspiracy; lord chief justice of the king's bench June 8, 1592, which office he held for fifteen years, during which he was noted for his extreme severity to prisoners and his impartiality in trials involving party disputes. He presided at the trials of Sir Christopher Blunt, Sir Walter Raleigh, Guy Fawkes, and other noted persons. He was the author of a part of Popham's *Reports*, which are of little authority. D. June 10, 1607. He was active in colonization schemes, and was one of the patentees associated with Sir Ferdinando Gorges and George Popham. —George Popham, b. in Somersetshire, England, about 1550, was a brother of Sir John Popham, and was, with him and Sir Fernando Gorges, one of the patentees of an extensive territory in the present State of Maine in the U. S. He sailed from Plymouth May 31, 1607, with two ships and 100 men, and landed Aug. 15 at the mouth of the Kennebec or Sagadahoc river, where they built a rude fort which they named Fort George. This was the first English settlement in New England, but in the spring of 1608, after the death of Popham (Feb. 5), it was abandoned by the colonists, who returned to England.—Sir Francis Popham, probably a son of Sir John, was also a patentee of New England and was a member of Parliament in 1620. F. Sturges Allen.

Popish Plot: See Oates, Titus.

Poplar [M. Eng. *popler*, from O. Fr. *poplier* > Mod. Fr. *peuplier*, *peuple*: Ital. *pioppo*: Span. *pobo* < Lat. *pō'pulus* and Vulg. Lat. **plōpus*, poplar]: properly the name of any tree belonging to the genus *Populus* and family *Salicaceæ*, but popularly and very incorrectly extended to the Tulip-tree (*q. v.*) of the U. S. The true poplars have a light, white wood, which is very perishable if exposed to the weather or if not carefully seasoned. The common balsam-poplar, tacamahac, or balm-of-Gilead tree (*P. balsamifera*) produces a copious fragrant resin on its buds; it is a handsome tree of North America and Asia. Several of the poplars of the U. S. are called cottonwood, although this name is properly applied to the Carolina poplar (*P. monilifera*). (See Cottonwood-tree.) The cottonwoods are useful for fuel and timber, but liable to warp unless prepared with care. The white poplar, or American aspen, *P. tremuloides*, is a handsome tree, as is the *P. grandidentata*. *P. heterophylla* is a large cottonwood with large, downy leaves. The abele, or silver-leaf poplar of Europe, *P. alba*, is frequently planted in the U. S. It spreads rapidly by the roots. Its timber is excellent, as also is that of the gray and black European poplars, *P. canescens* and *nigra*. The Lombardy poplar (*P. nigra*, var. *italica*) is remarkable for the singular upward tendency of its branches. One of the most important of the more recent economic uses of the poplars is the manufacture of paper-pulp from their wood. Several poplars from Russia have been introduced into the U. S. for planting in the northern prairie States. Of these the best is *P. laurifolia*, the Certinensis poplar, which is the European representative of the American cottonwood. For an account of the cultivated poplars, see Bulletin 68, Cornell University experiment station. Revised by L. H. Bailey.

Poplar Bluff: city; capital of Butler co., Mo.; on the Big Black river, and the St. L., Iron Mt. and Southern Railway; 74 miles W. S. W. of Cairo, 166 miles S. of St. Louis (for location, see map of Missouri, ref. 8–J). It has manufactories of lumber, staves, pottery, brick, and tile, and contains a State bank with capital of $50,000, and 2 daily and 2 weekly newspapers. Pop. (1890) 2,187; (1900) 4,321.

Popocatepetl [Aztec, smoking mountain]: a quiescent volcano of Mexico: on the confines of the states of Mexico and Puebla; 43 miles S. E. of Mexico city; height about 17,800 feet, or 380 feet less than Orizaba, the highest peak in Mexico. From about 14,800 feet (in January) it is covered with snow; below this there is a broad zone of pine- and oak-forest. The ascent is difficult. There are two principal craters; the upper and more recent one is about 1,000 feet deep and has large deposits of sulphur, which are regularly mined. There is no clear record of an eruption within historical times; sulphur fumes and occasionally smoke are given out. Herbert H. Smith.

Poppy [M. Eng. *popy* < O. Eng. *popig*, from Lat. *papaver*, poppy]: any plant of the genus *Papaver* of the family *Papaveraceæ*. The flower is large and showy, the corolla being generally four-petaled and the calyx two-leaved. The stigma is in the form of rays, ranging from four to twenty in number. It springs directly from the ovary and persists upon the capsule. The latter is one-celled, though with imperfect partitions, and contains numerous seeds which escape by pores under the flaring stigma. The poppy is an annual or perennial herbaceous plant, and abounds in a milky juice. There are about a score of species, natives of Europe and Asia, most of which are found only in the warm temperate regions. By far the most important species is *P. somniferum*, from which the drug opium is obtained. (See Opium.) There are several varieties of this species, of which the most prominent are called the *white* and *black* poppy, respectively, from the color of the seeds. The flower of the former is white—that of the latter generally red or violet, though also sometimes white. This species of poppy has been known from a remote period in the countries bordering on the eastern coast of the Mediterranean, and is now extensively grown in Asiatic Turkey, Persia, Egypt, Europe, India, and China. In the Oriental countries it is cultivated for opium, but in France and Germany principally for a bland fixed oil, *poppy-oil*, found in the seeds. This oil exists in the seeds in about the proportion of 40 per cent., is entirely devoid of narcotic properties, and is used extensively for the same purposes as olive-oil, which it much resembles. In England there occurs in abundance a species of poppy called the *red poppy* or *corn-rose* (*P. rhœas*), having a fiery-red flower, the scarlet petals of which are used in pharmacy to impart a brilliant color to mixtures. In the U. S. the *P. somniferum* has been naturalized, but is cultivated principally as a garden-flower. The Iceland poppy (*P. nudicaule*), with white and yellow long-stalked flowers, is a spring-flowering species which is grown for ornament. Revised by L. H. Bailey.

Poppy Family: the *Papaveraceæ*; dicotyledonous herbs, with a white or red latex; leaves alternate; flowers perfect; perianth double, the sepals two, the petals four to eight, or more; pistil one, superior, compound, one-celled, of two to sixteen carpels, placentæ two to many, parietal; ovules usually many. About 160 species are known, mostly natives of the temperate and sub-tropical regions of the northern hemisphere. As here treated the family includes a considerable number of plants cultivated for their beautiful flowers and foliage, e. g. the California poppy (*Eschscholtzia californica*), blood-root (*Sanguinaria canadensis*), prickly poppy (*Argemone*, of several species), poppy (*Papaver*, of many species, including *P. somniferum*, the opium-poppy), bleeding-heart (*Bicuculla spectabilis*), fumitory (*Adlumia fungosa*), and many species of *Corydalis* and *Fumaria*.

Charles E. Bessey.

Population [from Lat. *popula'tio*, liter., peopling, deriv. of *popula're*, people, populate, deriv. of *po'pulus*, people, whence Eng. *people*]: the total number of inhabitants of a country, district, city, or region. The population of any part of the earth's surface is determined by one or more of several causes. The most important of these may be enumerated as, first, adaptation of soil and climate to produce food; second, natural advantages for the manufacture of articles desired; third, facilities for moving products from regions where there is excess to regions where there is scarcity; fourth, enterprise and ingenuity of men in availing themselves of existing advantages; and, fifth, knowledge and public spirit in warding off the natural and artificial checks upon increase of population. See Political Economy.

The tendency of all animal as well as vegetable life to increase in geometrical ratio is kept in check by various counteracting influences. In the case of man not only war and pestilence but also certain social conditions tend to retard the natural increase. In a complicated society where there are already marked social distinctions it is noteworthy that the increase among the poorer classes is more rapid than

among the rich. Malthus and others have accounted for this difference by an absence of prudential conditions on the part of the poor. Where there is no hope of bettering the condition there is a tendency to recklessness of indulgence, but where wealth and social distinctions have been established marriages on the part of the wealthier classes are often postponed and consequently the number of children born is diminished.

Until recently the various natural and artificial checks upon the growth of population have very nearly counterbalanced the tendencies to increase. The introduction of civilized methods of government into countries formerly barbaric has lessened war, famine, and pestilence, and thus removed some of the most powerful checks upon growth. The general advances of civilization have tended in the same direction. The more general prevalence of hygienic methods of life, greater care in furnishing supplies of untainted water, a better understanding of the causes of various diseases and the means of preventing them, and, above all, the more general adoption of sanitary drainage, have tended very greatly to diminish the death-rate and so remove some of the checks upon the increase of population. The most powerful of all influences in this direction have been the methods and facilities introduced within the nineteenth century for the more easy distribution of surplus products. Regions which formerly seemed incapable of supplying the necessities of mankind are now supplied from remote regions, and the consequence is that all over the civilized world population has increased with a rapidity hitherto entirely unknown. Within one century the population of the various countries of Europe has increased more than it had increased for several centuries before. The following table will show not only that this tendency is still going on in the Old World as well as in the New, but also will enable the reader to judge as to the comparative rate of increase in the cities and in the several countries:

* No census since 1879.

The density of the population per square mile in various countries in 1891 is indicated by the following figures: Belgium, 535·81; the Netherlands, 359·55; Great Britain, 311·88; China, 295·07; Japan, 264·59; Italy, 263·59; Germany, 234·05; France, 187·26; Switzerland, 184·69; Denmark, 162·72; Austria-Hungary, 161·88; India, 150·43; Spain, 84·23; Russia, 45·75; U. S., 20·77. The most recent estimate of the total population of the world is fourteen hundred and eighty millions. C. K. ADAMS.

Porbeagle: a shark of the genus *Lamna*, especially *L. cornubica*, a species common in the North Atlantic, which reaches a length of 10 feet. The porbeagles have rather slender teeth and feed on fishes.

Porcelain: See POTTERY AND PORCELAIN.

Porcelain, Réaumur's: a porcelain-like substance, first obtained by Réaumur by devitrifying ordinary glass. Excessively slow cooling will sometimes produce devitrification, particularly in very calcareous glasses, but it often oc-

curs in actual glass-working as an effect of careless and repeated heating and cooling. The glass becomes opaque, tougher, and less susceptible to fracture from sudden heating and cooling, having really something of a porcelain-like character. It is attributed to the formation of crystalline compounds in the mass, which, when once formed, are difficult of refusion.

Porch: a covered and partly inclosed approach to an entrance-door, as of a church or dwelling-house; also, by extension, a covered or partly inclosed room or hall not necessarily leading into or connected with an inclosed building; a covered promenade, or portico: in this sense the term is going out of use; no one would call the Stoics the philosophers of the *porch*, but the word portico or stoa would be used. In the first sense, the porch of a Greek or Roman temple, the *pronaos*, might be the first thing entered from without, or might be inclosed by the peristyle or continuous portico of columns; it was an outer vestibule. The porch of a Gothic church was sometimes such a vestibule, projecting like a small wing or pavilion from the larger structure, and was sometimes merely a deeply recessed doorway, as in the great cathedrals. In this latter case the actual working thickness of the wall of the building was often added to by an outer gable or screen, so as to make the depth of the porch greater. In modern times the *carriage-porch* is built well outside of the main structure, and has this peculiarity that the carriage is not to enter the building, but only to discharge or take up its passengers and then pass on. A carriage-porch differs from a marquise in being more solid and architectural. Russell Sturgis.

Porcupine [M. Eng. *porkepyn*, from O. Fr. *porc espin*, liter., spine-hog < Lat. *por'cus*, pig + *spi'na*, spine, thorn]: any one of various rodents characterized by the development of sharp spines among the hairs. These spines or quills are really greatly exaggerated hairs, and almost every degree of development, from soft hairs to strong, stiff spines, may be found in the same animal. These quills, which are the weapons of the porcupine, can be erected by means of peculiar muscles, and the animal, when attacked, bristles up and charges backward. The spines are finely barbed at the tip, and frequently become detached and stick in the assailant's hide or nose, and this has given rise to the fable that the porcupine shoots his quills. Porcupines belong to two distinct groups—the *Hystricidæ*, with the genera *Hystrix*, *Acanthion*, and *Atherura*, peculiar to the Old World, and the *Spalacopodidæ*, with the genera *Erethizon*, *Cercolabes*, and *Chætomys*, restricted to America. By many zoölogists these two groups are considered as divisions of one family. The best-known species, the African porcupine (*Hystrix cristata*), found in Spain, Sicily, Italy, and Northern Africa, is a stout, heavily built animal, a little over 2 feet in length, with a crest of very long, stiff hairs down the nape. The quills on the hinder part of the body are very long, and, like the hairs, marked with rings of black and white. The quills upon the short tail are truncated and open at the ends. The animal dwells in burrows or crannies among the rocks, lives on vegetables, and is sometimes sold in the markets for food. The common porcupine of North America, *Erethizon dorsatum*, is prevailingly gray or blackish, and large specimens attain a total length of nearly 3 feet. The quills are abundant and very sharp, but are comparatively short, being in winter almost concealed by the long hair. The tail is of considerable length, and the animal strikes with it very effectively. This species is found from Maine westward through the northern part of the U. S. and over a great part of British America. In the West it is replaced by another species, *Erethizon epixanthus*, distinguished by the yellowish color of the long outer hairs. These animals climb readily, live on leaves and bark, and are extremely fond of salt, sometimes eating into barrels of salt provisions stored by lumbermen. The South American porcupines of the genus *Cercolabes*, or *Synetheres*, which range from Mexico to Brazil, are distinguished by long prehensile tails. They are thickly clad with short spines. The Brazilian porcupines of the genus *Chætomys* are characterized by short, weak, wavy spines, which, except about the shoulders, are scarcely more than very strong bristles. The species of *Atherura*, known as brush-tailed porcupines, found in the Malay Peninsula, some of the large adjacent islands, and Africa, have short and rather weak flattened spines. F. A. Lucas.

Porcupine Ant-eater: the Echidna (*q. v.*).

Pordeno'ne: town; in the province of Udine, Italy; on the right bank of the Noncello; about 30 miles from the city of Udine (see map of Italy, ref. 2–E). Of its ancient walls and splendid castle only the ruins remain. In the Palazzo Comunale, the cathedral (begun 1347), and in several smaller churches may be seen oil-paintings and frescoes by Licinio, also called Il Pordenone, and others of his school. Pordenone has utilized its abundant water-power, and has cotton, silk, and earthen and iron ware manufactories. Pop. 5,100.

Pordenone: See Licinio.

Pore [viâ Fr. from Lat. *po'rus* = Gr. *πόρος*, pore, ford, means, etc., liter., way, passage]: a very narrow passage in any solid substance; particularly an efferent duct of the glands in the skin of animals. The largest and least abundant of these are the ducts of the sebaceous glands, which secrete an oily substance. They are numerous on the head and face and near the orifices of the body, but elsewhere fewer or even wanting. The ducts of the sweat-glands are most numerous on the palm of the hand, where 2,800 have been counted in 1 sq. inch. Krause estimates the number on a single person at 2,381,248.

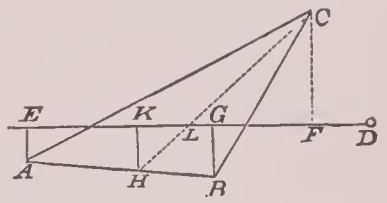
Porfi'rio Di'az, Ciudad' (formerly *Piedras Negras*): a frontier town of the state of Coahuila, Mexico; on the Rio Grande, opposite Eagle Pass, Tex.; on Mex. Internat. Railroad (see map of Mexico, ref. 3–G). It is in the "free zone," and its custom-house has to do principally with goods in transit. H. H. S.

Porfyrius: See Optatianus.

Porgy: a name applied in different localities to any one of several different fishes. In Europe it is given to *Pagrus vulgaris*; on the eastern coast of the U. S. to the scup, *Stenotomus argyrops*, and sometimes to the menhaden, *Brevoortia tyrannus*; rarely to the moonfish or angel-fish, *Chætodipterus faber*. See Fisheries. F. A. L.

Porifera: See Sponges.

Po'rism [viâ Fr. and Lat. from Gr. *πόρισμα*, thing procured, hence a deduction from a demonstration, corollary, deriv. of *πορίζειν*, carry, bring, furnish, procure]: a name given by ancient geometers to a class of propositions having for their object to show what conditions will render certain problems indeterminate. In order that the solution of a problem may be determinate, there must be as many independent conditions as there are parts to be determined. If, therefore, any supposition can be made on the data of the problem that will cause one of the given conditions to depend upon one or more of the others, the solution will become indeterminate; that is, the problem will have an infinite number of solutions. The object of the porism is, then, to discover an hypothesis that will make one of the given conditions of a determinate problem dependent upon one or more of the others. The nature of a porism will be illustrated by an example: Let A B C be a given triangle, and D any point in its plane; it is required to draw a line through D such that the sum of the perpendiculars to it from the two vertices on one side shall be equal to the perpendicular to it from the vertex on the other side. Suppose the problem solved, and let D E be a line such that the sum of A E and B G is equal to C F. Draw C H bisecting A B at H and cutting D E at L; also draw H K perpendicular to D E; then will H K = ½(A E + B G), or C F = 2H K. From the similar triangles L K H and L F C we have H K : H L : : C F : C L, or C F = 2H L. Hence the line D E must cut H C at a point one-third of the distance from H to C, and this no matter what may be the position of D. In the general case—that is, when D and L do not coincide—the problem is determinate, and admits of but one solution. Now let it be required to find the condition that will make the problem indeterminate. If we suppose D to coincide with L, the preceding proportion will be true whatever may be the direction of E K; hence the condition required is that D shall coincide with L, and the finding of this condition constitutes the essential part of the porism. The porism just considered may be enunciated as follows: To find in the plane of a triangle a point such that if any line is drawn through it, and perpendiculars let fall upon it from the vertices, the sum of the perpendiculars on one side shall be equal to the perpendicular on the other side.



Revised by R. A. Roberts.

Porosity [deriv. of *porous*, deriv. of *pore*. See PORE]: a property of matter in accordance with which its molecules are separated by intervals or pores. The porosity, for instance, of stone or wood is proved by immersing the object in water under the receiver of an air-pump; when the air is exhausted from the surface, that inclosed in the pores of the object will rise to the surface in the form of bubbles. The porosity of cast iron has been proved by forcing water through the pores of a plate 4 inches thick, and the porosity of liquids is exhibited by mixing alcohol and water, when the volume of the mixture is found to be less than the sum of the volumes of the components.

Porphy'rio, POMPONIUS: a Latin grammarian of the fourth century, perhaps from Africa, whose commentary on the works of Horace is still extant. Edition by W. Meyer (Leipzig, 1874).

Porphyrogenitus: See CONSTANTINE VII.

Porphyry [Gr. *πορφυρίτης*, from *πορφύρα*, purple]: See ROCKS and BUILDING-STONE.

Porphyry, or (Lat.) **Porphyrius**: Neoplatonist philosopher; b. at Batanea, Syria, 233 A. D.; received the instruction of Origen at Cæsarea; studied afterward at Athens under Longinus, and finally in Rome under Plotinus, of whom he became a passionate disciple; traveled in Sicily and other countries, but returned subsequently to Rome, where he died about 305. Of his numerous works, the greater part is not extant. The most important of his lost productions was his work against Christianity, which was publicly burned by order of Theodosius II. in 448. Among the works which have come down to us are biographies of Plotinus and Pythagoras; a commentary on Aristotle's *Categoriæ*, generally printed as an introduction to the *Organon*; a treatise *de Abstinentia*, etc. There is no collected edition of his works.

Porpoise [M. Eng. *porpeys*, from O. Fr. *porpeis*, liter., hogfish < Lat. *por'cus*, hog + *pis'cis*, fish]: any one of various small cetaceans, rarely over 8 or 9 feet in length, belonging to the family *Delphinidæ*, properly distinguished from the dolphins (see DOLPHIN), which are also called porpoises, by not having the anterior part of the head prolonged into a distinct beak. They have sharp conical teeth in both jaws, adapted for seizing slippery living prey. They go in

The porpoise.

shoals, sometimes containing many hundreds, and are found in nearly all seas, but more especially in temperate latitudes, and usually not very far from land. The common species, *Phocæna communis*, known also as puffing-pig and puffer, attains a length of 6 feet, has peculiar compressed teeth, and is glossy black above, lighter beneath. It sometimes ascends rivers for considerable distances. The skunk-porpoise, *Lagenorhynchus acutus*, of the North Atlantic, is larger, with broad stripes of white and yellow on the sides. In favorable localities various species are taken for their blubber, which yields oil, and for their skins, which make good leather. F. A. LUCAS.

Porrigo: See FAVUS.

Porro, EDUARDO, M. D.: gynæcologist; b. near Padua, Italy, Sept. 17, 1842; studied medicine in Pavia, graduating M. D. in 1865; from 1865–68 was assistant at the Milan Ospedale Maggiore; in 1868 he was appointed assistant and subsequently Professor of Obstetrics at the University of Milan. He accepted the same chair in the University of Pavia in 1875, and remained there until 1883, when he returned to Milan. In 1876 he published a method of amputating the uterus that served to give him worldwide prominence. He is the author of a number of monographs on gynæcological topics. S. T. ARMSTRONG.

Por'sena (less correctly *Porsen'na*): king of the Etrurian city of Clusium, under whose leadership the Etruscans compelled Rome to capitulate, and, as Pliny the elder reports, to surrender all weapons and agree to employ iron henceforth only for agricultural implements. How long this subjection continued and how the Romans regained their independence we do not know. The disgrace of the event, knowledge of which we owe to incidental remarks of Tacitus and Pliny, was concealed under the romantic stories, narrated by Livy, of Horatius at the bridge, of Scævola's sacrifice of his hand in the flame to show Porsena the character of Roman patriotism, and of the consequent voluntary withdrawal of the Etruscan forces. G. L. HENDRICKSON.

Porson, RICHARD: Greek scholar; b. at East Ruston, Norfolk, England, Dec. 25, 1759; was educated at Eton and at Trinity College, Cambridge, where he won the Craven scholarship, the chancellor's medal, and a fellowship 1782; began the publication of a series of critical labors upon the texts of classical authors; published in 1790 his famous *Letters* on the spuriousness of the text of the three witnesses; resigned his fellowship 1791 from conscientious scruples about subscribing to the Thirty-nine Articles; became Regius Professor of Greek at Cambridge, and librarian of the London Institution 1806. Next to Bentley, Porson is the greatest text-critic whom England has produced. Published critical editions of Euripides's *Hecuba* (with a famous introduction on Greek versification), *Orestes*, *Phœnissæ*, and *Medea*; Æsehylus (2 vols.); and many contributions to the text of Greek authors. D. in London, Sept. 25, 1808. See *Tracts and Miscellaneous Criticism of Richard Porson* (edited by Kidd, 1815), and J. S. Watson's *Life of Richard Porson* (1861). Revised by A. GUDEMAN.

Por'ta, CARLO: b. at Milan, 1776; was an intimate friend of Alessandro Manzoni and of Tommaso Grossi. His poems in the Milanese dialect, which have passed through many editions, the most celebrated is the one entitled *Disgrazi de Giovanin Bongee*. Porta was an amiable satirist, most true to nature, and full of power and vigor. D. 1821.

Porta, BACCIO della: same as BARTOLOMMEO (*q. v.*).

Porta, GIACOMO, della: architect; b. at Milan, Italy, in the beginning of the sixteenth century. He began modeling stucco bas-reliefs under Gobbo, but he studied architecture under Vignola, whom he succeeded as architect of St. Peter's. He finished the Palace of the Senator on the Capitol of Rome, which Vignola had continued after the drawings of Michelangelo. He constructed the Gregorian chapel for Gregory XIII., which cost the pope 80,000 scude, the Greek church in Via Babuino, the Church of the Madonna dei Monti, and a portion of that of the Florentines in Via Giulia in Rome. At the Certosa of Pavia he designed the tomb of the Conte di Virtù, and worked on the façade of the church. In 1531 he was invited to Genoa, where he built in the cathedral the chapel of St. John the Baptist, which was decorated with sculpture by his nephew William. Lastly, together with Fontana, he constructed the cupola of St. Peter's, changing, with Sixtus V.'s permission, Michelangelo's design by making the curve of the dome more elliptical than in the original model. He built also the façade of San Pietro in Vincoli, besides many fountains in Piazza Navona, Piazza Colonna, and Piazza del Popolo. D. in 1604. W. J. STILLMAN.

Porta, GIAMBATTISTA, della: philosopher; b. in Naples about 1543; traveled much in Italy, Spain, and France; founded in his native city the first society for the study of physical science in Italy, called Academia Secretorum Naturæ, which held its meetings in his own house, and to which no one was admitted unless he had made some discovery in natural philosophy; was accused of magic, and, though acquitted by the pope, was compelled to dissolve his academy; wrote many volumes on natural magic, geometry, optics, the human physiognomy, etc.; and invented the camera obscura. D. in Naples, Feb. 4, 1615.

Portadown: town; in the county of Armagh, Ireland; on the Bann; 25 miles by rail S. W. of Belfast (see map of Ireland, ref. 5–I). It has large distilleries and manufactures of linen and linen yarn, and an active trade in agricultural produce. It communicates by canal with the sea at Newry. Pop. (1891) 8,430.

Portage: city (founded in 1838, formerly called Winnebago Portage); capital of Columbia co., Wis. (for location, see map of Wisconsin, ref. 6–D); on the Wisconsin river, the ship-canal connecting the Wisconsin and Fox rivers, and the Chi., Mil. and St. P. and the Wis. Cent. railways; 30 miles N. of Madison, 85 miles N. W. of Milwaukee. It is in an agricultural and lumbering region, has important commercial and manufacturing interests, and contains a State bank with capital of $75,000, and a daily newspaper and four weekly ones. Pop. (1880) 4,346; (1890) 5,143; (1900) 5,459. EDITOR OF "STATE REGISTER."

Portage la Prairie: town; in the province of Manitoba, Canada; on the Assiniboine river; 56 miles by rail W. of Winnipeg; on the Canadian Pacific, Manitoba and Northwestern, and Northern Pacific railways. It is the market-town of a rich farming country, has flour-mills, grain-elevators, a biscuit-factory, paper-mill, etc., and a semi-weekly and two weekly newspapers. Pop. (1891) 3,363.

Portalis, pōr'tăă'lees', JEAN ÉTIENNE MARIE: jurist; b. at Bausset, in Provence, France, Apr. 1, 1745; attended the university at Aix, and became an advocate in 1765 and later the leader of the bar at Aix. He was for some years active in politics in opposition to the party of Mirabeau, and opposed the measures of the Constituent Assembly, but in 1790 abandoned politics, retiring to Lyons. In 1793, after the proclamation of the republic, he returned to Paris and resumed his law practice, and after the death of Robespierre became the leader of the moderate party opposed to the Directory; was later proscribed and escaped to Switzerland, whence he returned after Bonaparte became the First Consul. He early showed a thorough insight into the spirit of the French law and a marked ability in the matter of developing and systematizing it. By Napoleon he was made a member of the commission for drawing up the Civil Code, of which he was the principal author, the treatment of many of the most important subjects, especially those of marriage and heirship, being intrusted to him, and to those labors he chiefly owes his fame. In 1801 he was put in charge of the department of public works, and in this capacity had the chief share in the drawing up of the Concordat; in 1803 was a member of the Institute; in 1804 Minister of Public Worship, in which capacity he was the leader in reorganizing the French Church; in 1805 was made a Knight Grand Cross of the Legion of Honor. D. in Paris, Aug. 25, 1807. See René Lavollée's *Portalis, sa vie et ses œuvres* (Paris, 1869). F. STURGES ALLEN.

Port Arthur: town; in the province of Ontario, Canada; on Thunder Bay, an arm of Lake Superior; on the Canadian Pacific Railway; 993 miles from Montreal and 431 miles from Winnipeg. Steamships ply between it and Owen Sound on Georgian Bay. The town has docks, a grain-elevator, some manufactures, and a trade in lumber. It has a daily and two weekly newspapers. Pop. (1891) 2,698.

Port Arthur (called by the Chinese *Lü-shun-k'ow*): a landlocked harbor on the Strait of Pechili, near Kin-chow-t'ing and the southwest extremity of the province of Liao-tung or Shing-king, Manchuria (see map of China, ref. 3–K). The harbor is almost surrounded by hills from 300 to 1,500 feet in height, with cultivated valleys between. In 1881 it was merely a good wind-bound harbor for junks trading along the coast. It was then decided to make it the chief naval station of China, and the neeessary docks, dry-docks, refitting-basins, foundries, workshops, and dockyards, were completed (1891) by French contractors. The harbor entrance, which is from 200 to 300 yards wide, was deepened so as to admit the heaviest war-vessels, and well-constructed forts armed with modern guns were constructed to defend the port both from land and sea attacks. The village, consisting (1881) of about sixty mud huts, became a well-built town (1893) of about 1,000 houses and shops, with 6,000 inhabitants, exclusive of the garrison of 7,000 soldiers. It had 4 native banks, 2 temples, and 2 large theaters. The port is free from ice throughout the winter. Port Arthur was captured (Nov. 22, 1894) by the Japanese under Marshal Oyama, and held until Jan., 1896. C. C. ADAMS.

Port-au-Prince: capital and most important city and port of the republic of Haiti; on a deep bay of the western coast (see map of West Indies, ref. 5–G). The harbor is good and safe. The city, built on sloping ground, is regularly laid out, with wide streets; but it is very dirty, there are few pretentious edifices, and numerous ruins attest the ravages of the civil wars. Nearly all the houses are of wood, as building with stone was abandoned after the disastrous earthquakes of 1751 and 1770; the place has suffered even more from fires, some of them the work of political leaders. The surrounding scenery is very beautiful, but the mountains shut off the winds and make Port-au-Prince one of the hottest places in the island. Except during epidemics of yellow fever it is not, however, very unhealthful. The commeree is important, the principal exports being coffee, logwood, hides, and cacao. The city was founded in 1749. Pop. from 30,000 to 60,000. HERBERT H. SMITH.

Port Chester: village (incorporated in 1868); Westchester co., N. Y. (for location, see map of New York, ref. 8–J); on Long Island Sound, and the N. Y., N. H. and Hart. Railroad; 26 miles N. E. of New York city, 30 miles W. S. W. of Bridgeport, Conn. It contains a national bank with capital of $100,000, a savings-bank with deposits of over $925,000, 2 primary schools, public high-school, an institute, a public library, 3 carriage-factories, 2 iron-foundries, 2 screw- and bolt-factories, woolen-mill, shirt-faetories, carriage-coupling works, and a monthly and 2 weekly periodicals. Pop. (1880) 3,254; (1890) 5,274; (1900) 7,440. EDITOR OF "JOURNAL."

Port Clinton: village; capital of Ottawa co., O.; on Lake Erie at the mouth of the Portage river, and on the Lake Shore and Mich. S. Railway; 14 miles W. N. W. of Sandusky, 35 miles E. N. E. of Toledo (for location, see map of Ohio, ref. 1–E). It has considerable lake commeree, is engaged principally in fishing and in grape and peach culture, and contains a high-school, a State bank with capital of $35,000, and 4 weekly newspapers. Pop. (1880) 1,600; (1890) 2,049; (1900) 2,450.

Port Deposit: town; Cecil co., Md.: on the Susquehanna river, and the Penn. and the Phila., Wilm. and Balt. railways; 41 miles E. N. E. of Baltimore (for location, see map of Maryland, ref. 1–G). It has a large lumber-trade, and contains valuable granite-quarries, foundry, grist-mill, a national bank with capital of $100,000, and a weekly newspaper. Pop. (1880) 1,950; (1890) 1,908; (1900) 1,575.

Porte cochère: a door in the outer wall of a house, large and high enough to allow a carriage and horses to pass in and out. Such a door generally leads to a stable beyond the house or opening on the court. The use of this term for a carriage-porch is improper.

Port Eliz'abeth: the principal seaport of the eastern part of Cape Colony, South Afriea; 839 miles from Cape Town, and connected with that city and with Kimberley by rail (see map of Afriea, ref. 10–F). It was founded in 1820, and is situated on Algoa Bay. Its growth has been steady and rapid. The wool-trade of all the eastern districts of the eolony is concentrated here, and fine warehouses line the bay. Pop. (1891) 23,266. Revised by C. C. ADAMS.

Porte, Ottoman Porte, or, more commonly, **Sublime Porte**: an official title of the Ottoman Government. The Ottomans liken their government to a tent, at whose porte or door justice is administered and deliberations held. At Constantinople the name *Bab-i-Humayoun*, Exalted or Sublime Porte, is also applied to the main entrance of the Seraglio. E. A. G.

Porter: See BEER.

Porter, ALEXANDER: jurist; b. near Armagh, Ireland, in 1786; removed to the U. S. 1801; engaged in mercantile pursuits in Nashville, Tenn.; studied law and was admitted to the bar in 1807; settled at St. Martinsville, La., 1810; was a member of the convention which formed a State constitution 1811; gained prominence as a jurist and as a Whig politician; beeame a judge of the Supreme Court of Louisiana 1821; was U. S. Senator 1834–37, and opposed the abolition of slavery in the District of Colnmbia and advocated the recognition of the independence of Texas; again elected in 1843, and served till incapacitated by ill-health. D. at Attakapas, La., Jan. 13, 1844. The moulding of the jurisprudence of Louisiana in its present form is largely due to the labors of Judge Porter.

Porter, ANDREW, A. M.: soldier; son of George Bryan Porter, Governor of Michigan; b. at Lancaster, Pa., July 10, 1820. Educated as a civil engineer at Lafayette College, Pennsylvania, he practieed his profession for several years, and was appointed first lieutenant U. S. Mounted Rifles May 27, 1846; captain May, 1847. He served in the Mexican war, and was breveted major for gallantry at Contreras

and Churubusco, and lieutenant-colonel at Chapultepec; colonel Sixteenth Infantry May 14, 1861, and brigadier-general of volunteers May 17, 1861. He served in the Bull Run campaign and battle, and was subsequently provost-marshal of Washington, D. C. Honorably mustered out of volunteer service Apr., 1864, he resigned from the army May, 1864. D. in Paris, Jan. 3, 1872. JAMES MERCUR.

Porter, CHARLES T.: mechanical engineer; b. at Auburn, N. Y., Jan. 18, 1826; graduated at Hamilton College, 1845; studied law and was admitted to the bar 1847; practiced in Rochester and New York city, but after a few years abandoned the law for mechanical pursuits, especially steam-engineering; patented the central counterpoise governor for steam-engines 1859, and an isochronous centrifugal governor for marine engines 1861; became associated with John F. Allen in the manufacture of the Porter-Allen engine, the constructive features of which were designed by him; was the first manufacturer to use high rotative speeds in stationary steam-engines with success. He published an essay on the use of the Richards indicator (1874), and a volume entitled *Mechanics and Faith: a Study of the Spiritual Truths in Nature* (1885). He was one of the organizers of the American Society of Mechanical Engineers, and was for several years a member of its council.

Porter, DAVID: naval officer and diplomat; b. in Boston, Mass., Feb. 1, 1780; served from boyhood on board a merchant-vessel under his father, who was a sea-captain; entered the U. S. navy as midshipman Apr., 1798; was on board the Constellation during her engagement with a French frigate 1799; became a lieutenant Oct., 1799; was wounded in an action with pirates on the coast of Santo Domingo Jan., 1800; took part in the naval war upon Tripoli 1801–06; was captured in the Philadelphia Oct., 1803, and held for eighteen months a prisoner; was given command of the frigate Essex (32 guns) in 1812; captured the Alert, the first man-of-war taken from the British; sailed to the Pacific Jan., 1813; captured several whalers and trading-vessels, but his own ship was captured in the harbor of Valparaiso Mar. 28, 1814, by two British vessels after a severe fight; published a *Journal of the Cruise of the Essex* (2 vols., Philadelphia, 1815; 2d ed. New York, 1822); was a navy commissioner 1815–23; commanded an expedition against West Indian pirates 1824; was court-martialed and suspended for six months in 1825 for disobedience to orders in a difficulty with the Spanish authorities of Puerto Rico; resigned his commission Aug. 18, 1826, and accepted the command of the Mexican navy; was sent as consul to Algiers 1829; was made *chargé d'affaires* to Turkey 1831; was afterward appointed minister resident and negotiated several treaties with the Porte. D. at Pera, near Constantinople, Mar. 3, 1843. His remains were buried in the grounds of the U. S. Naval Asylum at Philadelphia. From his letters to a friend a work was compiled, *Constantinople and its Environs* (2 vols., 1835). See the *Life* by his son David D. Porter (Albany, 1875).

Porter, DAVID DIXON: naval officer; b. at Chester, Pa., June 8, 1813. His father, the gallant Porter of Essex fame, having accepted the position of commander-in-chief of the naval forces of Mexico during her war with Spain, obtained an appointment for his son as a midshipman in the Mexican navy. Two years after David D. Porter entered the U. S. navy as a midshipman, and as a lieutenant eighteen years later was actively engaged in all the operations of the navy on the east coast of Mexico. When the civil war broke out, Porter, then a lieutenant, was dispatched in the Powhatan to the relief of Fort Pickens, Fla. He then fitted out a mortar-flotilla for the reduction of the forts guarding the approaches to New Orleans by the lower Mississippi. After the fall of New Orleans the mortar-flotilla was actively engaged at Vicksburg, and in the autumn of 1862 Porter was placed in command of all the naval forces on the western rivers above New Orleans, with the rank of rear-admiral. His ability as a commander-in-chief was then exhibited, not only in the battles which he fought, but also in the creation of a formidable fleet out of river-steamboats, which he covered with such plating as they could bear. In 1864 Porter was transferred to the Atlantic coast to command the naval forces destined to operate against the defenses of Wilmington, N. C., and on Jan. 15, 1865, the fall of Fort Fisher ended his arduous war-service. In 1866 he was made vice-admiral, and appointed superintendent of the Naval Academy; and on the death of Farragut (1870) he became the admiral of the navy. He was the author of *Allan Dare and Robert le Diable* (New York, 1885); *The Adventures of Harry Marline* (1885); *Incidents and Anecdotes of the Civil War* (1885); and was a contributor to current literature. D. at Washington, D. C., Feb. 13, 1891.

Porter, FITZ JOHN: soldier; b. at Portsmouth, N. H., 1822; graduated at U. S. Military Academy; entered the army as brevet second lieutenant July 1, 1845; served in the war with Mexico; from 1849 to 1855 was stationed at West Point either as instructor or adjutant of the Military Academy; was appointed assistant adjutant-general June, 1856; served as chief of staff in department of the West during the Kansas troubles (1856) and on the Utah expedition 1857–59. In Apr., 1861, he was assigned to the duty of maintaining railway communication through Baltimore to Washington. While at Harrisburg, and when communication with Washington was broken, Porter was shown telegrams from Hon. Francis P. Blair through Gov. Curtin to the President, asking that the Missouri troops be mustered and used for the protection of that State. He at once assumed the authority of the Secretary of War in giving the orders requested. This was approved by the authorities in Washington. Until Aug., 1861, he served in Maryland and Virginia with the army under Gen. Patterson and his successor, Gen. Banks; and was then appointed colonel of U. S. infantry and brigadier-general of volunteers and assigned to duty in Washington.

In 1862 he took part in the Virginia peninsular campaign; was made director of the siege of Yorktown, and upon the evacuation of that place was placed in command of the Fifth Army-corps, with which he fought several battles, including those of Mechanicsville and Gaines's Mill. In the transfer of the Army of the Potomac from the peninsula to Northeastern Virginia he was ordered to stop at Williamsburg and become the rear guard of the army, which would pass through his lines to Yorktown and Fortress Monroe. Reliably informed that Lee was hastening to crush Pope before he could be re-enforced by the Army of the Potomac, and knowing that the army in withdrawing was not molested, Porter instead continued the march and thereby joined Pope several days earlier than if he had complied with orders. Pope highly approved of this action. Porter fought under Pope the memorable second battle of Bull Run. (See BULL RUN, SECOND BATTLE OF). He was then placed in command of the defenses of Washington, S. of the Potomac; then was ordered to rejoin the Army of the Potomac, at that time in Maryland, and was permitted to select a division of 12,000 men. At the battle of Antietam this division was held in reserve, but after it Porter followed the enemy into Virginia and with his corps alone fought the battle of Shepherdstown, capturing many prisoners and a battery of artillery which had been lost at the first battle of Bull Run.

On Nov. 12 he was relieved from command and ordered to Washington. Here he was tried by court martial on alleged disobedience of orders under Pope, declared guilty and cashiered. A re-examination was made of the charges in 1878, resulting in his complete vindication. Against many difficulties in Congress from 1879 to 1886 a bill was finally passed restoring him (Aug. 6, 1886) to the army as a colonel of infantry from May 14, 1861, and, at his own request, he was immediately placed on the retired list. D. May 21, 1901.

Porter, HORACE: soldier; b. in Huntington, Pa., Apr. 15, 1837; graduated at U. S. Military Academy 1860; chief of artillery at the capture of Fort Pulaski; on the staff of Gen. McClellan in 1862; chief of ordnance on the staff of Gen. Rosecrans in 1863; aide-de-camp of Gen. Grant till the close of the war, and his private secretary during his first presidential term. He was breveted brigadier-general for gallant and meritorious services. He is noted as an after-dinner speaker. He was appointed ambassador to France in Mar., 1897.

Porter, JANE: novelist; b. at Durham, England, in 1776; daughter of a surgeon in the Sixth Dragoons, who died during her childhood; was educated at Edinburgh; afterward lived with her mother successively at London, at Ditton-on-Thames, and at Esher; published in 1803 her popular novel, *Thaddeus of Warsaw*; in 1810 the equally successful *Scottish Chiefs*; wrote, at the request of George IV., *Duke Christian of Luneburg, or Traditions from the Hartz* (3 vols., 1824); and, besides several other novels issued in 1831, a fictitious but highly circumstantial *Narrative of the Shipwreck of Sir Edward Seaward*, which by some reviewers was deemed a genuine narrative of facts. D. at Bristol, May 24, 1850. Revised by H. A. BEERS.

Porter, Josias Leslie, D. D., LL. D., D. Litt.: clergyman and author; b. at Burt, Ireland, Oct. 4, 1823; was educated at the Universities of Glasgow and Edinburgh, and at the Free Church College, Edinburgh; was pastor at Newcastle-on-Tyne in the Presbyterian Church of England 1846–49; missionary of the Presbyterian Church of Ireland in Damascus 1849–59; was Professor of Biblical Criticism in the Assembly's college in Belfast 1860–77; commissioner of education in Ireland 1878; president of Queen's College, Belfast, 1879, till his death there Mar. 16, 1889. He is the author of *Five Years in Damascus* (London, 2 vols., 1855; 2d ed. 1870); *Handbook for Syria and Palestine* (1858; 2 vols., 3d ed. 1875); *The Pentateuch and the Gospels* (1864); *The Giant Cities of Bashan* (1865); *The Life and Times of Henry Cooke, D. D., LL. D.*, his father-in-law (1871; 3d ed. 1877); *The Pew and Study Bible* (1876), etc.

Revised by S. M. Jackson.

Porter, Noah, D. D., LL. D.: educator and author; b. at Farmington, Conn., Dec. 14, 1811; son of Rev. Noah Porter, D. D., minister of Farmington nearly sixty years (b. 1781; d. Sept. 24, 1866); graduated at Yale College 1831; master of Hopkins grammar school, at New Haven, 1831–33; was tutor at Yale 1833–35, pursuing theological studies at the same time; became pastor of the Congregational church at New Milford, Conn., Apr., 1836; settled at Springfield, Mass., 1843; was chosen Clark Professor of Metaphysics and Moral Philosophy at Yale College 1846; spent a year (1853–54) in Europe, chiefly in Germany, where he made a close study of modern German philosophy; was elected president of Yale College on the resignation of Dr. Woolsey in 1871. President Porter resigned the presidency in Oct., 1885, to take effect at the following commencement. He retained the office of Clark Professor of Metaphysics and Moral Philosophy until his death in New Haven, Conn., Mar. 4, 1892. He was author of a prize essay on *The Educational Systems of the Puritans and the Jesuits compared* (New York, 1851); *The Human Intellect, with an Introduction upon Psychology and the Soul* (New York, 1868); *Books and Reading* (1870); *American Colleges and the American Public* (1870; 2d ed., with additions, 1878); *Elements of Intellectual Philosophy* (1871), being an abridgment of the larger work; *The Science of Nature versus the Science of Man* (1871); *Science and Sentiment* (1882); *Elements of Moral Science* (1885); *Bishop Berkeley* (1885); and *Kant's Ethics* (1886). Dr. Porter was the principal editor of the revised edition of *Webster's Dictionary* (1864, 1880, and 1890), and contributed abundantly to religious and literary reviews and periodicals. He was one of the ablest of metaphysicians, and a man of varied talents and attainments.

Revised by G. P. Fisher.

Porter, Peter Buel: soldier; b. at Salisbury, Conn., in 1773; studied law; settled in New York State; was elected to Congress in 1808, re-elected in 1810, and the year following, as chairman of the committee on foreign relations, prepared and introduced the celebrated report recommending war with Great Britain. Hostilities having begun, he resigned his seat in Congress and served throughout the war with distinction, holding important commands. In acknowledgment of his services the city of New York presented him with the freedom of the city, the State of New York voted him a sword, and he received the thanks of the Congress of the U. S., with a gold medal. He was appointed in 1816 by President Madison a commissioner under the treaty to settle the boundary-line between Canada and the U. S. An early projector of the Erie Canal, he with Morris and Clinton constituted the first board of commissioners for selecting its route. In 1828 he was appointed Secretary of War, and held the office during Adams's administration. D. at Niagara Falls, N. Y., in 1844.

Porter, Sir Robert Ker: historical painter and traveler; brother of Jane Porter, the novelist; b. at Durham, England, about 1775; went to Spain with Sir John Moore 1808; was knighted in 1811; was consul in Venezuela 1826–41; lived many years in Russia. Among his most remarkable paintings are *The Siege of Acre*; *Peter the Great planning the Port of Cronstadt and St. Petersburg*, a fresco painted on the walls of the admiralty in St. Petersburg; and *Christ blessing the Little Children*, which, together with an *Ecce Homo*, was painted in Caracas. D. in St. Petersburg, May 4, 1842. He was the author of *Travels in Russia and Sweden* (1808); *Letters from Portugal and Spain* (1809); *An Account of the Russian Campaign* (1813); and *Travels in Georgia, Persia, and Armenia* (1821–22).

Porter, Thomas Conrad, D. D., LL. D.: botanist; b. at Alexandria, Pa., Jan. 22, 1822; educated in Harrisburg Academy, Lafayette College, and Princeton Theological Seminary; minister of the Gospel 1844–49; Professor of Natural Sciences in Marshall College 1849–53; same in Franklin College 1853–66; Professor of Botany in Lafayette College, Easton, Pa., 1866; professor emeritus and dean of the Pardee Scientific Department, 1898. Among his scientific publications are *Sketch of the Flora of Pennsylvania* (1872); *Sketch of the Botany of the United States* (1873); *A Synopsis of the Flora of Colorado* (prepared conjointly with John M. Coulter, 1874); *A List of the Carices of Pennsylvania* (1887); *A List of the Grasses of Pennsylvania* (1893); and many shorter papers. D. Apr. 27, 1901.

Porter, William David: naval officer; son of David Porter, naval officer; b. at New Orleans, La., Mar. 10, 1809; entered the U. S. navy as midshipman Jan. 1, 1823; became lieutenant Dec. 31, 1833; was the originator of the light-house system in use in the U. S.; served in the Gulf of Mexico during the war between the U. S. and Mexico; was retired 1855; re-entered the navy 1859; built and commanded the ironclad Essex in the Mississippi flotilla 1861–62; participated in the attacks on Forts Henry and Donelson; sailed down Mississippi river to New Orleans, forcing a passage by several Confederate batteries; took part in engagements at Vicksburg, Baton Rouge (where he effected the destruction of the Confederate ironclad Arkansas), Natchez, and Port Hudson, and was made commodore July 16, 1862. Owing to feeble health he took little part in subsequent naval service. D. in New York, May 1, 1864.

Por'teus, Beilby, D. D.: bishop; b. at York, England, May 8, 1731; was educated at Christ's College, Cambridge, where he obtained a fellowship and gained the Seatonian prize for poetry; became chaplain to Archbishop Secker 1762, and to George III. 1769; was appointed Bishop of Chester 1776, and of London 1787. D. in London, May 13, 1809. Author of a *Review of the Life and Character of Archbishop Secker* (1797), in which the efforts of the primate to accomplish the introduction of bishops in the American colonies were detailed and defended; *A Summary of the Evidences of Christianity*; and other works, of which a collected edition, preceded by a memoir, was published in six volumes, 1811.

Revised by W. S. Perry.

Port Glasgow: town of Renfrewshire, Scotland; on the Clyde; 20 miles W. N. W. of Glasgow (see map of Scotland, ref. 11–F); has large quays, ship-building docks, extensive manufactures of sail-cloth and ropes, iron- and brass-foundries, and considerable importation of American timber. Pop. (1891) 14,647.

Port Hamilton: a spacious harbor in the island of Kŭwŭn, one of the Nanhow group, lying S. of Korea, just N. of 34° N. lat. (see map of China, ref. 5–M). Only three of these islands are of importance. When Great Britain and Russia seemed (Apr., 1885) on the verge of war over their conflicting Asian interests Great Britain seized Port Hamilton, against the protests of China and Japan, as a coaling-station and naval port of much strategic value, commanding the Korea Strait. It was found that the anchorage-ground was poor, that adequate fortifications would cost enormously, and Great Britain (Jan., 1887) transferred the islands to China.

C. C. Adams.

Port Hudson: post village; in East Baton Rouge parish, La. (for location of parish, see map of Louisiana, ref. 9–E); on left bank of the Mississippi. Pop. about 250. Port Hudson stands on a high bluff at a sharp bend of the river. During the late summer and autumn of 1862 Confederate batteries, heavily mounted, well-protected, and strongly manned, had been erected along the bluffs for a distance of about 3 miles, completely commanding the river. On the night of Mar. 14–15, 1863, the Union fleet of four sloops-of-war and five gunboats, under Farragut, attempted to pass these batteries. Of these the Hartford and the gunboat Albatross succeeded, but the remainder were driven back, one being destroyed and four disabled. The place was invested by Gen. Banks, May 21–26, 1863, and a general assault was made May 27, which was repulsed, the Union loss being 1,995 killed and wounded; the Confederate loss was not more than 300. An effort to carry the works by storm (June 14) was repulsed with a Union loss of about 1,805. On July 7 tidings were received that Vicksburg had fallen three days before, and negotiations for the surrender of Port Hudson were at once opened. The surrender was made

July 9. There were about 6,400 prisoners of war, 51 guns, 5,000 small-arms, much ammunition, and 2 steamers were also captured. The siege had lasted forty-five days. The entire Union loss was about 4,300 men; the Confederate loss about 800, exclusive of prisoners. The capture of Port Hudson opened the entire course of the Mississippi.

Revised by JAMES MERCUR.

Port Huron: city (settled by whites in 1686, originally called Desmond, incorporated as a city in 1857); port of entry; capital of St. Clair co., Mich.; on the St. Clair and Black rivers, at the foot of Lake Huron, and on the Grand Trunk, the Chi. and Gr. Trunk, and the Flint and Pere Marquette railways; 56 miles N. N. E. of Detroit (for location, see map of Michigan, ref. 7–K). It contains 13 churches, 14 public-school buildings, public-school property valued at over $200,000, Academy of the Sacred Heart, several parochial and private schools, 5 public parks, Holly system of water-works, with supply from Lake Huron, public library, U. S. Government building that cost $250,000, hospital, a national bank with capital of $135,000, 3 State banks with combined capital of $250,000, a private bank, and 2 daily, 6 weekly, and 3 monthly periodicals. It has 16 miles of paved streets, 7 of electric railway, electric-light plant, 2 fuel and gas-light plants, 25 hotels, and many handsome business buildings. It has a large grain-, lumber-, and wool-trade. Among the industrial works are the locomotive-shops of the Grand Trunk Railway, which also has car- and repair-shops, threshing-machine manufactory, 7 grain-elevators, 3 flour-mills, 3 dry-docks, 4 foundries, 6 carriage- and wagon-shops, 4 marble-works, 5 cigar-factories, 1 planing-mill, 2 engine-works, 2 breweries, 4 bottling-works, 2 lime-kilns, and a plant for manufacturing paper from spruce wood. The city is connected with Sarnia, Canada, by a steam-ferry and by a tunnel constructed in 1888–92 to accommodate the connecting U. S. and Canadian railways. Pop. (1880) 8,883; (1890) 13,543; (1900) 19,158.

L. A. SHERMAN, EDITOR OF "TIMES."

Portici, pōr'tĕe-chĕĕ: town; in the province of Naples, Italy; on the Bay of Naples, at the western foot of Vesuvius; about 5 miles S. E. of the city of Naples (see map of Italy, ref. 7–F). Since 79 A. D. the volcano has poured its burning lava seven times over the spot on which Portici now stands, and as many times it has been rebuilt. The excavations in search of the treasures of HERCULANEUM (*q. v.*) were begun here in 1714. The modern town contains a long street, a fine square, a mole for the convenience of the shipping, a little fort which commands the roadstead, and an agricultural college, formerly a royal palace, built in 1737. The industry of Portici consists of fishing, a small coasting trade, and the manufacture of silk and ribbons. Pop. 12,272.

Port Jervis: village; Orange co., N. Y. (for location, see map of New York, ref. 7–J); at the confluence of the Neversink and the Delaware rivers, and the intersection of the boundary-lines of New York, New Jersey, and Pennsylvania; on the Erie and the Port Jervis, Monticello and N. Y. railways, and the Del. and Hudson Canal; 21 miles W. S. W. of Middletown, 88 miles N. W. of New York city. It is widely noted for the beauty of its location and surrouding scenery, and contains 2 national banks with combined capital of $230,000, a soldiers' monument (unveiled in 1886), a district-school library, repair-shops of the Erie Railroad, 2 glass-factories, 2 foundries, and boot and shoe factory, and manufactories of saws, harness, shirts, and gloves. It has a monthly, 2 daily, and 3 weekly periodicals. Pop. (1880) 8,678; (1890) 9,327; (1900) 9,385.

EDITOR OF "GAZETTE."

Portland, N. B.: a suburb of ST. JOHN (*q. v.*).

Portland: town; Middlesex co., Conn. (for location, see map of Connecticut, ref. 9–H); on the Connecticut river, and the N. Y., N. H. and Hart. Railroad; nearly opposite Middletown. It is best known for its quarries of brown sandstone. Other industries are ship-building and the manufacture of steam-governors and various kinds of tinware. It has water-works, electric lights, a national bank with capital of $150,000, a savings-bank, and a weekly and a monthly periodical. Pop. (1880) 4,157; (1890) 4,687; (1900) 3,856.

EDITOR OF "MIDDLESEX COUNTY RECORD."

Portland: city; capital of Jay co., Ind.; on the Salamonie river, and the Grand Rapids and Ind. and the Lake Erie and West. railways; 43 miles N. of Richmond, 49 miles S. by E. of Fort Wayne (for location, see map of Indiana, ref. 5–G). It is in a natural-gas region, has a large lumber-trade, and contains several manufactories. 2 State banks with a combined capital of $110,000, and a daily and 4 weekly newspapers. Pop. (1880) 1,694; (1890) 3,725; (1900) 4,798.

Portland: city (settled by the English in 1632, incorporated as a town in 1786, as a city in 1832); port of entry; capital of Cumberland co., Me. (for location, see map of Maine, ref. 10–B); on Casco Bay, and the Boston and Maine, the Maine Cent., and the Gr. Trunk railways; 63 miles S. S. W. of Augusta, 108 miles N. N. E. of Boston. It is the largest and most important city in the State, is built on a peninsula jutting into the bay, and has a picturesque harbor dotted with islands and defended by Forts Preble and Williams, and by important forts on Cushing's and Diamond islands, partially built and now in process of construction, and by a modern torpedo system. Communication by water is afforded by a daily steamboat-line to Boston and a semi-weekly line to New York city, in winter six weekly steamship-lines to Europe, and in summer two weekly lines to Europe. The city is the winter port of the ocean steamships connecting with the Grand Trunk Railway at Montreal in summer. The harbor is accessible without a pilot in all kinds of weather, and has been the scene of commercial activity, particularly in the line of trade with the West Indies, for many generations. Portland constitutes a U. S. customs district; in 1900 merchandise to the value of $759,121 was imported and domestic products to the value of $9,486,187 were exported. The city contains a U. S. custom-house of granite, a U. S. post-office and court building of white marble, an imposing city-hall of olive-colored freestone, 8 national banks with combined capital of $3,650,000, 3 trust companies, 2 savings-banks with aggregate deposits of $13,889,300, 6 private banks, and 4 daily, 11 weekly, 9 monthly, and 4 quarterly periodicals. The principal churches are the Cathedral of the Immaculate Conception (Roman Catholic), St. Luke's Cathedral (Protestant Episcopal), the Payson Memorial, the First Baptist, the First Parish, the double-spired Chestnut Street Methodist Episcopal, St. Paul's and St. Stephen's (Protestant Episcopal), and St. Dominic's (Roman Catholic). The public-school property is valued at over $600,000, and comprises 33 school-buildings. There are 9 libraries of all kinds, containing over 80,000 volumes. Those of the Maine Historical Society and the Portland Society of Natural History are in a building erected by James P. Baxter in 1889 and presented to the two societies for use in common. Among the notable buildings is the Longfellow homestead, the birthplace of the poet, on Congress Street, which was erected in 1785–87 and presented to the Maine Historical Society in 1893. The principal industries are meat-packing and the manufacture of marine boilers, foundry and machine-shop products, and boots and shoes. In 1900 the assessed valuation of the city was $44,630,960, and in 1900 the net debt was $1,323,082. The original settlement was destroyed by the Indians in 1676, and its successor by the French and Indians in 1690. In 1775 the village was bombarded and burned by a British fleet, and in 1866 a third part of the city was destroyed by fire. Pop. (1880) 33,810; (1890) 36,425; (1900) 50,145.

GEORGE S. ROWELL, EDITOR OF "ADVERTISER."

Portland: city (laid out in 1845, incorporated as a city in 1851, enlarged by the annexation of Albina and East Portland in 1891); capital of Multnomah co., Ore.; on the Willamette river, 12 miles above its confluence with the Columbia, and the N. Pac., the S. Pac., the Union Pac., and the Portland and Willamette Valley railways (for location, see map of Oregon, ref. 2–C). The city is built on sloping ground, the river dividing it nearly in the middle. A range of hills on the W., within easy walking distance, rises to an elevation of 1,000 feet. The Cascade Mountains, with the snow-capped peaks of Mt. Hood, Mt. Adams, Mt. St. Helen's, and Mt. Rainier, and the picturesque gorge of Columbia, are in plain view. Although the city is 120 miles from the ocean, its location at the head of deep-water navigation on the two rivers makes it in reality a seaport. The largest steamships are able to go direct to the city wharves at all seasons of the year, and the city has regular water-communication with the greater part of the State of Washington, with Astoria, the Dalles, Albany, Corvallis, and Dayton, in Oregon; with Lewiston, in Idaho; with Puget Sound, British Columbia, Alaska, and San Francisco; and with the principal Siberian, Chinese, and Japanese ports. Lying in the heart of a great producing region, with exceptional shipping facilities by rail and water, the city is an important center

of commercial aetivity. In 1900 the deep-sea commerce of the port was, foreign, $10,100,000; coastwise, $4,000,000—total, $14,100,000; and the shipments of produce and merchandise eastward aggregated over $8,000,000. The wholesale jobbing trade exceeded in value $110,000,000. The aggregate banking capital was over $16,000,000, and the bank clearings of the year were $106,926,526. The census returns of 1890 showed that 504 manufacturing establishments (representing 88 industries) reported. These had a combined capital of $16,808,028, employed 9,240 persons, paid $7,179,733 for wages and $12,427,071 for materials, and had products valued at $24,429,449. The principal industries, in the order of capital employed, were those connected with lumber, printing and publishing, malt liquors, furniture, awnings, tents and sails, bridges, and slaughtering and meat-packing. Portland is supplied with water from a stream 30 miles distant, which has its source on Mt. Hood; is lighted with gas and electricity; has over 125 miles of street-railway; contains a number of massive buildings, including the U. S. Government building, city-hall, Chamber of Commerce, Union Depot, and the Hotel Portland; and has 3 daily, 23 weekly, a semi-monthly, and 15 monthly periodicals. There are 30 churches; 15 public-school buildings, public-school property valued at over $600,000, the Bishop Scott Academy (Protestant Episcopal, opened 1870), St. Helen's Hall (Protestant Episcopal, chartered 1869), St. Michael's College (Roman Catholic, opened 1871), Portland Academy (non-sectarian), the medical departments of the State and the Willamette Universities, and a business college. In 1900 the assessed valuations of the city aggregated $33,000,000, and on Jan. 1, 1901, the bonded debt was $2,381,000. Pop. (1880) 17,577; (1890) 46,385; (1900) 90,426.

H. W. Scott, editor of "Oregonian."

Portland, Dukes of: See Bentinck.

Portland Cement: See Cement.

Portland, Isle of: a peninsula on the coast of Dorsetshire, England; about 4 miles by rail S. of Weymouth. It is connected with the mainland by a ridge of loose shingle, the Chesil Bank, and reaches 495 feet in height at the Verne, from which it slopes gradually to Portland Bill, its southern extremity, where there are two lighthouses. Portland is noted for its quarries of excellent building-stone, the stone of which St. Paul's Cathedral, in London, is built; other features are the old castle erected by Henry VIII.; the magnificent breakwater, with which are connected a naval station and a harbor of refuge; its prisons, capable of accommodating 1,500 convicts; Bow and Arrow Castle, ascribed to Rufus; and the Pennsylvania Castle (1800), built by Governor Penn. (See Breakwater.) Pop. (1891) 11,000.

Portland Vase: See Glass (*Glass in Artistic Use*).

Port Lavaca: town; capital of Calhoun co., Tex.; on Matagorda Bay, and the S. Pac. Railroad; 20 miles from the Gulf of Mexico (for location, see map of Texas, ref. 6–I). Indianola, the former capital of the county, a port of entry, and a town of large commercial importance, was almost entirely swept away by a flood in 1875, and what was left was destroyed by a second flood in 1886. The business of the town was then transferred to Port Lavaca, which was made the county-seat. The principal industries are fishing, oystering, and fruit-cultivation. Pop. (1890) 365; not returned separately in 1900.

Port Lou'is: capital of the British colony of Mauritius (*q. v.*); on the northwest of the island. It is well built and strongly fortified, has a good harbor, barracks, a public library, a theater, a botanic garden, and is the commercial center of the colony. Pop. (1891) 62,046.

Port Mahon' (anc. *Portus Magonis*): capital of Minorca, on the southern coast of the island (see map of Spain, ref. 6–M). It has a spacious and safe harbor, capable of accommodating a fleet of men-of-war. It was made a first-class fortress by the British, who held Minorca twice during the eighteenth century. Cattle, cotton, shoes, and honey are exported. Pop. (1887) 18,445.

Portneuf: village; Portneuf County, Province of Quebec, Canada; on the St. Lawrence at the mouth of the Portneuf river, and on the Can. Pac. Railway; 35 miles S. W. from the city of Quebec (see map of Quebec, ref. 4–C). The St. Lawrence has a beautiful appearance as it bends into the bay which forms the harbor of the village. Opposite is Point Platon with its picturesque village. There are several mills, the chief industry being the manufacture of paper. Pop. of the parish about 1,850. J. M. Harper.

Por'to Ale'gre: capital and largest city of the state of Rio Grande do Sul, Brazil; beautifully situated on the Guahyba or broadened lower part of the river Jacuhy; 38 miles from its mouth in the Lagoa dos Patos, and by the latter and the Rio Grande, 246 miles from the sea (see map of South America, ref. 7–F). The town is built partly on flat land, partly on a low promontory. There are few pretentious edifices. The outskirts, reached by horse railways, are adorned with beautiful gardens. Porto Alegre is one of the cleanest, prettiest, and most thriving cities of Brazil, and it is very healthful. Vessels which can pass the Rio Grande bar ascend to this place and load directly at wharves; and small steamboats connect the port with towns on the Jacuhy and with numerous German and Italian colonies on the branch rivers; much of the trade is in the hands of German merchants. The city is the emporium of the agricultural region in the northern part of Rio Grande do Sul, and is growing rapidly. Pop. (1894) about 45,000. H. H. S.

Porto-Ferraio, pōr'tō-fer-raa'yō: capital of the island of Elba (*q. v.*). Pop. 3,737.

Port of Spain: capital and principal town and port of the island of Trinidad, West Indies; on the Gulf of Paria (west coast of the island), fronting a small bay (see map of West Indies, ref. 9–M). It is well laid out on flat ground, and has many handsome buildings, especially in the outskirts, where the houses of the better class are surrounded by extensive gardens. The Botanical Garden is one of the finest in the British colonies. The governor's residence, a fine edifice, is in this garden. Port of Spain has most of the commerce of the colony, and is the entrepôt for much of the English trade with the northern part of South America; regular lines of steamers connect it with Europe, the U. S., the Venezuelan ports, and the Orinoco. The harbor is safe, but vessels are obliged to anchor at some distance from the shore. The climate is hot, but generally healthful. Pop. (1890) 31,858. Herbert H. Smith.

Porto Maurizio, maă-oŏ-rit'si-ō (anc. *Portus Mauritii*): chief town in the province of the same name, Italy; about 14 miles from San Remo and 41 miles by rail E. by N. of Nice (see map of Italy, ref. 4–B). It consists of an old town on a hill and a new one by the sea. The former was once well fortified and walled. The harbor is formed by two moles, and is entered from the S. S. W. There is a large production of olives and a considerable coasting trade. Pop. 6,309. The province has an area of 455 sq. miles. Pop. (1892) 142,200.

Port Orchard: naval station (name changed from Sidney, 1894); capital of Kitsap co., Wash.; on Port Orchard Bay, an arm of Puget Sound, 18 miles W. of Seattle (for location, see map of Washington, ref. 3–C). A tract of 200 acres was secured by the U. S. Government in 1891, and Congress appropriated $700,000 for the construction of a timber dry dock 600 feet long, 75 feet wide on the floor, and of sufficient depth to accommodate vessels of 30 feet draught, the largest dry dock in the U. S. Congress also authorized a survey for a canal to connect the sound at this point with Lake Washington, a fresh-water body 2½ miles inland, for the purpose of affording the station a harbor where vessels could be free from the attacks of shipworms. Pop. (1900) 197.

Porto Rico: See Puerto Rico.

Porto Seguro, Baron and Viscount of: See Varnhagen, Francisco Adolpho, de.

Portraiture, or **Portrait-art**: the fine art which has for its subjects the likenesses of men and women, and by extension ideal attempted likenesses of those who are dead. So little of what the oldest races did in this field remains to us that until Mariette's discovery in Lower Egypt of portrait-statues belonging to the third dynasty (B. C. 4449) it was believed by some that the art of portraiture was of recent origin. Coming down to historic times, the earliest portraits of which we have any mention are those Apelles made of Alexander and Antigonus. We have but little record of the subsequent history of portraiture in Greece, for nearly all traces of Greek painting have disappeared, and no well-authenticated portrait-bust or statue of antique Greek workmanship exists. The painters and sculptors of the Renaissance and the succeeding epoch were very much occupied with portrait-art. An important exception is Michelangelo, who left no portraits. Even the statues of Lorenzo and Giuliano in the Medici chapel he declared he did not intend for portraits. Raphael and his contemporaries, and their immediate successors, brought the art to its full perfection.

In Spain Velasquez is the greatest name, but less skill than his, which was supreme, would have sufficed to give pre-eminence in a country where portrait-painting was so little practiced as it was in the Peninsula. N. of the Alps, Van Eyck, Cranach, Dürer, Holbein, Rubens, Franz Hals, and Rembrandt distinguished themselves in portraiture. Holbein belongs, however, as much to England as to Germany; most of his finest portraits are in England. Since his time Germany has not produced any great portrait-painter. In France no native-born portrait-painter of any distinction appeared until the eighteenth century. Francis I. invited several Italian artists into France, chief among them Leonardo da Vinci, from whose hand the king hoped he might get other portraits equal to that of Mona Lisa del Gioeondo, now in the Louvre, on which Leonardo worked for four years, and which Francis bought of him for 4,000 golden crowns; but, as is well known, Leonardo did not paint a single picture while he was in France.

In England, Holbein may be said to have created portrait-painting; he had many imitators, some of them most skillful, yet, though the country did not produce many portrait-painters of consideration before the eighteenth century, she welcomed good painters from other lands. In Mary's time, Antonio Moro came from Utrecht, and in Elizabeth's reign Federigo Zucchero, an Italian, was in vogue. A Dutch painter, Lucas de Heere, also found employment. Later were the two Olivers, of French extraction; they were miniature-painters, and contemporary with them was Nicholas Hilliard, one of the first Englishmen by birth who gained distinction in the art. The brief visit of Rubens gave, after Holbein, the second great impetus to the art of portrait-painting in England. He remained in the island only one year, but he painted many portraits. He was followed by his great pupil, Van Dyck, who became for England a standard of excellence in portraiture. Peter Lely, a Westphalian, went to England and established himself as a portrait-painter. Besides Cromwell and many of his chiefs, he painted all the beauties of Charles II.'s court. Cornelis Janssen, of Leyden, a good painter, went over in 1618. While Lely was flourishing, Gottfried Kneller, a native of Lubeck, arrived; he had already gained some distinction in Europe. He had great success in England, and painted Dryden, Addison, and Pope, and nearly every notable man and woman of his time in the island. With the appearance of Sir Joshua Reynolds (1723–92) began a new and more fruitful period, the third important influence affecting the growth of painting, and particularly of portrait-painting, in England; and from his time to the present the history of English portraiture has never lacked great names. Thomas Gainsborough, his contemporary (1727–88), would have been a dangerous rival if he had devoted himself as exclusively to portraiture as Reynolds did, but he preferred landscape-painting, and though his portraits are charming, he is most known as one of the founders of landscape-painting in England. Another notable painter of this time was Romney (1734–1802), whose reputation has increased with time. John Opie (1761–1807) also gained considerable distinction.

The modern French school began with David (1748–1825), who was before all a so-called historical painter, but who made some excellent portraits. France, however, has never had a great artist whose name is identified exclusively with portrait-painting, or even to any considerable extent so identified. With those even who have excelled in it, it has always been held of secondary importance. Yet Gérard (1770–1837) made many interesting portraits, and those of Ingres (1781–1867) must surely outlive all but two or three of the imaginative compositions on which he thought to build his fame.

Sculpture in England has been more successful in portraiture than in ideal work. It owed its modern impulse to a Frenchman, Roubiliac (1695?–1762), who went to England in 1720, and by the very excess of his dramatic conception and the superfluous energy of his execution gave an impetus to his art in England which in a dull, pedantic time bore down everything before it. He was followed by a number of distinguished sculptors—Flaxman, Banks, Nollekens—of whom Flaxman was the greatest artist, but less known as a sculptor of portraits than the others. More recent are Westmacott, Gibson, Foley, Bell, Marshall-Wood, Boehm, and Woolner. The portrait-busts of the last two are productions of singular merit; they include busts of Carlyle and Tennyson.

In the U. S. the art of portraiture properly begins with Copley, who was born in Boston in 1737, but lived in England from 1774 till his death in 1815. His manner of painting was somewhat cold and hard, but he drew well, his color is agreeable, and he gave a good deal of life and animation to his heads. He was followed by John Trumbull, who, though he failed as an historical painter, deserves to be remembered for his miniatures. Another excellent miniature-painter was Malbone. The most distinguished name after Copley is, however, that of Gilbert Stuart (1756–1828), an artist who when at his best was one of the most excellent painters of his time. Other notable names are those of Leslie, Sully, Inman, Harding, Healy, Elliot, Baker, Huntington, Page, and Furness. Revised by Russell Sturgis.

Port-Royal (or, more properly, **Port-Royal des Champs**): an institution founded in 1204 by Matthieu de Montmoreney at Chevreuse, near Versailles, as a monastery for Bernardine or Cistercian nuns. In the course of time it became noted as an educational institution, to which the French nobility sent their young daughters, but at the same time it lost to some degree its religious character, until in the beginning of the seventeenth century the abbess, Mère Marie Angélique (see Arnauld, Marie Angélique), thoroughly reformed the establishment and revived the old religious discipline, with its rigid seclusion, poverty, and ascetieism. She was a sister of Antoine Arnauld, "the great Arnauld," Professor in Theology at the Sorbonne and an ardent disciple of Jansen, and thus the monastery became Jansenistic. It flourished, and the number of nuns increased rapidly. In 1625 the Hôtel de Clugny, in the Faubourg de St. Jacques, Paris, was bought, and a branch institution was founded here under the title of Port-Royal de Paris, and in 1626 a new and extended abbey was erected at Port-Royal des Champs. Meanwhile a number of pious and learned men had established themselves at a farmhouse near Port-Royal des Champs, called Les Granges, for the purpose of leading a secluded and ascetic life, devoted to studies and religious exercises: and when the nuns removed to the new abbey these "solitaries of Port-Royal" were allowed to occupy the old place under the immediate jurisdiction of the Archbishop of Paris. They were all Jansenists, and soon Port-Royal became famous as the center of the whole Jansenistic movement and the focus of the opposition to the Jesuits. Here the Jansenists founded a school which numbered among its pupils some of the most famous men of the time, as, for example, Tillemont and Racine, and here were prepared those formidable attacks on the Society of Jesus which startled the whole world. In 1669 the two monasteries, Port-Royal des Champs and Port-Royal de Paris, were separated, and the latter reorganized under the influence of the Jesuits; and when the nuns of Port-Royal des Champs still refused to subscribe to the papal condemnation of Jansen, they were dispersed in 1709 and imprisoned in various other monasteries of France, and the buildings of their abbey leveled to the ground. See Fontaine, *Mémoires pour servir à l'Histoire de Port-Royal* (2 vols., 1736); Racine, *Histoire abrégée de Port-Royal* (1742); Sainte-Beuve, *Port-Royal* (5 vols., 1842–78); Beard, *Port-Royal* (2 vols., 1861).

Port Royal: town; in Beaufort co., S. C.; terminus of Port Royal and Augusta Railway (for location of county, see map of South Carolina, ref. 8–E); noted for one of the earliest settlements made by the Spaniards within the present limits of the U. S., for important events during the civil war, and as the rendezvous of the North Atlantic squadron of the U. S. navy. The harbor is one of the finest in the world. A large dry-dock was completed in 1895. Pop. (1900) 601.

Port-Royal, Little Schools of: See the Appendix.

Port Saïd': town; in Egypt, at the junction of the Suez Canal with the Mediterranean (see map of Africa, ref. 1–F). No village existed here in 1859 when, near the present site, the first spadeful of earth was turned in digging the canal. Port Saïd is built mainly on earth since dug out. In 1897 the population was 42,095. Its fine harbor, entirely artificial, is formed by two moles, that on the W. over 8,000 feet long. E. A. G.

Port Sarnia: See Sarnia.

Portsmouth: town of Hampshire, England; on the island of Portsea; 23 miles S. E. of Southampton and 74 miles S. W. of London (see map of England, ref. 14–I). The limits of the municipal and parliamentary borough, which are identical, comprise, in addition to Portsmouth proper, the town of Portsea, the suburbs of Landport and Southsea, and nearly the whole of Portsea island. Portsmouth and Portsea were encircled by a fortified enceinte, a portion of which has been removed as useless since 1872; but under

the action of the defense commission appointed in 1859 a chain of works was built on modern types from 3 to 5 miles distant. This includes the Hilsea lines and the forts of Portsdown Hill on the land side, and the SPITHEAD (*q. v.*) forts on the sea side. Portsmouth proper presents for the most part an unattractive appearance, but many improvements have been made. A new town-hall was opened in 1890. Among the old buildings may be mentioned the Church of St. Thomas, originally dating from the twelfth century, and the Early English garrison chapel, restored by Street in 1867. In Portsea there is a convict prison, and Landport has a people's park, opened in 1878. Southsea is a fashionable watering-place with assembly-rooms, a pier, and an esplanade 2 miles in length.

Portsmouth harbor, which is about 400 yards wide at its entrance between Portsmouth and GOSPORT (*q. v.*), expands into a spacious basin, stretching 4 miles inward N. W. of the town. It affords anchorage to large war-vessels at all times, as there are 24 feet of water in the channel at low water. The dockyard is the most important establishment of the kind in Great Britain. It covers an area of 293 acres and contains dry-docks capable of admitting the largest vessels, warehouses, anchor-forges, iron and copper mills, rope-houses, hemp-stores, sail-lofts, etc., in addition to the twelve wet-docks, which are from 22 to 36 feet deep, lined with solid masonry, roofed over, and closed by lock-gates.

The local trade is chiefly supported by the Government establishments. Brewing is carried on, and there is considerable traffic in coal, timber, cattle, and agricultural produce.

Portsmouth's importance began with Henry VIII., the town was fortified by Edward IV., and the works were continued at intervals afterward. In 1642 it was taken by the Parliamentary forces. It returns two members to Parliament. Pop. (1901) 189,160. R. A. ROBERTS.

Portsmouth: city (settled in 1623, became Portsmouth township in 1653, incorporated as a city in 1849), port of entry, and one of the capitals of Rockingham co., N. H.; on the Piscataqua river, and the Boston and Maine and the Concord and Montreal railways; 54 miles N. by E. of Boston (for location, see map of New Hampshire, ref. 10–G). It is the only seaport in the State, is built on a peninsula 3½ miles from the sea, and has a very spacious harbor, from 35 to 75 feet deep, which is never frozen. The harbor is protected by earthworks on Gerrish's island and Jerry's Point near its entrance, and farther up are two disused stone forts, Constitution and McClary. Bridges connect the city with Kittery, Me., and with Newcastle on Green island. The U. S. navy-yard, officially known as the Portsmouth navy-yard, is on Continental island, half a mile from the city, and belongs to Kittery, Me. It comprises 170 acres of ground, has a large balance dry dock and several ship-houses, and has turned out a number of noted wooden war-vessels. The city contains a U. S. Government building, a life-saving station, and a signal-service station. There are 12 churches, 9 public-school buildings, public-school property valued at over $85,000, 2 libraries (the Athenæum, which also has a valuable museum, and the Free Public) containing over 26,000 volumes, 2 academies, 4 national banks with combined capital of $800,000, 2 savings-banks, a trust and guarantee company, and 3 daily and 3 weekly newspapers. Portsmouth has been noted for its ship-building for more than two centuries. Among the early vessels of note built there were the Falkland, 54 guns, in 1690, and the America, 50 guns, in 1749, both on orders from the British Government, and the Ranger, 18 guns, in 1777, ordered by the Continental Congress. The latter vessel was first commanded by John Paul Jones, and was the first one to carry the Stars and Stripes and to receive a salute. The city contains a number of historic buildings, a hospital, Home for Indigent Women, Female Asylum, Home for Children, board of trade, marble-works, and several breweries, planing-mills, machine-shops, shoe-factories, copper and brass foundry, and hosiery, glove, and soap factories. Pop. (1880) 9,690; (1890) 9,827; (1900) 10,637.

Portsmouth: city; capital of Scioto co., O. (for location, see map of Ohio, ref. 8–E); at the confluence of the Ohio and Scioto rivers; on the Balt. and O. S. West., the Norfolk and West., and the Cin., Ports. and Va. railways; at the S. terminus of the Ohio and Erie canal; 100 miles S. of Columbus, 114 miles S. by E. of Cincinnati. It is built on a plain partly inclosed by high hills, the ground on the opposite side of the Ohio river rising to a height of 500 feet. The region is rich in agricultural lands and in mineral resources, particularly iron ore, and the city is a shipping-point for a large variety of productions. The industrial establishments include rolling-mills, iron and steel works, extensive shoe-factories, lumber and planing mills, flour-mills, stove-foundries, several distilleries, fire-brick plants, furniture and veneer factories, and wheel-works. The city has water supplied from the Ohio river by the Holly system, electric lights, 7 public-school buildings, public-school property valued at over $180,000, public library (founded in 1879), the Ohio Military Academy (non-sectarian), 3 national banks with combined capital of $475,000, a State bank with capital of $50,000, an incorporated bank, and a daily and 5 weekly newspapers. Pop. (1880) 11,321; (1890) 12,394; (1900) 17,870. EDITOR OF "TIMES."

Portsmouth: city; capital of Norfolk co., Va.; on the east bank of the Elizabeth river and the Atlantic and Danville, the Seaboard Air Line, and the Norfolk and Carolina railways; opposite NORFOLK (*q. v.*), with which it is connected by ferry (for location, see map of Virginia, ref. 7–J). The U. S. navy-yard, officially known as the Norfolk navy-yard, is at Gosport, the southern extremity of the city. There are also a large dry dock, naval hospital, and marine barracks. The city has a steamboat line to Baltimore and regular steamship connection with the principal Atlantic ports, and with Norfolk constitutes a U. S. customs district, from which are exported large quantities of cotton, lumber, oak staves, naval stores, pig iron, and, to Northern cities, early vegetables. It contains the shops of the Seaboard Air Line Railroad, 3 State banks with combined capital of $201,500, and a daily and a weekly periodical. Pop. (1880) 11,390; (1890) 13,268; with suburbs, 19,268; (1900) 17,427. EDITOR OF "PROGRESS."

Port Townsend: city (laid out in 1852), port of entry for the Puget Sound customs district, and capital of Jefferson co., Wash.; on Quimper peninsula, between Port Discovery and Port Townsend Bays, and on the Port Townsend Southern Railroad; 65 miles N. by W. of Seattle, 90 miles E. of the Pacific Ocean (for location, see map of Washington, ref. 2–C). It is in an agricultural, mineral, and lumbering region, and is a place of large strategic importance. The U. S. Government has established Fort Townsend on the west side of Port Townsend Bay, 2½ miles by water and 5 miles by land from the city, and has reserved Point Hudson, Point Partridge, Marrowstone Point, and Admiralty Head as sites for fortifications. It has also established a quarantine station and a marine hospital. The city has gas and electric light plants, a system of water-works supplied from Little Quilcene river by gravity, several lines of street-railway, a line of daily steamers to Victoria, British Columbia, a national bank with capital of $100,000, 3 State banks with combined capital of $180,000, and 2 daily and 3 weekly newspapers. There are several foundries and machine-shops, saw and flour mills, steel, wire, and nail works, and other manufactories. Pop. (1880) 917; (1890) 4,558; (1900) 3,443. EDITOR OF "CALL."

Por'tugal, Port. pron. pōr-too-gaal' [from Portug. and Span. *Portugal* < Late Lat. *Portus Cale*, liter., the Harbor of Cale, orig. name of the city of *Oporto*]: a kingdom of Europe, occupying the southwestern part of the Iberian Peninsula, between Spain and the Atlantic (see map of Spain and Portugal). Area (of the continental portion only), 32,528 sq. miles, and of the islands of MADEIRA and the AZORES (*qq. v.*), 1,510.

Physical Features.—Portugal is not naturally divided from Spain; as a whole, it is lower than Spain, with more low ground. The northern half is essentially mountainous, and its scenery is very picturesque. The Serra da Estrella crosses the center. Its peaks attain 6,539 feet, and are covered with snow during the winter months. Southern Portugal consists of plains and rolling lands, varied toward the S. W. by spurs of the Sierra Morena. One of these spurs, the Serra de Algarve, extends to the ocean. The principal rivers rise in Spain. The Minho and Guadiana, on the frontiers, are navigated by boats. The Douro, which crosses the mountain region, is also navigable for barges, and its mouth forms the harbor of Oporto. The Tejo or Tagus crosses the southern plain, and its broadened mouth is the splendid harbor of Lisbon. Seagoing vessels ascend to Santarem, about 40 miles. The northern and southern coasts are generally rocky. Between Oporto and Cape Carvoeiro there are extensive sand-dunes, backed by marshes. Almost the only good harbors are at Lisbon and Oporto.

Climate, Soil, and Natural Productions.—The climate is mild and equable; on the coasts frosts are rare. Olives and

oranges grow well nearly everywhere, and palms flourish in the S. Rains are abundant. The available lands are generally very fertile; exceptions are the oak-barrens of Alemtejo. Considerable tracts of forest remain. The common trees are oaks, pines, and chestnuts. The cork-oak grows wild and is cultivated. The coast fisheries of sardines, tunnies, etc, compete with those of France. The most important mineral products are copper, antimony, manganese, lead, and salt from the coast lagoons; a little gold, zinc, iron, and coal are obtained.

Agriculture.—Wine is the most important product and export, including port from the valley of the Douro and various light-red wines from near Lisbon. The Portuguese oranges, olives and olive oil, figs, tomatoes, etc., are known throughout the world. Cereals (maize, wheat, rye, and a little rice) occupy the largest area. Stock-raising is increasing. Large herds of swine run almost wild in the oak-barrens of Alemtejo. Agricultural methods are backward, partly owing to ignorance and lack of tools, partly to excessive division of land and the absence and neglect of the large proprietors.

Manufactures.—Besides the numerous establishments for oil and wine making and for canning fruits, there are important factories, especially in Lisbon and Oporto. Cotton and silk thread and cloths, veil stuffs, gold and silver filigree work, shoes, gloves, etc., are made. Ship-building is now confined to a few yards.

Commerce and Communications.—The most important exports are wine, cork, fish, copper ore, and fruits. In 1891 the exports were valued at 31,872,000 milreis; the imports at 50,024,000 milreis. About one-fourth of the trade is with Great Britain. Portugal now has good roads and telegraph system and nearly 1,000 miles of railways. Over one-third of the latter belong to the state and the rest have state subventions. See PORTUGAL in the Appendix.

People and Government.—The Portuguese, like the Spanish, are descended from Celto-Iberic tribes, more or less modified by Latin, Visigothic, and Moorish blood. The language, laws, and many arts and customs have come down with little change from the Romans. The educated class is comparatively small, but has nearly all the wealth and influence. The lower classes are ignorant and superstitious, but industrious and shrewd. Population in 1890, 5,082,247. The annual increase is slight, owing to the constant drain to Brazil. The Government is a constitutional monarchy. Parliament consists of a house of peers and a house of delegates. Adult males who can read and write and have a clear income of 100 milreis possess the right of suffrage. The state religion is the Roman Catholic, but other creeds are tolerated. Primary education is nominally compulsory, but the illiterate class is still very large. Lisbon and Oporto have schools of medicine, law, fine arts, technology, etc. The University of Coimbra is one of the oldest and most celebrated in Europe.

Weights, Measures, and Coins.—The metric system is in general use. The Portuguese *libra* is 1·012 lb. avoirdupois; the *alqueire* is 0·36 bush. The *milreis* or 1,000 *reis* is equal to $1.08; the *conto* is 1,000 milreis. In expressing sums of money the milreis or dollar mark is written after the milreis but before the odd reis; thus 1,230$178 means 1.230 milreis (or 1 conto and 230 milreis) and 178 reis. The testoon or *tostão* is 100 reis—about 10 cents—and the *vintem* is 20 reis. Gold is the standard. Gold coins of 10 milreis (coroa) and 5, 2, and 1 milreis are used, and there are smaller coins of silver and bronze.

Finances.—In June, 1900, the external debt was 65,098,865 milreis; the internal debt 87,894,879. Most of the debt is now funded at 4½ and 4 per cent. Of late years there has been an almost constantly recurring deficit, with defaults or delays in payments: measures have been taken for retrenchment. The annual revenue is about 50,000,000 milreis.

History.—Portugal was one of the little kingdoms formed when the Christians began to drive back the Mohammedans. Henry of Burgundy married the daughter of Alfonso VI., and, about 1095, received her dowry, the lately conquered Portocallo, or Northern Portugal, as a fief of Galicia. By wars and conquests the region was consolidated and made independent. Henry's son, Affonso Henriques (1128–85), is called the founder of the monarchy, because he took the title of king (1139 or 1140), and drove the Moors far southward, capturing Lisbon in 1147. About 1250 the Moors were finally driven from Algarve. By a revolution in 1383 the throne passed from the line of Burgundy to that of Aviz. John II. broke the power of the nobles, and made that of the crown absolute. Exploration was stimulated by Prince Henry, the Navigator, who conceived or adopted the idea of circumnavigating Africa to reach India. Madeira and the Cape Verde islands were discovered and colonized; and Bartolomeu Diaz reached the Cape of Good Hope (1486). Portugal became the center of maritime knowledge; a papal bull and the Treaty of Tordesillas (1494) gave the eastern hemisphere to Portuguese conquest and the western to Spain. In 1497 Vasco da Gama reached India by the Cape of Good Hope; trading-posts were speedily established on the Asiatic coasts; Ceylon and the Moluccas were conquered, and within a few years the whole stream of Eastern trade was turned into Lisbon. Brazil was discovered in 1500. The soldiers and statesmen seldom returned from the East, and the laborers were drained into Brazil. King Sebastian perished with his army in a war with the Moors of western Africa (1578), and Portugal was seized by Philip II. of Spain. At once the fabric fell to pieces; the Dutch seized the Eastern trade, the African posts, and part of Brazil, and Portuguese commerce was swept from the seas. The successors of Philip failed to keep his promise to preserve the autonomy of Portugal, and a revolution, begun in 1640 and supported by England, wrested the country from Spain and gave the crown to the house of Bragança, in which it still remains. The Brazilian possessions, recovered from the Dutch, became a new source of wealth, especially after the discovery of gold and diamonds. On Nov. 1, 1755, occurred the great earthquake which destroyed Lisbon, the only severe one in the history of Portugal. In 1807 the Portuguese court fled to Brazil before the armies of Napoleon. The French were soon driven out by the British. A popular revolution in 1820 ended in the adoption of a constitution: John VI., returning from Brazil soon after, was compelled to sign this. In 1822 Brazil became independent under Pedro I., son of the Portuguese king; this blow nearly ruined Portugal. By the death of John VI. in 1826 the crown fell to the Brazilian emperor, who resigned it in favor of his infant daughter, Maria da Gloria; she was, for a time, robbed of her rights by the usurpation of Dom Miguel (1828), but Dom Pedro, having resigned the Brazilian throne, headed a successful revolt in favor of his daughter, who became queen in 1834. Several petty political revolts followed until 1852, when the constitution was revised to suit all parties. Since then Portugal has been at peace and generally advancing, but she has incurred a crushing public debt, and the growth of the republican party threatens trouble for the future. The African colonies have been expanded into large possessions and are carefully cherished, but they have given rise to boundary disputes with Great Britain.

Colonies.—The following table shows the (approximate) extent and population of the Portuguese colonies:

POSSESSIONS.	Area in sq. m.	Population.
Cape Verde, Princess, and St. Thomas islands..	2,104	131,970
West African possessions.....	489,500	2,800,000
East Africa	261,700	1,500,000
Possessions in Asia and the East Indies (Goa, Macao, Timor, etc.).....	7,900	939,320
Totals.....	761,204	5,371,290

HERBERT H. SMITH.

Portuguese-Brazilian Literature: the literature of Brazil, from the time of its settlement down to the present. Since Brazil was colonized by the Portuguese, this literature is in the Portuguese language, and for this reason it would be possible to treat it as a part of Portuguese literature. Since Brazil has become an independent nation, however, it seems better to discuss the manifestations of Brazilian national feeling and thought in a distinct article.

I. *Colonial Period.*—During the colonial period of three centuries Brazil received nearly all its impressions of the outer world through Portugal. There were few schools except the Jesuit colleges, and hardly any libraries or books. Wealthy young men went to Portugal to study law or divinity, and either remained there or returned to take secular and Church offices. Under these circumstances there was

little chance for the growth of a distinctively Brazilian literature; the few writers of note generally followed Portuguese models. The Jesuit missionaries—commonly of European birth—were the first colonial authors. Living among the Indians they imbibed the spirit of the forests and plains, and in their letters—especially in those of Anchieta—we may trace the first germs of a national literature. The same order gave to the colony its only great genius—Antonio Vieira, who was a Brazilian by education, though not by birth. He was the first of the Portuguese orators, one of the first prose-writers, and a statesman of worldwide fame. In history the sixteenth and seventeenth centuries produced only missionary chronicles like those of Vasconcellos and Jaboatão, or local accounts of wars and discoveries, like the *Castrioto Lusitano* of Frei Raphael de Jesus, or the *Noticias* of Vasconcellos; the endless *relatorios* and *roteiros*, most of them unpublished, are valuable as documents, but mere rubbish from a literary standpoint. In 1730 Rocha Pitta, a native of Bahia, published his *Historia da America Portugueza*, the first complete and really readable history of Brazil. This was followed by the local *Annaes historicos do Maranhão* (1749), by Berredo, a Portuguese governor; the *Memoria sobre a capitania de São Vicente* (1797), of Frei Gaspar Madre de Dios, etc. In natural science, ethnology, and geography we have many scattered notices, but no special works of any note by Brazilian authors before the end of the eighteenth century; the reports of the naturalist Alexandre Rodrigues Ferreira and the engineer Ricardo Franco, who were attached to the boundary commission, 1783–93, have only been published in part in modern times. Perhaps the first Brazilian poet worth naming was Gregorio de Mattos Guerra (Bahia, 1633–96); his biting satires would have won him fame had not so many of them been defaced by obscenity. Later several poets of note clustered around the viceregal court at Rio de Janeiro, or found their way thence to Europe; such were Frei Francisco de São Carlos (1763–1829), whose saered epic, *Assumpção da Santissima Virgem*, is, in some sense, comparable to *Paradise Lost*; Antonio Pereira de Souza Caldas (1762–1814), writer of sacred odes; the mulatto José Basilio da Gama (1740–95), best known for his historical poem, *Uruguay*; Manuel Ignacio da Silva Alvarenga, whose pastorals and love-songs are still widely read; the lyric poets Domingos Caldas Barboza and Antonio Diniz; and Frei José da Santa Ritta Durão, author of *Caramurú* (1781), the first epic founded on Indian life. Antonio José da Silva (1705–39) went from Rio de Janeiro to Portugal, became famous as an author of comedies, and eventually met a tragic death at the hands of the Inquisition. Equally sad was the fate of a brilliant coterie of poets in Minas Geraes; Claudio Manuel da Costa, unrivaled for his sonnets and odes; Thomaz Antonio Gonzaga, with his melodious verses to "Marilia"; and Alvarenga Peixoto. They were involved in an alleged conspiracy in 1789; Costa committed suicide, and the others went into penal servitude. To this list we may add Botelho d'Oliveira, a native of Bahia who published his *Musica do Parnaso* in 1705. All these follow, more or less, the Portuguese classic or romantic models; but here and there we can see the true national spirit struggling for utterance, as in some passages from Botelho and Gonzaga. Santa Ritta Durão clung to a severely classic measure and style; and the incongruity of Indians who talk and act like Greek heroes is too great a strain for the modern reader; it obscures the real merit of his verse.

II. *Modern Period.*—The sojourn of the Portuguese court at Rio de Janeiro (1807–21) was marked by increased literary activity, prineipally in the prose domains of history and geography; then appeared Pizarro's *Memorias historicas*, Sanctos's *Memorias do Reino do Brazil*, Ayres de Cazal's *Corographia Brasilica*, and Velloso's *Flora Fluminensis*. The independence brought a host of political writers, brilliant orators, such as the Andradas (one of them a well-known naturalist also), and economists. The King of Portugal had left one priceless legaey to Brazil—his historical library, which became the nucleus of the great public library at Rio de Janeiro. Distinguished naturalists visited the country and wrote enthusiastically about it; and Brazilian authors began to see that their inspiration lay in the magnificent scenes about them. French literature became very popular, and doubtless had a strong influence, but in the main the best writers became nationalized. The reign of Pedro II. saw the birth of a new school, which is still in its infancy, but has a brilliant future. Almost every page of it bears the impress of tropical nature—the forests and mountains, the gigantic rivers, and vast plains of the interior; above all the Indians, who are so indissolubly connected with colonial history and country life. One poet of the first rank has appeared—Antonio Gonçalves Dias—and the brilliant coloring of his descriptive verses, combined with their tender sentiment, has made them household words in Brazil and Portugal. Poems like *Rosa no mar*, *Piaga*, *A tempestade*, and *O gigante de pedra* will live as long as the language does; and the lines beginning

> Minha terra tem palmeiras
> "Onde canta o sabiá,"

might almost be called the Brazilian national hymn. Magalhães, another poet of note, has been called the founder of the Brazilian school. It is certain that his Indian epic, *A confederação dos Tamoyos*, contains passages of rare beauty, but it lacks the fire of Dias. Among a multitude of lesser poets we may mention Casimero de Abreu, well known for his delightful love-songs; Sylvio Romero, Araujo Porto-Alegre, and Castro Alves. In romance Alencar is the best known. The popularity of his Indian stories is rather undeserved, though they contain excellent descriptive passages. Very much superior in plot, description, and character-drawing are the novels of Escragnolle Taunay. His *Innocencia* has been translated into English, but only one familiar with country life in Brazil can appreciate its fidelity to nature. Taunay's descriptive powers are also well seen in his *Retraite de Laguna* (originally written in French) and *Scenas de Viagem*, both relating episodes of the Paraguayan war. Macedo is another novelist of note. The greatest of the Brazilian historians is Varnhagen (Viscount of Porto Seguro), whose *Historia do Brazil* is a classic. Other historians of note are Pereira da Silva, Lisboa (also noted for his essays), and Fernandes Pinheiro. The historical criticisms of Capistrano de Abreu are excellent. Caetano da Silva in historical geography; Beaurepaire Rohan, Cunha Mattos, and others in geography and travels; Couto de Magalhães in ethnology; and Bocayuva and Patrocinio in journalism, are all well-known names. In natural science foreigners as yet occupy the first place. See Pereira da Silva, *Os varões illustres do Brazil* (1858); Pinheiro, *Litteratura nacional* (1862); Mello Moraes Filho, *Curso de Litteratura Brazileira* (1882); F. Wolf, *Histoire de la Littérature brésilienne* (Berlin, 1863). HERBERT H. SMITH.

Portuguese Language: the national language of Portugal, used also in the Portuguese colonies and Brazil, and (in a dialectal form) in the border province of Galicia in Northwestern Spain. The number of native speakers of the language can not be even approximately given; it is probably over 10,000,000, and may reach 20,000,000.

The system of sounds of the language is complex and ill indicated by the usual etymologieal spelling. Disregarding some minute shades we may describe it as follows: There are eleven oral vowels: two *i*'s (about as in English *machine*, written *i*, *y*, *e*; or English *hill*, written *i*); two *e*'s (one close, written *e*, *ê*; one open, written *e*, *è*, *é*); three *a*'s (one as in English *father*, written *a*, *á*; one differently described as like English *a* in *about* or French *a* in *dame*, written *a*, *â*; one about like the sound in English *hot*, written *a*, *á*); two *o*'s (one close, written *o*, *ô*, *ou*; one open, written *o*, *ó*); a *u*, as in English *rule*, written *u*, *o*; a vowel comparable with the French mute *e*, written *e*, *i*. There are five nasal vowels: the nasal of the first *i*, written *im*, *in*; that of close *e*, written *em*, *en*; that of the second *a*, written *am*, *an*, *ã*; that of close *o*, written *om*, *on*, *õ*; that of *u*, written *um*, *un*. These are not like the French nasal vowels. Noteworthy are also certain nasal diphthongs, as *ãe* and *õe* (both these end in the sound of nasal *i*). The consonants, like the vowels, are differently given by different observers; we reckon here twenty-five: *p*, *b*, a bilabial *v* (written *b*), *f*, *v*, *w* (consonantal *u*, written *u*, *o*), *m*, *t*, *d*, *l*, *n* (these four more dental than in English), a dental spirant (as in English *that*, written *d*), a gutturalized *l*, *s* (written *s*, *c*, *ç*), *z* (written *z*, *s*)), two varieties of *r* as in Spanish, one strongly rolled (written *r*, *rr*, *rh*), the other not so rolled (written *r*), both pronounced with the tip of the tongue, sibilants as in English *shut* (written *x*, *ch*, *s*, *z*) and *pleasure* (written *j*, *g*, *s*, *z*), a palatal *l* resembling English *lli* in *million* (written *lh*), a palatal *n* resembling English *ni* in *union* (written *nh*), *y* (consonantal *i*, written *i*, *e*), *k* (as in English *cool*, *key*), *g* (as in English *good*, *gild*), and (not always recognized) the nasal sound in English *sing*, *song* (written *n*, which at the same time indicates nasality of the preceding vowel).

The grammatical structure of the language is similar to that of Spanish, and the same resemblance exists for the sources of its vocabulary, though it has borrowed more from France. A peculiar feature is the inflexion of the infinitive with personal endings, which helps to make clear the person thought of. The original pluperfect is now generally a conditional, as in Spanish, but the original sense also exists. The use of Portuguese in writings preserved dates from about the end of the twelfth century. In the sixteenth century, later than in Italy and Spain, appear the beginnings of grammatical treatment. A dictionary begun by the Academy in 1793 was not carried beyond the letter A, but Bluteau's *Vocabulario portuguez e latino* (8 vols., 1712–21, with a supplement in 2 vols., 1727–28) is earlier, and the *Elucidario das palavras, termos e frases que em Portugal antigamente se usaram*, etc., of Joaquim de Santa Rosa de Viterbo appeared in 1798–99. The best historical study of phonology and inflexions is that of Cornu in Gröber's *Grundriss der romanischen Philologie*, i., 715 ff. The description of the modern sounds given above is based mainly on A. R. Gonçalves Vianna's *Exposição da pronuncia normal portugueza* (Lisbon, 1892); see also his earlier study in *Romania*, xii., 29 ff., and the articles of Prince L.-L. Bonaparte in *Trans. of the Philological Society* (1880–81), p. 23 ff. (1882–84), p. 404 ff., and H. Sweet, *ib.* (1882–84), p. 203 ff. Work on Portuguese philology, including dialects, has been done by J. Leite de Vasconcellos. F. A. Coelho, Carolina Michaelis de Vasconcellos (e. g. *Der "portugiesische" Infinitiv* in *Romanische Forschungen*, vii., 49 ff.), H. Schuchardt (especially his *Kreolische Studien* in the publications of the Vienna Academy), H. R. Lang, and others; see articles in the *Revista lusitana* and other periodicals, and the bibliographies in the *Zeitschrift für romanische Philologie*.

Portuguese Literature: the works in prose and verse, written in the Portuguese tongue, whether in Portugal or in the Portuguese colonies, with the exception of Brazil. (See Portuguese-Brazilian Literature.) Owing to the comparatively restricted territory and population of Portugal, her literature can not be esteemed one of the great European literatures. Moreover, the national life has not had the fullness and original energy requisite for the creation of a really independent literary tradition. Portugal has, in the main, followed intellectual movements received from abroad, and the periods of her literature must all be denominated according to these successive foreign influences. At the same time, the temperament of the people is distinctly marked with its inclination to melancholy, to reverie, to sentimental longings—in short, to what the Portuguese themselves call by the untranslatable name *saudades*; and the literature, even where its matter is entirely borrowed, has an air and a charm all its own.

First Period (1200–1385); *French and Provençal Influence.*—During this period the Spanish province of Galicia, whose dialect had not yet become distinct from Portuguese, must be included with Portugal. Although there were certainly in this considerable region indigenous intellectual traditions dating from the Roman time, and although the neighborhood of the Arabs, since the eighth century, had had its effect on culture, still the first influences tending to arouse imaginative and literary activity in modern Portugal came from the N. of the Pyrenees—i. e. from France and Provence. These influences began to be felt as early as the ninth century, when the shrine of St. James at Compostella became the chief object of veneration and goal of pilgrimages for all Western Europe. Then the wars against the Moors brought many French soldiers into the Peninsula; and after Toledo had been recovered (1085), many French clergy and scholars, and even colonists, were invited to settle in the new-won territory. Intermarriages also between the peninsular princes and nobility and the French became frequent, and finally came the establishment of the Burgundian family on the Portuguese throne. As early as the twelfth century—the great literary period of mediæval France—there was imitation among the Portuguese-Galician nobility of the courtly lyrics of their northern neighbors. The earliest of these that have come down to us, however, are of the beginning of the thirteenth century. In accordance with the essentially aristocratic character of the new poetry, the models followed were rather Provençal than French proper. During the thirteenth century the school of Portuguese-Galician troubadours rapidly developed, and, indeed, the Portuguese-Galician dialect became the regular language even for the Spanish lyric poets. The full splendor of this new art was reached in the second half of the century, especially at the court of King Dionysius (Dom Diniz, 1279–1325), who was a poet himself, and whose two natural sons were poets. The Spanish king Alfonso X., el Sabio (1252–84), had also given distinction to the style by writing his lyric poems, both sacred and profane, in the Portuguese-Galician tongue. The active production of such lyric poetry continued till about 1350, and the list of poets contains more than 150 names, many of them princes and other persons of high rank. The poems themselves, in so far as they are left to us, are contained in several songbooks, or *Cancioneiros*, of which the most important are the so-called *Cancioneiro da Ajuda*, preserved in Portugal, and the Italian *Cancioneiro do Vaticano* (*Cod. Vat.*, 4803) and *Cancioneiro Colocci-Brancuti* (belonging to Count Brancuti di Cagli). The numerous poetical forms include all the important varieties employed by the troubadours of Provence. The most serious defect of the mass of poems is their almost complete artificiality.

Contemporary with this lyric production we find traces in Portugal of general interest in the historic or romantic traditions treated in the narrative poems of Northern France and of Spain. The Arthurian legends, the heroic tales about Charlemagne and his peers, and certain of the Spanish popular historic themes were undoubtedly sung in Portugal. Perhaps at this time the famous romance of *Amadis de Gaula* began to take shape. (See Lobeira, Vasco, de.) No other considerable work, however, on any of these subjects seems to have been produced. The works in prose of this period are of slight account, being mainly either translations from Latin, French, and Spanish books, both religious and secular, or meager chronicles and genealogies of the Portuguese nobility (*Livros de Linhagens*, or *Nobiliarios*).

Second Period (1385–1521); *Spanish Influence.*—This period, intermediary between the Middle Ages and the modern world, was rather one of intellectual preparation than of actual literary achievement. A great change had to be undergone by Portugal, as by the rest of Europe, under the influence of that revival of classical studies which had been initiated in Italy by Petrarch and Boccaccio. The University of Lisbon had already been founded by Dom Diniz in 1291, and, though shifted several times from the capital to Coimbra and back again, speedily acquired great importance for Portuguese culture. During the fourteenth and fifteenth centuries we find a wide extension of the study first of the Latin and later of the Greek classics. At the same time intercourse with Italy became more constant, and Italian literary ideals gradually replaced the older French and Provençal traditions. The first effect of the readjustment was almost a cessation of poetical composition. From the middle of the fourteenth to the second half of the fifteenth century we have no Portuguese poetry of importance. Then there was developed at the royal court a school of poets, which, while not completely assimilating the new ideas, still served to introduce them. These singers, commonly called *poetas palacianos*, did not directly imitate the Italians, but instead the Spanish imitators of the Italians, like the Marques de Santillana, Juan de Mena, Jorge Manrique, etc. The number of the *poetas palacianos* was large, and included persons of the highest rank. Their verses were collected and printed in 1516 by the courtier and poet Garcia de Resende in the volume entitled *Cancio-*

neiro Geral, which contains about 1,000 poems, all written apparently after 1448.

The most noteworthy prose works of this period are the first great Portuguese chronicles. Four of these were written during the fifteenth century—those of Fernam Lopez, Gomes Eannes de Zurara, Vasco Fernandes de Lucena, and Ruy de Pina. Furthermore, there was a remarkably rich literature of translations, especially from the Latin classics.

Third Period (1521–80); *Italian Influence.*—This, the golden age of Portuguese literature, is ushered in by three writers still closely allied with the past, but at the same time innovators and indicators of tendencies destined to become dominant in the future—Gil Vicente (1502–36), Christovam Falcão (d. 1550?), and Bernardim Ribeiro (b. 1486?). The first of these was the founder of the Portuguese drama and at the same time one of the richest and most varied geniuses of his native land. The impulse to the creation of his dramatic pieces (*autos*) seems to have come from the *Autos* or *Eclogas* of the Spanish Juan del Encina (see Encina, Juan, del), published in 1496; but the Portuguese poet far outdid his models in variety and originality. His dramas, which are both religious and secular, show the most remarkable commingling of all kinds of elements—mediæval and Renaissance, popular and learned, sacred and profane. Falcão and Ribeiro, on the other hand, introduced that expression of sentimental feeling in pastoral form which, on the whole, has best fitted the Portuguese temperament. Their inspiration seems to have proceeded first from the pastoral works which the Italians began to write at the very dawn of the Renaissance (see Pastoral Poetry); but certainly they owed much to the popular pastoral songs (*serranilhas*, etc.) which are among the most characteristic products of the Portuguese genius.

The note given uncertainly by these poets was first struck with fullness and power by Francisco de Sâ e Miranda (1495–1557), the first classic writer of Portugal. After he had already become a learned man, this poet in 1521 undertook a journey to Italy and Spain with the avowed purpose of learning what was newest and best in literature and art. He remained five or six years in Italy, entering into relations with the most eminent writers and scholars, and after his return to Portugal he speedily became almost a literary dictator. Humanistic studies were, as a consequence, pursued with far greater zeal, and Portuguese poets cultivated ideals quite different from those of their predecessors. In particular, Sâ e Miranda put forward Petrarch and his Italian disciples as the only true models for lyric poets; he greatly strengthened the impulse to the pastoral form; and his introduction of comedy after the manner of the Italians and of Plautus and Terence gave the drama a new direction. His followers and imitators were many, but only one can be mentioned here, Jorge Ferreira de Vasconcellos (d. 1585), whose tragedy in the antique style, *Ines de Castro*, still remains unsurpassed in Portugal.

The poet who combines within himself all these tendencies and who gave them ultimate expression was Luis de Camões (1524–80), the greatest figure in the history of Portuguese letters. Of passionate and impressionable temperament, yet capable of feeling to the full the glories of the great period of Portuguese discovery and conquest in the East and West Indies, Camões gave utterance to his own experiences and emotions in exquisite lyrics, and to the heroic history of his country in an epic, *Os Lusiadas*, which is among the best the moderns have produced. So commanding was his genius that the succeeding generation of poets in both kinds may best be grouped under the one name *Camonistas*, or disciples of Camões.

Despite the greater importance of poetry, prose also flourished greatly in this period. Its most remarkable monuments were historical works, of which may be mentioned the *Décadas* of João de Barros (1496–1570); the *Historia do Descobrimento da India* of Fernam Lopes de Castanheda (d. 1559); the *Historia da Provincia de Santa Cruz* of Pedro de Magalhães Gandavo; the *Chronica de D. Manoel* and *Chronica de D. João II.* of Damião de Goes (1501–72); the Latin *De rebus Emanualis libri XII.* of Jeronymo Osorio (d. 1580), later made a classic in the translation of Francisco Manoel do Nascimento (publ. 1804); the *Chronica de D. João III.* of Francisco de Andrade (1540–1614); and the often too imaginative book of travels in Asia, *Peregrinacões*, of Fernam Mendes Pinto (1509–80). Of other works in prose from this time the most notable are the romances of chivalry, the number of which is great. The best of them, however, *Palmeirim de Inglaterra*, we have only in a garbled Spanish form. Worth mentioning here, though not written till about 1595, is the pastoral romance by Fernam Alvares do Oriente, entitled *A Lusitania trasformada*, based on Sannazaro's *Arcadia*.

Fourth Period (1580–1700); *Spanish-Italian Culteranistic Influence.*—As in Spain, the golden age was followed by a long period of literary decay. That curious literary movement known in Italy and France as Marinism, in England as Euphuism, in Spain as Gongorism or Culteranism, extended also to Portugal. Command of the substance of poetry having been lost, poets strove to make up for it by intricacies and artificialities of style. The large and gracious manner of the classic writers was succeeded by the tortured and laborious efforts of the makers of *concetti*. Accordingly, in all this long period we have but a few great names. Francisco Manoel de Mello (1611–66) showed both in lyric poetry and in the pastoral romance something of the old charm. Francisco Rodrigues Lobo (d. 1625) attained a certain success in the latter form. In the sacred and profane lyrics of D. Francisco de Portugal and of the nun Sor Violante do Ceo (1601–93) an occasional note of truth and power is struck. The numerous epic poets rarely produce a readable work—for example, the *Malacca Conquistada* of Francisco de Sâ e Menezes (d. 1664), and the *Viriato tragico* of Braz Garcia de Mascarenhas. The oratory of the Jesuit preacher Antonio Vieira (1608–97) could become at times direct and strong. Most characteristic of the time was the formation of numerous literary academies, after the fashion of the Italians—some of them with the most fantastic names and the strangest conceptions of literary art.

Fifth Period (1700–1825); *Pseudo-Classicism.*—Like the rest of Europe, Portugal gave the eighteenth century to the contest between the old manner of thinking and living and rapidly invading science and rationalism; and here, as elsewhere, it was France that gave rise to the revolutionary impulses. Despite all the efforts of the conservative part of society, aided by the ruthless cruelties of the Inquisition, the movement could not be stayed. Gradually here and there one of the numerous academies became a meeting-place for enlightened men eager to share the scientific advances of their time. Such were the Academia Portugueza, founded early in the century by Francisco Xavier de Menezes, Count of Ericeira, and the Arcadia Ulyssiponense, established in 1756 by Antonio Diniz da Cruz e Silva and others. At the same time literature began to adopt as models first the great French writers of the age of Louis XIV., and later Voltaire, the Encyclopædists, and to some extent Rousseau. While this process of regulating and rationalizing was going on, it must be admitted that the interest of literary art decidedly diminished. For some reason Brazil for the moment fairly eclipsed the mother-country. In the latter the chief names are Antonio Diniz da Cruz e Silva (1731–99), mentioned above, and Francisco Manoel do Nascimento (1734–1819). Serving as links to connect this with the following period, we have Manoel Maria Barbosa du Bocage (1765–1805) and José Agostinho de Macedo (1761–1831).

Sixth Period (since 1825); *Romanticism.*—The literary phenomena of the romantic movement were the same in Portugal as elsewhere. The scientific studies of the eighteenth century had greatly enlarged the range of intellectual interests, and the agitations of the revolutionary period turned the attention of the best spirits to the furthering of patriotic national life. These efforts only the more alarmed the Portuguese conservatives, and as a result many of the liberals were forced into temporary exile, thus becoming all the better acquainted with the tendencies of contemporary Europe. The true initiator of Romanticism in Portugal was João Baptista da Silva Leitão, Viscount of Almeida Garrett (1799–1854), who was equally influential in politics and in literature. It was he who established a national theater and provided it with a series of dramas full of national reminiscences and of patriotic feeling. He produced in his novel *O Arco de Santa Anna* (1846) one of the chief romantic historical novels in the language. He also encouraged the collection of popular songs and traditions, which have done much to strengthen the sense of national life among the Portuguese. Only less important than his efforts were those of Alexandre Herculano de Carvalho e Araujo (1810–77), the chief of the Portuguese historical novelists as well as an historian of the first rank. Somewhat aside from the romantic movement, on the other hand,

stood Antonio Feliciano de Castilho (1800–75), the master of an exquisite poetic style, with but little originality of ideas.

Romanticism everywhere in Europe easily degenerated into extravagance, and the succeeding generation of Portuguese writers did not escape the danger. While novelists like Rebello da Silva, Mendes Leal, and Andrade Corvo succeeded in giving something of measure to their work, too many others fell into the merest literary oddities. The poets, like Soares dos Passos (1826–60), abandoned wholesome and generous life for melancholy and dilettante sentiment. Since 1865, however, a strong reaction has set in, finding expression in the utterances of the so-called Coimbra school (*eschola de Coimbra*). The representatives of this new movement have striven to replace the triviality and vagueness of the ultra-romanticists by serious studies in the literature, art, and history of Portugal as well as of other countries. Noteworthy names here are those of the Positivist and literary historian Theophilo Braga (b. 1843), the philologist F. A. Coelho, the critic and scholar J. Leite de Vasconcellos. To pure literature belongs the poet João de Deus (Nogueira Ramos), one of the most excellent of the contemporary lyric poets of Europe.

Bibliography.—The best sketch of Portuguese literature is that of Carolina Michaëlis de Vasconcellos, in Gröber's *Grundriss der romanischen Philologie*, vol. ii., pt. 2 (Strassburg, 1894), which contains full bibliographical information. In Portuguese we have the long series of volumes by Theophilo Braga, which, though issued under various titles, form parts of the author's early conceived *Historia da Litteratura Portugueza* (1870, *seq.*). These are impaired by numerous inconsistencies and changes of view. See also Costa e Silva, *Ensaio Biographico-Critico sobre os melhores Poetas Portuguezes* (10 vols., Lisbon, 1850–56); Andrade Ferreira and C. Castello-Branco, *Curso de Litteratura Portugueza* (Lisbon, 1875–76); Barbosa-Machado, *Bibliotheca Lusitana* (4 vols., 1741–52); Francisco da Silva, *Diccionario Bibliographico Portuguez* (continued by Brito-Aranha; 15 vols. up to 1890); R. Pinto de Mattos, *Manual Bibliographico Portuguez* (Oporto, 1878); Maxime Formont, *Le mouvement poétique contemporain en Portugal* (Lyons, 1893); Candido de Figueiredo, *Homens e lettras* (1881). A. R. Marsh.

Portuguese Man-of-war: any one of the large siphonophores of the genus *Physalia*. See Siphonophoræ.

Portulacaceæ: See Purslane Family.

Port Whitby, Canada: See Whitby.

Port Wine: See Wine.

Po'rus: a king of India, ruling E. of the Hydaspes; attacked Alexander when he tried to cross this river, but was defeated, wounded, and captured. He was treated with great kindness, however, by Alexander, and restored to his kingdom, which was much enlarged. As an ally of the Macedonians he afterward supported them on their further expedition into India, but after the departure of Alexander he was put to death by Eudemus, who was left in command of the Greek army of occupation.

Pöschl, Thomas: religious leader; b. at Höretz, in Bohemia, Mar. 2, 1769; was appointed chaplain at Ampfelwang, in Upper Austria, in the beginning of the nineteenth century, and caused great commotion there and in the adjacent districts by the singular doctrines he propounded—that women could hear confession and give absolution, that a certain process of purification which produced convulsions was necessary to salvation, etc. He found many adherents, and finally formed an independent sect, the Pöschlians; but, as the wildest excesses took place in their assemblies, the police interfered. Pöschl was arrested and found completely insane, and was taken to a lunatic asylum in Vienna, where he died Nov. 15, 1837. His followers, who went so far as to offer human sacrifices, were dispersed by force.

Posei'don (in Gr. Ποσειδῶν): in Grecian mythology, son of Cronus and Rhea, brother of Zeus, and husband of Amphitrite. When the universe was apportioned out, after the conquest of the Titans, he received as his portion the empire of the sea, an element of peculiar importance in the Greek mind. He is the equal of Zeus, he surrounds and holds the earth, he is lord over all other sea divinities, he sends storms and quiets the waves, he sends earthquakes (which the Greeks thought originated in the sea), he dwells in the sea. Like the sea, he is ever prone to stormy anger; the waves are his horses (and so he was regarded as the creator of the horse, and the patron of the chariot-race); the trident, a stroke of which blasts rocks and makes water to spring forth, is his awful scepter. Relatively speaking, he is rarely depicted in art, but on this point see the article *Poseidon* in Baumeister's *Denkmäler*. J. R. S. Sterrett.

Posen, pō'zen: province of Prussia; bounded by Silesia, Brandenburg, Pomerania, West Prussia, and Poland. Area, 11,184 sq. miles. The land is a low and level plain, intersected by the Netze, the Warthe, and the Obra, tributaries of the Oder, and bounded for a short distance on the N. E. by the Vistula. It is dotted all over with small lakes, and covered to a great extent with fine forests. The soil is fruitful and well cultivated. Cattle of superior quality are reared, and large crops of wheat, rye, barley, and oats are raised. Manufactures of cloth, machinery, sugar, and tiles are carried on. Posen formed a part of Poland until the first partition of that country, when Prussia took the largest part of the present province. This was enlarged at the two following partitions, an act solemnly sanctioned at the Congress of Vienna in 1815. Nearly two-thirds of the inhabitants are Poles, who are principally Roman Catholics, while the Germans are mainly Protestants. Pop. (1895) 1,828,658.

Posen: capital of the province of Posen, Prussia; at the confluence of the Zybina and Warthe; 150 miles E. of Berlin and 90 miles N. of Breslau (see map of German Empire, ref. 3–I). The Prussian Government has made it one of its great fortified places, and surrounded it by a modern enceinte with citadel and outworks at a cost of 114,000,000 thalers. It contains many fine buildings, including a town-hall and a cathedral, many promenades and public squares, several good educational and benevolent institutions, and manufactures of tobacco, sealing-wax, wax candles, leather, furs, liqueurs, gold and silver ware, woolen and linen fabrics, arms and carriages. Posen is the seat of a Roman Catholic archbishopric. Pop. (1900) 117,014.

Posey, Thomas: soldier; b. in Eastern Virginia, July 9, 1750; removed to Western Virginia in 1769; was quartermaster of Lewis's division of Lord Dunmore's expedition against the Ohio Indians, and took part in the memorable battle of Point Pleasant Oct. 10, 1774; was in the following year a member of the Virginia committee of correspondence, and captain of a company which he raised for the Seventh Virginia Regiment; participated in the defeat of Lord Dunmore at Gwynn's island July 8, 1776; joined the Continental army at Middlebrook, N. J., early in 1777; was transferred to Morgan's famous rifle regiment; distinguished himself in an action at Piscataway, N. J., and in the battles of Bemis Heights and Stillwater under Gen. Gates; commanded the regiment with the rank of major in an expedition against the Indians in the Wyoming valley Oct., 1778; commanded the Eleventh Virginia Regiment 1779, distinguishing himself at the head of a battery at Stony Point; was present at the surrender of Yorktown; served under Wayne in Georgia; defeated the Indians June 23, 1782; resided in Spottsylvania co., Va., for many years after the war; was appointed brigadier-general Feb. 14, 1793, and served under Gen. Wayne in his campaigns against the Indians in the Northwest; removed soon afterward to Kentucky, where he became lieutenant-governor and major-general, 1809; was U. S. Senator from Louisiana 1812–13; succeeded Harrison as Governor of Indiana Territory 1813, and became agent for Indian affairs 1816. D. at Shawneetown, Ill., Mar. 19, 1818. His *Life* was published in Sparks's *American Biography*.

Posido'nius (Gr. Ποσειδώνιος): Greek philosopher of the Stoic school; historian, physicist; b. at Apamea, in Syria (128 B. C.); founded a school in Rhodes, which Cicero attended; traveled far and wide. His great work was a history in fifty-two books, a continuation of Polybius, embracing the period from 145–82 B. C. D. 45 B. C. Fragments are given in Müller's *Fragmenta Historicorum Græcorum*, vol. iii., pp. 245–296. B. L. G.

Posilipo, pō-see'li-pō [Ital. < Lat. *Pausily'pum* = Gr. Παυσίλυπον, liter., stopping or ending care]: the name of a villa of the notorious epicure Vedius Pollio, afterward extended to the entire eminence which bounds the city of Naples on the W. See Naples.

Positivism [deriv. of *positive*, in the sense of indubitable, certain]: the system of philosophy and religion founded by Auguste Comte (1798–1857). (See Comte.) In his youth he showed a strong taste for mathematics, and it was while engaged in teaching geometry in Paris that he became associated (1818–24) with Saint-Simon, the celebrated founder of a sect of world-menders. It appears to have been during this period

that he began to conceive his great scheme for the reorganization of society by philosophy. Comte maintained that the phenomena of society conform to fixed and ascertainable laws, no less than the phenomena of chemical combination or planetary rotation. To discover the laws or most general aspects of the succession of social events was therefore the great task which Comte set before himself; but from his standpoint such a task as this required systematic preparation on an immense scale, for the phenomena of human society are by far the most complicated with which investigation has to deal. In two ways the successful study of them involves a previous study of the most general aspects of all other phenomena; for, in the first place, the human units of society conform to physical, chemical, and biological laws, so that these must be known before we can give a complete account of the actions of social units; and, in the second place, each science has devices for getting at the truth about things which are to some extent peculiar to itself, so that we must look over the whole field in order to equip ourselves adequately for a research which will call into play all the devices we can bring to bear. One science, for example, succeeds pre-eminently by the use of experiment, while another, in which experiment is less likely to return finally satisfactory answers, gets along best by using the comparative method. Let us, therefore, study each method in that science which best illustrates the proper use of it, and then we shall be the better prepared to investigate the excessively complex questions presented by the phenomena of human society.

Classification of the Sciences.—Thus in the attempt to inaugurate a scientific theory of social phenomena Comte was led incidentally to work up the elements of a grand theory of scientific method. As his acquaintance with physical science was wholly at second-hand, he fell into many errors in the details of his scheme, but he nevertheless accomplished so much as to entitle him to a very high place as a writer on method. His first task was to classify the various sciences in the order of their logical dependence. Having made a division between abstract and concrete sciences, corresponding nearly to the old division between natural philosophy and natural history, Comte arranged his so-called abstract sciences in a linear series. He began with the most simple and general phenomena, to proceed step by step to those which are most complex and special. Upon this principle the inorganic sciences, as a group, were manifestly to come before those which deal with organic phenomena. For example, we can study thermal radiations and chemical reactions without taking vital forces into the account, but we can not study living organisms without appealing to physics and chemistry at every step. In the region of inorganic science Comte placed astronomy first, as dealing (in his time) only with gravitative force as manifested in the relatively simple phenomena of the mutual attractions of the heavenly bodies; whereas physics, which he placed next, treats not only of gravitative force as manifested throughout relatively complex terrestrial phenomena, but also of such modes of forces as cohesion and capillarity, and of the varieties of wave-motion known as sound, heat, light, magnetism, and electricity. Chemistry, dealing with the still more complex phenomena in which the relative positions of molecules are altered heterogeneously, resulting in new compounds with new properties, was ranked third in order. Passing then to organic science, Comte grouped together, under the head of biology, the most general aspects of nutrition and reproduction, of muscular contractility and nervous sensibility; under the last-named head he included all the phenomena of mind, leaving no place for psychology as an independent science, and setting aside altogether the study of the subjective phenomena of consciousness by introspective observation. Last in the series, as obviously the most complex and specialized of all, was ranked the science of sociology. Mathematics, on the other hand, was placed before all these sciences, the phenomena of number, form, and magnitude being universal, and capable of generalization without reference to other phenomena. The "hierarchy of the positive sciences" thus came out in the following order: (1) mathematics; (2) astronomy; (3) physics; (4) chemistry; (5) biology; (6) sociology. According to Comte, this arrangement represented not only the logical order in which the sciences depend one upon another, but also the historical order in which they have been successively developed and in which they have aided each other's advance. Thus astronomy, according to Comte, was truly a science in the days of Hipparchus, while physics became a science, in the true sense of the word, only when Galileo discovered the increment of velocity in falling bodies; chemistry was not scientific until the time of Lavoisier; biology was first organized into a coherent body of doctrine by Bichat; and sociology had to wait until all these lines of inquiry were gathered together in the hands of the founder of positivism. This Comtist classification of the sciences has fascinated many minds, but it is not at present accepted by scientific thinkers. For a full examination of this subject the reader may be referred to Herbert Spencer's essays on the *Classification of the Sciences* and the *Genesis of Science*, and to John Fiske's *Outlines of Cosmic Philosophy*, part i., ch. viii.

Methods of Scientific Inquiry.—Comte's classification, however, was not a bad one for the practical ends which he had in view. He cared much less about organizing a coherent body of doctrine concerning the various provinces of nature than about co-ordinating the methods of research which the sciences severally best illustrate. His most important step consisted in assigning to each class of phenomena its appropriate method of investigation, and in clearly marking out the limits within which each method is applicable. It is this which makes it still interesting and profitable to read his great work, even in those chapters on physics, chemistry, and biology, which in nearly all other respects the revolutions in science have rendered thoroughly antiquated. According to Comte the resources at our disposal for the inductive investigation of phenomena may be classified as observation, experiment, and comparison. In simple observation we merely collate the phenomena as they are presented to us; in experiment, we artificially vary the circumstances; in comparison, we watch the circumstances as they are varied for us on a great scale by nature. The conditions of successful observation are best studied in astronomy, where experiment is out of the question, owing to the magnitude and inaccessibility of the phenomena, and where the comparative method is only beginning to be applied. Physics and chemistry, on the other hand, are, *par excellence*, the sciences of experiment, since we can vary the phenomena almost indefinitely. In biology, experiment is also indispensable, nearly all our knowledge of the more important organic functions having been gained through vivisection and other forms of experiment; but experiment is far more complicated and difficult to interpret in biology than in physics, partly owing to the subtlety of the causes in operation, partly because the experiment itself sets in motion a new series of phenomena which are liable to mask and obscure those which we wish to observe. Hence the practical study of experimentation should not begin in biology, but in physics or chemistry, where the conditions are simpler. On the other hand, it is in biology that we can best learn the use of the comparative method, since here we have a vast hierarchy of organisms, in which various organs and their corresponding functions appear in all stages of development. It was in biology that the method of comparison was first employed upon a great scale, and since the time of Cuvier its extension over all departments of sociological inquiry, including linguistics, mythology, and jurisprudence, is perhaps the most striking event in the history of science.

The Three Stages.—Perhaps no better illustration of the use of the comparative method could be found than is furnished by Comte's first wide generalization from the facts of history. When, after his preparatory discussion of scientific methods, Comte endeavored to sum up the most prominent aspects of social progress, both intellectual and material, his first achievement was his celebrated theory of the "three stages" through which men's conceptions must pass. This theory constitutes the most essential part of the structure of positivism. He who intelligently accepts the so-called "law of the three stages" may properly be regarded as a positivist; he who rejects the so-called "law," as an inadequate and misleading description of the phenomena which it seeks to generalize, must be ranked among the antagonists of the positive philosophy.

At the beginning of his great work Comte tells us that "the mind employs successively in each of its researches three methods of philosophizing, of which the character is essentially different and even radically opposed—first, the theological method, then the metaphysical, lastly the positive. The theological system arrives at the highest perfection of which it is susceptible when it has substituted the providential action of a single Being for the capricious play of the innumerable independent deities which were primitively imagined. Likewise the perfection of the metaphysical

system consists in conceiving, instead of many particular entities, one grand entity, Nature, as the source of all phenomena. Finally, the perfection of the positive system would be to represent all observable phenomena as particular cases of a single general fact." In accordance with this general view Comte maintains that in every department of inquiry human speculation has passed through or is passing through these three stages; and, by way of welding firmly together the different parts of his system, he affirms that the order in which the respective sciences have advanced toward the positive stage is truly represented by the order in which they are ranked in his linear classification. Obviously we have here a very important theorem; for if this view of intellectual progress could be demonstrated it would follow that the conceptions of mankind must eventually become "positive" with reference to all questions, and Comte's claim to be regarded as the philosophic lawgiver for the whole future of the human race might not seem extravagant.

When Herbert Spencer's system of philosophy was beginning to attract general attention (about 1860), and while it had as yet been but partially expounded, it was very frequently confounded with Positivism. In truth the Spencerian philosophy is the very antipodes of Positivism, and a statement of their fundamental difference serves most vividly to illustrate the real character of the latter.

With regard to the doctrine of the "three stages," Spencer and his school hold a position diametrically opposed to that held by the Positivists. Between the three terminal conceptions—of God, of Nature, and of Law—as above described by Comte, Spencer denies that there is any incongruity, or that the latter supersedes the former; he maintains, on the contrary, that science, when properly understood, remains quite at one with metaphysics and theology in the assertion of Unconditional Existence as the source of Conditioned Existence. While in Comte's system, therefore, the assumed conflict between science and religion is emphasized and perpetuated, in Spencer's system it disappears entirely. The system of Spencer has by many persons been supposed to be akin to positivism, because, like the latter, it rejects as illegitimate sundry *a priori* methods of arriving at truth which have hitherto been more customarily associated with the processes of metaphysics and theology than with those of science; but this surface resemblance only shows that all modern philosophy, following out a tendency which has been apparent for two centuries, is becoming more and more thoroughly permeated by the scientific spirit of wariness in its method of reaching conclusions. The difference between positivism and evolutionism is the difference between a system that is radically revolutionary and quasi-atheistical, and a system that is conservatively progressive and in the deepest sense theistic.

Social Philosophy.—This difference is further elucidated by Comte's theory of sociology, and it serves in turn to elucidate that theory. The fifth volume of his great work is a brilliant survey of European history, in which the "law of the three stages" is applied and illustrated with admirable ingenuity. It should be read in connection with the *History of Civilization* by Guizot, which in some respects it resembles, though the latter writer, while inferior to Comte in depth of thought, yet far surpasses him in philosophic appreciation of the democratic and Protestant aspects of modern society. Along with the progress from theological to positive habits of thought, Comte joins the progress from military to industrial modes of life, and maintains—incorrectly, as evolutionists hold—that the latter change is determined by the former. This brings us to his fundamental point. He passes over the history of moral progress, and while admitting as a fact the growth of the sympathetic and social feelings at the expense of the selfish and unsocial, he yet fails to take this into the account as the preeminent factor in social changes, and always argues as if social amelioration were the product of a reformation of speculative beliefs. Instead of recognizing that the framework of society is based ultimately upon *character*, he regards it as based ultimately upon *opinion*. To this, as to nearly all the theorems of positivism, the Evolutionists of Spencer's school oppose a directly contrary theorem. They hold that, in order to improve society, it is not enough to effect a change of beliefs, but it is further necessary that there should be a gradual change in men's dispositions and prevalent motives. Now, improvement in character is a slow result of countless influences summed up in what has been called social discipline, and accordingly Evolutionists do not suppose it possible to effect a radical reformation of society—to bring in the millennium, for example—by any such movement, taken separately, as can be carried out by one man or a single generation of men; least of all, do they believe it possible to reform society by means of philosophy. The whole structure of positivism, the whole lifework of Comte, is founded on the precisely contrary belief, that society can be reorganized by means of philosophy—that in order to insure a more harmonious co-operation of human interests it is sufficient to effect a unification of men's beliefs. The evil which Comte always regarded as the grand fundamental evil to be remedied, and which is always thus alluded to by his followers, is what they are fond of calling "the intellectual anarchy of the Western World." The belief that individuality, as involving variety in opinion and behavior, is equivalent to "anarchy," and that "order" means uniformity, is profoundly in accordance with the general temper of Comte's mind. It was to put an end to this "anarchy," and to inaugurate an era of uniformity in belief and conduct, that Comte entered upon his long series of philosophical labors; and from first to last he kept this end steadily in view. All his profound studies in the philosophy of method, and all his elaborate historical generalizations, were merely as incidents in the accomplishment of this great central task.

The Positive Polity and Religion of Humanity.—In 1845 Comte's old project, of inaugurating a new philosophy which should renovate human society, assumed the form of an attempt to institute a new religion, which Prof. Huxley has happily and tersely described as "Catholicism minus Christianity," and in which Comte, instead of the pope, was to be sovereign pontiff. In one of his works, published some seven years after this time, he alludes to it as the era in his life when to the career of Aristotle, which he had hitherto followed, he added the career of St. Paul! Yet the philosophic germs of this later career, as above hinted, are apparent enough in his earlier work. There was no such break between his earlier and his later speculations as one would infer from reading Mill's *Auguste Comte and Positivism*. The early philosophic project for reorganizing society came to be transfigured into a quasi-religious project, but its general outlines underwent no further change than was necessarily implied in such a transfiguration of external aspect. The end in view still was to insure a fixed and uniform standard of social action by establishing a fixed and uniform standard of belief; but the attainment of such a standard by means of scientific methods was no longer deemed sufficient; in addition to this there must be a uniform religious impulse and a uniform cultus; but as the assumed outgrowing of the theological stage of thought involved the ignoring of Deity, and as even Comte was not able to imagine a religion without some sort of a god, it became necessary to furnish some new kind of deity as the source of this new religious impulse and the object of this new cultus. This new kind of deity, according to Comte, is Humanity, and the religious impulse of the future is to be the impulse to serve Humanity and to deserve well of it. It must be admitted that the ethical side of this conception of religion is lofty enough, but the speculative side of it may well seem too grotesque to be seriously entertained by any one endowed with the slightest modicum of that sense of humor which, next to religious faith, is the most desirable possession of a human being. Comte spent the later years of his life in rearing upon this basis a system of practical philosophy astonishingly minute in detail, which in complicated absurdity has probably never been matched by the productions of any other human mind. The ideal of society, as described by Comte, is a state in which everything—even to the minutest details of life—is to be prescribed by unquestioned authority, in which the New Pope or "high priest of Humanity" is to decide upon the age at which each man shall be married, what profession he shall choose, upon what scientific researches he shall enter, and when he shall become *emeritus* as to the general work of life. No caliph, in his wildest dreams of absolutism, ever imagined such a state of things as Comte sought to work out for his ideal society. The main features of this scheme were shaped in curious accordance with the Roman Catholic ideal as conceived by the mediæval popes. There was to be a class of philosophers corresponding to the class of priests under the old *régime*, with unlimited control over opinions. The arch-philosopher, or "high priest of Humanity," was to supersede the pope; and Paris was to be the holy city of the Positivist as Rome had been the holy city of the Roman Catholic.

A new calendar was to be instituted, beginning with the French Revolution of 1789, and like the old one was to be made up of saints' days, save that philosophers, poets, legislators, inventors, and pre-eminently deserving men of all sorts, and of all ages and countries, were to be substituted for the saints of the old calendar; and for the Virgin Mother an antitype was to be found in the ideal of Humanity, symbolized as "a woman of thirty with a child in her arms." And so on throughout a host of arbitrary details.

Subjective Synthesis.—In the very last years of Comte's life symptoms of mental aberration became unmistakable. After finishing the *Positive Polity* he began a new work, called *Subjective Synthesis*, in which it is recommended that decimal numeration should be abandoned in favor of a septimal system, because seven is a sacred number, and, moreover, being a prime number, is better fitted to inspire the human intellect with a sense of its necessary limitations! Every volume, moreover, constituting a distinct treatise, should consist of "seven chapters, besides the introduction and the conclusion; and each of these should be composed of three parts. Each third part of a chapter should be divided into seven sections, each composed of seven groups of sentences, separated by the usual break of line," etc. The author did not live to complete this work, but died soon after his first volume was published.

Comte's Followers.—At his death Comte left one great disciple, Émile Littré, one of the most consummate scholars that France has produced; but Littré was regarded as half a heretic by the thoroughgoing disciples of Comte, as he refused to follow the teacher through his later vagaries. Robinet, the eminent physiologist, became a follower of Comte; and besides this a small number of Positivists, under the leadership of Laffitte, continued for some years in Paris to profess the "religion of humanity." In Germany, positivism has never gained any footing at all; in England, only a precarious one. Among the declared followers of Comte in England are Congreve, Prof. E. S. Beesly, Frederic Harrison, and Dr. Bridges; and John Morley has been considerably influenced by him. As a rule, the positivist school is characterized by a sympathy with communists and boycotting strikers, a partiality for the short and sharp despotic method of settling social questions, a tendency to regard politics from the sentimentalist point of view, a dislike to individuality of thought, an obtuseness to the requirements of scientific method, and (in the speculative region) hostility to the theory of evolution, the doctrine of the correlation of forces, and other theories which have assumed prominence since the time when their master Comte stigmatized all such kinds of theorizing as "metaphysical" and "chimerical."

Bibliography.—The works of Auguste Comte are as follows: *Cours de Philosophie positive* (6 vols., Paris, 1830–42; since republished with preface by Littré, 1864); *Traité élémentaire de Géometrie analytique* (1843); *Traité philosophique d'Astronomie populaire* (1844); *Discours sur l'Esprit positif* (1844); *Discours sur l'Ensemble du Positivisme* (1848; afterward included in the *Politique positive*); *Calendrier positiviste* (1849); *Culte systématique de l'Humanité* (1850); *Catéchisme positiviste* (16mo, 1852); *Système de Politique positive, ou Traité de Sociologie, instituant la Religion de l'Humanité* (4 vols., 1852–54); *Appel aux Conservateurs* (1855); *Synthèse subjective* (vol. i., 1856)—all at Paris, and, except the *Catéchisme*, in 8vo. English translations: *The Positive Philosophy*, by Miss Harriet Martineau, very much abridged (2 vols. 8vo, London, 1853; New York, 1858); *Catechism of Positive Religion*, by Richard Congreve (12mo, 1858); *A General View of Positivism* (*Discours sur l'Ensemble*, etc.), by J. H. Bridges (8vo, 1865)—all in London. Part of the first volume of the *Philosophie positive*, translated by W. M. Gillespie, was published (New York, 1858) under the title *Philosophy of Mathematics*. A review entitled *La Philosophie positive*, conducted by Littré and Wyrouboff, was published six times a year in Paris, 1867–74. As auxiliary expositions and discussions of the positive philosophy, the student should consult Littré, *Auguste Comte et la Philosophie positive* (Paris, 1864); *Paroles de Philosophie positive* (1863); *Auguste Comte et Stuart Mill* (1866); Pellarin, *Essai critique sur la Philosophie positive* (Paris, 1864); Robinet, *Notice sur l'Œuvre et sur la Vie d'Auguste Comte* (Paris, 1864); Blignières, *Exposition de la Religion et de la Philosophie positive* (Paris, 1857); Mill, *Auguste Comte and Positivism* (London and Boston, 1866); Bridges, *The Unity of Comte's Life and Doctrine* (London, 1866); C. G. David (pseudonym for David G. Croly), *A Positivist Primer* (New York, 1871); Lewes, *Comte's Philosophy of the Sciences* (London, 1853); *History of Philosophy* (3d ed. 2 vols., London, 1867). Edward Caird's *The Social Philosophy and Religion of Comte* (New York, 1885) is a criticism from a metaphysical standpoint. These are the principal works out of a considerable body of literature on the subject. For hostile criticisms see Huxley, *The Scientific Aspects of Positivism*, in his *Lay Sermons* (London, 1870; reprinted in New York); Spencer, *Recent Discussions in Science, Philosophy, and Morals* (New York, 1873); and *Outlines of Cosmic Philosophy* (2 vols., London, 1874, and Boston, 1875), by the present writer. John Fiske.

Pos'se Comita'tus: a law Latin phrase, meaning literally "the power of the county." By the common law the sheriff while engaged in executing process, especially when it was criminal, or in pursuing and arresting felons, or in exercising his functions generally as the chief administrative officer charged with the duty of enforcing the keeping of the peace, was authorized to summon to his aid, if necessary, all the men above the age of fifteen years within the county, with the exception of the sick or infirm, ecclesiastics, and peers, and they constituted, in the ancient technical nomenclature, the *posse comitatus*. The same authority is given to the sheriff in the U. S., although its exercise is often regulated by statute. The ordinary cases in which such a resort is had to the active assistance of private citizens are the quelling of riots, the overcoming of forcible seizures or detainers of land, the subduing of forcible rescues made or attempted of persons arrested pursuant to the command of a proper writ, and the resistance to any forcible measures in opposition to the execution of public justice; in short, wherever a breach of the peace has attained, or threatens to attain, such magnitude that the officials themselves are unable to suppress it. Since the sheriff may call out the entire power of the county, he may likewise, under the circumstances above described, summon one or more individuals, or any number less than the whole. In Great Britain the calling out of the *posse comitatus* is expressly authorized by the Sheriffs Act, 1887, sec. 8, subsec. 2, for the purpose of resisting the execution of a writ.

Revised by F. Sturges Allen.

Postal Service: that branch of the public service which is concerned particularly with the conveyance and delivery of letters and other documents, newspapers, book-packets, etc., the issue of money-orders, and in some instances with the management of the telegraphs, savings-banks, etc., as in Great Britain.

Origin and Early History.—The beginnings of the present highly organized postal systems of the world are doubtless to be found in the lines of couriers which rulers early established for the prompt transmission of decrees and other dispatches connected with governmental affairs. The earliest known system was that established in 559 B. C. by Cyrus the Elder, King of Persia, who maintained relays of mounted men at fixed stations, ready at a moment's notice to forward the king's messages from post to post. China has maintained such a system from a very early date, and Marco Polo tells us that in his day (the latter part of the thirteenth century) the "Great Khan" maintained 10,000 post-stations, and more than 300,000 horses for the use of his messengers and couriers, who traveled "a good 200 or 250 miles in the day and as much in the night," a fresh horse and rider being supplied without delay every 25 or 30 miles. Establishments of this kind existed among the Romans in the time of Augustus, B. C. 31, and in France under Charlemagne, but the first actual letter-post for commercial purposes appears to have originated in the Hanse towns early in the twelfth century. A century later the University of Paris established an efficient postal system, which continued till the beginning of the eighteenth century. One of the earliest posts in Europe for general accommodation was that established in 1516 by Franz of Thurn and Taxis, for Maximilian, the Emperor of Germany. The office of postmaster-general became hereditary in the Counts of Thurn and Taxis, and was held by them until the dissolution of the German empire in 1806.

England.—As early as 1252 royal messengers, called nuncii, were employed in England for the conveyance of letters, and in 1470, when Edward IV. was waging war on Scotland, he established post-stations 20 miles apart, between that country and England; but it appears that until the time of Henry VIII. no regular system of posts existed in England.

Though these establishments were primarily for the transmission of the royal letters, and the conveyance of persons traveling on the king's business, the post-riders and postmasters soon found it both convenient and profitable to undertake the conveyance of private letters and private travelers, and so extensive had this practice become that Elizabeth commanded that all packets on the queen's business or the affairs of state should have precedence of private correspondence. In 1603 James I. issued a proclamation giving to post-agents the exclusive right of letting horses to travelers, and a later proclamation (1609) forbade all persons not duly authorized by the master of the posts from collecting, carrying, and delivering letters. This was the beginning of the state monopoly of letter-carrying in England.

At this time there were only four official post-routes in the kingdom, one through Kent to Dover and the continent of Europe, one to Plymouth, where the royal dockyard was situated, one to Ireland by way of Beaumaris, and one to Scotland viâ Berwick. In 1619 the Du Questres, father and son, were placed in charge of the first of these routes. Their successor, Thomas Witherings, introduced many postal reforms, and in 1635 was ordered by Charles to establish a running post between London and Edinburgh (410 miles), to go day and night, and return in six days. Witherings was succeeded by Prideaux, who not only established weekly posts all over England, but seems to have made the service self-supporting. In 1650 he undertook to pay a fixed rent of £5,000 a year for the exclusive right to run the post-office, and thus began the system of farming the postal service, which continued well into the eighteenth century.

While letters could be sent from London to many places in the country, it was not until 1680 that citizens in one part of London could communicate by letter with persons in other parts or in the suburbs. Such a system was introduced by a London merchant named William Dockwra, who divided London and its suburbs into seven districts, each with its own sorting-office, and opened between 400 and 500 receiving-offices at which messengers called every hour for letters or parcels. The amount charged for each package was 1*d*., provided it did not exceed 1 lb. in weight or £10 in value. Deliveries were made in the business parts of the city ten or twelve times a day, and elsewhere from four to eight times. The success of the undertaking excited the greed of the Duke of York, on whom the revenue of the post-office had been settled, and in less than five years from its introduction this penny post was incorporated with the General Post-office, and Dockwra was later appointed comptroller. In 1701 this rate was advanced to 2*d*., an increase legalized by Parliament in 1730. Similar posts were established in Edinburgh, Manchester, Bristol, and Birmingham in 1793; and in Dublin in 1773.

In 1780 the monopoly of letting post-horses was abolished, and four years later mail-coaches were introduced with success by John Palmer, manager of the Bath theater, and did good service for sixty years. Steamships were first used for the conveyance of mails in 1821, and railways in 1830.

United States.—The post-office existed in America from its earliest settlement. Originally it was merely a receptacle in the coffee-house, where letters arriving from abroad were deposited, to be taken by those to whom they were addressed or carried to them by their neighbors. The first legislation on the subject is found in the records of the general court of Massachusetts for 1639, and the next in the colonial law of Virginia in 1657. The former provides "that notice be given that Richard Fairbanks his house in Boston is the place appointed for all letters which are brought beyond the seas or are to be sent thither, to be left with him; and he is to take care that they are to be delivered or sent according to the directions; and he is allowed for every letter a penny, and must answer all miscarriages through his own neglect in this kind." The colonial law of Virginia required "every planter to provide a messenger to convey the dispatches, as they arrived, to the next plantation, and so on, on pain of forfeiting a hogshead of tobacco for default." Gradually a postal service was established between the several colonies along the coast, and in 1672 there was "a post to goe monthly from New York to Boston." In the year 1692 Thomas Neale received letters patent, good for twenty-one years, authorizing him to set up posts in North America, and under this grant the postal affairs of the colonies of North America were conducted by Neale's representative and his successors until 1710, when the postal service of the British empire was consolidated into one establishment, with chief offices at London, Edinburgh, Dublin, and New York. One of the earliest acts of the Continental Congress was the establishment of a post-office and post-routes from Falmouth, Me., to Savannah, Ga., "for conveying intelligence and letters throughout this continent," and to spread knowledge of the acts of Congress and the progress of the Revolution among the different colonies. Benjamin Franklin was the first postmaster-general, and under his practical management the postal service was soon extended through all the colonies. Newspapers were generally published by the postmasters of the several cities, and their papers had not only been sent free through the mails, but all others excluded. Franklin was the first to give equal privilege to all publishers; subsequently a small sum was charged as postage, which seems to have been a perquisite of the postmaster, but no regular postage on newspapers was established by law until 1792.

Postage, or fixed charges for the conveyance of letters, was first introduced in England by Witherings about 1635, when the royal sanction was first given to a scale of 2*d*. for a single letter (that is, written on only one sheet of paper) for any distance under 80 miles, 4*d*. for over 80 and under 140, and 6*d*. for distances above 140; 8*d*. to Scotland, and 9*d*. to Ireland. From that date until 1840 the basis of rate continued to be distance and not weight, except in regard to the penny post already referred to. Parliamentary regulation of rates began in 1657, and these were increased and decreased from time to time according to the exigencies of Government or of the pension-list. In 1812 the rates were for a third time increased, 4*d*. being charged for 15 miles, 5*d*. for distances over 15 and under 20 miles, 6*d*. above 20 and under 30 miles, 7*d*. above 30 and under 50 miles, 8*d*. above 50 and under 80 miles, and so on, 17*d*. being charged for any distance above 700 miles. These rates were almost prohibitory, and many curious devices were employed for the purpose of avoiding payment. In 1837 Mr. (afterward Sir) Rowland Hill began an agitation for cheaper rates, and proposed an inland or domestic rate of 1*d*. for every letter weighing not more than half an ounce, the abolition of the FRANKING PRIVILEGE (*q. v.*), more frequent mails, and speedier delivery. Three years later his agitation was successful, and penny postage became the rule for the United Kingdom. Since 1871 the rates there have been 1*d*. for a letter not exceeding 1 oz.; exceeding 1 oz., but not exceeding 2 oz., 1½*d*.; 2 oz., but not exceeding 4 oz., 2*d*.; from 4 to 6 oz., 2½*d*.; 6 to 8 oz., 3*d*.; 8 to 10 oz., 3½*d*.; and so on at the rate of ½*d*. for every additional 2 oz. Double postage is charged when not prepaid, and deficient postage entails a charge of double the deficiency. The fee for registration is 2*d*., with compensation (in case of loss) up to £5, 3*d*., with compensation up to £10, and so on, with 1*d*. additional for each added £5 of compensation, up to £50. Newspapers registered at the General Post-office and published in the United Kingdom are carried for ½*d*. each. For books the charge is ½*d*. for every 2 oz. or fraction thereof. No package of newspapers must exceed 14 lb. in weight, 2 feet in length, or 1 foot in width or depth. Book-packets must not exceed 6 by 9 by 18 inches, or 5 lb. in weight.

In the U. S. for some years after 1776 postage was paid in currency, and was increased as the currency depreciated until finally the rate was reduced and made payable in specie. The rates fixed in 1792 were: For 30 miles and under, 6 cents; over 30 and not exceeding 60 miles, 8; between 60 and 100 miles, 10; between 100 and 150 miles, 12; between 150 and 200 miles, 15; between 200 and 250 miles, 17; between 250 and 350 miles, 20; between 350 and 450 miles, 22; over 450 miles, 25. Few letters were sent at such high rates, and from 1800 to 1830 the increase scarcely kept pace with the growth of the population. Many letters were sent privately, and after the express companies were started a great many were sent by them at less than the postage, in spite of the opposition of the post-office department. The first important changes in postage were made in 1845, when a scale based on both weight and distance was introduced. The rates were for letters not exceeding ½ oz. carried for any distance under 300 miles, 5 cents; over 300 miles 10 cents; and an additional rate for every additional half ounce or fraction thereof. Newspapers were carried free for 30 miles; for over 30 and under 100, or within the State, 1 cent; over 100 miles, or out of the State, 1½ cents. The next most important change was in 1851, when a single letter weighing not more than ½ oz. was charged 3 cents for distances under 3,000 miles (5 cents if not prepaid), and 6 cents over 3,000 miles (12 cents if not prepaid). In 1855 the rate was made

3 cents for all distances under 3,000 miles, and 10 cents for distances over 3,000 miles. In 1863 the element of distance dropped out of the scale, and a uniform rate of 3 cents was charged on all domestic letters not exceeding ½ oz. or fraction thereof. In Oct., 1883, ordinary letter-postage was reduced 33⅓ per cent., and the rates are now for letters 2 cents for each ounce or fraction thereof; for postal cards, 1 cent; for second-class matter or regular publications, 1 cent a pound; for third-class or transient newspapers, and all other kinds of printed matter, 1 cent for each 2 oz.; for fourth-class, or merchandise, 1 cent an ounce. The limit of weight of third or fourth class matter, books excepted, is 4 lb. This postage must be fully prepaid on all matter except letters; on these at least 2 cents must be prepaid. The fee for the registration of letters or other articles is 8 cents.

Stamps.—The stamps used by the Counts of Thurn and Taxis are to be found in many collections, but the modern postage stamp dates back no further than 1840, when it was introduced into general use in Great Britain by Rowland Hill. Zurich and Brazil adopted the idea in 1843, the U. S. in 1847, Russia in 1848, France, Bavaria, Tuscany, Belgium, and New South Wales in 1849, and Austria-Hungary in 1850. Since then its use has become universal. See STAMPS.

Organization.—In the United Kingdom the management of the postal service is under the direction of the Postmaster-General, who is a member of the Government, frequently a cabinet minister, and goes out of office with the administration. The permanent officials are a chief secretary, a financial secretary, four other secretaries, each of whom takes charge of some separate branch, a secretary for Ireland, a surveyor-general for Scotland, and an accountant-general. During the year 1893 the postal service of Great Britain and Ireland employed a permanent force of 71,956 persons, of whom 10,465 were women, besides about 59,000 other persons employed by local postmasters, of whom 16,000 were women and girls. In the U. S. the head of the postal service is the Postmaster-General, who has been a cabinet minister since 1826. Under him are four assistant postmasters-general (appointed by the President), of whom the first is the general executive, in charge also of the dead-letter office, the free-delivery service, and the money-order system; the second has charge of the transportation of all mail matter; the third is the bookkeeper of the department and attends to the issuing of stamps and the classification of the mail matter; and the fourth manages post-office inspections, receives the bonds of postmasters, appoints fourth-class postmasters, etc. The sixth auditor is the officer of the U. S. Treasury who has charge of post-office accounts. Over 500 clerks are employed in his department, which annually audits about 450,000,000 accounts. Over 200,000 persons are employed in the U. S. postal service.

Postal Union.—At the invitation of Germany, a postal congress of all the states of Europe, the U. S., and Egypt, was held at Berne in Oct., 1874, for the purpose of considering how greater uniformity in the treatment of correspondence could be secured, how accounts could be simplified, and rates reduced, etc. A postal convention was agreed upon, which was signed by the delegates from the countries of Europe and from the U. S., was ratified by the several governments, and went into effect July 1, 1875. A postal union was organized, with a central office at Berne, under the supervision of the post-office department of Switzerland, for the purpose of considering and working out all questions in the interests of the union. These conventions are now held every three years. Instead of the varying rates theretofore prevalent, the following uniform postage was adopted for mail matter from any country of the union to any other: 5 cents on prepaid and 10 cents on unprepaid letters weighing not over ½ oz.; newspapers not over 2 oz. in weight, 1 cent; books and other printed matter and patterns of merchandise not exceeding 8¾ oz., 1 cent for each 2 oz.; postal cards, 2 cents. Prepayment is invariably required except on letters. The union now embraces nearly every country in the world except China, which has no modern postal system.

Canada.—Down to the time of the confederation in 1868 each province controlled its own postal system, but since that date the rate of domestic letter-postage is 3 cents per oz. (in the U. S. it is 2 cents). By an agreement made between Canada and the U. S. in 1875 each country receives and delivers the letters of the other at their respective inland rates without keeping account of the same, as each country retains the full amount of postage collected by it. In 1879 Canada entered the Postal Union.

The statistics for the year ending June 30, 1893, are as follows: Letters, 106,290,000 (of which 3,254,000 were registered); postal cards, 22,790,000; newspapers and periodicals sent by individuals, 24,220,000; newspapers sent from office of publication, 66,150,916; books, circulars, samples, etc., 2,626,200; and parcels, 343,000. Number of offices, 8,475, of which 1,168 issued 967,866 money-orders aggregating $12,902,976, of which $10,404,857 were payable in Canada and $2,269,635 were payable abroad.

Australasia.—The first Australasian post-office was established at Sydney in 1810, and the postmaster was allowed to charge 8*d.* for every English or foreign letter of whatever weight and 1*s.* 6*d.* for every parcel not exceeding 20 lb. Colonial letters were charged 4*d.* irrespective of weight, and soldiers' letters were free.

The first postal act was passed in 1825, but its provisions were not put into full force until 1828, when the lowest rate for a letter weighing ¼ oz. was 3*d.* In 1831 a twopenny post was established in Sydney; in 1837 a post-office was established in Melbourne, then a part of New South Wales. In Oct., 1891, the seven colonies entered the Universal Postal Union.

The following table shows the postal business of each of the colonies during 1890:

COLONY.	Post-offices.	Letters and post-cards.	Books, parcels, and packages.	Newspapers.
New South Wales	1,338	58,385,300	8,939,600	40,597,200
Victoria	1,671	62,526,448	7,684,915	22,729,005
Queensland	892	14,709,504	2,047,446	11,463,726
South Australia	609	16,794,679	1,251,416	9,460,075
Western Australia	82	2,629,698	329,871	2,135,906
Tasmania	315	5,172,824	963,167	4,941,571
New Zealand	1,058	22,877,320	4,403,181	11,137,846
Australasia	5,965	183,095,773	25,619,596	102,465,329

Registered Letters.—It would seem that in the English post-office all correspondence was registered from a very early period. An order in council dated July, 1556, and another in 1603 provide that "every post shall keepe a large and faire leger paper booke to entre our packets in as they shal be brought unto him with the day of the moneth, houre of the day or night, that they came to his handes, together with the name of him or them by whom or unto whom they were transcribed and directed." This practice was confirmed in 1792, but no receipts were given the sender until 1814. During the year ending Mar. 31, 1893, 12,132,144 letters and parcels were registered in the United Kingdom, and under the new system of registration and insurance introduced on Dec. 1, 1892, compensation amounting to £550 was paid on 507 registered packages that had been lost or damaged. Registration was introduced into the U. S. in 1854. The number of pieces of mail matter registered during 1892–93 was 15,561,410 (2,759,016 free of charge).

Free Delivery.—Until 1774 there was no free delivery in England except in a few of the larger cities and towns, and it was not until many cases had been decided by the courts against the postal authorities that letter-carriers were appointed, and the customary delivery fee of 1*d.* or more was omitted. Free delivery is now universal throughout the United Kingdom. In the U. S. the free-delivery system in cities was begun in 1863, and only in large cities. This was extended in 1887 to all cities with a population of over 10,000 or a postal revenue of $10,000.

Special delivery was introduced into the U. S. in 1885. By this a fee of 10 cents secures immediate delivery by special messenger. In 1892–93 3,375,693 pieces were mailed for special delivery, 1,500 messengers were employed, and the average time of delivering a packet was nineteen minutes. In Great Britain an "express delivery" corresponds somewhat to the special delivery of the U. S.

Parcels-post.—There is no inland parcels-post, strictly so called, in the U. S., the classification of fourth-class matter, by which books and many kinds of merchandise may be transmitted through the mails, taking its place. There is a parcels-post, however, with Mexico, Hawaii, the Windward and Leeward islands, and several of the countries of South America, and to them 48,966 parcels were dispatched in 1892–93, an increase of 8,716 over the preceding fiscal year. A parcels-post between the United Kingdom and India had long existed, but it was not until Aug. 1, 1883, that an inland parcels-post was established. The limit of weight is 11 lbs.; the rate is 3*d.* for 1 lb. or less, and 1½*d.* for every additional lb. During the year ending Mar. 31, 1893, 52,370,326 parcels were carried for £1,151,051.

Money-order System.—This had its origin in 1792 in a private venture of three English post-office clerks who, under the name of Stow & Co., used the postal facilities at their command for the transmission of small sums of money to different parts of the country. The fee in these early days was 8*d.* per £1, of which 3*d.* went to the postmaster issuing an order, 3*d.* to the postmaster who paid it, and 2*d.* to the company. In 1838 this business was incorporated with the post-office department. In the three months ending Oct. 10, 1800, 697 orders for £8,863 were issued. For the year ending Mar. 31, 1893, 10,442,918 orders were issued in the United Kingdom, amounting to £28,683,951. The system was introduced into the U. S. in 1864. During the year 1892–93 13,309,735 domestic orders, aggregating $127,576,433.65, were issued by 18,434 U. S. money-order offices, and 1,055,999 international orders, aggregating $16,341,837.86, were issued by 2,407 offices. Postal notes or orders were introduced in Great Britain in 1881, and in the U. S. in 1883. At first these were payable to bearer, but as many abuses in the way of fraudulent negotiation had crept in, the British authorities have insisted since 1892 on the insertion of the name of the payee. In the U. S. the postal-note system was abolished in 1894 and incorporated with the regular money-order system. In Great Britain in 1891 56,590,668 postal orders were issued. During 1892–93 7,753,210 postal notes, to the value of $12,903,076.73, were issued in the U. S.

Post-office savings-banks were established in the United Kingdom in 1861, and flourished in the British colonies as well as in several of the countries of Europe. In Great Britain the interest allowed is 2½ per cent.; the lowest deposit is one shilling, and one person's deposits may not exceed £30 in any one year, nor £150 in all. On Dec. 31, 1892, 10,519 post-offices were open for the transaction of a savings-bank business, and in that year the number of accounts opened was 1,036,622, the amount deposited amounting to £21,334,903, and the total amount standing at the credit of depositors was £75,853,079. Postal savings-banks were introduced into France in 1881. On Dec. 31, 1893, the accounts numbered 2,095,622, with aggregate deposits of 607,871,925 francs. See the article SAVINGS-BANKS.

Telegraphs.—In 1870 the British Government acquired possession of all the telegraph lines then existing, and placed them under the management of the post-office. The rates charged have consequently been cheapened and the number of messages sent greatly increased; in 1893 this was 69,907,848 for Great Britain and Ireland.

Statistics.—The growth of the postal systems of the world since the introduction of cheap postage has been phenomenal. In Great Britain the total number of letters mailed in 1839 was 76,000,000. In 1840, the year in which penny postage was introduced, the number was 169,000,000. In 1882–83 it had increased to 1,280,000,000, while in 1892–93 the total deliveries amounted to 2,785,270,000; of these 1,790,500,000 were letters, an average of 46·6 to each person. In India in 1856 there were only 753 post-offices; in 1892 there were 21,465, and through these passed 308,403,108 letters, post-cards and money-orders, 25,910,386 newspapers, 2,108,685 parcels, and 10,711,051 book and other packets, making a total of 347,133,230 pieces. In the U. S. the growth has been still more remarkable. In 1790 there were only 75 post-offices and 1,875 miles of post-road open, while the number of letters and transient papers delivered did not exceed 2,000,000. On June 30, 1893, the number of post-offices was 68,403 (of which 610 were free-delivery offices); the number of mail routes was 30,831, including 1,116 railway lines and 36 steamboat lines, and aggregating 453,832·83 miles in length; and for the year 1892–93 the total number of pieces of mail matter handled was 10,236,314,985, of which 7,131,627 were sent to the dead-letter office in Washington. This increase is in part due to the remarkable growth of the efficiency of the service. The railway post-office system, in which each mail car is converted into a distributing post-office, lessens very greatly the average time of transmission. In the year 1892–93 the pieces of mail matter distributed in transit on railway and steamship lines numbered 9,772,075,810.

Revenue.—The British post-office has always been a paying concern. In 1893 its income (£10,344,353) exceeded its expenditures by £2,826,756. In the U. S., on the other hand, there has long been an annual deficiency, caused chiefly by the cheap rates (1 cent per lb.) at which second-class matter is carried. During the year ending June 30, 1893, the gross revenue was $75,896,933, and the expenditures $81,074,104, leaving a deficit of $5,177,171. See FINANCE.

Offenses against Postal Laws.—A brief notice of the provisions of the postal laws of the U. S. is all that can be given here, but these provisions may be taken as giving a general idea of those in force in most countries.

It is unlawful to deposit in the mail any article intended or adapted for any indecent or immoral use, or any printed or written matter giving information where such things can be secured; also to send by mail any letter or circular concerning any kind of lotteries, or concerning any scheme or device intended to defraud and deceive the public, or to aid in obtaining money under false pretenses. The act of sending through the mail any matter having on the outside any language of a threatening, inflammatory, or libelous character, or which is obviously intended to reflect injuriously upon the character or conduct of another, is also unlawful; thus dunning-notes should not be sent on postal-cards. The use of the mail in order to defraud by, or to sell, dispose of, or furnish, any counterfeit or spurious coin, bank-notes, or other security is a crime punishable by fine or imprisonment, or both.

Opening the letters of other persons, even though not sealed, is forbidden by law. This may be done only under a warrant particularly describing the thing to be seized. It is an offense punishable by a fine of not more than $100 to knowingly and willfully obstruct or retard the passage of the mail. Statutes also exist imposing imprisonment at hard labor for embezzlement or destruction of mail matter by postal employees, for stealing from the mail by other persons, and for robbing any mail from a mail-carrier or agent.

LILLEY.

Postlim'iny [from Lat. *postlimi̇nium*, liter., condition after having crossed the threshold; *post*, after + *limen, li̇minis*, threshold]: in Roman law, return from a state of capture and its consequences, or restoration to former political and other rights. Capture of a Roman in war, as well as of any one else, was held to make him a slave; and as a slave could make no will nor have any civil rights, the captured Roman's rights of property, citizenship, even of family, would be by this calamity not merely suspended, but brought to an end. The right of testament was saved from the effect of capture by the fiction of the Cornelian law, according to which the soldier was conceived of as having been killed in battle while yet a free Roman. The rights of citizenship, family, and property were saved by the *jus postliminii*, also a legal fiction, by which, if he had freed himself during war or had been restored by treaty, it was assumed that he had never been away. This doctrine of postliminy has been imported from the Roman into the international law, unnecessarily perhaps, to explain the revival of the title of an original owner to his property upon its recapture. Thus a ship if retaken (but by U. S. usage not after condemnation by a prize-court) reverts to the original owner, subject to salvage. (See RECAPTURE.) In like manner is restored the sovereignty of a territory which has temporarily passed into the power of an invader, but later drives him out or is abandoned by him. Nevertheless, many non-political acts of the temporary sovereign which are in the line of lawful government are binding after the restoration. Revised by T. S. WOOLSEY.

Post-mortem Examination [*post mortem* is Lat. for after death]: the examination of the body to determine the cause and manner of death. In cases of poisoning the nature of the poison and possibly the manner of its administration may be determined; in death from violence the examination will often reveal the nature of the weapon used in the infliction of the wounds and the relative positions of the victim and assailant at the time. Such examinations are also made in order to study the lesions which are produced in various organs as the result of disease. The brain is removed and examined by making an incision across the top of the head between the ears, dissecting back the scalp, and sawing through the skull. All of the thoracic and abdominal viscera are examined by making a single long incision which passes from the root of the neck to the symphysis. After a thorough examination and description all the organs are replaced, and the body carefully cleaned and

sewed up. The incisions are made in such a manner that no trace of them is visible when the body is again dressed.

W. T. Councilman.

Post-office: an office where letters, etc., are received for transmission to various destinations, and from which letters that have been received are delivered. The name is also applied to that department of the public service which is charged with the reception, conveyance, and delivery of letters, etc. See Postal Service.

Post-tertiary Period: See Pleistocene Period.

Potash: See Potassium.

Potassæ Bitartras: See Cream of Tartar.

Potassium [Mod. Lat., from Eng. *potash*; *pot* + *ash*]: a metallic element discovered by Davy in 1807 while experimenting on the action of a powerful electric current on molten caustic potash (potassium hydroxide, potassic hydrate). *Potash* is potassium carbonate, a constituent of wood-ashes, from which caustic potash (KOH) is obtained. Lavoisier first suggested that the caustic alkalies were compounds of oxygen, but the evidence was furnished by Davy's experiments. It was later shown by Brunner that the metal can be made by distilling at a white heat an intimate mixture of potassium carbonate and charcoal, and this method is now used for the purpose of preparing the metal on a large scale. Potassium occurs in many minerals, principally in feldspar, which is very widely distributed in nature. It occurs in combination with chlorine as carnallite and sylvite in the great deposits at Stassfurt, Germany; in combination with sulphuric acid and aluminium as alum; with nitric acid as saltpeter or potassium nitrate. Potassium is found, further, in combination in all soils in consequence of the natural decomposition of the minerals containing it. It is taken up by the plants, and when vegetable matter is burned it remains behind, principally as the carbonate. When the ash is treated with water the carbonate dissolves, and by evaporating the solution thus obtained the carbonate remains behind in impure condition. Potassium occurs further in the form of a salt of tartaric acid in grape-juice, and is deposited from this. The deposit is called crude tartar. An intimate mixture of potassium carbonate and charcoal, which is used in the manufacture of potassium, is made by heating this crude tartar in a closed vessel. To make potassium, the intimate mixture thus obtained is placed in a wrought-iron retort connected with a closed flat receiver of sheet iron. The retort being heated to a high temperature, the metal distills over into the receiver, which, at the end of the operation, is placed under petroleum.

Potassium has a bright metallic luster on its freshly cut surfaces, but this quickly tarnishes on account of the ease with which moisture acts upon it. The metal is soft, and lighter than water. When thrown upon water the latter is decomposed, the products of the action being potassium hydroxide, KOH, and hydrogen. The heat evolved is sufficient to set the hydrogen on fire, and at the same time a little of the potassium is burned, so that the flame has the characteristic violet color of potassium flames. The symbol of potassium is K; its atomic weight 39.

Compounds of Potassium.—Potassium chloride, KCl, as already stated, is found in the deposits at Stassfurt as sylvite, and in combination with magnesium chloride, $MgCl_2.KCl + 6H_2O$, as carnallite. *Potassium bromide*, KBr, is largely used in medicine. It is prepared by artificial methods. The *iodide*, KI, is also extensively used in medicine and in photography. The *hydroxide* or *hydrate*, KOH, commonly called caustic potash, is made by treating the carbonate in solution with lime. The solution thus obtained is drawn off and evaporated in iron or silver vessels. Solid caustic potash is a white, brittle substance. In contact with air it absorbs water and carbonic acid. It decomposes Fats (*q. v.*), forming Glycerin (*q. v.*) and soaps. (See Soap.) It is an extremely energetic Base (*q. v.*). The *sulphides* of potassium are formed by melting together potassium carbonate and sulphur. *Acid potassium tartrate* (see Cream of Tartar). *Potassium nitrate* (see Saltpeter). *Potassium carbonate*, K_2CO_3, is the principal soluble ingredient of wood-ashes and is extracted by treating the ashes with water. Formerly all the potassium carbonate made was obtained from wood-ashes, but at present not more than half of the supply comes from this source. The other sources are the residues from the manufacture of beet-sugar, potassium sulphate and chloride, and wool-fat. *Potassium silicate* is prepared in solution by dissolving sand in potassium carbonate or hydroxide. It is prepared on a large scale by melting together quartz-powder and purified potash. It is known as *water-glass*, or, to distinguish it from that made with sodium carbonate or hydroxide, *potash water-glass*. *Potassium ferrocyanide* or *yellow prussiate of potash*, $K_4Fe(CN)_6$, is a beautiful yellow compound obtained by heating refuse animal matter, such as horn, hoofs, blood, etc., with impure potassium carbonate and scrap iron. The salt is of great value, as it is the starting-point in the preparation of all the cyanides, and is used in the manufacture of Prussian blue.

Regarding the relations of potassium salts to the growth of plants, see Agricultural Chemistry. Ira Remsen.

Medicinal Uses of Potassium Compounds.—Potassium hydroxide (caustic potash), from its strong chemical affinities, is powerfully caustic to living tissues. It unites with water and with albuminous substances, and from its deliquescence and high diffusive power rapidly penetrates the tissues, and thus carries its destructive effects very deeply. The slough is black, slimy, and pultaceous. Taken internally, alone or in strong solution, it is a violent corrosive poison. The antidote is some organic acid, such as acetic (vinegar), citric, or tartaric. In weaker solution caustic potash swells and softens epithelium, producing a slippery feel to the fingers. It is used in surgery as a caustic, being fused and run into cylindrical moulds about the size of a goosequill, so as to form conveniently shaped sticks. A solution of specific gravity 1·065 is official in the *United States Pharmacopœia*, and may be used for the general purposes of alkaline medication; but alkaline salts of the same base are preferable, and this solution is therefore employed more in pharmacy than in medicine. *Potassium carbonate* and *bicarbonate* are strongly alkaline, and have essentially the physiological properties of solution of caustic potash. They are used externally in weak solution as lotions in skin diseases to remove dried epithelial crusts and scabs and control the excessive secretion of such diseases as eczema. They are not much given internally. They are sufficiently alkaline to be poisonous in large doses. *Potassium acetate* and *citrate*, though of neutral reaction, become converted into carbonates in the blood through decomposition of the organic acids. They thus tend to increase the alkalinity of the blood, to alkalize the urine, and especially to diminish the quantity of uric acid present in the system. They are used medicinally in rheumatism, gout, and uric-acid gravel to diminish the excess of acidity characteristic of those diseases, and in dropsy and deficient secretion of urine to produce diuresis. Solution of the citrate, freshly made by saturating lemon-juice with potassium carbonate and drunk during effervescence, is a favorite mode of giving the salt for the above purposes, and is also a very refreshing fever-draught, for allaying nausea, and for reducing over-action of the heart in acute febrile states. *Potassium and sodium tartrate* (Rochelle or Seignette salt) is of low diffusion power, and in large dose is purgative simply, producing, like other cathartic salts, watery stools. In smaller quantities, as a drachm, given considerably diluted, it is absorbed and its acid decomposed, and then under the form of carbonate it produces the effects and may be used for the purpose stated for potassium acetate and citrate. It is also employed as a purgative, and is most commonly given in the form of the *seidlitz powder* (*pulvis effervescens compositus* of the *United States Pharmacopœia*). A seidlitz powder consists of 2 drachms of the Rochelle salt and 40 grains of sodium bicarbonate, put up in a blue paper, and 35 grains of tartaric acid, put up in a white paper. The contents of the two papers are to be separately dissolved in about 2 fluid-ounces of water, and the solutions mixed and drunk during their effervescence. *Acid potassium tartrate*, or cream of tartar, is a powerful diuretic, and in full dose is purgative. It ought not to be used, therefore, for alkaline internal medication, like the acetate or citrate. *Neutral potassium tartrate* is also purgative, but, from its disagreeable taste, the acid tartrate is medicinally preferable. *Potassium sulphate* is purgative, but is harsh and may be poisonous, and is therefore little used. *Potassium nitrate* (niter or saltpeter) is irritant, and in large dose poisonous, inflaming the stomach, causing vomiting and purging, and also having an effect, common to many of the stronger potassium compounds, of affecting the heart, enfeebling its power, and even causing death by syncope. Niter is used in medicines as an ingredient of cooling saline draughts in fever, to reduce over-action of the heart, and was at one time largely employed in acute rheumatism. Niter has nothing to do with the so-called *sweet spirit of niter*, which is a peculiar

ethereal compound containing nitrous ether and alcohol. *Potassium chlorate*, though of high diffusion power like niter, is less freely soluble, and is hence not so strongly irritant, yet it is the most poisonous salt of potassium, except the cyanide, producing, in addition to local changes, a rapid breaking down of the blood and intense inflammation of the kidneys. This salt is peculiar in being largely excreted by the salivary glands and increasing their secretion. Medicinally, its use is almost confined to inflammatory and ulcerative diseases of the mouth and throat, over which it often has a remarkable power. A saturated solution may be gargled, or a few of the crystals may be held in the mouth and allowed slowly to dissolve. It should not be swallowed, except in very small quantities.

The other potassium salts used in medicine derive peculiar powers from their several acidifying principles. *Potassium cyanide* is intensely poisonous, and has essentially the properties of Hydrocyanic Acid (*q. v.*). *Potassium ferrocyanide* has but feeble physiological action, and is practically used only in pharmacy and the arts. The properties of *potassium iodide* will be found described under Iodine (*Medicinal Uses of*). *Potassium bromide* has peculiar powers over the nervous system, in addition to possessing the properties of potassium salts in general, of enfeebling the heart and tending to cause diuresis. The nervous influence is first a mere blunting of reflex excitability, cerebral and spinal, passing to complete paralysis if the drug be administered too long in inordinate quantities. The production of an eruption on the face like acne, and moderate salivation with a fœtid breath, are minor effects following the continued use of the drug. This salt is largely used in medicine to allay morbid nervous irritability, and is of special curative power in epilepsy, for the treatment of which it is the best remedy yet found. *Potassium sulphide* is used in medicine for the sulphur it contains. (See Sulphur, *Medicinal Uses of.*) *Potassium bichromate* is irritant and caustic, and internally a corrosive poison. It is official in the *Pharmacopœia* for pharmaceutical use, being employed for the preparation of sodium valerianate. It is also used rarely in medicine. *Potassium permanganate* in concentrated solution is slowly caustic, but the medicinal use of the salt is as a disinfectant and emmenagogue. As a disinfectant it acts by oxidation through giving up some of its own oxygen, and in weak solution is an excellent disinfectant application to wounds, foul sores, and ulcers.

Revised by H. A. Hare.

Potato [from Span. *patata*, *batata*, from Haytian, *batata*, sweet potato]: the most widely cultivated and valuable of esculent tubers. It is the *Solanum tuberosum*, the typical species of a typical genus, of vast extent and widely differing characteristics (see Nightshade Family), and is allied to several powerful narcotics, such as tobacco, henbane, and belladonna, as well as to other esculents, such as the tomato, egg-plant, and capsicum. The potato is a native of the elevated tropical valleys of Chili, Peru, and Mexico, and a form of it, scarcely distinct (var. *boreale*), occurs as far N. as Southern Colorado. It probably was carried to Spain from Peru early in the sixteenth century, and introduced into Virginia from Florida by the Spanish explorers, and into Great Britain from Virginia by Sir John Hawkins in 1565, though the credit is usually assigned to Sir Walter Raleigh, who was never in Virginia. It is found in several varieties in a wild state in Peru, Chili, and the island of Chiloe, the wild plant bearing still a close resemblance to the cultivated, except in the abnormal development of the tuber in the latter. The common potato was described in 1597 under the name of *Batata virginiana* by Gerard in his *Herball*, and in the following century it was cultivated on a small scale in the Netherlands, Burgundy, and Italy, and on account of its great yield was recommended by the Royal Society of London in 1663 for introduction into Ireland as a safeguard against famines; but it was not until near the middle of the eighteenth century that it acquired any real importance in Europe outside of Ireland. It was little regarded in Virginia, and seems to have been unknown in New England until the eighteenth century, when it was carried thither from Ireland. The potato is not mentioned in *The Complete Gardiner*, a work published in 1719, and as late as 1771 only two varieties, a white and a red, were mentioned in the most important English work on gardening, and they were considered chiefly as food for swine and cattle. The roots are distinct from the tuber, which is in reality an underground stem, naturally of considerable size, and abnormally developed by cultivation, through the accumulation of starch for the use of the plants growing from the *eyes* or buds. Under proper trimming and management the branches above ground may be made to assume several of the characteristics of the tubers.

The potato is a perennial plant, with smooth herbaceous stems, from 1 to 3 feet in height, with pinnate leaves, flowers varying in breadth from an inch to 2 inches, and in color from bluish white to purple, and consisting of a wheel-shaped corolla, more or less veined, bearing a globular purplish fruit or seed-ball of the size of a gooseberry, and an herbage characterized by a narcotic smell, and practically useless, though it may be eaten by cattle, and, like spinach, by man. One of the leading qualities of the potato is an extraordinary productiveness, far exceeding that of any esculent with which it can be placed in competition, an equal amount of ground yielding, according to Humboldt, thirty times greater weight of potatoes than of wheat. Potatoes consist almost wholly of starch, and are accordingly deficient in nitrogen, and ill-adapted for an exclusive article of diet. They are hardy, and grow well throughout a vast extent of the earth's surface. In the U. S. they yield best in the extreme north, especially in New York and New England, and also in Canada; and in Europe are successfully cultivated up to 60° N. lat. in Sweden. Formerly planted exclusively by hand in hills 3 or 4 feet apart, they are now dropped extensively in drills. Where large quantities of potatoes are grown, various mechanical devices are in use for dividing the drills and throwing up the tubers, ready to be gathered by hand. There is a bitter principle subsisting in the potato which may be considered as somewhat poisonous, and which is aggravated by the action of light to such a degree as to turn green: this principle must be removed by cooking before the tuber is fit for food; hence the water in which such potatoes have been boiled should never be employed in the preparation of other food. The particular variety of potato can be secured only by planting the tubers. The seed of a single ball will often produce many varieties of potatoes, and can not be depended upon to propagate the parent stock. The varieties most esteemed in the U. S. in the first half of the nineteenth century seemed to receive a complete check by the potato-rot of 1845, and they afterward practically fell into discsteem, and were replaced by others. The best of the old favorites was probably the Mercer or Neshannock (so called from having originated on Neshannock Creek, Mercer co., Pa.); its place in point of popularity was thereafter filled by the Jackson, White Garnet, Chili, Peach-blow, and Early Goodrich, most of which were originated by Rev. Chauncey E. Goodrich, of Utica, N. Y., to whom the world is largely indebted for the improvement of this important plant. Later, Early Rose, Beauty of Hebron, Burbank, and other varieties, became popular and superseded the old ones; and these varieties are in turn giving place to others. Varieties of potatoes soon disappear or "run out." The early varieties of potatoes now seldom produce seed-balls, and the late sorts are less productive of seed than formerly. This is due to the excessive deflection of the vital energy to tuber production in the highly improved varieties, and the failure of the flowers is particularly marked in the early kinds, probably because the energy is deflected to the tubers before the flowers are formed.

There are several serious enemies to the potato-plant, of which the best known is the Colorado Potato-bug (*q. v.*). The blight or rot has been somewhat prevalent since its first destructive appearance about 1840, although it is not equally bad in all years. The true potato blight and rot is caused by a fungus known as *Phytophthora infestans*, and it is readily kept in check by frequent and thorough sprayings with Bordeaux mixture. (See Fungicide.) It is thought, however, that some forms of blight and rot are due to a bacterium, the exact nature of which is not known.

The potato crop is less important in the national economy in the U. S. than in Europe. The crop of Europe aggregates more than the entire wheat crop of the world. The average annual production in the U. S. from 1881 to 1890 was 169,809,053 bush., while that of a like period in France was 396,746,138; in Austria, 306,984,697; in Germany, 891,732,040; in Russia, 300,315,070; in the United Kingdom, 228,093,397. In 1893 the U. S. exported $708,757 worth of potatoes and imported $1,998,708 worth. For further information, consult the experiment station bulletins, Carman's *New Potato Culture*, and Terry's *A B C of Potato Culture*. See also Food.

Revised by L. H. Bailey.

Potato-bug: a name applied indiscriminately by farmers to a great many different insects that attack the potato. Among them are the following: *Boring in the stalk*—the stalk-borer (*Gortyna nitela*); the potato-stalk weevil (*Baridius trinotatus*). *Feeding upon the leaves*—the potato-worm (*Sphinx 5-maculata*); the three-lined leaf-beetle (*Lema trilineata*); the cucumber flea-beetle (*Haltica cucumeris*); over half a dozen species of blister-beetles, belonging to the genera *Lytta* and *Epicauta*; and finally the Colorado potato-beetle (*Doryphora 10-lineata*), a hemispherical yellow beetle about one-third of an inch long, with ten black stripes on the elytra. This last alone is treated in this article. See Entomology.

Few insects have attracted greater attention than has this species since 1860. First described by Thomas Say, who found it common on the upper Missouri in 1824, it was afterward scarcely heard of till 1859. It fed originally on the sand-burr (*Solanum rostratum*), a wild plant belonging to the same genus as the potato. It was first found falling in large numbers on the cultivated potato about 100 miles W. of Omaha, Neb., in 1859. In 1861 it invaded Iowa; in 1862, Southwest Wisconsin; in 1864 and 1865 it crossed the Mississippi to the western part of Illinois; in 1866 it occupied most of the U. S. W. of a line drawn between Chicago and St. Louis; in 1867 it reached Southwest Michigan and Western Indiana; in 1868 many parts of Ohio, and from that time on kept spreading from year to year, until, in 1874, it touched the Atlantic seaboard at numerous places, and in 1875 was common from Virginia to Maine. It thus traveled over 1,500 miles in a direct line within 16 years, and spread over an area of something like 1,500,000 sq. miles. Though most injurious during the first few years of its advent, it always remains where it has once obtained a foothold.

Natural History.—The insect hibernates in the perfect or beetle state. As vegetation starts in spring the insect issues from the ground, and long before potatoes are up, or even planted, it may be seen flying in search of food and company. It frequently works into a sprouting hill of potatoes as these are raising the soil, and feeds upon the tender sprouts and tubers; and as soon as the plant shows itself the female begins to lay her oval orange eggs in clusters of from ten to forty, each attached by one end to the under side of a leaf or to a stem. With favorable weather there hatches, in the course of a week, from each egg a small, dark red, hunchbacked larva, which becomes paler and acquires a double row of lateral black spots as it advances toward full growth. This period arrives in about three weeks from hatching, and the larva finally burrows into the ground, where it becomes a pupa, and finally a beetle in from seven to ten days, the whole cycle of its transformations from the egg to the beetle requiring rarely more than a month. In the latitude of St. Louis there are three broods annually, the last brood of beetles issuing from the ground early in the fall. The migratory habit is often very noticeable in this last brood of the beetles, and for weeks they may be seen flying in bevies or traveling on foot in immense armies. The beetle feeds less than the larva, but is, nevertheless, very tenacious of life. The period of oviposition covers about a month for each female, and the number of eggs produced by each averages about 500. While the species feeds by preference on plants belonging to the genus *Solanum*, and it is doubtful whether it could thrive for any length of time on other plants than those of the family *Solanaceæ* yet in its march across the U. S. it has adapted itself in an emergency to a number of other species. In the article Entomology (*q. v.*) there is an illustration of the insect in its various stages.

Natural Enemies.—With the insect's advance the number of its natural enemies has increased. The rose-breasted grosbeak often effectually clears a potato-patch of the pest, and the domestic chicken has in some sections acquired a taste for it. The crow, the quail, the skunk, the toad, and some species of the long-legged harvestmen or "grandfather graybeards" (*Phalangium*) feed upon it. The most efficient aids, however, are found in its own class. Over two dozen of these have been described. The only true parasite known to infest it is a tachina-fly (*Lydella doryphoræ*) belonging to the Diptera, and having the general appearance of a common house-fly. Certain asilus-flies—a family of the same order—pounce upon and suck out the juices of the beetle. In its own order a number of ground-beetles (*Carabidæ*) devour it, and several species of lady-bird (*Coccinellidæ*) feed greedily on its eggs. Among bugs (*Heteroptera*) several species are also very efficient, piercing the beetle, and more particularly the larva, with their strong beaks, and sucking out the vitals. These are especially the spined soldier-bug (*Arma spinosa*), the many-banded robber (*Harpactor cinctus*), and the ring-banded soldier-bug (*Perillus circumcinctus*).

Methods of Combating it.—The first beetles and eggs to appear should be destroyed, but great care must be had to discriminate between the eggs of the ladybirds, which resemble those of *Doryphora* in color and mode of attachment, but are invariably somewhat smaller. Numerous mechanical means—machines used by hand, and even by horse-power—have been devised to knock the insects off the vines and collect them; and during very hot and dry summer weather in the more western parts of the U. S. the insects perish when merely knocked on to the ground. The only cheap and effective way of protecting the plants when once the insect has been allowed unduly to multiply is by the use of Paris green or London purple. This poison is now very generally employed, either as a powder with about twenty-five parts of some diluent, such as ashes, lime, bran, or flour—the last the best; or in suspension at the rate of a tablespoonful of the pure green to 3 gal. of water, and with a certain portion of molasses or other cheap sticky substance to facilitate adhesion.

This article would be incomplete without a reference to the bogus Colorado potato-beetle (*Doryphora juncta*), which so closely resembles the species under consideration that it was formerly often mistaken for it, even by good entomologists. In *juncta*, as compared with *10-lineata*, the eggs are paler; the larva is paler, with but one row of lateral

Bogus Colorado potato-beetle: *a a*, eggs; *b b*, larva; *c*, beetle; *d*, enlarged elytron; *e*, enlarged leg. Colors, *a*, whitish yellow; *b*, cream yellow, brown, and black; *c*, black, yellow, and brown.

black dots, instead of two; the beetle has the second and third black stripes on the elytra (counting from the lower edge) joined at the ends, instead of the third and fourth; the punctures of elytra more regularly in rows, and the legs with pale instead of dark tarsi, and with a black spot on the thighs. It feeds on the nettle (*Solanum carolinense*), has always existed in the southern half of Missouri eastward, and never touches the cultivated potato.

Potato-fly: See Cantharis.

Potato, Sweet: See Sweet Potato.

Pote'khin, Alekseĭ Antipovich: author; b. at Kineshma, government of Kostroma, Russia, July 1, 1829. After finishing his studies he settled in St. Petersburg. He has described with unsparing fidelity the darker side of the life of the lower classes. Among his novels are: *The Peasant Woman*, *For Money* (a description of factory life), and *Young Inclinations* (1879). Many of his peasant tales are excellent, for instance, *Tit Sofronov Kazanok*, *The Sick Woman* (1876), *Under the Spell of Money* (1876), *Before the Community* (1877), *Village Leeches* (1880). On account of the sharp criticism of Russian conditions which they provoke, his dramas have not been allowed by the censors to be put on the stage. Among the best known are *The Voice of the People not the Voice of God* (1853), *Ill-gotten Goods do not Prosper* (1854), *Tinsel*, *The Severed Limb*, *A Profitable Undertaking* (1870), *A Love Match*, and *The Guilty Woman*.

A. C. Coolidge.

Potem'kin, Gregor Alexandrovitch: Russian minister of state; b. in 1739 of a family of Polish nobility on its estate in the government of Smolensk; entered the Russian army, and was ensign in the imperial body-guard when he attracted the attention of Catherine II., shortly after her accession to the throne, by his handsome person. He was appointed gentleman of the bedchamber by the empress, and superseded Orloff as her lover. This intimacy did not last long, and he was absent from court for some time, serv-

ing in the war against Turkey, but on his return enjoyed a greater influence than ever. By his entire freedom from jealousy and by his mastery of the art of making himself interesting and indispensable, he retained his influence over the empress to his death. Not only the empress herself, but foreign monarchs—Frederick the Great, Maria Theresa, and Joseph II.—loaded him with honors and riches and submitted to all his whims; and as an alliance with Russia at this time began to be of the utmost importance to the neighboring states—Sweden, Poland, Prussia, Austria, and Turkey—he, as the dispenser of this alliance, played an important part in the politics of Europe. That he had some ability is shown by the success of many of his undertakings, but in private life he was capricious, vain, and licentious, and his public career affords no proof that he possessed a high order of statesmanship. Among the acts of his ministry were the foundation of the cities of Kherson, Kertch, Nikolaiev, Sebastopol, etc., the creation of a Russian fleet in the Black Sea, the Turkish wars which resulted in the acquisition of the Crimea, Caucasus, etc. D. on the road between Jassy and Nikolaiev, Oct. 15, 1791. See Cérenville, *Vie de Prince Potemkin* (1807); *Memoirs of Potemkin* (London, 1814); and de Ligne, *Mémoire de la Cour de Russie* (1859). Revised by F. M. Colby.

Potential [from Lat. *poten'tia*, power, possibility, deriv. of *pos'se*, be able]: in mathematics, a scalar function, usually called V, of the co-ordinates of a point, first introduced by Laplace in the discussion of gravitation in his *Mécanique Céleste*. The name *potential* was given to it by George Green, in his now famous *Essay on the Application of Mathematical Analysis to the Theories of Electricity* (Nottingham, 1828). Green almost created the theory as we have it, but so completely buried was his essay for nearly twenty years that most of its important theorems had in the meantime been rediscovered by Gauss, Charles, Sturm, and Thomson.

The introduction of the term *potential* into practical and even elementary electricity is a remarkable example of the influence of pure mathematics on the development and rationalization of a science. It is entirely probable that the extensive use of the term potential, and the ideas which it directly or remotely represents, have been due in great degree to the predominant influence on scientific thought of the principle of the conservation of energy. See Energy.

The *mutual potential energy* of a system of two bodies in any given position is the amount of *work* done by their mutual repulsion in separating them to an infinite distance. When the bodies mutually attract their potential energy is conventionally negative. Work, which is the measure of energy, is the product of the force acting and the component of the motion produced in the direction of the force.

The *potential* at any point, due to any attracting or repelling agent, is the mutual potential energy between it and a *unit quantity* of the agent placed at that point. Thus the gravitational potential at a point is the work required to remove unit mass of matter from the point to an infinite distance.

Potential is applied to central forces, and generally, though not necessarily, to those varying as the inverse square of the distance. Thus the force at P, due to the acting agent q, distant r from the point, is $\frac{q}{r^2}$ if the unit quantity is so chosen as to render the constant in the expression for the force equal to unity. The work done in moving the unit quantity at P a distance dr along a line of force is $\frac{q}{r^2}dr$. A *line of force* is a line tangential at each point to the direction of the force.

If we integrate the above expression between the limits r and infinity, the work done will by definition be the potential at P, or $\int_r^\infty \frac{q\,dr}{r^2} = \frac{q}{r}$.

If the potential at P is due to several acting masses, then the total potential at P is the value of $\frac{q}{r}$ for all the acting masses conjointly, or $V_P = \Sigma\frac{q}{r}$. Thus the electrical potential at the center of a sphere, charged with a quantity of electricity Q, is $\Sigma\frac{q}{R} = \frac{1}{R}\Sigma q = \frac{Q}{R}$, where R is the radius. See Electricity.

From the definition of the potential at a point it follows that the excess of the potential at the point A over that at B is the work which must be expended against the acting forces in moving unit mass from B to A. The word *mass* here denotes the acting agent of any kind. The work done is independent of the path traversed; otherwise it is obvious that by moving unit mass back and forth along suitable paths between the two points an infinite amount of work might be done without any expenditure of energy.

An *equipotential surface*, in gravity a level surface, is one having the same value of the potential at all points. There is therefore no difference of potential on the surface, and no work is done in moving any mass of the acting agent from one point to any other on an equipotential surface. Hence there is no component of force along such a surface, or it is perpendicular to all the lines of force meeting it.

Let there be two equipotential surfaces with potentials V_1 and V_2; then the work done in displacing unit mass from any point on one surface to any point on the other is $V_1 - V_2$. It is independent of the position of the points on the two surfaces and the path traversed from one point to the other.

The work done in transferring a mass, m, from one surface to the other is $m(V_1 - V_2)$.

Force is a function of potential. Consider two equipotential surfaces indefinitely near each other, their distance along a normal being dn. Let F be the force along this line. Then $Fdn = V_1 - V_2 = -dV$, if V_1 and V_2 are the indefinitely near values of the potentials on the two surfaces.

Therefore $F = -\frac{dV}{dn}$, or the force at any point is equal to the negative derivative of the potential with respect to the normal to the equipotential surface passing through the point. The force along any line may be similarly expressed. Let α be the angle which the line makes with the normal to the equipotential surface, and let ds denote the portion of the line lying between the two indefinitely near surfaces. Also let F_s be the force along the line. Then $F_s = F\cos\alpha = -\frac{dV}{dn}\cos\alpha$. But $\cos\alpha = \frac{dn}{ds}$. Hence

$$F_s = -\frac{dV}{dn}\cdot\frac{dn}{ds} = -\frac{dV}{ds}.$$

Thus the component of the force in any direction is the partial derivative of the potential in this direction. In other words the force along any line is the rate at which the potential decreases per unit length of the line.

Potential plays a paramount part in the study of electrical phenomena. Positive electricity tends to flow from places of higher to places of lower potential. Hence the surface of a charged conductor *in electrical equilibrium* is an equipotential surface. Moreover, all points of such a conductor have the same potential. The potential of a sphere is therefore the same as the potential at its center, or $\frac{Q}{R}$.

The *capacity* of a conductor is the quantity of electricity required to raise its potential from zero to unity; and since the potential increases directly as the charge, it follows that the capacity equals $\frac{Q}{V}$ (quantity per unit potential). Since the potential of a sphere is $\frac{Q}{R}$, dividing Q by $\frac{Q}{R}$ we have R as the capacity, or the capacity of a sphere is numerically equal to its radius. A sphere of unit radius has unit capacity.

The *energy* of a charge may be expressed as a function of the potential. If a quantity of electricity, Q, is transferred from potential V_1 to V_2, the work done during the flow, or the energy converted into other forms, is $Q(V_1 - V_2)$, V_1 being greater than V_2. If, however, a conductor has its potential raised from zero to unity by a charge, Q, then the potential energy stored up is $\frac{1}{2}QV$; or, since $Q = CV$, the energy of the charge is $\frac{1}{2}CV^2$. This may be demonstrated as follows: Let dQ be an element of the charge; to transfer it from a place of zero potential to the conductor at potential V_o requires that work be done upon it equal to $dQ\,V_o$. But since $Q = CV_o$, $dQ = C\,dV_o$. Hence

$$dQ\,V_o = C\,V_o\,dV_o, \text{ and } \int_o^V C\,V_o\,dV_o = \tfrac{1}{2}CV^2.$$

Now the capacity C is a constant. Therefore the potential energy of the charge is proportional to the square of the potential to which the conductor is raised by the charge. If the capacity of a charged conductor could be doubled, both the potential and the stored energy would be reduced to one-half.

In current electricity the difference of potential between two points plays a most important *rôle*. It is numerically equal to the work done in carrying a unit of electricity in the positive direction from one point to the other. Thus the potential difference between the terminals of a battery when the circuit is closed is the energy represented by the passage of a unit of electricity from the positive pole around through the external circuit to the negative. The total energy transformed during the passage of Q units is Q times the potential difference. This remains true whether the energy expended in the transfer is converted into heat because of the ohmic resistance, or whether a portion does mechanical work by means of a proper motor device in the circuit, or whether the energy is in part stored up by electrolysis, or whether it is stored up by producing that strain in the ether called a magnetic field

The potential difference between two points on a circuit is numerically equal to the electromotive force (written E. M. F.) producing the current flow from one point to the other, so long as the circuit joining the points contains no source of E. M. F. In such portion of a circuit the current flows from higher to lower potential, but within the region where the E. M. F. has its origin the current flows from lower to higher potential, being so impelled by the cause there acting to produce an electric flow.

In any part of a conducting circuit the loss of potential is jointly proportional to the electrical resistance and the current strength. This loss is a fall of potential so long as no source of E. M. F. is encountered. It may exactly counterbalance the gain due to the E. M. F.'s encountered. In this case there will be a current flow produced by an E. M. F. without any potential differences. Potential differences are therefore due to E. M. F.'s rather than the reverse.

Potential differences are established by contact of dissimilar substances, by chemical action, by heat, by pressure, in physiological processes, and by the relative movement of a conductor and the lines of force surrounding a magnet.

A potential difference produces in insulators or dielectrics a displacement stress by which electricity is displaced in the direction of the potential decrease. If the medium is of such a nature that it can oppose or resist this stress it is called a non-conductor; but if it yields to the electric stress the medium is a conductor, the potential energy of the state of strain is converted into heat, and a continuous current flows so long as the potential difference is maintained.

HENRY S. CARHART.

Potentil'la [dimin. of Lat. *potens*, powerful, from its supposed virtues]: a genus of herbs and shrubs of the family *Rosaceæ*. There are many species, mostly herbs, about forty of which are natives of the U. S. The plants known as cinquefoil, five-finger, and tormentil belong to this genus. They have a highly astringent property, which is useful in medicine, and in the Orkneys and Lapland their roots have been employed in domestic tanning and dyeing.

Poten'za: chief town of the province of Potenza, Italy; on a hill near the river Basento (anc. *Casuentus*); 103 miles E. by S. of Naples (see map of Italy, ref. 7–G). The chief buildings are the cathedral, the seminary, and the hospital of San Carlo. It takes its name from the ancient *Potentia*, which was founded by the Lucanians on a site lower down the hill. It was almost totally destroyed by an earthquake on Dec. 17, 1857. There is now little activity of any kind here, though the neighboring country is agriculturally rich, producing silk, honey, and cheese. Pop. (1892) 18,500.—The province (formerly called Basilicata) has an area of 3,845 sq. miles. Pop. (1892) 541,865.

Potgieter, EVERHARD JOHANNES: critic and poet; b. at Zwolle, Holland, June 27, 1808; d. at Amsterdam, Feb. 3, 1875. His earlier life was given to trade, first at Amsterdam, then at Antwerp, and finally at Amsterdam once more. His tastes, however, were always literary, and he speedily became acquainted with a circle of brilliant young writers. In 1837, in company with certain of these, he founded the best of the Dutch reviews, *De Gids*, of which he was editor for thirty years. The influence of this periodical on Dutch letters has been very great; and Potgieter, with his friend and fellow contributor, Bakhuizen van den Brink, became the head of the new school that was trying to do away with the artificiality of style and triviality of matter all too prevalent in Dutch literature in the first half of the nineteenth century. Besides a number of short stories, he wrote a vast number of critical articles and a considerable body of poetry. In 1864 he issued a collection of the former, entitled *Proza* (2 vols.); and later two volumes of the latter, *Poëzy* (2 vols., 1868–69). After his death Joh. C. Zimmerman issued six volumes of his literary remains—*Verspreide en Nagelaten Werken: Proza, Poëzy, en Kritische Studien* (1875–85). Later still the same editor printed his entire *Werken* in 18 vols. (Haarlem, 1885). A. R. MARSH.

Pothier, pō'ti-ā', ROBERT JOSEPH: law-writer; b. at Orleans, France, Jan. 9, 1699; was educated in the College of the Jesuits, and afterward studied law in the University of Orleans, and in 1720 was made one of the counselors, or magistrates, of the presidial (a local court of last resort), which position his father had held before him; in 1749 became Professor of Law in the University of Orleans, and wrote many treatises on the law, among the best known of which are *Pandectæ Justinianæ* (3 vols., 1748–52), often reprinted; *Maritime Contracts*; *Contracts of Sale*; *The Law of Obligations of Contracts*, etc. Of all French legal writers he is the one oftenest and most confidently cited as an authority, and fully three-quarters of the Civil Code is taken almost verbatim from his works. Many posthumous works by him were published, which, however, are of much less value than his others. D. at Orleans, Mar. 2, 1772. F. S. ALLEN.

Pot-hole: an approximately vertical and cylindric cavity in rocks, produced by a whirling current of water. The cutting is done by sand-grains, and especially pebbles and bowlders, which by their weight are kept at the bottom and whirled about by the water. While the whirling motion can not be directly seen, it is inferred from the circular character of the holes, and from the fact that some of them are channeled about the periphery of the bottom as though cut by a diamond drill. Pot-holes occur on the beds of streams whose steep grades give them high velocity, and they are often many feet in depth. It is believed that they are formed also beneath glaciers, where crevasses permit streams of water to plunge from the surface to the base. As the ice moves forward crevasses are successively formed at the same spot, and the plunging water is thus enabled to excavate deeply. There is a series of holes referred to this action near Cohoes Falls, N. Y., and one of these was determined to have a depth of over 60 feet.

The deep pool usually found beneath a cataract is closely allied to the pot-hole, in that it is excavated by stones driven violently by a plunging stream of water; but the motion in this case is not ordinarily gyratory, and the excavation is less symmetrical. G. K. GILBERT.

Poti: Russian fortress; in the Trans-Caucasus, on the Black Sea, at the mouth of the Rioni (see map of Russia, ref. 12–F). It was captured from the Ottomans (1809), but restored at the treaty of Bucharest and finally ceded to Russia by the treaty of Adrianople (1829). This stronghold is exceedingly important as commanding the shore route between Persia and Russia. Pop. (1890) 4,813. E. A. G.

Poto'mac: a river of the U. S., forming through its whole course the boundary between Maryland and Virginia, and West Virginia. It is formed by the junction of two branches, of which the northern rises in the Alleghanies of West Virginia, and the southern in the Shenandoah range, Va. It resembles a bow in form, is nearly 400 miles in length, receives as tributaries from Virginia the Shenandoah, Savage, and Monocacy rivers, is an estuary from 6 to 8 miles wide for 100 miles of its lower course, and enters Chesapeake Bay 75 miles from the Atlantic. Washington, D. C., the national capital, is situated upon its left bank, 125 miles above its mouth, to which point the tide ascends, and it is navigable for large vessels. Above Washington are several falls. The scenery of the upper Potomac is remarkably picturesque, especially the junction of the Shenandoah at Harper's Ferry. On its lower course are the birthplace and the residence of Washington, and in its whole extent it formed an important strategical line during the civil war.

Potomac Formation: the lowest of the geological formations representing the Cretaceous period on the Atlantic coast of North America. The rocks are variegated clays, friable

sandstones, gravel, and sand, with many alternations, forming a series from 5 to 500 feet thick; they rest unconformably on crystalline rocks and on upturned and eroded strata of the Newark system, and are overlaid by fossiliferous Eocene and Neocene strata. The group forms a belt about 10 miles wide in Maryland but narrowing southward, which has been traced from the Delaware along the west side of Chesapeake Bay, and to the E. of Washington and Richmond, to Weldon, N. C., a distance of 300 miles. The Raritan formation in New Jersey, which includes the Amboy and Woodbridge clays, is thought to belong to this terrane, as are also the Tuscaloosa formation of Alabama, and the Trinity beds of Texas and Arkansas. Great numbers of fossil leaves, principally of broad-leaved trees, have been found in these rocks in Virginia, Maryland, and New Jersey; a few freshwater shells and the bones of large reptiles, allied to Jurassic species, have also been discovered. Consult W J McGee, *Am. Jour. Sci.*, vol. xxxv. (1888); *Twelfth Annual Report*, U. S. Geol. Survey (1890–91), pp. 421–424; W. M. Fontaine, Monograph No. 15, U. S. Geol. Surv.; O. C. Marsh, *Am. Jour. Sci.*, vol. xxxv. (1888). ISRAEL C. RUSSELL.

Potosí, pō-tō-see′: a city of Bolivia; on the side of the Potosí Mountain, a peak of the Eastern Cordilleras; 47 miles S. W. of Sucre (see map of South America, ref. 6-D). It is one of the highest inhabited places in the world, being 13,324 feet above sea-level. The climate is cold and changeable, though not unhealthful to regular residents; owing to the rarefied atmosphere new-born children often die or become deaf. Silver lodes were discovered here in 1546, and were long the richest known deposits in the world; up to 1864 they had yielded the sum of $2,919,899,400. The deposits are far from being exhausted, but, owing to the great depth to which shafts have been sunk and the difficulty of drainage, most of them have become unprofitable by the mining systems now in vogue; about 2,000 shafts have been abandoned. The yield in 1890 was 196,365 oz. During the eighteenth century Potosí, with its immediate vicinity, is said to have had a population of 170,000. The fine mint and the cathedral attest its former grandeur. Pop. about 12,000. It is the capital of the department of Potosí, which embraces that portion of the Bolivian mountain region adjacent to the Argentine Republic and Chili, with an area of 85,046 sq. miles (claimed), and a population (1888) of 237,755. It is noted principally for its silver mines, including, besides Potosí, those of Porco and Huanehaca, the latter now the most productive in Bolivia. Gold and tin are also mined. HERBERT H. SMITH.

Potosí, Mexico: See SAN LUIS POTOSÍ.

Potsdam: city; in the province of Brandenburg, Prussia: at the confluence of the Ruthe and the Havel, 17 miles S. W. of Berlin (see map of German Empire, ref. 3-G). It is well laid out and well built, having many fine streets, public squares, promenades, public edifices, gates, bridges, and monuments. It contains large barracks and other military establishments, educational and benevolent institutions, and a great number of royal palaces and summer houses, old and new, some of which are built on a grand scale and surrounded with extensive gardens and parks. Here is an astro-physical observatory, founded 1874, with two equatorial refractors, for spectroscopic, photographic, and other observations. Potsdam was founded by the elector Frederick William, who built a palace here in 1673, but its modern splendor is principally due to Frederick the Great, while each of his successors contributed to the embellishment and extension of the town. Its industries comprise market-gardening, manufactures of firearms, and the production of sugar, chocolate, tobacco, and cotton and woolen goods. Pop. (1895) 58,455.

Potsdam: village; St. Lawrence co., N. Y.; on the Racket river and the Rome, Watertown and Ogdensburg Railroad: 22 miles E. of Ogdensburg (for location, see map of New York, ref. 1-H). It is principally noted for its extensive quarries of sandstone of a geological formation to which the name of the village has been given. The region traversed by the Upper Racket river affords an immense supply of lumber which is floated in rafts down the stream. Potsdam has a Holly system of water-works, improved sewerage, electric lights, a State normal and training school, agricultural fair grounds, public library, a national bank with capital of $200,000, a State bank with capital of $50,000, several foundries, machine-shops, saw-mills, furniture-factories, agricultural implement works, and other manufactories, and three weekly newspapers. Pop. (1880) 2,762; (1890) 3,961; (1900) 3,843. EDITOR OF "COURIER AND FREEMAN."

Potsdam Sandstone: in geology, a formation of the Cambrian period occurring in New York and Canada N. of the Adirondack Mountains. It is the basal member of the NEW YORK SYSTEM (*q. v.*), and was long supposed to be the oldest American Palæozoic formation. The name has been applied also to sandstones at the base of the Palæozoic series in various other parts of North America, but it has now become known, from a comparison of fossils, that not all such sandstones are of the same age as the Potsdam. According to Walcott the Potsdam sandstone is the chronologic equivalent of certain limestones occurring S. of the Adirondacks and in Vermont, of the Knox shales of Tennessee and the Connasauga shales of Alabama, of the St. Croix sandstone in Minnesota, of the basal sandstone in Dakota, Montana, Wyoming, and Colorado, of the Gallatin limestones of Montana and the Hamburg limestone of Nevada, of the Tonto group of Arizona, and of the Katemcy group of Texas. Other Cambrian formations of the U. S., so far as determined, are of earlier date. In the district N. of the Adirondacks the sandstone has a maximum thickness of 500 feet. It is rather thinly bedded, and is usually yellowish brown or reddish brown. It is extensively quarried for paving blocks and to less extent for flagging and building stones. See CAMBRIAN PERIOD, and consult Bulletin No. 81, U. S. Geological Survey. G. K. GILBERT.

Potstone: a variety of talc, sometimes wrought, like soapstone, into pots, stoves, and kettles. It abounds in Europe, and is coarser and more granular than the best soapstone.

Pott, AUGUST FRIEDRICH: comparative philologist, b. at Nettelrede, in Hanover, Nov. 14, 1802; studied philology at Göttingen; was appointed professor in Halle in 1833. The *Etymologische Forschungen*, his greatest work, was published in 1836 (2d ed. 5 vols. and index vol., 1859–76). He also wrote *Die Zigeuner in Europa und Asien* (2 vols., Halle, 1845); *Die quinaere und vigesimale Zälmethode* (1847); *Die Personennamen und ihre Entstehungsarten* (1853; 2d ed. 1859); *Anti-Kaulen* (1863); *Die Sprachverschiedenheiten in Europa an den Zahlen nachgewiesen* (Halle, 1868); *Wurzelwörterbuch der indog. Sprachen* (1867–73, and in *Etymolog. Forschungen*, 2d ed. vol. ii., part 2); *Wilhelm von Humboldt und die Sprachwissenschaft* (2 vols., Berlin, 1876; 2d ed. 1880); and important articles in journals, collected in full by Horn in *Bezzenbergers Beiträge*, xiii., 338 ff. D. at Halle, July 5, 1887. Revised by A. GUDEMAN.

Pott, PERCIVAL: surgeon; b. in London, England, 1713; was apprenticed in his sixteenth year to a surgeon of St. Bartholomew's Hospital, with whom he served six years; in 1745 was made assistant surgeon, and from 1749 to 1787 was surgeon to St. Bartholomew's Hospital. His investigations into the causes of certain forms of spinal disease are classic. Some of his publications are *A Treatise on Ruptures* (London, 1756); *Observations on the Nature and Consequences of Wounds and Contusions of the Head, etc.*, (1760); *Remarks on that Kind of Palsy of the Lower Limbs which is Frequently found to accompany a Curvature of the Spine* (1779). D. Dec. 22, 1788. S. T. ARMSTRONG.

Pottawatomi Indians: See ALGONQUIAN INDIANS.

Potter, ALONZO, D. D., LL. D.: bishop; b. at La Grange, N. Y., July 10, 1800; graduated in 1818 at Union College, and afterward married the only daughter of President Nott; became a college tutor 1819, and held a mathematical professorship in Union College 1821–26; took deacon's orders in the Protestant Episcopal Church 1821; was advanced to the priesthood 1824; was rector of St. Paul's, Boston, 1826–31; Professor of Moral Philosophy and vice-president of Union College 1831–45; became Bishop of Pennsylvania in 1845; was one of the founders of the Episcopal Hospital and the Divinity School, Philadelphia. Author of *Political Economy* (1841); *Handbook for Readers and Students* (1847); *Discourses, etc.* (1858); *Religious Philosophy* (1870), and other works. D. in San Francisco, Cal., July 4, 1865. Revised by W. S. PERRY.

Potter, ELIPHALET NOTT, D. D., LL. D.: educator; son of Bishop Alonzo Potter; b. at Schenectady, N. Y., Sept. 20, 1836; graduated at Union College 1861; studied theology; took orders in the Episcopal Church; was pastor of churches at Bethlehem, Pa., and Troy, N. Y.; built at the former place three churches, and at the latter two chapels; became Professor of Christian Evidences at Lehigh University 1866, and president of Union University (formerly called Union College) 1871, adding the duties of chancellor of that

institution 1872. He resigned in 1884, and became president of Hobart College, Geneva, N. Y. He was elected Bishop of Nebraska, but declined the office. He is author of *Parochial Sermons*, and has also prepared a work on *Christian Evidences at the Close of the Nineteenth Century*. Revised by W. S. Perry.

Potter, Henry Codman, D. D., LL. D., D. C. L.: bishop; b. at Schenectady, N. Y., May 25, 1835, the son of Bishop Alonzo Potter; graduated at the Protestant Episcopal Theological Seminary, Virginia, 1857; became rector of Grace Church, New York, 1868; bishop of New York, 1887. He is the author of *Sisterhoods and Deaconesses at Home and Abroad* (New York, 1871); *Gates of the East: a Winter in Egypt and Syria* (1876); *Sermons of the City* (1881); *Waymarks 1870–1891; being Discourses with Some Account of Their Occasions* (1892).

Potter, Horatio, D. D., LL. D., D. C. L. Oxon.: bishop; b. at La Grange, N. Y., Feb. 9, 1802; a brother of Bishop Alonzo Potter; graduated at Union College 1826; took deacon's orders in the Protestant Episcopal Church 1827; was advanced to the priesthood 1828; was Professor of Mathematics in Washington (now Trinity) College, Hartford, Conn., 1828–33; became in 1833 rector of St. Peter's, Albany; in 1854 became provisional bishop, and in 1861 Bishop, of New York. Bishop Potter's episcopate was wise, conservative, and in the main conciliatory. D. in New York, Jan. 2, 1887. Revised by W. S. Perry.

Potter, John, D. D.: archbishop; b. at Wakefield, Yorkshire, England, about 1674; educated at the Wakefield free school; entered University College, Oxford, in 1688; published a volume of *Variantes Lectiones* on one of the works of Plutarch (1693); became fellow of Lincoln College 1694; edited Lycophron's *Alexandra* 1697; was ordained in the Anglican Church 1697; published his principal work, *Archæologia Græca* (2 vols., 1697–98); became chaplain to Archbishop Tenison 1706; Regius Professor of Divinity at Oxford 1708; Bishop of Oxford 1715, having just finished his edition of *Clemens Alexandrinus*, and became Archbishop of Canterbury 1737. D. at Lambeth, Oct. 10, 1747. His *Theological Works* appeared in 3 vols., 1753. Revised by W. S. Perry.

Potter, Paul or Paulus: painter; baptized at Enkhuizen, Holland, Nov. 20, 1625. He studied art with his father at Amsterdam, and subsequently at Haarlem under Jacob de Weth. He painted at Delft two years, then went to The Hague, where he married in 1650; settled in Amsterdam in 1652; d. there, Jan. 17, 1654. Among his best-known works is that at The Hague called the *Young Bull*, painted in 1647; a finer but smaller picture of the same subject is at Buckingham Palace. His works are to be found in the principal collections at The Hague, Amsterdam, St. Petersburg, Copenhagen, Paris, Turin, and London. A portrait of Paul Potter by Van der Helst is in The Hague Museum. W. J. Stillman.

Potter, William James, A. B.: clergyman and author; b. at Dartmouth, Mass., Feb. 1, 1830; educated at Friends' Boarding School, Providence, R. I., Bridgewater, Mass., Normal School, Harvard College, Harvard Divinity School, and in Germany; taught in district schools one year; usher in Bristol Academy one year; instructor in Cambridge High School two years; was pastor of the Unitarian church, New Bedford, Mass., thirty-three years, including one year spent in military service (1863–64) with title of hospital chaplain; detailed for special service under the Secretary of War: aided in establishing the American Free Religious Association; was its secretary from its origin, 1867, to 1882, and its president 1882–93; editor of *The Index* 1880–87; author of *Twenty-five Sermons of Twenty-five Years* (1885), a highly representative expression of later Unitarian thought; *A History of the First Congregational Society in New Bedford* (1888); *Four Discourses Suggested by the Life and Tragic Death of Abraham Lincoln* (1865), and various sermons, essays, and addresses, many of which may be found in *The Radical*. J. W. Chadwick.

Pottery and Porcelain [*pottery* is from Fr. *poterie*, deriv. of *pot*, pot; *porcelain* is from O. Fr. *porcelaine*, from Ital. *porcellana*, a sea-shell, sea-mussel, hence fine clay, porcelain, deriv. of Lat. *porcus*, in its obscene sense of pudenda muliebria, to which the shell of the sea-mussel was compared]: *pottery* denotes, first, objects made of material (generally clay) which is moulded while soft and then baked until it becomes hard; second, a place where such objects are produced; and third, the art and process of their manufacture. In a narrower and more customary sense, the word pottery is applied only to the coarser varieties of such objects; porcelain comprising the finer, translucent, or semi-translucent kinds. Both are generally made of clay, and are keramic ware (see Keramics), but the terms are stretched to cover some wares that are not clay wares.

Materials.—Clay is very widely dispersed over all the continents and the larger islands of the world, and everywhere has been used for making vessels since the most remote antiquity. It is easy to mould by hand or by tools, keeps its shape well if kept moist, and can be remoulded as often as desired. When baked, or *fired*, it hardens without serious shrinkage or deformation, and will then keep its shape permanently. Different kinds of clay give different colored baked wares; thus at Apt, in Provence, there are beds of pale-brown clay, which have been in use during the eighteenth and nineteenth centuries by potters in that town, and which furnish the *terrines*, or covered pots in which various delicacies for the table are put up, these terrines being almost exactly of the same color as the unbaked clay. While the clay described above, and that of which yellow bricks and cream-colored terra-cotta are made, is hardly changed in color by firing, on the other hand, all clays which contain much iron turn red in the oven; thus common red bricks are not red before firing, but generally of a pale mud-color. The clay which forms the chief ingredient of porcelain is called Kaolin (*q. v.*). This is white and mealy, and consists of decomposed feldspar. Clay made very thin, to be applied to the surface of a piece of pottery and baked with it, is called *slip*. The piece may be dipped in the slip, or the slip may be poured on from the nose of a can, as when used to make stripes and bands for ornament. The glaze or enamel with which the clay body is covered in many kinds of pottery and porcelain is more diverse in composition. The extremely thin glaze of some fine kinds of ancient pottery has not been successfully analyzed. The equally thin glaze on the hard *stoneware* of which vinegar-jugs, Selters-water bottles, English beer bottles, etc., are made, is produced by throwing common salt into the oven, where it is decomposed, the soda of the salt combining with the alumina of the clay to form a thin, hard silicate. Other kinds of stoneware, and some kinds of soft earthenware, are covered with a lead glaze, made from white lead, flint, fragments of glass, and other materials in smaller quantities. These are ground together to a very fine powder, and mixed with water to form a thin paste, which is applied to the surface by dipping, or with the brush. The glaze of porcelain is made of a mixture of quartz and kaolin, or of feldspar and kaolin, with small quantities of other ingredients. In all glazes the requirements are that they shall combine readily with the surface of the body, and cling to it, that they shall fuse and become vitrified at a lower temperature than that needed for firing the body, and that the surface, when baked, shall be hard and insoluble in ordinary liquids. It is also generally a requisite that the glaze should not contract so much in the firing as to crack; but the *crackle*, which is so great an ornament to many Oriental wares, is produced by allowing the glaze to shrink and separate, and then, in some cases, filling the cracks with color before another firing.

When a glaze is opaque and put on rather thickly, it is called *enamel*. The most common enamel is stanniferous—that is, made in part of an oxide of tin. Such an enamel is perfectly opaque, pure white, lustrous, and with a soft surface which receives color well, so that good painting on the surface of such an enamel is often more beautiful than the painting on porcelain. It is sometimes impossible to tell in ancient pieces whether the thick white coating is enamel or slip. The pigments used for painting on pottery and porcelain are fusible or vitrifiable colors. These have often a very different appearance before firing to that which they are to give to the finished piece.

Processes of Manufacture.—The chief implement used by the maker of pottery or porcelain vessels is the *potter's wheel*, a horizontally revolving disk, upon which the lump of clay is held, and which the workman revolves at his wish. By the rotary motion a true roundness is given to the vessel, and the soft clay is shaped and reshaped very quickly by a skillful hand, the vase or jar being drawn out larger, or spread broader, or modified in its shape by a touch as it whirls. The simplest potter's wheel is turned by hand, but other arrangements are made to turn it more easily, or without the effort of the potter, and the best form seems to be one with a treadle for the foot, acting on the vertical axis,

to which are attached the flat disk for the clay, at the top, and a fly-wheel at the bottom. Handles and spouts are

Fig. 1.—The potter's wheel.

moulded separately, either by hand or in plaster moulds, and stuck on to the body while still soft. Elaborately modeled ornaments, figures of men and animals, and the like, whether attached to vessels or forming ornamental objects by themselves, are made with the sculptors' modeling tools.

When the shaping is done, the piece is allowed to dry somewhat before firing, but care must be taken not to let it dry so much as to crack. Common earthenware is fired only once. Glazed and enameled wares are fired once for the body and once for the covering. Painted wares are fired a third time for all colors which are applied upon the glaze, and a fourth time, always with decreasing temperatures, for gilding. The firing (see Kiln) is sometimes repeated more frequently, because the degree of heat and the length of the exposure may greatly modify the color which a pigment will furnish, and because retouches and alterations need new baking. Moreover, different workmen employ different processes: thus much Japanese porcelain is fired before the under-glaze colors are applied, then fired for those colors, all before the first glaze has been put on. Some of the celebrated colors, or the cloudings and stainings of color, are the result of accidents occurring in spite of all care and skill, and some of these accidental colors it has been found impossible to reproduce at will.

Decorating is chiefly accomplished by painting with a brush, the pigments being earthy or metallic, usually metallic oxides. Borax and other materials are used as fluxes,

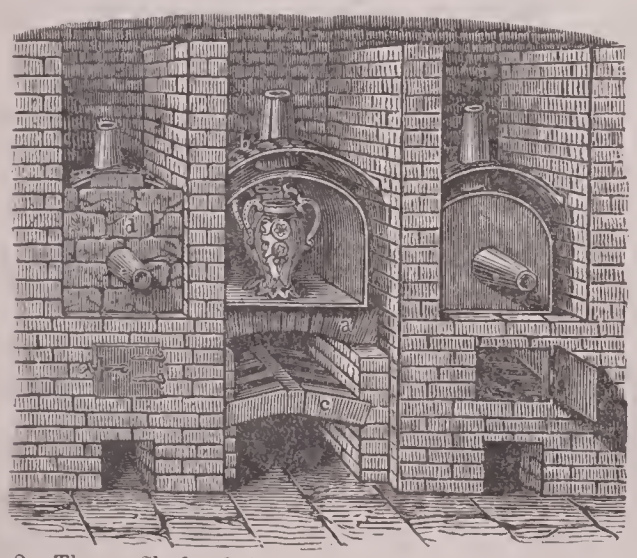

Fig. 2.—The muffle for fixing the colors on decorated porcelain.

and some kind of oil is used to facilitate the laying on. The color when fired becomes glass, either in a solid mass of some thickness or in a mere film. Some colors are applied upon the body under the glaze, but few can bear the great heat necessary for firing the body. Some painting is done upon the unbaked but dried surface of the stanniferous enamel when applied to the body; the color for this must also be very resistant. Other work is done upon the enamel after baking, and for this the low heat of the muffle is sufficient. Gold is applied with a brush, as powder, and is burnished after firing. Luster is generally metallic, the metal being very finely divided, so as to give its effect when laid on as a paint and fired without burnishing.

Besides painting with the brush, some effects are produced by putting on the color in mass and letting it trickle down the surface until stopped and fixed by the heat of the kiln. Other similar effects are got by blowing color from a tube, or splashing or sprinkling it in drops. Sometimes an accidental form, as of a seeming cloud or mountain, produced by splashing or smearing, has given a suggestion for a design, which has then been carried out deliberately. Sometimes the decoration is in form as well as color, the one aiding the other, as when a vase is covered with a raised pattern, simulating basket-work, which is then heightened with color and gold.

Earthenware. Unglazed.—What is called *prehistoric* ware is that to which no approximate date can be given with any certainty, and which is not even associated with an epoch which can be fixed. Thus the burial-mounds of Europe and America have furnished enormous numbers of vases of different kinds which can not be dated at all. Under ordinary conditions, earthenware which is well baked will last indefinitely under ground, and a burial-vase found to-day in France or England may be of a time only just before the Roman occupation or centuries older than that. Vessels found in these depositories are sometimes filled with bones and ashes of the dead, sometimes they are vessels for drinking or for food, and sometimes they seem to be merely ornamental. All are made simply of clay, and this, while still soft, has been impressed with patterns of different sorts or even cut through, the openings being arranged for decorative effect. These impressions and cuttings are fixed by the baking of the clay, and endure as long as the vessel lasts. Circles have been made by the impression of a ring, perhaps the end of a round stick with the center cut away; groups of dots or punctures have been made by a stick with a notched end, or cut into teeth in its length; zigzags and bands have been drawn with a sharp point; in short, there are found all the devices which would suggest themselves to a savage having soft clay before him and desiring to ornament it. The forms of these vases are often rather graceful, though rude, and evidently modeled by hand alone, and the ornament well applied and effective.

The next step is to ornament the vessels with *slip*, or clay thinned with water and applied to the surface. This may be a finer and whiter clay, and in this way effective patterns are produced. Handles and purely ornamental strips and lumps of clay, whether of the same clay as the body of the piece or of the finer slip, are often applied. The slip may be used also to fill up patterns impressed deeply into the surface.

One of the most remarkable uses to which earthenware was put in ancient times is that of inscribed tablets. In Mesopotamia immense numbers of these square tiles have been found, impressed with characters which have been read by modern scholars. They are practically books, and whole libraries of these are known and are gradually yielding up their record of times which can be fixed approximately at from 4000 or 4500 to 2000 B. C. This land of the Euphrates and Tigris, Syria, Cyprus, parts of Asia Minor, and Greece have yielded a great amount of what is called *archaic* pottery—that is, ware which can be associated with other monuments, such as bronzes and gems, and in this way dated approximately, though belonging to a time little known by historical records. These pieces have been made on the potter's wheel, and are therefore fairly regular and smooth. Their forms are varied endlessly and are often very beautiful, and impressed ornaments, like those of the prehistoric pottery, but far more neatly worked, are freely used. Patterns are also made in white or yellow slip on a darker body, and these are very effective. Painting is used also, the colors being earths, such as ocher. The painting is very thin, and is rather a staining of the surface. It is applied upon the body and upon the slip alike.

In later times unglazed earthenware has been less used for ornamental vessels, because more decorative kinds of ware have been made, but statuettes and groups, architectural ornaments and the like, have been made by the Etruscans, by the ancient Greeks, and by all the peoples of Europe and Asia from antiquity to the present. Earthenware used in this way is generally called *terra-cotta*. Great numbers of such sculptures in unglazed terra-cotta exist in public museums, and among these is much fine art of a very refined type of various dates from the Egyptian and Etruscan burial-urns to the portrait-busts made by sculptors in Europe

and America at the close of the nineteenth century. There is constant use of unglazed earthenware for bricks, roof-tiles, drain-tiles, and other articles of utility.

Earthenware, Glazed and Enameled.—The utility of glazing is that it makes porous-clay vessels water-tight, but it is employed equally for decorative effect and to protect surface decoration in colors. Sometimes this glaze is a mere film; thus in fine Greek vases its thickness can hardly be seen in the fracture; it is a mere glassy film. Sometimes it is solid and opaque, as thick as very stout paper, and covers up the body of the ware so that this can not be seen at all, as in MAIOLICA (*q. v.*). Sometimes it is thick and yet translucent, as in some Chinese and Japanese wares of which the body is impressed with deeply sunk patterns, the glaze usually of what is called a celadon green, showing a deeper color where it fills the sunken lines.

This class is the largest, and includes the greatest number of sub-classes. Perhaps nine-tenths of the keramic ware which students and collectors prize belongs to this class. The painted Greek vases are of this class, because the black coating which makes up so important a part of their system of decoration, though its exact composition is disputed, is clearly of the nature of an enamel; and because the glossy surface of the whole vase has been produced by the use of a very thin glaze. In the fine Greek vase (Fig. 4) the figures are of the color of the yellowish-red clay, the background black, made of the enamel mentioned above, put on with the brush, and worked around the figures. Many vases of the same epoch are known which are entirely covered with the black glaze, and depend upon their form and slight ornaments in relief for their effect. This example (Fig. 4) is one of the so-called red-figured vases which are considered as belonging to the finest class of Greek keramic art, and of the fourth century B. C. Vases earlier than this, but still later and finer than the *archaic* ware described above, and fully glazed, had the figures in black on the red ground. No kind of earthenware known is more interesting than these Greek vases, thousands of which have been found in Southern Italy, in Greece, and in other Mediterranean lands. They give the only clear notion of what Greek painting must have been. In themselves, too, they are of great artistic value, as their forms are of incomparable grace, and the figure subjects, however formal and incomplete the pictures may seem, have very important artistic qualities. It seems certain that this great industry had ceased altogether long before the Christian era. No such vases were produced under the Roman empire, although sculpture and painting, glass and metal-work, and most of the fine arts of the Greeks were still flourishing.

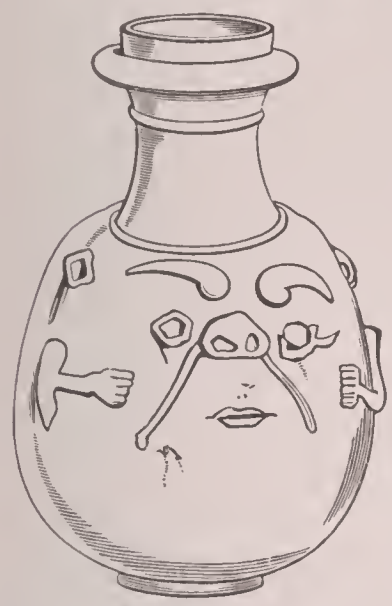

FIG. 3.—Egyptian bottle of unglazed ware, ornamented with grotesque head of the god Bes.

Greek painted vases were called Etruscan in the eighteenth century, probably because those found in the tombs of ancient Etruria were the first to attract notice. It is known now that they were brought from Greece in large numbers. There was also a real Etruscan pottery. Most of the pieces known are unglazed black ware, but some vases exist which have a thin glaze nearly like that of the Greeks.

Under the Roman dominion, glazed pottery was made in many parts of the empire. The type of it is the red ware, of fine texture and smooth surface, generally rather soft and easily broken, and covered with a very thin glaze. This is called Samian ware, from the Isle of Samos, but there is no certainty as to its place of manufacture. Early in the nineteenth century it was discovered that a ware very similar to this was made at Arezzo, in Tuscany, and the Samian ware was probably made in many places, varying slightly in color and character. It was often adorned with arabesque and figures in relief.

Ware with a thick and opaque enamel was not used by the Greeks, nor, apparently, under the Roman empire, but it had been used by the Egyptians at an early date, and the most splendid specimens of it known had been made before the Parthenon was built. Persia, always a center of fine decorative art, had possessed from the time of Darius large friezes of life size, human figures, and animals in relief, decorated with enamels of the most brilliant coloring.

FIG. 4.—Birth of Athene, on a Greek pelike, from Vulci.

The Louvre now has a number of the figures, and their beauty and brilliancy almost exceed belief. Other specimens of this art, from the somewhat more recent palace of Artaxerxes Mnemon, are almost equal in merit. These colored reliefs, twenty-three centuries old, are the finest known instances of color applied to architecture, as well as unequaled pieces of enameled earthenware. In Persia this splendid art was not allowed to die out, and specimens of it of all ages are known. In the eleventh and following centuries of the Christian era the Persian vases, dishes, hanging lamps for mosques and the like, and the imitations of them made in Rhodes and other parts of the Levant, were the most beautiful keramic wares made anywhere to the W. of China, and the influence of the designs and manufacture of these was felt throughout the south of Europe. In Spain, Sicily, and the Balearic islands a beautiful ware, decorated with a few simple colors and a free use of metallic lustrous glazes, was made; this is known as Hispano-Moresque ware. In Italy, in the fourteenth and following centuries, the splendid ware called MAIOLICA (*q. v.*) was made, perhaps surpassing Persian ware in beauty, especially as regards the metallic luster, which is the most vivid and striking of all keramic decorations.

FIG. 5.—Etruscan wine-pitcher, of black ware: Perseus and the Gorgons.

Earthenware with an opaque enamel was next to conquer the North. In France, after the great achievements of PALISSY (*q. v.*), a number of less peculiar and abnormal kinds of faïence were produced. What is known as Rouen ware reached its greatest development in the seventeenth century. The faïence of Nevers, that of Moustiers-la-Reine, succeeded; then the potteries of Strassburg, those of Niederwiller in Lorraine, Marseilles, and Sceaux. In the eighteenth century enormous quantities of these

wares, decorated with bouquets and festoons and figures in color on a white ground, were made in France and Germany. Some attempts were made to imitate the rich and solid coloring of maiolica, and some Oriental designs were copied, but generally a delicate and light-colored style prevailed. Dutch ware, known generally as Delft, is of the same epoch. The Delft pieces most commonly met with are painted in blue on a white ground, in imitation of Chinese porcelain, but there is also a great deal of it decorated in several colors with gold. There are many, also, which are painted with scenes of life, landscapes, and animals both domestic and wild. The forms of the pieces during the seventeenth century are generally very simple and refined, with some tendency toward imitation of the shapes of Chinese pieces of the best styles. There are also many *plaques*, or flat slabs, for hanging on a wall, and these are often painted with pictures of an elaborate sort.

FIG. 6.—Proto-Samian cup, with an amazonomachia in relief, from Athens.

In England but little artistic faïence was made. The "ironstone china" and other varieties of what the French call *faïence fine*, together with Wedgwood ware, are mentioned below under *Stoneware*. Inexpensive tableware is often decorated with transferred patterns. These are first printed upon paper and then transferred from the paper to the unbaked ware. Cheapness is secured in this way, but the process has nearly ruined English pottery as a decorative art, and has done great harm on the Continent.

In China and Japan the abundance of porcelain and (in Japan) of the hard and durable stonewares of yellow body has always kept down the supply of glazed earthenware; moreover, less of it is known in the West because of the attractiveness of those above-named keramic vases. It may be said that for the common needs of life the Orientals use hard earthenware with only a very thin siliceous glaze, and that this kind of pottery approaches common stoneware so closely that it is impossible to draw the line between them. These peoples of the extreme East are such skilled potters that they use all processes freely, very often to the confusion of the Western student of keramics. Thus a very ornamental kind of ware is made with a dark-brown and very hard body, the surface of which is very smooth and fine but not glossy; upon this a white or buff porcelaneous glaze is applied in places, so that the two colors contrast with one another. A statuette, for instance, will have the flesh of the brown earthenware and the dress of the whitish glaze, and this glaze may then be painted in many colors. Completely covered faïence, where no part of the body shows, is also made. Decorative pieces are sometimes brought to the West. The great "porcelain tower" near Nanking, which was destroyed in the Tai-ping rebellion, was faced with faïence, covered with thick enamel, and richly painted, some of the white bricks being a true porcelain.

Stoneware.—Much the most famous variety of this hard and thoroughly baked pottery is that known as Cologne ware, or as *Grès-de-Flandres*. During the seventeenth century splendid vessels were made of this, the forms most varied and fantastic, the ornamentation applied in relief by means of a great number of stamps, and the color-effect limited to the combination of a cold blue in places with the soft gray of the ware itself. This is the more interesting that the pieces differ so slightly from the commonest vessels of daily use. The finest Cologne ware tankard is only a common vinegar jug or beer mug somewhat adorned, and it is the more valuable to the student of design on that account. *Wedgwood ware* should be considered in connection with stoneware because of the non-porous character of the paste. The chief kinds are cream-ware or queen's-ware, of a light buff, colored throughout the body, used for fine dishes and other table utensils; jasper, which was generally either blue or white, very uniform and fine grained, and capable of taking the sharpest edges and neatest impressions, and therefore used for bas-reliefs small and large; basalt, a black paste, also very fine, and used for ornamental vases, but also for tea-sets and the like; crystalline, in which are included imitations of natural agates, porphyries, and marbles, the colored veins going through the body. From 1780 to 1810 Wedgwood's pieces were exported largely to the Continent, and were used freely in England. Bas-reliefs in white on a blue ground were used for buttons and brooches, and larger ones were set into mantels and the paneling of rooms, or hung up like the plaques of Delft and Moustiers. Vases, sometimes mounted in gilt metal, and often set upon high pedestals, were sent as ceremonial gifts, and used for the decoration of the most stately apartments. John Flaxman (see FLAXMAN, JOHN) was employed upon the bas-reliefs, and some of his portrait medallions and groups in white "jasper" are of real interest as sculpture. The most important single piece made by Wedgwood is an imitation of the famous Portland vase, of which a number of copies were made. Other English wares, distinguished by the French writers as *faïence fine*, and known in England by various special names adopted by the makers, are half way between stoneware and artificial porcelain, their composition partaking of both. The paste is light-colored and solidly baked, and the glaze is thin and transparent. It is rare that they have much artistic merit, but they are excellent as tableware. Some of them approach closely to Wedgwood's queen's-ware in appearance.

The yellow ware of Japan, known to the West chiefly as Kioto and Satsuma pottery, is very hard and not porous in the body, and has a very thin and transparent glaze not changing the color of the piece. It is therefore more nearly stoneware than earthenware. Vases and dishes, statuettes, and groups of this beautiful ware are very well known. The artistic merit of the decoration is of many degrees; there are some pieces in which the delicacy and softness of effect entitles the ornament to be considered as beautiful and as truly appropriate to keramic ware as any that is known, but most of the pieces are somewhat more harsh in color, and the painting often tends toward extreme minuteness and the display of technical skill.

PORCELAIN.—This appears to be the discovery of the Chinese, and all its highest attainments are due to that people. Few persons are aware of the endless variety of decoration to be found in Chinese porcelain, for no collection in any public museum contains nearly all the varieties that exist. Japanese porcelain is hard and fine, and exquisitely made and finished, but there are only three or four styles of painting used in its decoration, while the Chinese styles can be counted by hundreds. There are many vases and plates in Western collections which are painted most artistically and delicately with flowers, groups of men and women in rich costumes, and other subjects, all vivid colors treated in the most judicious manner. Blue painting on white, when carried to its highest pitch of excellence, is extraordinarily decorative. The fault of too great sharpness of outline and of too sudden contrast between pattern and background is not to be found with the best pieces. Of Japanese porcelains the best known is also the finest—viz., the "Old Japan" or Hizen porcelain, painted in blue under the glaze and then enameled colors and gold upon the glaze. The general effect is a combination of dull blue and dusky red with pale gold, on a brilliant white ground.

Porcelain was first made in Europe by Böttger in the employ of the Elector of Saxony about 1710. Previous to that time a factory kept up by the Medici at Florence had made a few pieces of a ware very like a real porcelain, and long thought to be so, but now known to be not a clay ware. The sight of the Saxony porcelain excited afresh the makers of fine pottery in France and England, and many attempts to imitate this and the Oriental porcelains were made. These attempts resulted in soft porcelain (*pâte tendre*), and in English artificial porcelain, both very complicated in their make, with many ingredients in the body and the paste, but hardly clay wares. About 1770 the secret of the kaolin or true porcelain clay became known in France, and from that time real porcelain was made at Sèvres; but the artistic qualities of Saxony and Sèvres porcelain are by no means equal to the skill shown in the manufacture or to the enormous prices paid for fine pieces. The Saxony porcelain—generally called Dresden, or, more properly, Meissen, from the town where the factory is situated—that of Vienna beginning about 1745, and that of Berlin from about 1750 may all be considered rivals of Sèvres porcelain in the favor of collectors. The German pieces are generally still less artistic and appropriate in design than those of France, but these, as well as the Sèvres, command admiration for their delicate finish and the wonderful skill of the makers and decorators of the finer pieces. Each of these factories has always been a Government enterprise,

and the most important productions are generally to be seen in palaces, having been sent as gifts from one court to another.

Exceptional Wares.

Egyptian Green Ware.—This curious ware, commonly called "porcelain," is almost wholly composed of sand, half melted, held together by a little plastic material, and glazed with silex; in other words, it is a half-made glass, and is very easily broken. It is of a beautiful green or blue tinge, and decorated with simple patterns, generally in a darker blue.

Henri Deux Ware.—This extraordinary pottery was a mystery to students until Benjamin Fillon located its manufacture in the east of France, calling it Faïence d'Oiron, from a village in the department of Deux-Sèvres. It is now called Faïence de St.-Porchaire, from a village in the Charente-Inférieure. There are only fifty-three pieces of it known, of which about a dozen are in one glass case in the Louvre: all of the same general style of make and design; all are without doubt the product of one and the same private workshop. The great peculiarity of the decoration is the inlaying of clay of one color in a clay body of another color. Little metal stamps, like bookbinders' stamps, were used for this, the clay being removed from the parts cut out by the stamps, and the clay of a different color put in, after which the whole was fired, and then glazed and fired again.

Soft Porcelain.—The early Sèvres ware brings enormous prices, mainly because of its rarity, but it is really somewhat more refined in effect because of the slight absorption of the colors by the paste. As was said above of Chinese porcelain, so European real or hard porcelain seems to many persons harsh in its sharp-edged and strongly contrasting colors, while *pâte tendre* is softer in its gradations.

English Porcelain.—This, in its different varieties—Derby, Chelsea, Bow, "Spode," Worcester, Lowestoft—is generally made of an artificial mixture, and is rather glass than keramic ware. It is rarely fine in design, the more expensive pieces being very clumsy in form, and painted and gilded in execrable taste, and the cheaper pieces ruined by having the colored patterns transferred to their surface from prints on paper. This is a way of getting an appearance of decoration cheaply, but no process is more devoid of true ornamental effect. Some fine Derby ware statuettes and groups have been sold in the biscuit, unglazed and uncolored, and these are very attractive, the example of Wedgwood ware and Flaxman's designs carried out in this material having influenced English work more as to sculptured form than in other ways.

Modern Wares.—At the close of the nineteenth century there are so many different wares and so many different processes of manufacture, many of these latter being also kept secret, that classification is extremely difficult. Generally the forms are ugly, partly because the art of modeling simple and suitable teapots and cups has been lost by the workmen, and only a trained artist can satisfy himself without inartistic additions and attempts at novelty, partly because the demand for extreme neatness and uniformity makes all natural grace impossible. The decoration in color and gold is usually disagreeable from its hard monotony. In France, however, some simple faïence is decorated with flower patterns, of which the outline is printed or transferred, but the filling in with natural-seeming colors is done by hand. At a higher price are made some tea-sets and the like, which are painted entirely by hand, a spray of roses or other flower being laid across each plate, very well drawn and colored, though not very well arranged as decoration. One exceptional style of decoration is that called *à pâtes rapportées* or *pâte sur pâte*, in which pure white semi-translucent reliefs are raised on a colored ground, the color showing through the thin edges, and the relief growing more purely white as the *pâte* grows thicker. This has been in use since 1852; it is often called by the name of Solon, who produces it for a London dealer, but it is also made at Sèvres. In the U. S. some private persons have painted clever designs of wild plants variously grouped. The Rookwood pottery, of Cincinnati, turns out large and small decorative pieces of great variety of forms. These, and the tableware, are decorated with very able painting of natural-looking sprigs and bouquets in white, buff, gray, etc., on a ground of dark brown, dark green, and similar colors passing into one another by gradations. Gallé, of Nancy, in France, makes ornamental vessels of the most extraordinary and unexpected designs, always interesting but often more novel than beautiful. Delaherche, of Paris, makes noble vases decorated with strong dark-colored glazes with fine gradation, somewhat like Chinese single-colored porcelains. Massier, of the Gulf Juan, near Toulon, makes the most exquisite pieces, decorated with mere zigzags and cloudings, and half-seen bouquets, but this ware is unfortunately extremely soft, and its paste is scratched by a touch. The royal factory of Copenhagen turns out dishes and vases painted with landscape effects, birds, etc., in pale grays and white, some of which are very decorative in a subdued way. The Japanese makers of the close of the century are also vying with one another in the production of extremely delicate and highly ornamented pieces, as well as tableware, and the cheapness of even their very beautiful productions is remarkable. Tiles for wall decoration are made in endless variety in Europe and the U. S., the best in color being French, but some of those with figure subjects and heads in low relief made in the U. S. are extremely effective.

Pottery and porcelain are made at many places in the U. S. At East Liverpool, O., are about thirty different establishments, some of which produce decorative wares. At Trenton, N. J., are perhaps as many separate establishments. At Cincinnati, O., are two or three commercial manufacturing establishments, besides the private associations, in which much very novel and sometimes successful artistic work has been produced. Besides these there are works in New Hampshire, at Keene; in Massachusetts, at Cambridge, Chelsea, and East Boston; in Connecticut, at Hartford; in New York, at Utica, Greenpoint (Long Island), Syracuse, and the city of New York; in New Jersey, at Perth Amboy and Menlo Park; in Pennsylvania, at Beaver Falls, Morrisville, Pittsburg, Phœnixville, Spring Mills, and Philadelphia; in Maryland, at Baltimore; in West Virginia, at Wheeling; in Georgia, at Atlanta; in Kentucky, at Covington; in Ohio, at Akron, Steubenville, and Zanesville; in Indiana, at Indianapolis and Anderson; in Illinois, at Peoria; in Wisconsin, at Edgerton. According to the U. S. census of 1890 the value of the clay and pottery products of the 707 establishments which reported was $22,057,090, excluding bricks and tiles.

For European wares of the sixteenth and eighteenth centuries, besides the general works mentioned under Keramics and at the end of this article, see Garnier, *Histoire de la Céramique* (1883). Garnier's *Dictionnaire de la Céramique* is perhaps the latest, and is one of the best on majolica. For English pottery and soft porcelain, see Miss Metcyard's several books on *Wedgwood Ware*, Binn's *Century of Pottery in Worcester*, and Owen, *Ceramic Art in Bristol.* General books on English wares are Solon, *The Old English Potter*; Jewett, *Ceramic Art of Great Britain*; and Church, *Catalogue of English Pottery.* For Chinese and Japanese wares, see Bushell, *Oriental Ceramic Art*, magnificently illustrated (1897); Jacquemart and Le Blant, *Histoire de la Porcelaine*; Audsley and Bowes, *Keramic Art of Japan* (London,

1875), uncritical, but finely illustrated; du Sartel, *La Porcelaine de Chine*; Stanislas Julien, *Histoire de la Porcelaine de Chine*. A recent and thorough work on pottery and porcelain in the U. S. is by E. A. Barber, and has many illustrations. For general works on pottery and porcelain, besides the books named under KERAMICS. see Brongniart, *Traité des Arts céramiques* (Paris, 1844); W. Chaffers, *Marks and Monograms on Pottery* (London, 1863); Treadwell, *Manual of Pottery and Porcelain* (New York, 1872); Eliza Meteyard, *Wedgwood and his Works* (London, 1873); Champion, *Two Centuries of Ceramic Art in Bristol* (London, 1873); Beckwith, *On Pottery* (New York). RUSSELL STURGIS.

Pottinger, pot'in-jer, Sir HENRY: diplomat; b. in County Down, Ireland, in 1789; went in 1804 as a cadet to India, where he rose through all the grades of the service; was political resident in Cutch and Scinde 1824–39: was made a baronet Dec., 1839; went to China as ambassador and superintendent of British trade 1841; co-operated with Admiral Parker in effecting the capture of Amoy and other places; concluded the treaty of peace of Aug. 29, 1842, which opened five Chinese ports to the commerce of all nations; was appointed governor of Hongkong Apr., 1843; became privy councilor on his return to England May, 1844; was governor of Cape Colony 1846–47, and governor and commander-in-chief of Madras presidency 1847–54. Author of *Travels in Beloochistan and Sinde* (1816). D. at Valetta, Malta, Mar. 18, 1854.

Pot'to: a name applied to the KINKAJOU (*q. v.*).

Pott's Disease of the Spine: See SPINAL CARIES.

Pottstown: borough; Montgomery co., Pa.; on the Schuylkill river, the Schuylkill Canal, and the Phila. and Reading and the Penn. railways; 18 miles E. S. E. of Reading, 40 miles W. N. W. of Philadelphia (for location, see map of Pennsylvania, ref. 6–I). It is in an agricultural and mineral region, and is widely known for its manufactures, particularly of iron and steel. Besides the plant of the Pottstown Iron Company, which includes furnaces, rolling-mill, steel-works, and machine-shops, and that of the Philadelphia Bridge Company, there are 3 rolling-mills, a steel-mill, 2 nail-factories, a furnace for pig-iron, boiler-works, agricultural-implement works, 5 cigar-factories, 3 carriage-factories, 2 planing-mills, and other industrial works, including in the borough and its vicinity more than 20 creameries. The borough contains 22 churches, public-school property valued at over $115,000, Normal Institute, Hill School, 2 school libraries (High and Hill) containing over 5,000 volumes, 3 national banks (combined capital of $600,000), and 2 daily and 2 weekly newspapers. Pop. (1880) 5,305; (1890) 13,285; (1900) 13,696. EDITOR OF "DAILY NEWS."

Pottsville: borough; capital of Schuylkill co., Pa.; on the Schuylkill river, and the Lehigh Valley, the Penn., the People's, and the Phila. and Reading railways; 35 miles N. W. of Reading, 93 miles N. W. of Philadelphia (for location, see map of Pennsylvania, ref. 5–H). It is in the extreme southern part of the great Schuylkill anthracite coal-field, where shafts have been sunk in the valleys to a depth of 1,600 feet to reach the underlying coal-beds, while on the mountain-sides the coal-beds crop out, and it is the chief shipping-point of this coal region. It was here that anthracite coal was first successfully used for smelting purposes in 1839, and the prize of $5,000 offered by wealthy Philadelphians to the individual who would succeed in smelting iron ore with anthracite coal was awarded to the Pottsville furnace. There are 3 national banks with combined capital of $800,000, a State bank with capital of $200,000, a trust company with capital of $250,000, and a private bank. The public-school property is valued at over $300,000. There are excellent public schools, comprising besides the lower grades 2 grammar schools and a high school, and a commercial business college, 2 private schools, and 2 parochial schools. There are 3 libraries (Athenæum, Public School, and the Schuylkill County Law) containing over 10,000 volumes, and 3 daily and 7 weekly newspapers. The churches and chapels number 23. The borough has gas and water works, electric lights, electric railways connecting the adjoining towns, and a steam-heating plant. The industrial works include furnaces, rolling-mills, stove and other foundries, several boiler, engine, and machine shops, pottery, bolt and nut factories, planing-mills, spike-mills, shirt and stocking factories, large breweries, an extensive silk-mill, and bridge-works. Pop. (1880) 13,253; (1890) 14,117; (1900) 15,710. BAIRD HALBERSTADT.

Pouched Rat: See GOPHER.

Poughkeepsie: city; capital of Dutchess co., N. Y.; on the eastern bank of the Hudson river; 75 miles N. of New York and 69 miles S. of Albany (see map of New York, ref. 7–J). It is the eastern terminus of the Poughkeepsie and Eastern Railway, and is on the lines of the N. Y. C. and H. R. Railroad and the Philadelphia, Reading and New England Railroad, which last here crosses the Hudson river on a cantilever bridge at an elevation of 212 feet. (See BRIDGES.) Connection also is here made with the West Shore Railroad by ferry. Poughkeepsie was settled by the Dutch at the close of the seventeenth century. The first substantial building was erected not far from 1705. The Legislature of New York met in Poughkeepsie in 1778 to accept the articles of confederation adopted by delegates from the thirteen States. Here also on July 26, 1788, a State convention, through the eloquent and patriotic endeavors of Alexander Hamilton, ratified the national Constitution. The city is partly upon a hillside sloping to the river, but largely upon table-land extending eastward to Vassar College, 2 miles away. At the N. is College Hill, whose summit is 500 feet above the town. The whole of this hill, excepting the reservoir-grounds, has been given to the city by one of its citizens as a public park; its area is nearly 100 acres. The city is lighted by electricity, and its streets are traversed by electric cars, by which communication is held with Vassar College and Wappinger's Falls, a manufacturing village 8 miles below. Poughkeepsie is distinguished for its seminaries of learning, of which VASSAR COLLEGE (*q. v.*), Riverview Military Academy, Eastman's Business College, and Lyndon Hall are prominent. It has 23 churches, 6 national banks, a savings-bank, a public library, Orphan Asylum, Old Ladies' Home, Old Men's Home, hospital, and many other charitable institutions, while to the N., just outside the city limits, is the Hudson River Hospital for the Insane. There are many important and flourishing manufacturing interests, and 4 daily, a semi-weekly, 3 weekly, and 2 monthly periodicals. The city is supplied with water from the Hudson. Pop. (1880) 20,207; (1890) 22,206: (1900) 24,029.

Poulp [from Fr. *poulpe*]: a common name for any species of eight-armed Cephalopod. See MOLLUSCA.

Poultice: a soft composition of bread, flaxseed, meal, slippery-elm bark, or herbs, applied warm or at as high a temperature as the part to which it is applied will bear, in order to hasten inflammation and produce suppuration. Cold poultices or other cataplasms—for instance, of cotton-wool steeped in water—are applied to prevent inflammation or mitigate pain.

Poultney: town; Rutland co., Vt.; on the Poultney river, and the Del. and Hudson Railroad; 7 miles S. by W. of Castleton, 18 miles S. W. of Rutland, the county-seat (for location, see map of Vermont, ref. 7–B). It is in an agricultural region, and has several slate-quarries, slate-manufactories, foundry, machine-shops, the Troy Conference Academy (Methodist Episcopal, chartered in 1834), a national bank with capital of $50,000, and a weekly newspaper. Pop. (1880) 2,717; (1890) 3,031; (1900) 3,108.

Poultry [from O. Fr. *pouleterie*, deriv. of *poulet*, chicken]: domestic fowls, either gallinaceous or aquatic. Of the former there are sixty-eight breeds, each bred to a standard of points and possessing certain characteristics of color, form, and habits. The standard breeds are classified as American, Asiatic, Mediterranean, Polish, Hamburg, French, English, Game, Game Bantam, Bantam, and Miscellaneous.

American.—The American class comprises the Plymouth Rocks, Wyandottes, Javas, Dominiques, and Jersey Blues. The Plymouth Rocks are subdivided into White, Buff, and Barred varieties, the Javas into Black, White, and Mottled, and the Wyandottes into White, Golden, Silver, Buff, and Black. They are of medium size, and vary in color. With the exception of the Dominiques, which have rose-combs, they possess single straight combs which are serrated. The fowls of the American class are good layers. The color of the eggs is usually light brown, sometimes nearly white. The hens are persistent sitters.

Asiatic.—In this class are included the Light Brahmas, Dark Brahmas, Partridge Cochins, Black Cochins, White Cochins, Buff Cochins, and Langshans. They are the largest of the gallinaceous fowls, the Light Brahmas leading in weight. All fowls of this class have feathered legs, and all have single combs, with the exception of the Light Brahmas and Dark Brahmas, which possess pea-combs. They are

FANCY POULTRY.

hardy, large, and adapted to confinement. The hens are excellent layers and mothers.

Mediterranean.—To the Mediterranean class belong the Leghorns, Minorcas, Andalusians, and Black Spanish. The Leghorns are subdivided, according to the color of the plumage, into black, white, brown, dominique, and buff. There are also two varieties known as rose-comb brown and rose-comb white. The Minorcas are separated into two varieties—white and black. The fowls of the Mediterranean class are small, of active habits, unfitted for confinement, and are excellent foragers on a range. They are not sitters. They rank first as layers, but are deficient in size and attractiveness as market-fowls. Like all non-sitters, they lay eggs entirely white in color.

Polish.—The fowls of the Polish class are non-sitters, and are excellent layers during spring and summer, but are not very hardy. They are valued chiefly for their beautiful plumage. They possess large crests, and some varieties have beards. The Polish breeds are subdivided into the white-crested black, golden, silver, white, bearded golden, bearded silver, bearded white, and buff laced.

Hamburg.—This class includes the Hamburgs and Red Caps. They have rose-combs, are small, lay white eggs, and are non-sitters. They are not adapted to confinement, but are excellent foragers on a range. As table and market fowls they are not in favor, and also lack in hardiness. They are beautiful in plumage, and are second to the Polish as ornamental fowls. The Hamburgs are separated into golden-spangled, silver-spangled, golden-penciled, silver-penciled, white, and black.

French.—The French class comprises the Houdans, Crèvecœurs, and La Flèches. They are non-sitters and excellent table-fowls, but are unable to endure severe winters and damp weather. The fowls of the Houdan breed, however, are raised successfully in some sections of North America. The Houdans and Crèvecœurs possess crests and beards, while the La Flèche is without either. The Houdan possesses a fifth toe on each foot.

English.—The Dorkings compose the English class, being separated into white, gray, and colored. For the table they are unrivaled. The chicks are difficult to raise, and the adults are not well adapted to the climate of the U. S. The Dorking has five toes on each foot, is very compact in body, and the eggs are white in color. The females are excellent sitters and mothers.

Game.—To this class belong the Malays, Sumatras, Black-breasted reds, the various Duckwings—brown, white, pyle, and Indian. Games intended for combats in the pit differ from the standard varieties in being bred without regard to color or form, as courage is more essential. The Game fowls are excellent for the table and have an abundance of "breast meat." The females are superior sitters and mothers, but are not above the average as layers.

Bantam.—The Game Bantams do not differ from the standard Game fowls except in size. They are esteemed as pets. Cocks should not exceed 22 oz. in weight nor hens 20 oz. The Black-breasted reds are the favorites. Of Bantams other than Game are the Pekin (or Cochin), Booted, Japanese, white-crested White Polish, Rose-comb Black, Rose-comb White, Golden Sebright, and Silver Sebright.

Miscellaneous.—The miscellaneous class includes the Sultans, Silkies, Frizzles, Russians, and breeds that are considered oddities. They possess no merit of importance, with the exception of the Russian, which is a desirable breed for the market, the hens also being excellent layers and mothers.

Characteristics of Breeds.—As cattle have been classified into breeds, as milk, butter, and beef producers, so do the breeds of fowls differ in points of merit. The same breed can not be superior as egg-producers and in furnishing choice meat for the table, as egg-production is antagonistic to the production of meat of the best quality. The Asiatic class is composed of fowls that have been reared in confinement for many years until their wings have been so reduced in size as to render flying impossible, while the size of the body has been increased. These fowls fatten very readily, and if judiciously managed produce eggs during all seasons. As the motive power of the wings is in the muscles of the breast, the amount of "breast meat" has been lessened and the quality of the flesh is inferior, although their large size is an advantage in making an attractive display in market.

Fowls of the active breeds, such as the Leghorns, Hamburgs, and Minorcas, convert a large proportion of their carbonaceous food into force, and consequently they do not fatten as readily as the large breeds. They are non-sitters, although experiments demonstrate that hens of all breeds become broody when they have too much food and become fat. Fowls of American breeds are hardy, and while not equaling those of the Mediterranean class as layers nor rivaling the Dorkings in quality of flesh, they are above the average in both respects, but are liable to become overfat unless fed carefully during the winter. They are partially adapted to confinement, but, like fowls of all breeds, thrive best on a range. The best breeds for egg-production, considering hardiness and adaptability to climate, are the Leghorns, Minorcas, Wyandottes, Plymouth Rocks, Brahmas, and Langshans, in the order named. If the object is to produce poultry for market the breeds should be selected without regard to their laying qualities. Considering hardiness as a factor, the best breeds for market are the Plymouth Rocks, Light Brahmas, Cochins, Wyandottes, and Langshans, the last-named breed, however, not possessing the desired yellow skin and legs. For the table the Dorkings and Games are unexcelled, but they are too difficult to raise for market, owing to rapid feathering when very young.

Turkeys and Guinea-fowls.—There are six breeds of turkeys—the buff, bronze, slate, white, black, and Narragansett. The leading breeds are the bronze and white, the others being rare and possessing no especial merit. The bronze is the heaviest, the required weight of the adult male being 32 lb. and that of the female 22 lb. There are three varieties of guinea-fowls—the pearl, white, and bronze. They are not recognized in the list of domestic breeds and find no sale in market. On farms, however, they are regarded as excellent layers and their flesh is considered delicate. The period of incubation is the same as that of the turkey, and their habits are nearly the same in the domesticated state.

Aquatic Fowls.—Geese are separated into the Toulouse, Embden, African, Canada, Egyptian, White China, and Brown China breeds, all rare except the first two. Of ducks there are the Pekin, Aylesbury, Rouen, White Muscovy, Colored Muscovy, and Cayuga, all well-known breeds. The Call and East Indian are very small and are seldom kept on farms. The crested duck is bred more as a novelty than for practical purposes. The Muscovy ducks differ from the others in requiring a longer period for incubation and in producing sterile progeny when crossed with other breeds; the cross-bred female lays eggs which will not hatch. It is therefore doubtful if the Muscovy is really a duck; its period of incubation and habits approach more nearly those of the goose. See Goose and Duck.

Feeding.—Laying hens require food of a character entirely different from that suitable for non-producers. An egg is composed of 12½ per cent. of albumen, 21 per cent. of oil and fat, and 10 per cent. of mineral matter, the greater proportion of the egg being water. As grain is deficient in lime and is largely starch, it has a tendency to fatten rather than to supply the elements composing the egg. Digestion and assimilation are promoted when the food is varied, and egg-production is increased when the ration is well balanced. The individual characteristics of the hens must be considered, as no two hens are alike even when of the same breed, one requiring more food than another and preferring kinds that may not be acceptable to her companions. Bulky food—such as chopped grass, clover, vegetable tops, cooked potatoes, and turnips—is essential because grain is too concentrated. Pounded bones, meat, and milk should always be included in the ration, as they are highly nitrogenous and seldom fail to promote laying.

It is difficult to prescribe a routine course of feeding. During the winter season the first essential is warmth, which is promoted by shelter and a liberal supply of grain. Ground food, scalded, is excellent as a morning meal, or the ground grain may be mixed with clover hay which has been cut very fine and scalded. The allowance of food should be light, and to induce the hens to exercise a small quantity of millet seed should be scattered in cut straw, leaves, or litter of any kind. No food should be given at noon. Late in the afternoon about 1 lb. of chopped lean meat or ground bone may be allowed twenty hens, after which wheat or corn, or both, should be scattered over the ground in order that the hens may exercise in securing it. Troughs should not be used except when feeding moistened ground grain. During the summer months the hens can secure all food required on a range, as grass, seeds, and insects will be abundant. Water should be at all times where it can be procured easily by

the fowls. No fixed allowance of food for a flock can be determined upon, especially when the food is varied. It will require about 5 pecks of corn, or its equivalent, to support a hen for a year.

Turkeys and guinea-fowls thrive best on a range, and are capable of securing the whole of their food during the greater portion of the year. A meal, composed of corn or wheat, given at night, will induce them to come up regularly to roost near the dwelling-house. In winter they should have grain twice a day. Geese and ducks are partial to green foods, and if grass is abundant they will have no difficulty in securing food in summer. A meal of cooked turnips, thickened with bran, given twice a day in winter, with a supply of chopped clover hay, scalded, will keep them in good condition.

Care of the Young.—Chicks are hatched at a temperature of 103°. Hens seldom become broody during the winter season, and many poultrymen resort to incubators and brooders during that period. No food is required for thirty-six hours after hatching. The chicks should be given dry food in preference to dough of any kind. Oatmeal, or rolled oats, should be kept in a little trough before them, and three times a day they should be fed on a mixture of equal parts, by weight, of corn meal, middlings, sifted ground oats, and ground meat, moistened and cooked as bread. When ten days old they should receive cracked corn, wheat, finely cut clover (scalded), cooked potatoes or turnips, or anything that will be acceptable. They should be kept warm and dry; water should be given in vessels that permit them to wet their beaks only. Young turkeys require food that is highly nitrogenous, as they grow feathers so rapidly as to become debilitated, while the least dampness is injurious. They may be fed in the same manner as chicks, but, in addition, should be given chopped eggs that have been boiled, finely chopped onion-tops, milk curds, and cooked lean meat. Goslings and ducklings require soft food, such as cooked turnips or potatoes, with ground grain of any kind, given in troughs. Water must be supplied freely for drinking purposes, but they should not be allowed on ponds until well feathered, as they may become chilled and perish.

Management.—Lice and disease are the chief drawbacks. If the poultry-houses are kept clear of lice the fowls can then rid themselves of vermin by the use of the dust-bath. Drenching the poultry-house with an emulsion of kerosene is the most effective remedy. Large gray lice destroy many young chicks and turkeys; anointing the heads with a few drops of sweet oil is the remedy. Roup is the most prevalent disease among gallinaceous birds, and exists in many forms, the symptoms being hoarse breathing, swelled eyes and heads, discharge from the nostrils, and in the malignant or contagious form it is accompanied with a very foul odor, the birds gradually drooping. There is no remedy for the disease, the most economical method being to destroy the sick birds and thoroughly to clean and disinfect the premises. Cholera is a rare disease, the supposed cases being mostly indigestion resulting from overfeeding. There is no sure remedy for cholera, but good results have been obtained by adding a teaspoonful of liquid carbolic acid to each quart of drinking-water. The symptoms are greenish droppings, intense thirst, prostration, and death or relief within forty-eight hours. Chicks should not be kept with adults until well advanced in growth, and pullets intended for laying the next season will thrive best when not with the young cockerels. The poultry-house should be cleaned daily, and if the flock is confined in yards it will be an advantage to have two yards for each flock, so as to change from one yard into the other. The unoccupied yard should be used for growing green food, the top soil being turned under; in this way the yards can be kept clean. Poultry will always give the best results on a range, and an orchard serves the purpose well. Although prices of eggs are higher in winter than in summer, the small cost of the food and the larger number of eggs secured afford a greater profit on poultry and eggs in summer than in winter. Poultry-houses should be well lighted with windows, as fowls will not remain in a dark poultry-house during the day even if the weather is stormy. The decimal system will serve to guide in making many estimates. Only ten hens should be allowed with one male, ten chicks in one brood are a sufficient number, and ten hens should have a house 10 feet square. Ten weeks is enough for a chick to make sufficient growth to reach the market, and the pullets of the large breeds should begin to lay when ten months old.

Although aquatic birds prefer to have access to a body of water, yet they are very susceptible to dampness, and will thrive best when kept in houses having board floors, upon which straw should be placed. Turkeys always seek high roosts, and should be given an open shed with the roosts near the roof as a protection against storms. When compelled to roost in the open air they become liable to roup, a disease which destroys a large number of them.

PATRICK H. JACOBS.

Pound: See AVOIRDUPOIS and WEIGHTS AND MEASURES.

Pound-nets: See FISHERIES.

Pound Sterling: a denomination of English money, equal in value to 20 shillings, or 240 pence, into which a pound of silver was anciently divided, thus giving origin to the term "pound." The word "sterling" is of obscure origin, but probably is derived from *Easterling*, the popular name of the Baltic and German traders who visited London in the Middle Ages. The silver penny was first called Easterling. See COINAGE.

Poussin, GASPARD: See DUGHET.

Poussin, poo'săn', NICOLAS: painter; b. at Villers, in Normandy, June, 1594. Quintin Varin, of Les Andelys, taught him painting. He went to Paris at the age of eighteen and studied there for a time. He was not able to get to Rome till the age of thirty. There he lived with Du Quesnoy, afterward called Il Fiammingo; this artist was of much service to him in the development of his style. Poussin studied anatomy in Rome and attended the academy of Domenichino. He endured great poverty until Cardinal Barberini, who had been ambassador in France and Spain, took him under his protection on his return to Rome, and commissioned him to paint two pictures—*The Death of Germanicus* and *The Capture of Jerusalem*. The patronage of the cardinal brought him good fortune and when, after an absence of sixteen years, he returned to Paris he was introduced to Louis XIII. by Cardinal Richelieu. The king gave him the appointment of court painter with rooms in the Tuileries and a salary of 120 francs a year. He returned to Rome to fetch his wife, but as Louis XIII. died about this time Poussin spent his remaining years in Rome. He died Nov. 19, 1665, and was buried in San Lorenzo in Lucina. More than 200 prints have been engraved after his pictures. Poussin had an immense influence in landscape-painting. Gaspard Dughet was his brother-in-law and pupil. W. J. STILLMAN.

Pout: See BIB.

Pouter: a breed of pigeons characterized by the great dilatation of the gullet, which can be distended with air until the neck assumes a globular shape. This is simply the swelling of the neck seen during the act of cooing, carried to a greatly exaggerated condition by selection. The legs are long and feathered, tail and wings long, the latter pointed and weak. The pouter has one more pair of ribs and two more presacral vertebræ than ordinary pigeons. F. A. L.

Powder: See EXPLOSIVES and GUNPOWDER.

Powderly, TERENCE VINCENT: labor leader; b. at Carbondale, Pa., Jan. 22, 1849; attended a district school; was switch-tender on the Delaware and Hudson Railroad 1862–64; car-repairer 1864–66; served apprenticeship at machinist's trade 1866–69; removed to Scranton, Pa., 1869; worked as a machinist until 1877; elected mayor of Scranton 1878; re-elected 1880, 1882; elected general master workman, Knights of Labor, 1879, and held office until 1894; admitted to the bar 1894. He has lectured on industrial questions in the principal cities of the U. S. and Canada; has published *Thirty Years of Labor*, and is a contributor to *The Journal of the Knights of Labor*, *The North American Review*, and other periodicals.

Powell, BADEN, F. R. S.: mathematician and theologian; b. at Stamford Hill, near London, Aug. 22, 1796; educated at Oriel College, Oxford, and graduated 1817; took orders in the Church of England; became vicar of Plumstead 1821; was Savilian Professor of Geometry at Oxford from 1827 till his death in London, June 11, 1860. He contributed to scientific periodicals, wrote mathematical treatises, and among his other works are *The Connection of Natural and Divine Truth* (1838); *The Order of Nature considered in Reference to the Claims of Revelation* (1859); and an essay *On the Study of the Evidences of Christianity*, in the celebrated volume entitled *Essays and Reviews* (1860).

Powell, F. YORK: See the Appendix.

Powell, JOHN WESLEY, Ph. D., LL. D.: geologist and anthropologist; b. at Mt. Morris, N. Y., Mar. 24, 1834. The

son of a Methodist minister, his youth, in Ohio, Wisconsin, and Illinois, was attended with hard work, exposure, and privation. He studied as he had opportunity at Illinois, Wheaton, and Oberlin Colleges, teaching meantime and making scientific collections. During the civil war he rose from the ranks to a lieutenant-colonelcy in the Second Illinois artillery, and lost his right arm at Shiloh. In 1865 and 1866 he served as professor in the Wesleyan College and the Illinois Normal University successively, and during the next year he led an exploring party through the hitherto unvisited canyon of the Colorado river. The success of this expedition caused Congress to authorize a survey of this mysterious river and the Rocky Mountain region and to place Maj. Powell at its head. In 1879 the four separate surveys operating in the Territories were consolidated, named the U. S. Geological Survey, and made a bureau of the Department of the Interior, and the same year the Bureau of Ethnology was organized with Maj. Powell as its chief, as a part of the Smithsonian Institution. The next year, on the retirement of Clarence King, Maj. Powell became director of the survey also. The reports and monographs issued under his direction have been the handsomest and most valuable publications of the Government, and in 1891 the French Academy awarded to him and his scientific corps the famous Cuvier prize. He has received degrees from Harvard and Heidelberg, is a member of the chief scientific societies of the U. S., of some of which he has held the presidency, and has been made honorary or corresponding member of the important scientific societies in all countries. In the summer of 1894 he resigned his position as director of the Geological Survey, but retained that of the Bureau of Ethnology. Among his best known books are *Exploration of the Colorado River* (1875); *Report on the Geology of the Uinta Mountains* (1876); *Report on the Arid Region of the United States* (1879); *Introduction to the Study of Indian Languages* (1880); *Studies in Sociology* (1887); *Canyons of the Colorado* (1893).

Powell, Maud: See the Appendix.

Power, Henry, M. B. Lond., F. R. C. S.: ophthalmologist; b. at Nantes, France, Sept. 3, 1829; studied medicine at St. Bartholomew's Hospital, London, becoming in 1851 a member, and in 1854 a fellow, of the Royal College of Surgeons; subsequently became a member of the council and vice-president of that body; was appointed ophthalmic surgeon and lecturer on diseases of the eye at St. Bartholomew's Hospital; was lecturer on physiology at the Westminster Hospital, and edited the 6th, 7th, 8th, and 9th editions of *Carpenter's Principles of Human Physiology*; was examiner in natural sciences for the Universities of Oxford and Cambridge; was co-editor of *A Biennial Retrospect of Medicine and Surgery* from 1865–74. While he has practiced his specialty, ophthalmology, he is equally well known as a physiologist. His important works are *Illustrations of some of the Principal Diseases of the Eye* (London, 1868) and *Elements of Human Physiology* (1884). S. T. Armstrong.

Power, Tyrone: actor; b. in County Waterford, Ireland, Nov. 2, 1797; removed to Wales in early life; made his *début* at the Cardiff theater; retired from the stage for several years; played in the principal cities of England, including London; excelled in the delineation of Irish characters. During his last engagement at the Haymarket theater Power's salary was advanced to £150 per week. He made successful tours in the U. S. 1833–35 and 1840–41, and embarked for Europe Mar. 11, 1841, in the steamship President, which was never heard of afterward. He wrote two novels and *Impressions of America* (2 vols., London, 1835).

Power-loom: See Loom.

Power of Attorney: a written instrument conferring upon one person the power to act for another. It is a deed, or sealed instrument, at common law; but modern statutes frequently dispense with the seal. It ordinarily contains the name of the principal, the name of the agent, a precise statement of the authority conferred, with a declaration that the principal ratifies and confirms all authorized acts of the agent, and the seal and signature of the principal. Often it gives to the agent the power to substitute a third person in his stead. A power of attorney may be revoked, unless the power is coupled with an interest. See Agent.

Francis M. Burdick.

Power, Polyphase Transmission of: See the Appendix.

Powers: in the real property law of England and the U. S. an authority vested in one person to dispose of an estate which is vested in another. It may be created by the deed or will by which the estate itself is conveyed, and the power to make a further disposition of the estate may be reserved by the person making the conveyance, or may be conferred by him on the grantee of the estate or on a stranger. A usual mode of creating a power at common law is for the grantor or donor of the estate to convey it by deed or will to A for life, at the same time giving A the power to appoint, by deed or will, the person who should have the estate after A's death. Here the grantor of the estate is called the *donor* of the *power*. A is known as the *donee* or *appointer*, and the person designated by A to take the estate after the termination of his own life-estate is called the *appointee* under the power.

The effect of the execution of the power by A is to vest the estate at once in the appointee, and the latter is considered to have derived his estate, not from A (who was never seised of it himself), but from the original donor, and through and by virtue of the will or deed by which the power of appointment was created.

The institution of powers was one of the devices of the great land-owners for tying up estates for the benefit of their families and for restricting, to some extent, the alienation of the estates by their immediate descendants. They owed their origin to that highly artificial but flexible system of conveyancing which resulted from the operation of the Statute of Uses. (See Uses.) They have greatly diminished in importance but are still in use in England and in the U. S., though in many of the States their use is much restricted by statute. The principal employment of powers at the present time is to confer on executors or trustees the authority to sell lands under a will, for the payment of debts, legacies, or for other purposes. Where such a power is given, without any estate in the land, it operates by way of executory devise in favor of the person to whom the land is sold under the power, and the purchaser takes as devisee under the will and not by way of conveyance from the trustee or executor. The fee in the meantime goes to the heir until the power is executed; but where the land itself is devised to the trustee or executor for the purpose of the sale, the purchaser derives his title from him and not from the will.

The leading treatise on this intricate branch of the law is Sugden on *Powers*. See also *American and English Encyclopædia of Law*, article *Powers*. George W. Kirchwey.

Powers, Hiram: sculptor; b. at Woodstock, Vt., July 29, 1805. In 1817 his parents removed to Cincinnati, O., where he lived until 1835, and where he began his life work by learning to take casts from models and by making wax figures for a museum. In 1835 he went to Washington, D. C., where he constructed a revolving *jet d'eau* for the Capitol grounds, and modeled the heads of several distinguished men, including J. Q. Adams, Jackson, Van Buren, Webster, Calhoun, and Preston. After spending two winters in Washington, Powers, with the assistance of friends, removed to Florence, Italy, in 1837. His busts acquired a reputation for fidelity to nature and the highest possible finish, and the insufficiency of his pecuniary resources obliged him to confine himself to this branch of his art to the extent of his orders; but he devoted every spare moment to ideal work, and the *Greek Slave*—finished in 1843, and purchased by Alexander T. Stewart—secured for its author a certain position among modern sculptors. Many repetitions of this statue were made, most of them for England. In the winter of 1872–73 his already declining health became so impaired that he was obliged to discontinue work, and on June 27, 1873, the sudden rupture of a blood-vessel closed his life. Besides the above-named works, Powers executed a large number of ideal busts of great merit, as well as many statues; among the latter, those of Washington, *The Fisher Boy*, *America*, *Eve Disconsolate*, and *The Last of the Tribes*. Revised by Russell Sturgis.

Powers, Mechanical: See Mechanical Powers.

Powhatan': the principal chief of several confederate clans or tribes of Eastern Virginia at the time of the settlement of Jamestown in 1607, usually called "emperor" by the early writers, though the number of his subjects was estimated at only 8,000. He was hostile to the English, with whom he repeatedly came into collision. Powhatan's principal residence was at Werowocomoco on York river, within the present limits of Gloucester County, where he maintained considerable pomp, being always attended by a body-guard of four warriors. D. in Apr., 1618.
